**Methods:** This was a cross-sectional study conducted using data collected at the time of patient enrolment in the PRIME registry. The PRIME Registry is a large, independent, prospective, observational cohort initiated in October 2019 that comprises patients diagnosed with RA, SLE, PsA or AS by a rheumatologist, and is being actively followed up. IRB approval and informed consent was obtained. We assessed the data for RA patients. The clinical variables studied were gender, age, smoking habits, body mass index, education status, marital status, disease duration, comorbidities (using Charlson Comorbidity Index). Education status was stratified by whether participants completed secondary (high) school education. The SF-12 Physical Component Score (PCS-12) and Mental Component Score (MCS-12) was also measured. Evaluation of disease activity and severity was made as per internationally agreed definitions, such as: swollen joint counts, tender joint counts, deformed joint counts, and DAS-28. All participants were directly inquired at the interview during the time of patient enrolment about the presence or otherwise of mental/emotional stress at home, and to rate it from 1-3 (mild, moderate, severe). For better understanding and ease of statistical analysis, dichotomous variable was made with moderate-to-severe stress patients were categorised into one group and none-to-mild stress patients into second group.

**Results:** The data from consecutive 1016 RA patients (mean age 40.8±13 years, 78.6% female, disease duration of 65±67 months) was reviewed. Forty-nine percent of patients accepted to have moderate-severe stress at home. Female gender (p=0.003), low education status (p=0.050), being unmarried (p=0.051), and MCS, PCS, CCI (p<0.001) were associated with moderate-severe stress. However, no statistical association of age and disease duration was noted. On univariate analysis, significant association of moderate-severe stress at home was noted with deformed joint counts (p=0.003), higher DAS-28 scores (p<0.001), low education status (p=0.02) and being married (p=0.001). Weak statistical association of age (p=0.30), disease duration (p=0.12), low education status (p=0.14), female gender (p=0.24) was noted. On multiple logistic regression analysis, a significant association of moderate-severe stress at home was observed with higher DAS-28 scores (OR 2.38, CI 2.00-2.84, p<0.001), MCS-12 (OR 0.65, CI 0.61-0.69, p<0.001), comorbidities-CCI (OR 1.41, CI 1.15-1.74, p=0.001) and being unmarried (OR 0.55, CI 0.36-0.83, p=0.005). The final regression model resulted in a statistically significant improved association/prediction of worse moderate-severe stress at home (R square=71%). Following variables were included in multiple stepwise regression analysis: age, disease duration, gender, education status, marital status, comorbidities index, major trauma/stress in last one year, DAS-28, MCS-12 and PCS-12 scores.

**Conclusion:** Nearly half of the cohort was noted to have moderate-severe level of stress at home, and is associated with important adverse clinical outcomes. These findings demonstrate an important need for integration of rheumatologic, social workers and mental health services.

DOI: 10.1136/annrheumdis-2022-eular.4234
Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease leading to significant increase in cardiovascular morbidity and mortality. Development of atherosclerotic lesions of the carotid arteries in RA patients is associated with the accumulation of traditional risk factors and immunoinflammatory disorders.

Objectives: To evaluate the detection rate of subclinical carotid atherosclerosis and clinical significance of immunoinflammatory markers in RA patients with low cardiovascular risk (CVR) in comparison with the control group.

Methods: The study included 275 RA patients (with low CVR and no established cardiovascular diseases) and a control group comprising 100 people without autoimmune diseases. The groups were comparable in terms of sex, age, traditional risk factors, and CVR value. CVR was calculated using the QRISK3 scale. All study participants had a low CVR (QRISK3<20%). All patients and control group members underwent carotid duplex ultrasonography. Atherosclerotic lesions of the carotid arteries were assessed by the detection of atherosclerotic plaque (ASP) - the cause of IMT ≥ 1.2 mm. Concentration of sICAM-1, sVCAM, and sCD40L in blood serum was determined by enzyme immunoassay using reagent kits and according to Bender MedSystems protocols (USA).

Results: Carotid ASP were observed more frequently in RA patients (27%) with low CVR than in the control group (17%), p=0.03. ASP were detected more frequently in men than in women with RA (50% versus 24%, p=0.01). The frequency of ASP in RA patients with low CVR did not depend on the disease’s stage or activity.

In RA patients, there was a significant correlation between carotid IMT and age (R=0.48), CVR value determined by QRISK3 (R=0.36), level of total cholesterol (R=0.28), LDL cholesterol (R=0.18), systolic blood pressure (R=0.37), diastolic blood pressure (R=0.38), p=0.05 in all cases. No correlation between carotid IMT and blood concentrations of sCD40L, sVCAM, and sICAM1 was found in RA patients or controls.

A higher concentration of sVCAM was detected in RA patients compared with the control group (1520 [945; 1915] ng/mL versus 790 [605; 1307] ng/mL, p=0.01), and in RA patients with carotid ASP compared with patients without carotid ASP (1680 [1460; 3350] ng/mL versus 1210 [865; 1810] ng/mL, p=0.01).

In RA patients with carotid ASP, sCD40L level was associated with carotid IMT (R=0.40, p=0.04) and cholesterol concentration (R=0.38, p=0.01). In RA patients without ASP, sCD40L level was associated with cholesterol concentration (R=0.41, p=0.02) and diastolic blood pressure level (R=0.3, p=0.04).

Conclusion: Subclinical atherosclerotic lesions of the carotid arteries were observed in a quarter of RA patients with low CVR and were detected at a significantly more frequent rate compared to the control group. The evaluation of carotid IMT is recommended for RA patients with low CVD. These results suggest that there is an association between carotid IMT and traditional CVR factors and immunoinflammatory markers in RA patients.

ASSOCIATION BETWEEN CARDIOVASCULAR OUTCOME AND RHEUMATOID ARTHRITIS: NATIONWIDE POPULATION-BASED COHORT STUDY

S. Kang1, K. D. Han2, S. Lee1, Y. Eun1, H. S. Cha1, E. M. Koh1, J. Lee1, H. Kim1.
1Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea); 2Shanxi Medical University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)

Background: Many studies have shown increased risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA). Despite a growing burden posed by CVD in RA patients, large scale studies which examined the association between characteristic of RA patients and CVD risks, and studies which adjusted for various confounding factors are lacking.

Objectives: This study aimed to investigate the association between CVD risk and RA in large-scale, nationwide cohort of Korean population, and to examine which characteristics of RA patients are associated with increased CVD risk.

Methods: We enrolled 136,469 patients with RA who participated in national health examinations within 2 years of RA diagnosis between 2010 and 2017 and non-RA controls matched by age and sex (n= 682,345). The cohort was followed until the end of 2019. The outcome was occurrence of myocardial infarction (MI) or stroke. MI was defined as one hospitalization or two outpatient visit with ICD-10-CM codes I21 or I22. Stroke was defined as one hospitalization with ICD-10-CM codes I63 or I64 and a claim for brain imaging (CT or MRI). The Cox proportional hazard model and Kaplan Meier curve were used for the analysis.

Results: Mean follow up duration was 4.7 years. The incidence rate of CVD was higher in RA group than control (MI: 3.20 vs 2.08; stroke: 2.84 vs 2.33 per 1,000 person-years). The risk of CVD was higher in RA patients. (MI adjusted HR 1.54, 95% CI 1.46-1.61; Stroke: adjusted HR 1.22, 95% CI 1.16-1.28). The association between RA and CVD was prominent in female (MI: adjusted HR 1.41 in male, 1.60 in female, p for interaction = 0.0293; Stroke: adjusted HR 1.13 in male, 1.27 in female, p for interaction = 0.03) and younger-age subgroups (MI: adjusted HR 2.9 in <40 years, 1.52 in 40-64 years, 1.51 in ≥65 years, p for interaction<0.0001; Stroke: adjusted HR 2.35 in <40 years, 1.21 in 40-64 years, 1.21 in ≥65 years, p for interaction = 0.0100) after adjusting for confounding variables. The association between RA and MI of risk was significant in those without DM. (adjusted HR 1.30 in DM, 1.61 in non-DM, p for interaction<0.0001; Stroke: adjusted HR 2.35 in <40 years, 1.21 in 40-64 years, 1.21 in ≥65 years, p for interaction = 0.0005)

Conclusion: RA patients had increased risk of CVD events compared to age- and sex-matched control group, and this association was stronger in female and younger-age subgroups. Therefore appropriate screening for CVD would be important in all RA patients including female and younger patients.

THE REDUCTION OF TURICIBACTER IN GUT MICROBIOTA ASSOCIATED WITH SJOGREN'S SYNDROME SECONDARY TO RHEUMATOID ARTHRITIS

M. J. Chang1,2,3, S. X. Zhang3,2, J. Qiao3,4, Q. Wang3,5, R. X. Gu1, C. Wang3,2,3, Q. Yu6,3, P. F. He1, Shanxi Medical University, School of Management Shaxi Medical University, Taiyuan, China; 2Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China; 3Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 4The Second Hospital of Shanxi Medical University, The Second Hospital of Shaxi Medical University, Taiyuan, China; 5Shanxi Medical University, School of Basic Medical Sciences, Taiyuan, China; 6Shanxi Medical University, Medical Data Sciences, Taiyuan, China

Background: Secondary Sjogren's syndrome (SS) is a common extra-articular manifestation of rheumatoid arthritis (RA)1. RA patients with SS have different outcomes from those without SS2. However, the studies investigated the characteristics of gut microbiota in patients with RA and SS is limited.

Objectives: To investigate the characteristics of gut microbiome and the associations between flora and peripheral lymphocyte subpopulations in RA patients with or without Sjogren's syndrome.

Methods: A total of 326 samples from 145 RA patients without SS, 23 RA combined with SS patients(RA-SS) and 168 healthy controls (HCs) were recruited in this study from The Second Hospital of Shanxi Medical University (Taiyuan, Shanxi, China). The gut microbiota were investigated via 16s RNA sequencing and the peripheral T lymphocyte subsets of these participants were assessed by flow cytometry. The Wilcoxon rank-sum test was used to compare alpha diversity indices between groups. Differential abundance analysis was carried out the STAMP software. Spearman's correlation analysis was used to assess the correlations between the relative abundances of bacterial genera and clinical measures.

Results: Patients with RA and RA-SS exhibited a significant reduction in the richness and diversity of gut microbiota compared with those of HCs (Figure 1 A-B, p < 0.05), whereas there was no significant difference between RA and RA-SS patients. Principal co-ordinates analyses based on Bray Curtis distance suggested that these there microbiota states explained a definable proportion of observed variance in microbiota composition (ANOSIM R2 = 0.074, p < 0.001; Figure 1 C). Compared with HCs, 58 species of flora were discovered to be distinctly different in RA patients without SS at the genus level of which 6 species of flora unique to RA-SS patients were presented much fewer ([Eubacterium] halii_group, Anaerostipes, CAG-56, Fusobacterium, Turicibacter and Enterococcus). Among these RA-SS patients' unique species of flora, it seems that Turicibacter is the key species of flora, owing to whose has a positive correlation with most of lymphocytes such as T, B, CD4+T, CD8+T and NK cells suggesting a close association with intestinal immunity. (Figure 1 F-G, P<0.05)

Conclusion: RA patients with deficiency of Turicibacter in flora had higer occurrence of Sjogren's syndrome sjojgren's syndrome complication, which was correlated with peripheral lymphocyte subpopulations and cytokines.

EFFECT OF EARLY ETANERCEPT TREATMENT ON CIRCULATING LIPOPROTEINS DIFFERS TO TREATMENT WITH METHOTREXATE AND IS MODULATED BY CLINICAL DISEASE ACTIVITY

R. Shukla1,2, A. Burska3, P. Emery4, D. Plant2, M. H. Buch1,2,3, University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; 2Manchester University NHS Foundation Trust, NIHR Biomedical Research Centre, Manchester, United Kingdom; 3University of Leeds, Leeds Institute of Rheumatism and Musculoskeletal Medicine, Leeds, United Kingdom; 4Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: A reduction in serum lipids such as total cholesterol (TC) and low-density lipoprotein (LDL) has been associated with increased risk of cardiovascular events in active RA, paradoxical to the general population4. The effect of DMARDs and active inflammation on lipid profiles has been investigated in RA

REFERENCES:

Acknowledgements: This work was supported by the National Natural Science Foundation of China (No. 82001740).
but detailed lipid profiling has been lacking in very early disease and across the spectrum of disease activity.

**Objectives**: In a treatment naïve early RA trial cohort, we sought to compare circulating lipid profiles between patients treated with first line etanercept + methotrexate (ETN-MTX) versus methotrexate treat-to-target (MTX-TT) regime and between clinical remission and high disease activity.

**Methods**: VEDERA trial (Very early Etanercept and Methotrexate versus Methotrexate with/without Delayed Etanercept in RA) randomised 120 treatment-naïve RA patients to either first-line ETN-MTX or MTX-TT regime with escalation to ETN-MTX if not in DAS28ESR remission at week 24. TC, triglycerides (TG), high density lipoprotein (HDL) and LDL were measured; apolipoproteins and atherogenic indices such as TC/HDL, atherogenic index of plasma (AIP) and apolipoprotein B/Ai ratio (aparatio) were calculated at baseline, weeks 12, 24 and 48. Linear mixed effects regression was used to test the effect of treatment on lipids and atherogenic indices in states of remission (DAS28-ESR ≤ 2.6) and high disease activity (DAS28-ESR > 5.1).

**Results**: Baseline clinical characteristics of individuals and lipid profiles including atherogenic indices were comparable between the two treatment groups (Table 1).

![Figure 1: Predicted trends in HDL and LDL in remission (left) vs high disease activity in MTX- TT and ETN-MTX groups](image)

**Conclusion**: Effect of early ETN treatment on HDL, and to a lesser extent LDL, differs from MTX and is modulated by clinical disease activity. Further investigations is needed to understand the basis for these findings and the clinical implication of observed differences in LDL and HDL. These data may indicate direct effect of therapies on the qualitative and functional components of metabolic lipid pathway.

</table>

In clinical remission, a lowering of atherogenic indices and TC, TG, LDL levels as well as a rise in predicted HDL levels were observed. In high disease activity, both HDL and LDL were increased along with the atherogenic indices TC/HDL-C, AIP and aporatio. However, the predicted values at different weeks did not reach statistical significance (not shown).

Treatmen with MTX-TT and ETN-MTX had opposing effects on predicted HDL levels in remission and high-disease activity (Figure 1). In remission, MTX-TT treatment resulted in a predicted rise in HDL whilst with ETN-MTX a small reduction was observed (estimate 0.004, p < 0.02). Similar trends were observed for HDL in high disease activity (p < 0.5). In remission, both treatments resulted in a reduction in LDL (p < 0.5), whilst in high disease activity ETN-MTX treatment resulted in a modest rise in LDL compared to MTX-TT (p < 0.06). At weeks 24 and 48, significant differences were observed in LDL values between treatment groups in high disease activity (estimate 0.57, p < 0.05 and estimate 1.13, p < 0.04 respectively).

---

**Figure 1**: Predicted trends in HDL and LDL in remission (left) vs high disease activity in MTX-TT and ETN-MTX groups

**Conclusion**: Effect of early ETN treatment on HDL, and to a lesser extent LDL, differs from MTX and is modulated by clinical disease activity. Further investigations is needed to understand the basis for these findings and the clinical implication of observed differences in LDL and HDL. These data may indicate direct effect of therapies on the qualitative and functional components of metabolic lipid pathway.

**Recent advances in orphan rheumatic diseases**
Objectives: Describe disease characteristics, phenotypes, and performance of the 2011 CDC and 2019 ACR/EULAR classification criteria in patients with IgG4-RD in Norway.

Methods: Consenting, adult patients with a clinical diagnosis of IgG4-RD, seen at the Department of Rheumatology, Oslo University Hospital were included. Two experts (J.V., D.M.) assigned patients to phenotypes ("Pancreato-Hepato-Biliary", "Retroperitoneum and Aorta", "Head and Neck-Limited" or "Mikulicz and Systemic") based on pattern of organ involvement. Fulfillment of the CDC and classification criteria were assessed. Disease activity and damage were scored with the IgG4-RD responder index (IgG4-RD RI). We used descriptive statistics.

Results: We identified 60 patients with IgG4-RD (Table 1). Clinical characteristics were as expected, with approximately equal number of patients in each phenotype group. Of all patients diagnosed by expert opinion, 42 (70%) fulfilled the ACR/EULAR classification criteria. Reasons for not fulfilling the criteria were (i) failure to meet the inclusion criterion (n = 3) due to "atypical" organ involvement: tonsils (n = 1), nasal cavity (n = 1); coronary artery (n = 1); (ii) presence of ≥ 1 exclusion criterion (n = 5); fever (n = 1), leukaemia (n = 1), thrombocytopenia (n = 1), positive anti-MPO-ANCA (n = 3), anti-SSA (n = 1); and (iii) score < 20 points (n = 10). In the latter group, 8 (80%) were not biopsied, and 1 (10%) had only performed fine needle biopsy. Among the patients not meeting the inclusion criterion or having ≥ 1 exclusion criteria, 1 (33%) and 4 (80%) scored ≥ 20 points, respectively. Of all patients, 56 (93%) fulfilled CDC, with 32 (53%), 3 (17%) and 14 (23%) patients characterized as "definite", "probable" and "possible" IgG4-RD, respectively. Of the 18 patients not fulfilling the ACR/EULAR classification criteria, 15 (83%) fulfilled CDC (4 "definite", "probable", 8 "possible"). Of the 4 patients not fulfilling CDC, 1 fulfilled the ACR/EULAR classification criteria.

Conclusion: Despite expected clinical characteristics, phenotype distribution and fullfillment of CDC in our cohort, the performance of the ACR/EULAR classification criteria was lower than expected, especially in the "Retroperitoneum and Aorta" and "Head and Neck-Limited" phenotypes. This may have important implications for the comparability across studies and inclusion in future clinical trials.

POS0216 CARDIAC SARCOIDOSIS: AN UNDERDIAGNOSED, LIFE-THREATENING YET TREATABLE DISEASE

P Webster 1, Y. Rochlani 2, K. Loupasakis 3. 1Montefiore Medical Center, Albert Einstein College of Medicine, Rheumatology, New York, United States of America; 2Montefiore Medical Center, Albert Einstein College of Medicine, Cardiology, New York, United States of America; 3Montefiore Medical Center, Albert Einstein College of Medicine, Rheumatology, New York, United States of America

Background: Cardiac sarcoidosis (CS) is potentially life-threatening and it typically causes heart failure, ventricular arrhythmia, AV block or sudden death. CS has been reported to account for 25% of sarcoidosis patient deaths, thus highlighting the importance of early diagnosis and treatment. Diagnostic challenges and lack of a unified screening approach make it difficult to estimate its prevalence. Immunosuppression is the mainstay of treatment, but there is paucity of data on optimal dose, duration and efficacy of steroids and synthetic (a) or biologic (b) disease-modifying anti-rheumatic drugs (DMARDs).

Objectives: To describe the demographic and clinical characteristics of our CS patients, and to study their clinical response to steroids, synthetic and biologic DMARDs.

Methods: A retrospective cohort study with a prospective ongoing phase was conducted. ICD-10 codes were used to identify patients over 18 years old with sarcoidosis and CS followed at Montefiore Medical Center from 2017 to 2021. The following variables were recorded: demographics (age, sex, ethnicity), BMI, smoking status, presenting manifestations, histopathology (cardiac and extracardiac), imaging, treatment (corticosteroids and s/bDMARDs), dose and duration of therapy, steroid-sparing effect, response to treatment based on clinical and imaging improvement (echocardiogram, cardiac MRI, PET).

Results: 220 patients with sarcoidosis were identified. 154 (70%) female and 124 (56.4%) Black. 42 out of 220 (19.1%) met diagnostic criteria for CS 1,2. Mean age of CS patients was 61.6 years. 23 (54.8%) were male and 24 (57.1%) Black. Heart

*p < 0.05 by one-way ANOVA

*2 patients switched from MTX to MMF and 3 from sDMARDs to bDMARDs
failure (54.8%), arthralgias (47.6%) and heart block (28.6%) were the most common presenting manifestations. 28.6% had isolated CS. 5 (11.9%) underwent endomyocardial biopsy and 2 of them (40%) had histopathologic evidence of CS. Mean left ventricular ejection fraction (LVEF) was 40.6 % on echocardiogram, and 29 patients (69%) had PPM/ICD placed for arrhythmia prevention. 35 (83.3%) underwent cardiac MRI, 37 (88.1%) cardiac PET scan and 23 (62.3%) had a follow up PET. 33 (78.6%) CS patients were treated with corticosteroids for a mean duration of 17.3 months. 21 of them were also treated with sDMARDs and 3 were subsequently switched to bDMARDs (Table 1). Mean prednisone dose at 12 months was 4.8 mg/day. 11 patients (33%) were tapered off corticosteroids.

Conclusion: In our sarcoid patient population, the prevalence of CS is 19.1%, which is higher than previously reported in the literature, suggesting CS may be underdiagnosed. There was a greater proportion of male patients in the CS population (54.8%) than the generalized sarcoidosis population (30%). This indicates that males with sarcoidosis may be more likely to have cardiac involvement. Patients treated with sDMARDs had a high response rate as reflected by clinical and imaging improvement. Steroid-sparing effect is suggested by the low prednisone dose at 12 months (Table 1). Methotrexate was the most commonly used DMARD (76.2%). Randomized clinical trials are needed to establish robust guidelines for the treatment of CS.

ALL-CAUSE AND CAUSE SPECIFIC MORTALITY AMONG PATIENTS WITH BEHÇET’S DISEASE VERSUS GENERAL POPULATION

A. Shin1, S. R. Choi2, Y. J. Ha1, Y. J. Lee3, E. B. Lee4, E. H. Kang5, 1Seoul National University Bundang Hospital, Department of Internal Medicine, Seongnam-si, Korea, Rep. of (South Korea); 2Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Behçet’s disease (BD) is a systemic vasculitis with multiorgan involvement.

Objectives: To compare the risk of all-cause and cause specific mortality among patients with BD compared to general population

Methods: Using the 2002-2017 Korea National Health Insurance database, we conducted a cohort study among BD patients compared to general population matched on age and sex at a 1:5 ratio. The primary outcome was death of any cause, and the secondary outcomes were cause-specific mortality for top 5 causes of death. Cox proportional hazards models estimated hazard ratios (HRs) and 95% confidence intervals (CIs), comparing BD patients versus general population.

Results: The PS-matched study cohort (mean age 42.1 years; 32.0% male) included 32288 BD patients and 161440 controls. During a mean follow-up of 9.6 years, 2214 deaths occurred. The HR [95%] for all-cause mortality was 10.6 [9.6-11.6]. The Top 5 causes of death derived from malignancy, cardiovascular disease, infection, respiratory disease, and injury: the HR [95%] for mortality from these causes were 8.5 [7.2-10.1], 10.8 [8.6-13.6], 14.6 [8.1-26.3], 12.0 [8.5-17.0], and 8.0 [5.0-13.0], respectively.

Conclusion: This population-based cohort study warns exceptionally heavy burden of the disease showing approximately 10 times higher mortality of BD patients compared to general population. In line with this, risk of cause specific mortality was also significantly higher among the BD patients, for 5 top causes of death.

DECREASED MIR-122-5P IN NEUTROPHIL-DERIVED EXOSOMES ATTENUATED IMMUNOREGULATORY FUNCTION ON MACROPHAGES BY TARGETING IRF5 EXPRESSION IN BEHÇET’S DISEASE

X. Yu1, C. Li2, J. Liu1, H. Chen1, W. Zheng1, 1Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Rheumatology, Beijing, China; 2Shangqiu Hospital of Peking University, Department of Rheumatology, Beijing, China

Background: Behçet’s disease (BD) is a chronic systemic vasculitis characterized by the overactivation of neutrophils and macrophages. Exosomes are membrane-derived vesicles that mediate intercellular communications and neutrophil-derived exosomes account for the major portion of serum exosomes in BD. However, the role of neutrophil-derived exosomes in BD remains unknown.

Objectives: 1) To investigate the production of exosomes by BD neutrophils; 2) To elucidate the regulation of macrophage by BD neutrophil-derived exosomes; 3) To explore the mechanism of immunoregulatory functions of BD neutrophil-derived exosomes.

Methods: BD and healthy control (HC) neutrophil-derived exosomes were extracted and quantified. Human monocyte-derived macrophages (HMDM) were stimulated with BD and HC neutrophil-derived exosomes, and TNF-α and IL-6 production were examined. Differently expressed miRNAs in BD neutrophil-derived exosomes were analyzed using miRNA sequencing. LPS-induced HMDM were treated with miRNA mimics or inhibitors, and TNF-α and IL-6 production were detected. miRNA was overexpressed in macrophages, and RNA sequencing was performed to analyze regulating pathways. Dual-luciferase assays were performed to confirm miRNA-mRNA interaction.

Results: BD neutrophils produced a significantly lower level of exosomes than HC ones. Both BD and HC neutrophil-derived exosomes suppressed TNF-α and IL-6 production by macrophages, but to a lesser extent by BD neutrophil-derived exosomes. Six downregulated miRNAs were presented in BD neutrophil-derived exosomes, including mir-122-5p, mir-122-5p mimics inhibited IL-6 and TNF-α production while miR-122-5p inhibitor promoted IL-6 and TNF-α production by HMDMs. Overexpression of mir-122-5p attenuated TLR4 and IFN-γ signaling. mir-122-5p directly targeted 3'UTR of IRFS, the TF regulating TLR4 pathway and autocrine of IFN-γ, and downregulated IRF5 expression confirmed by dual luciferase assay. Knockdown of IRFS dampened IL-6 and TNF-α production in HMDMs.

EARLIER AND MORE AGGRESSIVE TREATMENT OF MAJOR ORGAN INVOLVEMENT WITH BIOLOGICS MAY PREVENT RELAPSES OR FURTHER NEW ORGAN INVOLVEMENT IN A SUBGROUP OF BEHÇET’S DISEASE PATIENTS

T. Bozkurt1, M. Karabacak2, H. Karataş1, S. Kutlu Ağaçkan2, T. Ergün3, H. Direskeneli4, F. Albaz-Oner6, 1Marmara University School of Medicine, Department of Internal Medicine, ISTANBUL, Turkey; 2Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, ISTANBUL, Turkey; 3Marmara University School of Medicine, Department of Dermatology, ISTANBUL, Turkey

Background: Conventional immunosuppressives (cIS) are the choice of treatment for major organ (ocular, vascular, central nervous (CNS) and gastrointestinal (GIS)) involvement to prevent relapses and organ damage in patients with Behçet's disease (BD).

Objectives: We aimed to investigate the rate of new major organ involvement in BD patients under cIS treatments during follow-up and to assess the characteristics and treatment protocols of these patients.

Methods: The files of 1114 patients diagnosed with BD and followed (1992-2019) in the Marmara University Behçet's Clinic were overviewed retrospectively. Patients with follow-up duration less than 6 months were excluded. A total of 806
patients, of whom 56% were male and included in the analysis. Demographic and clinical characteristics, follow-up and treatment data of the patients were recorded from files. Relapse of the same organ and/or major organ development during the follow-up period of patients receiving cSiS was defined as “event under cSiS.”

Results: Median age at diagnosis was 29 (10-65) years and median follow-up duration was 68 months (6-272). Genital ulcer, erythema nodosum and arthritis/arthralgia were more common in women, whereas papulopustular lesions, vascular, and ocular involvement were more common in men (p<0.005 for all). Presence of major organ involvement was 56.9% (n=459) and the frequencies of vascular, ocular, CNS and GIS involvement were 29.8%, 33.5%, 9.7%, and 2%, respectively. At diagnosis 232 (50.5%) patients had major organ involvement, whereas it developed in 227 patients during a follow-up of median 3 years (0.5 - 32) after diagnosis. Major organ involvement developed earlier in males compared to females (median 2 years vs 4 years, p = 0.012). In patients with a first-degree relative history of BD, major organ involvement also developed earlier, however without reaching significance (median 1 year vs 3 years) (p=0.066). 440 patients had follow-up data under cSiSs with the follow-up duration of median 65.5 months (6-272). Main reason for cSiS use was major organ involvement (86.8%), less frequent reasons were mucocutaneous disease (9.3%) and joint involvement (3.8%). An event under ISs (mainly relapses) occurred in 160 (36.4%) patients with median 23 months after cSiS initiation. Majority of events (68%) were relapses of the same major organ (Figure 1). The most commonly used cSiS agent was azathioprine (87%). Among patients having an event under cSiSs, 91% of the relapses and 75% of new major organ involvement developed under azathioprine treatment. In patients with an event under cSiSs, treatment mostly switched to other ISs such as cyclophosphamide, interferon-α, and high dose corticosteroids. In 22% of patients, azathioprine was switched to tumor necrosis factor (TNF) inhibitors.

Conclusion: In our study, major organ involvement developed in 57% of the 806 BD patients. We observed that disease course was more severe under cSiS treat-ment in male patients diagnosed at a younger age and with the history of familial BD. In one third (36%) of the patients under cSiS treatment, a relapse or a new major organ involvement developed despite the cSiS use, mainly under azathioprine. TNF-inhibitor use was approved for BD treatment within the last decade in Turkey. Therefore, azathioprine was switched to a TNF inhibitor in only 22%. Our results suggest that earlier and more aggressive treatment of major organ involvement with biologics may be an option in young male patients especially with the history of familial BD, who had the highest risk for severe disease course.

Background: The cryopyrin-associated periodic fever syndromes (CAPS) are hereditary monogenic autoinflammatory diseases with severe systemic and organ inflammation due to increased production of Interleukin-1β (IL-1β). The subcutaneously administered monoclonal antibody canakinumab (CAN) effectively inhibits IL-1β and results in rapid remission of CAPS symptoms in clinical trials as well as in real-life.

Objectives: The RELIANCE registry is designed to explore long-term safety and effectiveness of CAN under subcutaneous clinical practice conditions in pediatric (∗2 years) and adult patients with CAPS, including Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome (FCAS), and neonatal onset multisystem inflammatory disease (NOMID)/chronic infantile neurological cutaneous and articular syndrome (CINCA).

Methods: This prospective, non-interventional, observational study with a 3-year follow-up enrols patients in Germany with clinically confirmed diagno-ses of CAPS routinely receiving CAN. In 6-monthly visits, clinical data, physician assessments and patient-reported outcomes are evaluated starting at baseline.

Results: 98 CAPS patients (52% female; 15 [15%] NOMID/CINCA subtypes) were enrolled by December 2021 (Table 1). At baseline, median age was 20 years and median duration of prior CAN treatment was 6 years. At the 36 months visit, 74% of patients reached disease remission by physicians’ assessment along with increasing rates of absent disease activity (patient’s assessment, median 2.0 at baseline and 0.0 month 36). In addition, patients reported low levels of fatigue (absent to mild/moderate: 87% at baseline and 95% at month 36). At baseline, CAPS impaired social life in 47% of patients (37% at month 36) and 33% (23% at month 36) reported days off from school/work. Lab parameters were within normal limits. Remission and disease control were sustained as evaluated parameters remained stable or even decreased over time.

10. University Hospital Tübingen, Department of Pediatrics, Division of Pediatric Rheumatology, Tübingen, Germany.

Background: Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is a rare hereditary autoinflammatory disease characterized by periodic fever as well as severe systemic and organ inflammation. Successful treatment was achieved with the interleukin-1β inhibitor canakinumab (CAN) in a pivotal phase 3 study, in which 45% of patients reached clinical remission after 16 weeks (primary endpoint). CAN has been approved and applied for the treatment of TRAPS patients since 2017.

Objectives: The present study explores the long-term efficacy and safety of CAN under routine clinical practice conditions in pediatric (age ≥2 years) and adult TRAPS patients.

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany. Patients with clinically confirmed diagnosis of TRAPS who routinely receive CAN are enrolled in order to evaluate efficacy and safety of CAN under standard clinical practice conditions at baseline and at 6-month intervals.

Results: The interim analysis of TRAPS patients enrolled by December 2021 includes baseline (N=19, 1 patient with atypical TRAPS) and preliminary 24-month data. Of these patients, N=12 (63%) were females and median age at baseline was 16 years (3–43 years). Preliminary results indicate stable remission by physicians’ assessment and laboratory parameters. Disease control by patients’ assessment showed no major changes over time (Table 1). In total, N=7 adverse drug reactions were observed, of which none was classified as severe.

Conclusion: Baseline characteristics and interim data of TRAPS patients are available from the RELIANCE study. Further interim and end-of-study data will be analyzed to assess efficacy and safety of long-term treatment as well as dosing effects in TRAPS patients.

POS0222
POLYARTICULAR ARTHRITIS AND ADULT-ONSET OSTEOLYSIS CAUSED BY MUTATIONS IN THE ASAH1 GENE: FARBER DISEASE CLINICAL PRESENTATIONS IN THE CONTEXT OF A FIRST-EVER NATURAL HISTORY STUDY

L. Seefried1, K. Crosby2, A. Solyom3,1 University of Wuerzburg, Musculoskeletal Center Wuerzburg, Wuerzburg, Germany;
2 Aceragen, Patient Engagement, Durham, United States of America;
3 Aceragen, Rare Disease Development, Basel, Switzerland

Background: Farber disease is frequently misdiagnosed as polyclarticular juvenile idiopathic arthritis or seronegative rheumatoid arthritis which leads to a delay in diagnosis for many patients. Farber disease is an ultra-rare lysosomal storage disease caused by mutations in the ASAH1 gene. The resulting deficiency of the acid ceramidase enzyme leads to accumulation of the pro-inflammatory and pro-apoptotic sphingolipid ceramide. Accumulation of ceramide throughout the body leads to the symptoms of Farber disease. Cardial symptoms include joint disease (polyarticular arthritis and contrac- tures), subcutaneous nodules, and a hoarse or weak voice due to laryngeal nodules. The phenotypic spectrum of Farber disease ranges from rapidly progressive disease causing death in infancy to moderate or slowly progressive disease with survival into late adulthood. Symptoms may vary in severity across patients and phenotypes.

Objectives: To further define the symptoms of Farber disease, including joint disease, subcutaneous nodules, dysphonia, and osteolysis, which can lead to referral to rheumatology or related specialties. To understand the clinical present- ation and broad phenotypic spectrum of this rare disease to aid in clinical diagnosis and reduce diagnostic delay.

Methods: The Observational and Cross-Sectional Cohort Study of the Natural History and Phenotypic Spectrum of Farber Disease (NCT03323841) was the first systematic clinical study of the natural history of Farber disease. The study collected retrospective and prospective data on living and deceased patients, including demographics, clinical presentation, phenotype, diagnostic history, and patient reported outcomes.
Results: 45 patients with Farber disease (27 living, 18 deceased) who had or had not undergone hematopoietic stem cell transplant (HSCT) were enrolled from 16 centers in 9 countries. A cohort of 24 living non-HSCT patients were followed prospectively. The patients represented the broad phenotypic spectrum of Farber disease, from rapidly progressive (severe) to slowly progressive (attenuated). In patients whose data was available for analysis, the average age of patients at enrollment was 72 years (range 1 to 28 years). The average age of onset of joint disease (arthritis and/or contractures) was 15 months (range 3 months to 7 years), of subcutaneous nodules was 13 months (range 3 months to 5 years), and of dysphonia was 13 months (range birth to 8 years). The average time from onset of symptoms to Farber disease diagnosis was 2 years (range <1 to 12 years). At baseline, the mean number of joints affected with active arthritis was 113 (range 0-36) and the mean number affected with contractures was 18 (range 0-38). 12.5% of patients were reported to have a bone disorder such as osteoporosis or osteomyelitis. The Child Health Assessment Questionnaire Disability Index ranging from 0 (no impairment) to 3 was used with mean scores of 2.62-3.00 across visits.

Conclusion: Data from the Farber disease natural history study further defined the cardinal symptoms, phenotypic spectrum, and high disease-related burden in patients with Farber disease. The large number of joints affected with arthritis or contractures reflects that patients with Farber disease are often referred to rheumatology and can be misdiagnosed with particular juvenile idiopathic arthritis or seronegative rheumatoid arthritis. Demographic information and number of patients enrolled indicate that Farber disease is likely not as rare as previously thought. ASAH1 genetic testing for adult and pediatric patients referred to the rheumatology clinic with symptoms including polyarticular arthritis, subcutaneous nodules, dysphonia, or osteomyelitis, may shorten the time to diagnosis in patients with Farber disease.

A NOVEL TNFRSF1A MUTATION ASSOCIATED WITH TNP-RECEPTOR ASSOCIATED PERIODIC SYNDROME AND ITS METABOLIC SIGNATURE

J. Steiner1, A. Antebi1, A. Annibai1, T. Kubacki2. 1Max Planck Institute, Max Planck Institute for Biology of Ageing, Cologne, Germany; 2University Hospital Cologne, Cologne, Germany, Department II of Internal Medicine and Center for Molecular Medicine Cologne, Cologne, Germany

Background: Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an autosomal dominant syndrome characterized by prolonged episodes of fever, arthralgia, myalgia, abdominal pain and erythematous rash. We report a new mutation in the TNFRSF1A gene which is associated with TRAPS and AA-amyloidosis. Furthermore we analyzed the metabolic changes using a metabolomics approach.

Objectives: To describe a novel mutation in the TNFRSF1A gene that causes TRAPS.

Methods: Case series. For pathogenity predictions we used the PolyPhen-2 web-software2 and PROVEAN3. Metabolomics: Mass spectrometry was performed

## Conclusion

Data from the Farber disease natural history study further defined the cardinal symptoms, phenotypic spectrum, and high disease-related burden in patients with Farber disease. The large number of joints affected with arthritis or contractures reflects that patients with Farber disease are often referred to rheumatology and can be misdiagnosed with particular juvenile idiopathic arthritis or seronegative rheumatoid arthritis. Demographic information and number of patients enrolled indicate that Farber disease is likely not as rare as previously thought. ASAH1 genetic testing for adult and pediatric patients referred to the rheumatology clinic with symptoms including polyarticular arthritis, subcutaneous nodules, dysphonia, or osteomyelitis, may shorten the time to diagnosis in patients with Farber disease.
on patient plasma and healthy controls using an UHPLC system (Vanquish, Thermo Fisher Scientific, Bremen, Germany) coupled to an HRAM mass spectrometer (Q-Exactive Plus, Thermo Fisher Scientific GmbH, Bremen, Germany).

**Results:** A 44-year-old man (patient 1) presented to our hospital with abdominal pain, elevated inflammation parameters, renal failure and large proteinuria. Renal biopsy revealed AA amyloidosis. Further anamnesis showed he had suffered from recurrent attacks of abdominal pain with fever and elevation of inflammation markers since he was 16 years old. He also reported that his father, aunt, sister and daughter have had similar problems. His daughter (patient 2) reported recurrent episodes of abdominal pain. Since she was 11 years old and her 46-year-old sister (patient 3) reported similar symptoms starting at 12 years of age. Upon presentation patient 3 showed proteinuria of 2000mg/g creatinine (albuminuria 1500mg/g creatinine) strongly indicating early renal AA-amyloidosis. All symptomatic family members underwent genetic testing that revealed the yet uncharacterized TNFRSF1A-variant c.332A>G (p.Q111R). In silico analysis of the mutation by PolyPhen-2 software and PROVEAN classified the mutation as probably pathogenic culminating in the diagnosis of TRAPS. All patients received canakinumab for treatment and responded with normalization of the inflammatory parameters. Patient 3 showed a marked reduction of proteinuria after 6 months of treatment. Using a metabolomics approach we were able to detect 158 distinct metabolic compounds of which 32 were up- and 35 downregulated, respectively. Two patients were analyzed before and after treatment with canakinumab. The treatment with canakinumab, however, appears to have no effect on the metabolic changes caused by TRAPS. Significantly upregulated metabolic pathways included purine metabolism, glycolysis/glyconeogenesis, glutathione metabolism, pyrimidine metabolism and phenylalanine, tyrosine and tryptophan biosynthesis. Downregulated pathways included Aminoacyl-tRNA biosynthesis, arginine and proline metabolism, arginine biosynthesis among others.

**Conclusion:** Here we present a novel mutation in the TNFRSF1A gene that causes TRAPS and is associated with AA-amyloidosis. Canakinumab is an effective treatment in this variant and led to improvement in proteinuria in one of the patients with presumed early renal AA-amyloidosis. We observed significant changes in the metabolite in comparison to healthy controls. Treatment with canakinumab appeared to have no effect on these metabolic changes caused by TRAPS.

**FLUIDIC SHEAR STRESS REDUCES TNF-α MEDIATED CARTILAGE DAMAGE IN A 3D MODEL OF DEGENERATIVE JOINT DISEASE**

D. H. Do Nguyen1, C. Lubahn1, T. Leeuw2, F. Buttgereit1, T. Gaber3, A. Damerau1 on behalf of AG Buttgereit.

**Background:** Pathomechanisms of degenerative joint diseases such as osteoarthritis (OA) ultimately result in the breakdown of cartilage tissue. To date, the exact underlying mechanisms of both cause and progression of OA remain unclear. Therefore, developing complex and long-lasting in vitro components of a human joint including cartilage, subchondral bone, synovial membrane and tendons that simulate the 3D architecture and the metabolic, hormonal and cellular interplay of the joint components is needed to study the long-lasting course of OA pathogenesis. Beside the impact of metabolic components and 3D architecture, mechanical forces are well-known to be key modulators of joint health, while abierant forces are primary etiological factors leading to cartilage degeneration.

**Objectives:** Here, we aimed to (i) develop a long-lasting human in vitro 3D cartilage model using alternated perfused cultivation and (ii) simulate TNF-α-mediated cartilage degradation. As a mechanical force we used the perfusion-mediated fluid shear stress (FSS) to enhance chondrogenesis and mimic FSS during joint movement.

**Methods:** Human bone marrow-derived mesenchymal stromal cells (MSC) were used to develop and to 3D cartilage model incubated in a bioreactor with a perfusion cycle that facilitates mechanical stimulation via FSS and daily sampling. Within the bioreactor, MSC mass cultures were subjected to FSS at 10 dyn/cm² by medium circulation three times a day for 1.5 hours. The approach of using optimized FSS rate, cycles and cultivation period of 18 days for MSC mass cultures was compared to a non-perfused control based on cell viability (live-dead and viability-assay), apoptosis (TUNEL-assay, caspase-3/7-activity, BCL2, BAX) metabolic activity (oxygen and glucose consumption, lactate production), chondrogenic gene expression (ACAN, COMP, COL2A1, COL1A1, COL2A1/COL1A1) and matrix metalloproteinase expression (MMP-1, -13).  

**Results:** Alternate perfused long-term cultivation at 10 dyn/cm² did not affect cell survival; it rather reduced apoptosis, did not affect oxygen consumption but reduced glucose consumption and lactate production and enhanced chondrogenic gene expression compared with reduced perfusion rates (MAP2K1 and COMP gene expression compared with non-perfused conditions). Mimicking pathophysiology of OA we simulated the 3D cartilage model with 100ng/mL TNF-α for 6 hours under non-perfused and perfused long-term cultivation with FSS at 10 dyn/cm² as a chemical stimulus. Compared to untreated perfused conditions, TNF-α stimulation (i) did not affect overall cell survival but enhanced apoptosis (demonstrating efficacy of stimulation), (ii) did not affect oxygen consumption and glycolysis, (iii) enhanced MMP expression and protected against TNF-α-mediated cartilage degradation.

**DEFICIENT CHAPERONE-MEDIATED AUTOPHAGY CONTRIBUTES TO JOINT DAMAGE IN OSTEOARTHRITIS**

I. Lorenzo1, U. Nogueira-Recalde1, C. Garcia-Dominguez2, N. Oreiro2, J. A. Pinto Tasende3, M. LOTZ2, F. J. Blanco1,2, B. Caramés1, Instituto de Investigación Biomédica de A Coruña (INIBIC), Unidad de Biología del Cartílago, Grupo de Reumatología, A Coruña, Spain;1Complexo Hospitalario Universitario A Coruña, Grupo de Reumatología Clínica, A Coruña, Spain;3Scripps Research, Molecular Medicine, La Jolla, United States of America

**Background:** In Osteoarthritis (OA), defects in macroautophagy are evident and precede joint damage. Indeed, pharmacological activation of macroautophagy protects against joint damage and disease.

**Objectives:** Therefore, identifying hallmarks associated with specific autophagy subtypes could shed light to fundamental mechanisms of joint disease and facilitate the development of therapeutic strategies to prevent OA progression.

**Methods:** A gene expression analysis of 35 autophagy genes was performed from blood from a Prospective OA Cohort of A Coruña (PROCOAC) of non-OA (Age:61,44±1,16 years; BMI:25,25±5,02; Females, n=18) and knee OA subjects (Age:65,50±1,05 years; BMI:29,55±0,67; Females, n=18, OA grade III-IV) and by using SYBR green array. The differential expression of candidate genes in blood (n=30/group) and knee cartilage (Non-OA, n=12; Knee OA donors, n=21) was confirmed by using Taqman Technology. HSP90AA1, a chaperone mediated autophagy (CMA) mediator, and HSP90AB1, involved in key joint tissues (i.e. cartilage, meniscus, ACL and synovium) with different KL grades (0, 2, 4, 6, 8, 10 and 12 months old, n=3 each time) and surgically-induced OA mice (10 weeks after surgery, n=4 each) by immunohistochemistry. The functional consequences of HSP90AA1 deficiency on inflammation, oxidative stress, senescence and apoptosis were studied in human OA chondrocytes by gene and protein expression and flow cytometry. The potential contribution of CMA to chondrocyte homeostasis was studied by assessing the capacity of CMA to restore proteostasis upon macro-autophagy deficiency by ATG5 knockdown. To study the therapeutic potential of targeting CMA, HSP90AA1 was overexpressed in human OA chondrocytes.

**Results:** 16 autophagy-related genes were significantly downregulated in knee OA subjects (p<0.05). Macroautophagy-related genes ATG8L2, ATG12, ATG4B and MAP1LC3B were significantly downregulated (p<0.05). Interestingly, HSP90AA1 and HSPA5, CMA mediators involved in stress response and protein folding, were significantly downregulated (p<0.001). Confirmatory studies showed a downregulation of MAP1LC3B and HSP90AA1 in blood (p<0.001) and cartilage (p<0.05) from
Results: hASCs. After 12 weeks of implantation, rabbits were sacrificed for analysis. In order to possiblity of differentiating to complete cartilage, Fibrin only group and Fibrin filled with perfectly differentiated chondrocytes. Although Fibrin with hASCs MAP with hASCs group had the best healing and covered with hyaline cartilage. Moreover, histological assessment showed that implanted hASCs had been remained in target defect rather than dispersed to other sites of the knee. Dead fluorescent staining. The implanted cells were labeled with DiD for in vivo imaging cells to differentiate directly to chondrocytes.

Objectives: We developed biocompatible adhesive which enables implanted chondrogenic-enhanced hASCs being strongly fixed to the lesion site of defected cartilage, and thus, the implanted cells can survive lengthy in defect site allowing cells to differentiate directly to chondrocytes.

Methods: MAP was produced and purified for in vivo applications using a bacterial expression system as previously reported [1]. The cell encapsulated coacervate was formulated with two polyelectrolyte, the MAP and 723 kDa hyaluronic acid (HA). The DiD labeled cell was dispensed into the solution in which the MAP microdroplets with hyaluronic acid and subsequently gelated into microparticles, which is highly viscous and strongly adhesive. In vivo efficacy of MAP in rats - the osteochondral defects using stem cell therapy-based tissue engineering have been developed and used for more than 20 years; however, the low viability and high possibility of dispersion of injected cells to target defect sites have remained challenge. Mussel adhesive protein (MAP) receiving increasing attraction as functional underwater adhesive ability if the bioengineered MAP, therefore it could be applied on various environment of lesion site. Objectives: Background: Cartilage has limited intrinsic healing capacity, motivating the application of stem cells for regenerative therapies. Treaties to treat osteochondral defects using stem cell therapy-based tissue engineering have been developed and used for more than 20 years; however, the low viability and high possibility of dispersion of injected cells to target defect sites have remained challenge. Mussel adhesive protein (MAP) receiving increasing attraction as functional underwater adhesive ability if the bioengineered MAP, therefore it could be applied on various environment of lesion site.

Background: Cartilage has limited intrinsic healing capacity, motivating the application of stem cells for regenerative therapies. Treaties to treat osteochondral defects using stem cell therapy-based tissue engineering have been developed and used for more than 20 years; however, the low viability and high possibility of dispersion of injected cells to target defect sites have remained challenge. Mussel adhesive protein (MAP) receiving increasing attraction as functional underwater adhesive ability if the bioengineered MAP, therefore it could be applied on various environment of lesion site.

Methods: MAP was produced and purified for in vivo applications using a bacterial expression system as previously reported [1]. The cell encapsulated coacervate was formulated with two polyelectrolyte, the MAP and 723 kDa hyaluronic acid (HA). The DiD labeled cell was dispensed into the solution in which the MAP solution and the HA solution were mixed in a ratio of 7:3 (v/v). MAP formed liquid microdroplets with hyaluronic acid and subsequently gelated into microparticles, which is highly viscous and strongly adhesive. In vivo efficacy of MAP in rats - the osteochondral defects using stem cell therapy-based tissue engineering have been developed and used for more than 20 years; however, the low viability and high possibility of dispersion of injected cells to target defect sites have remained challenge. Mussel adhesive protein (MAP) receiving increasing attraction as functional underwater adhesive ability if the bioengineered MAP, therefore it could be applied on various environment of lesion site.

Results: Results: The fluorescence cell images exhibit the viability of cells under encapsulated condition in coacervate. The cell viabilities were determined with Live/ Dead fluorescent staining. The implanted cells were labeled with DiD for in vivo visualisation. After 7-10 days, fluorescent signals were more potently detected for MAP with hASCs group than Fibrin with hASCs group in osteochondral defect model. Implanted hASCs had been remained in target defect rather than dispersed to other sites of the knee. Moreover, histological assessment showed that MAP with hASCs group had the best healing and covered with hyaline cartilage-like tissue. The staining image shows that MAP with hASCs group were filled with perfectly differentiated chondrocytes. Although Fibrin with hASCs group had better healing, it was filled with fibrous cartilage which owes its flexibility and toughness. As MAP with hASCs group has higher possibility of differentiating to complete cartilage, Fibrin only group and Fibrin with hASCs group have failed to treat OA by rehabilitating cartilage. In order to clarify the evidence of remaining human cell proving efficacy of newly developed bioadhesive, human nuclear staining was proceeded with sectioned rabbit cartilage tissue. The results explicitly showed MAP with hASCs group have retained more human cells than Fibrin only and Fibrin with hASCs groups.

Conclusion: We investigated the waterproof bioadhesive supporting transplanted cells to attach to defect lengthy in harsh environment, which prevents cells from leaked to other region of cartilage. Collectively, the newly developed bio-adhesive, MAP, could be successfully applied in OA treatment as a waterproof bioadhesive with the capability of the strong adhesion to target defect sites. Our study suggests a new effective strategy for cartilage regeneration using MAP in tissue engineering fields.

POS0228 HYPOXIA AND INHIBITION OF WNT SIGNALING PROMOTE EXPRESSION OF THE PROTECTIVE MOLECULE ANP32A IN CARTILAGE

J. Quintens1,2, F. M. F. Cornelis1, A. De Roover1, A. Escrivanò Núñez3, S. Monteagudo4, R. Lories1,2,5, CU Leuven, Laboratory of Tissue Homeostasis and Disease, Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, Leuven, Belgium; UZ Leuven, Division of Rheumatology, Leuven, Belgium

Background: Osteoarthritis (OA) is the most common joint disorder and is characterized by cartilage damage. To date, no cure exists (1). Previously, an association between polymorphisms in the acidic leucine-rich nuclear phosphoprotein-32A (ANP32A) gene and OA was described (2). Our group showed that ANP32A plays a key protective role in OA by preventing oxidative stress (3). In OA cartilage, ANP32A is downregulated as compared to non-OA cartilage (3).

Objectives: Taking together, we identified HSP90A, a marker of CMA, as a key regulator of chondrocyte homeostasis underlying a relevant mechanism in OA. A better definition of the cross-talk between CMA and macroautophagy defects might reveal its role as a hallmark of OA.

METHODS: In vivo efficacy of MAP in rats - the osteochondral defects were created on the patellar groove of distal femora in rats with sharp excision. After transplantation of human adipose derived stem cells (hASCs), the fluorescence images was taken in every 7 days. Animals were allocated into two groups as follows: MAP with hASCs; fibrin with hASCs. The MAP with chondro-induced hASCs were implanted on the osteochondral defect created in the patellar groove/condyle of OA-induced rabbits. Rabbits were allocated to three different groups as follows: Group 1 - Fibrin only; Group 2 - Fibrin with hASCs (1.5 x 10^5 chondro-induced hASCs); Group3; MAP with hASCs. After 12 weeks of implantation, rabbits were sacrificed for analysis.

RESULTS: The fluorescence cell images exhibit the viability of cells under encapsulated condition in coacervate. The cell viabilities were determined with Live/Dead fluorescent staining. The implanted cells were labeled with DiD for in vivo visualisation. After 7-10 days, fluorescent signals were more potently detected for MAP with hASCs group than Fibrin with hASCs group in osteochondral defect model. Implanted hASCs had been remained in target defect rather than dispersed to other sites of the knee. Moreover, histological assessment showed that MAP with hASCs group had the best healing and covered with hyaline cartilage-like tissue. The staining image shows that MAP with hASCs group were filled with perfectly differentiated chondrocytes. Although Fibrin with hASCs group had better healing, it was filled with fibrous cartilage which owes its flexibility and toughness. As MAP with hASCs group has higher possibility of differentiating to complete cartilage, Fibrin only group and Fibrin with hASCs group have failed to treat OA by rehabilitating cartilage. In order to

Background: Osteoarthritis (OA) affects 12% of the population, and yet we still have no disease-modifying treatment. Cartilage breakdown is the hallmark of OA, and patients suffer from pain and loss of joint function/independency, severely affecting quality of life. Therefore, there is a huge unmet clinical need. Receptor tyrosine kinase-like orphan receptor 2 (ROR2) is a non-canonical WNT receptor that regulates the planar cell polarity pathway, controlling limb outgrowth. During skeletal development chondrocytes require ROR2 to undergo hypertrophy in the process of endochondral bone formation (1). Loss of function mutations in human causes Recessive Robinow Syndrome (limb shortening and brachydactyly type C, 2,3,4). Although absent from healthy adult articular cartilage, our initial studies identified high ROR2 expression in chondrocytes from patients with OA, suggesting a role in the disease process.

In a murine model of OA, blocking ROR2 in therapeutic regime using siRNA resulted in reduced cartilage destruction and rapid and sustained pain relief. Due to the limited expression pattern of ROR2 in adulthood, no systemic or local toxicity were expected, nor were any observed. We also found that blocking ROR2 supports cartilage formation in a human cartilage organoid model in nude mice using chondrocytes from patients with OA, and proposed ROR2 blockade as a potential disease-modifying OA treatment. The mechanism of action of ROR2 blockade was independent of modulation of canonical WNT signaling. YAP inhibition was required, but not sufficient, for the chondrogenic effect (4). Therefore, additional, yet unknown mechanisms must be involved downstream of ROR2 blockade.

Objectives: To study the phosphorylation events downstream of ROR2, to further our understanding of the mechanism of action of ROR2 blockade.

Methods: Phosphoproteomics (label free liquid chromatography tandem-mass spectrometry with TiO2 based phospho-enrichment), in vitro studies in cells, CRISPR.

Results: WNT5A is the most well established ligand for ROR2. We confirmed that WNT5A stimulation leads to time-dependent phosphorylation of ERK in C3H10T1/2 cells. We then deleted ROR2 in C3H10T1/2 cells by CRISPR, and performed phosphoproteomics analysis on wildtype (control) C3H10T1/2 cells and ROR2-CRISPR C3H10T1/2 cells stimulated with 100ng/ml recombinant WNT5A for 5 or 15 minutes. ROR2-dependant phosphorylation targets were defined as proteins differentially phosphorylated in control cells upon WNT5A stimulation, but that did not occur in ROR2-CRISPR cells.

YAP phosphorylated by WNT5A in a ROR2-dependant manner. WNT5A/ ROR2 also modulated the YAP signaling pathway at other levels. KEGG analysis revealed that other pathways with known roles in the pathogenesis of OA were enhanced, including NF-kB, mTOR signaling and cellular senescence.

With the current technology, ROR2 blockade requires intra-articular injections of siRNA conjugated to atelocollagen every 5 days. Preliminary efficacy data of potentially longer-acting ROR2 blockers are promising.

Conclusion: ROR2 blockade has potential as a disease-modifying treatment for OA, resulting in cartilage protection and rapid and sustained pain relief in a murine model. Here, we studied the mechanism downstream of ROR2 blockade using a phosphoproteomics approach. We confirmed that YAP signaling was modulated by ROR2, and identified novel pathways and cellular processes regulated by WNT5A/ROR2. Further studies are needed to clarify their role downstream of ROR2 blockade in OA.

Our current siRNA-atelocollagen based technology requires intra-articular injections too frequently to be acceptable for patients. We are developing ROR2 blockade which can be administered systemically or intra-articularly not more often than every 3 months.

Background: Knee osteoarthritis is the most prevalent chronic musculoskeletal debilitating disease. Current treatments are only symptomatic and to improve this, we need a robust prediction model to stratify patients at an early stage according to the risk of joint structure disease progression. Some genetic factors, including single nucleotide polymorphism (SNP) genes and mitochondrial (mt) DNA haplogroups/clusters, have been linked to this disease.

Objectives: For the first time, we aim to determine, by using machine learning, whether some SNP genes and mtDNA haplogroups/clusters alone or combined could account for knee osteoarthritis structural progressors.

Methods: Participants (901) were first classified for the probability of being structural progressors. Genotyping included SNP genes TP63, FTO, GPNL3, USP45, GDF5, SUPT3H, MCF2L, TGFα, mtDNA haplogroups H, J, T, U, others, and clusters HV, TJ, KU, C-others. They were considered for prediction with major risk factors of osteoarthritis, namely, age and body mass index (BMI). Seven supervised machine learning methodologies were evaluated. The support vector machine was used to generate gender-based models. The best input combination was assessed using sensitivity and synergy analyses. Validation was performed using 10-fold cross-validation as well as an external cohort (TASOAC).

Results: From 277 models, two were defined. Both used age and BMI in addition for the first one of the SNP genes TP63, USP45, GDF5, FTO with an accuracy of 85.0%; the second profits from the association of mtDNA haplogroups and SNP genes FTO and SUPT3H with 82.5% accuracy. The highest impact was associated with the haplogroup H, the presence of CT alleles for rs8044769 at FTO, and the absence of AA for rs10948172 at SUPT3H. Validation accuracy with the cross-validation (about 95%) and the external cohort (90.5%, 87.5%, respectively) was excellent for both models.

Conclusion: This study introduces a novel source of decision support in precision medicine, in which, for the first time, two models were developed consisting of i) age, BMI, TP63, USP45, GDF5, FTO and ii) the optimum one as it has one less variable, age, BMI, mtDNA haplogroup, FTO, SUPT3H. Such a framework is translational and type deconvolution and dissecting gene regulatory networks.

Conclusion: These data provide detailed insight into the cellular and molecular mechanisms underpinning subchondral bone and BMAT remodeling in OA. An expansion of pre-adipocyte populations along altered function of BMAT adipocytes might represent a previously unrecognized mechanism regulating subchondral bone sclerosis. TFs driving core gene regulatory networks might be promising therapeutic targets for knee OA.

POS0233  COMPARISON OF 3D QUANTITATIVE OSTEOARTHRITIS IMAGING BIOMARKERS: A STUDY USING PAIRED CT AND MR IMAGES FROM THE IMI-APPROACH STUDY.

A. Brett1, M. A. Bowes1, P. G. Conaghan1. 1Iompics Ltd. Clinical Applications, Manchester United Kingdom; 2University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: MRI bone surface area and femoral bone shape (B-score) measures have been employed as quantitative endpoints in DMOAD clinical trials. The B-score (typical range -2 to +7) has been shown to be an objective, automated assessment of OA status, with clinical risk defined for current and future patient, functional limitation and total knee replacement. Computerized Tomography (CT) imaging is more commonly used for 3D visualization of bone anatomy due to its high bone-soft tissue contrast. Also, CT images are not subject to the geometric distortion in MR images due to the presence of inhomogeneities, a problem addressed in DMOAD clinical trials by positioning the knee near the magnet isocenter. Measurement of 3D joint space width (3DJSW) has been previously reported using CT images but is possible from MR images.

Objectives: To test the robustness of the B-score, bone area and 3DJSW imaging endpoints to the choice of imaging modality, we compared the results of automated analysis of CT and MR image pairs acquired at baseline and 24-month timepoints.

Methods: We used image data from the IMI-APPROACH exploratory, 2-year prospective cohort study. High resolution CT images were acquired at baseline and 24-months. These were matched with 3D T1w MR images with fat-sat or SE sequences. CT and MR images were acquired within a mean of 12 days of each other. Additional test-re-test MR images with repositioning were available from 37 subjects. Kelgren-Lawrence Grades (KLG) were read centrally from screening weight-bearing x-rays. Femur and tibia bones were automatically segmented with sub-voxel accuracy from CT or MR images using active appearance models, a machine learning model trained to search images (Imorphics, Manchester, UK). Bone area measurement was produced for MF.tAB, LT.tAB, MT.tAB and LT.tAB regions. Average 3DJSW was measured in central regions of the medial or lateral tibial plateaus, normal to the tibial surface. Linear regression was used to test for correlation between measures. Limits of agreement and systematic bias were tested using Bland-Altman analysis. Smallest detectable difference (SDD) for MR B-score was computed from test-re-test image pairs using Bland-Altman analysis. Images acquired from the same subject at both baseline and 24-month timepoints were treated as independent.

Results: Baseline and 24-month CT-MR pairs of the same knee were available from 231 and 203 subjects respectively. 338 were female knees (78%). KLG was KLG0 (19%), KLG1 (31%), KLG2 (30%), KLG3 (16%) and KLG4 (3%) with 5 knees ungraded (1%). SDD of the B-score measure was 0.227. Table 1 presents summary statistics for shape, area, and 3D JSW measures. Figure 1 shows linear regression and Bland-Altman analysis for B-score.

Conclusion: B-score measures were highly correlated with CT and showed good agreement with a relatively small bias of 0.1 suggesting that B-score may be measured reliably using either modality. All 4 area measures were highly correlated and showed negative bias (MR smaller). It is likely that the bone surface identified using MR and CT will be at slightly different positions within the bone/cartilage boundary. A consistent negative bias suggests the MR bone boundary is inside the CT boundary. This is consistent with the positive bias in favour of MR for 3DJSW. However, the MR-CT difference for medial 3DJSW is larger than for lateral 3DJSW, possibly due to a difference in knee pose during acquisition (fully extended for CT, flexed for MR) – the tibia is more externally rotated with respect to the femur in the fully extended knee.

Rheumatoid arthritis: JAKi and beyond_________

POS0234  HOW CLOSELY DO GERMAN RHEUMATOLOGISTS FOLLOW THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF RHEUMATOID ARTHRITIS WHEN MAKING THERAPEUTIC DECISIONS?

Y. Meissner1, D. Huschek1, A. Zink1, J. Kaufmann2, M. Bohl-Buehler1, A. Strangfeld3. 1German Rheumatism Research Centre Berlin, Epidemiology and Health Services Research, Berlin, Germany; 2Private Practice, Rheumatology, Ludwigsfeld, Germany; 3Private Practice, Rheumatology, Potsdam, Germany

Background: EULAR developed recommendations for the management of rheumatoid arthritis (RA) suggesting treatment escalation and changes at different stages of the disease to reach at least low disease activity with latest updates in 2015[1], 2016[2], and 2019[3]. The recommendation to consider adding a biologic disease-modifying anti-rheumatic drug (DMARD) – or, since 2016, a Januskinase inhibitor (JAKi) – after the first conventional synthetic (cs) DMARD had failed and if poor prognostic factors (PPF) are present, was strengthened 2019. Since then, it is recommended that a bDMARD or a tsDMARD should be added.

Methods: Data were used from the long-term observational cohort RABBIT, which enrolls patients with RA starting a bDMARD or JAKi, or a csDMARD after at least one previous csDMARD failure. According to the publication of the recommendations, periods from [I] 01/2014 – 12/2016, [II] 01/2017 – 06/2020 and [III] 07/2020 – 04/2021 were investigated. Patients who were in at least moderate disease activity (DAS28<3.2) were selected and analysed, if they started a csDMARD, a bDMARD, or a JAKi. Patients were further stratified by prior treatments and by the presence of PPF (≥4 swollen joints, positive rheumatoid factor or ACPA, erosions).

Results: Of the 15,150 patients with RA enrolled since 2007, 2,922 treatments were initiated in period [I], 4,580 in [II] and 415 in [III] (see Table 1). The proportion of patients with 1 previous csDMARD and 1 PPF who – in agreement with the recommendations – switched to bDMARD or JAKi, increased from 30% (only csDMARDs) in period [I] to 68% (bDMARDs + JAKi) in [III]. The proportions were even higher in patients with 2 previous csDMARDs (86% in [I], 93% in [III]). As recommended, JAKi were used more often as first line therapy (after csDMARD) in period [III].

Conclusion: JAKi have become more established, especially in bionaive patients, but have not reached the significance of biologics in certain patient groups. The early decision for a bDMARD or JAKi has been made more frequently in recent years, yet one third of patients did not receive the recommended treatment escalation. We cannot conclude from the data, which considerations led to the decision not to escalate. Of note, German rheumatologists should rather follow the German treatment guidelines, which are, however, very similar to the EULAR recommendations.

EULAR treatment recommendations are indicated in green. *JAKi were not available. **Recommendation in period [I]: Addition of a bDMARD should be considered; in [II]: Addition of a bDMARD or a tsDMARD should be considered, current practice would be to start a bDMARD; in [III]: a bDMARD or a tsDMARD should be added. PPF, poor prognostic factor.

Background: The preferential Janus kinase-1 inhibitor FIL significantly improved signs and symptoms of RA in Phase 2 and 3 trials. FIL is approved for treatment of moderate to severe active RA in Europe and Japan. Integrated safety analysis of FIL with patient data through 2019 was presented at the 2020 ACR virtual meeting. 6

Objectives: To report updated, as-treated data from the FIL integrated safety analysis with increased study drug exposure.

Methods: Data were integrated from 2 Phase 2 (NCT01668641, NCT01894516), 3 Phase 3 (NCT02889796, NCT02873936, NCT02886728), and 2 long-term extension (LTE) (NCT02085700, NCT03025308) trials. Phase 2 and 3 LTE data were through Nov 2020 and Jan 2021, respectively. The as-treated analysis set included all available data for pts receiving ≥1 dose FIL 200 (FIL200) or 100 mg FIL 100 (FIL100).
(FIL100), including those rerandomized to FIL for LTE. Exposure-adjusted incidence rates (EAIRs) of treatment-emergent adverse events (TEAEs) and malignancies excluding NMSC (total FIL 0.5 to 0.6).

Results: 3691 pts received FIL200 or FIL100 for 8085.1 PYE (median 2.2, maximum 6.8 y). In the as-treated set, 61% of FIL200 and 45% of FIL100 pts received FIL for ≥2 y, 19% and 5% for ≥3 y, and 11% and 0.5% for ≥4.5 y, respectively. EAIRs for AESIs were comparable between doses (Table 1). EAIRs for AESIs tended to decrease since the previous update, except for venous thromboembolism (total FIL 0.1 to 0.2) and malignancies excluding NMSC (total FIL 0.5 to 0.6).

Conclusion: With 1 additional year of exposure since the 2020 report, FIL continued to be well tolerated with no new safety concerns emerging. EAIRs of TEAEs, including deaths, and AESIs remained stable or decreased since the 2020 report, except for slight increases in rates of NMSC and malignancies excluding NMSC. In the context of demonstrated efficacy, both FIL doses had an acceptable risk/benefit profile.

Background: Vagus nerve stimulation (VNS) activates innate immunoregulatory reflexes that have been shown to reduce pro-inflammatory cytokines and clinical disease activity in subjects with rheumatoid arthritis (RA) 1. We now report 24-week efficacy and safety findings from this study.

Objectives: Determine the long-term safety and exploratory efficacy of neurostimulation using a novel, miniaturized VNS device in patients with multiple drug refractory RA who were previously enrolled in a first-in-human study.

Methods: The primary study enrolled active adult patients with active moderate-to-severe RA with incomplete response or intolerability to at least two biologic and/or targeted synthetic DMARDs having at least two different mechanisms of action. The study was enrolled in 2 Stages: Stage 1 (n=3) was open-label, and Stage 2 (n=11) was randomized and sham-controlled (Figure 1). Three weeks after MR implantation, the first 3 subjects in Stage 1 received active VNS for 1 minute, once per day (QD). Following safety review board approval, 11 patients in Stage 2 were implanted with the MR and randomized 1:1:1 into one of two active VNS groups (1 minute of VNS QD or 1 minute of active VNS 4 times per day [QID]) or a sham group. At Week 12, the blind was lifted, sham subjects were re-randomized and crossed over to either QD or QID active VNS dosing, and all actively treated subjects remained on their dosing through Week 24. Safety and tolerability were determined, and several secondary efficacy endpoints were evaluated measuring the change in disease activity from the start of active VNS to Week 24.

Results: There were no device-related adverse events from Week 12 through Week 24. Improvement in clinical disease activity was sustained through Week 24.
EULAR response criteria for DAS28-CRP at Week 24 (Table 1) vs. 5/10 at Week 12 (one Week 12 responder was lost to follow-up). Similarly, 6/9 patients in the original, active VNS treatment group met or exceeded the MCID in CDAI at Week 24 vs. 5/10 at Week 12. In the long-term extension, 1/4 sham crossover patients had both EULAR and CDAI response after 12 weeks of VNS (1/2 QD, 0/2 QID). Co-treatment with a b/tsDMARD was initiated in 2 subjects (Table 1). One crossover subject was treated with oral methylprednisolone at week 19 due to worsening RA disease activity. VECTRA composite scores and component analysis revealed an 18-point decrease in median multi-analyte disease activity index in the QD group over 24 weeks of VNS with a decrease in serum levels of several analytes in key component categories (IL-6, serum amyloid A, and VCAM-1). Erosion progression by hand MRI was stabilized or decreased in all but 1 of the stimulated patients at Week 24.

Conclusion: Improvements in clinical disease activity and pro-inflammatory cytokine suppression were maintained through 24 weeks of VNS treatment. Safety outcomes continue to support the risk/benefit profile of VNS as a treatment option for patients with multiple-drug refractory RA.

Background: ORAL Surveillance was a post-authorisation safety study of tocilizumab vs TNF inhibitors (TNFi) in rheumatoid arthritis (RA) patients (pts) aged ≥50 yrs with ≥1 additional cardiovascular (CV) risk factor and an inadequate response to methotrexate (MTX). CV disease has overlapping risk factors with malignancies and venous thromboembolism (VTE), including older age, smoking, hypertension and diabetes.1,2

Objectives: To evaluate the impact of pts' baseline (BL) CV risk on the incidence and risk of major adverse CV events (MACE), malignancies and VTE in ORAL Surveillance.

Methods: Pts on stable MTX were randomised 1:1:1 to receive tofacitinib 5 or 10 mg twice daily (BID) or a TNFi (adalimumab 40 mg every 2 weeks or etanercept 50 mg once weekly). Incidence rates (IRs; pts with first events/100 pt-yrs) and hazard ratios (HRs; tofacitinib vs TNFi) were evaluated for adjudicated MACE (defined as CV death [excluding CV death due to pulmonary embolism (PE)], nonfatal MI and non-fatal stroke), malignancies (excluding NMSC) and VTE (including fatal/non-fatal deep vein thrombosis and PE). Across safety outcomes, IRs/HRs were stratified by BL CV risk score; pts were first categorised by history of coronary artery disease (HxCAD); pts without a HxCAD were further stratified by BL CV risk score categories (high ≥20%, intermediate ≥7.5–20%, borderline [≥5–<7.5%] and low [≤5%] risk), with a 1.5 multiplier applied per EULAR recommendations.3

Results: 4362 pts were included: tofacitinib 5 mg BID, n=1455; tofacitinib 10 mg BID, n=1456; TNFi, n=1451. In these treatment groups, during a median follow-up of 4.0 yrs, MACE was reported in 47 (3.2%), 51 (3.5%) and 37 (2.6%) pts, malignancies in 62 (4.3%), 60 (4.1%) and 42 (2.9%) pts, and VTE in 17 (1.2%), 34 (2.3%) and 10 (0.7%) pts, respectively. Approximately two-thirds of pts had intermediate to high CV risk, or HxCAD, and risk was well-balanced across treatment groups (Table 1). Across treatments, MACE and malignancies IRs were highest in pts with a HxCAD or high BL CV risk score (Figure 1). IRs/HRs for MACE, malignancies and VTE were generally higher with tofacitinib vs TNFi. Differences between tofacitinib vs TNFi in MACE and malignancy IRs/HRs were typically more pronounced in pts with a HxCAD or at least intermediate BL CV risk score, and less so in pts with lower BL CV risk score (Figure 1). In tofacitinib 10mg BID-treated pts, VTE IRs/HRs (vs TNFi) were clearly highest in pts with a HxCAD or high BL CV risk score; no association between VTE and BL CV risk scores was observed (Figure 1).

Table 1. Percentages of pts with a HxCAD and pts without a HxCAD categorised by BL CV risk scores, per ASCVD-PCE risk calculator4 with a 1.5 multiplier applied3

and address CV risk in RA pts.

Acknowledgements: Study sponsored by Pfizer Inc. Medical writing support was provided by Tanya Guha, CMC Connect, and funded by Pfizer Inc.

REFERENCES:

Conclusion: In this post hoc analysis of data from ORAL Surveillance, IRs for MACE and malignancies (excluding NMSC) were highest across treatments, and increased with both tofacitinib doses vs TNFi, in pts with a HxCAD or high BL CV risk score; a similar finding was observed for VTE IRs in pts treated with tofacitinib 10 mg BID. These findings support recommendations to regularly assess and address CV risk in RA pts.

BACKGROUND: During the pandemic, hydroxychloroquine (HCQ) became a household name, yet despite more than 70 years as a csDMARD treatment, relatively little is known about its overall side effect (SE) profile.

Objectives: To understand the types, severity, and rates of patient-reported side effects of HCQ in adults with RA, SLE, and other RMDs alone and in comparison with methotrexate (MTX).

Methods: Adult participants in the Forward Databank observational registry reported all medication use and medication side effects through biannual questionnaires from 1999 through 2021. Incident use of HCQ and MTX were measured at enrollment and longitudinally with additional reporting of severity of side effects, certainty of medication as cause of side effect, and affected body systems. We analyzed incident rates of side effects overall and by HCO and MTX categorical use, respectively: monotherapy, with concomitant use of another csDMARD, or with concomitant use of a bDMARD or tsDMARD. Finally, the likelihood of having any side effects was analyzed in Cox regression models by comparing HCO initiators to MTX initiation, and within each, combination MTX or HCQ with csDMARD or bDMARD to monotherapy; these findings support recommendations to regularly assess and address CV risk in RA pts.
models were adjusted for age, sex, RD Comorbidity Index, patient global, pain, disease duration, and number of csDMARDs used.

Results: Overall, 5874 patients initiated HCQ and 10420 initiated MTX, with RA as the predominant diagnosis. Mean baseline characteristics were similar for RA: 59 years old, 80% female and 12 years of RA duration. MTX was mostly used with other csDMARDs, while MTX was mostly used with bDMARDs. In the other RMD and SLE groups, most were on HCQ monotherapy. For all RMDs, SE incidence for HCQ (16 – 17%) was lower than MTX (26 – 39%). The Table 1 provides incidence rates by HCQ/MTX for any SE, those that force medication discontinuation, and SE leading to hospitalization. Reported SE rates were always higher for MTX vs. HCQ for all SE severity and diagnoses.

Conclusion: This is the largest study yet to review patient-reported SEs from HCQ and MTX in RA and other RMDs over a 20-year period. While validating SEs was beyond the scope of the current study, we found an overall low incidence of SEs from HCQ use, with an adjusted rate half of those reported for MTX, and that this low rate did not differ by diagnosis or concomitant DMARD use.

Disclosure of Interests: None declared

Methods: Pts on stable MTX received tofacitinib 5 or 10 mg twice daily (BID) or a TNFi (etanercept 50 mg weekly or adalimumab 40 mg once every 2 weeks). Incidence rates (IRs; pts with first events/100 pt-yrs; PY) and 95% CIs were calculated for adjudicated VTE, DVT, and PE (overall by 6-month interval and for pts with/without history of VTE). For overall VTE, DVT and PE, numbers needed to harm (NNH); tofacitinib 5 or 10 mg BID vs TNFi were calculated post hoc. Multivariate Cox models were used post hoc to identify overall independent baseline (BL) risk factors for PE. Censoring time was a 28-day on-treatment period (minimum of last contact date or last study treatment date +28 days).

Results: Analysis included 1455, 1456 and 1451 pts receiving tofacitinib 5 mg BID, 10 mg BID and TNFi, respectively. Generally, across 6-month intervals to >54 months, VTE, DVT and PE IRs were numerically higher with both tofacitinib doses vs TNFi, and with tofacitinib 10 vs 5 mg BID; IRs were consistent across time (data not shown). Across treatments, VTE, DVT and PE IRs were higher in pts with vs without history of VTE; however, only a small number

JAK INHIBITORS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: EXPLORING EARLY RESPONSE ON CENTRAL SENSITIZATION AND CATASTROPHISM SYMPTOMS

F. Salato1, M. Di Carlo1, M. Carotti2, L. Ceccharelli3, S. Fulginei1, S. Farah1, A. Giovangioni1, 1Università Politecnica delle Marche, Dipartimento Di Scienze e Molecolari, Ospedale “Carlo Urbani”; Jesi, Italy; 2Università Politecnica delle Marche, Dipartimento di Scienze Radiologiche, Ospedali Riuniti, Ancona, Italy; 3Azienda Ospedaliero-Universitaria Sant’Anna, Department of Interventional and Diagnostic Radiology, Ferrara, Italy

Background: Catastrophizing has been demonstrated to be linked with central sensitization (CS), although few studies have investigated the potential of interactions between catastrophizing and CS in patients receiving JAK inhibitors.

Objectives: To explore the link between changes in Simplified Disease Activity Index (SDAI) and changes in pain catastrophizing, pain intensity, neuropathic pain component (NPC) and CS symptoms that occur with the introduction of a novel treatment targeting the JAK/STAT signalling pathway.

Methods: 115 patients in an ongoing prospective observational analysis filled out questionnaires at the start and conclusion of the research, using the Pain Catastrophizing Scale (PCS) and Central Sensitization Inventory (CSI). The study included 22 patients on tofacitinib monotherapy (5 mg BD), 19 on tofacitinib and MTX, 17 on baricitinib monotherapy (4 mg OD), 17 on baricitinib and MTX, 17 on upadacitinib monotherapy (15 mg OD), 16 on upadacitinib and MTX, and 8 on filgotinib (200 mg OD) and MTX. The disease activity index was evaluated by the simplified disease activity index (SDAI). The US scoring system validated in the US-CLARA was used. The Semantic Questionnaire for Rheumatology (SOR) and PainDETECT questionnaire (PDQ), were used to assess pain severity and NPC. Using multivariable linear regression models, we investigated the connection between changes in SDAI and in CSI, PCS, PDQ, SQR and US score.

Results: At baseline, the percentage of RA patients who exceeded the thresholds for the presence of NPC (PDQ > 19 points) of the CSI (> 40 points) and PCS (> 30 points) were 43.5%, 36.5%, and 62.6%, respectively. After 4 weeks of treatment, the patient-reported scores and the disease composite index decreased significantly, SRO (p<0.0001), PDQ (p=0.0084), PCS (p=0.0066), CSI (p=0.0165) and SDAI (p<0.0001). The US score did not change significantly (5.25 to 5.03; p=0.248), SDAI achieved 10.6% remission and 15.2% low disease activity at week 4. Multivariate regression analysis indicated that changes in SDAI were exclusively connected to changes in catastrophizing (coefficient=0.500, P=0.0224).

Conclusion: After starting a Jak inhibitor, pain catastrophizing, but not articular inflammation on US, diminishes along with disease activity. These findings provide evidence to the concept of catastrophizing as a dynamic construct that may be adjusted by therapy aimed at reducing inflammatory disease activity and pain levels in the RA patient.

THE EFFECT OF ANTIMALARIALS ON THE OVERALL SAFETY AND PERSISTENCE OF TREATMENT WITH BIOLOGIC AGENTS OR JAK INHIBITORS IN RHEUMATOID ARTHRITIS

M. Bredemeier1, A. Duarte1, M. Pinheiro1, B. Stadler2, J. C. Maceira2, R. Ranzza1, J. Miranda1, V. Valim3, G. Castro3, M. Bertolo4, M. D. F. Sauma1, V. Fernandes1, A. C. Medeiros-Ribeiro1, R. Botelho1, C. Brenol1, H. M. Da Silveira DE Carvalho1, S. Studart1, G. Da Rocha Castelan Pinheiro1, L. Rocha1, H. De Leon de Lima1, I. Pereira1, M. Ohira Gazzeta1, A. Kakehasi1, P. Louzada Jr1, A. L. S. Hayata1, F. Pina1, M. Pires Ferreira1, L. Balanini1, I. G. Silveira1, S. Kowalski1, D. Titton1, R. Mendonça Da Silva Chakr1, A. Ranzolin1, I. Laurindo1, R. Xavier1 on behalf of BiobadaBrasil. 1Brazilian Society of Rheumatology, Register BiobadaBrasil, São Paulo, Brazil

Background: Antimalarials (AM) are frequently part of the initial scheme of conventional synthetic DMARDs in the treatment of rheumatoid arthritis (RA), and have been associated with lower incidence of diabetes and better lipid profile in these patients (1). However, the role of AM in schemes involving biologic (b-) or targeted synthetic (ts-) DMARDs has been much less extensively studied. In addition, a recent large scale study (2) and a consensus article (1) casted doubt on the long-term cardiovascular safety of AM.

Objectives: To evaluate the association of concomitant use of AM with the overall safety and survival of treatment course among patients receiving one or multiple courses of bDMARDs or tsDMARDs.

Methods: BiobadaBrasil is a multicentric registry-based cohort study of Brazilian patients with rheumatic diseases starting their first bDMARD or tsDMARD (3). The present analysis includes RA patients recruited from Jan 2009 to Oct 2019, followed-up over one or multiple (up to six) courses of treatment (latest date, Nov 19, 2019). A treatment course is defined as a period during which the medication scheme does not change. The primary outcome was the incidence of serious adverse events (SAEs). Total and system-specific adverse events (AEs), treatment interruption for any reason, interruption due to AEs and due to inefficacy served as secondary outcomes. Negative binomial regression with generalized estimating equations (to calculate the incidence rate ratios [IRRs]) and extended (frailty) Cox proportional hazards models were used for statistical analyses (both types of analyses including time-varying covariates over multiple courses of treatment). Results: In total, 1316 patients (2335 treatment courses, 671 patient-years [PY]) were enrolled. The overall incidence of serious adverse events was 9.2/100 PY. AM were used over 354 courses (1254.5 PY) of therapy. The IRRs for the primary and secondary outcomes are presented in Table 1. AM were also associated with better treatment course survival (Figure 1), reducing the risk of interruption due to AEs (multivariate hazard ratio: 0.56, 95% CI: 0.39 to 0.81, P=0.002) and inefficacy (0.65, 0.48 to 0.87, P=0.003).

Disclosure of Interests: None declared

ASSOCIATION OF PROTEINASE 3 GENE (PRPTN) VAL119ILE POLYMORPHISM (SNP RS351111) WITH RISK OF RELAPSE AMONG HOMOZYGOUS PATIENTS WITH PR3 ANCA-ASSOCIATED VASculITIS

M. Casal Moura1, Z. Deng2, S. Brooks2, W. Teal2, A. Hummel1, F. Fervenza3, C. Kallenberg1, C. Langford4, P.A. Merkel5, P.A. Monach6, P. See7, R. Spiera8, W. St. Clair9, J. H. Stone10, M. Prunotto11, P. Grayson12, S. Specks1. 1Mayo Clinic, 2Thoracic Disease Research Unit, Division of Pulmonary & Critical Care Medicine, Department of Medicine, Rochester, United States of America; 3National Institute of Health, Translational Autoinflammatory Diseases Section (TADS), NIAD/NIH, Bethesda, United States of America; 4Genentech Inc., a member of the Roche Group, I2O Technology & Translational Research, San Francisco, United States of America; 5Mayo Clinic, Division of Nephrology and Hypertension, Department of Medicine, Rochester, United States of America; 6University of Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; 7Cleveland Clinic, Rheumatology, Cleveland, United States of America; 8University of Pennsylvania, Division of Rheumatology, Department of Medicine, Division of Clinical Epidemiology, Department of Biostatistics, Epidemiology, and Informatics, Philadelphia, United States of America; 9University of Boston, Rheumatology, Boston, United States of America; 10Johns Hopkins Medicine, Rheumatology, Baltimore, United States of America; 11Weill Cornell Medical College, Hospital for Special Surgery, Rheumatology, New York, United States of America; 12Duke University, Rheumatology, Durham, United States of America. 13University of Geneva, Medicine, Geneva, Switzerland

Background: The frequency of the proteinase 3 gene (PRPTN) polymorphisms in patients with ANCA-associated vasculitis (AAV) is not well characterized. We hypothesize that PRPTN3 gene polymorphisms induce allostatic changes in PR3 conformation which may alter its interaction with ligands and PR3-ANCA during inflammation with potential implications for disease presentation and clinical outcomes.

Objectives: To analyze the association of PRPTN3 Val119Ile polymorphism (SNP rs351111) with risk of relapse among homozygous patients with PR3 ANCA-associated vasculitis.

METHODS: DNA variant calling for SNP rs351111 (chr.19:844020, c.355G>A) in PRPTN gene assessed the allelic frequency in patients with PR3-AAV included in the Rituximab versus Cyclophosphamide (RAVE) trial. This was followed by RNA-seq variant calling for SNP rs351111 (chr.19:844020, c.355G>A) in PRPTN gene assessed the allelic frequency in patients with PR3-AAV included in the Rituximab versus Cyclophosphamide (RAVE) trial. This was followed by RNA-seq variant calling to characterize the mRNA expression. We compared clinical presentation and outcomes between patients homozygous for PR3-Val119Ile and PR3-Val119.

RESULTS: Serum samples for DNA calling were available in 188 of the 197 patients with AAV in the RAVE cohort. 75 PR3-AAV patients had the allelic variant was found in 35 PR3-AAV patients: 13 patients were homozygous for PR3-Ile119 and 62 patients were heterozygous PR3-Val119Ile with an allele frequency threshold of 29.3 – 55.1% of reads (Figure 1A and 1B). RNA-seq was available for 89 patients and the mRNA expression corresponding to the allelic variant was found in 35 PR3-AAV patients: 13 patients were homozygous for PR3-Ile119 and 22 patients were heterozygous PR3-Val119Ile with an allele frequency threshold of 11.1 – 62.8% of reads (Figure 1A and 1C). The agreement between the DNA calling results and the mRNA expression of the 86 patients that overlapped was 100%. We found an additional homozygous patient for PR3-Val119 in which blood was not available for DNA calling.

We compared the clinical presentation and outcomes of 74 patients with PR3-AAV: 13 homozygous for PR3-Ile and 51 homozygous for PR3-Val (Table 1). The frequency of severe flares at 18 months in homozygous PR3-Ile was ≥2x higher when compared with homozygous PR3-Val (46.2% vs. 19.6%, p=0.048). We found no differences in clinical presentation.

**Figure 1.** RAVE trial population distribution according to the zygosity status for PRTN3 gene (PR3 and MPO-ANCA patients) and DNA or RNA variant calling (panel A). Allelic frequency for rs351111, chr19:844020 (c.355G>A) in PRTN3 among patients with AAV (PR3 and MPO-ANCA) in the DNA (panel B) and RNA (panel C) variant calling.

| Table 1. Outcomes of patients with PR3-ANCA according with PRTN3 zygosity. |
|-----------------------------|-----------------------------|-----------------------------|
| PR3-ANCA (n=64)             | Homozygous PR3-Val (n=51)   | Homozygous PR3-Ile (n=13)   |
| **Remission, n (%)**        | 45 (88.2)                   | 13 (100)                    |
| Complete remission, n (%)   | 36 (70.6)                   | 10 (76.9)                   |
| Any flare 18 months, n (%)  | 30 (58.8)                   | 7 (53.8)                    |
| Severe Relapse 18 months, n (%) | 10 (19.6) | 6 (46.2) | 0.048 |

*Relapse was considered “Severe” if Birmingham Vasculitis Activity Score for Wegener’s Granulomatosis (BVAS/WG) > 3 or one major item as per the RAVE trial definition.

**Conclusion:** In patients with PR3-AAV the presence of PRTN3 Val allele polymorphism was associated with higher frequency of severe relapse. Further studies are necessary to understand the association of this observation with the risk of severe relapse.

**PROTEIN PROFILING IN PRE-SYMPTOMATIC ANCA-ASSOCIATED VASULITIS INDIVIDUALS.**

M. Brink, E. Berglin, A. J. Mohammd, A. Alexyenko, K. Lejon, S. Rantapää Dahlqvist, Umeå university, Public Health and Medicine/Rheumatology, Umeå, Sweden; Lund University, Clinical Sciences/Rheumatology, Lund, Sweden; University of Cambridge, Department of Medicine, Cambridge, United Kingdom; Karolinska Institute, Department of Microbiology, Stockholm, Sweden; Umeå universitet, Department of Clinical Microbiology, Umeå, Sweden

**Background:** Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a chronic relapsing condition, with unknown etiology.

**Objectives:** This study was undertaken to gain insight to the molecular processes and to find potential biomarkers in blood samples collected prior to the onset of symptoms of AAV.

**Methods:** The National Patient Register and Cause of Death register were searched for AAV-ICD codes and linked to the registers of five biobanks. Eighty-five AAV cases were included. For each case two controls matched for sex, age, and sampling date were included. Samples were analyzed using ELISAs for PR3- or MPO-ANCA specificities. Ninety-two protein markers were analyzed using Olink Inflammation panel (OLINK, Uppsala, Sweden) with 73 eligible after quality control.

**Results:** Eight protein markers were significantly altered between pre-AAV and controls, with higher levels of CCL23, CXCL5 (p< 0.01-0.05) and lower levels of Fli3L, STAMBPL, ADA, TNFB, CX3CL1 and IL-15RA (p< 0.01-0.05) in the pre-AAV individuals. Nine protein markers were found significantly associated with time to symptom onset; CXCL9, CD344, VEGFA, CXCL1, TNFSP5, CPG, CSF-1, IFN-gamma and DDAO (p< 0.01-0.05). In pre-AAV individuals, six proteins were associated with MPO-ANCA-positivity compared with the MPO-ANCA-negative pre-AAV individuals which showed no overlap with the seven proteins related to PR3-ANCA-positivity.

**Conclusion:** To our knowledge our study is the first to analyze for and identify protein markers before symptom onset in AAV. This allowed for further studies of underling cellular and molecular mechanisms in pre-AAV patients as well as the diversification into PR3-ANCA and MPO-ANCA subphenotypes.

systemic manifestations (19/34; 56%), or of both systemic and respiratory symptoms (11/34; 32%). All except one patient were receiving oral corticosteroids, at a median dosage of 25 mg/day (10-38). Mepo was started after a median of 14 months (6-23) from RTX initiation and after a median of 5 months (IQR 3-11) from the last RTX administration. Mepo was used at the dosage of 1000mg/4 weeks in 32/34 (94%), mostly for the control of respiratory manifestations (25/34, 74%). At the time of starting Mepo, the median BVAS was 4 (2-8), and the median prednisolone dose 10 mg/day (7-15). After a median follow-up of 28 months (IQR 23-33) from starting Mepo, the median BVAS decreased to 1.5 (IQR 0-4) and the median corticosteroid dosage to 5 mg/day (2.5-5), with 7/34 (21%) patients being off steroids. At last follow-up, most patients were off RTX (28/34), typically due to stable disease remission (20/34; 59%).

Both RTX and Mepo were well-tolerated; 5 patients had adverse events on RTX (none serious), and 5 on Mepo (including one serious infection).

Conclusion: Sequential use of RTX and Mepo seems to be effective for remission induction and maintenance in EGPA.

Disclosure of Interests: Alessandra Bettoli: None declared, Maria Letizia Urban: None declared, Federica Bello: None declared, Davide Fiori: None declared, Irene Mattioni: None declared, Giuseppe Lupalco: None declared, Florenzo Iannone: None declared, Allyson Egane: None declared, Luca Moroni: None declared, Lorenzo Dagna Consultant of: Consultation honoraria from GSK outside the current work, Marco Caminati: None declared, Simone Negri: None declared, Paolo Cameli: None declared, Marco Folci: None declared, Paola Toniati: None declared, Roberto Padoan: None declared, Olivier Flossmann: None declared, Roser Solans-Laqué: None declared, Laura Losappio: None declared, Jan Schroeder Consultant of: Advisory Board fees from AstraZeneca, whereas secondary outcome included the incidence of infectious events compared. Primary outcome was defined as relapse-free days from treatment initiation, whereas secondary outcome included the incidence of infectious events requiring hospitalization within 48 weeks from treatment initiation. Multivariable analysis was performed to assess the relationship between tapering pace and clinical outcomes.

Methods: In this multicenter (25 sites in Japan), observational, retrospective study of AAV, 541 patients who had initial or severe relapse were enrolled between January 2017 and June 2020. Of these, 500 patients with microscopic polyangiitis (MPA) or granulomatosis with polyangiitis (GPA) who entered in the GC dose, clinicians often taper it slower than recommended due to concerns of potential disease relapse. However, such slower taper may prolong GC exposure for the patients, increasing the risk of adverse events, particularly infection.

Objectives: The aims of our study were (1) to clarify GC dose tapering in the treatment of AAV in a real-world setting, in contrast to the EULAR recommendation of 2015 and (2) to compare the incidence of AAV relapse and severe infection between patients underdosing EULAR-recommended tapering and those undergoing slower tapering than the recommendation.

Background: Antineutrophil cytoplasmic antibody -associated vasculitis (AAV) is usually treated with combination of high-dose glucocorticoid (GC) and immunosuppressive agents, followed by tapering GC dose. Although the European League Against Rheumatism (EULAR) has specific recommendations for tapering the GC dose, clinicians often taper it slower than recommended due to concerns of potential disease relapse. However, such slower taper may prolong GC exposure for the patients, increasing the risk of adverse events, particularly infection.

Objectives: The aims of our study were (1) to clarify GC dose tapering in the treatment of AAV in a real-world setting, in contrast to the EULAR recommendation of 2015 and (2) to compare the incidence of AAV relapse and severe infection between patients underdosing EULAR-recommended tapering and those undergoing slower tapering than the recommendation.

Methods: In this multicenter (25 sites in Japan), observational, retrospective study of AAV, 541 patients who had initial or severe relapse were enrolled between January 2017 and June 2020. Of these, 500 patients with microscopic polyangiitis (MPA) or granulomatosis with polyangiitis (GPA) who entered in GC tapering phase after successful induction treatment were included. These patients were then grouped on the pace of GC tapering, defined as the GC dose at 12 weeks after treatment initiation: (1) EULAR group: 7.5-10 mg/day of GC, according to the EULAR recommendation of 2015, and (2) SLOWER group: >10 mg/day of GC. Their baseline characteristics and clinical outcomes were compared. Primary outcome was defined as relapse-free days from treatment initiation, whereas secondary outcome included the incidence of infectious events requiring hospitalization within 48 weeks from treatment initiation. Multivariable analysis was performed to assess the relationship between tapering pace and clinical outcomes.

Results: There were 44 patients (12.6%) in the EULAR group and 290 (83.2%) in the SLOWER group. Regarding baseline characteristics, compared with the EULAR group, the SLOWER group had significantly higher serum C-reactive protein level (EULAR, 5.89 ± 6.89 mg/dL vs SLOWER, 7.56 ± 6.01 mg/dL; p = 0.03), as well as a trend toward higher Birmingham Vasculitis Activity Score
Subclinical PMR has a predilection for affection of large vessels, followed by isolated cranial pattern (i.e. isolated temporal artery involvement) and with clearly different pattern than classical GCA.

Conclusion: Subclinical GCA in PMR shows a principal isolated extra-cranial involvement and with clearly different pattern than classical GCA.

Acknowledgements: To the GCA/PMR study group

Subclinical PMR has a predication for affection of large vessels, followed by isolated cranial pattern (i.e. isolated temporal artery involvement) and with the mixed (cranial and extra-cranial) form. On the contrary, in classical GCA an isolated cranial involvement represents the more common pattern, followed by the mixed and finally isolated large vessel involvement.

Conclusion: Subclinical GCA in PMR shows a principal isolated extra-cranial involvement and with clearly different pattern than classical GCA.

Acknowledgements: To the GCA/PMR study group

FIBROBLAST ACTIVATION PROTEIN AS A LINK BETWEEN INFLAMMATION AND VASCULAR REMODELING IN GIANT CELL ARTERITIS

S. Xu1, W. F. Jiem1, A. Boots1, Y. Van Sleen1, K. Van der Geest1, P. Heeringa2, E. Brouwer1, M. Sandoval1. 1University Medical Center Groningen, University of Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, University of Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands

Background: Giant cell arteritis (GCA) can present with serious complications such as blindness, stroke and aortic aneurysm that are related to both inflammation and remodeling of the vessel wall. GCA frequently overlaps with polymyalgia rheumatica (PMR). The pathogenesis of GCA starts in the adventitia where fibroblasts are the major stromal cell population. A preliminary study reported the migration of adventitial fibroblasts to the intima, contributing to intimal hyperplasia. Such a role for adventitial fibroblasts in early stages of GCA was observed in an animal model. In patients with GCA and PMR, fibroblast activation protein (FAP) is involved in GCA vascularopathy due to its pro-inflammatory and pro-fibrotic effects.

Objectives: As a first step to unravel the contribution of FAP to the vasculopathy in GCA, we determined FAP plasma levels and FAP protein expression at the site of vascular inflammation in GCA.

Methods: Eight rheumatology European centers participated in the study. Cohort A represented consecutive newly diagnosed patients with PMR who fulfilled the 2012 EULAR/ACR Provisional Classification Criteria for Polymyalgia Rheumatica and had no symptoms or signs suggestive of GCA. Ultrasound (US) examination of four vessel territories (i.e. temporal, carotid, subclavian and axillary arteries) was performed bilaterally. Cohort B included all consecutive patients with the diagnosis of GCA evaluated on the fast-track clinic of one of the hospitals (HULP). The halo sign was considered as positive US finding for GCA. In addition, intima-media thickness of arteries was measured, with a cut-off 0.34 mm for temporal arteries (TA) frontal and parietal, 0.42 mm for common TA, and ≥1 mm for common carotid, axillary and subclavian arteries for positive result. The clinical characteristics of PMR patients were recorded and the frequency of subclinical GCA determined.

Results: Cohort A included 41 PMR patients with subclinical GCA. Cohort B was formed by 97 GCA. The characteristics of the patients are shown in the Table 1. Figure 1 shows the different subtypes of vessel involvement in patients with PMR and subclinical GCA and in patients of the fast-track clinic with the diagnosis of GCA in a single hospital.

Subclinical PMR can be a condition of serious complications such as blindness, stroke and aortic aneurysm that are related to both inflammation and remodeling of the vessel wall. GCA frequently overlaps with polymyalgia rheumatica (PMR). The pathogenesis of GCA starts in the adventitia where fibroblasts are the major stromal cell population. A preliminary study reported the migration of adventitial fibroblasts to the intima, contributing to intimal hyperplasia in GCA. Fibroblast activation protein (FAP) is a non-classical serine protease which can be present in both a membrane-bound form and a soluble form and has been demonstrated to promote inflammation and fibrosis in coronary artery disease and rheumatoid arthritis. We hypothesize that FAP is involved in GCA vascularopathy due to its pro-inflammatory and pro-fibrotic effects.

Objectives: As a first step to unravel the contribution of FAP to the vasculopathy in GCA, we determined FAP plasma levels and FAP protein expression at the site of vascular inflammation in GCA.

---

Science Abstracts

Methods: In our prospective cohort of GCA, PMR and healthy elderly (GPS), we measured the plasma FAP levels with ELISA in new-onset, treatment-naive GCA (N=62), and PMR (N=63) patients and 42 age-matched healthy controls (HC). In addition, we measured the plasma FAP levels at follow-up (3-months, 1-year, 1.5-year and treatment-free remission (TFR)). Temporal artery biopsies (TAB) from treatment-naive GCA patients (n=9) and non-GCA patients (n=9), aorta samples from GCA-related aneurysm (n=9) and atherosclerosis (n=11) were stained for FAP using immunohistochemistry. Immunofluorescence staining for CD90, CD68, αSMA and FAP was performed to detect FAP expression in fibroblasts, macrophages and vascular smooth muscle cells (VSMC), respectively.

Results: Baseline plasma FAP levels were significantly lower in GCA patients (52.72±2.93 ng/ml) than in PMR patients (66.42±2.86 ng/ml) and HC (80.47±3.38 ng/ml). FAP levels at baseline correlated inversely with C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), interleukin (IL)-6, macrophage-associated protein YKL-40 (Chitinase 3-like 1/CHI3L1) levels and monocyte counts. Plasma FAP levels in GCA patients decreased even further at 3 months (37.23±2.10 ng/ml) upon glucocorticoid-induced remission, and 20 with MPA (19.2%). mtDNA levels were significantly elevated in AAV plasma (8.7±10^7 copies/ml plasma, 95% CI: 5.3±10^7 to 1.3 ±10^8), compared to HC plasma (6.7±10^7 copies/ml plasma, 95% CI: 5.4±10^7 to 9.1±10^7, p<0.0001). mtDNA levels in contrast did not differ between AAV (4.0±10^6 copies/ml plasma), 95% CI: 2.7±10^6 to 5.0±10^6) and HC (3.3±10^6 copies/ml plasma, 95% CI: 2.4±10^6 to 4.7±10^6, p=0.30). ROC analysis showed that a cut-off value of 1.3±10^7 mtDNA copy numbers differentiated between AAV and HC with 89.4% sensitivity, 82.6% specificity and an AUC of 0.94. For AAV patients with active AAV, a cut-off value of 2.9±10^7 mtDNA copy numbers differentiated between AAV and HC with 96.1% sensitivity, 98.9% specificity and an AUC of 0.99 (Figure 1a).

Conclusion: FAP expression is clearly modulated both in plasma and at the site of vascular inflammation in GCA and may represent a pathogenic link between the inflammatory and remodeling processes in GCA. As such, FAP may have utility as a biomarker and should be further investigated as target for therapeutic intervention.

POS0250 PLASMA MITOCHONDRIAL DNA AS A BIOMARKER IN THE DIAGNOSIS AND FOLLOW-UP OF ANCA-ASSOCIATED VASCULITIDES

S. Giaglis1, 2, D. Kyburz1, 2, J. Thiel1, N. Venhoff2, U. Walker1, 2
1University of Basel, Department of Biomedicine, Experimental Rheumatology Laboratory, Basel, Switzerland; 2University Hospital of Basel, Department of Rheumatology, Basel, Switzerland

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) include granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) (1, 2). ANCA recognize the antimicrobial proteins proteinase 3 (PR3) or myeloperoxidase (MPO) (1,2) and trigger the formation of neutrophil extracellular traps (NETs), which release DNA into the extracellular space and systemic circulation. This cell-free (cf)DNA induces endothelial damage, vascular inflammation and necrosis (3).

Objectives: The nature, diagnostic and prognostic value of cfDNA in AAV is still unknown. The aim of the present study was to examine the clinical utility of cfDNA quantification as a biomarker in AAV.

Methods: Total DNA was isolated from platelet-free plasma samples of healthy controls (HC) and consecutive AAV patients. Plasma and clinical data were collected at baseline and follow-up. Copy numbers were quantified by qPCR for mtDNA (ATP-6 gene) and nuclear (n) DNA (GAPDH gene) (4). Patients with eosinophilic GPA (EGPA) were excluded.

Results: Ninety-two HC (median age 51 ± 9, 48.2% female) and 104 AAV patients (median age 64 ± 10, 48% female, mean BVAS: 0; range: 0-40) were available for analysis. Eighty-four (80.8%) of these patients were diagnosed with GPA, and 20 with MPA (19.2%). mtDNA levels were significantly elevated in AAV plasma (8.7±10^7 copies/ml plasma, 95% CI: 5.3±10^7 to 1.3 ±10^8), compared to HC plasma (6.7±10^7 copies/ml plasma, 95% CI: 5.4±10^7 to 9.1±10^7, p<0.0001). mtDNA levels in contrast did not differ between AAV (4.0±10^6 copies/ml plasma, 95% CI: 2.7±10^6 to 5.0±10^6) and HC (3.3±10^6 copies/ml plasma, 95% CI: 2.4±10^6 to 4.7±10^6, p=0.30). ROC analysis showed that a cut-off value of 1.3±10^7 mtDNA copy numbers differentiated between AAV and HC with 89.4% sensitivity, 82.6% specificity and an AUC of 0.94. For AAV patients with active AAV, a cut-off value of 2.9±10^7 mtDNA copy numbers differentiated between AAV and HC with 96.1% sensitivity, 98.9% specificity and an AUC of 0.99 (Figure 1a).

With the exception of the peripheral nervous system involvement, there was no association of mtDNA elevation with any particular type of active organ involvement at the time of blood sampling. A positive correlation between all cell-free DNA species and anti-MPO antibody titres was observed, as expected (for cfDNA, nDNA and mtDNA - r=0.25, p=0.01; r=0.21, p=0.02; r=0.22, p=0.02, respectively).

AAV patients with active disease (BVAS>0) had a mean of 2.0±10^7 copies/ml of mtDNA in plasma which was higher compared to HC (p<0.0001) and AAV patients in remission (BVAS=0) (6.2±10^7 copies/ml, p<0.03). For nDNA on the other hand, there were similar levels in active disease as in remission (3.5±10^7 and 4.8±10^7 copies/ml, respectively; p=0.64) (Figure 1b).

Follow-up data were available for 27 AAV patients (median follow-up: 6 ± 6 months, IQR: 12). Longitudinal changes in mtDNA levels robustly correlated with changes in BVAS (r=0.56, p<0.002, Figure 1c).

Conclusion: The quantification of cell free mtDNA - but not nDNA - copy numbers allows a sensitive and specific distinction between healthy individuals and patients with active AAV. mtDNA levels correlate cross sectionally with disease activity in AAV patients. Plasma mtDNA quantification may therefore aid in the diagnosis of AAV and in monitoring AAV activity.

DISCLOSURE OF INTERESTS: None declared.

Background: Giant cell arteritis (GCA) is a chronic disease, and affected patients suffer from relapses and glucocorticoid (GC)-related toxicity. Targeted therapies are emerging with the aim of achieving better disease control and reducing GC exposure. Blocking IL-6 receptor with tocilizumab has been a major advance in the treatment of GCA. However, approximately 40% of patients treated with tocilizumab in combination with GCs experience a flare or tocilizumab-related adverse event. Blockade GM-CSF receptor α with mavrilimumab significantly reduced risk of relapse and improved sustained remission at week 26 vs placebo in Phase 2 trial. Not all patients satisfactorily respond to any therapy, indicating heterogeneity in leading pathogenic pathways among patients. For these reasons, it is crucial to understand the specific impact of targeted therapies on vascular lesions.

Objectives: In this study we investigated transcriptomic changes induced by tocilizumab or mavrilimumab in ex vivo cultured arteries from patients with GCA. Genes were selected for validation based on high level of expression and differential changes elicited between treatments. Of those, only 9 transcripts remained significant after correction for multiple comparisons, with a false discovery rate ≤0.05. 81 transcripts were differentially expressed in at least one comparison across groups (Figure 1A). 15 transcripts were lower, and 6 were higher in the mavrilimumab group vs placebo; 3 transcripts were lower, and 2 were higher in the tocilizumab group vs placebo. Most changes elicited between treatments were unique, but CXCL1 was common (Figure 1B). None remained significant after correction for multiple comparisons. The effects of mavrilimumab and tocilizumab on GNAS, CXCL1, IL8, IL2, IRF3, MRC1 and BCL6 expression by Nanostring were consistent with the effect assessed using real time PCR in the separate validation cohort (Figure 1C).

Conclusion: Mavrilimumab and tocilizumab have a different transcriptomic impact on cultured arteries from patients with GCA, with some overlapping effects, although differential effects may have been attenuated by prior GC use. A better understanding of the impact of targeted therapies on vascular inflammation is needed to improve treatment options for patients with GCA.

Disclosure of Interests: The authors would like to thank: the Genomics core facility of the Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS) and Emily Plummer, PhD, Kiniksa Pharmaceuticals, for her invaluable contribution. The study was funded by Kiniksa Pharmaceuticals, Ltd. With support from: Fundació Clinic Barcelona, Fundació Privada Cellex, IDIBAPS, Universitat de Barcelona, Vasculitis Foundation, Marie Curie Actions, and Gobierno de España, Ministerio de Economía, Industria, y Competitividad.

mononuclear cells (PBMC) and vascular cells thus obtained were co-cultured for 7 days in different conditions. Vascular cells were cultured in the presence or absence of IFN-γ and tumor necrosis factor alpha (TNF-α) or interleukin-6 (IL-6) and were treated with IL-6 for 72 hours. When cells reached confluence, they were cultured alone or with allogenic PBMC activated with anti-CD3/CD28 microbeads. After 7 days of culture, cells were separated with a treatment with EDTA and studied by flow cytometry.

**Results:** Confocal microscopy analyses of GCA arteries showed that neointima was mainly composed of myofibroblasts (MF) (α-SMA+Desmin+MHC11lowCD90+) in contact with CD45+ cells and that MF expressed HLA-DR, the phosphorylated form of STAT1 (pSTAT1) and in a lesser extent pSTAT3, strongly suggesting the activation of the IFN-γ signaling pathway rather than the IL-6 pathway. The phenotype of cultured vascular cells isolated from fresh TAB was consistent with MF. When MF were exposed to IFN-γ and TNF-α in vitro, their proliferation capacity decreased and their levels of expression of HLA-DR and CD86 increased (median fluorescence intensity [MF]) from 0 to 57 (p<0.03) and from 34 to 103 (p=0.03), respectively. In addition, co-cultures of MF and activated PBMC revealed that MF maintained the polarization of T cells into Th1 and Th17 cells (p≤0.001) and to a lesser extent into Th17 and Tc17 cells (p=0.03). This effect was even more significant when MF were previously exposed to IFN-γ and TNF-α but not when they were exposed to IL-6.

**Conclusion:** Our results show that myofibroblasts are present in the neointima of GCA patients and that these MF activate signalling pathways indicative of IFN-γ exposure. Moreover, these MF, especially when exposed to IFN-γ, maintain the polarization of T cells into Th1 and Th17 cells, which contributes to amplify the production of IFN-γ and thus initiate a pro-inflammatory amplification loop that likely participates in vascular inflammation and remodelling.

Background: Rheumatic musculoskeletal diseases (RMD) are pathological conditions characterized by an impaired immunological system that is determinant both in the pathogenesis and in the inadequate response to infections. The use of disease-modifying anti-rheumatic drugs (DMARDs), which include conventional synthetic (cs) or biologic and targeted synthetic (bs) DMARDs, contribute to compromise immunological reactivity.

Objectives: To analyze the immune response to SARS-CoV-2 in patients with rheumatoid arthritis (RA) or spondyloarthritis (SpA) receiving treatment with DMARDs and to investigate the effect of the different classes of drugs on humoral and cellular response.

Methods: Patients were tested for anti-SARS-CoV-2 IgG, IgM and IgA antibodies to nucleoprotein (N) and receptor-binding domain (RBD) through ELISA and neutralization assays. Then, we performed a flow cytometry analysis of monocytes, NK cells, B and T lymphocytes from PBMCs of serologically positive patients. We also included a cohort of non-RMD individuals recovered from COVID-19 as a reference group of non-immunosuppressed subjects. A first recruitment occurred in May-June 2020 (T1) and a second recruitment, 3-4 months after (T2), allowed to evaluate the persistence of the antibody response over time and to investigate the cellular immune response to SARS-CoV-2 in RMD patients having resolved the infection.

Results: During T1, 358 patients with RA (n=200) or SpA (n=158) were recruited. Mean age was 52.8, 62% were female. All patients were treated with DMARDs: 299 with b/tsDMARDs and 59 received csDMARDs alone. One third was also receiving corticosteroids (CS). At T2, 36 subjects were recruited. We found a seroprevalence rate of 18.4%, which did not significantly differ between RA and SpA groups, and between patients treated with b/ts-DMARD or csDMARDs, either alone or in combination with CS (Table 1). Antibody levels of RMD patients were lower than non-RMD individuals (Figure 1), with CTLA4-Ig-treated patients having the lowest IgG levels. This difference was less marked in symptomatic RMD patients. 72% of seropositive patients elicited neutralizing sera. Despite an overall decrease in anti-RBD and anti-N titers, more than two-third of patients treated with b/tsDMARD had significant impaired antibody response compared to patients treated with other biologic and targeted synthetic disease modifying anti-rheumatic drugs (csDMARD).

Conclusion: Our data provide a comprehensive picture of the humoral and cellular immune responses to SARS-CoV-2 infection in RMD patients. We showed that DMARDs treatments did not alter a successful antibody response to the virus and did not hamper the antibody neutralizing ability. However, the magnitude of antibody response was slightly reduced compared to non-RMD individuals, especially in patients receiving CTLA4-Ig. We did not observe marked differences in the B- and T-cell populations between RMD patients compared to non-RMD individuals. However, in patients receiving anti-TNFα we found a higher relative abundance of effector adaptive population compared to other bDMARDs.

**Conclusion:** Patients with IRD getting vaccinated with two doses of COVID19 vaccine during the treatment with rituximab have the ability to develop antibody response although the response is impaired. For each month passed after the last rituximab course and vaccination, participants have the highest chance of achieving a good antibody response.

**Results:** We studied 1138 RMD patients on immunosuppression: most were female (93%) and white (91%) (Table 1). One-hundred and fifteen (10%) had anti-RBD response in the negative range at a median (IQR) of 29 days (28-34) following completion of vaccine series. A greater proportion of participants with negative response were non-white, received J&J vaccine, reported use of mycophenolate, rituximab, or glucocorticoids. Antibody response differed by immunosuppressive regimen, with those receiving rituximab having poorest response (Figure 1). Use of mycophenolate (aOR 9.9, p=0.001), rituximab (aOR 56.9, p=0.001), glucocorticoids (aOR 2.9, p=0.001) and receipt of J&J (aOR 3.13, p=0.039) were associated with negative antibody response.

Rheumatology Service, Tel Aviv, Israel; Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel; Meir Medical Center; Pediatric Rheumatology Unit, Kfar Saba, Israel; University Children's Hospital, University Medical Center Ljubljana, Department of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia; Tel Aviv Medical Center, Allergy and Clinical Immunology Unit, Tel Aviv; Meir Medical Center, Pediatrics, Kfar Saba, Israel; Ruth Rappaport Children's Hospital of Rambam Medical Center, Pediatric Rheumatology Service, Haifa; Tel Aviv Sourasky Medical Center, Hospital Management, Information and Operation Branch, Tel Aviv, Israel; Tel Aviv Sourasky Medical Center, Department of Endocrinology Metabolism and Hypertension, Tel Aviv, Israel; Tel Aviv Sourasky Medical Center, Rheumatology Department, Tel Aviv, Israel.

Background: Adolescents with juvenile-onset autoimmune inflammatory rheumatic diseases (AIIRD) could be at risk for disease flare secondary to SARS-CoV-2 infection or to withholding anti-inflammatory therapy. While vaccination can protect against COVID-19, safety and immunogenicity data regarding anti-
SARS-CoV-2 vaccines among adolescents with AIIRD are limited.

Objectives: This international, prospective, multicentre study evaluated the safety and immunogenicity of the BNT162b2 anti-SARS-CoV-2 vaccine among adolescents and young adults with juvenile-onset AIIRD, 80% of whom are on chronic immunomodulatory therapy.

Methods: Vaccine side effects, disease activity, and short-term efficacy were evaluated after 3 months in 91 patients. Anti-S1/S2 IgG antibody levels were evaluated in 37 patients and 22 controls, 2–9 weeks after the second dose.

Results: Ninety-one patients and 40 healthy controls were included. Safety profile was good, with 96.7% (n=88) of patients reporting mild or no side-effects, and no change in disease activity. However, 3 patients had transient acute symptoms: 2 following the first vaccination (renal failure and pulmonary haemorrhage) and 1 following the second dose (mild lupus flare vs. viral infection). Seroconversion was 97.3% in the AIIRD group compared with 100% among controls. However, anti-S1/S2 antibody titres were significantly lower in the AIIRD group compared with controls (242±136.4 vs. 387.8±57.3 BAU/ml, respectively; p<0.0001). No
cases of COVID-19 were documented during the 3-month follow-up.

Conclusion: Vaccination of juvenile-onset AIIRD patients demonstrated good short-term safety and efficacy, high seropositivity rate, but lower anti-S1/S2 antibody titres compared to healthy controls. These results should encourage age vaccination of adolescents with juvenile-onset AIIRD, even while on immunomodulation.

**A RANDOMIZED CLINICAL TRIAL OF 2-WEEK METHOTREXATE DISCONTINUATION IN RHEUMATOID ARTHRITIS PATIENTS VACCINATED WITH INACTIVATED SARS-COV-2 VACCINE**

C. Scognamiglio Renner Araujo1, A. C. Medeiros Ribeiro1, C. Saad1, K. Bonfiglioli1, D. S. Domiciano1, A. Yukie Shimabuco1, M. Rodrigues Silva1, E. Neves1, S. Pasoto1, T. Pedrosa1, L. Kanda Kupa1, G. Zou1, R. M. Pereira1, C. A. Silva1, N. Akawa1, E. Bonfa1 on behalf of COVID-19 CoronaVac in Patients With Autoimmune Rheumatic Diseases and HIV/AIDS (CoronaRheum).

**Background:** Patients with rheumatoid arthritis (RA) on methotrexate have reduced vaccine responses. Temporary discontinuation has improved immunogenicity of anti-influenza vaccine, but this strategy has not been evaluated in anti-SARS-CoV-2 vaccines.

**Objectives:** To evaluate the effect on immunogenicity and safety of 2-week methotrexate (MTX) discontinuation after each dose of the Sinovac-CoronaVac vaccine versus MTX maintenance in rheumatoid arthritis (RA) patients.

**Methods:** This was a single-center, prospective, randomized, investigator-blinded, intervention study (#NCT04754698, CoronaRheum), including adult RA patients (stable CDAI≤10, prednisone ≤7.5mg/day), randomized (1:1) to withdraw MTX (MTX-hold) for 2 weeks after each vaccine dose or maintain MTX (MTX-main), evaluated at D0, D28 and D69. Co-primary outcomes were anti-SARS-CoV-2 S1/S2 IgG seroconversion(SC) and neutralizing antibody (NAB) positivity at D69. Secondary outcomes were geometric mean titers (GMT) and flare rates. For immunogenicity analyses, we excluded patients with baseline positive IgG/NAb, and for safety reasons, those who flared at D28 (CDAI>10) and did not withdraw MTX twice.

**Results:** Randomization included 138 patients with 9 exclusions (5 COVID-19, 4 protocol violations). Safety evaluation included 60 (MTX-hold) and 69 (MTX-main) patients. Further exclusions: 27 patients [13 (21.7%), n=20 (30%), p=0.848] with positive baseline IgG/NAb and 10 patients (21.3%) in MTX-hold with CDAI>10 at D28. At D69, MTX-hold (n=37) had a higher rate of seroconversion than MTX-main (n=55) [29 (78.4%) vs 30 (54.5%), p=0.019], with parallel augmentation in GMT [34.2 (25.2-46.4) vs 16.8 (11.9-23.6), p=0.006]. No differences were observed for NAB positivity [23 (62.2%) vs 27 (49.1%), p=0.217]. At D28 flare, rates were comparable in both groups (CDAI, p=0.122; DAS28-ESR p=0.576), whereas CDAI>10 was more frequent in MTX-hold at D69 (p=0.024).

**Conclusion:** We provide novel data that 2-week MTX withdrawal after each Sinovac-CoronaVac vaccine dose improves anti-SARS-CoV-2 IgG response. The increased flare rates after second MTX withdrawal may be attributed to the short-term interval between vaccine doses. This strategy requires close surveillance and shared decision making due to the possibility of flares.

**LONG-TERM HUMORAL RESPONSE TO SARS-COV-2 VACCINATION IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASE**

**Background:** The first vaccine against SARS-CoV-2 was approved in December 2020. Immunogenicity of SARS-CoV2 vaccines in patients with immune-mediated inflammatory disease (IMID) have so far been evaluated in the 2-6 weeks after vaccination, but the long-term course of humoral response to vaccination is lacking. We have initiated a prospective dynamic cohort of IMID patients and healthy controls in February 2020 to monitor immune response to SARS-CoV-2 and respiratory infections including COVID-19 (1). Participants who contributed data starting from the 4 weeks before their first vaccination onwards were included in this analysis. Antibodies against SARS-CoV-2 spike protein were quantified with an ELISA from Euroimmun (Lübeck, Germany) with an optical density cutoff of 0.8. We fitted linear mixed-effect models for log-transformed antibody levels using time splines with adjustment for age and sex. Marginal mean antibody levels with 95% confidence intervals (CI) were estimated at selected time points for IMID patients and controls with double vaccination. We descriptively analyzed the observed antibody levels over time in cohort participants receiving two vaccinations vs. three vaccinations.

**Methods:** With a prospective cohort design, we recruited adult IMID patients and healthy controls in February 2020 to monitor immune response to SARS-CoV-2 in a large prospective cohort of IMID patients and non-IMID controls with a follow-up duration of up-to to 10 months after the first vaccine dose.

**Results:** Among 5076 cohort participants, 3147 IMID patients and healthy controls in February 2020 to monitor immune response to SARS-CoV-2 and respiratory infections including COVID-19 (1). Participants who contributed data starting from the 4 weeks before their first vaccination onwards were included in this analysis. Antibodies against SARS-CoV-2 spike protein were quantified with an ELISA from Euroimmun (Lübeck, Germany) with an optical density cutoff of 0.8. We fitted linear mixed-effect models for log-transformed antibody levels using time splines with adjustment for age and sex. Marginal mean antibody levels with 95% confidence intervals (CI) were estimated at selected time points for IMID patients and controls with double vaccination. We descriptively analyzed the observed antibody levels over time in cohort participants receiving two vaccinations vs. three vaccinations.
In IMID patients, age and sex-adjusted estimated marginal mean antibody levels waned after week 16 and were substantially reduced at all time points compared to the controls, finally dropping to the borderline range (1.01, 95%CI 0.86 to 1.19) at week 40 (Figure 1A, Table 1). A third dose was given to 128 (7%) of IMID patients with a poor response to 2 vaccine doses after a median 20 weeks of the second dose (IQR 10 to 26 weeks). After the third dose, antibody levels in IMID patients were comparable to those of healthy controls at 40 weeks who had three vaccine doses. These were also higher than that of IMID patients and controls who did not receive a third dose (Figure 1B).

Conclusion: Humoral response to vaccination against SARS-CoV-2 was weaker in IMID patients compared to controls at all time points after the first vaccine dose and practically disappeared after 1 year. IMID patients can still achieve a good antibody response with a third dose even after a weak response with two doses.

† Systemic lupus, systemic sclerosis, Sjögren’s syndrome, vasculitis. Estimated marginal means adjusted for age and sex.

Figure 1.
less than 9 months. For the majority of RTX treated patients, the recommended six months since last RTX is insufficient to develop a humoral response to COVID-19 mRNA vaccines. Our data suggest that the current recommendations of a 6 months interval should be revised.

Conclusion: SARS-CoV-2 vaccination was safe for GCA/PMR patients and immunogenicity was comparable to other older individuals. However, patients using methotrexate and particularly >10mg/day prednisolone did show lower vaccine responses, which corroborates findings in older non-autoinflammatory patient populations. These patients may therefore be at higher risk of (potentially even severe) breakthrough SARS-CoV-2 infection.

POS0263

RE-VACCINATION COMPARED TO BOOSTER COVID-19 mRNA VACCINATION SIGNIFICANTLY INCREASES THE SEROLOGICAL RESPONSE IN RITUXIMAB-TREATED PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES WITHOUT A PRIMARY DETECTABLE SEROLOGICAL COVID-19 VACCINE RESPONSE

C. Ammitzbøll1, 2, M. K. Thomesen3, 2, M. L. F. Hermansen1, S. R. Viis1, 4, J. B. Andersen1, A. D. Johansen1, F. Szabados1, C. M. Jørgensen1, 2, 4, M. C. L. Larsen1, C. Erikstrup1, 2, 3, E. M. Hauge1, 2, A. Trolberg1, 4, Aarhus University Hospital, Rheumatology, Aarhus, Denmark; 2Aarhus University, Clinical Medicine, Aarhus, Denmark; 3Aarhus University Hospital, Clinical Microbiology, Aarhus, Denmark; 4Aarhus University Hospital, Clinical Immunology, Aarhus, Denmark

Background: Reports of an impaired humoral response after COVID-19 vaccination in patients treated with rituximab (RTX) have raised particular concern for patients with inflammatory rheumatic diseases (IRD) receiving RTX (1). This calls for strategies to enhance a humoral response in RTX-treated patients. At present, there is no data on whether it is best to increase the humoral response with a third vaccine dose (a booster) or with a third and fourth dose (re-vaccination).

Objectives: In IRD patients treated with RTX, without a detectable humoral response after the first vaccination course (two shots), we aimed to investigate the difference of either a booster vaccine (dose 3) or a new re-vaccination course (dose 3+4) on the serological response of the COVID-19 mRNA vaccines.

Methods: We included 84 patients with IRD treated with RTX, all without measurable total SARS-CoV-2 antibodies after a full primary COVID-19 vaccination course (2 doses three weeks apart). All patients were offered a new re-vaccination course with the mRNA vaccine not used primarily (Pfizer/Biontec or Moderna). A small number of patients declined the re-vaccination, and received a booster with the mRNA vaccine used initially. Serum total antibodies were measured before and six weeks after the last dose against recombinant SARS-CoV-2 spike S1 protein (VITROS). In addition, CD19+ B-cells were measured at inclusion.

Results: Patient characteristics are in Table 1. The median age was 64 years; 68% were female with a disease duration of 5 years. Sixty-nine out of 84 were re-vaccinated (3+4 dose). Details previous exposure to RTX are given in Table 1. CD19+ B-cells were measurable in 12/81 at inclusion.

We found a combined seroconversion rate of 33% six weeks after the last shot. There was no statistical difference between the booster (38,5%) and the re-vaccination group (32,3%), p=0.67 (Pearson's chi-squared). IRD patients with a humoral response in the re-vaccination group had significantly higher levels of total SARS-CoV-2 antibodies (median(IQR) 306(49-444) AU/ml) compared to the booster group (14(4-15) AU/ml) p=0.02, Figure 1A. In multiple logistic regression model, we found that levels of CD19+ B-cells were the only variable able to predict a humoral response, Figure 1B. However, only 39% of the patients with...

REFERENCES:
a humoral response to vaccination had measurable CD19+ B-cells before vacci-
nation. We found no effect of age, sex, diagnosis, treatment, and RTX exposure on the chance of seroconversion in multiple logistic regression models when corrected for CD19+ B-cells.

Conclusion: We found that re-vaccination (dose 3+4) with COVID-19 mRNA vaccines favored a high humoral response in patients with IDR treated with RTX, who did not have a detectable humoral response after the first two vaccine doses, compared to a booster shot (dose 3). A detectable humoral response after re-vaccination was seen in more than half of the patients with no measurable CD19+ B-cells before vaccination. Presence of circulating CD19+ B-cells are a significant predictor of humoral response to mRNA COVID-19 vaccination.

POS0264
CHARACTERIZATION OF THE IMMUNE RESPONSE IN PATIENTS WITH INFLAMMATORY IMMUNE-MEDIATED DISEASES ON IMMUNOSUPPRESSIVE TREATMENT AFTER ONE MONTH OF SARS-COV-2 VACCINATION
A. Martínez-Felto1, P. Nozal1, M. Novella-Navarro2, E. Fernández-Fernández2, L. Del Pino Molina3, M. Casas Temprano3, I. Akabat Bousaid1, M. D. Martin Arranz4, A. Balsa5, C. Plascencia6, La Paz University Hospital, Immunology, Madrid, Spain; 2La Paz University Hospital, Rheumatology, Madrid, Spain; 3IdiPAZ, Lymphocyte Pathophysiology in Immunodeficiencies, Madrid, Spain; 4La Paz University Hospital, Gastroenterology, Madrid, Spain

Background: The relevance of studying immune response after SARS-Cov-2 vaccination in patients with inflammatory immune-mediated diseases (IMIDs) represents a deep concern regarding the risk estimation and management of patients with these diseases on immunomodulatory drugs. It is well known that certain treatments as anti CD20 therapies results in a diminished immunogenicity against common vaccines but it is a scarce data regarding the cellular protection obtained upon vaccination between patients with different IMID and between different treatments.

Objectives: To compare a potential detrimental on cellular and antibody-medi- ated protection upon SARS-CoV-2 vaccination in patients with IMID treated with immunosuppressive drugs.

Methods: We recruited 73 patients with rheumatoid arthritis-RA(n=49), spondylarthritis-SPA(n=19), inflammatory bowel disease-IBD(n=5), idiopathic juvenile arthritis-IAA(n=2) and heterogeneous group composed of sclerodermia, lupus, uveitis...(n=6). They were treated mainly with rituximab (n=27), TNFi (n=37) or JAKi (n=3). We collected data of age, sex, csDMARDs, previous SARS-CoV-2 infection, last RTX infusion and prednisone use. After one month of vaccination, we assessed the humoral response performing the Thermo Scientific EIA SARS-CoV-2-Sp1 IgG Test (positivity cut-off >0.70 IU/ml) which was also compared with the data of with 35 healthy controls. In addition, in 40 patients who had serum antibody levels under 100U/ml, we analysed the cellular response by the use of the QuantiFENOM SARS-CoV-2 Starter Pack (Quigain). A cut-off value of 0.15 IU/ml discriminate between positive or negative cell-mediated immune responses.

Figure 1. Concentration of total SARS-CoV-2 antibodies measured 6 weeks after COVID-19 re-vaccination or booster shot. A: Total antibody concentration presented by vaccination group: 1) d1 (booster) or 2) d3 (re-vaccination). The chart presents percent of patients with a positive total antibody measurement post-vaccination. Circles with straight line indicate mean concentration with confidence intervals. B: Total antibody concentration presented by pre-vaccination measurement of circulating CD19+ B-cells in peripheral blood. A) indicate booster and B) indicate re-vaccination group.

Figure 1

We compared differences among the different IMIDs and between the different immuno suppressive treatments through non-parametric test (p<0.05)

Results: Regarding demographic characteristics of patients, older patients (>56 years) and female sex were factors which were associated with low titles of serum antibodies. Anti-spike IgG antibodies were present in an 86% of the IMIDs patients and in 100% healthy controls with significant different IgG titre (median [IQR]): 51[11-184] vs 700[440-940]; p=0.0001.

The differences between (median [IQR]) serum antibody levels were statistically significant between IMID types: 33[1-138] in RA vs 94[34-191] in SpA vs 204[187-204] in IBD vs 133[61-204] in IJA vs 13[1.5-31.8] in the rest; p<0.04. Remarkably, patients with IBD who had the highest antibodies titles were the youngest compared with the other patients.

Target of the therapy played also an important role in serum antibody levels being these: 3.6 [0-7.51] in RTX patients vs 156 [45-204] in TNFi for 40 [18-58] in JAKi patients; p=0.0001. In those patients who the last infusion of rituximab was, at least, one year before vaccination presented CD19+ B-cells detected by flow cytometry and anti-spike IgG antibodies as well.

Cell-mediated responses to SARS-CoV-2 were positive in 33% of IMIDs patients, indeterminate in 3% and negative in 65% of the patients. Strikingly, out of the 33% positive patients, 85% were treated with RTX. A 61% of the RTX patients had inducible cell-mediated responses vs 14% of the patients treated with TNFi; p<0.01. On the other hand, there were no differences in cell-mediated responses between positive and negative antibody patients.

Conclusion: Titors of serum antibodies against spike protein of SARS-CoV-2 were lower in IMIDs patients than in controls. Patients with RTX had lower rates of positivity humoral response as well as lower serum titles than patients treated with TNF inhibitors regardless the patients age. Nevertheless, in those patients in whom RTX infusion was delayed because of vaccination they conserved a humoral response.

On the other hand, more patients treated with RTX had indiscernible cell-mediated responses compared with patients with TNFi.

SERUM PROTEOMICS IN GIANT CELL ARTERITIS IN RESPONSE TO A THREE-DAY PULSE OF GLUCOCORTICOID FOLLOWED BY TOCILIZUMAB MONOTHERAPY (THE GUSTO TRIAL)
L. Chrig1, A. Gloor2, F. Kollert1, S. Reichenbach1,2, P. Villiger3, Inselspital, Bern University Hospital, Department of Rheumatology and Immunology, Bern, Switzerland; 2Inselspital, Bern University Hospital, Department of General Internal Medicine, Bern, Switzerland; 3University of Bern, Institute for Social and Preventive Medicine, Bern, Switzerland; 4Medical Center Monbijou, Rheumatology, Bern, Switzerland

Background: Measuring disease activity in Giant Cell Arteritis (GCA) remains a challenge, particularly, if Tocilizumab (TCZ) is prescribed which blunts the acute phase response. A proteome analysis may not only serve to identify biomarkers, but also to shed light on pathophysiology. The sequential administration of Glu cocorticoids (GC) and TCZ as done in the GUSTO study (GCA treatment with ultra-short GC and TCZ) provides a unique opportunity to dissect the effects of GC and TCZ.

Objectives: To investigate the effects of pulse GC-treatment and of ensuing long-term TCZ monotherapy on serum proteins in GCA; to compare the sereo logical findings with clinical response; to search for proteins which are not under control of IL-6 and may be unstable as biomarkers of disease activity.

Methods: Eighteen patients with newly diagnosed GCA received 500 mg methy lprednisolone intravenously for 3 consecutive days (NCT03745586). Thereafter, GC treatment was discontinued and a single dose of TCZ (8 mg/kg body-weight) was administered intravenously, followed by weekly subcutaneous TCZ injections (162 mg) from day 10 until week 52. Serum samples were collected prior to treat ment (day 0), at day 3 (after GC treatment), day 10 and at weeks 4, 24, and 52

Achy-Breaky vessels.
POS0266  EFFECTIVENESS OF A SPACING-UP STRATEGY AFTER ONE-YEAR COURSE OF WEEKLY TOCILIZUMAB IN PATIENTS WITH GIANT CELL ARTERITIS: A SINGLE-CENTRE PROSPECTIVE STUDY

A. Tomelleri1, C. Campochiaro1, S. Sartorelli1, L. Mariotti1, E. Baldissera1, M. Matucci-Cerinic1, L. Dagna1. IRCCS San Raffaele Hospital, Unit of Immunology Rheumatology Allergy and Rare Diseases, Milan, Italy

Background: Although tocilizumab (TCZ) is extensively used for the treatment of giant cell arteritis (GCA), there is still uncertainty with regard to optimal treatment duration. The GIACTA open-label extension phase showed that 58% of patients treated with a 12-month course of weekly TCZ had a disease flare in the 2 years following therapy suspension, suggesting that some patients may need a more prolonged duration of this therapy.

Objectives: To evaluate efficacy and safety of low-dose TCZ maintenance in GCA patients who achieved remission after one year of standard TCZ therapy.

Methods: GCA patients eligible for TCZ according to the 2018 EULAR recommendations and who achieved remission after one year of weekly subcutaneous TCZ therapy were prospectively enrolled. TCZ was administered every-other-week (EOW) for additional 12 months, and eventually suspended. Patients were evaluated 4-monthly during TCZ therapy, and 1 and 6 months after TCZ suspension (Figure 1). In patients with large-vessel (LV) involvement at baseline, PET scan was performed 12 and 24 months after TCZ start. Primary outcome was relapse-free survival at month 6 since TCZ suspension. Relapse-free survival during TCZ therapy and imaging response at PET scan were also evaluated. Adverse events were recorded.

Results: 17 patients were enrolled (12 women, 71%; mean age 71.5±8.7 years). Disease features at diagnosis and TCZ start are listed in Table 1. Reasons for TCZ start were clinical or imaging disease flare (n=9), persistence of disease activity (n=5), and steroid-related adverse events (n=3). At TCZ start, median disease duration was 8 (3-22) months, serum C-reactive protein (CRP) was 13 (6-22) mg/L, daily prednisone (PND) dose was 25 (15-375) mg; 4 patients were already on methotrexate (MTX) which was maintained in 1 of them; 10 patients (59%) had LV involvement on PET scan. At TCZ EOW start, no patient was on PND and 1 patient was on MTX; MTX was added in another patient due to persistence of LV involvement at PET scan. All patients completed the 24-month TCZ course. Two patients (12%) had a polymyalgic flare while on EOW TCZ: one patient at month 1 and one patient at month 6; of note, one of them had a polymyalgic flare also while on weekly TCZ. Both flares were managed with a PND course with complete clinical remission. No patient had active LV involvement at 24-month PET scan. All patients completed the 24-month TCZ course. Two patients (12%) experienced a flare, which was successfully managed in all cases with weekly TCZ re-introduction; in 2 patients, a PND course was also started.

Conclusion: In this proof-of-concept study, low-dose TCZ maintenance in GCA showed excellent disease control, which was maintained in most patients after therapy suspension. Longer follow-up and replication in larger cohorts are required.

OUTCOMES DURING AND AFTER LONG-TERM TOCILIZUMAB TREATMENT IN PATIENTS WITH GIANT CELL ARTERITIS

M. Mata2, N. DAgincourt2, S. Mohan1, A. Pavlov1, J. Han1, J.H. Stone1, S. Unizony1, 1Massachusetts General Hospital - Harvard Medical School, Vascularitis and Glomerulonephritis Center, Boston, United States of America; 2Everest Clinical Research, Statistical Operations, Markham, Canada; 3Genentech, Inc., US Medical Affairs, South San Francisco, United States of America; 4Genentech, Inc., Biometrics, South San Francisco, United States of America

**Background:** Data on the long-term efficacy and safety of tocilizumab (TCZ) for giant cell arteritis (GCA), including incidence and timing of disease relapse after TCZ discontinuation, is limited.

**Objectives:** We aimed to evaluate the long-term outcomes of GCA patients treated with TCZ in a real-world setting.

**Methods:** Retrospective analysis of GCA patients treated with TCZ for >9 months at a single center between 2010-2021. Time to relapse and annualized relapse rate were assessed. Relapse was defined as the re-appearance of clinical manifestations of GCA that required treatment intensification regardless of the erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) levels. Kaplan-Meier (KM) estimated relapse rates on TCZ were 10.5% and 14.9% at 12 and 18 months, respectively (Figure 1A). TCZ was discontinued due to long-term remission in 37 (64.9%) patients and after an adverse event in 6 (10.5%) patients. Of the 43 patients stopping TCZ due to remission or adverse event, 19 (44.2%) subsequently relapsed. KM estimated relapse rates after TCZ discontinuation were 30.4% and 44.0% at 12 and 18 months, respectively (Figure 1B).

**Results:** A total of 57 GCA patients were followed for a mean (SD) period of 3.4 (1.7) years. Baseline characteristics and treatments received are shown in Table 1. Patients were maintained on their initial TCZ course for a mean (SD) period of 2.0 (1.3) years. The initial TCZ course lasted >12 months in 50 (88%) patients. During the initial TCZ course, 8 (14.0%) patients relapsed. Kaplan-Meier KM estimated relapse rates on TCZ were 10.5% and 14.9% at 12 and 18 months, respectively (Figure 1A). TCZ was discontinued due to long-term remission in 37 (64.9%) patients and after an adverse event in 6 (10.5%) patients. Among the 43 patients stopping TCZ due to remission or adverse event, 19 (44.2%) subsequently relapsed. KM estimated relapse rates after TCZ discontinuation were 30.4% and 44.0% at 12 and 18 months, respectively (Figure 1B). Overall, 12 patients received more than one TCZ course. The aggregation of all TCZ courses (mean 2.5 years) and all periods off TCZ following the initial TCZ treatment (mean 0.9 years) showed that 11 (19.3%) patients relapsed while on TCZ and 20 (35.1%) patients relapsed during time off TCZ. An analysis adjusting for age, sex, prednisone dose at initiation of first TCZ course, and disease type (new onset vs. relapsing) at initiation of first TCZ course showed an annualized relapse rate (95% CI) of 0.1 (0.0-0.2) during TCZ treatment and 0.4 (0.3-0.7) off TCZ (rate ratio 0.2, p<0.0001). By the end of follow up, 42 (73.7%) patients were able to wean off prednisone. During the study, 12 serious adverse events occurred in 11 (19.3%) patients. Among those 12 events, 3 (25%) were related or possibly related to TCZ exclusively (i.e., osteoporotic fracture, diabetic ketoacidosis and stroke), and 2 (16.7%) to either TCZ or prednisone (i.e., pneumonia and sepsis).

**Conclusion:** Long-term TCZ treatment was efficacious in maintaining disease remission and sparing the use of prednisone in patients with GCA. Over 40% of patients stopping TCZ after long-term remission or adverse event relapsed following TCZ discontinuation.

INTRAVENOUS TOCILIZUMAB FOR THE TREATMENT OF GIANT CELL ARTERITIS: A PHASE IB DOSE-RANGING PHARMACOKINETIC BRIDGING STUDY

C. Schmitt1, L. Brockwell1, M. Giraudon1, M. Zucchetto1, L. Christ2, B. Bannert3, T. Daeke4, P. Villiger4, F. Hoffmann-La Roche Ltd, Clinical Pharmacology, Basel, Switzerland; 3K. Hoffmann-La Roche Ltd, Product Development – Immunology, Infectious Diseases, and Ophthalmology, Welwyn Garden City, United Kingdom; 4F. Hoffmann-La Roche Ltd, Pharmaceutical Sciences, Basel, Switzerland; 5Paraxel International, Biostatistics, Milan, Italy; 6Inselhospital, University Hospital Bern, Rheumatology and Immunology, Bern, Switzerland; 7USB - University Hospital Basel, Rheumatology, Basel, Switzerland; 8Medical Center Monbibiou, Rheumatology, Bern, Switzerland

**Background:** Subcutaneous (SC) tocilizumab (TCZ), a recombinant humanized anti-interleukin-6 receptor (IL-6R) monoclonal antibody, is approved globally for systemic juvenile idiopathic arthritis, rheumatoid arthritis, polyarticular juvenile idiopathic arthritis, adult systemic onset juvenile idiopathic arthritis, giant cell arteritis, and rheumatoid vasculitis.

**Objectives:** We aimed to evaluate the safety, tolerability, and pharmacokinetics of SC TCZ in adult patients receiving SC TCZ at a dose ranging from 8 to 164 mg.

**Methods:** Retrospective analysis of GCA patients treated with TCZ for >9 months at a single center between 2010-2021. Time to relapse and annualized relapse rate were assessed. Relapse was defined as the re-appearance of clinical manifestations of GCA that required treatment intensification regardless of the erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) levels. Kaplan-Meier KM estimated relapse rates on TCZ were 10.5% and 14.9% at 12 and 18 months, respectively (Figure 1A). TCZ was discontinued due to long-term remission in 37 (64.9%) patients and after an adverse event in 6 (10.5%) patients. Among those 12 events, 3 (25%) were related or possibly related to TCZ exclusively (i.e., osteoporotic fracture, diabetic ketoacidosis and stroke), and 2 (16.7%) to either TCZ or prednisone (i.e., pneumonia and sepsis).

**Conclusion:** Long-term TCZ treatment was efficacious in maintaining disease remission and sparing the use of prednisone in patients with GCA. Over 40% of patients stopping TCZ after long-term remission or adverse event relapsed following TCZ discontinuation.

**Figure 1A. Time to relapse on initial TCZ treatment**

* Patients were censored if tocilizumab (TCZ) was discontinued for any reason or the patient was lost to follow-up.

**Figure 1B. Time to relapse after discontinuation of initial TCZ treatment**

* Time to relapse in patients that discontinued TCZ due to either long-term remission or an adverse event and who had follow-up beyond their TCZ discontinuation date. Patients were censored if TCZ was re-started for any reason other than relapse or the patient was lost to follow-up.

**DOI:** 10.1136/annrheumdis-2022-eular.1108
the treatment of giant cell arteritis (GCA), with once weekly injections, based on the GIACCTA trial.

**Objectives:** This Phase Ib study (NCT02892378) investigated the pharmacokinetics (PK), pharmacodynamics (PD), safety and exploratory efficacy of 2 doses of TCZ given intravenously (IV) in patients with GCA. The purpose was to explore an IV dose resulting in a minimum exposure level within the range of effective trough concentrations achieved with TCZ SC dosing in GCA and not exceeding the exposure of the well-tolerated 8 mg/kg IV every 4 weeks (Q4W) in rheumatoid arthritis (RA).

**Methods:** This study enrolled patients with GCA in Switzerland who had received ≥5 consecutive doses of TCZ IV 8 mg/kg (off label) Q4W and were in remission. Patients received 5 or 6 doses of TCZ IV 7 mg/kg Q4W in period 1 and, if still in remission, then received 5 or 6 doses of 6 mg/kg Q4W in period 2. Glucocorticoid use was at the investigator’s discretion. PK endpoints were maximum concentration (C_{max}), minimum (trough) concentration (C_{trough}), area under the curve (AUC) over a dosing interval (τ) and average concentration (C_{mean}) calculated as AUC/τ of TCZ after the last dose of each period. Other endpoints included PD markers (IL-6, soluble IL-6R [sIL-6R], C-reactive protein [CRP] and erythrocyte sedimentation rate [ESR]), safety (adverse events [AEs], serious AEs [SAEs]) and exploratory efficacy (rates of flare and remission).

**Results:** In 24 patients enrolled, median (range) age was 65.5 (57-90) years and the majority were female (62.5%). All patients had a history of elevated ESR and/or CRP and evidence of GCA by temporal artery biopsy and/or evidence of large vessel vasculitis at GCA diagnosis. The mean PK profile following TCZ IV 7 mg/kg Q4W in Period 1 was of a similar shape to mean PK profile following TCZ IV 6 mg/kg Q4W in Period 2, with a slightly lower exposure at the 6-mg/kg dose level (Figure 1). Compared with the 7-mg/kg dose, TCZ exposures (C_{max} and AUC) were on average 11.2% and 20.0% lower at the 6-mg/kg dose (Table 1). Mean IL-6 serum concentrations were elevated at baseline due to previous TCZ treatment and remained elevated throughout the study, with slightly higher concentrations in Period 1 (7 mg/kg) than Period 2 (6 mg/kg). Mean sIL-6R concentrations were elevated at baseline and comparable between the 2 doses at steady state. As expected for patients in remission, CRP levels and most ESRs were within the normal ranges at baseline and throughout the study. Overall, 22 patients (91.7%) had ≥1 AE; infections were the most frequently reported AEs. Two patients (8.3%) experienced a Grade ≥3 AE. The majority of AEs (70.8%) were TCZ-related. Four patients (16.7%) reported an SAE; 1 (pneumococcal pneumonia) was considered TCZ-related by the investigator and 3 led to treatment interruption. There were no deaths. No patients experienced a GCA flare, and all patients remained in remission throughout the study.

**POS0269 RESULTS OF ONE YEAR OBSERVATIONAL EXTENSION OF THE BRIDGE-PMR STUDY, A RANDOMIZED DOUBLE-BLIND PLACEBO CONTROLLED TRIAL WITH RITUXIMAB IN POLYMALGIA RHEUMATICA.**

T. Bolhuis1, D. Marsman1, A. Den Broeder1, N. Den Broeder1, A. Van der Maas1, 1Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands

**Background:** Glucocorticoids (GC) are the cornerstone of treatment in Poly- myalgia rheumatica (PMR) [1]. However, they are associated with considerable toxicity and inefficacy in part of the patients. Rituximab (RTX) was effective for PMR in a 21-week randomized controlled trial (RCT), however results from longer follow-up is still absent [2].

**Objectives:** To assess, in a randomized double blinded fashion, the clinical and GC-sparing effects one year after RTX.

**Methods:** In the BRIDGE-PMR, an RCT of 38 recently diagnosed and 9 relapsing PMR (2012 EULAR/ACR classification criteria) patients recruited from the Sint Maartenskliniek, patients were randomly allocated in a 1:1 ratio and treated with 1x 1000mg RTX / placebo (PCB) iv, identical pre-medication and an accelerated GC tapering protocol. After the 21-week study, patients were assessed in a double blinded prospective extension study up to one year after infusion. The primary outcome at one year was between group difference in GC-free remission (PMR-activity score < 10). Analysis was performed with Fischer’s exact test and a two-tailed p-value < 0.05 was considered significant. Secondary outcomes were proportion of relapsing patients during the extension, proportion of patients with CRP > 5mg/l during the extension, cumulative GC dose, DMARD use, EQ-5D score, and adverse events (AE).

**Results:** The proportion of patients in GC-free remission after one year was significantly higher in the RTX group (48%, 11/23) compared to the PCB group (17%, 4/24), with an absolute difference of 31% (95%-CI 6-56), a relative risk of 2.9 (95%-CI 1.1-7.7), p=0.03. The secondary outcomes showed statistically significant differences in RTX versus PCB in median GC cumulative dose: 1595 versus 2302 mg (p = 0.04) and median PMR-AS: 6 versus 15 (p = 0.02) (Table 1 and Figure 1). No differences were seen in other secondary outcomes.

Notes: * Relapse was defined as therapy intensification, based on either a) an increase in oral prednisolone, b) adding intramuscular methylprednisolone, or c) starting or switching a DMARD due to treatment inefficiency. ** Remission is based on the PMR-AS, calculated by oral prednisolone, b) adding intramuscular methylprednisolone, or c) starting or switching a DMARD due to treatment inefficiency. 

Conclusion: Efficacy of 1x1000 mg RTX in PMR was maintained up to 1 year follow-up, while also demonstrating a GC sparing effect. A larger trial, also assessing effect of on demand retreatment, is needed to confirm our results, and provide insight in which patients most likely benefit from RTX.

development of aortic aneurysm/dilatation in a prospective cohort of patients with biopsy-proven giant-cell arteritis: early identification of patients at risk.

J. Marco Hernandez1, A. García-Martínez1, S. Prieto-González2, A. Suso1, G. Espigol-Frigole1, P. Arguis1, R. Gilabert2, M. Alba2, J. Hernández-Rodríguez2, M. C. Cid1. 1Hospital Clínic de Barcelona, Vasculitis Research Unit, Barcelona, Spain; 2Hospital Clinic de Barcelona, Radiology Department, Barcelona, Spain

Background: Up to 10-33% of patients with giant-cell arteritis (GCA) develop aortic structural damage (ASD) (aneurysm or dilatation), typically involving the ascending aorta (1,2). Systematic use of imaging reveals radiological features of aortitis in 45-85% of patients at diagnosis (3). This finding has been associated with future aortic dilatation in retrospective studies (4). Objectives: To investigate the prevalence of thoracic ASD in a large prospective cohort of patients with GCA subjected to periodic imaging. To evaluate the association between features at diagnosis with ASD development.

Methods: Patients were included in the study if consented, had biopsy-proven GCA and met the 1990 ACR criteria for GCA classification. Patients were prospectively followed and treated according to uniform criteria. Since 1985 patients were subjected to systematic imaging screening aimed to detect thoracic ASD. Until November 2006 it consisted of a chest X-ray that was performed at least 4 years after diagnosis and repeated every 4 years. When aortic dilatation was minimal suspected, patients underwent contrast-enhanced computed tomography (CT) scan. Since November 2006, most of patients were prospectively studied with CT angiography at diagnosis, after 1 year and every 4 years. The diagnosis of ASD was confirmed by CT, defined as an aortic diameter > 4 cm at the ascending aorta or >4 cm at the aortic arch or the descending aorta. Data regarding demographic characteristics, cardiovascular risk factors, GCA symptoms, laboratory tests, chronic medication at time of GCA diagnosis and corticosteroid tapering were recorded. Kaplan-Meier survival plot was used to present the cumulated incidence of thoracic ASD over time and patients were censored at the time of ASD diagnosis or at the time of the last screening in those without ASD. We also investigated which variables present at the time of GCA-diagnosis were associated with future development of ASD. Patients were classified in two groups according to whether they developed ASD or not during a follow-up period of 8 ± 1 years from the time of diagnosis.

Results: Thoracic ASD was confirmed by CT in 58 patients (21.6% of the patients with systematic screening diagnosed from 1994 to 2018) after a median follow-up of 4.7 years (0.05-7.5). Ascending aorta was involved in 56 patients (96.5%), followed by the aortic arch in 11 patients (18.9%), and descending aorta in 5 (8.6%). 14 patients (24.1%) had more than 1 aortic segment involved. Figure 1 shows the number of patients with thoracic ASD detected during follow-up.

Disclosure of Interests: None declared

Figure 1. Thoracic ASD was detected within the first 4 years from GCA-diagnosis in 19 out of the 58 patients who developed ASD (32.7%) but was severe (≥ 50 mm) in only 3 (15.8% out of those 19 patients). Most ASD was detected between 5 and 9 years after GCA-diagnosis. Patients who developed ASD during follow-up experienced less often cranial ischemic symptoms (14.8% vs 41.1%; p=0.003) and polymyalgia (33.3% vs 51.8%; p=0.057), and less frequently had a previous diagnosis of hypertension (66.7% vs 79.3%; p=0.081). Age, sex, clinical or laboratory findings or chronic therapies used at time of GCA-diagnosis were not significantly different between groups. After multivariate analysis, the presence of cranial ischemic symptoms (HR 0.180, 95% CI 0.065-0.495, p=0.001) and polymyalgia rheumatica (HR 0.329, 95% CI 0.136-0.793, p=0.013) remained inversely associated with thoracic ASD development.

Conclusion: ASD is frequent and probably an underdiagnosed complication of GCA. There is no consensus yet regarding the optimal screening protocol during follow-up and early identification of patients at risk is crucial for this purpose. The presence of cranial ischemic symptoms or polymyalgia rheumatica were inversely associated with thoracic ASD development in our prospective cohort.

Giant Cell Arteritis (GCA) is the most common form of primary systemic vasculitis in patients aged >50 years. It predominantly affects the cranial arteries; however, extra-cranial disease involving the aorta and its major branches can also be present. Currently, ultrasound of the temporal (TA) and axillary (AX) arteries is the first imaging modality recommended in patients with suspected predominantly cranial GCA. Nevertheless, other arteries such as facial (FA), occipital (OC), subclavian (SC), and common carotid (CC) arteries can also show vasculitic changes on ultrasound. However, there are still conflicting data to support the inclusion of these arteries in the routine ultrasound assessment of patients with suspected GCA.

**Objectives:** To assess the value of adding the evaluation of the FAs, OCs, SCs and CCs in the ultrasonographic diagnosis of patients with GCA.

**Methods:** Single-center observational retrospective study, using data from patients diagnosed with GCA registered at the Rheumatic Diseases Portuguese Registry (Reuma.pt). All patients underwent ultrasound of the TAs and AXs ± FAs, OCs, SCs or CCs at the time of diagnosis. The halo sign was considered a positive ultrasonographic finding for GCA. Only patients with the presence of halo sign in at least one of the arterial segments assessed were included. Binary logistic regression modelling was performed to explore associations between the presence of halo sign in different arterial segments.

**Results:** We included 84 patients, 57 (67.9%) females, with a mean ± standard deviation age at diagnosis of 75.6 ± 8.8 years. Halo sign was found in the TAs of 66/84 (78.6%) patients, AXs of 40/84 (47.6%) patients, FAs of 37/74 (50.0%) patients, OCs of 15/61 (24.6%) patients, SCs of 30/49 (61.2%) patients and CCs of 13/60 (21.7%) patients. Of the 44/84 patients with GCA without the presence of TA halo, 17/18 (94.4%) showed halo in the AXs, 1/18 (5.6%) in the FAs, 3/18 (16.7%) in the OCs, 15/17 (88.2%) in the SCs and 6/16 (37.5%) in the CCs. Of the 44/84 patients with GCA without the presence of AX halo, 43/44 (97.7%) showed halo in the TAs, 24/39 (61.5%) in the FAs, 12/32 (37.5%) in the OCs, 4/18 (22.2%) in the SCs and 3/33 (9.1%) in the CCs. A total of 83/84 (98.8%) patients had halo sign on the ultrasound of either the TA or AX arteries. The patient with normal TA and AX ultrasound had the presence of halo sign in the SCs. Table 1 shows the proportion of patients with positive TA and AX ultrasounds according to the presence of halo in the FA, OC, SC or CC arteries. Patients with involvement of the cranial arteries were more likely to have a TA halo (OR 30.6, 95% CI 3.8-247.3; OC: OR not applicable) and less likely to have an AX halo (OR 0.37, 95% CI 0.14-0.95; OC: OR 0.19, 95% CI 0.05-0.77). As opposed to patients with involvement of the extra-cranial arteries in whom the halo sign was more frequently found in the AXs (SC: OR 18.2, 95% CI 4.2-78.9; CC: OR 5.9, 95% CI 1.4-24.4) but not in the TAs (SC: OR 0.12, 95% CI 0.02-0.60; OC: OR 0.32, 95% CI 0.09-1.15).

**Table 1. Differences in the presence of halo sign in the temporal and auxiliary arteries according to the arterial segment affected.**

**Conclusion:** Our results support the need to assess both TAs and AXs in patients with suspected GCA, resulting in a diagnostic sensitivity of 99%. Only by adding the evaluation of the SCs to the already recommended TAs and AXs increased the diagnostic sensitivity of ultrasound to 100%. All patients with a positive FA, OC or CC ultrasound for GCA also showed a halo sign in either the TAs or AXs. Hence, the additional assessment of these arteries did not improve the diagnostic yield of ultrasound and, therefore, should not be recommended in routine practice.

life-threatening disease complications. Certain population subsets seem to be at increased risk of developing such complications, such as elderly and/or immuno-compromised patients.

Objectives: To assess the persistence of immunity following SARS-CoV-2 mRNA vaccine and the magnitude of the humoral response after the booster dose in a cohort of patients affected by giant cell arteritis (GCA).

Methods: Patients with GCA regularly followed at the Rheumatology Department of the University of Pavia, Italy, who received a booster dose of SARS-CoV-2 mRNA vaccine (BNT162b2 Pfizer/BioNtech or mRNA-1273 Moderna) between October 1st and December 31st, 2021 were included. Humoral response was assessed by measuring SARS-CoV-2 Trimeric S (TSAs) and Neutralizing (NAbs) antibodies, with a cut-off of 33.8 Binding Antibody Units (BAU)/mL and 1:10 dilution, respectively. Blood samples from each patient were drawn at least 4 months after the second and three weeks after the third vaccine dose.

Results: Forty-two patients who received the booster dose of SARS-CoV-2 mRNA vaccine were enrolled. Thirty (71.4%) were females, mean age 73.2±4.7 years, disease duration 58±38 months, 19 (45.2%) had large-vessel vasculitis. Thirty-two (76.2%) were on glucocorticoids (GCs) at a mean dose ≥7.5 mg/day prednisone equivalents had negative NAbs before the third dose. Thirty-nine (55.3%) patients were on methotrexate (MTX) and 30 (71.4%) NAbs. The median TSAb titre was 134 BAU/mL (IQR 2080-2080) (p<0.001), while the median NAb titre increased 24-32 fold after the third vaccine dose. All patients developed TSAbs, even those with negative NAbs after the second dose.

Data regarding antibody response after the booster dose were available for 35 patients (83.3%). Blood collection occurred at a median of 25 days (IQR 24-32) after the third vaccine dose. All patients developed TSAbs, even those who did not respond to the previous shots. The median TSAb titre rose to 2080 BAU/mL (IQR 2080-2080) (p<0.001), while the median NAb titre increased from 1:10 to 1:320 (p<0.001). One patient (2.9%) treated with prednisone 8.75 mg/day plus MTX 12.5 mg/week did not develop NAbs. NAb levels were >7.5 mg/day prednisone equivalents seemed to blunt NAb levels along time: 28.6% patients on GCs ≥7.5 mg/day prednisone equivalents had negative NAbs before the third dose vs. 80.0% of those taking <7.5 mg/day (p=0.007) as well as lower NAb titres (Figure 1B).

Conclusion: In our cohort, most patients who seroconverted after the second dose of vaccine retained the humoral immunity, with excellent seroconversion rates following the booster dose. However, GCs, especially at doses ≥7.5 mg/day prednisone equivalents, may contribute to the waning of NAb titres. On the other hand, immunosuppressants like MTX, especially when combined with GCs, might impair the magnitude of the humoral response to the booster dose.

Disclosure of Interests: None declared

Figure 1. (A) TSAb levels before and after the booster dose among patients on GC + MTX. (B) NAb titres before and after the booster dose according to treatment with prednisone ≥7.5 mg/day or (C) MTX in combination with GCs or (D) MTX alone.
appropriate sequence of use of US and CR in patients with suspected CPPD: in case of a positive CR at any of the 3 sites (menisci and HC) no additional exam is necessary, and the same in case of a negative US in at least two sites; however in case of a negative CR, US could help in a statistically significant way to identify CPPD patients, and further in case of a positive US in a single site CR can offer additional information.

Figure 1. evaluation of sequence of US and CR

Conclusion: US confirmed a high diagnostic accuracy in identifying patients affected by CPPD at knee level, while CR demonstrated a high specificity but a low sensitivity. Performing both diagnostic tests could make sense in case of a negative CR or in case of an inconclusive US (only one positive site). To our knowledge, this is the first study that investigates the role of the combination of the two exams in CPPD. Further studies in a large number of patients and in different joints would be helpful to address this point.

POS0278 COMPARISON OF ULTRASOUND BEAM ATTENUATION BY CALCIUM PYROPHOSPHATE, HYDROXYAPATITE AND MONOSODIUM URATE CRYSTALS: A PROOF-OF-CONCEPT STUDY

E. Cheremushkina1,2, M. Eliseev1, O. Sheliabina1, A. Novikova3, S. Glukhova4.
1VA Nasonova Research Institute of Rheumatology, Laboratory of Laboratory Microcrystalline Arthritis, Moscow, Russian Federation; 2VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation; 3Laboratory Axial Spondyloarthritis, Moscow, Russian Federation

Background: Ultrasound (US) demonstrated to be reliable and accurate for the diagnosis of crystal induced arthropathies, especially gout and calcium pyrophosphate deposition disease (CPPD) and validated definitions for uric acid and calcium pyrophosphate deposition in joints were released by the Outcome Measures in Rheumatology (OMERACT) US group. Less is known regarding hydroxyapatite (HA) deposition disease (HAAD) and the role of US in the assessment of HA crystal deposition.

Objective: To assess the effect of colchicine, hydroxychloroquine, and methotrexate on cardiovascular outcomes (CVO) in CPPD pts.

Methods: The study included 305 pts with CPPD: 115 (37.7%) men, 190 (62.3%) women. The average follow-up period was 3.9±2.7 yrs. Among the factors influencing CVO were considered: gender, age, smoking, alcohol intake ≥20 standard doses/week, hypertension, history of cardiovascular disease (CVD);
computed tomography (CT) and dual-energy CT (DECT) in vivo[1]. The density of the agar-based lipogel background was intentionally increased to mimic the X-ray attenuation of hyaline cartilage (i.e., 100-120 HU at 120 kVp). Each crystal suspension was placed in a plastic container filled with US gel, next to the control (i.e., crystal-free background) calibration phantom. We acquired all US images using a Samsung RS80A system equipped with a high-frequency linear array transducer (4-18 MHz) set at the maximum frequency, by applying the same settings. All scans were performed by a single experienced sonographer, blinded to the crystal type and concentration. For each of the 16 crystal suspensions, at least two images were recorded both in the long- and short-axis views, the latter including the control phantom in the field of view. Interpretation of US images for the extent of US beam attenuation and the presence of acoustic shadowing was performed in consensus with a second experienced sonographer.

Results: None of the five CPP phantoms generated posterior acoustic shadowing or US beam attenuation regardless of CPP concentration. HA 31 mg/mL did not generate US beam attenuation, while HA 62, 92 and 123 mg/mL generated a progressively increasing US beam attenuation with posterior acoustic shadow clearly generated by HA 153 mg/mL. Similarly, MSU 90 mg/mL did not generate US beam attenuation, while HA 62, 92 and 123 mg/mL generated only a very faint US shadow clearly generated by HA 153 mg/mL. Conversely, MSU 195 mg/mL generated only a very faint US shadow clearly generated by HA 153 mg/mL. None of the five CPP phantoms generated posterior acoustic shadowing or US beam attenuation even if a clear posterior acoustic shadow was detectable only with MSU 420 and 500 mg/mL (Figure 1).

Conclusion: This proof-of-concept study confirmed that in the concentrations of crystals encountered in vivo, CPP do not generate posterior shadowing, while MSU and HA determine US beam attenuation proportionally to the concentration of the crystals. Being this a proof-of-concept study, attenuation of the US beam was assessed empirically and not in a quantitative or semi-quantitative way. However, this study highlights the potential of US to differentiate between CPP, MSU and HA crystals based on their appearance on gray scale imaging. Future studies should be carried out with different crystal concentrations, different US equipment and settings in order to create a scoring system for US beam attenuation that is actually lacking.

Background: Despite the disproportionately worsening disease burden of female gout in recent years and its frequent associations with key cardiovascular risk factors (more often than male gout), there remains a paucity of specific data about female gout, particularly about its impact on mortality and fatal coronary heart disease. Compared to women without history of gout or CHD, women with gout at baseline in 1982 tended to be older (mean age 7.8 (SD 7.6) years).

Methods: Using data from the Nurses’ Health Study (NHS), an ongoing prospective cohort study in which female nurses in the United States completed detailed mailed questionnaires regarding their medical history, lifestyle, and other risk factors at baseline and every two years thereafter, we prospectively analyzed the association between gout status and mortality, specifically in female gout to help curtail the rising disease burden of gout worldwide.

Results: These prospective data indicate that women with gout have a higher risk of all-cause mortality, which is primarily driven by higher risk of CVD deaths. These findings closely agree with the UK general population data of both sexes that showed unclosing mortality gap over the past two decades. Together, these findings provide support for rigorous cardiovascular risk factor modification specifically in female gout to help curtail the rising disease burden of gout worldwide.

SUA decreased from mean 500 µmol/L at baseline to 311 µmol at 1 year and 324 µmol/L at year 2. Flares were seen in year 1 in 81.2% (155/186) and year 2 26.0% (45/173) of patients. The total sum of SUA changes over 2 years as a global measure for individual SUA fluctuation was related to flares in all 3-month periods during year 1 (Table 1) and for year 1 overall (Figure 1), but not for year 2.

**Table 1. Flares and fluctuation of serum urate (SUA) measures during defined observation periods.**

*P<0.05, **P<0.01 for comparisons +/Flare

Other measures of SUA fluctuation (SUA change during periods, and exceeding thresholds of change) were generally not related to incidence of flares, neither were sensitivity analyses for incidence of flares in periods succeeding observed SUA fluctuations.

**Conclusion:** Fluctuation in SUA, defined as the total sum of mean SUA changes between all study visits, was related to gout flares during year 1. Our findings support that a pattern of SUA fluctuation is related to gout flares.

**Figure.** Fluctuation of serum urate and flare during months 0-12

**POS0282 UPDATE ON COMPARATIVE CARDIOVASCULAR SAFETY OF FEBOXOSTAT VersUS ALLOPURINOL AMONG PATIENTS WITH GOUT**

A. Shin, Y. J. Ha, Y. J. Lee, E. B. Lee, E. H. Kang. 1. Seoul National University Bundang Hospital, Department of Internal Medicine, Seongnam-si, Korea, Rep. of (South Korea); 2. Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

**Background:** Gout is associated with an increased risk of cardiovascular (CV) disease.

**Objectives:** To update comparative CV safety of febuxostat versus allopurinol among patients with gout

**Methods:** Using the 2011-2019 Korea National Health Insurance database, we conducted a cohort study comparing gout patients initiating febuxostat versus allopurinol, with study participants matched on a propensity score (PS) for 65 covariates at a 1:1 ratio. The primary outcome was composite CV outcome of myocardial infarction, coronary revascularization, and stroke. Secondary outcomes were CV and all-cause mortalities in addition to individual components of the primary outcome. Cox proportional hazards models estimated hazard ratios (HRs) and 95% confidence intervals (CIs), comparing febuxostat versus allopurinol initiators.

**Results:** We included 160,930 febuxostat users PS-matched on 160,930 allopurinol users (mean age 59.3 years, 79.6% male). During a mean follow-up of 250 days, the incidence rate of the primary outcome was 2.27 and 2.06 per 100 person-years for allopurinol and febuxostat users respectively, with the PS-matched HR [95% CI] of 1.03 [0.95-1.12]. Analysis on secondary outcomes also showed a similar result except for all-cause mortality with a significantly reduced risk among febuxostat users with a PS-matched HR [95% CI] of 0.84 [0.78-0.91] (Table 1).

*IR is per 100-person years, HR=incidence rate, HR=p-value, CIs=confidence interval, MI=myocardial infarction, FY=person-years, TIA=transient ischemic attack

**Conclusion:** This large population-based cohort study showed a similar CV safety profile between febuxostat and allopurinol users but found a 16% reduced all-cause mortality among febuxostat users compared to allopurinol, primarily derived from non-CV death reduction.

**Disclosure of Interests:** None declared

**POS0283 DOES A GOUT STIGMA AMONG RHEUMATOLOGISTS INFLUENCE PERCEPTIONS OF PATIENTS AND TREATMENT DECISIONS?**

N. L. Edwards, B. Lamoreaux, A. Magerman, J. Hunger, J. Vitriol.

1. University of Florida College of Medicine, Rheumatology, Gainesville, United States of America; 2. Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; 3. Saint Joseph's University, Haub School of Business, Philadelphia, United States of America; 4. Miami University, Psychology, Oxford, United States of America; 5. Stony Brook University, Political Science, Stony Brook, United States of America

**Background:** Gout is an inflammatory condition caused by chronic hyperuricemia, often causing physical and emotional distress and a lower quality of life (QOL),1-4 Gout stigma is common and impactful,5 with physicians often perceiving gout as a “lifestyle” disease caused by personal dietary and exercise choices. Further, patients can internalize and anticipate this stigma, influencing how they seek healthcare and adhere to medical therapies.6

**Objectives:** This study investigated whether or not a gout stigma exists among rheumatologists and, if so, how it influences physicians’ perceptions of patients and treatment decisions. Rheumatoid arthritis (RA) was used as a comparator disease.

**Methods:** 106 practicing rheumatologists completed an online survey regarding perceptions of, experiences with, and recommendations for patients with controlled gout, uncontrolled gout, and rheumatoid arthritis (RA). Disease states were presented in random order. Each set of measures examined rheumatologists’ perceptions and judgments of each disease condition on a range of dimensions, including (a) perceptions of patient’s compliance with treatment recommendations and responsibility for their disease condition, (b) causal attributions for contributing factors to disease condition, and (c) efficacy of recommended treatment decisions. Answers were provided using a 7-point Likert scale (e.g., patient compliance: 1 = will not comply, 7 = will comply; patient responsibility for condition: 1 = not responsible, 7 = responsible). Prior to analyses, all responses were converted to a 0 to 1 scale for ease of comparison and interpretation.

**Results:** Responses regarding controlled and uncontrolled gout patients were not significantly different, so these two groups were pooled. Compared to patients with RA, rheumatologists perceived patients with gout as significantly more responsible for their disease (p<0.05) and significantly less likely to comply with prescribed treatment regimens (p<0.05, Figure 1). Further, rheumatologists perceived patient personal behavior, diet, BMI, and patient adherence as...
greater contributing factors to gout than to RA (all p<0.01). Similarly, change in diet, increased exercise, and weight loss were perceived as more beneficial for managing gout than RA (all p<0.01), and biological treatments were perceived as more effective for managing RA than gout (p<0.01).

Conclusion: Despite good intentions when treating gout patients, rheumatologists appear to have causal beliefs and illness perceptions that reflect negative gout-related stereotypes. Compared to RA patients, gout patients were perceived as being more responsible for their condition and were expected to be less compliant with medications and less likely to benefit from biological therapies. Interestingly, there were no differences in rheumatologists’ judgments between patients with controlled and uncontrolled gout, suggesting that their beliefs may refer to gout itself rather than the degree of control or management. Educating physicians, particularly rheumatologists, on the myths surrounding gout may improve clinical care and, therefore, patient outcomes.

SUB-STANDARD CARE FOR PATIENTS WITH GOUT, DESPITE UPDATED GUIDELINES: A UK-WIDE, POPULATION-BASED COHORT STUDY

M. Russell1, A. Rutherford2, B. Ellis3, S. Norton1, A. Douiri2, M. Guillford2, A. Cole3, J. Galloway2. 1King’s College London, Centre for Rheumatic Diseases, London, United Kingdom; 2Imperial College Healthcare NHS Trust, Department of Rheumatology, London, United Kingdom; 3King’s College London, School of Population Health and Environmental Sciences, London, United Kingdom

Background: Treat-to-target urate-lowering therapy (ULT) is highly effective at preventing flares and improving quality of life for patients with gout. However, in 2012, only 27% of patients with gout in UK primary care received prescriptions for ULT within 12 months of diagnosis. Since then, EULAR and BSR gout management guidelines have been updated, to recommend that all patients with gout should have ULT discussed and offered to them, with uptitration of dosing until target urate levels are achieved. We investigated whether gout management has improved in recent years.

Objectives: To assess temporal trends in the initiation of ULT and attainment of serum urate targets following new gout diagnoses in UK primary care from 2004 to 2020.

Methods: The Clinical Practice Research Datalink (CPRD) Gold database was used to assess the management of patients with index diagnostic codes for gout in UK primary care between January 2004 and October 2020. We analysed the proportion of patients with the following outcomes within 12 months of diagnosis: i) initiation of ULT (allopurinol, febuxostat, benzbromarone, probenecid or sulfinpyrazone); ii) serum urate ≤360 µmol/L; iii) serum urate ≤300 µmol/L; iv) treat-to-target urate monitoring (defined as two or more urate ≤300 µmol/L). Interrupted time-series analyses (ITSA) were used to estimate the impact of updated EULAR and BSR gout management guidelines on these outcomes. Multivariate logistic regression was used to analyse predictors of ULT prescription and target attainment following new gout diagnoses.

Results: 129,972 patients had index gout diagnoses between January 2004 and October 2020, of whom only 37,529 (28.9%) had ULT initiated within 12 months of diagnosis. ULT initiation improved modestly over the study period, from 26.8% for those diagnosed in 2004 to 36.6% in 2019, decreasing to 34.7% in 2020 (Figure 1). Of patients diagnosed in 2020 who had a serum urate performed within 12 months of diagnosis, 36.0% attained a urate ≤360 µmol/L, while 17.1% attained a urate ≤300 µmol/L. Of all participants, 18.9% received treat-to-target urate monitoring. In ITSA models, no statistically significant improvements in ULT prescription or urate target attainment were observed after publication of updated
EULAR (2016) or BSR (2017) gout management guidelines, relative to before publication of these guidelines. In multivariate logistic regression models, comorbidities including chronic kidney disease, heart failure and obesity, and diuretic use were associated with increased odds of ULT initiation but decreased odds of attaining target urate levels by 12 months.

Conclusion: In this UK-wide study, we demonstrate that the initiation of ULT and attainment of serum urate targets following new gout diagnoses remain poor, despite the introduction of updated management guidelines. If the evidence-practice gap in gout management is to be bridged successfully, strategies to implement best practice gout care are urgently needed.

All you want to know about bDMARDs in RA

POS0286

CAN PATIENTS WITH CONTROLLED RA RECEIVING ANY CLASS OF TARGETED THERAPY WITH METHOTREXATE (MTX) SUSTAIN DISEASE CONTROL AFTER TAPERING MTX? A SYSTEMATIC REVIEW AND META-ANALYSIS

Background: Patients with RA frequently struggle with intolerance of MTX and adherence to MTX remains highly variable. Guidelines conditionally recommend the tapering of MTX before tapering biologic (b)DMARDs, but acknowledge there is an absence of direct evidence. Prior reviews on this topic have focused on tapering of MTX from combination treatment with TNF-inhibitors(i) only. There have been no updated reviews addressing MTX tapering from other targeted therapies such as IL6-i or JAK-i, nor has there been a systematic review addressing this question.

Objectives: To determine the feasibility of tapering MTX to targeted therapy (bDMARDs or JAKi) alone in patients whose RA is controlled (LDA or remission).

Methods: A systematic literature search combining MeSH terms and key words was conducted in Medline, Embase and Cochrane Library for studies reporting remission outcomes after tapering MTX from targeted therapies in RA. Non-English and animal studies were excluded. Meta-analyses were conducted using random effects models. Forest and funnel plots were created and heterogeneity was calculated.

Results: Our search identified 5762 citations. After removal of duplicates and screening title/abstract using the COVIDENCE platform, 504 full-text articles were reviewed. Of the 10 articles meeting our inclusion criteria of tapering MTX to monotherapy with a targeted therapy, 3 studies tapered to etanercept, 3 to tocilizumab, 1 to tocilcitinib, 1 to adalimumab and 1 to abatacept monotherapy. Nine studies were RCTs and one was a long-term extension study (LTE) (Table 1). Disease duration was longer in 7 studies (6–11 years) and early in 3 studies (1–9 months). The MTX tapering strategy was gradual in 2 and rapid in 8 studies. Follow-up ranged from 3–18 months in RCTs, and up to 3 years in the LTE. Studies reporting outcomes up to 1 year after tapering had remission rates ranging 48–76%, but this dropped to 40% in one study reporting 18-month remission outcomes. Our meta-analysis conducted in 2000 RA participants from 10 studies showed that patients who tapered MTX to targeted therapy alone could maintain remission with an overall pooled OR of 0.81 (0.68, 0.97) (Figure 1). There was no heterogeneity among the studies in this group (I²=0.0%, p=0.788). Our funnel plot indicated high precision and potentially less publication bias. No significant difference in remission outcomes between early RA [OR 0.63 (0.33, 1.18)] and established RA [OR 0.84 (0.69, 1.03)] was observed.

EUA etanercept, ABA abatacept, TOFA tocilizumab, TCZ tocilcitinib, CZP certolizumab pegol, ADA adalimumab, REM remission, wk week, mo month, DAS28 Disease Activity Score 28, SDAI Simplified disease activity index.

Conclusion: Patients with controlled RA have a high probability of maintaining disease control after tapering their MTX to targeted therapy alone, up to 18 months. This review may inform patients with controlled disease on any of a range of targeted therapies and MTX, but who are struggling with MTX-related adverse effects and wish to taper it. Longer follow-up studies with attention to radiographic, functional and patient reported outcomes are needed. The possibility of disease worsening must be discussed with the patient in advance with careful follow-up and prompt re-treatment of disease worsening.

Background: BAT1806/BIBIB800 is a proposed biosimilar to reference tocilizumab (TCZ). A Phase III randomised, double-blind, active-controlled clinical trial was conducted as part of a biosimilar development programme. Objectives: To evaluate the efficacy, pharmacokinetics (PK), safety and immunogenicity of BAT1806/BIBIB800 in comparison with EU-sourced TCZ in subjects with inadequately controlled severe rheumatoid arthritis with inadequate response to methotrexate (MTX). Methods: The study was conducted at 55 centres in China and Europe, between June 2018 and January 2021. Eligible subjects were randomised in a 2:1:1 ratio to one of three treatment groups: (1) BAT1806/BIBIB800 up to Week 48, (2) TCZ up to Week 48, or (3) TCZ up to Week 24, followed by BAT1806/BIBIB800 from Week 24 to Week 48, administered intravenously every 4 weeks at a dose of 8mg/kg. The primary endpoint was the proportion of subjects achieving an ACR20 response at timepoints pre-specified to meet the requirements of different Regulatory Agencies: Week 12, for EMA; Week 24, for FDA and NMMPA. Equivalence margins applied to differences in ACR20 response rates in the BAT1806/BIBIB800 and TCZ treatment groups were pre-specified as follows: +/- 14.5% for EMA (95% confidence interval (CI)) -12.0%, 15.0% for FDA (90% CI); +/- 13.6% for NMMPA (95% CI). Secondary endpoints included pharmacokinetics, safety and immunogenicity. The ICH E9(R1) estimands framework including intercurrent events (related or unrelated to the COVID19 pandemic) was implemented for the ACR20 evaluation. A logistic regression model including ‘region’ (China and Eastern Europe) and ‘previous biologic or targeted synthetic DMARD use’ (Yes/No) as captured in Interactive Web Response System as stratification factors was utilised to assess equivalence for the primary endpoint. The difference in response rates was estimated and corresponding confidence intervals were derived to assess equivalence for the primary endpoint. This abstract presents results up to Week 24.

Results: In total, 621 subjects were randomised to receive BAT1806/BIBIB800 (N=312), TCZ (N=155), or TCZ followed by BAT1806/BIBIB800 (N=154). The groups were comparable in terms of baseline demographics and disease characteristics, including age, gender, disease activity and disease duration. The estimated proportions of subjects achieving an ACR20 response in the BAT1806/BIBIB800 vs. the TCZ groups, respectively, were 68.97% vs. 64.82% at Week 12 and 69.89% vs. 67.94% at Week 24. The estimated difference between ACR response rates was 4.15% (95% CI -3.63, 11.93) at Week 12, and 1.94% (90% CI 4.04, 7.32; 95% CI -5.18, 9.07) at Week 24. The CIs for the estimated differences between the treatment groups were within the pre-defined equivalence margins (Figure 1). The treatment groups were comparable in terms of serum trough levels, incidence of TEAEs and ADA/NAb positivity (Table 1).

Conclusion: BAT1806/BIBIB800 has demonstrated equivalent efficacy at Week 12 and Week 24 and a similar PK, safety and immunogenicity profile as reference tocilizumab up to Week 24.

A CANADIAN RETROSPECTIVE CHART REVIEW EVALUATING CONCOMITANT METHOTREXATE DE-ESCALATION PATTERNS IN RA PATIENTS TREATED WITH BIOLOGIC OR TARGETED SYNTHETIC DMARDs

L. Bessette, B. Florica, P.A. Fournier, T. Girard, L. Naik, D. Sholter, P. Baer. 1 Faculty of Medicine - University Laval, Department of Medicine, Québec, Canada; 2 University of Toronto, Department of Internal Medicine, Toronto, Canada; 3 Abbvie Corporation, Medical Affairs, St-Laurent, Canada; 4 University of Saskatchewan, Department of Adult Rheumatology, Saskatoon, Canada; 5 University of Alberta, Department of Medicine, Edmonton, Canada; 6 Baer Weinberg MPC, Medicine, Scarborough, Canada

Background: Rheumatoid arthritis (RA) guidelines recommend methotrexate (MTX) as anchor therapy in combination with biologic or targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs). However, its tolerability is challenging with a significant proportion of patients not adhering to their prescribed MTX regimen following a b/tsDMARD initiation. Rates of MTX tapering and withdrawal have been reported elsewhere but Canadian data are lacking.

Objectives: This multi-centre, retrospective chart-based cohort study assessed the frequency of MTX withdrawal or tapering following initiation of a b/tsDMARD in Canadian adults with RA.

Methods: Patients were eligible if they received MTX for ≥3 months before initiation of a b/tsDMARD that was then prescribed continuously for ≥18 months and was initiated in combination with MTX. Patients taking oral prednisone or equivalent at a dose >10 mg per day, and those whose b/tsDMARD was prescribed prior to 2014, were excluded.

Results: Data from 889 patients were included in the analysis. Mean age was 50.6 years and 72.6% were female. Mean time since diagnosis was approximately 8 years. Of the 46.1% of patients with a documented assessment of disease status at baseline, 62.7% of patients had high disease activity. Baseline mean (SD) MTX dose was 18.9 (6.63) mg/week, administered orally (57.4%), subcutaneously (41.3%), or intramuscularly (1.2%). Overall, 270 (30.4%) patients either tapered (123, 13.8%) or discontinued (147, 16.5%) their MTX within 2 years of initiating the b/tsDMARD. Methotrexate dose was unchanged for 582 (65.5%) subjects and increased for 37 (4.2%) subjects. The prescribed b/tsDMARD was most often a tumor necrosis factor inhibitor (TNFi, 52.1%), followed by a Janus kinase inhibitor (JAKI, 18.3%).

In the MTX Tapered group, the most common reasons for MTX dose change were planned tapering (36.6%) and adverse events (29.3%). In the MTX Increased group, insufficient clinical response (73.0%) was the most common reason provided for MTX dose change. Baseline factors associated with MTX dose discontinuation and tapering by multiple logistic regression analysis included a shorter time since diagnosis (Odds ratio (OR): 0.981; 95% confidence interval [CI]: 0.964 – 0.999; P=0.0401), use of non-DMARD medications excluding steroids (OR: 0.883; 95%CI: 0.503 – 0.929; P=0.0150) and a greater number of comorbidities (OR: 1.054; 95%CI: 1.001 – 1.100; P=0.0444). The mean (SD) weekly MTX dose at the end of the data extraction period was 14.13 (4.81) mg for the MTX Tapered group, with 109 (88.6%) subjects taking a weekly MTX dose ≥10mg. In the MTX Increased group, the mean (SD) weekly MTX dose was 22.3 (3.74) mg. Interpretation of the effect of MTX dose on disease activity, fatigue, pain and functional status is challenging due to missing data, but most patients in all 4 groups transitioned to low disease activity or remission during the study period.

Conclusion: Methotrexate withdrawal or tapering occurred in 30.4% of Canadians with RA within two years following b/tsDMARD initiation. There was no evidence of worsening disease activity in these patients. These proportion of Canadian RA patients who reduce or discontinue MTX after the initiation of a b/tsDMARD are generally consistent with those reported in other regions of the world.

Acknowledgements: AbbVie Corp. funded the research for this study and provided writing support for this abstract. AbbVie participated in the study design; study conduct and analysis; and writing, reviewing, and approving this abstract for submission. All authors had access to the data; participated in the development, review, and approval of the abstract; and agreed to submit this abstract to EULAR 2022. AbbVie and the authors thank all study investigators for their contributions and the patients who participated in this study. Medical writing support was provided by Judy drill PhD of Medpace Scientific and funded by AbbVie, LLC.

Figure 1. A conceptual framework of descriptions of the course and timeframe of adverse drug reactions reported by patients using a biologic for immune-mediated inflammatory diseases

Conclusion: We identified six themes in patient-reported descriptions of the course of ADRs of biologics. These themes provide information about ADRs on a broader level than the currently available information on nature and frequency. Information about ADRs enriched with details on the course is essential. A framework of ADRs may support healthcare professionals in improving clinical practice by discussing ADRs with patients and finding practical solutions in dealing with ADRs. This will ultimately lead to more optimised medical treatment.

Background: Olokizumab (OKZ) is an interleukin-6-inhibitor for treatment of rheumatoid arthritis (RA). In these analyses we present patient reported outcomes (PROs) reported by TNF-IR patients with moderate to severely active RA receiving OKZ or placebo in a phase 3 randomized controlled trial (RCT) (ClinicalTrials.gov number, NCT02760433).
Results: Baseline demographics and disease characteristics were comparable between groups. At week 12, treatment with OKZ q2w compared with placebo resulted in significantly greater LSM changes from baseline in Pain, HAQ-DI, FACIT-F, SF-36 PCS, MCS and 4 domains; with OKZ q4w in PTGA, Pain, SF-36 MCS and 4 domains (Table 1, Figure 1). Improvements reported at week 12 in PROs continued or increased with both doses of OKZ until week 24. Post hoc analyses demonstrated that a higher proportion of patients receiving OKZ reported improvements ≥minimum clinically important differences vs placebo (p<0.05) in FACIT-F, SF-36 PCS and MCS scores, indicating that these changes translated into clinically meaningful benefits on an individual patient basis. Numbers needed to treat to gain these benefits in fatigue and physical function ranged from 9.2 - 15.4 with OKZ q2w vs 10.5 - 13.3 with OKZ q4w, respectively.

POS0292 INCREASE OF PRO-INFLAMMATORY CYTOKINES IS ASSOCIATED WITH ANTI-IDIOTYPE EVENTS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH INFLIXIMAB OR ADALIMUMAB

D. X. Xibille Friedrich1, S. M. Carrillo Vazquez2, J. Gonzalez Christen3, D. Vega Morales4, M. Garza Elizondo5, R. Hernandez2, J. E. Ortiz Panozo6, J. L. Montiel Hernandez7. 1Hospital General de Cuernavaca, Rheumatology, Cuernavaca, Mexico; 2Hospital Regional 1 de Octubre, Rheumatology, CDMX, Mexico; 3Universidad Autonoma del Estado de Morelos, Facultad de Farmacia, Cuernavaca, Mexico; 4Universidad Autonoma de Nuevo Leon, Rheumatology, Monterrey, Mexico; 5Hospital de Especialidades, Centro Medico Nacional S. XXI, Rheumatology, CDMX, Mexico; 6Instituto Nacional de Salud Publica, Epidemiology, Cuernavaca, Mexico

Background: A significant percentage of rheumatoid arthritis (RA) patients undergoing Infliximab (IFX) or Adalimumab (ADA) treatment develop antidrug antibodies with potential negative effects over their clinical activity; however, it is unknown if these anti-idiotype events could be associated with changes in cytokines levels

Objectives: To evaluate the association between blood cytokine levels, anti-idiotype events and clinical activity in RA patients treated with IFX or ADA

Methods: All patients complied with ACR/EULAR 2021 criteria for RA and received anti-TNFa agents. Blood samples were collected during the drug trough and kept at -75ºC until analysis. Clinical activity was based on DAS28-ESR. Specific anti-drug antibodies to IFX and ADA were evaluated by sandwich ELISA. Cytokine blood levels were quantified using a multiplex system or sandwich ELISA.

Results: 57 patients with RA were recruited, 17 treated with IFX and 40 with ADA. According to the presence of anti-drug antibodies and sub-optimal levels of the biologic drug, patients were classified as immunogenic (29.8%; n=17) and non-immunogenic (70.2%; n=40), the latter showed significantly higher ESR (p<0.001) and DAS28 (p<0.005). A significant association was seen between antidrug antibodies and increases of IFNg (2.1 OR, CI95%:1.2-3.8, p<0.01); MCP-1 (3.9 OR, CI95%:1.1-14.5, p<0.05); MIF (2.8 OR, CI95%:1.3-5.7, p<0.01) and TNFa 3.0 OR, CI95%:1.3-6.6, p<0.01 (see Table 1). Although anti-idiotpe events were more frequent in IFX treated patients (41%), a significant difference was not seen when comparing with ADA treated patients (25%).

POS0293

IN VITRO RESPONSE TO DISEASE MODIFYING
ANTIRHEUMATIC DRUGS LINK MOLECULAR DRUG
TARGET WITH SYNOVIAL TRANSCRIPTIONAL
SIGNATURE

M. B. Kristensen1, U. Ahmadov1, M. A. Nielsen1,2, L. S. Kristensen1,
T. W. Kragstrup1,2. 1Aarhus University, Department of Biomedicine, Aarhus C,
Denmark; 2Aarhus University Hospital, Department of Rheumatology, Aarhus,
Denmark
Background: Immune-mediated inflammatory arthritis (IMIA) is a group of diseases characterized by chronic synovitis including rheumatoid arthritis (RA),
psoriatic arthritis (PsA), and spondyloarthritis (SpA). Some disease modifying
antirheumatic drugs (DMARDs) have demonstrated efficacy in several of these
diseases (e.g. TNFα inhibitors) while others have not (e.g. IL-17A inhibitors in
RA). Furthermore, within each disease there are patient subgroups experiencing
different responses to the same drug, which underlines the need for further elucidation of pathogenic processes to guide personalized in IMIAs.
Objectives: Here we investigated if clinical features and synovial transcriptional signature could predict in vitro efficacy of specific DMARDs across different IMIAs.
Methods: Synovial fluid mononuclear cells (SFMCs) from patients with SpA
(n=13), RA (n=16), PsA (n=13), juvenile idiopathic arthritis (JIA) (n=7) or undifferentiated arthritis (n=5) were included. SFMCs from each patient were cultured
for 48 hours (drugs listed in Table 1). Culture medium and DMSO were used as
negative controls. In vitro drug response was assessed by measuring monocyte
chemoattractant protein 1 (MCP-1) by ELISA. SFMC baseline gene expression of
270 genes related to inflammation was measured using the NanoString nCounter
Human Inflammation V2 Panel. Drug responses (ΔMCP-1) were compared with
clinical diagnosis, serostatus in RA patients, HLA-B27 status in SpA patients,

Drug

Target

Adalimumab
Etanercept
Tocilizumab
Anakinra
Ustekinumab
Secukinumab
Tofacitinib
Baricitinib

TNFα
TNFα
IL-6
IL-1β
IL-12/23
IL-17A
JAK1/3
JAK2/3

Results: DMARDs with a similar molecular target had comparable effects on
ΔMCP-1. The TNFα inhibitors adalimumab and etanercept (r=0.86) had similar
drug responses, and so had the JAK inhibitors tofacitinib and baricitinib (r=0,71).
In contrast, drugs with different modes of action had diverse responses (Figure 1). High HLA-DRA gene expression associated with high responses to TNFα
inhibitors (both p<0.05). JAK inhibitors reduced MCP-1 secretion significantly
more in SFMCs from seropositive than seronegative RA patients (p<0.05).
Drug response was greater in SFMCs from patients with low DAS28-CRP
scores (DAS28-CRP <2.5) compared with patients with a high DAS28-CRP
score (DAS28-CRP >5.2) for TNFα inhibitors, tocilizumab and JAK inhibitors (all
p<0.05). Patients clustered with either an overall high or an overall low response
to almost all DMARDs, or with a significant response to only one or a few of
the DMARDs. Transcriptional signature of patient SFMCs primarily responding
to TNFα inhibitors was different compared with the signature of patient SFMCs
primarily responding to JAK inhibitors. Diagnosis, HLA-B27 status, failed modes
of action and years since diagnosis did not affect ΔMCP-1 in this in vitro setup.

Figure 1. Association between DMARD molecular target and in vitro response as measured
by change in MCP-1 secretion.

Conclusion: Similarities and differences in mode of action for 8 different
DMARDs were captured in drug response as measured by MCP-1 change in
SFMC cultures from 54 patients with inflammatory arthritis. We were able to identify interesting differences in gene expression when comparing cells responding
to TNF inhibitors to cells responding to JAK inhibitors. Drug responses were only
to a minor extent associated with clinical features.

POS0294

ARTIFICIAL INTELLIGENCE TO CONNECT THE
USE OF BIOLOGICS AND SMALL MOLECULES IN
RHEUMATOID AND PSORIATIC ARTHRITIS WITH A
MULTIDISCIPLINARY EVALUATION: A REAL WORLD
EVIDENCE APPROACH THROUGH NATURALLANGUAGE PROCESSING

P. Moranding1, F. Maffia1, F. Puggioni2, F. Motta3, M. Vecellio3, A. Costanzo4,
V. Savevski1, C. Selmi3. 1Humanitas Research Hospital - IRCCS, Artificial
Intelligence, Rozzano, Italy; 2Humanitas Research Hospital - IRCCS, Asthma,
Allergy, and Personalized Medicine, Rozzano, Italy; 3Humanitas Research


Background: The management of rheumatoid arthritis (RA) and psoriatic arthritis (PsA) is often relying on a multidisciplinary approach with different specialists evaluating the patient for treatment choices. The ultimate impact of such management on the use of systemic glucocorticoids and more innovative drugs such as biologics and small molecules, however, is unclear. Artificial intelligence tools, particularly natural language processing and machine learning, allow to manage large datasets and investigate associations between variables.

Objectives: To use a natural language processing approach to demonstrate whether a multidisciplinary approach to RA or PsA changes treatment choices.

Methods: We analysed the clinical notes of hospital encounters between 2017 and 2020 of patients with a terminated or ongoing care process at outpatient clinics included in the Humanitas Center for immune-mediated disease. To extract structured information from text data we used regular expressions (RegEx), a technique that allows to define elastic search patterns. RegEx were also used to detect negations to consider only affirmative citation of diseases or prescribed therapy. Care processes were described by binary flags which express the presence of RA or PsA and the prescription of glucocorticoids and biologics / small molecules for each patient. Working with only categorical data, we relied on the chi squared test to detect possible correlations between prescribed treatments and the characteristics of the care process, including whether a multidisciplinary evaluation had occurred.

Results: Our analysis included 1839 patients with RA (77% women, mean±standard deviation age 58±16 years) and 1652 patients with PsA (46% women, age 57±15 years), accounting for 5517 and 3992 outpatient visits with different specialists over the study period, respectively. Among patients with RA and PsA, 378 (22%) and 371 (25%) were prescribed biologics or small molecules, respectively, while 830 (47%) RA and 431 (29%) PsA cases received a prescription for systemic glucocorticoids during one of the visits and patients seen three of more times by the rheumatologists received significantly more biologics / small molecules. Importantly, 4.5% of patients with RA and 9.4% of patients with PsA were evaluated also by dermatology, gastroenterology, allergy and pulmonary disease specialists and these patients were treated more frequently with glucocorticoids (70% vs.47% for RA, P<0.001; 60% vs. 29% for PsA, P<0.001) as well as with biologics / small molecules (42% vs. 22% for RA, P<0.001; 58% vs. 25% in PsA, P<0.001).

Conclusion: Natural language processing and machine learning were applied to unstructured electronic clinical charts in a large Center dedicated to immune-mediated diseases and allowed to demonstrate that patients with RA or PsA undergoing multiple evaluations are more likely to receive biologics / small molecules. The occurrence of serious infections between groups (defined as infections requiring hospitalization and/or parenteral antibiotics). We deployed the nearest-neighbour matching algorithm (1:4), based on Propensity Score (PS), in order to adjust for non-randomization. The McNemar's test was used to compare the frequency of serious infection in the two groups.

Results: DEN group consisted of 36 patients were recruited, while the cohort of patients in noDEN group consisted of 547 individuals (Table 1). After PS matching only 58 patients were noDEN group, matched for disease duration, presence/absence of ACPA antibodies, baseline BMI, baseline DAS28 and daily prednisone dosage. In the matched cohort, we found an increase in terms of frequency of serious infections in DEN group, even if not statistically significant (Figure 1). All the infections were completely resolved after hospitalization and/or parenteral antibiotic treatment, without fatal events or irreversible complications. Both groups were not stratified for bDMARDs mechanism of action (MoA). Of note, in the DEN group Rituximab therapy was administered in 22% of patients, while in noDEN group in 12% of them.

Figure 1. Occurrence of serious infections at 12-months follow-up.

Conclusion: The occurrence of serious infections among RA patients receiving denosumab in combination with bDMARDs ± MTX for RA was not significantly increased compared to those receiving bDMARDs ± MTX alone at 12 months from treatment baseline. Further studies powered for detecting difference between bDMARDs MoA are necessary in order to assess the infection risk of denosumab co-administration.
AxSpA: About treatments and outcomes

Tofacitinib 5 mg BID was well tolerated over 48 Wks in pts with AS, and safety was consistent with the established safety profile of tofacitinib.

**Legend:** BASMI: Bath Ankylosing Spondylitis Metascore Index; HAQ: Health Assessment Questionnaire modified for spondyloarthritis; ASDAS: Ankylosing Spondylitis Disease Activity Score; ESR: erythrocyte sedimentation rate

**Conclusion:** In a real-life clinical-setting, PROSPECT proved to be safe and effective in axSpA, mainly in naïve-patients, with a notable drug-retention-rate. No differences were observed between r-axSpA and nr-axSpA.
Background: Patients with axial spondyloarthritis (axSpA) in clinical remission tapered Tumor Necrosis Factor inhibitor (TNFi) therapy according to a clinical guideline and had 2 years’ follow-up [1].

Objectives: We aimed to investigate flare frequency, dose at which flare occurred, type of flare (clinical/ Bath ankylosing spondylitis disease activity index (BASDAI)/magnetic resonance imaging (MRI)) and predictors of flare.

Methods: Patients in clinical remission (BASDAI<40, physician global score<40 during tapering to discontinuation, but above half not before receiving 1/3 dose or less. Higher physician global score was the only independent predictor of flare after tapering to 2/3 dose (Odds ratio=1.19 (95% Confidence Interval=1.05-1.41); p=0.011) (Table 1). Changes in clinical and/or imaging variables in the 16 weeks prior to tapering did not predict flare (data not shown).

Conclusion: Almost all (99%) axSpA patients in clinical remission flared during tapering to discontinuation, but above half not before receiving 1/3 dose or less. Higher physician global score was the only independent predictor of flare.

Background: Axial spondylarthrititis (axSpA) is characterised by inflammation of the sacroiliac joints (SIJ) and the spine. Secukinumab (SEC) treatment was clinically efficacious and reduced SIJ bone marrow oedema as detected by magnetic resonance imaging (MRI) in patients (pts) with non-radiographic (nr) axSpA through 52 weeks in the PREVENT (NCT02696031) study.1

Objective: To report radiographic progression and the course of inflammation as assessed by X-ray and MRI of SIJ and spine over 2 years in the PREVENT study.

Methods: Study design and key endpoints have been reported earlier.1 In total, 555 pts were randomised (1:1:1) to receive SEC 150 mg, with (LD) or without loading (NL) doses, or placebo (PBO). Switch to open-label (OL) SEC or standard -label (SoC) was permitted after Week (Wk) 20. All pts (except those who switched to SoC) received OL SEC from Wk 52. Radiographs of the spine and SIJ were collected at baseline (BL) and Wk 104; MR images of the spine and SIJ were collected at BL, Wk 16, 52, and 104. Spinal radiographs were scored using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) and SIJ radiographs according to modified New York criteria (mNY). Pts whose screening SI joint radiographs fulfilled mNY criteria during the eligibility reading session were excluded from the study. Spinal MRI images were assessed for signs of inflammation with the Berlin score. SIJ bone marrow oedema was assessed according to the Berlin Active Inflammatory Lesions Scoring. All images were evaluated in blinded fashion independently by 2 central readers. All data are reported from the Wk 104 reading session and are presented as observed.

Results: The vast majority (98%) of pts treated with SEC 150 mg (pooled LD and NL) showed no structural progression, defined as change in total mSASSS score ≤ smallest detectable change (SDC) of 0.76 (80% agreement level) over 2 years. At BL, 62 pts (43 in SEC, 19 in PBO) presented with ≥1 syndesmophytes (≥1 vertebral unit scored by ≥1 reader). Among these pts, 9 in SEC (20.9%) and 7 in PBO (36.8%) groups had developed ≥1 new syndesmophytes by Wk 104. Among 237 SEC and 117 PBO pts without syndesmophytes at BL, only 4 pts on SEC (1.7%) and 4 pts on PBO (3.4%) developed ≥1 new syndesmophytes by Wk 104. SEC radiographs showed that 88% of pts on SEC and 86% on PBO had no progression in SIJ (defined as change ≤ SDC (0.46) in total mNY score) by Wk 104. No patient had an increase in total mNYC score of 2 or more. When screening radiographs of eligible pts were scored alongside post-BL images in the final reading campaign, approximately 25% of pts (68/277 and 34/139) in the SEC and PBO groups, respectively) were evaluated as mNY-positive at screening (pts were considered mNY-positive if ≥1 reader evaluated them as mNY-positive). Of these, 11/68 pts in the SEC (16.2%) and 5/34 in the PBO (14.7%) groups were evaluated as mNY-negative at Wk 104. In the SEC and PBO groups, 202 (96.7%) and 102 (97.1%) pts who were mNY-negative at screening stayed negative through Wk 104, respectively. Only 7 pts in the SEC (3.3%) and 3 in the PBO (2.9%) groups who were mNY-negative at BL were scored as mNY-positive at Wk 104. In both groups, fewer pts progressed from mNY-negative to mNY-positive than had a change in the opposite direction (from positive to negative), resulting in an overall negative net progression.

Spinal inflammation on MRI (Berlin score) was low at BL with a mean of 0.62 in SEC and 1.07 in PBO groups with no meaningful change up to Wk 104 (mean of 0.56; SEC). SEC reduced SIJ bone marrow oedema score versus PBO at Wk 16 and Wk 52 with sustained reduction through Wk 104 in the overall patient population, with greater reduction in pts with BL score >2 (Figure 1).

Conclusion: Most pts initially randomised to SEC or PBO showed no radiographic progression through 2 years. There was some discrepancy between SIJ eligibility and efficacy reads. SEC reduced SIJ inflammation (bone marrow oedema) on MRI in pts with active nr-axSpA.

Background: While data on real-life SEC retention rate in patients (pts) with axSpA are accumulating, there are no data on predictive factors for this retention. Presence of objective sign of inflammation (OSI) is known to be predictive of efficacy of anti-TNFs and their retention in axSpA.

Objectives: To assess whether OSI were predictive of SEC retention at 1 year in axSpA.

Methods: French retrospective study collecting between October 2019 and September 2020 data from axSpA pts a) having initiated and received at least one dose of SEC between August 11th 2016 and August 31st 2018, b) with at least one a year follow-up period. Retention of SEC at 1 year was estimated by the Kaplan Meier (KM) method. OSI were defined by at least one of the following: CRP > N, MRI-inflammation at the sacroiliac or spine level. Preselected factors of SEC retention at 1 year (~1 OSI, age, sex, BMI, smoking, HLA B27, non-radiographic axSpA, past or present uveitis / Inflammatory Bowel Disease (IBD) / psoriasis / arthritis or synovitis, diagnostic delay, disease duration, SEC line of biological therapy, SEC maintenance dose, concomitant csDMARD / oral corticosteroids / proton pump inhibitor, history of depression / fibromyalgia) were analyzed by multivariate cox model regression. Only variables with <20% missing data were included in the model after imputation and stepwise selection (significance level for entering variables = 20%; for removing variables = 10%). OSI was forced into the model whatever its significance level or rate of missing data.

Results: In total, 906 pts from 47 centers (male: 42.2%, mean age: 46.2 ± 11.7 years, mean disease duration: 9.3 ± 9.1 years), were included in the analysis. At initiation of SEC, 86.3% of pts had ≥1 OSI and respectively 8.0%, 14.9% and 77.1% were in 1st, 2nd and ≥3rd line (L) of biological targeted synthetic DMDAR. The 1 year KM survival rate for SEC was 59% [95%CI:55%-62%] overall, 58% [54%-62%] and 63% [53%-73%] for pts with or without OSI, and was numerically greater in 1st L vs 2nd and ≥3rd L (70% [59%-81%], 62% [54%-70%], 57% [53%-61%] respectively). In multivariate analysis absence of OSI, lack of prior exposure to anti-TNF inhibitors, absence of IBD, and absence of history of depression were associated with a better SEC retention at 1 year (Table 1).

# without imputation for missing datainterpretation HR > 1: the hazard of discontinuation at 1 year is X times higher vs reference

Conclusion: The overall retention of SEC at 1 year in daily practice at the time of its launch in France was 59% for axSpA patients and OSI, prior exposure to TNF inhibitors, IBD and history of depression were identified as predictive factors of SEC retention.

STRUCTURAL OUTCOMES IN THE SACROIILAC JOINT AFTER IXEKIZUMAB TREATMENT FOR 16 WEEKS IN PATIENTS WITH ACTIVE NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS STRATIFIED BY GENDER, HLA-B27, AND BASELINE MRI INFLAMMATION

W. P. Maksymowycz, X. Baraliakos, R. G. Lambert, R. B. M. Landewé, D. Sandałow, H. Cartier, J. Lisse, X. Li, M. Hojkă, M. Østergaard, Division of Rheumatology at the University of Alberta, Department of Medicine, Alberta, Canada; 2Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet Herne, Herne, Germany; 3University of Alberta, Department of Radiology & Diagnostic Imaging, Alberta, Canada; 4Amsterdam Rheumatology and Immunology Center, Department of Clinical Immunology and Rheumatology, Amsterdam, Netherlands; 5Eli Lilly and Company; Lilly Corporate Center, Indianapolis, United States of America; 6Eli Lilly and Company, Immunology Medical, Brussels, Belgium; 7Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, and Department of Clinical Medicine, University of Copenhagen, Glostrup, Denmark

Background: Ixekizumab (IXE) has demonstrated clinical efficacy in patients with active non-radiographic axial spondyloarthritis (nr-axSpA) together with significant repair of structural lesions in the sacroiliac joint (SIJ) on MRI. There is, however, a paucity of data as to which patients may be most responsive.

Objectives: We aimed to evaluate whether patients’ gender, HLA-B27 status, and presence of MRI inflammation impacted the effect of treatment with IXE versus placebo (PBO) on MRI structural lesions in the SIJ in patients with nr-axSpA.

Methods: Patients with active nr-axSpA, biologic-naïve (COAST-X, NCT02757352) were randomized 1:1:1 to ixekizumab 80 mg every 4 (Q4W) or 2 weeks (Q2W) or PBO. Structural lesions on SIJ MRI were assessed by the Spondyloarthritis Research Consortium of Canada (SPARC) MRI SIJ structural score (SSS). Treatment comparisons used analysis of covariance based on observed cases. SPARC SSS subgroup analyses were performed according to baseline gender, HLA-B27 status, and SPARC MRI SIJ bone marrow oedema (BME) ≤4 and ≥4 subgroups, which reflects a definite MRI for inflammation in the SIJ typical of nr-axSpA.

Results: Of 303 randomized patients, 266 patients (Q4W: n=85, Q2W: n=91, PBO: n=90) had an MRI scan at baseline and week 16. At baseline, SPARC SSS scores were consistently higher in males, and mostly higher in HLA-B27 and BME≥4 positive subgroups. Significant differences between patients treated with IXE versus PBO were observed for male patients, HLA-B27 positives, and those with baseline SPARC BME ≥4. Numerically similar changes were observed in female patients, with negative HLA-B27, and patients with SPARC BME<4, though not statistically significant.

Conclusion: Effects of IXE on structural repair are most evident in males, HLA-B27 positives, and patients with definite MRI inflammation at baseline.

CFB=change from BL, BL=baseline, LS=least squares.
Background: So far, no consensus has been reached on a definition of early axSpA. The ASAS-SPEAR (Spondyloarthritis EARly definition) project aims to develop a consensual definition. Therefore, it is important to know whether treatment earlier in the disease course compared to treatment of established disease leads to better outcomes in axSpA.

Objectives: To summarize the evidence on the relationship between symptom duration or the presence of radiographic damage and clinical response in patients with axSpA treated with NSAIDs, bDMARDs or tsDMARDs.

Methods: A SLR was conducted using Medline, EMBASE and the Cochrane Library (April 28, 2021), supplemented by hand-searches in the FDA website. Randomized controlled trials (RCTs) and cohort studies in patients with axSpA addressing the impact of symptom duration or disease duration and presence of radiographic damage on treatment response (to NSAIDs, b/tsDMARDs) were included. Based on a cut-off of symptom/disease duration or the absence/presence of radiographic damage, groups of ‘early’ and ‘established’ disease were compared. Treatment outcomes were measures of disease activity, function or quality of life.

Two reviewers independently identified eligible studies and extracted the data, including the risk of bias (RoB) assessment. For categorical outcomes we calculated relative risk (RR), relative risk ratio (RRR) and number needed to treat (NNT), and differences in differences (DID) for continuous outcomes.

Results: From the 8769 articles retrieved, 23 were included and 3 added by hand-search, most of them with low RoB. Nineteen studies (9 RCTs) compared groups based on symptom (n=6)/disease duration (n=13) and 7 studies (4 RCTs) based comparisons on absence/presence of radiographic damage in posthoc analyses.

When early axSpA was defined by symptom duration in RCTs (n=4), in patients with axSpA, early treatment was associated with higher RR and RRR and lower NNT for ASAS40 in two studies (Table 1); a third study showed that patients achieving ASDAS-ID and ASAS-PR had shorter symptom duration than those not achieving this. Lastly, in one study including patients with axSpA patients, no difference in treatment response was observed based on symptom duration. In most of the cohort studies using a definition based on symptom/disease duration (n=10), no association was found between symptom/disease duration and treatment response (n=8). Only in one cohort study, disease duration was a significant predictor of quality of life, and in another cohort study, it was a predictor of functional improvement.

When early axSpA was defined based on disease duration or the presence of radiographic damage, there was no significant difference in response to treatment between early and established axSpA.

Conclusion: Studies addressing treatment response based on symptom duration or radiographic damage in axSpA are scarce. When defining early axSpA based on symptom duration, in n-axSpA, treatment with bDMARDs may lead to better outcomes compared to established axSpA whereas in axSpA there is no difference in response to treatment between early and established disease.

When early axSpA is defined based on disease duration or radiographic damage, no differences in response to treatment are found between early and established disease.

TREATMENT DECISIONS IN AXIAL Spondyloarthritis are MORE THAN TREAT TO TARGET

J. W. Bolt1,2, C. Aalbers1,2, L. H. Wiele2,1, L. Van Mens3,2, J. C. Van Denderen3,2, I. Van der Horst-Bruinisma1,2, L. Van Baarren1,2, R. B. M. Landewé1,2, M. G. H. Van de Sande1,2,1, Amsterdam UMC, University of Amsterdam, Department of Rheumatology & Clinical Immunology and Department of Experimental Immunology, Amsterdam, Netherlands; 2Amsterdam Rheumatology and Immunology Center (ARC), Amsterdam, Netherlands; 3Reade, Department of Rheumatology, Amsterdam, Netherlands; 4Radboud University Medical Centre, Department of Rheumatology, Nijmegen, Netherlands

Background: Several guidelines treating axial spondyloarthritis (axSpA) patients according to the ‘treat-to-target principles’ (T2T)1 although a clear target has not yet been defined. Disease activity measures, which are often used as targets, do not always reflect pure inflammatory disease activity. Currently it is not known if T2T is applied in axSpA clinical practice and what factors influence treatment decisions.

Objectives: To assess residual disease activity according to the physician's opinion, patient's opinion and disease activity measures and the subsequent treatment decisions made in axSpA patients.

Methods: This cross-sectional multicentre study included 249 patients with a clinical diagnosis of axSpA > 6 months. Remission and low disease activity according to Bath Ankylosing Spondylitis Disease Activity Index (BASDAI <1.9 and <3.5 respectively), physician's, and patient's opinion was assessed. Questionnaires including patient reported outcomes (PROs) such as the Patient Global Assessment (PGA) of disease activity, Bath Ankylosing Spondylitis Functional Index (BASFI), ASAS-Health Index (ASAS-HI), central sensitization inventory (CSI), Brief Illness Perception Questionnaire (B-IPQ), and satisfaction with treatment; or questions regarding motivations for treatment decisions were filled in by patients and physicians respectively.

Results: In this cohort, 115/249 patients were in remission according to the physician. Of these 115 patients, 67% (n=80) indeed perceived their disease as being inactive, but only 37% (n=43) reached remission according to the BASDAI. This shows a significant level of discrepancy in comparison with the physician's opinion. Of note, 30 (n=35) even reported a BASDAI >3.5. In 93% (n=107) treatment-intensity remained unchanged and in 6% (n=5) treatment was tapered. Physicians motivated that treatment was left unchanged in the majority of these patients because of remission (n=5, 10%) and disease activity (n=5, 25%), or complaints not related to axSpA (n=13, 12%). The latter two motives were most frequently mentioned for the patients with a BASDAI >3.5 (respectively n=13, 39% and n=9, 27%). Residual disease activity was present in 134/249 patients according to the physician's opinion and 67% (n=90) of these patients also perceived their disease as active. In 89% (n=119) BASDAI score was >1.9 and in 62% (n=83) >3.5. In 61% (n=51) of these patients with residual disease and a BASDAI >3.5, treatment remained unchanged, as well as in 84% (n=43) of the patients with a BASDAI between 1.9 and 3.5. Physician's most frequently mentioned motives for not changing treatment in the residual disease activity group were low disease activity achieved (n=29, 25%), the need to await the effect of the current treatment (n=23, 20%), or complaints that were not related to axSpA (n=9, 8%). The second (n=20, 39%) motive was most frequently mentioned for unchanged treatment in the BASAI >3.5 group and additionally, physicians mentioned that these patients had a preference to continue their current treatment despite high disease activity (n=5, 10%). Analyses of PROs showed significantly higher scores for PGA of disease activity, several subdomains of the B-IPQ, general fatigue and morning stiffness in patients with remission according to the physician despite a BASDAI >3.5.
compared to patients with residual disease according to the physician with a BASDAI <19.

**Conclusion:** This study shows that physicians in daily clinical practice do not always adjust treatment according to the T2T-principles in patients with residual disease activity when measured by BASDAI scores, either because low disease activity is achieved, because they classify the patient as being in remission, as having low disease activity, or because there was a need to await the efficacy of the current treatment. Further studies are needed to investigate if treatment choices made in clinical practice result in under-treatment of axSpA patients with worse outcome in comparison to the T2T approach.

**REFERENCES:**

**Disclosure of Interests:** J.W. Boit: None declared, Caroline Aalbers Speakers bureau: I am paid by Novartis as a speaker, Laura H Walet: None declared, Leonie van Mens: None declared, J.C. van Denderen: None declared, Irene van der Horst-Bruinsma

**Methods:** Data from the international ASAS Health Index Validation Study were used. Included patients had a diagnosis of SpA and fulfilled the ASAS classification criteria for axial/peripheral SpA. Patients were assessed at baseline, and for those who required a therapeutic change (initiation of NSAID, csDMARD or TNFi) due to high disease activity, a follow-up assessment was conducted. The current analysis included only those with a therapeutic change. Data on demographics, disease characteristics and disease activity (ASDAS, BASDAI, CRP) were available. Depressive symptoms were assessed with the depression subscale of the Hospital Anxiety and Depression Scale (HADS-D, range 0-21 [best-worst]). HADS-D scores ≥8 and ≥11 indicated possible and probable depression, respectively. Change in depressive symptoms from baseline was compared between treatments (CS) and is associated with higher levels of pain and functional disability. Tofacitinib is oral JAK inhibitor approved for the treatment of AS. In pts with AS, greater improvements in fatigue were seen with tofacitinib vs placebo (PBO).

**Objectives:** To estimate the time to improvement in fatigue in pts with AS treated with tofacitinib.

**Methods:** This post hoc analysis used data from a Phase 3 trial (NCT03502816) in pts with AS receiving tofacitinib 5mg twice daily (BID) or PBO for 16 weeks; after Week (W)16, all pts received open-label tofacitinib until W48. Fatigue was assessed by Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F) total score (range 0–52; higher scores indicate less fatigue). A series of time to improvement analyses were performed using non-parametric Kaplan–Meier models.

**Results:** Overall, 269 pts were assessed; baseline demographics/disease characteristics have been previously reported. The median times to initial improvements in FACT-F total score were assessed based on different thresholds. The initial improvement event was defined as time to first improvement in FACT-F total score. For example, median time to initial improvement in FACT-F total score was significantly (p < 0.05) shorter in pts receiving tofacitinib 5mg BID vs PBO (Figure 1). For example, median time to
initial improvement of 30% in FACIT-F total score was 16 weeks in pts receiving tofacitinib 5 mg BID; however, in pts receiving PBO, the median time for this event was not achieved up to W16. More pts receiving tofacitinib 5 mg BID vs PBO experienced initial improvement events up to W16 (Table 1). For example, 36.1% of pts receiving tofacitinib 5 mg BID experienced 50% improvement of fatigue up to W16, compared with 19.9% of pts receiving PBO.

Table 1. Proportions of pts who experienced initial improvement events in FACIT-F total score up to W16

N=133 (tofacitinib 5 mg BID); N=136 (PBO). aTest of equality over strata log-rank test, p<0.05

Conclusion: In pts with AS, initial improvements in fatigue, as determined by FACIT-F total score, occurred faster and were larger in magnitude with tofacitinib vs PBO up to W16. These results may help physicians better understand the speed and magnitude for fatigue benefit in pts receiving tofacitinib.

Background: Upadacitinib (UPA) was shown to be safe and effective through 2 years in patients (pts) with active ankylosing spondylitis (AS) naïve to biologic disease-modifying antirheumatic drugs (bDMARDs) in the pivotal phase 2/3 SELECT-Axis 1 trial.

Objectives: To assess the efficacy and safety of UPA in pts with active AS with an inadequate response (IR) to bDMARDs.

Methods: SELECT-Axis 2 (NCT04169373) was conducted under a master protocol and includes two separate studies (one for AS bDMARD-IR and one for non-radiographic axial spondyloarthropathies [n-axSpA]). The AS bDMARD-IR study is a randomized, double-blind, placebo (PBO)-controlled, phase 3 trial that enrolled adults ≥18 years with AS who met modified New York criteria, had BASDAI and pt’s assessment of total back pain scores ≥4 (numeric rating scale 0–10) at study entry, and had an IR to one or two bDMARDs (TNF inhibitor or IL-17 inhibitor). Pts were randomized 1:1 to receive oral UPA 15 mg once daily (QD) or PBO during the 14-week (wk) double-blind treatment period. The primary endpoint was ASAS40 response at wk 14. Multiplicity-adjusted secondary endpoints evaluated at wk 14 were improvements from baseline in disease activity (ASDAS CRP), ASDAS LDA (<1.3), ASDAS Lans<0.2, BASDAS05, ASAS20, and ASAS PR), pain (total and nocturnal back pain), function (BASFI), objective measure of inflammation (SPARCC MRI score of the spine), spinal mobility (BASMI), enthesitis (MASES), and quality of life (ASQoL and ASAS HI). Non-responder imputation incorporating multiple imputation (NRI-MI) was used to handle intercurrent events and missing data for binary endpoints. Cochran-Mantel-Haenszel (CMH) test and mixed-effect model for repeated measures (MIMM) were used for analyzing binary and continuous endpoints, respectively. Treatment-emergent adverse events (TEAEs) assessed through wk 14 are reported for pts who had ≥1 dose of study drug.

Results: All 420 randomized pts with active AS received assigned treatment (UPA 15 mg, n=211; PBO, n=209); 409 (97%) received study drug through wk 14. Baseline demographic and disease characteristics were generally similar between treatment groups and reflective of an active AS bDMARD-IR population (74% male; mean age 42.4 years; mean disease duration 7.7 years; 83% HLA-B27 positive; mean BASDAI 6.8). Significantly more pts achieved the primary endpoint of ASAS40 response at wk 14 with UPA vs PBO (45% vs 18%; P<0.0001; Figure 1). UPA showed onset of effect in ASAS40 as early as wk 4 (nominal P<0.05). All multiplicity-controlled secondary endpoints met statistical significance for UPA vs PBO at wk 14 across multiple clinical domains of AS (P<0.0001; Figure 1). The rate of TEAEs was similar between treatment groups through wk 14 (UPA, 41%; PBO, 37%). TEAEs led to discontinuation in 3 (1.4%) pts treated with PBO and none with UPA. Serious infections occurred with UPA (2.4%) but not with PBO and included 4 events of COVID-19 and 1 event of uveitis. Additional events of uveitis occurred in 1 (0.5%) pt on UPA and none on PBO. No malignancy, major adverse cardiovascular events, venous thromboembolic events, or death were reported with UPA; 1 event of malignancy was observed with PBO.

Conclusion: UPA 15 mg QD was significantly more effective than PBO over 14 wks of treatment in pts with active AS and IR to bDMARDs. No new safety risks were identified with UPA compared with its known safety profile. These findings are consistent with and complementary to those of SELECT-Axis 1 (bDMARD-naive AS population), and support the use of UPA in pts with active AS, including those who had a previous IR to bDMARD therapy.

REFERENCES:
Background: Psoriatic arthritis (PsA) and psoriasis are both strongly associated with impaired glycaemic control and type 2 diabetes. The risk of developing type 2 diabetes is estimated to be ~40% higher in PsA compared to controls [1]. However, these observational findings are susceptible to bias from reverse causality, insulin resistance and impaired glycaemic control are evident well over a decade before clinical onset of type 2 diabetes [2]. Therefore, whether impaired glycaemic control is a cause or consequence of PsA is unclear. Testing this hypothesis using traditional observational designs is challenging since longitudinal assessments of glycaemic control before PsA onset are often not available. Mendelian randomisation (MR) is an epidemiologic method that provides evidence about putative causal relationships between modifiable exposures and disease outcomes using genetic variants as instrumental variables. MR is less likely to be affected by confounding or reverse causation than conventional observational designs because genetic variants are randomly allocated at conception.

Objectives: To estimate the effect of genetically predicted glycaemic traits - glycaemic control may reduce PsA risk, although further studies are required to confirm these findings and to compare PsA directly against cutaneous only psoriasis.

Methods: We selected 320 independent (r²<0.01) genome-wide significant (p<5x10⁻⁸) variants as instruments for HbA1c from a UK biobank genome-wide association study (GWAS) of 3,448,182 individuals, and 14 variants for 2hG, 67 for FG and 38 for F1 from up to 200,622 individuals from a MAGIC consortium meta-analysis that adjusted for body mass index. Genetic associations for PsA were obtained from a GWAS comprising 3,609 cases (majority fulfilling CASPAR criteria) and 9,192 controls. Psoriasis data were obtained from 5,278 cases (96% European, defined using ICD and phenotypes) and 650,391 controls from the UK biobank, FinGen and BioBank Japan [3]. We used the inverse-variance weighted method to combine effect estimates from each variant using fixed-effect meta-analysis.

Results: Genetically predicted HbA1c increased risk of PsA (OR 1.18 per standard deviation (6.7 mmol/mol) increase in HbA1c; 95%CI 1.10, 1.26) and FG (OR 1.21 per SD (0.7 mmol/L) increase; 95%CI 1.04, 1.40) and 2hG (OR 1.21 per SD (0.6 mmol/L) increase; 95%CI 1.04, 1.40). Estimates were smaller when comparing PsA directly against cutaneous only psoriasis. Improving glycaemic control may reduce PsA risk, although further studies are required to confirm these findings and to compare PsA directly against cutaneous only psoriasis.

REFERENCES:

Acknowledgements: This work was supported by Versus Arthritis (grant number 21173, grant number 21754 and grant number 21755). This study provides supportive genetic evidence that impaired glycaemic control increases risk of PsA. By contrast, estimates were smaller when comparing psoriasis against controls with confidence intervals including the null. Improving glycaemic control may reduce PsA risk, although further studies are required to confirm these findings and to compare PsA directly against cutaneous only psoriasis.

Clinical aspects in Psoriatic Arthritis

---

Figure 1. Mendelian randomisation estimates of the effect of glycaemic traits on risk of psoriatic arthritis and psoriasis.

Conclusion: This study provides supportive genetic evidence that impaired glycaemic control increases risk of PsA. By contrast, estimates were smaller when comparing psoriasis against controls with confidence intervals including the null. Improving glycaemic control may reduce PsA risk, although further studies are required to confirm these findings and to compare PsA directly against cutaneous only psoriasis.
Background: Gusekumbab (GUS), a selective IL-23 inhibitor, is efficacious in treating bio-naive and TNFi-experienced active PsA patients (pts).1,2 In the COSMOS study of active PsA pts with lack of efficacy/intolerance, i.e., inadequate response (IR), to ≥2 TNFi, GUS demonstrated significantly greater response rates and mean improvements in PsA signs and symptoms vs. placebo (PBO) at Week (W) 24.3

Objectives: Evaluate baseline (BL) serum levels of pro-inflammatory biomarkers (CRP, serum amyloid A [SAA], TNFα, IFNγ, IL-6, IL-10, IL-17F, IL-17A, IL-22) and their relationship to BL disease activity, GUS treatment (tx), and clinical response in COSMOS TNFi-IR pts.

Methods: TNFi-IR pts ≥18 yrs with active PsA (≥3 swollen & ≥3 tender joint counts [SJC/TJC]) were randomized 2:1 to GUS 100 mg every 8 W (Q8W) through W44 or PBO with early escape (W16) or crossover (W24) to GUS Q8W. Samples for serum biomarker analyses, collected at W0, 4, 16, 24, and 48 from consenting pts, were compared with healthy controls (HC); independent of COSMOS TNFi-IR pts. Associations between early biomarker changes and BL disease activity, GUS tx, and clinical response at W24 were assessed.

Results: Among 285 COSMOS pts, 50/95 PBO and 100/190 GUS pts had available biomarker data. BL characteristics of the biomarker cohort were similar to the overall COSMOS population and well balanced across tx arms. At BL, levels of TNFα, IFNγ, IL-6, IL-10, IL-17A, IL-17F, and IL-22 were significantly upregulated in TNFi-IR pts vs. HC (Table 1). IL-6, CRP, and SAA levels were associated with BL joint disease severity per Disease Activity Score (DAS) 28 (CRP [≥3] in W24 with SJC [0-66]/TJC [0-68]). IL-17A and IL-17F levels were associated with BL PASI score. Through W24, significant decreases from BL levels in CRP, SAA, IL-6, IL-17A, IL-17F, and IL-22 were seen in GUS-, but not PBO-tx pts. Reductions in IL-17A, IL-17F and IL-22 with GUS were significant by W4, decreased further by W16, and were sustained through W24 and W48. In GUS-tx pts, serum levels of IL-17F (from W16) and IL-22 (from W4) were not significantly different vs. HC. At W48, reductions in these same markers were seen in PBO-tx pts who crossed over to GUS at W26/W44 (Figure 1; IL-17A, IL-17F, & IL-22 data shown). In these TNFi-IR pts, GUS-tx pts achieving ACR20 at W24 exhibited higher IL-22 and IFNγ levels at BL than nonresponders (NR). All other biomarkers evaluated were not significantly associated with ACR20 response to GUS. In the subset of pts with IGa of psoriasis assessed, BL IL-6 and SAA levels were upregulated in W24 ACR 0/1 responders (R) vs. NR in the GUS arm. ACR20 and IGA 0/1 R at W24 exhibited an earlier reduction in IL-6 expression (at W4) than did respective NR in the GUS arm. No BL biomarkers were associated with ACR50 or PASI75 responses to GUS at W24.

</table>

Data are mean (SD); *p<0.05 and fold difference >1.44, adjusted for confounding factors age & sex.

Conclusion: GUS-tx TNFi-IR pts showed response-specific associations with BL biomarkers (IL-22, IFNγ, IL-6, and SAA). GUS resulted in decreased levels of elevated CRP, SAA, IL-6, IL-17A, IL-17F, and IL-22, while no significant change was observed with PBO tx. Reductions in these biomarkers were evident as early as W4 and approximated levels seen in HC from W16 onward (W4 for IL-22), suggesting apparent normalization of effector cytokines associated with the IL-23/Th17 axis following GUS tx.

POS0309
ARE PATIENTS' AND RHEUMATOLOGISTS' PERCEPTIONS OF THE BURDEN AND TREATMENT OF PsORIATIC ARTHRITIS ALIGNED? RESULTS FROM THE UPLIFT SURVEY

P. Richter1, W. Tillett2, A. Ogdie3, A. B. Gottlieb4, S. Jardon5, S. Richter5, A. Flower5, J. Merola6, 1Hôpital Lariboisière, AP-HP, Paris, France; 2University of Bath, Department of Pharmacy & Pharmacology, Bath, United Kingdom; 3University of Pennsylvania, Rheumatology, Philadelphia, United States of America; 4Ichan School of Medicine at Mount Sinai, Dermatology, New York, United States of America; 5Amgen Inc, Medical Affairs, Thousand Oaks, United States of America; 6Brigham and Women's Hospital, Dermatology, Boston, United States of America

Background: Alignment of patient and clinician goals and perceptions of psoriatic arthritis (PsA) burden and treatment are important to improving disease management.

Objectives: To describe patient and rheumatologist perceptions on factors contributing to PsA severity, treatment goals, and attributes of ideal therapy.

Methods: Understanding Psoriatic Disease Leveraging Insights for Treatment (UPLIFT) was a multinational Web-based survey that included adults who reported a healthcare provider (HCP) diagnosis of PsA and/or psoriasis, as well as rheumatologists and dermatologists. This analysis focused on survey responses from patients with PsA and rheumatologists. Respondents ranked their top 3 contributing factors for PsA severity, treatment goals, and ideal attributes for therapy. Results were analyzed using the sum of scores.

Results: In all, 1256 patients with PsA and 450 rheumatologists completed the respective surveys between March and June 2020. An oligocarticular (≤4 joints involved) pattern of involvement was prevalent in 43.8% of patients (Table 1). Involvement of large joints (78.8%) was most common, followed by intermediate (9.3%) and small (51.8%) joints. Only half of patients reported seeing an HCP for PsA in the last year (Table 1). Patients and rheumatologists agreed that joint pain is a top factor contributing to disease severity; patients also ranked the impact on quality of life and type of symptoms as top factors whereas rheumatologists placed greater importance on the number of joints involved and joint erosion or deformity (Figure 1). Top treatment goals for patients were reducing joint pain and stiffness and stopping the progression of joint damage or erosion (Figure 1). Rheumatologists agreed that inhibiting progression of joint damage or erosion and reducing joint pain were among the top treatment goals, and they rated disease remission or low disease activity (LDA) as the most important goal (Figure 1). Rheumatologists identified consistent treatment goals for patients
regardless of degree of joint involvement (oligoarthritis vs polyarthritis). Patients and rheumatologists agreed that long-term safety and efficacy are key attributes of an ideal PsA therapy. The top attribute for patients was joint pain reduction, whereas achievement of remission or LDA was the top attribute identified by rheumatologists (Figure 1). Despite general alignment between patient and rheumatologist responses across metrics, 87.1% of patients reported they did not feel that their treatment goals matched those of their current HCP.

The N represents the total sample. The number of patients with data available may vary. *COVID-19 restrictions may have impacted a patient’s ability to have an HCP visit from March 2 to June 3.

Conclusion: In the UPLIFT survey, patients with PsA and their rheumatologists generally agreed on the top factors contributing to disease severity, treatment goals, and attributes of ideal PsA therapy. However, the majority of patients with PsA did not feel aligned with their current HCP regarding treatment goals. Development of methods for treatment goal discussion and alignment are important to promoting patient outcomes.

POS0310 DO AXIAL PSORIATIC ARTHRITIS PATIENTS MEET ASAS CLASSIFICATION CRITERIA FOR AXIAL SPONDYLOARTHRITIS?

F. Gubar1, T. Korotaeva1, E. Logina1, Y. Korsakova1, S. Glukhova2, I. V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritides and Psoriatic Arthritis, Moscow, Russian Federation; 2 I. V. A. Nasonova Research Institute of Rheumatology, Medical and Social Problems in Rheumatology, Moscow, Russian Federation

Background: There isn’t any generally accepted definition and diagnostic criteria for axial psoriatic arthritis (axPsA). According to most recent data, classification criteria for axial spondyloarthritis (axSpA) may not be applied to axPsA (1).

Objectives: To analyze, in clinical practice, whether axPsA patients (pts) meet classification criteria for axSpA and ankylosing spondylitis (AS).

Methods: 52 pts (MF=32/20), a hospital cohort, with PsA according to CASPAR criteria were observed. All pts had back pain at one time or another, which rheumatologist suspected to be axial involvement. Pts’ age 43.0 [35.0; 54.0], disease duration 3.4 yrs [0.2; 32.0]. Me BASDAI 5.3 [3.6; 7.0]; ASDAS-CPS 3.3 [2.2; 4.1]; DAPSA 36.3 [19.3; 50.5]; CRP 6.9 [0.1; 18.6] mg/L; ESR 31 [3; 99] mm/h. Enthesi- sis was found in 69.2% and dactylitis in 61.5% of pts. All pts had psoriasis with Me BSA (body surface area) of 4 [1; 8]. Me PASI (Psoriasis Area Severity Index) of 9.6 [5.6; 17.4]. Nail psoriasis was found in 38 (73.1%) pts, 40.4% of them had onycholysis. All pts were evaluated for presence of inflammatory back pain (IBP) by ASAS criteria. Pts underwent sacroiliac joint (SIJ) X-ray (pelvic radiographs), cervical and lumbar spine, hands and feet X-rays, so that 50 pts had complete sets of radiographs. Radiographic sacroilitis (rSI) was defined as bilateral grade ≥ 2 or unilateral grade ≥ 3. Pts without rSI underwent SI MRI on Philips Multiscan 1.5 T scanner. Active MRI sacroilitis (MRI-SI) was categorized using ASAS 2016 criteria. Radiographic spondylitis (rSp) was defined as ≥1 marginal/paramarginal syndesmophyte(s) of the cervical and/or lumbar spine. All radiographs and MRI results were interpreted by two experienced musculoskeletal radiologists. 45 pts underwent HLA B27 examination. Me [Q25; Q75] and Pierson-y2 tests were performed. All p<0.05 were considered to indicate statistical significance.

Results: IBP was found in 34 (66.7%) and rSI in 30 (57.7%) pts. 15 (30.0%) pts had rSI along with rSp, while in 15 (30.0%) pts rSI was without it, and 9 (18.0%) pts had rSp alone. 2 pts of the 17 examined, had MRI-SI, HLA B27 was present in 15 (33.3%) pts examined. 37 (71.2%) pts met ASAS criteria for axSpA as follows: 22 pts met the imaging arm (rSI or MRI-SI + ≥1 SpA feature), 5 pts met the clinical arm (HLA B27+ ≥ 2 other SpA features) and 10 pts met both of those. 10 (19.2%) pts didn’t meet ASAS criteria for axSpA: they had neither rSI/ MRI-SI nor HLA B27; however, 9 of them had syndesmophytes. 30 pts had rSI with 21 of them (40.4% of all pts) meeting modified New York (mNY) criteria for AS, because along with rSI, they had at least 1 of the 3 clinical criteria (IBP for > 3 months, limitation of lumbar motion in sagittal and frontal planes, limitation of chest expansion). The pts who met both CASPAR and mNY criteria, however, had typical axPsA features: 85.7% of them had polyarthritis with multiple joint erosions, 61.9% had osteology and/or juxtaarticular new bone formation, 61.9% dactylitis, 33.3% non-marginal asymmetrical syndesmophytes, 44.4% were HLA B27 negative, 43.3% didn’t have IBP: all pts developed psoriasis many years before the onset of PsA.

Conclusion: Among PsA pts with axial involvement there is an alternative phenotype group (18% of our cohort) with neither sacroilitis (rSI/MRI-SI) nor HLA B27. Such pts do not meet ASAS criteria for axSpA. The alternative phenotype is characterized by isolated spondylitis (syndesmophytes) without sacroilitis. Axial disease cannot be ruled out in PsA pts without spinal radiographs, regardless of symptoms. Pts meeting both CASPAR and mNY criteria and featuring typical axPsA symptoms cannot be diagnosed as having AS along with concomitant psoriasis, because axPsA patients with psoriasis seem to be two distinct diseases. There is an urgent need for a unified definition of axial involvement in PsA.

POS0311 FLARES IN PATIENTS WITH RECENT-ONSET PSORIATIC ARTHRITIS: PREDICTIVE MODEL BASED ON MACHINE LEARNING

R. Queiroz Silva1, D. Seoane-Mato2, A. Laiz4, E. Galindez-Agirregiokoa3, J. D. D. Cañete5, J. Gratacos-Masmitja6, X. Juanola-Roura7, J. Fiter2,1

E. Galindez-Agirregiokoa3, J. D. D. Cañete5, J. Gratacos-Masmitja6, X. Juanola-Roura7, J. Fiter2,1
Background: An important aspect in the clinical care of patients with PsA is to be able to predict the occurrence of a flare using tools and information that are readily available in daily clinical practice. This information would provide added value in disease management, yet, unfortunately, scarcely any studies provide it.

Objectives: To identify patient- and disease-related characteristics that make it possible to predict flares in recent-onset PsA.

Methods: We performed a multicenter observational prospective study (2-year follow-up, regular annual visits), promoted by the Spanish Society of Rheumatology [1]. The study population comprised patients aged ≥18 years who fulfilled the CASPAR criteria [2], with less than 2 years since the onset of symptoms. The intention at the baseline visit was to reflect the patient’s situation before disease onset, but progress was modified by the treatments prescribed in the rheumatology department. All patients gave their informed consent. The study was approved by the Clinical Research Ethics Committee of the Principality of Asturias.

Flares were defined as inflammatory episodes affecting the axial skeleton and/or peripheral joints (joints, digits or entheses) and diagnosed by a rheumatologist between the previous and the current visit. The dataset contained data for the independent variables from the baseline visit and from follow-up visit number 1. These were matched with the outcome measures from follow-up visits 1 and 2, respectively. We trained logistic regression models and a random forest–type machine learning algorithm to analyze the association between the outcome measure and the variables selected in the bivariate analysis (statistical significance was defined as p value <0.05). We used a confusion matrix to visualize the performance of the final model. This matrix shows the real class of the data items, together with the class predicted by the machine learning algorithm, and records the number of hits and misses.

Results: The sample comprised 158 patients. 14.6% were lost to follow-up. At the first follow-up visit, 37.6% of the patients who attended the clinic had age-adjusted Charlson comorbidity index and physical activity and positive for PsAID score and level of physical activity. The direction of the association was negative for flares between visits selected in this analysis were age-adjusted Charlson comorbidity index, physical activity, PsAID score, and level of physical activity. The results of the logistic regression analysis. The variables predicting flares between visits selected in this analysis were age-adjusted Charlson comorbidity index, PsAID score, number of digits with onychopathy, and level of physical activity. The direction of the association was negative for the Charlson index and physical activity and positive for PsAID score and onychopathy.

Table 1. Variables associated with flares between visits selected in the logistic regression analysis.

When the random forest machine learning algorithm was trained with these 4 variables, the order of importance (from more to less) attributed by the model was as follows: PsAID score, number of digits with onychopathy, age-adjusted Charlson comorbidity index, and level of physical activity. The percentage of hits in the confusion matrix was 78.38%.

Conclusion: PsAID score was the first variable in the predictive hierarchy generated in our model, supporting its importance in the management and follow-up of PsA patients.

POS0312 REAL-WORLD EVIDENCE ON ASSESSING PSORIATIC ARTHRITIS BY DISEASE DOMAIN: AN EVALUATION OF THE COREVITAS PSORIATIC ARTHRITIS/SPONDYLOARTHROPATHY REGISTRY

P. J. Mease1, T. Blachley2, J. O’Brien3, N. Middaugh4, G. Krilocan5, S. Sykier6, D. Collier7, O. Agee8. 1Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Rheumatology, Seattle, United States of America; 2CorEvitas, LLC, Research, Waltham, United States of America; 3AmerGen Inc., Research, Thousand Oaks, United States of America; 4University of Pennsylvania, Rheumatology, Philadelphia, United States of America

Background: Psoriatic arthritis (PsA) is a burdensome, chronic disease that can impact patient functionality and quality of life. Real-world data are limited regarding the most common disease domain combinations in patients with PsA receiving biologic disease-modifying anti-rheumatic drugs.

Objectives: The objective of this study was to describe PsA disease domain frequency, the most common disease domain combinations of PsA manifestations, and pairwise disease domain prevalence in patients initiating treatment with tumor necrosis factor inhibitors (TNFIs) or interleukin-17 (IL-17) inhibitors.

Methods: The CorEvitas PsA/Spondyloarthropathy (SpA) Registry is a prospective, observational registry for patients with PsA or SpA under the care of a rheumatologist. The current analysis included adults with PsA who initiated treatment with a TNFi (adalimumab, etanercept, certolizumab pegol, infliximab, golimumab), etanercept (ETN; independent exploratory evaluation as a subset of the TNFI group), or an IL-17 inhibitor (ixekizumab, secukinumab) from January 2013 through December 2020. Baseline disease characteristics among the total population and by therapy group were examined for 6 PsA domains, including enthesitis (ET), dactylitis (DA), peripheral arthritis (PA), nail psoriasis (NP), axial arthritis (AX), and skin disease (SD). The top 5 most common domain combinations and pairwise combination of other concomitant disease domains within each domain subpopulation are presented.

Results: Among 1005 patients initiating treatment for PsA (mean age, 52.9 years; 57% female, 90% white), the prevalence of disease domains was PA (86%), SD (82%), NP (57%), ET (38%), DA (23%), and AX (20%); these proportions were similar among the therapy groups. The frequency of high skin disease (body surface area [BSA] ≥10%) at baseline was highest in IL-17 initiators (23% vs 16% for TNFI and 9% for ETN). TNFI (40%) and ETN (48%) were more frequently observed as first-line therapy compared with IL-17 inhibitors (14%). The most common disease domain combination overall (14%) was PA, NP, and SD; frequency of the top 3 most common domain combinations were similar among therapy groups (Table 1). Overall, PA and SD were the most common concomitant disease domains observed in each PsA disease domain subpopulation (Figure 1). Results were similar by therapy group (data not shown).

THE ASSOCIATION BETWEEN BODY COMPOSITION AND PHYSICAL ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS: THE TRONDELAG HEALTH STUDY

A. A. Osman1, M. Hoff2, V. Viden3,4, 1Norwegian University of Science and Technology’s, Department of Clinical and Molecular Medicine, Trondheim, Norway; 2Norwegian University of Science and Technology’s, Department of Neuromedicine and Movement Science, Trondheim, Norway; 3St. Olav’s University Hospital, Department of Rheumatology, Trondheim, Norway; 4St. Olav’s University Hospital, Department of Immunology and Transfusion Medicine, Trondheim, Norway.

**Background:** Persons with psoriatic arthritis (PsA) have an altered body composition compared to the general population, including overweight, which may increase the risk of several comorbidities. However, the associations of physical activity (PA) with body composition among persons with PsA is not well described.

**Methods:** The study utilized data from the population-based Trøndelag Health Study (HUNT4, 2017-2019), where all inhabitants ≥ 20 years of age in northern Trøndelag were invited. Data comprised questionnaires, measurements, and blood sample analyses. Persons with PsA (n=291, CASPAR criteria) were identified from hospital case notes. The remaining participants with complete data for relevant variables (n=38 955) were used as controls.

**Results:** Patients with PsA had higher weight, body mass index, VFM and PBF than controls, and they were less physically active (Table 1). The interaction term between PsA and age was statistically significant in both models (p<0.05), showing that the difference in VFM and PBF with PsA compared to controls was relatively larger in persons < 40 years (VMF difference: 3.6kg (95% CI 1.4, 5.9kg) vs. ~1.1 kg in older age groups, PBF difference: 5.2% (1.9, 8.5%) vs. ~1.5% in older age groups).

The associations between PA and VFM or PBF were similar with and without PsA. In Model 1 (R²=0.17), moderate or high physical activity was significantly associated with lower VFM. The moderate activity group had 0.8 kg (0.7, 0.9kg, p<0.001) and the high activity group had 2.6 kg (2.5, 2.7, p<0.001) lower VFM compared to the low physical activity group. In Model 2 (R²=0.38), moderate or high physical activity was significantly associated with lower PBF. The moderate activity group had 1.4% (1.2, 1.5%, p<0.001) and the high activity group had 4.3% (4.1, 4.5%, p<0.001) lower PBF compared to the low physical activity group.

**Conclusion:** Patients with PsA had increased PBF and VFM, and moderate or high physical activity was associated with significant reductions in both endpoints. Physical activity may reduce the comorbidity burden among persons with PsA and should be a focus in clinical treatment plans.

**Rheumatology, Rheuma-Zentrum Wien-Oberlaa, Vienna, Austria;** Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Deutsches Zentrum för Immuntherapie, Erlangen, Germany; TAmiRNA GmbH, Vienna, Austria; Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Dermatology, Erlangen, Austria.

**Background:** MicroRNAs (miRNAs) are small non-coding RNAs that control gene expression. Specific miRNA signatures have been identified in numerous diseases and may serve as potential biomarkers or new drug targets. Whether certain miRNA signatures are associated with psoriatic joint disease is currently unknown.

**Objectives:** To search for circulating miRNA signatures in psoriasis patients with subclinical joint disease and in patients with psoriatic arthritis (PsA).

**Methods:** Analyses of serum miRNA were done in three groups: (1) PsA patients fulfilling CASPAR criteria (PsA), (2) healthy controls without past or present signs of musculoskeletal disease (HC) and (3) psoriasis patients with musculoskeletal pain but no signs of clinical PsA (PsO). PsO and PsA patients received a hand MRI, which was scored according to PsAMRIS method. miRNA analysis of serum samples was performed stepwise using RT-qPCR (TAmiRNA Vienna). In the discovery phase 192 miRNA assays were analyzed in 48 samples (N=16 each group). In the validation phase 17 miRNAs (Table 1) were selected and analyzed in 94 samples (N=35 PsA, N=24 PsO, N=35 HC) based on results of discovery phase and previous reports in literature. Results presented as means/SD/median (IQR), p-values are adjusted for multiple testing.

**Results:** 51 PsA patients (age: 51.3±14.4 years; 56.9% females), 40 PsO patients (51.4±11.0; 37.5%) and 50 HC (51.0±10.5; 52.9%) were assessed. Duration of psoriasis was 12(25) years in PsA and 15(22.8) years in PsO. Duration of joint disease in PsA was 1.0(4.8) year. 51% of PsA and 5% of PsO patients were on biological disease modifying drugs (bDMARDs), 49% vs. 10% on conventional DMARDs. The most frequent findings in the MRI were erosions (PsA 59.6%; PsO 40%) and synovitis (PsA 49%; PsO 10% vs. 10% on conventional DMARDs). New bone formation on radiographs was detected in 39% of PsA and 13% of PsO patients. Significantly higher frequencies of tenosynovitis and enthesitis were observed on US compared to clinical examination alone.

**Conclusion:** PsA and PsO patients show miRNA signatures different from HC. Top candidate miRNA differentially regulated in PsA and PsO have been previously reported in alteration of bone metabolism and osteoarthritis indicating the intimate association of psoriatic inflammation with bone and cartilage changes.

Diagnosis of Psoriatic Arthritis with or without integration of Ultrasound

Y. Geng1, Z. Song2, X. Zhang1, X. Deng1, Y. Wang1, Z. Zhang1, 1Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

**Background:** Although the CASPAR criteria in the diagnosis of psoriatic arthritis (PsA) have been validated, CASPAR based on physical examination (PE) is not “gold standard.” The ultrasound (US) could improve the diagnostic accuracy as compared to clinical examination alone.

**Objectives:** To evaluate the diagnostic performance of CASPAR criteria for psoriatic arthritis (PsA) with or without integration of ultrasound (US).

**Methods:** The patients with a hint of PsA were enrolled. Tender and swollen joint counts, presents of enthesis and dactylitis were collected by physical examination (PE). US was performed to evaluate peripheral joints, entheses and tendons. The additional value of US to CASPAR criteria were analysed.

**Results:** 326 consecutive patients were enrolled, with 164 PsA and 162 non-PsA. Significantly higher frequencies of tenosynovitis and enthesis on US and new bone formation on X-ray were found in PsA than non-PsA patients (56.7% vs. 13.0%; 62.2% vs. 14.2%; 62.2% vs. 8.0%; p<0.01 for all). Logistic regression analysis showed that dactylitis (OR=12.0, p<0.01), family history of PsO/ PsA (OR=3.1, p<0.05), nail involvement (OR=3.5, p=0.01), new bone formation (OR=14.8, p=0.01) and tenosynovitis on US (OR=213, p<0.01) enthesitis on US (OR=217, p<0.01) were independent risk factors for PsA. Adding US tenosynovitis and/or enthesis to CASPAR criteria showed better performance by improving the specificity (91.4% vs. 67.9%) and meanwhile keeping sensitivity (92.1% vs. 96.3%). When replacing hand X-ray by US in CASPAR criteria, the sensitivity and specificity were comparable to CASPAR criteria adding with US. The diagnostic accuracy was 82.2% for CASPAR criteria based on PE, 91.7% for CASPAR integrated with US, and 91.4% for CASPAR with US to replace X-ray.

**Conclusion:** CASPAR criteria based on US improve the diagnosis utility of PsA than CASPAR criteria based on PE. US assessment is valuable in the diagnosis of PsA.

Assessment of Synovitis on US-Guided Synovial Membrane Biopsies is Contingent on Disease Phase and Predictive of Treatment Response in Naïve to Treatment Psoriatic Arthritis

D. Bruno1,2, B. Tolusso1,2, M. Gessi3, C. DI Mario1,4, M. R. Gigante5, L. Petricca5, D. Bruno1,2, B. Tolusso1,2, M. Gessi3, C. DI Mario1,4, M. R. Gigante5, L. Petricca5

Background: Ultrasound (US)-guided minimally invasive Synovial Tissue (ST) biopsy serves as a safe and well-tolerated procedure for basic and translational research on chronic inflammatory joint disease.

Objectives: (i) to assess the diagnostic value of the Krenn score (KSS) on ST samples obtained from US-guided biopsies in a large bio-samples dataset of patients with Psoriatic Arthritis (PsA) across different disease phases; (ii) to develop a multiparametric nomogram integrating clinical and histological characteristics enabling treatment response prediction in naïve to treatment PsA.

Methods: 410 patients fulfilling the CASPAR criteria for PsA who underwent US-guided ST biopsy were enrolled. At baseline, patients were categorized based on their disease phase and treatment: n=207 naïve to DMARDs; n=101 resistant to c-DMARDs; n=48 resistant to b-DMARDs and n=54 in sustained clinical and ultrasound remission or in low disease activity (LDA) state (DAPSA ≤ 4 or among 4-14, respectively). Clinical, demographic, and immunological characteristics were recorded for each patient. All ST specimens were stained with H&E and classified by a pathologist, blinded to clinical characteristics, using the Krenn score to assess ST inflammation degree (1) implemented with the determination of lymphocytes, plasma cells, granulocytes and tissue oedema presence. Each naïve to treatment PsA was treated according to the EULAR recommendations (2) and DAPSA remission rate at 6 months was recorded.

Results: Considering the whole enrolled cohort, the distribution of KSS was significantly different among patients across the different PsA phases (ANOVA p<0.001). In particular, among the different phases, KSS was significantly higher in b-DMARDs resistant (p<0.0001) and c-DMARDs resistant (p<0.0001) compared to remission/LDA disease patients as well as naïve to treatment PsA (p<0.0001). Interestingly, regardless to the disease phase, KSS of the biopsied joint directly correlated to disease activity in terms of DAPSA (r=0.476, p<0.001) and DAS28 scores (r=0.476, p<0.001). Considering the naïve to treatment PsA cohort, patients achieving DAPSA defined-LDA/remission had, before treatment, significantly lower KSS (p<0.001), lower rate of ST plasmacells presence (p<0.001) and shorter symptoms duration (p=0.01) as compared to naïve to treatment PsA not achieving this clinical outcome. Moreover, considering distinct clinical phenotype domains, naïve to treatment PsA patients with concomitant dactylitis and skin disease were less likely to achieve DAPSA LDA/remission (p<0.001), regardless of treatment scheme. On logistic regression, at baseline, having a KSS >5 (OR: 5.30 (95%CI 2.21-12.74) p<0.001), absence of plasma cells ST infiltrate (OR: 3.87 (2.11-7.10 95%CI) p=0.001), concomitant dactylitis (OR: 2.55 (95%CI 1.24-5.25) p=0.01) and skin involvement (OR: 2.06(95%CI 1.17-3.62) p=0.01) were independent factors associated with DAPSA score-LDA/remission achievement at 6 months. Finally, a multiparametric nomogram integrating baseline clinical and histological characteristics of naïve PsA enabling to predict up to 75% of probability to achieve DAPSA remission at 6 months was developed.

Conclusion: KSS is a reliable tool for synovial assessment in PsA, being contingent on disease phases, related to disease burden and included within a treatment response predictive multiparametric nomogram in naïve PsA.

Mortality, Co-morbidity and disease burden

WORLD MORTALITY OF SPONDYLOARTHROPSIS AND INFLAMMATORY BOWEL DISEASES IN 2015 AND ITS EVOLUTION BETWEEN 2001 AND 2015

O. Fahk1, C. Pratt1,2, D. Wending1,3, F. Verhoeven1,2, Centre Hospitalier Régional Universitaire de Besançon, Rheumatology, Besançon, France; 1UFR Santé, Université de Franche-Comté, EA 4267 ‘PEPITE’; Besançon, France; 2UFR Santé, Université de Franche-Comté, EA 4266 ‘EPILAB’; Besançon, France

Background: There is little epidemiological data on mortality in spondyloarthrits (SpA).

Objectives: To determine countries’ mortality rates of ankylosing spondylitis (AS) and psoriatic arthritis (PsA), as well as chronic inflammatory bowel diseases (IBDs), which are physiologically related to SpA, and to describe their evolution between 2001 and 2015.

Methods: We used mortality data from the World Health Organisation (WHO), freely available on its website, which shows the number of deaths classified by age, sex, and cause of death coded by ICD-10. The code M45 was used for AS, L405 for PsA, K56 for Crohn’s disease (CD), and K51 for ulcerative colitis (UC). Age-standardized mortality rates (ASMR) were constructed using the 2015 WHO reference population and are expressed as deaths per million inhabitants. Temporal trend analyses of ASMR were performed between 2001 and 2015, considering only countries with up to 3 years of missing data, using joinpoint regression.

Results: In 2015, the global ASMR of AS was 0.13 (0.11-0.14), ranging from 0.02 in Japan to 2.00 in Iceland (Figure 1A). The ASMR was 0.20 (0.18-0.23) for men and 0.07 (0.06-0.09) for women (p<0.001). The trend analysis did not show any significant variation between 2001 and 2015. The ASMR in Europe (0.17 (0.15-0.20)) was significantly higher than in North America (0.12 (0.09-0.14)) (p=0.008), South America (0.09 (0.06-0.12)) (p=0.001) and Asia (0.08 (0.05-0.10)) (p=0.001).

Figure 1. 2015 ASMR by country for ankylosing spondylitis (A), psoriatic arthritis (B), Crohn’s disease (C) and ulcerative colitis (D).
For PsA, the global ASMR in 2015 was 0.04 (0.03-0.05), ranging from 0.01 in Mexico to 0.13 in Greece (Figure 1B). The ASMR was 0.06 (0.04-0.07) for men and 0.03 (0.02-0.04) for women (p=0.01). The trend analysis showed a significant increase from 2001 to 2015 with a mean annual percent change (APC) of 5.94% (p=0.02). The ASMR in Europe (0.05 (0.03-0.06)) was significantly higher than in South America (0.02 (0.00-0.03)) (p=0.02).

For CD, the global ASMR in 2015 was 0.86 (0.82-0.89), ranging from 0.02 in Thailand to 5.25 in Luxembourg (Figure 1C). The ASMR was 0.41 (0.38-0.43) for men and 0.38 (0.36-0.41) for women (p=0.17). The trend analysis showed a significant decrease from 2001 to 2015 with a mean APC of -0.82% (p=0.049). The ASMR in Europe (1.12 (1.05-1.19)) was significantly lower than in North America (1.31 (1.21-1.41)) (p=0.001), but significantly higher than in Latin America (0.57 (0.51-0.64)) (p<0.0001) and Asia (0.27 (0.23-0.32)) (p<0.0001).

For UC, the global ASMR in 2015 was 0.76 (0.73-0.79), ranging from 0.03 in Thailand to 5.48 in Saint Lucia (Figure 1D). The ASMR was 0.37 (0.35-0.39) for men and 0.23 (0.21-0.24) for women (p>0.0001). The trend analysis showed a significant decrease from 2001 to 2015 with a mean APC of -12.9% (p<0.001). The ASMR in Europe (0.64 (0.57-0.71)) (p<0.0001), Africa (0.57 (0.41-0.72)) (p<0.0001), South America (0.84 (0.76-0.91)) (p=0.003), Asia (0.47 (0.93-1.06)) and Oceania (0.58 (0.38-0.79)) (p=0.003).

Conclusion: ASMR for IBD are higher than those for SpA and are decreasing over time, in contrast to SpA where they remain essentially stable. There are geographical disparities which must be interpreted with caution due to the declarative nature of the data.

DISEASE BURDEN OF PRIMARY SJÖGRENS SYNDROME: A RETROSPECTIVE UNITED STATES CLAIMS DATABASE STUDY

L. Kalouche-Khalli1, R. Gandhi2, L. Hao3, E. Smolikina4, F. Schumacher5, 6

Sanofi Genzyme, MS Global Medical Affairs, Paris, France; 2Sanofi Genzyme, MS Medical Affairs, Cambridge, United States of America; 3Sanofi GenMed, RWE, Bridgewater, United States of America; 4Sanofi, Global HEVA Neuro Immunology, Amsterdam, Netherlands; 5Sanofi Translational Medicine and Clinical Pharmacy, Frankfurt, Germany

Background: Primary Sjögren’s syndrome (pSS) is a chronic and complex systemic autoimmune disease, primarily characterised by inflammation and progressive destruction of the exocrine glands (ie, autoimmune epithelitis) [1].

Objectives: We evaluated disease progression, treatment patterns, mortality, and healthcare resource utilization (HCRU) of pSS patients in the United States (US) to understand the real-world experiences of patients with pSS.

Methods: This retrospective cohort study utilised data from US Optum Clinfor matics claims database claims between 01 May 2000 and 31 December 2020. The study included pSS patient cohort and general population cohort, matched (1:1) on age, sex, and index date. Baseline period of 365 days prior to the index date was used for assessment of baseline comorbidities. Descriptive statistics were used to describe baseline characteristics, HCRU, and treatment pattern while multivariable models were used to assess hazard ratios (HRs) and risk factors.

Results: Overall, 23,168 patients with pSS (ICD-9 710.2 Sicca syndrome and ICD-10 M35.0 Sjögren Syndrome and excluding patients with Rheumatoid arthritis [RA], Systemic sclerosis [SS] and Systemic lupus erythematosus [SLE] diagnoses codes) were included in the cohort (mean SD age: 61.5 [15.3] years; females: 85%). At baseline, 79.4% and 8.2% of pSS patients had systemic complications and organ-specific autoimmune comorbidities, respectively. In a subset of the cohort including patients with at least 5 years of follow-up, by the end of 5 years 96.6% and 16.5% of patients developed systemic complications and organ-specific autoimmune comorbidities, respectively (Table 1). The most frequently occurring organ-specific autoimmune comorbidities over the 5-year follow-up included Graves disease (5.4%), Hashimoto disease (3.7%), and discoid/subacute cutaneous lupus erythematosus (3.5%). Mortality was reported in 7.4% of the patients during 5-year follow-up. Risk factors associated with higher mortality included systemic complications in renal (HR [95% CI]: 2.29 [2.08–2.52]), cardiovascualr (HR [95% CI]: 2.42 [2.19–2.67]), lungs (HR [95% CI]: 3.41 [3.41–4.09]) and haematological domains (HR [95% CI]: 2.83 [2.56–3.13]), non-Hodgkin’s lymphoma (HR [95% CI]: 2.58 [2.12–3.14]), and primary biliary cirrhosis (HR [95% CI]: 2.17 [1.60–2.96]). Corticosteroids (28.2%), hydroxychloroquine (15.7%), and cyclosporine (10.9%) were most frequently used medications. During the year following the first pSS diagnosis, defined as the first claim with the Sjögren Syndrome ICD code (index date), the mean all-cause healthcare costs have increased by 27% from $21,634 to $27,526 per patient per year.

**EPIDEMIOLOGY AND HEALTHCARE RESOURCE UTILIZATION OF PATIENTS WITH EGPA IN THE UNITED KINGDOM**

J. Hwee, 1 O. Fu2, 1 H. Harper3, 1 K. Niranrathakumar2, 3 R. Goel3, 1 R. Jakes4, 1 GSK, Value Evidence Outcomes, Mississauga, Canada; 2 GSK, Value Evidence Outcomes, Collegeville, United States of America; 3 University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom; 4 GSK, Epidemiology, London, United Kingdom

Background:  Eosinophilic granulomatosis with polyangiitis (EGPA) is characterized by eosinophilic inflammation of small with or without medium arteries. EGPA is a rare disease with varying prevalence and incidence rates globally. To date, limited information is available on the prevalence, incidence and burden of disease in the United Kingdom (UK).

Objectives:  The objectives were to estimate the prevalence and incidence of EGPA, and to describe the healthcare resource utilization (HCRU) among patients with EGPA in the UK.

Methods:  This retrospective database study used the UK-based Clinical Practice Research Datalink (CPRD)-AURUM database linked to the Hospital Episode Statistics (HES). Prevalence was estimated from 2005 to 2019, and incidence was estimated from 2006 to 2019. HCRU was assessed in the 12-months following the first recorded diagnosis of EGPA (index date), and included hospitalizations, emergency room visits, procedures, outpatient specialist visits, primary care visits, and oral corticosteroid use.

Results:  764 people were identified with EGPA in the UK. The prevalence of EGPA, reported in the database, increased from 22.7 to 45.6 per 1,000,000 persons from 2005 to 2019 (Figure 1), whereas the incidence of EGPA from 2006 to 2019 ranged from 2.28 to 4.00 per 1,000,000 person-years. 377 patients with EGPA were successfully linked to the CPRD-HES database. Patient characteristics were as follows: mean age (SD) was 57 years (14.2); 49% were male; 81% had asthma; and 11% had peripheral neuropathy prior to the index date. For patients with EGPA, 19% had an EGPA-related hospitalization and 50% had any-cause hospitalization within 1 year of the index date (Table 1). The mean length of stay was, 18 days and 16 days for EGPA-related and any-cause hospitalizations, respectively. 52% of patients with EGPA had undergone a medical procedure, 89% of patients with EGPA had an outpatient visit to a specialist. Almost all patients with EGPA visited a general practitioner within 1 year of their EGPA diagnosis (97%) and averaged 16.0 visits in 1 year. A significant proportion of the EGPA population were prescribed OCS; most EGPA patients had a prescription in the 0–3 months after the index date (64%), and patients on average had a prescription for OCS for 6 out of the 12 months after the index date.

A&E: Accident and Emergency; EGPA, eosinophilic granulomatosis with polyangiitis; HCRU, healthcare resource utilization.

Conclusion:  The prevalence of EGPA increased over the study period in the UK, and the data show significant HCRU within 1 year of the first recorded diagnosis of EGPA. Almost all of the patients with EGPA were found to frequently visit the primary care physician and seek specialist care, and almost half required hospitalization. Funding:  GSK [207888]

**CO-MORBIDITY IN POLYMYALGIA RHEUMATICA**

M. Yates1, 2, A. Ittkihar Talib1, C. Aldus2, J. Brown3, 4, A. Macgregor1, 2, 1University of East Anglia, Centre for Epidemiology, Norwich, United Kingdom; 2Nortis and Norwich University Hospital, Rheumatology, Norwich, United Kingdom; 3Prescribing Services Limited, Eclipse, Buxton, United Kingdom; 4Litcham Medical Practice, General Practice, Litcham, United Kingdom

Background:  Polymyalgia rheumatica (PMR) is the most common autoimmune musculoskeletal condition in the developed world, with UK prevalence of 1.7% in those aged older than 55 years. Current guidelines recommend glucocorticoid treatment for one to two years. Since PMR affects older individuals and is associated with prolonged treatment with glucocorticoids, patients are at risk of developing or worsening co-morbidity.

Objectives:  This national study aimed to establish the prevalence of PMR from routinely recorded administrative care records from community-based primary care practices; secondly to calculate the most common comorbidities and their relative risk amongst those diagnosed with PMR.

Methods:  The ECLIPSE database covers over 230 patients across 2400 general practices in England and provides insights for enhanced clinical pathway management and to support patient safety in primary care. Routinely recorded diagnoses from primary care data are updated daily, along with administrative prescribing data. Using standardised nationally agreed disease coding frameworks, all diagnoses of PMR were retrieved from the live patient population of 23.3m individuals registered with general practices across England. Comorbidity was recorded similarly. Diagnoses of PMR were categorised in 12-month bands since their date of diagnosis to examine the rates of prednisolone prescription by time since diagnosis.

Results:  Amongst the 23.3 million patient care records there were 146,252 diagnoses of PMR, resulting in a prevalence of 2.2% for those aged older than 55 years. The average age of those with PMR was 77.5 years. There were between 9863 to 11036 diagnoses of PMR made each year over the past five years. The proportion of those receiving prednisolone were highest amongst those most recently diagnosed: 76.4% for those in the last year; 48.4% for those diagnosed between a year and two years ago; 33.0% for those diagnosed between two to three years ago; 28.8% for those diagnosed between three to four years ago, and 24.9% for those diagnosed between four to five years ago. On average each patient with PMR had 3.5 co-morbid conditions and was prescribed 5.4 different medications. The top ten co-morbid conditions were, in rank order: hypertension (53.6%), osteoarthritis (48.6%), anxiety and depression (275%), chronic kidney...
CARDIOVASCULAR RISK FACTORS AND RISK OF GIANT CELL ARTERITIS AND/OR POLYMyalGIA RHEUMATICA: RESULTS FROM THE FRENCH E3N COHORT STUDY

F. Barrière, C. Macdonald, S. Asclier, F. Artau, X. Mariette, M. C. Boutron-Ruault, Y. Nguyen, R. Serot, Université Paris-Saclay; UVSQ, Inserm, Institut Gustave Roussy; Exposome and Heredity Team, CESP, Villejuif, France; Centre Hospitalier Régional d’Orléans, Rheumatology, Orléans, France; Hôpital Lariboisière AP-HP, Rheumatology, Paris, France; Université Paris-Saclay; AP-HP, Hôpital Bicêtre, Rheumatology, Le Kremlin Bicêtre, France; Université Paris-Saclay, France, AP-HP, Hôpital Bicêtre, National Reference Center for Rare Systemic Autoimmune Diseases, INSERM UMR1184, Le Kremlin Bicêtre, France; AP-HP Nord, Hôpital Beaujon, Université de Paris, Internal Medicine, Clichy, France.

Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are two associated inflammatory diseases with incompletely known common pathophysiological mechanism. Cardiovascular (CV) risk factors have been thought to play a role in the underlying chronic vascular inflammation involved in GCA and PMR pathophysiology. However, available data on CV risk factors are conflicting.

Objectives: To investigate the association between CV risk factors and the risk of GCA and/or PMR in a large prospective cohort of French women.

Methods: The E3N cohort study (Étude Épidémiologique auprès des femmes de la Mutuelle générale de l’Education Nationale) is a French prospective cohort including 98,995 French women born between 1925 and 1950, recruited in 1990. They completed biennial mailed questionnaires to update their health-related information. A validation study based on the use of a specific GCA/PMR questionnaire and medication reimbursement database was conducted prior to this study. The history of CV risk factors (hypertension, type 2 diabetes, dyslipidemia, and active smoking status and family history of cardiovascular disease) was self-reported at each questionnaire. Hazard ratios (HRs) and their 95% confidence intervals (95%CIs) for incident GCA and/or PMR were estimated by Cox proportional hazards regression models with age as the time scale. Multi-adjusted intervals (95% CIs) for incident GCA and/or PMR were estimated by Cox proportional hazards regression models with age as the time scale.

Results: The overall population included 79,804 women, during a total follow-up of 1,899,742 person-years. Among them, 399 incident GCA and/or PMR cases were identified (incidence 31/100,000 person-years): 282 GPMR alone, 112 GCA cases, and 5 patients who could not be classified. Incident GCA/PMR cases were diagnosed after a mean of 17.9 (± 5.2) years after recruitment. Mean age at diagnosis was 69 (± 7.2) years. Type 2 diabetes was inversely associated with the risk of incident GCA/PMR in age-adjusted and multivariable models (HR 0.41; 95%CI 0.2–0.9) in multivariate model. Other CV risk factors such as hypertension, smoking status, dyslipidemia, familial history of cardiovascular events were not associated with incident GCA/PMR (Table 1). The inverse association remained statistically significant when studying separately the risk of incident PMR (HR 0.3; 95%CI 0.09–0.91) but no longer with incident GCA (HR 0.5; 95%CI 0.1–2.0), probably due to a reduced statistical power.

Conclusion: Type 2 diabetes was associated with a decreased risk of subsequent GCA/PMR development. Further research should be carried out to determine potential mechanisms, and especially to analyze the respective role of diabetes itself and its treatments.

Acknowledgements: The authors are indebted to all participants for their continued participation. The authors would like to thank Pascale Gerbouin-Rerolle, Mariam Alyanakiyan, Sofiane Harizi and Roselyn Rima Gomes for their help on data management. The present work was performed using data from the Inserrm E3N cohort and support from the MGEN, Gustave Roussy, and the Ligue contre le Cancer for setting up and maintaining the cohort. The cohort was supported by a state grant ANR-10-COHO-0006 from the Agence Nationale de la Recherche within the Invesettsement dAvenir program. The present work was conducted thanks to a research grant from the Agence Régionale de Santé – Île de France. lementsed to declare.

M1: Adjusted for age and educational level educational level (< high school, up to 2 years of university, > 3 years of university). M2: M1+ smoking status, body mass index(kg/m2), hypertension, diabetes, dyslipidemia
CRP and ESR levels and drugs used were analyzed to identify the risk of having MACE in IA patients.

Results: A total of 17,732 (12,505 RA patients, 1,789 PsA patients and 3,893 AS patients) patients with IA were recruited. After a mean follow-up of 8.7 ± 3.1 years, 1,069 (6.0%) patients developed a first MACE. At baseline, the MACE group was older (68.12 vs 53.15, p < 0.001), had more traditional cardiovascular risk factors, higher levels of CRP (2.7 ± 1.5 vs 1.7 ± 1.3, p < 0.001) and ESR (57.8 ± 32.4 vs 42.5 ± 29.2, p < 0.001), and less exposure to biologic DMARDs (bDMARDs) (10% vs 3%, p < 0.001) and non-selective NSAIDs (nsNSAIDs) (63.4% vs 71.1%, p < 0.001). After adjusting for age, sex, baseline cardiovascular comorbidities using multivariable Cox regression analysis, IA patients with higher inflammatory burden (as reflected by the time-varying CRP [hazard ratio (HR) 1.11, 95% confidence interval (CI) 1.10–1.12, p < 0.001]) and ESR levels (HR 1.02, 95% CI 1.01–1.01, p < 0.001) and the use of steroid (HR 1.79–1.88) were independently associated with a higher risk of developing MACE (Table 1). In contrast, exposure to nsNSAIDs had a protective effect against MACE (HR 0.76, 95% CI 0.66–0.89, p < 0.001), while bDMARDs were not associated with MACE.

Explanation: Increased inflammatory burden as reflected by elevated ESR and CRP level over time, and increased exposure to steroid were independently associated with increased risk of MACE, while the risk was significantly reduced with non-selective NSAIDs in IA patients.

Background: Cardiovascular diseases (CVDs) are among the most common comorbidities in rheumatic diseases, causing also increased risk of MACE [1]. However, there is limited data on how the risk of CV comorbidities varies between different rheumatic diseases. Objectives: The aim of our study was to estimate the risk of certain CV comorbidities across rheumatic diseases. Methods: The ongoing FinGen project links nationwide healthcare register data with genome data. The study (data freeze 7) included 321,302 individuals and, from this group, we identified patients with seropositive (N=4293) and seronegative (N=1733) rheumatoid arthritis (RA), ankylosing spondylitis (AS, N=1247), psoriatic arthritis (PsA, N=1235), systemic lupus erythematosus (SLE, N=386), primary Sjögren’s syndrome (pSS, N=557) and gout (N=2178). Each patient was matched based on age, sex and municipality of residence with twenty individuals without any rheumatic conditions. The CV comorbidities studied were any CV disease (CVD), major coronary heart disease event (myocardial infarction and/or revascularization; CHD), ischemic stroke, atrial fibrillation and flutter (AF), deep vein thrombosis of lower extremities (DVT) and pulmonary embolism (PE), chronic heart failure (CHF) and valvular heart disease excluding rheumatic fever (VHD). From the prevalence of each CV disease among rheumatic disease cohorts, we calculated the risk ratio (RR) for each CV disease by comparing the prevalence of these diseases between rheumatic diseases and controls.

Results: The average age at the time of diagnosis ranged from 39.6 to 64.4 years, and the average duration of follow-up varied from 9 to 19.5 years in different rheumatic diseases. The risk for any CVD was elevated in all rheumatic disease cohorts with RR varying from 1.14 in seropositive RA to 1.65 in SLE. SLE patients carried the highest relative risk for CV comorbidities, demonstrating over 2.5-fold risk for DVT/PE (RR 3.57), stroke (RR 2.57), CHF (RR 2.64) and VHD (RR 2.98). At least two-fold risk compared to controls was identified for AF (RR 2.03), DVT/PE (RR 2.44) and CHF (RR 3.03) in patients with gout, for DVT/PE (RR 2.15) and CHF (RR 2.0) in patients with pSS, and for DVT/PE (RR 2.03) in patients with PsA. Seropositive and seronegative RA demonstrated similar CV risk profiles. In patients with seropositive or seronegative RA, PsA, pSS or SLE, DVT/PE demonstrated the highest RR's among various CV comorbidities.

Conclusion: The risk of CV comorbidities is increased in all studied rheumatic diseases, with the largest effects observed in patients with SLE and gout. Among CV comorbidities, DVT/PE displayed the largest effect sizes in several rheumatic diseases. The current results further strengthen the importance of evaluating and treating risk factors for CV comorbidities across rheumatic diseases, focusing also to the excess risk for thromboses.

Disclosure of Interests: None declared.
in waves 2–8 and knee pain in the same or previous wave of diagnosis were defined as having kOA (baseline). Participants with at least one body mass index (BMI) measurement and one follow-up assessment were included. Underweight/normal weight, overweight and obesity were defined using BMI <25 kg/m², 25–30 kg/m² and ≥30 kg/m², respectively. Education, occupation (current or last occupation if retired), wealth quintiles (all individual-based) and index of multiple deprivation quintiles (area-based) were used as SEP indicators. Outcome was the first self-reported kJRS (left or right knee) in waves 3–9. Cox proportional hazards models were used to investigate the associations of obesity and SEP with kJRS, controlling for baseline covariates. Person year follow up was calculated from baseline to either a) date of self-reported kJRS, b) loss to follow-up, c) end of follow-up (wave 9).

Results: The analysis sample included 1499 people who reported kOA and had ≥1 BMI measure (62.3% female; mean age 66.5y (SD 9.4); 96% white; 47% obese). Number of person-years included in the analysis was 8427. Over a mean follow-up of 4.7 years (SD 2.8), 144 (9.8%) reported having kJRS. Obese kOA patients were more likely to report kJRS than non-obese patients (adjHR 1.89 (95% CI 1.33, 2.68)), independent of age, gender, SEP, cardiovascular disease (self-reported) and HbA1c values (measured from collected blood samples). Education and occupation were not associated with kJRS. However, those living in the most deprived areas and with the least amount of wealth were less likely to undergo kJRS compared with the least deprived and wealthiest (HRs adjusted for age and gender 0.37 (95% CI 0.19, 0.73) and 0.55 (95% CI 0.33, 0.93), respectively). There was no evidence of interactions between obesity and SEP indicators.

Conclusion: Obesity increased the likelihood of undergoing kJRS in kOA patients. Therefore, reducing obesity in kOA patients may help to reduce the need for kJRS. Area-deprivation and lower wealth were associated with lower likelihood of kJRS. Taken together with findings from other studies which report associations between lower SEP and worse OA symptoms, our results suggest that there may be social inequalities in the provision of kJRS in England.

Table 1. The relationships between obesity at baseline and rates of knee joint replacement surgery over a mean of 4.7 (SD 2.8) years in follow-up in those with knee OA at baseline in the English Longitudinal Study of Ageing

New data on pathophysiology of spondyloarthritis including psoriatic arthritis

POS0326

THE TRANSCRIPTOMIC LANDSCAPE OF ACTIVE PSORIATIC ARTHRITIS: ACTIVATED INNATE IMMUNITY, EXTRACELLULAR MATRIX (ECM) TURNOVER, ABERRANT METABOLISM AND HEMOPOIETIC CELL - SKIN CROSSTALK.

A. Grivas1,2, M. Grigoriou1, G. Sentis2, A. Filia3, P. Katsimp1, V. Verginis3, B. Bournas2, National and Kapodistrian University of Athens, 4th Department of Internal Medicine, Athens, Greece; 1Biomedical Research Foundation of the Academy of Athens (BRFAA), Laboratory of Autoimmunity and Inflammation, Athens, Greece; 2Medical School, University of Crete, Heraklion, Greece

Laboratory of Immune Regulation and Tolerance, Division of Basic Sciences, Heraklion, Greece

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease whereby activated T lymphocytes and myeloid cells interact with tissue-resident cells in the skin and joints. Gene expression studies, mainly based on the microarray platforms, have provided an initial glimpse into disease pathogenesis highlighting, among others, the role of the TNFα and IL17 cytokine axis. Yet, the transcriptomic landscape of PsA remains largely unexplored, and the specific contribution of skin fibroblasts to disease pathogenesis remains elusive.

Objectives: To comprehensively characterize the gene expression profile in PsA, specifically in the blood and skin fibroblasts through next-generation RNA sequencing.

Methods: Peripheral blood (PB) was collected from PsA patients (n=30) after informed consent. Healthy individuals (HC) and patients with rheumatoid arthritis (RA) were used as healthy and disease controls (n=10/group) respectively. Psoriatic skin biopsies were obtained from a subset of three PsA patients and three HC. All PsA patients fulfilled the CASPAR criteria and displayed peripheral polyarthritis of moderate-to-high disease activity. Patient’s clinical and laboratory data were recorded at the time of sampling. Disease activity in PsA and RA was assessed using the Disease Activity Index for Psoriatic arthritis (DAPSA) and the Disease Activity Score-28 (DAS28), respectively. RNA from PB and skin fibroblasts was extracted. RNA libraries were prepared and sequenced. EdgeR package was used to call differentially expressed genes (DEGs). Statistical significance was set at p-value<0.05 and fold-change |FC| >1.5. Functional enrichment analysis and weighted gene co-expression network analysis (WGCNA) was implemented. Inference and analysis of blood immune cells-skin fibroblasts communication were performed with CellChat.

Results: 8 males and 22 female patients with PsA were included with median age 49 years old and median disease duration 4 years. The median DAPSA score was 44.3 and the median DAS28 score was 5.5 for RA patients, suggesting high disease activity in both groups. We found 46 DEGs in PsA versus HC blood (303 up- and 163 down-regulated). DEGs were significantly enriched in biological pathways related to immunity (i.e. inflammatory response, TNFα signaling via NFkB, IFNa & IFNγ response, complement, IL2 signaling), metabolism (i.e. oxidative phosphorylation, adipogenesis, fatty acid metabolism) and other signaling cascades of pathophysiologic relevance (i.e. WNTb catenin signaling, TGFβ signaling, MTORC1 signaling). WGCNA in blood revealed four gene modules containing highly correlated genes. These modules were enriched in myeloid leukocyte mediated immunity, neutrophil-mediated immunity, ECM and collagen metabolism, TGFβ and Pdgf signaling. Next, we characterized the ‘PsA specific activity signature’, taking the intersection of DEGs in PsA vs. HC and PsA vs. RA, which resulted in 67 DEGs enriched in response to TGF and Pdgf, ECM organization and degradation. CellChat analysis identified a higher number of interactions between blood immune cells and skin fibroblasts and increased strength of interactions in PsA compared to healthy state. Aberrant interactions between blood and skin fibroblasts in PsA included, among others, ligand-receptor pairs of the WNT, Notch, and GDF11 signaling pathways.

Conclusion: Our findings confirm the presence of an IFNγ signature and complement activation in PsA. The increased cardiometabolic burden and enhanced bone remodeling are reflected by the presence of pathways related to aberrant metabolism and ECM metabolism, respectively. The myeloid cell signature in active disease supports the emerging role of monocytes/macrophages in driving inflammation in PsA, while the aberrant blood-skin fibroblast interactions suggest a novel role for these resident cells in disease pathophysiology.

IRISIN: A NEW MARKER OF SUBCLINICAL ATHEROSCLEROSIS, CARDIOVASCULAR RISK AND DISEASE ACTIVITY IN AXIAL SPONDYLOARTHROPATHY.

S. Remuzgo-Martinez1, J. Rueda-Gotor1, V. Putilo-Cueto1, R. López-Mejías1, A. Corrales1, L. Lera-Gómez1, R. Pérez-Fernández1, V. Portilla1, I. Gonzalez-Mazon1, R. Blanco1, R. Expósito1, C. Mata2, J. Llorca1, V. Hernández-Hernández1, C. Rodríguez-Lozano1, N. Barbarroja Puerto1.
Background: Axial spondyloarthritis (axSpA) is an inflammatory disease with detrimental effects on the health status of the individuals affected by this condition. axSpA patients also exhibit high cardiovascular (CV) risk, mainly due to accelerated atherosclerosis [2]. Interestingly, the adipokine irisin was described to play a beneficial role in several physiological and pathophysiological processes such as inflammation, angiogenesis, oxidative stress, as well as lipid and bone metabolism [3]. However, studies on the role of irisin in CV risk in the setting of axSpA or in the pathogenesis of axSpA are limited [4].

Objectives: In this study we evaluated the role of irisin as a genetic and serological biomarker of subclinical atherosclerosis and CV risk in a large cohort of patients with axSpA. We also assessed its role as a marker of axSpA susceptibility and severity.

Methods: 725 patients who fulfilled the Assessment of SpondyloArthritis international Society classification criteria for axSpA were included in this study [5]. In these patients, the presence of subclinical atherosclerosis (plaques and/or abnormal carotid intima-media thickness values) was assessed by carotid ultrasound. Four irisin polymorphisms (rs16835198 G/T, rs3480 A/G, rs726344 G/A and rs1570569 G/T) were genotyped by TaqMan methods in all the patients and in 656 age, sex and ethnically-matched healthy controls. Additionally, serum irisin levels were determined by ELISA in all the patients. All analyses were performed using STATA v.11.1 statistical software, adjusting for potential confounding factors. The strength of associations is indicated as odds ratios (OR) [95% confidence intervals].

Results: Low levels of serum irisin were linked to the presence of plaques (p=0.002) and with atherogenic index values indicative of an adverse lipid profile (p=0.01). The minor alleles of rs3480 (G) and rs1570569 (T) were associated with higher values of Ankylosing Spondylitis Disease Activity Score (ASDAS) in axSpA patients (p=0.01 in both cases). In this line, the frequency of the minor allele of rs1570569 (T) was higher in patients with ASDAS values ≥2.1 (indicative of high disease activity) (OR: 1.46 [1.08-1.97], p=0.01), while the minor allele of rs16835198 (T) was less frequent in this group of patients (OR: 0.73 [0.57-0.92], p=0.01).

Conclusion: Low serum irisin levels could be indicators of the presence of subclinical atherosclerosis, high CV risk and more severe disease in axSpA patients. In addition, irisin may also constitute a genetic biomarker of disease activity in axSpA.

between JAK inhibition and FLS function improvement at synovial level is not fully understood.

**Objectives:** To evaluate the effect of tofacitinib on spontaneous autophagic activity of PsA FLS, and to confirm its effect on anti-inflammatory and anti-invasive properties of PsA FLS and synovial explants.

**Methods:** This is an in vitro study. Patients with active PsA underwent ultrasound-guided synovial biopsy. Histological evaluation was performed according to Krenn’s synovitis score. FLS, PBMCs and synovial explants cultures were set up, and cells were treated in vitro with tofacitinib 1 µM or vehicle control for 24h. Protein levels in cellular homogenates were analysed by western blot for relevant autophagy markers. Autophagy was also studied by fluorescence microscopy using GFP-LC3. Chemokinases/cytokines levels into culture supernatants were quantified by ELISA. Migration assays were used to investigate the effect of tofacitinib on invasive properties of FLS. Differences were determined adopting the non-parametric Wilcoxon signed rank test.

**Results:** 16 patients with moderately active PsA were enrolled (Table 1). Mean (SD) Krenn’s synovitis score was 4.4, (1.9). Tofacitinib significantly increased LC3-II and ATG7 levels in PsA FLS compared to vehicle control, while p62 levels were not significantly affected, suggesting an increase in spontaneous autophagy activity, confirmed by LCS-autophagic vesicles count (Figure 1). No effect was highlighted in PBMCs and synovial explants cultures. Tofacitinib significantly reduced migration properties of PsA FLS, as well as MCP-1 and IL-6 release into FLS and synovial explants cultures supernatants.

**Conclusion:** The induction of autophagy by tofacitinib might permit a better functioning of PsA FLS, with a coherent reduction in pro-inflammatory and pro-inflammatory properties. This may contribute to the rationale for tofacitinib use in PsA management.

**REFERENCES:**
Conclusion: a global DNA hypermethylation was observed in patients with axSpA, both in T CD4 lymphocytes and monocytes. These modifications involved both the radiographic and non radiographic forms. These results were weakly correlated with disease activity and only in monocytes. Collectively, these changes in DNA methylation could alter recruitment of methyl binding proteins (MBP) that regulate chromatin structure and/or impair binding of transcription factors, resulting in down regulation of gene expression relevant to the pathogenesis of axSpA. We currently evaluated the level of expression of DNA methyltransferase (DNMT) and MBP proteins and specific DNA methylation status of the promoters of gene involved in inflammation such as TNFa.

Differences in gut microbiota associated with lymphocyte subsets, cytokines and disease activity in ankylosing spondylitis

Z. Song1,2,3, S. X. Zhang1,2,3, T. Cheng1,2,3, R. Zhao1,2,3, J. Qiao1,2,3, S. Song1,2,3, Y. Li1,3, X. Li1,2,3, C. Wang1,2,3, 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 3Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China

Background: Ankylosing spondylitis (AS), a common chronic inflammatory disease, is a prototype of spondyloarthritis affecting sacroiliac joints and spine with or without peripheral arthritis and other systemic symptoms [1]. Environmental factors, especially microorganisms have been suggested to implicate with AS pathogenesis [2].

Objectives: Utilizing 16S rRNA genes sequencing on the feces of untreated AS patients and healthy controls (HCs), our study aimed to provide an in-depth understanding of AS gut microbiota and identifying a feasible diagnostic strategy for AS.

Methods: Fecal samples were collected from 62 AS patients and 62 age-and-gender- matched HCs. Microbial genome was extracted from approximately 250mg fresh fecal samples from all participants using QIAamp PowerFecal DNA Kit (Qiaigen). The V3-V4 variable regions of bacterial 16S rRNA genes were sequenced with the Illumina MiSeq PE300 system. QiIME2 based pipeline was used to process the raw sequence data. Alpha and beta diversities were assessed using result from QiIME2, and comparisons of gut microbiome profile was performed using linear discriminant analysis (LDA) effect size (LEfSe) to examine differences between AS and HCs. R (version 4.0.1) was used for comparative statistics, and pearson’s correlation was used to assess the correlations between the relative abundances of bacterial genera and clinical parameters; correlations with p < 0.05 were considered significant.

Results: AS for alpha-diversity, ACE and Chao1 indices were lower in AS compared with those HCs (Figure 1A, p < 0.05), though no significant differences were observed in Shannon and Simpson index. Bray curits distance-based beta-diversity analysis revealed significant differences in the microbial community between AS and HCs (Figure 1B, p = 0.003, ANOSIM). Fecal microbial communities in AS differed significantly from those in HCs, driven by higher abundances of Escherichia-Shigella, Turicibacter, Enterococcus, et al. and a lower abundance of Agathobacter, Roseburia, Eubacterium_eligens_group, et al (Figure 1C, p < 0.05). There was a significant positive correlation between ESR and Klebsiella, Butyricicoccus, Roseburia, CRP and Faecalibacterium, Muribaculaceae, ASDAS-ESR score and Faecalibacterium, Ruminococcus, total lymphocyte cells and Agathobacter, Ruminococcus, T cell and Agathobacter, CD4+ T cell and Agathobacter, B cell and Agathobacter, Streptococcus, Th1 and Prevotella, CAG–352, Th2 and Agathobacter, Th17 and Prevotella, Agathobacter, IL-2 and Agathobacter, IL-4 and Agathobacter, IL-6 and Lachnospiraceae_ UCG–004, Muribaculaceae, IL-17 and Eubacterium_hallii_group, IFNgama and Phascolarctobacterium. There were negative correlations between total lymphocytes and Escherichia–Shigella, CD4+ T cell and Enterobacteriaceae, Th2 cell and Escherichia–Shigella, IL-10 and CAG–352, Ruminococcus (Figure 2, p < 0.05).

Figure 1. Feature of gut microbiota in AS patients and HCs. (A) Alpha-diversity assessed by richness (Chao1, ACE) and diversity (Shannon, Simpson). Median estimates compared across cohorts. (B) PCoA plot based on the Bray curits distance of gut microbiota samples from AS patients vs. HC group (p = 0.003, ANOSIM). (C) Panel demonstrated the average relative abundance of different genus in AS and HCs. (D) Distribution of gut microbiota at genus level.

Correlations between the relative abundance of significantly different bacteria and clinical variables. *p<0.05, **p < 0.01, ***p <0.001, ****p < 0.0001.

Conclusion: Human gut microbiome in patients with AS differed from that of the HCs. Characteristics of bacteria communities were associated with disease activity.

Disclosure of Interests: None declared

Background: Enthesis or inflammation of the tendon/ligament anchorage points is the cardinal lesion in spondyloarthritis (SpA)[1]. Several key mediators have been shown to have a role in SpA including TNFα, IL-23, IL-17A and IL-17F [1]. There is a need for new therapeutic agents to treat SpA as current therapeutics fail to adequately target all its manifestations. Janus kinase (JAK) inhibitors have shown promise as disease modifying drugs and by targeting signaling components shared amongst several inflammatory pathways may be advantageous in treating inflammatory diseases with complex overlapping pathologic mechanisms, as seen in SpA[2]. Upadacitinib is an oral selective JAK inhibitor (JAK1 over JAK2/3) which in phase II/III trials has shown efficacy for both psoriatic arthropathy and ankylosing spondylitis, suggesting specific JAK1 targeting may be superior[3, 4]. The role of JAK/STAT signaling in enthesis has not been extensively explored and given the importance of the enthesis in the development of SpA it is crucial to gain a mechanistic understanding of how JAK inhibitors affect entheseal inflammation.

Objectives: To determine if upadacitinib could suppress innate and adaptive immune responses in an in vitro human enthesis model and elucidate mechanisms of suppression.

Methods: Normal spinous process enthesis was obtained from patients undergoing spinal decompression or surgery for scoliosis correction as previously described[5]. Enthesis cells were subsequently isolated by mechanical digestion. Enthesal cells were stimulated with IFNγ (JAK1 activator) with and without upadacitinib and STAT1 activation measured by phos-flow cytometry. Enthesal T-cells were stimulated with anti-CD3, anti-CD2 with IL-23 and anti-CD3 with IL-17 with and without upadacitinib. IL-17A and TNFα were quantified using intracellular flow cytometry and ELISA of supernatants. Enthesal cells were also stimulated with LPS with and without upadacitinib, and IL-23 and TNFα quantified by ELISA.

Results: Upadacitinib inhibited phosphorylation of STAT1 in entheseal cells, following IFNγ stimulation (Figure 1-A). Following stimulation of entheseal T-cells upadacitinib inhibited both TNFα and IL-17A production as assessed by both ELISA and intracellular flow cytometry (Figure 1-B, 1-C). Upadacitinib did not attenuate LPS induced IL-23 or TNFα from entheseal myeloid cells.

Conclusion: Upadacitinib inhibition of entheseal T cell derived TNFα and IL-17A, therefore interrupting the IL-23/IL-17/TNFα axis so prominent in SpA, may offer a mechanistic explanation for upadacitinib’s efficacy treating enthesis.

Conclusion: The findings reflect a possible relationship among the apical expression of CD71 in ileum with high levels of serum S IgA and activity, suggesting that retrotranscytosis mediated by this receptor might be a mechanism that mediate the intestine-joint axis in SpA.

CIRCULATING NON-CLASSICAL CD14LOW/CD16+ MONOCYTES AND THEIR EXPRESSION OF ARGINASE-1 ARE ASSOCIATED WITH THE ACTIVITY OF AXIAL SPONDYLOARTHRITIS

T. Tyirnova1, A. Morenkova1, M. Tikhonova1, O. Chumasova2, N. Ilina3, A. Fedorov4, A. Sizikov2, A. Ostanin1, E. Chernykh1, 1Research Institute of Fundamental and Clinical Immunology, Laboratory of Cellular Immunotherapy, Novosibirsk, Russian Federation; 2Research Institute of Fundamental and Clinical Immunology, Department of Rheumatology, Novosibirsk, Russian Federation

Background: Human peripheral blood monocytes represent heterogeneous population and can be divided into three major populations, classical (CD14+CD16−), intermediate (CD14−CD16+) and non-classical (CD14−CD16+) monocytes. All three monocyte populations are thought to have different functional activity, including their pro- and anti-inflammatory activity. The ratio between monocyte populations could change in inflammatory conditions that it is thought to be important for the development of adequate immune responses. Axial spondyloarthritis (axSpA) being autoimmune diseases is currently classified as an autoinflammatory disease based on a strong inflammatory component. Axial spondyloarthritis (axSpA) being autoimmune diseases is currently classified as an autoinflammatory disease based on a strong inflammatory component. It is accepted that increased concentration of pro-inflammatory mediators can cause an impairment of myelopoiesis.

Objectives: The present study aimed to analyze the frequency of blood monocyte subpopulations and their expression of the suppressor molecule arginase-1 (Arg1) in patients with axSpA.

Methods: The study included 14 healthy donors and 19 axSpA patients aged 23 to 59 years, including 15 men and 4 women. Ankylosing Spondylitis Disease Activity Score (ASDAS) was used to assess disease activity and high activity was determined as ASDAS≥2.1. The disease duration at the time of the study was 12 years (median). Phenotypic analysis of blood monocytes was performed by flow cytometry based on CD14 and CD16 expression.

Results: The frequency of monocyte subpopulations in patients with low/moderate activity of axSpA did not differ from the donor group. Patients with high very high disease activity showed an increased relative number of non-classical CD14+CD16+ monocytes (vs donors pU=0.007). All donor monocyte subpopulations expressed suppressor intracellular molecule Arg1 with higher expression in intermediate and non-classical monocytes. The expression of Arg1 in CD14+CD16+ monocytes was significantly reduced in patients with high activity (vs donors Me 41.5 vs 76.5%, pU=0.01). Patients with the presence of peripheral articular manifestations of axSpA were characterized by a decreased Arg1 expression in non-classical monocytes compared with the donor group (pU=0.02). However, patients without peripheral manifestations demonstrated a significant reduction of Arg1 expression in all monocyte subpopulations (pU<0.05).

Conclusion: Shifting of monocyte subpopulation toward a higher number of non-classical monocytes with the decrease in the expression of the suppressor molecule Arg1 in the high activity of axSpA can play important role in terms of the possible involvement of monocytes in maintaining inflammation and its regulation in autoinflammatory disease.

The reported study was funded by State Budgeted Project (registration ID 122011800037-3).

New insights into the management of JIA

A. I. Rebolli Gímenez1, A. Alongí2, G. Giancane1, R. Naddeo1, N. Ruperto1, A. Consolaro1, A. Ravelli1 on behalf of Pediatric Rheumatology Internationals Trials Organization (PRINTO), 1Istituto Giannina Gaslini, Pediatric and Rheumatology Clinic, Genoa, Italy; 2Azienda Ospedaliera di Rilievo Nazionale e di Alta Specializzazione Civico Di Cristina e Benfratelli, Pediatric Clinic, Palermo, Italy; 3Istituto Giannina Gaslini, Scientific Director, Genoa, Italy

Background: The ACR provisional criteria for defining inactive disease (ID) in Juvenile Idiopathic Arthritis (JIA) requires that the physician's global assessment of disease activity (PhGA) is marked as 0 on the visual analog scale (VAS). However, some investigators have noticed the tendency of some clinicians to mark the PhGA=0 even on resolution of active disease. Due to the fact that the PhGA and the count of active joints are the two main physician-centered measures included in ID criteria the analysis of their discordance may be of importance to address the issue.

Objectives: To investigate the frequency in which the physician provides a global assessment of disease activity (PhGA)0 and an active joint account (AJC)=0 in children with juvenile idiopathic arthritis (JIA) and search for determinants of divergence between the two measures.

Methods: Data were extracted from a multinational cross-sectional dataset of 7265 patients who had JIA by ILAR criteria, were recruited between 2011 and 2016 and had both PhGA and AJC recorded by the caring paediatric rheumatologist at the study visit. Determinants of discordance between PhGA and AJC=0 were searched for by multivariable logistic regression and dominance analysis.

Results: The PhGA was scored 0 in 1211 (32.4%) of 3668 patients who had an AJC=0 of 0. In 536 patients (14.6%) the PhGA was the single most frequent reason for not meeting the ID definition in patients with AJC=0. Independent associations with discordant assessment were identified for tender or restricted joint count>0, history of entheses, presence of active uveitis or systemic features, enthesitis-related or systemic arthritis, increased acute phase reactants, pain visual analog scale (VAS)>0, and impaired physical or psychosocial wellbeing. In dominance analysis, tender joint count accounted for 35,43% of PhGA variance, followed by an active joint account (AJC=0) (17 ,72%), restricted joint count>0 (16, 14%) and physical health score >0 (11,42%) (Figure 1).

Disclosure of Interests: None declared

Figure 1. Discrimination analysis of relative importance of predictive factors in explaining the variance in PhGA.
**Conclusion:** We found that many paediatric rheumatologists did not mark a score of 0 for patients who found not to have active joints. The presence of pain in joints not meeting the definition of active joint used in JIA was the main determinant of this phenomenon.

**COURSE OF UVEITIS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: DATA FROM THE INCEPTION COHORT OF NEWLY DIAGNOSED PATIENTS WITH JIA (ICON-JIA) STUDY**

**1German Rheumatism Research Center Berlin, Epidemiology, Berlin, Germany; 2Medizinische Hochschule Hannover, Paediatric Rheumatology, Hannover, Germany; 3University Hospital Münster, Department of Paediatric Rheumatology and Immunology, Münster, Germany; 4Huband Centre for Pediatric and Adolescence Rheumatology, Paediatric Rheumatology, Hamburg, Germany; 5German Centre for Child and Adolescent Rheumatology, Paediatric Rheumatology, Gammsich-Partenkirchen, Germany; 6Asklepios Kinderklinik St Augsburg, Centre for General Paediatrics and Neonatology, St. Augsburg, Germany; 7Olghospital Stuttgart, Center for Pediatric Rheumatology, Stuttgart, Germany; 8Ostkreis – Universitätsmedizin Berlin, Department of Paediatric Respiratory Medicine, Immunology and Intensive Care Medicine, Berlin, Germany; 9Klinikum Köln – Kinderkrankenhaus, Paediatric Rheumatology, Köln, Germany; 10Klinikum Bremen-Mitte, Prof-Hess-Kinderklinik, Paediatric Rheumatology, Bremen, Germany; 11St. Josef-Stift Sendenhorst, Clinic for Paediatric and Adolescent Rheumatology, Sendenhorst, Germany; 12Franziskus Hospital, Department of Ophthalmology, Münster, Germany.

**Background:** Uveitis is an extra-articular manifestation of Juvenile idiopathic arthritis (JIA) with a prevalence of up to 20% developing most frequently in young girls and patients positive for antinuclear antibodies (ANA). Untreated and uncontrolled uveitis may lead to vision-threatening complications and even blindness.

**Objectives:** The main objectives of the analyses were to determine the visual prognosis, uveitis complications and necessity of ocular surgery during the first five years of ocular disease. The likelihood of achieving an inflammation-free phase or even a remission without medication were investigated.

**Methods:** The Inception Cohort of Newly diagnosed patients with JIA (ICON) was initiated in 2010 in order to prospectively follow JIA patients up to 10 years after JIA disease onset. 953 Patients were assessed at enrolment, three-monthly during the first year, and six-monthly afterwards by a standardized phisician's patient's and patient's case report form including clinical parameters, treatment data and several laboratory parameters such as ESR, CRP or S100A12. Patients who developed uveitis underwent a regular ophthalmological assessment. The treatment ophthalmological for each patient was completed an additional questionnaire documenting the anterior chamber (AC) cell grade, current uveitis activity (UA) and UA during the previous three months, best corrected visual acuity (BCVA), uveitis-related complications, previous ocular surgery, current topical treatment
and clinical course of uveitis and additional parameters. Inactive uveitis was defined by AC cell grade of 0, quiescence of uveitis by inactive uveitis for at least 6 months, and remission by inactive uveitis for at least 6 months without topical steroids or systemic anti-inflammatory medication (steroids or DMARDs).

**Results:** A total of 133 children developed uveitis in the JIA disease course, of which 97 patients were documented via the ophthalmological questionnaire for at least two years resulting in a mean follow-up of 5.8 years (SD 1.8). 76% were female, 86% ANA positive, 70% oligoarthritis, and 22% rheumatoid factor negative polyarthritis and mean age at JIA onset was 3.1 (SD 2.1) and uveitis onset at 4.4 (SD 2.2) years. The mean duration between JIA onset and uveitis onset was 15.7 (SD 15.6) months. At least one ocular complication was reported for 24% of patients at first uveitis documentation and 47% of patients had at least one ocular complication until the five year follow-up. Among those, posterior synchiae (31%) and cataract (27%) were the most frequent, followed by an increased IOP (12%) with or without glaucomatous changes. Ocular surgery was rarely necessary, and visual acuity remained quite good in the majority of patients: After five years, >90% had BCVA of >0.4 LogMAR (Logarithm of the Minimum Angle of Resolution), and 63.5% even of >0.1 LogMAR. About half of the uveitis patients were already treated with DMARDs at uveitis onset. The rate of treatment with biological DMARDs increased from 10% at first uveitis documentation up to 20% at 5-year follow-up. Three in four patients were treated with topical steroids at first assessment, whereas this proportion decreased to 43%. 80 of 97 patients (83%) achieved uveitis quiescence during the first five years of disease, with more than 50% experiencing more than one episode (mean 1.5 episodes (SD 1.0)) during this time period. The mean duration of uveitis quiescence was 23.2 (SD 15.6) months. A total of 39 (40%) patients achieved uveitis remission during follow-up. The likeliness of remission was associated with a lower JIA disease activity (cJADAS10), lower erythrocyte sedimentation rate (ESR) and a higher age at JIA disease onset.

**Conclusion:** The rate of ocular complications is already remarkable at uveitis diagnosis, and increases during uveitis disease course despite anti-inflammatory treatment. However, the visual acuity frequently remains unaffected, and the majority of patients achieve uveitis quiescence and even 40% uveitis remission within 5 years of follow-up.

**DISTINCT CLUSTERS OF JIA AT METHOTREXATE INITIATION IDENTIFIED USING TOPOLOGICAL DATA ANALYSIS**

S. Shoop-Worrall1,2, K. Hyrich3,4, L. Wedderburn5,6, N. Geiffin7 on behalf of The CLUSTER Consortium, BSPAR-ETN Study, BCRD Study, CAPS, CHARMS. 1The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 2The University of Manchester, Centre for Health Informatics, Manchester, United Kingdom; 3Manchester University NHS FT, NHS Manchester BRC, Manchester Academic Health Science Centre, Manchester, United Kingdom; 4UCL Great Ormond Street Institute of Child Health, University College London, Centre for Adolescent Rheumatology Versus Arthritis at UCL, London, United Kingdom; 5Great Ormond Street Hospital NHS Foundation Trust, Paediatric Rheumatology, London, United Kingdom; 6NIHR Great Ormond Street Hospital Biomedical Research Centre, NIHR Great Ormond Street Hospital Biomedical Research Centre, London, United Kingdom; 7University of Surrey, School of Health Sciences, Faculty of Health and Medical Sciences, Guildford, United Kingdom

**Background:** Stratified medicine requires the identification of unique strata of a disease within which to base prognostic and treatment decisions. Juvenile idiopathic arthritis (JIA) offers a unique challenge in its inherent heterogeneity. The current ILAR classification, whilst useful for clinical categorisation, does not correlate with treatment outcomes. Therefore, further refinement, clustering and correlation of patient characteristics with treatment response are urgently required.

**Objectives:** To identify novel, phenotypically consistent subgroups of children and young people (CYP) with JIA at the point of starting methotrexate, across 19 demographic and clinical variables. ILAR categories across clusters were not always indicators of disease activity or symptom burden. Future analyses will correlate MTX treatment response within each cluster to understand what role these combined factors may have on initial treatment response.

**Disclosure of Interests:**

This study shows substantial heterogeneity in JIA at the point of MTX initiation, with six clusters identified across 19 demographic and clinical variables. ILAR categories across clusters were not always indicators of disease activity or symptom burden. Future analyses will correlate MTX treatment response within each cluster to understand what role these combined factors may have on initial treatment response.
Background: In recent years, transition clinics have been set up at an increasing number of paediatric rheumatology sites in Germany to reduce identified deficits in the care of young people with rheumatic diseases. In addition, the German Rheumatic Diseases League (Deutsche Rheuma-Liga, DRL), the largest self-help organisation in Germany, has been offering support services for young people in transition since 2016, including the interactive website www.mein-rheumakind.de.

Objectives: To assess the transition competence of young people with juvenile idiopathic arthritis (JIA) and their knowledge of self-help services.

Methods: Cross-sectional data of the National Paediatric Rheumatology Database (NPRD) from 2016 to 2020 were used to evaluate the health-related transition competence of young people with JIA aged ≥16 years. Health-related knowledge and health-care competence were assessed using a modified self-report instrument on a 4-point Likert scale as part of routine documentation in the NPRD. Young people were also asked about their information behaviour and knowledge of new support services. Linear mixed models were used to determine whether health-related transition competence changed between 2016 and 2020, adjusted for disease duration.

Results: From the years 2016 to 2020, between 1908 to 2536 patients with JIA aged ≥16 years were annually recorded in the NPRD from 56 to 61 paediatric rheumatology sites. The annual patient collective comprised 34% 39% oligoarthritis, 23-26% RF-negative or RF-positive polyarthritis and 22-27% enthesis-related arthritis cases. In the years from 2016 to 2020, about one-third of patients had inactive disease (cJADAS=0) and about 60% had no functional limitation (CHAQ=0).

Over the years, the proportions of patients who rated their disease knowledge and health care competence as “very well” increased significantly in most areas. Although over time, no increase in numbers of patients seeking information about their disease outside of rheumatology consultations was recorded (2016: 22.8%; 2020; 20.9%), awareness of the DRL’s new website for young people with rheumatic diseases increased from 7.7% in 2016 to 26.9% in 2020. Compared to those who were unaware of the new website, those who knew about the website were more likely to have received care in rheumatology settings that offer transitional care (cJADAS=10 vs 1) and had a higher school attendance (51% vs 46%) and to be slightly older (17.6 vs 17.1 years).

Conclusion: The transition competence of young people with JIA seems to have improved over the last five years. During this time, more transition services were made available for young people with rheumatic diseases. However, most young people are not yet aware of these services. Moreover, the effectiveness of the different measures/interventions has yet to be evaluated.

POS0339 POINTS TO CONSIDER AT THE EARLIEST STAGES OF THE DIAGNOSIS AND MANAGEMENT OF HEMOPHAGIC LYMPHOPHISTIOCYTOSIS/MACROPHAGE ACTIVATION SYNDROME (HLH/MAS)

B. Shaakyoo1, A. Geerlings2, M. Wijejo2, K. Kernan1, E. Demirkaya2, A. Ravel1, R. Sinha1, R. Goldbach-Mansky3, F. De Benedetti4, R. Marsh1, S. Canoa1 on behalf of EULAR/ACR HLH/MAS Working Group, 1NAID/NIH, 2Translational Autoinflammatory Disease Section, Bethesda, United States of America; 3London Health Sciences Centre, Hematology/Oncology, London, Canada; 4University of Pittsburgh, Critical Care Medicine, Pittsburgh, United States of America; 5Istituto Giannina, Rheumatology, Genoa, Italy; 6Systemic JIA Foundation, Head, Cincinnati, United States of America; 7Ospedale Bambino Gesù, Rheumatology, Rome, Italy; 8Cincinnati Children’s Hospital Medical Center, Bone Marrow Transplantation and Immune Deficiency, Cincinnati, United States of America; 9The Children’s Hospital of Philadelphia, Rheumatology & Immune Dysregulation, Philadelphia, United States of America

Background: Hemophagic Lymphohistiocytosis (HLH) and Macrophage Activation Syndrome (MAS) are life-threatening systemic hyperinflammatory syndromes that occur in many contexts and are often called by many names. They nevertheless can progress rapidly, and early identification and management are critical for preventing organ failure and mortality.

Objectives: The purpose of this effort was to develop a series of ‘points to consider’ to assist clinicians at the earliest stages of evaluation and diagnosis, monitoring, and management of patients with HLH/MAS in order to improve patient outcomes.

Methods: A working group of adult and pediatric rheumatologists (14), hematologists/oncologists (4), immunologists (2), infectious disease specialists (2), intensivists (3), allied health care professionals (1), and patients/parents (2) formulated relevant research questions for a systematic literature review (SLR). We then used the SLR results, Delphi questionnaires, and consensus methodology to devise and refine overarching and specific ‘points to consider’ statements.

Results: The group arrived at six overarching statements and 24 specific points- to-consider-relevant to early decision-making in diagnostics, initial management, and monitoring of HLH/MAS. Major themes included the a) need for prompt recognition, evaluation, and management of underlying triggers and conditions, b) multi-disciplinary/expert input, and c) early, tailored intervention with the goals of halting disease progression and preventing life- and organ-threatening immunopathology.

Conclusion: The 2022 EULAR/ACR Points to Consider provide guidance on the initial evaluation, management, and monitoring of patients during the initial consideration of HLH/MAS.

POS0340 PREDICTORS OF CLINICAL RESPONSE TO ABATACEPT IN CHILDREN WITH POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS

N. Ruperto1, H. Brummer1, A. Berman1, F. Avila Zapata1, G. Hornern1, L. Wagner-Weiner1, A. Beirc1, R. Burgos-Vargas1, M. L. Gármar Gármar10, C. Goldenstein-Schainberg11, M. T. Terrier12, M. Askell13, R. Wong14, A. Martin15, D. J. Lovell16 on behalf of Paediatric Rheumatology International Trials Organisation (PRINTO) and the Pediatric Rheumatology Collaborative

1Klinikum Stuttgart, Allgemeine und Spezielle Pädiatrie, Stuttgart, Germany; 2Universitätsklinik Freiburg, Zentrum für Kinder- und Jugendmedizin, Freiburg, Germany; 3Kinderärztpaarzugs Gündelfingen, Kinder- und Jugendheumatologie, Gündelfingen, Germany; 4Universitätsklinikum Tübingen, Klinik für Kinder- und Jugendmedizin, Tübingen, Germany

The transition competence of young people with JIA seems to have improved over the last five years. During this time, more transition services were made available for young people with rheumatic diseases. However, most young people are not yet aware of these services. Moreover, the effectiveness of the different measures/interventions has yet to be evaluated.
Background: For children with polyarticular juvenile idiopathic arthritis (pJIA) and inadequate response or intolerance to initial treatment with MTX, treatment options include abatacept. Abatacept, a selective T-cell co-stimulation modulator, has a distinct mechanism of action from other current treatments for rheumatic diseases, and factors predicting clinical response can help determine optimal treatment strategy. Two phase 3 studies demonstrated the efficacy and safety of IV and SC abatacept in patients with pJIA and an inadequate response to other DMARDs.

Objectives: To determine baseline and post-baseline factors that may predict a clinical response in children and adolescents with pJIA treated with abatacept for 2 years.

Methods: Baseline demographic and disease characteristics and post-baseline factors (50% and 70% improvement in ACR criteria [ACR50, ACR70] at days 57 and 85) were analyzed using data from 2 phase 3 studies of abatacept treatment, both time to JADAS10-CRP ID and time to JADAS10-CRP remission were predicted (nominal ≤ 0.05) by age (≤ 11 years: hazard ratio 2.05 [95% CI, 1.45–2.91]) and SC route of administration (HR, 2.05 [95% CI, 1.35–3.10], respectively), Parient/Parental Global Assessment of well-being (≤ 35.86: HR, 1.88 [95% CI, 1.41–2.51]) and ≥ 43.16: HR, 2.05 [95% CI, 1.35–3.10], respectively), and Childhood HAQ-DI (CHAQ-DI; ≤ 0.63: HR, 2.23 [95% CI, 1.47–3.39] and ≤ 0.75: HR, 1.84 [95% CI, 1.24–2.73], respectively) (remission data shown in Figure 1). Disease duration ≤ 2 years from baseline (HR, 1.66 [95% CI, 1.25–2.21]) and SC route of administration (HR, 2.05 [95% CI, 1.45–2.91]) also predicted ID. Among the post-baseline factors, ACR50 at days 57 and 85 predicted both ID (HR, 1.57 [95% CI, 1.04–2.36] and HR, 1.88 [95% CI, 1.41–2.51], respectively) and remission (HR, 1.96 [95% CI, 1.11–3.45] and HR, 3.05 [95% CI, 1.47–6.34], respectively); ACR70 at day 57 also predicted ID (data not shown). Patients with predictive factors for age, hsCRP Parent/Parental Global Assessment of well-being, and CHAQ-DI, and with lower disease activity achieved ID and/or remission earlier than patients with high disease activity.

Conclusion: We identified baseline and post-baseline factors that predicted JADAS10-CRP ID and remission in patients with pJIA treated with abatacept for 2 years. Screening of abatacept-treated patients with pJIA for such factors may help predict earlier achievement of ID and/or remission.

Background: Radiographs are not a sensitive or reliable imaging tool for detection of early sacroiliitis in juvenile spondyloarthritis (JSaPa). However, radiographs are still commonly performed in some areas due to difficulty in accessing MRI. As such, radiographs were included in the imaging data considered for an axial disease classification criteria development study, but only when there was no suitable MRI available.

Objectives: We aimed to define criteria for unequivocal evidence of sacroiliitis on pelvic radiography in skeletally immature children and adolescents for use in classification criteria.

Methods: Subjects were a cohort of JSaPa patients with suspected axial disease. All subjects had symptom onset prior to age 18 years and underwent MRI as part of a diagnostic evaluation for axial disease; a subset of subjects also had a dedicated pelvic radiograph. Using a web-based interface, 6 musculoskeletal imaging experts, blinded to clinical details, reviewed the radiographs and graded them according to the modified New York (mNY) criteria. A two-way random effects intraclass correlation coefficient (ICC) was used to assess agreement. Next, the central imaging team underwent an iterative consensus process to define unequivocal evidence of sacroiliitis on pelvic radiography in skeletally immature children. Radiographs with at least two raters assigning a non-zero mNY grade were re-reviewed for the presence/absence of "unequivocal evidence of sacroiliitis" according to the consensus definition. Agreement was assessed with Fleiss’s kappa statistic with agreement interpreted as poor ≤0.40, fair 0.41-0.59, good 0.60-0.74, and ≥0.75 excellent. Sensitivity, specificity, and positive and negative predictive values (PPV, NPV) were calculated to assess performance of the novel definition using structural lesion typical of juvenile axial disease on MRI as the reference standard (erosion in ≥3 sacroiliac joint (SIJ) quadrants or at least one of the following lesions in ≥2 SIJ quadrants: sclerosis, fat lesion, backfill, ankylosis).

Results: Radiographs from 120 subjects, 61% male, median age 14.7 years (range 6.7-20.1 years), had an AP dedicated pelvic radiograph available for scoring. The ICC for mNY grade amongst 6 central raters was 0.80 (95% CI: 0.63-0.90). After multiple iterations and discussion, the consensus definition of unequivocal sacroiliitis by radiograph in skeletally immature children and adolescents was deemed "Unequivocal lesion (erosion, sclerosis, or ankylosis [partial or complete]) that must include at least one iliac bone. When sclerosis is present in isolation, if measurable, should extend ≥5mm from the joint surface. The decision may be influenced by the presence of other lesions, which in themselves do not suffice to meet the criterion." Sixteen radiographs were assessed using the consensus definition. 8 (50%) were rated as unequivocal sacroiliitis and Fleiss’ kappa statistic was good at 0.61 (95% CI: 0.41-0.80). Across raters, the sensitivity, specificity, PPV and NPV of the consensus definition on radiograph using structural lesions typical of sacroiliitis on MRI as the reference standard were 80% (95%CI: 44.4-97.5), 100% (95% CI: 54.1-100), 100% (95% CI: 54.1-100), 100% (95% CI: 54.1-100), 100% (95% CI: 54.1-100) and 75% (95% CI:33.9-96.8), respectively.

Conclusion: We propose a consensus-defined definition of unequivocal sacroiliitis by radiography in skeletally immature children and adolescents with good expert rater agreement. Additionally, the consensus-definition had moderate to high sensitivity and PPV and high specificity and NPV with typical structural lesions typical of sacroiliitis on MRI as the reference standard.

POS0343 TREATMENT PERSISTENCE AND ADHERENCE AMONG PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS RECEIVING ABATACEPT OR TNF INHIBITORS USING US CLAIMS DATA

Objectives: To evaluate treatment persistence and adherence at 12- and 18-month follow-up in patients with JIA newly initiating either abatacept or a TNF.

Methods: This analysis used data from the IQVIA PharMetrics Plus claims database from Jan 2008–Apr 2021. We identified patients with ≥ 1 claim of abatacept or TNFi treatment (adalimumab, etanercept, ≥ 12 months before index date, patients receiving abatacept or TNFi treatment ≤ 12 months prior to index date and patients initiating combined abatacept + TNFi treatment on the index date were excluded. Specific outcomes included: discontinuation (absence of a new prescription for index treatment within the gap of 5x treatment half-life), persistence rate (proportion of patients continuing index medication without any gaps exceeding 5x treatment half-life), and treatment adherence (defined as medication possession ratio [MPR, proportion of follow-up period where medication supply is available] and proportion of days covered [PDC, proportion of follow-up period where a patient is covered by a given drug]). All outcomes were reported at 12 and 18 months. All statistical analyses are descriptive with the intent for hypothesis generation.

Results: There were 2847 patients (abatacept, n = 111; TNFi, n = 2736) at 12-month follow-up; fewer completed the 18-month follow-up (2403 patients: abatacept, n = 94; TNFi, n = 2309). At index date, treatment groups were similar for sex, geographic location, and comorbidities (Table 1). Numerically higher persistence was observed in patients prescribed abatacept compared with TNFi overall at both time points. Abatacept persistence was higher than etanercept but similar to adalimumab (Figure 1). At 12 months, the percent of patients with PDC ≥ 0.8 was 57% for abatacept, 51% for adalimumab, and 38% for etanercept, while MPR ≥ 0.8 was 63% for abatacept, 55% for adalimumab, and 42% for etanercept. Patients prescribed abatacept had numerically greater proportions of PDC ≥ 0.8 (abatacept, 48%; adalimumab, 40%; etanercept, 29%) and MPR ≥ 0.8 (abatacept, 53%, adalimumab, 44%, etanercept, 33%) at 18 months.

Novel molecular regulators of bone turnover.

**POSS0344**

O-GlcNAcylation on NUP153 regulates the early stages of osteoclastogenesis through MYC nuclear translocation

Y. N. Li1, C. W. Chen1, T. Trinh-Minh1, Z. Honglin2, P. Hubel1, J. Pfannstiel3, G. Schett4, J. H. W. Distler3. 1University Hospital Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany; 2Xiangya Hospital, Central South University, Department of Rheumatology, Changsha, China; 3University of Hohenheim, Core Facility Hohenheim, Stuttgart, Germany

**Background:** Bone homeostasis is maintained by the balance between bone formation and resorption. In inflammatory arthritis, such as rheumatoid arthritis (RA), the pro-inflammatory environment promotes osteoclast differentiation and skews this balance towards bone resorption, leading to destructive bone erosion and bone loss. O-GlcNAcylation is one of the most common post-translational modifications, which attaches a single N-acetylglucosamine (GlcNAc) moiety to the serine or threonine of the target protein. O-GlcNAcylation is controlled by the activities of a single pair of enzymes: OGT, which facilitates de-O-GlcNAcylation of the target protein, and O-GlcNAcase, which removes GlcNAc from proteins. The activity of O-GlcNAcylation has been reported to be involved in several cellular events, such as transcription, translation, intracellular trafficking, and differentiation. We previously showed that the dynamics of O-GlcNAcylation are essential for osteoclast differentiation. TNF-α, a key pro-inflammatory factor in RA, intensifies the O-GlcNAcylation dynamics. Inhibition of OGT arrests osteoclast precursors at early stages, whereas OGA inhibition blocks osteoclast differentiation. However, the molecular mechanism of these regulations remains unclear.

**Objectives:** We aimed to identify the O-GlcNAcylation targets in osteoclast precursors in a pro-inflammatory milieu and to decipher the molecular mechanism of O-GlcNAcylation mediated regulation of osteoclastogenesis.

**Methods:** We first identified the O-GlcNAc-dependent molecular pathways in osteoclast precursors with pharmacological OGT and OGA inhibition by RNA sequencing. Then, we identified the O-GlcNAcylated proteins by mass spectrometry-based proteomics analysis and confirmed by immunoprecipitation. We found the potential molecular mechanism by combining the data from transcripomics and proteomics. The proposed mechanism was further validated through siRNA-mediated knockdown and high-content screening analysis.

**Results:** Our transcripomics data showed that OGT inhibition arrested osteoclast differentiation at early stages through interfering the cytokine signaling and metabolic adaption. The upstream analysis proposed MYC as the most potent regulator for the transcripomic profile under OGT inhibition. Recent studies proposed MYC as a master regulator for metabolic reprogramming during osteoclast differentiation. However, O-GlcNAcylation of MYC was not detected by mass spectrometry, suggesting indirect effects of O-GlcNAcylation on MYC signaling in osteoclast precursors. We detected upregulated levels of O-GlcNAc on NUP153, MTDH, RBM27, IFT207 upon RANKL+TNFα stimulation. An integrated analysis of transcripomic and proteomic data by Ingenuity Pathway Analysis indicated that NUP153 might regulate the most DEGs among all the identified targets and indicated potential of NUP153 to regulate nuclear shuttling of MYC. Subcellular fractionation and confocal microscopy showed enhanced MYC nuclear translocation upon RANKL+TNFα stimulation, which could be blocked by NUP153 knockdown or OGT inhibition. Functionally, knockdown of NUP153 arrested cells at similar stages to OGT inhibition and reduced bone resorption ability. Together, these results suggest a model, in which O-GlcNAcylation regulates the shuttling activity of the nuclear pore component NUP153 to control the access of MYC to the nucleus during osteoclast differentiation.

**Conclusion:** Our results indicated that OGT inhibition arrests osteoclastogenesis at early stages through hampering MYC-dependent metabolic adaption. NUP153 was proposed as the most potent O-GlcNAcylated target by multi-omics data integration. NUP153-mediated MYC nuclear trafficking is required for osteoclast differentiation. These findings reveal the molecular mechanism of O-GlcNAcylation-dependent osteoclastogenesis and provide therapeutic insights on targeting O-GlcNAcylation in pathologic bone resorption.

**POSS0345**

Assessment of the effect of tofacitinib on bone marrow adipocytes and bone-forming osteoblasts under non-inflammatory and inflammatory conditions

**Background:** Systemic inflammation is the main factor underlying secondary osteoporosis in patients with rheumatoid arthritis (RA). The JAK inhibitors, such as Tofacitinib (Tofa), can control systemic inflammation and have beneficial effects on bone in various models. This might be due to direct effects on the bone microenvironment and not exclusively based on their anti-inflammatory function. Bone marrow adipocytes (BMA) are abundant in the bone microenvironment. The effect of JAK inhibitors on BMA is unknown, but evidence suggests that there is competition between human bone marrow-derived stromal cell (hBMSCs) differentiation routes towards BMA and osteoblasts (Ob) in osteoporosis.

**Objectives:** To determine in various models whether Tofa influences directly human cell commitment toward adipogenesis and osteoblastogenesis. Then, in a prospective pilot study, to investigate the potential effects of Tofa on bone marrow adiposity in patients with RA.

**Methods:** To study the effect of Tofa on cellular commitment, hBMSCs were cultured for 3 days in appropriate Ob- and BMA- differentiation media (Ob-3d and BM-3d), together with Tofa at 200, 400 (equivalent to a therapeutic dose of 5mg twice a day in RA patients) or 800 nM. To mimic inflammatory conditions, TNFα was added to the media at a dose of 1 ng/ml. This study was also conducted on mature BMAs and a similar treatment was applied for 6 days to mature BMA at 14 days of differentiation (BMA-20d). The impact of Tofa was determined by gene expression profile analysis, western-blot analysis and cell density monitoring. In parallel, in a pilot study of 9 RA patients treated with Tofa 5mg twice a day (TOFAT study; NCT04175886), proton density fat fraction (PDDF) was measured by MRI (Dixon technique) at the lumbar spine at the start of treatment and at 6 months.

**Results:** In non-inflammatory conditions, the gene expression of Runx2 decreased in Ob-3d treated with Tofa 400 and 800nM (p<0.05). Conversely, BMA-3d treated with Tofa (at 200, 400 and 800 nM) exhibited a substantial increase in the gene expression of PPARγ2 (the master regulator associated with lipid droplet formation) compared to controls (p<0.05). The increase in the expression of PPARγ2 was also confirmed at the protein level. In inflammatory conditions, BMA-3d and Ob-3d markers decreased considerably (PPARγ2 and RUNX2, respectively, p<0.05), but the addition of Tofa did not change the expression profiles of Ob-3d compared to TNFα controls. On the contrary, the analysis of PPARγ2 gene expression showed that Tofa limited the negative effect of TNFα on BMA differentiation (p<0.05). The positive effect of Tofa on mature adipocyte (BMA-20d) under inflammatory conditions was also supported by an increase in the density of differentiated BMAs (p<0.001). These findings were consolidated by an increase in PDDF at 6 months of treatment with Tofa in RA patients (+6.9%, p<0.01).

**Conclusion:** Overall, in vitro and clinical results suggest a stimulatory effect of Tofa on BMAs commitment and differentiation, which does not support a positive effect of Tofa on bone.

Background: The Paget's disease of Bone (PDB) is characterized by a chronic and focal disorder of bone remodeling. PDB is currently considered a complex and multifactorial disease, as a result of a synergistic association of genetic variants with environmental risk factors. The genetic component would explain certain epidemiological traits such as the predisposition to develop in certain ethnic groups and the strong tendency to family aggregation. The most important susceptibility gene for PDB is the Sequestosome-1 (SQSTM1) gene, which encodes a 440-amino-acid protein called p62 protein. SQSTM1 gene occurs in between 20 and 40% of patients with a family history of PDB, and 5 and 10% of patients with sporadic disease, according to the series studied. Thus far, 29 SQSTM1 mutations have been identified in patients with PDB.

Methods: The molecular study was carried out by sequencing the SQSTM1 gene (p62) in a population of 200 PDB affected patients and 200 hypernormal controls. An "in silico" functional analysis of the different genetic variants was performed using the information provided by the splicing prediction algorithms, the miRNA target prediction algorithms, the gene-specific algorithms for predicting pathogenicity (SIFT, PolyPhen, PMut) and the interspecific evolutionary conservation study. The statistical analysis was performed using SPSS statistical software Windows (v23) and the R software version 2.15.0 for Windows. The study was approved by the CEC (Hospital del Mar-Parc de Salut Mar (2007/2885/I)) and all participants signed an informed consent agreeing to participate in the study.

Results: The 27% of the PDB affected patients were carriers of different gene SQSTM1 mutations, being the most frequent identified the p.P392L, described in the 20% of cases. In terms of genotype-phenotype relation, being a carrier of gene SQSTM1 mutations is associated to a more severe phenotype based on a greater disease activity and a greater extent at diagnosis as well as higher complications during the course of it, without the presence of an associated familial history positive. In our patient cohort 17 mutations have been identified in coding regions of the SQSTM1, with six newly described "missense" genetic variants (p.R161W, p.H163Y, p.K238E, p.G262R, p.E274D,p.G405S), all of them associated to a greater susceptibility in the development of PDB and distributed in the different structural and functional domains of the p62 protein, being able to cause dysfunctions in the different cell signalling processes where intervenes apoptosis, autophagy, proteic degradation through the ubiquitin-proteasome system, the regulation of antioxidant response and the cell survival mediated by RANK-TRAF6-NF-kB signaling pathway), implicated in the pathogenesis of Paget's disease of bone.

Conclusion: In the molecular study of the SQSTM1 gene, seventeen mutations were identified in the coding regions of the gene, being six "missense" genetic variants of new description, associated all of them to a higher risk of developing PDB and distributed in different structural and functional domains of the p62 protein.

Background: Osteoporosis is a mineral bone disease arising from the pre-dominance of osteoclastic bone resorption. Bisphosphonates which inhibit osteoclasts are commonly used in osteoporosis treatment, but are not without severe adverse effects like osteonecrosis of the jaw. The mechanisms behind the development of such phenomena is not well understood. Bone homeostasis is achieved through an intimate cross-talk between osteoclasts and osteoblasts. Thus, it is important to visualise activities of these cells simultaneously in situ. Currently, there are means to visualise osteoclast shape and numbers with tartrate-resistant alkaline phosphatase (TRAP) staining but no practical and accurate methods to quantify osteoclast activity in situ.

Objectives: This investigation aims to establish the use of ELF97, a substrate of TRAP, to visualise and quantify osteoclast activity. This provides vital clues to mechanisms of various bone disorders. TRAP dephosphorylation of ELF97 results in a detectable fluorescent product at areas of osteoclast activity.

Methods: Osteoclastic activity was initiated in zebrafish by inducing crush injuries in tail fin rays. Colocalisation of ELF97 fluorescence with osteoclast-specific DsRed in transgenic zebrafish, visualised under confocal microscopy, is used to further establish the specificity of ELF97 to sites of osteoclastic activity. Quantification is established by comparing fluorescence between wild type, osteoclast-deficient mutants and bisphosphonate-treated zebrafish. The utility of ELF97 will also be investigated in terms of the stability of the fluorescent product.

Results: The investigation revealed that ELF97 and DsRed fluorescence were found commonly at crush sites with osteoclastic activity. Wild type zebrafish had greater fluorescence compared to osteoclast-deficient (p<0.0001) and bisphosphonate-treated zebrafish (p<0.0001) after 7 and 14 days post-crush, revealing that fluorescence from ELF97 corresponds to expected osteoclastic activity. Fluorescence of tail fins treated with ELF97 did not diminish over a period of 21 days of storage, demonstrating its stability.

Conclusion: ELF97 is thus a useful means to visualise osteoclast activity, potentially crucial in more advanced investigations to understand bone disorders. It could be used in combination with other cellular markers in whole biological samples to study and experimentally manipulate bone remodelling.

POS0349
decoy receptor 3 and its signal pathway contribute to pathogenesis in primary gouty arthritis

Y. Jiang1, X. Liao1, S. B. Wang1, Y. X. He1, Y. F. Qing1 on behalf of Institute of Research Center of Gout and Hyperuricemia of the Affiliated Hospital, North Sichuan Medical College. 1Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology, Nanchong, China

Background: Gouty arthritis (GA) is an autoimmune disease caused by the deposition of monosodium urate crystal (MSU) in the joints and surrounding tissues which lead to a series of complex inflammatory reactions and amplification reactions. The clinical symptoms of acute GA attack rapidly, but often alleviate spontaneously within 7 – 10 days, which is one of the significant characteristics different from other joint diseases or autoimmune diseases. However, the exact molecular mechanism of its inflammatory self limitation is still unclear. The biomechanical imbalance of Th1 / Th2 cells and the M1/ M2 polarization of macrophages may be involved in the inflammatory self limitation of gout[1]. Decoy receptor 3 (DCR3) can differentiate T cells into Th2 phenotype, promote M2 polarization of macrophages, and play the functions of immune regulation and repair[2]. DCR3 and its Signal Pathway are involved in the pathogenesis of tumors and a variety of autoimmune diseases, and have become an important research target of tumors and immune related diseases. However, studies on DCR3 related molecular pathway and GA are scarce, and the specific regulatory mechanism is unknown.

Objectives: To assess the contribution of DCR3 and its signal pathway to gout and the clinical importance of these genes in primary gouty arthritis.

Methods: The mRNA expression levels of DCR3 and its signal pathway (DR3, TL1A, Fas, Fasl, Ligh, Light, LtghtRNA) expression levels of DCR3 and its signal pathway (DR3gout and the clinical importance of these genes in primary gouty arthritis.nt research target of tumors and immune related diseases. However, studies on DCR3 related molecular pathway expression levels and laboratory features was analyzed in GA patients.

Results: The expression levels of DCR3, FasL were much lower in the AG and IG group than in the HC groups (p<0.05), and no significant difference was detected between AG and IG group than in the HC groups (p<0.05). The expression levels of DCR3 were much lower in the AG and IG group than in the HC groups (p<0.05), and much lower in the AG group than in the IG groups (p<0.05). The expression levels of TL1A were much higher in the AG group than in the IG and HC groups (p<0.05), and no significant difference was detected between IG and HC groups (p<0.05). The expression levels of Light, LightR were much lower in the AG group than in the HC groups (p<0.05), and no significant difference was detected between AG and IG groups, IG and HC groups (p<0.05). The expression levels of LtghtRNA were much higher in the AG group than in the HC groups (p<0.05), and no significant difference was detected between AG and IG groups, IG and HC groups (p>0.05). In GA patients, the levels of DcR3 related molecular pathway gene correlated with laboratory inflammatory and metabolic indexes.

Conclusion: Altered DCR3 and its signal pathway expression suggests that DCR3 related molecular pathway is involved in the pathogenesis of GA and participates in regulating inflammation and metabolism.

POS0350
micrornas associated with osteoporosis in patients with haemochromatosis arthropathy

S. Finzel1, A. Diendorfer2, B. Butzek3, M. Hackl2, R. Voltz, 1Freiburg im Breisgau, Department of Rheumatology and Clinical Immunology, University Medical Centre, Freiburg im Breisgau, Germany; 2TAmiRNA GmbH, Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Vienna, Austria; 3Hämoblastose-Vereinigung Deutschland e. V, HVD, European Federation of Associations of Patients with Haemochromatosis EFAPH, Hattingen, Germany; 4Freiburg im Breisgau, Department of Rheumatology and Clinical Immunology, University Medical Centre, Freiburg im Breisgau, Germany

Background: Haemochromatosis arthropathy (HA) is one of the most frequent manifestations of hereditary haemochromatosis (HH). Moreover, frequency of osteoporosis is increased in HH. MicroRNAs (miRNAs) are small non-coding RNAs involved in gene silencing, and onset and progression of disease is often reflected in aberrant miRNA expression patterns including osteitis and osteoporosis. Active or passive release of miRNAs from cells enables minimal-invasive detection in biofluids such as plasma (“circulating miRNAs”).

Figure 1. Relative Expression of DcR3 related molecular pathway gene in the PBMCs of Patients. The expression levels of DCR3, FasL were much lower in the AG and IG group than in the HC groups (p<0.05). The expression levels of DCR3 were much lower in the AG and IG group than in the HC groups (p<0.05), and much lower in the AG group than in the IG groups (p<0.05). The expression levels of TL1A were much higher in the AG group than in the IG and HC groups (p<0.05). The expression levels of Light, LightR were much lower in the AG group than in the HC groups (p<0.05). The expression levels of LtghtRNA were much higher in the AG group than in the HC groups (p<0.05).

Disclosure of Interests: None declared

OBJECTIVES: We aimed to investigate whether circulating miRNAs involved in osteoporosis as well as liver disease in healthy elderly individuals are also elevated in patients with HH.

METHODS: Plasma of 28 HA patients homozygous for C282Y (60.71% female), 8 HA patients heterozygous for C282Y (50% female), and 12 controls (66.67% female), was analyzed using the osteomiR and the hepatomiR RT-qPCR kits. Levels were normalized using spike-in controls and non-parametric analyses were performed to associate miRNAs to other clinical parameters and test for differential regulation of miRNAs between the groups.

RESULTS: Even though mean age was different between the three groups (70.64, 52.38, 61.92 years), correlation analysis identified only weak or no associations to miRNA levels. In patients with osteoporosis (n=9, all female, all homozygous) miR-203a-3p, 214-3p (both bone-related), and 122-5p (liver-related) were significantly downregulated (Kruskal Wallis p=0.024, p=0.037, and p=0.00024). Interestingly, miR-122-5p also showed a clear trend for down-regulation in homozygous HH compared to heterozygous HH and controls (p=0.087).

CONCLUSION: This is the first study reporting miRNAs involved in osteoporosis and liver diseases in patients homozygous for C282Y.

POSO351 NEITHER ANTI-CITRULLINATED PROTEIN ANTI-BODIES (ACPA) NOR POLYCLONAL lgG ARE ASSOCIATED WITH BONE MASS, IN ELDERLY MEN

M. Nurkkala1, M. Lagerquist1, P. Gupta1,2, D. Mellström1, C. Ohlsson1, C. Engdahl1,2, 1University of Gothenburg, CBU, Dept. of Rheumatology and Immunisation, Göteborg, Sweden; 2University of Gothenburg, CBU, Dept. of Internal Medicine, Göteborg, Sweden

BACKGROUND: Bone loss is associated with anti-citrullinated protein antibodies (ACPA) positivity in rheumatoid arthritis (RA) patients. This is shown in both in pre-clinical RA, and in more pronounced bone loss in serum positive patients compared to serum negative patients. Further, both ACPA and activated IgG stimulate osteoclastogenesis in vitro and in murine arthritis-mediated bone loss.

OBJECTIVES: Whether polyclonal IgG or autoantibodies are important for general bone architecture, and not only in arthritis-mediated bone loss, has not been determined but they may represent an important link between the immune system and bone.

METHODS: Polyclonal IgG and ACPA were measured with ELISA in serum of 600 elderly men (mean age 80.2±3.5 years), in the cohort MoS Gothenburg. In this cohort, bone was investigated with Dual-energy-x-ray absorptiometry (DXA) and high-resolution 3D peripheral quantitative computed tomography (HR-pQCT). In C57/Bl6 mice, high dose heat-activated polyclonal IgG was repetitively injected systemically or intraarticularly, and the bone was investigated with DXA and micro-CT.

RESULTS: No association was determined between existing serum polyclonal IgG and ACPA, with the measured bone parameters, not total bone density, trabecular or cortical bone in the MoS cohort. Systemic injection of activated IgG in mice did not affect general bone health, not total, trabecular, or cortical bone. Intraarticular injection of activated IgG was shown to give a local reduction in trabecular bone density of the tibia.

CONCLUSION: These data indicate that serum polyclonal IgG and ACPA do not influence general bone health in elderly men. However, in mice injection with activated IgG intraarticularly leads to a local reduction in trabecular bone mass. In conclusion, our data imply that ACPA and activated IgG need to be present in close connection to the bone, e.g., in the synovial area, to be able to mediate a reduction in bone mass.

PARE Poster Tour 2

POSO352-PARE PODCAST FOR RHEUMATISM SUFFERERS AND THEIR RELATIVES

M. Sibert1, T. Spichtig1, 1Swiss League Against Rheumatism, Communication, Zurich, Switzerland; 2Swiss League Against Rheumatism, Communication & Fundraising, Zurich, Switzerland

BACKGROUND: Two million people in Switzerland suffer from rheumatic diseases. The Swiss League against Rheumatism is committed to helping those affected. It provides them and their relatives with professional, neutral information on the subject of rheumatism. The Swiss League against Rheumatism has been publishing the podcast series “Rheumatism in person” since 2021. In it, affected people discuss relevant and current topics about living with rheumatism with experts. Another aim is to devote time to the personal experiences of sufferers. The pool of experts includes medical specialists, nutritionists, social counsellors and psychologists.

OBJECTIVES: The Swiss League against Rheumatism, as the national umbrella organisation, is expanding its communication services via the podcast in order to reach even more people with rheumatism in Switzerland. This makes it possible to increasingly address a younger, digital-savvy target group and to expand the service proposed for this target group. The podcasts are primarily aimed at people with chronic forms of rheumatism between the ages of 25 and 50 and their relatives in German-speaking Switzerland. A further aim is to bring the opinions of those affected to the attention of the public, as well as to provide information from specialists, thereby creating greater awareness of the disease.

METHODS: Each podcast episode is about 30 minutes long. According to experience, this length is the most popular with most listeners, whilst also allowing complex topics to be explored in depth. The podcasts are issued monthly. This enables listeners to be prepared for a fixed release date. The episodes are produced in cooperation with a podcast agency. The advantage of an agency lies in its expertise and experience, especially in the technical field. Funding for the podcast episodes can be secured from sponsors.

“When things get complicated – social counselling for rheumatism,” “Sport and rheumatism – anything but a contradiction?” or “Rare forms of rheumatism – lupus, EDS & co.” are popular episode titles, to name but a few.

The podcasts are available on various international podcast platforms. The episodes are distributed via blog posts, existing newsletters and social media (Facebook, Instagram and LinkedIn). External distribution channels are used in the form of the interviewees’ networks, the “Junge mit Rheuma” (young people with rheumatism) group, national patient organisations, cantonal/regional rheumatism leagues, the Swiss Society of Rheumatology and any media coverage attracted.

RESULTS: So far, the eleven episodes and accompanying trailer have been downloaded or streamed over 8,200 times by 5,300 unique listeners.

All eleven topics were of great interest. The episode on “Anti-inflammatory nutrition” generated the most downloads (1,550), closely followed by the episode on “The coronavirus pandemic with rheumatism,” which reached just under 1,300 downloads (as of 21 January 2022). On 15 March 2021, the podcast series also made it onto the podium of a well-known podcast chart in the field of medicine. This clearly shows that there is a need among rheumatism sufferers and their relatives to obtain information via podcasts.

The large quantity of positive feedback from patients, rheumatologists and other health professionals is particularly noteworthy. “From the first second: very interesting topics, well produced and a great voice,” shared a listener.

CONCLUSION: The podcast series has proved successful and will therefore be continued as a complementary communication tool for the Swiss League against Rheumatism. In addition to the episodes already released, another ten episodes are planned in German.

The Swiss League against Rheumatism is keen to extend the podcast series to the French-speaking part of Switzerland. The idea is therefore to include French episodes in 2022. There are specific plans to record three episodes, which will be broadcast in the second half of the year. The aim is to add more episodes to the French podcast series in the long term.

THE POLITICAL WORK FOR BETTER TREATMENT OF MUSCULOSKELETAL DISEASES IN DANISH MUNICIPALITIES

K. Hammendon1 on behalf of The Danish Rheumatism Association, 1The Danish Rheumatism Association, Department for Politics and Knowledge, Gentofte, Denmark

Background: Historically most treatment of musculoskeletal diseases in Denmark has taken place in hospitals. Today, treatment is split between different sectors, where the requirements are widely different. Physiotherapists, occupational therapists and dietitians are, to a certain extent, no longer found in the rheumatic sections of the hospitals, but rather expected to take care of rehabilitating treatment in one of the 98 municipalities. With the clinical guidelines, the Health Authorities has indicated which treatment areas the individual groups of patients will benefit from – however, there is lack of provision of these in many of the municipalities across the country.

Objectives: To secure that treatment guidelines - within the field of musculoskeletal diseases - made by The National Board of Health, are transformed into national quality standards for treatment in the municipalities.

Methods: To ensure that patients get the treatment needed, we have worked with external consultants resulting in two research papers (visible at link) on the subject at hand. One paper mapped how many of the 98 municipalities provides each of four treatment guidelines made by The National Board of Health. The four being - weight loss, education and physical training for hip- and knee osteoarthritis, education and physical training for patients with back conditions and interdisciplinary treatment for people with pain conditions. The other paper uncovered the potential economic gains for the public sector by introducing the treatment guidelines.

The Danish Rheumatism Association has used these research papers as a significant driver for a large conference in October 2021 at the Danish Parliament – Christiansborg. Essential national politicians where present and they acknowledged the need for an increased focus on the treatment areas.

The results of the reports has also been shared with government officials, an existing commission on labor supply as well as municipalities etc.

In connection with the recently held elections in Danish municipalities and regions, we have reached out to the local politicians experiencing a gap in the offerings either directly or through local media which will hopefully result in an uplift of the focus. In addition, we have made debate posts with among others - unions sharing our point of view.

Results: Essential national politicians acknowledged the need for an increased focus on the treatment areas.

We hope that both from the municipalities as well as from a national level initiative will be taken to introduce a set of national quality standards within the field of musculoskeletal diseases because of our forceful approach.

Conclusion: The increased focus on treatment of musculoskeletal diseases is the result of strong collaboration between The Danish Rheumatism Association department for Politics and Knowledge, Internal Communications and external partners. We believe that our work can inspire other European NGO’s who has a need to increase their political agenda and awareness. We made a long-term goal, focus on the treatment areas.

We believe that our work in collaborating with The Danish Rheumatism Association will help us achieve the goals.

LONGITUDINAL INVESTIGATION AND VISUALIZATION OF COURSE AND BURDEN OF ADVERSE DRUG REACTIONS IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES USING TNFα-INHIBITORS

M. De Boer1, H. Gosselt2, J. Jansen3, M. Van Doorn1,2,3, F. Hoentjen4,5, M. Nurmohamed1, P. Spuls2, S. Tas3,4, H. Vonkeman5,10, N. Jessurun6

1University of Alberta, 2Radboud University, 3Centre for Human Drug Research, N/A, Leiden, Netherlands, 4Erasmus MC, Department of Dermatology, Rotterdam, Netherlands, 5Centre for Human Drug Research, N/A, Leiden, Netherlands, 6Amsterdam Rheumatology Immunology Centre (ARC), N/A, Amsterdam, Netherlands

Background: Patients are increasingly involved in the decision process regarding their medicines, but a discrepancy exists between the information provided and preferred. Information on adverse drug reactions (ADRs) relies on frequency, but little is known about the course and burden of ADRs.

Objectives: We aimed to investigate the course and burden of ADRs over time attributed to using TNFα-inhibitors in patients with inflammatory rheumatic diseases (IRDs) and to assess whether Sankey diagrams and polar plots are suitable to provide visualization of these aspects.

Methods: We used data of the Dutch Biologic Monitor [1], in which biologic users with an immune-mediated inflammatory disease filled out bimonthly surveys about ADRs experienced and specifically the ADR course and burden. ADRs were coded according to the MedDRA terminology. ADR course was scored as worsening, improving, remaining stable or resolving over time, with room to give a description. Furthermore, it was assessed whether an ADR was recurrent or not. Patients scored burden on a scale ranging from 1 (no burden) to 5 (very high burden). We selected patients with rheumatoid arthritis (RA), psoriatic arthritis or axial spondyloarthritis using a TNFα inhibitor (adalimumab, certolizumab pegol, etanercept, golimumab or infliximab). They also had to report an ADR belonging to the system organ classes ‘Infections and infestations’ or ‘Skin and subcutaneous tissue disorders’, or the high level term ‘Injection site reactions’ and completed ≥2 consecutive questionnaires (representing circa ≥4 months). These types of ADRs were chosen as they impose the highest burden for patients. [2]

Results: A total of 202 patients met the inclusion criteria (71.6% female, mean age 54.8 years (±12.7 years)). The majority of the patients (61.9%) was diagnosed with RA. Most frequently used TNFα inhibitors were adalimumab (37.1%) and etanercept (54.0%). In total 353 ADRs were reported, of which 76 (21.5%) were categorized as ‘Skin and subcutaneous tissue disorders’, 122 (34.6%) as ‘Infections and infestations’ and 155 (43.9%) as ‘Injection site reactions’. The course of the ADRs is visualized in Sankey diagrams (Figure 1a–c); the flows show possible ADR courses, the width of each is proportional to the number of ADRs following that course. Most skin reactions did not change during follow-up (25.0%, Figure 1a), only a few were recurrent. Most infections resolved over time (50.8%, Figure 1b), with some remaining stable and some being recurrent. Most injection site reactions (72.3%, Figure 1c) were recurrent, and resolved in only a minority of the patients (13.4%) during follow-up. The polar plots (Figure 1d–f) visualizes the burden of the ADRs over time. For skin reactions and infections a decreasing trend was observed, represented by fading of the colors to the periphery. Infections had the highest burden at the start of the ADR, indicated by the darker colors in the inner circle. Injection site reactions had a relatively low and stable burden over time, shown by the lighter colors continuing over the circles.

Conclusion: Skin reactions attributed to the use of TNFα-inhibitors by IRD-patients show a stable course over time with a slightly diminishing burden over time. Infections have the highest burden at start but decrease over time and most of them resolve during follow-up. Injection site reactions are mostly recurrent with a low and stable burden over time. We propose that Sankey diagrams and polar plots are suitable to visualize the course and burden of ADRs over time.

Scientific Abstracts

POS0356-PARE

M. Nudel1. 1Mifrakim Tze’irim, None, Haifa, Israel

Since 2016 we had a dream to construct a self-management course for members of The Israeli association for RMDs patients Mifrakim Tze’irim. On September 2018, our CEO heard a lecture by Mrs. Mary Vella, the president of ARAM Malta, and the rest is history.

We approached PARE through AGORA for the Knowledge Transfer Program Grant, and got approved in February 2019. The need to develop such a course came from members of the association, as well as posts in Facebook groups. Concerns, fears, and uncertainties about how to live with a chronic illness.

Mitrakim Tz’eerim is committed to reaching out to children, youth, adults and seniors with autoimmune and inflammatory joint diseases and rare autoimmune and various inflammatory diseases and to their families. The association assists its members and provides them with support and available tools on a personal, family, and social level. Our goal is to act for increasing public awareness of these diseases and their day-to-day impact on patients, to expand knowledge and disseminate information about them, patient rights and innovations in treatment, as well as to promote access to a variety of advanced treatments and medications for the members.

Objectives: Providing tools for daily coping and optimal conduct in chronic illness situations in a wide range of aspects: a self-management triangle:

1. Medical / biological (better / helpful understanding of the situation)
2. Emotional (identify and manage the emotional impact)
3. Social (adjusting the way you manage your daily life)

METHODS:

1. Receiving a grant from PARE - The Knowledge Transfer Program Grant, through AGORA
2. Cooperation with ARAM - Arthritis & Rheumatism Association Malta
3. A study visits to Malta
4. Monitoring the process in Israel by ARAM
5. Founding a management team for the course
6. Localizing adaptation of the learned content for Israelis and introducing new content of our own
7. Promotion of the course to the association members, selecting participants
8. December 2019 the first course started. In 2020-2021 we had 3 more cycles of the course to the members. We had 40 participations
9. Following the pilot course - generating conclusions, lessons, and adjustment of the syllabus accordingly
10. Three more courses are planned for 2022

RESULTS:

1. Excellent feedback from ARAM during the control performed
2. Participants provided outstanding feedback on the course
3. Course graduates established designated WhatsApp groups for ongoing mutual support, thus creating empowerment circles, including periodic physical meetings

CONCLUSION:

1. In My Hands course provides a highly efficient and relevant toolbox.
2. The course should be continually offered to people coping with chronic diseases
3. Finger on the pulse - ongoing drawn conclusions to be implemented for adjusting the syllabus
4. The course should be promoted gently, since it marks a change in life, which can threat some people’s perception
5. We have expanded and offered participation to members of other patient associations that we collaborate with
6. Graduates of the course become ambassadors, spreading the benefits received by the course
7. Graduates of the course are a vivid example of the chance of improving your life even when you cope with chronic diseases
8. Graduates of the course influence their immediate circles to adapt and adopt changing habits

IN OUR HAND – SELF MANAGEMENT COURSE (FOR PEOPLE WITH CHRONIC RHEUMATIC DISEASES)

Figure 1. Summary diagrams and solar plots of the course and burden of eA skin and subcutaneous tissue disorders &ILD infections and reiterations and eA injection site reactions

M. Nudel1. 1Mifrakim Tze’irim, None, Haifa, Israel
Background: Patients with rheumatic diseases show impaired quality of life (QoL): disease activity, comorbidities and treatment-related side effects contribute to decrease physical, emotional, and social functioning. The COVID-19 pandemic challenges health care systems and patients with chronic conditions: hospital and outpatient clinics delayed access, unpredictable changes like non-adherence to medication, but also negative emotions, psychological conditions recognized as risk factors for the poor QoL [1-2].

Objectives: To describe the impact of the COVID-19 pandemic on the QoL of Italian patients with rheumatic diseases in the first period of the national lockdown.

Methods: APMARR (Associazione Nazionale Persone con Malattie Reumatologiche e Rare) invited Italian patients and caregivers to participate to an online structured survey in the period March–June 2020. Informed consent was retrieved. The questionnaire, promoted by the patient advocacy website, collected demographics, emotional and healthcare pattern information.

Results: 87.44% (N=215) complete questionnaires were retrieved (96.3% patients; 3.7% caregivers; 87.77% female; 2% aged <18 years, 16% aged 18-30 years, 82% aged >31 years; 0.53% missing data). Respondents were illustrative of the Patient Advocacy regional distribution (Puglia Region predominant). Rheumatoid arthritis regarded 29% of respondents, ankylosing spondylitis 17%, psoriasis 16%, remaining 38% other rheumatoid diseases. 96% of respondents were employed, 39% of which had to discontinue/change working activity during pandemics. 60% of respondents reported being worried about their disease. The deriving distress was the main cause of anxiety, which was not controlled even by compliance to the treatment plan (88%). 30% of respondents was worried about virus infection, Irritabilty, appetite and sleep disorders were also reported: anxiety had effects on irritability (46% sometimes more irritable) and sleep quality (38% always disturbed). GPs visits access was limited (40% considered it absent and 76% had to postpone it). Only 32% of specialist centers provided facilitated patterns of care.

Respondents suggested possible solutions to improve QoL during COVID-19 pandemic and over it. Psychologist support was suggested as useful by 44% of respondents to manage therapies and by 96% to enjoy daily life. The home infusion would be of support according to 44% of respondents (18% already got access to it). Patient Advocacy had a major role in the new care and life context: 80% would consider it useful to participate to and 81% was satisfied by the prompt and continuous support received during pandemics.

Conclusion: Similar results as far as distress were reported by Italian and foreign evidence, which demonstrated considerable COVID-19 related psychosocial burden in rheumatic disease patients [3-5]. Potential solutions are also with EULAR recent guidelines, which underlined how psychological interventions were found to reduce pain and fatigue even in difficult-to-treat patients [6] and how mental health needs should be periodically assessed, due to the link between better emotional well-being and better self-management [7]. Besides, the reported picture of reorganised care during pandemic corresponded to the real-world experience of the Italian Regions [8]. New approaches of care like home infusions and telemedicine supported by patient organisations should become routinary and may therefore benefit patients.

Disclosure of Interests: None declared

fever syndrome” (PFS), “familial Mediterranean fever” (FMF), “cycloprogn
associated periodic syndrome” (CAPS), “tumor necrosis factor associated
periodic syndrome” (TRAPS), “adult onset of still’s disease” (AOSD) and
“systemic juvenile idiopathic arthritis” (sJIA). For every keyword, the top 20
videos in their order of relevance were included. Video duration, number of
views, likes, dislikes, comments and uploading source were extracted.

The quality of a video’s information was evaluated independently by two
physicians based on the modified global quality scale (GQS) (2). Subgroup
analyses were performed classifying healthcare professionals and patients
as target group.

Results: In total 140 videos were screened. We excluded 5 videos due to
language other than English, 7 duplicates and 23 not suitable ones. 105
videos met the inclusion criteria for further analysis. Video characteristics
are presented in Table 1. Based on the GQS, overall quality of videos for
patients was found to be low in 64,8%, intermediate in 27,6%, and high in
7,6% of videos. The quality of videos for professionals was similar: 54,3%
were judged to be of low, 23,8% of intermediate, and 21,9% of high quality
(Figure 1). Subgroup analyses focusing on videos for professionals found
sJIA videos to achieve the highest scores (31,6% with high quality) whereas
videos regarding CAPS were rated the least useful ones (15,4% with high
quality). In videos for patients, sJIA videos also ranked highest (42,1% with high
quality) whereas no high quality videos could be identified for TRAPS.
Videos are more often aimed at specialists such as doctors or medical stu-
dents (65.7%) and less often at affected patients or relatives (34.3%). Video
duration was significantly longer in videos targeting a professional audience
(p < 0.001). In videos for professionals, length was significantly correlated
with higher quality (p < 0.001).

Conclusion: YouTube as a source of information could have great potential
for rare diseases. However, this study demonstrates that the majority of videos
regarding AIDs is of limited quality and available videos more often adress users
with a professional medical background. Only a small proportion of existing vid-
eos provide understandable and useful information for AID patients.

POSO360-PARE

EDUCATIONAL NEEDS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS AND HEALTH
PROFESSIONALS IN RHEUMATOLOGY: A SWISS CROSS-SECTIONAL QUALITATIVE ANALYSIS

A Grosse1, 2, C Madelaine-Bonjour1, 3, University of Geneva, Patient Education, Geneva, Switzerland; 1Sjögren Europe, Federation of European Sjögren’s Patient Associations, Bienne, Switzerland; 2Lausanne University Hospital, Rheumatology, Lausanne, Switzerland

Background: The content and delivery of patient education (PE) should be indi-
vidualy tailored and needs-based for people with inflammatory arthritis1. There-
fore, a patient trained in PE joined forces with a rheumatology clinical nurse
specialist to explore the needs for the management of patients with RA in a
Swiss local context (rheumatology department of a university hospital).

Objectives: To identify the difficulties and needs of patients with RA regarding
their disease and its management in a local context, from both perspectives:
patients and health professionals (HPs).

Methods: We developed 2 different semi-structured questionnaires for each sur-
veyed group. They were distributed to 93 patients and 62 HPs during Summer
2020. Only the fully completed surveys were analysed. A qualitative analysis of
the answers to the open questions was carried out and the phenomena thus
identified were then quantified.

Results: We collected 38 patient (40%) and 35 HP (56%) questionnaires, and 23
patients (25%) and 21 HPs (34%) filled them completely out. Participants among
patients were mostly female (74%) with a mean (SD) age of 54.8 (10.9). Mean (SD)
number of years of illness after diagnosis was 11.9 (12,6). HPs were nurses (57.1%),
medical doctors (19%), occupational therapists (14,3%), physiotherapists (4.8%) and assistant nurses (4.8%).
Almost half of HPs (48%) and 39% of patients experience difficulties to talk about
sensitive topics like sexuality, financial or emotional difficulties.

A third of patients (30%) wished a more supportive attitude from HPs and
HPs (62%) would like patients to be more involved in their care, more speci-
cifically regarding autonomy and treatment adherence. A few HPs (9%) and
patients (19%) want to improve patient-centred and personalised care. Most
of HPs (81%) and patients (87%) state that they have no objection or reluc-
tance to PE being developed in the department. Some HPs see PE as an
additional workload (19%) and others as a tool to involve the patients more
in their care (43%).
HPs (43%) express a need for patient’s and disease’s management training
and wish to acquire additional tools and methods to better assist their patients
(43%). A third of them (33%) report a lack of communication, collaboration and
interdisciplinarity to support patients. Furthermore, due to the lack of time and
availability, 67% of them are not able to provide adequate time for meeting the
patients’ needs. Some HPs feel powerless to help their patients (19%). Some oth-
ers (18%) highlight the difference of perspectives and concerns between patients
and HPs.
Patients and HPs agreed on most of the main difficulties related to the disease
and follow-up. It should be noted that HPs were not aware of the difficulties
related to their patients’ sleep. The painful and distressing psychological and
emotional impact of RA is the difficulty most cited by patients (74%) and the
second most mentioned by HPs. More than half of patients (61%) have difficulty
managing their pain.

Conclusion: The results of this study confirm the need for PE in the depart-
ment. Communication is a challenge for both populations. HPs know their
patients well, but patients and HPs have different expectations regarding
disease’s management and follow-up. This work shows the importance of
analysing educational needs: it brings out dimensions of the disease and its
management that are sometimes hidden or underinvestigated. It thus helps
us to have a better understanding of the reality and difficulties as they are
experienced by people in order to propose appropriate solutions. This
work provides a basis for reflection and discussion for the future develop-
ment and implementation of a PE program, based on the paradigm of the
patient-HP partnership. In addition to being an example of an advanced
and successful patient-HP partnership, it also demonstrates the benefits of
such collaboration.

Systemic Lupus Erythematosus: monitoring and management

FACTORS ASSOCIATED WITH CHANGES IN COPING BEHAVIOUR IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS - A LONGITUDINAL STUDY OF THE LULU COHORT

E. Reutemann1, R. Brinks2, J. G. Richter3, R. Fischer-Betz4, B. Winkler-Rohlfing4, M. Aringer1, G. Chehab1
1Policlinic for Rheumatology & Hill Research Unit for Rheumatology, Medical Faculty, Heinrich-Heine University, Düsseldorf, Germany; 2Chair for Medical Biometry and Epidemiology, Witten/Herdecke University, Faculty of Health/School of Medicine, Witten, Germany; 3German Lupus Self-Help Community, Wuppertal, Germany; 4Department of Medicine III, Division of Rheumatology, TU Dresden, Dresden, Germany

Background: Patients with Systemic Lupus Erythematosus (SLE) experience both physical and psychosocial restrictions that negatively impact their quality of life. Coping mechanisms have turned out to be important contributors to health-related outcomes, not only in SLE but also other chronic conditions. However, there is limited understanding of factors that enhance or hamper coping in SLE.

Objectives: To analyse parameters associated with longitudinal changes in coping behaviour in patients with SLE who take part in a long-term SLE patient cohort study.

Methods: Since 2001, the German nationwide SLE patient longitudinal (Lupus Langzeit ‘LuLa’) study annually administers self-reported questionnaires to SLE patients. In addition to demographic and the annually probed extended clinical data (e.g., medication, disease activity, fatigue, depression), in both 2009 and 2014 we assessed the Pain-related Self Statements Scale (PRSS) to perceive information related to coping behaviour. This includes ‘positive coping’ as well as catastrophizing as a dysfunctional form of coping behaviour.

Statistical analysis was accomplished by a linear regression model adjusting for age, pain, number of comorbidities and net income. The PRSS score difference from 2009 and 2014 was used as the dependent variable. Factors from the i) medical (infection, mood, fatigue), ii) activity (basic, leisure, sports), iii) intrinsic (depression, kinesiophobia, perceived health control), and iv) social participation categories were entered as independent variables.

Results: 272 patients (96.7% female) provided valid PRSS questionnaires in both 2009 and 2014. In 2009 the mean age in this cohort was 51 ± 12 years (SD 11.2) with an average disease duration of 16.2 years (SD 8.3). The mean reported lupus activity (VAS 0-10) during the last three months was 3.7 (SD 2.4). During the six-year observation period, the proportion of improvement (46.2%) and deterioration (47.4%) in coping score was almost balanced, while in catastrophizing score more participants improved (50.0%) than deteriorated (37.0%). A perceived high health-related control, thus the belief that health outcomes are contingent on personal behaviour, was associated with an improvement in the coping score [HLC, b=0.061 (95%-CI 0.014; 0.109), p=0.012]. Conversely, high external control convictions, e.g., the belief that doctors and other third parties determine health outcomes, were associated with a worse coping score [HLC, b=-0.090 (95%-CI -0.154; -0.028), p=0.006]. Deterioration in depression [ADS-L, b=0.015, (95%-CI 0.006; 0.023), p=0.002] and impaired social participation [IMET, b=0.043, (95%-CI 0.000; 0.085), p=0.050] were associated with a deterioration of catastrophizing, whereas better internal control [HLC, b=-0.046, (95%-CI -0.080; -0.012), p=0.009] was associated with its improvement.

Mucocutaneous involvement, fatigue, and the extent of physical activity were not significantly associated with either coping or catastrophizing scores in the regression analysis.

Conclusion: In line with data from other chronic diseases, our findings in a longitudinal SLE cohort emphasise the role of intrinsic factors, such as mental health status and self-efficacy, improving the quality of life in SLE patients via successful coping behaviour. Affirmative action measures and programs to improve social participation may yield additional benefits.

DOI: 10.1136/annrheumdis-2022-eular.4974
clinical SLEDAI ≥5 and 98 (24.6%) had clinical SLEDAI 1-4. The mean total SLEDAI was 3.02±2.87 and PGA score was 0.60±0.53. A total of 178 patients (44.6%) had SDI score ≥1. The mean SIMPLE index was 25.6±12.8. SIMPLE index correlated significantly with clinical SLEDAI (ρ=0.75; p<0.001), total SLEDAI (ρ=0.75; p<0.001) and PGA score (ρ=0.41; p<0.001). At visit 3, 87 and 38 patients, respectively, had a drop in total SLEDAI score by ≥1 and ≥4, and the corresponding change in SIMPLE index was 35.3±13.7 to 25.0±10.1 (p<0.001) and 42.9±19.9 to 26.0±11.1 (p<0.001). Conversely, 103 and 29 patients, respectively, had an increase in total SLEDAI score by ≥1 and ≥4. The corresponding change in SIMPLE index was 23.5±11.3 to 25.7±10.1 (p=0.007) and 25.3±13.7 to 27.3±11.6 (p=0.27). Change in SIMPLE index from visit 1 to 3 correlated significantly with the change in total SLEDAI (ρ=0.35; p<0.001), clinical SLEDAI (ρ=0.19; p<0.001) and PGA (ρ=0.14; p=0.005). ROC analysis performed with pooled data from all the 3 visits showed that a SIMPLE index ≥34 points best predicted a clinical SLEDAI score of 1-4 (area under the curve [AUC] 0.72[0.68-0.75]; sensitivity 0.65; specificity 0.64), and ≥31 points best predicted a clinical SLEDAI score of ≥5 (AUC 0.84[0.77-0.91]; sensitivity 0.76, specificity 0.81).

Conclusion: The SIMPLE index shows a good correlation with SELENA-SLEDAI and PGA. It is also sensitive to change in SLEDAI and PGA score during subsequent visits. The SIMPLE index is a simple tool that enables patients to self-report disease activity and communicate with the health care team more efficiently.

POS0364 UNMET NEEDS IN THE TREATMENT OF EXTRA-RENAL FLARES IN SLE PATIENTS: REAL LIFE EXPERIENCE VS ARTIFICIAL APPROACH

M. Maffi1, L. Scagnellato1, A. Collesei2,3, E. Elefante1, C. Stagnaro1, F. Ferro1, L. Carli1, V. Signorini1, D. Zucchi1, F. Trentin1, C. Tani1, M. Mosca1,1University of Pisa, Rheumatology, Pisa, Italy; 2University of Padua, Surgery, Oncology and Gastroenterology, Padua, Italy; 3Familial Cancer Clinics, Veneto Institute of Oncology, IOV-IRCCS, Padua, Italy

Background: Systemic lupus erythematosus (SLE) is a heterogeneous disease which can affect various organs and is characterized by different clinical phenotypes. While the treatment of renal involvement is quite standardized, the therapeutic approach to extra-renal manifestations is subjected to a degree of variability.

Objectives: 1. To describe extra-renal disease flares in terms of clinical phenotype and outcomes in SLE patients 2. To compare data from a real-life setting with a machine learning (ML) approach.

Methods: This study is a retrospective analysis of data from a monocentric cohort of SLE patients who experienced a disease flare between 2015 and 2020. Each flare was followed for one year and was classified according to the organ involvement and categorized according to the BILAG definition of flare. At baseline and at 3,6,12 months the following variables were collected: disease activity (SELENA-SLEDAI) and categorized according to the BILAG definition of flare. At baseline and during follow up were analyzed in terms of explained variance across the dataset’s Principal Components and clustered with a hierarchical unsupervised learning approach. A ML model based on neural networks was built to early detect flares’ therapeutic difficulty: it was validated after data augmentation to satisfy statistical requirements during the training phase.

Results: 66 extra-renal flare were investigated (Table 1); 5 flares (7.5%) were treated with glucocorticoid (GC) pulses and 61 (92.5%) with oral GC therapy, while an immunosuppressive (IS) treatment was prescribed in 44 flares (66.7%). The remission rate at 12 months for the whole group was 50%, with musculo-skeletal (MS) flares, mucocutaneous (MC) flares and others (neuropsychiatric, cardiopulmonary, constitutional, haematologic) that were respectively 63.6%, 31.3% and 41.2%, showing lower rate of remission for MC flares.

Figure 1. Flare clusters.

Conclusion: These data suggest that, in a real-life setting, the clinical response rate to therapy of patients with an extra-renal flare is not satisfactory, thus identifying an unmet need in the treatment of SLE and highlighting the absence of a standard treatment. Both the real-life data and the machine learning approach identify flares with MC manifestations as the most difficult to treat with the lower rate of remission after one year. Further prospective studies are necessary to improve the neural network model; ML techniques could help in the early identification of difficult to treat flares to be candidates for new and more aggressive therapeutic strategies for extra-renal manifestations.

POS0365 RELAPSES ARE COMMON IN SEVERE HEMATOLOGIC SLE: REAL-LIFE EXPERIENCE FROM THE “ATTIKON” LUPUS COHORT

G. S. Moysidou1, S. Flouda1, M. Kosmetatou1, N. Kapsala1, D. Tseronis1, M. Aggelakos1, T. Karageorgas1, D. Nikolopoulos1, K. Chavatzis1, A. Filippopoulou1, K. Zoupidou1, P. Katsimpi1, A. Fanourakis1, D. Boumpas1,1National and Kapodistrian University of Athens, 4th Department of Internal Medicine Attikon University Hospital, Athens, Greece

Background: Hematological manifestations are common in systemic lupus erythematosus (SLE), and are thought to result from immune-mediated peripheral cell destruction or bone marrow failure (1,2).

Objectives: To assess the clinical characteristics and outcomes of severe hematological disease in a large cohort of lupus patients.

Methods: Retrospective analysis of the “Attikon” lupus cohort (over 800 patients total) (3) for the identification of patients with a history of severe hematological manifestation. The latter were defined as: thrombocytopenia with a platelet count <30,000/mm3, hemolytic anemia with an hemoglobin <8 g/dL, neutropenia with less than 500 neutrophils/mm3, history of thrombotic microangiopathy (TMA) or macrophase activation syndrome (MAS). Treatments and long-term outcomes (relapses, mortality) were recorded.

Results: Among 300 patients with hematologic manifestations, 40 patients had severe disease. Most of them were women (75%). Mean age at SLE diagnosis was 41.1 years and mean disease duration at diagnosis of cytopenia was 3 “flare in polymorphic disease with mild activity” and cluster 4 “recurrent skin flares”. Interestingly, cluster 4 (recurrent skin flares) was associated with the lowest rate of remission at 12 months with respect to clusters 1, 2, and 3 (33% vs 40%, 76.5% and 56% respectively). Moreover the neural network model correctly predicts difficult to treat flares in up to 80% of the cases.

POSO366 MODERATE RATES OF TREATMENT INTENSIFICATION IN SLE PATIENTS WITH RESIDUAL DISEASE ACTIVITY

O. Gioi1, M. Nikoloudaki2, K. Chavatza3, E. Kalav1, A. Elezoglu4, P. Sidiropoulos2, G. Bertias2, D. Boumpas2, A. Fanouriakis5, A. Asklepioi1 General Hospital, Department of Rheumatology, Athens, Greece; 1University Hospital Heraklion, Rheumatology, Clinical Immunology and Allergy, Crete, Greece; 2Attikon University Hospital, Athens, Greece; 3University Hospital Heraklion, Rheumatology, Clinical Immunology and Allergy, Crete, Greece; 4University Hospital Ana Kari, Athens, Greece; 5Axion Medical Center, Athens, Greece

Background: The treat-to-target (T2T) strategy has gained significant attention in SLE,1 whereas UPLAR has set remission or low disease activity as the goal of treatment.2 Nevertheless, the degree to which T2T is followed in real-life clinical settings has not been extensively studied.

Objectives: To assess the proportion of lupus patients with residual disease activity that had their therapy intensified during their most recent visit, identify associated factors, and assess the validity of the SLEDAI-2k as a predictor of therapy intensification.

Methods: Cross-sectional study of SLE patients who were evaluated in three tertiary centers in Greece during their last visit. Patients were categorized in four disease activity states (remission on and off treatment, low disease activity and non-optimally controlled), according to definitions used in previous studies.3 Intensification of treatment was defined as addition/increase of glucocorticoids (GC) or addition/increase of immunosuppressive (IS) agent (conventional or biologic). Logistic regression analysis was used to identify factors associated with treatment intensification and ROC analysis to calculate sensitivity, specificity of different SLEDAI-2k cut-off values to predict this escalation.

Results: 332 patients were included [93.1% female, mean (SD) age 48.5 (14.7) years, median (IQR) disease duration 6.5 (12.4) years]. Regarding disease activity states, 23.2% (n=77) of patients were in remission (off or on therapy), 36.7% (n=122) were in LDA, while 40.1% (n=133) were categorized as non-optimally controlled disease.

Within patients with residual disease activity, therapy intensification was offered to 25.6% and 48.9% of those with low disease activity and non-optimally controlled disease, respectively. In multivariable analysis, proteinuria (OR 6.78, 95% CI 2.06 – 22.23), arthritis (OR 5.48, 95% CI 3.20 – 9.40) and rash (OR 5.23, 95% CI 1.81 - 15.76), were associated with intensification of therapy. The AUC of the ROC analysis for total SLEDAI-2k to predict therapy escalation was 0.761, indicating only fair accuracy; the cut-off value with the best combination of sensitivity and specificity was 3 (sensitivity 87%, with a specificity of 55%). For clinical SLEDAI-2k, the respective AUC was marginally better (0.779), with a cut-off of 3 being associated with the best sensitivity (80%), with compromised specificity (64%)

Figure 1. ROC analysis of total and clinical SLEDAI to predict any increase in therapy

Conclusion: In real-life clinical settings, no therapy intensification was offered in more than half of patients categorized as non-optimally controlled disease. Total and clinical SLEDAI-2k showed only fair accuracy to predict therapy escalation, reflecting the role of additional parameters in the decision to escalate therapy in an individual patient.

POSO367 IMPROVEMENT OF INDIVIDUAL MUCOCUTANEOUS MANIFESTATIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH ANIFROLUMAB

V. Werth1, J. Wissmar2, A. Strömbäck3, R. Tummalà4, C. Kleudel5, M. Albulescu5, University of Pennsylvania and CorporaI Michael J. Crescenz Veterans Administration Hospital, Department of Dermatology, Philadelphia, PA, United States of America; 2AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden; 3AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America; 4AstraZeneca, BioPharmaceuticals R&D, Cambridge, United Kingdom

Background: Patients with cutaneous lupus erythematosus (CLE) experience disfiguring and painful lesions that can lead to psychological distress and significant impacts on quality of life.1 Treatment of patients with systemic lupus erythematosus (SLE) with anifrolumab, a type I interferon receptor antagonist, was associated with CLE Disease Area and Severity Index–Activity (CLASI-A) improvements compared with placebo through Week 52 in the phase 3 TULIP-1
and TULIP-2 SLE trials.2,3 CLASI assesses overall skin improvement and may be driven by erythema over the other components.4

Objectives: To better understand the effect of anifrolumab on mucocutaneous SLE manifestations by analyzing the individual domains of CLASI-A using pooled data from the TULIP trials.

Methods: TULIP-1 (NCT02444692) and TULIP-2 (NCT02444689) were randomized, double-blind, placebo-controlled, 52-week trials that evaluated efficacy and safety of intravenous anifrolumab administered every 4 weeks in patients with moderate to severe SLE despite standard therapy.5 In a post hoc analysis, individual CLASI-A domains (erythema, scale/hypertrophy, alopecia, and mucosa) were assessed at Week 24 (time point chosen to ensure adequate duration for improvement in slow-remitting manifestations [eg, scale, alopecia]) in 2 patient subgroups: 1) the “chronic” mucocutaneous subgroup (resembling chronic/discoid CLE), defined as patients with a baseline erythema score ≥4 and scale score ≥2, and alopecia score ≥1 or baseline mucosal lesions or ulceration score of 1; and 2) the “extended” mucocutaneous subgroup (resembling all CLE subtypes), defined as patients who met the “chronic” criteria or those who had a baseline erythema score ≥8.

Results: Across the pooled TULIP trials, 360 patients received anifrolumab 300 mg and 366 patients received placebo. In patients with assessments at Week 24 in the “chronic” (anifrolumab n=58, placebo n=50) and “extended” (anifrolumab n=104, placebo n=96) subgroups, anifrolumab led to a greater mean percent reduction from baseline compared to placebo in erythema (chronic: −63.6% vs −39.9%; extended: −63.7% vs −41.2%); scale/hypertrrophy (chronic: −72.2% vs −42.6%; extended: −45.3% vs −7.3%); anifrolumab-treated patients in both subgroups had no worsening in alopecia (chronic: 93.5% [95% CI 66.0%–96.0%] vs 95.3% [92/96]; or mucocutaneous (chronic: 95.0% [95% CI 67.0%–96.0%] vs 96.0% [48/50]; extended: 96.3% [103/107] vs 94.8% [91/96]) from baseline to placebo (Table 1).

| No worsening | 57 (95.0) | 48 (96.0) | 103 (96.3) | 91 (94.8) |

aIf baseline score ≥1. bIf baseline score =1.

Conclusion: In the phase 3 TULIP trials, SLE patients with mucocutaneous manifestations treated with anifrolumab experienced numerical improvements in erythema and scale/hypertrophy and no worsening in alopecia or mucous membrane CLASI-A domains compared with placebo, regardless of whether skin disease was classified by chronic or extended definitions. These encouraging data support further evaluation of anifrolumab in patients with CLE.

REFERENCES:

Figure 1. Efficacy-related survival of belimumab according to improvement or not of PGA at 3 months since treatment initiation.
Conclusion: In real-life setting, about 28% of SLE patients discontinue belimumab due to suboptimal treatment response per physician judgement, especially those with moderate-to-high activity and severe arthritis. Improvement in PGA at 3 months predicts long-term drug maintenance, therefore suggesting its value for patient monitoring. Our data confirm the very good tolerability of belimumab and identify hydroxychloroquine co-administration as a predictor for prolonged safety-related drug survival.

DOI: 10.1136/annrheumdis-2022-eular.4046
Results: Among 4,677 patients, the mean age at HCQ initiation was 52 years; 83% were female. The racial/ethnic composition included 51% non-Hispanic White, 19% Hispanic, 14% Asian, and 11% Black patients. 756 (16.2%) and 3,921 (83.8%) patients initiated HCQ with the primary definition of the treatment strategies >5 and ≤5mg/kg/day, respectively. The weighted kappa was 0.80 for SD-ICT reliability. 164 patients developed HCQ retinopathy (100 mild, 38 moderate, and 26 severe cases). The cumulative incidence of retinopathy over 18 years was 37.6% for >5 and 5.7% for ≤5mg/kg of HCQ in our primary analysis. The corresponding risk was 26.5% for >5 and 3.2% for ≤5mg/kg in our secondary analysis using >80% of prescription days. Compared with ≤5mg/kg of HCQ, the HRs of retinopathy were 9.65 (95% CI 5.73-16.65) and 10.79 (95% CI 6.40-20.07) for >5mg/kg using the primary and secondary definitions of HCQ dose categories, respectively (Figure 1).

Conclusion: The risk of HCQ retinopathy associated with long-term adherence to >5mg/kg dosing was high, approximately 10 times that of ≤5mg/kg dosing. However, most cases identified during the study were mild and pre-symptomatic, supporting the value of regular screening. These data should be incorporated into individualized discussions about long-term use of HCQ.

CAN WE ENHANCE ADHERENCE TO MEDICATIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS? RESULTS FROM A QUALITATIVE STUDY

S. Emamikia1, C. Gentline1, Y. Enman1, I. Parodis1,2,1 Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine, Solna, Sweden; 2 Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden

Background: Medication non-adherence is common among patients with systemic lupus erythematosus (SLE) [1] and may lead to poor clinical outcomes [2,3]. Objectives: Our aim was to identify influential contributors to medication non-adherence to suggest interventions that could increase adherence.

Methods: Patients with SLE from two Swedish tertiary referral centres (N=205) participated in a survey assessing self-reported adherence to medications. Medication adherence was self-reported and measured using the generic instrument Medication Adherence Self-Report Inventory (MASRI) and the rheumatic disease-specific instrument Complianc Questionnaire Rheumatology (CQR). Responses were used to select patients for qualitative interviews (N=15). Verbatim interview transcripts were analysed by two researchers using content analysis methodology.

Results: The mean age of the interviewees was 39 years, 87% were women, and their mean SLE duration was 11.6 years. Patients’ medications and adherence levels are detailed in Table 1. We categorised reasons for non-adherence thematically into (i) patient-related e.g., unintentional non-adherence due to forgetfulness or intentional non-adherence due to disbelief in medications, (ii) healthcare-related e.g., untrustworthy relationship with the treating physician, authority fear, and poor information about the prescribed medications or the disease, (iii) medication-related e.g., fear of side-effects, and (iv) disease-related reasons e.g., lacking acceptance of a chronic illness or perceived disease quiescence. Interventions identified that healthcare could implement to improve patients’ adherence to medications included (i) increased communication between healthcare professionals and patients, (ii) patient education, (iii) accessible healthcare, preferably with the same personnel, (iv) smooth transition from paediatric to adult care, (v) regularity in addressing adherence to medications, (vi) psychological support, and (vii) involvement of family members or people who are close to the patient.

Hoffman-La Roche AG.
Background: Patients with systemic lupus erythematosus (SLE) are at increased risk of severe COVID-19 and the underlying disease complications and in need of immunosuppressants (IS). An alternative option would be to adopt telemedicine (TM) to maintain medical care while minimizing exposure. Despite being widely adopted during the pandemic, the evidence supporting the use of TM in rheumatology has been limited.

Objectives: We primarily aimed to evaluate the effectiveness to maintain disease activity control using TM delivered care compared to conventional in-person follow-up in patients with lupus nephritis (LN). The secondary objectives were to compare the patient reported outcomes, safety, and cost-of-illness from the patients’ perspective between the 2 modes of health care delivery.

Methods: This was a 1-year, single-center, RCT conducted at a regional hospital in Hong Kong. From May 2020, consecutive adult patients with a SLE according to the 2019 EULAR/ACR classification criteria followed up at the LN clinic were invited to participate in the study. Participants were randomized 1:1 to either TM (TM group) or standard FU (SF group). Patients randomized to receive TM FU were scheduled for a video consultation via a commercial software ZOOM. Patients in the SF group received standard in-person outpatient care. SLE disease activity at each consultation was assessed by SLEDAI-2k and physician global assessment (PGA).

Results: A total of 144 patients with LN were randomized and 3 patients self-withdrew from the study. The mean age was 44.5±11.4 years and the median time from diagnosis to randomization was 168 months (range: 1-528). Most of the patients had class III, IV or V LN (87.2%) and were on prednisolone (89.4%, median dose 5mg daily). Many of them (68.1%) were on IS. While 66.0% of the patients were in lupus low disease activity state (LLDAS), none had disease remission. There were no baseline differences, including demographics, SLEDAI-2k (TM: 3.8±3.3, SF: 3.2±2.2, p=0.13), PGA (TM: 6.2±5.6, SF: 4.6±5.9, p=0.13) and SLE damage index (TM: 1.1±1.3, SF: 0.8±1.1, p=0.10), between the 2 groups. At one year, 80.0% and 80.2% of the patients in the TM group and SF group were in LLDAS or remission respectively. SLE disease activity indices including SLEDAI-2k, PGA, proteinuria amount and serum anti-dsDNA level remained similar between the 2 groups. Within the study period, 28 (40%) patients in the TM group and 21 (29.6%) patients in the SF group had disease flare (p=0.20). There were no differences in the SF-36, lupusQoL and HADS scores between the 2 groups at the end of the study. The overall patient satisfaction score was higher in the TM group with a significantly shorter waiting time before seeing doctors. At the end of the study, 67.9% of the overall participants agreed to (versus 15.0% who did not agree) to use TM as a mode of future FU. The mean indirect costs of illness (HKD26,681 vs HKD12,016, p=0.20) and the out-of-pocket costs for health care services were similar between the 2 groups (TM: HKD13,547 vs SF: HKD12,297, p=0.08) in one year. The total number of FU was similar (TM: 60±20, SF: 67±17, p=0.40). However, significantly more patients in the TM group (29/70, 41.4% vs 47/11, 5.6%, p<0.01) requested change mode of FU. The proportion of patients requiring hospitalization during the study period was also higher in the TM group (TM: 23/70, 32.9% vs 11/71, 15.5%; p=0.02). After adjusting for age and prednisolone dosage, not being in LLDAS at baseline was the predictor of hospitalization (OR 3.4, 95%CI 1.20-9.65). None of the participants was tested positive for COVID-19.

Conclusion: The results of the study suggest that TM delivered care could help minimizing proportion of patients cared by TM required in-person visits or were hospitalized. Satisfaction in patients with LN compared to standard care. However, a significant proportion of patients cared by TM required in-person visits or were hospitalized. The results of the study suggest that TM delivered care could help minimizing exposure to COVID-19, but it needs to be complemented by physical visits, particularly in those with unstable disease.

POS0374
MONITORING CHRONIC INFLAMMATORY MUSCULOSKELETAL DISEASES WITH A PRECISION DIGITAL COMPANION PLATFORM(TM)—RESULTS OF THE DIGIREUMA RASIBILITY STUDY

D. Benvent1, F. J. Núñez-Benjumea2, L. Fernández-Luque2, V. Navarro-Compañ1, M. Sanz3, E. Calvo Aranda3, L. Lojo3, A. Balsa1, C. Plasencia1,2 1Hospital Universitario La Paz, IdiPaz, Department of Rheumatology, Madrid, Spain; 2AdheraHealth Inc., Palo Alto, United States of America; 3Hospital Universitario Infanta Leonor, Department of Rheumatology, Madrid, Spain

Background: Patients with rheumatic and musculoskeletal diseases (RMDs) require a tailored follow-up that is limited by the capacity of healthcare professionals. Innovative tools need to be implemented effectively in the clinical care of patients with RMDs.

Objectives: To test the feasibility of a Precision Digital Companion Platform™ for real-time monitoring of disease outcomes in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA).

Methods: Digireuma was a prospective study including patients with RA and SpA, using the digital Precision Digital Companion Platform, Adhera for Rheumatology (ISRCTN11896540). During a follow-up of 3 months, patients were asked to report disease specific electronic patient reported outcomes (ePROs) on a regular basis in the mobile solution. Two rheumatologists monitored these ePROs and, patients were contacted for online or face-to-face interventions when deemed necessary by clinicians (Figure 1). Assessment measures included patient global assessment (PGA) of disease activity, tender joint count (TJC), swollen joint count (SJC), Health Assessment Questionnaire (HAQ) and pain visual analogue scale (VAS), for patients with RA; VAS, PGA, TJC, SJC, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and ASAS Health Index (ASAS-HI), for patients with SpA. In addition, flares, changes in medication and recent infections were asked. Usability of the digital solution was measured by the Net-Promoter Score (NPS).

Results: Forty-six patients were recruited of whom 22 had RA and 24 SpA. Mean age was 48 ± 12 and 42 ± 9 years in the RA and SpA groups, respectively. 18/22 (82%) patients with RA and 9/24 (38%) with SpA were female. Among the total included patients, 41 (89%) completed the onboarding (18/22 (82%) RA, 23/24 (96%) SpA) and 37 (80%) submitted at least one entry. In the RA group who completed the onboarding (n=18) there were a total of 4019 total interactions (2178 questionnaire items, 648 accesses to educational units, 105 quizzes, 1088 rated messages), while patients with SpA (n=23) had a total of 3180 interactions (1637 questionnaire items, 684 accesses to educational units, 77 quizzes, 762 rated messages). ePROS measurements completion rates for RA and SpA patients that completed any data during follow-up are shown in Table 1. Patients with RA completed a median of 9.5 ePROS during follow-up, whereas patients with SpA completed a median of 3. Regarding alerts, 15 patients generated a total of 26 alerts, of which 24 were flares (10 RA, 14 SpA) and 2 were problems with the medication (1 RA, 1 SpA). 18 (69%) of the alerts were managed remotely, 5 (19%) required a face-to-face intervention and in 3 (12%) patients did not respond before the consultation. Regarding usability and patient satisfaction, 14 patients provided feedback. According to the NPS, 9/14 were considered promoters, 4/14 passives and 1/14 detractor. The overall rating of these 14 patients for the app was 4.3 out of 5 stars.

Follow-up period was 3 months. Results are expressed in median (Q1, Q3) and in (%)

Conclusion: This study shows that the use of a digital health solution is feasible in clinical practice. Based on these preliminary results, the next step will be to further implement the Precision Digital Companion Platform, Adhera for Rheumatology, in a multicentric setting to analyze the added value for monitoring patients.

Objectives:
The sudden emergence of SARS-CoV-2 onto the world stage has accelerated a major change in the management of patients with chronic rheumatic diseases and has catalyzed the rapid emergence of telemedicine. Our aim was to describe which parameters were used by rheumatologists to monitor patients with rheumatoid arthritis (RA) in teleconsultation during the first wave of the pandemic and identify the most relevant for decision making.

Methods:
Retrospective monocentric routine care cross-sectional study including RA patients seen in teleconsultation between March and September 2020. Available parameters assessing disease status were collected in teleconsultation files. Clinic intervention was defined by treatment escalation and/or the need for a rapid face-to-face consultation or day hospitalization.

Results:
143 RA patients were included (117 females, mean age of 58±16 years, mean disease duration of 14±11 years). The presence or absence of patient self-reported RA flares concerned 43/143 patients (30%). The presence of patient self-reported RA flares concerning 43/143 patients (30%). The presence of patient self-reported RA flares associated with a detailed evaluation of patient in teleconsultation: The presence (or number) of tender joints and swollen joints were more significantly reported in patients who presented a flare (39/43, 91% vs. 70/100, 70%, p=0.008 and 25/43, 58% vs. 23/100, 23%, p<0.001, respectively). Teleconsultation led to a clinician intervention in 22/143 patients (14%), representing 51% of patients with self-reported flares (22/43 patients). Therapeutic escalation was necessary in 13 patients: introduction or dose increase of corticosteroids in 8 patients, introduction or dose increase of methotrexate in 4 patients and introduction of hydroxychloroquine in 1 patient. Face-to-face consultation or day hospitalization were organized for 10 patients. Active disease was confirmed during this next face-to-face visit in 9 patients, with DAS28 ranging from 3.35 to 5.62, leading to therapeutic modification. The 133 other patients were seen in face-to-face consultation 6±2 months after the teleconsultation. No DMARD modification was recorded during this next face-to-face consultation.

Conclusion:
Our study identified patient reported RA flares and increased CRP values as 2 red flags in teleconsultation, independently associated with therapeutic modification and/or the need for a rapid face-to-face consultation. These indicators may help clinician’s decision making in teleconsultation.

EVALUATION OF PATIENTS WITH RHEUMATOID ARTHRITIS IN TELECONSULTATION DURING THE FIRST WAVE OF THE COVID-19 PANDEMIC

J. AVOUAC1, A. MOLTÓ1, C. FRANTZ1, S. WANONO1, E. DESCAMPS1, O. FOGEL1, A. COMBIER1, L. POIUOX1, C. MICELI RICHARD1, Y. ALLARONE1, COCHIN HOSPITAL, RHEUMATOLOGY, PARIS, FRANCE

Background:
The relevance of early diagnosis in SARS-CoV-2 onto the world stage has accelerated a major change in the management of patients with chronic rheumatic diseases and has catalyzed the rapid emergence of telemedicine. Electronic consultation (e-Consults) is a tool for communication and a means for a rapid face-to-face consultation or day hospitalization.

Methods:
Available parameters assessing disease status were collected in teleconsultation files. Clinic intervention was defined by treatment escalation and/or the need for a rapid face-to-face consultation or day hospitalization.

Results:
143 RA patients were included (117 females, mean age of 58±16 years, mean disease duration of 14±11 years). The presence or absence of patient self-reported RA flares concerned 43/143 patients (30%). The presence of patient self-reported RA flares was mentioned in all medical files, followed by the presence and/or the number of tender joints (76%), the number of pain-related nocturnal awakenings (66%) and the CRP value (54%). Patient self-reported RA flares concerned 43/143 patients (30%). The presence of self-reported RA flares associated with a detailed evaluation of patient in teleconsultation: The presence (or number) of tender joints and swollen joints were more significantly reported in patients who presented a flare (39/43, 91% vs. 70/100, 70%, p=0.008 and 25/43, 58% vs. 23/100, 23%, p<0.001, respectively). Teleconsultation led to a clinician intervention in 22/143 patients (14%), representing 51% of patients with self-reported flares (22/43 patients). Therapeutic escalation was necessary in 13 patients: introduction or dose increase of corticosteroids in 8 patients, introduction or dose increase of methotrexate in 4 patients and introduction of hydroxychloroquine in 1 patient. Face-to-face consultation or day hospitalization were organized for 10 patients. Active disease was confirmed during this next face-to-face visit in 9 patients, with DAS28 ranging from 3.35 to 5.62, leading to therapeutic modification. The 133 other patients were seen in face-to-face consultation 6±2 months after the teleconsultation. No DMARD modification was recorded during this next face-to-face consultation.

Conclusion:
Our study identified patient reported RA flares and increased CRP values as 2 red flags in teleconsultation, independently associated with therapeutic modification and/or the need for a rapid face-to-face consultation. These indicators may help clinician’s decision making in teleconsultation.

Disclosure of Interests:
Jerome Avouac: Speakers bureau: Bristol Myers Squibb, PANOFI, galapagos, Lilly, Abbvie, Pfizer, Novartis, Biogen, Fresenius Kabi, Janssen, MSD, Roche-Chugui, Medac, Consultant of: galapagos, Abbvie, Pfizer, Bristol Myers Squibb, SANOFI, Nordic-Pharma, Grant/research support from: Bristol-Myers Squibb, Pfizer (Passerelle), Novartis (Dreamer), Fresenius Kabi, Anna Moltó: None declared, CAMELIA FRANTZ: None declared, Sarah Wanono: None declared, Elise Descamps: None declared, Olivier Fogel: None declared, Alice Combier: None declared, Lucile Poioux: None declared, Corinne Miceli Richard: None declared, Yannick Allarone: None declared.

ONE YEAR OF DIGITAL HEALTH APPLICATIONS (DiGA) IN GERMANY – RHEUMATOLOGISTS' PERSPECTIVES

J. G. Richter1, G. Chehab1, P. Stachwitz2, J. Hagen3, D. Larsen4, J. Knitz5, M. Schneider6, A. Voormann1, C. Specker7, 1Medical Faculty, Heinrich-Heine-University Duesseldorf, Policlinic for Rheumatology and Hiller Research Unit for Rheumatology, Düsseldorf, Germany; 2Health Innovation Hub of the Federal Ministry of Health, Health Innovation Hub of the Federal Ministry of Health, Berlin, Germany; 3Friedrich-Alexander University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3-Rheumatology and Clinical Immunology, Erlangen, Germany; 4German Society for Rheumatology, German Society for Rheumatology, Berlin, Germany; 5Clinic Essen-Mitte, Clinic of Rheumatology and Clinical Immunology, Essen, Germany

Background: Based on given legislation (§§ 33a and 139e SGB V, Social Code Book V) the German approach to digital health applications (Digitale Gesundheitsanwendungen, DiGA) allows reimbursed prescription of approved therapeutic software products (listed in the DiGA directory https://diga.bfarm.de/de/verzeichnis) for patients since October 6th, 2020.

Objectives: To evaluate the level of knowledge on DiGA among members of the German Society for Rheumatology (DGRh) after one year of DiGA under the conditions of the COVID-19 pandemic using the DiGA Toolbox of the ‘health innovation hub’ (hih), a think tank and sparring partner of the German Federal Ministry of Health.

Methods: Anonymous cross-sectional online survey using LimeSurvey (https://limesurvey.org). The survey was promoted by newsletters sent out to DGRh newsletter recipients and Twitter posts. Ethical approval was obtained.

Results: 75 valid participants reported that they care more than 80% of their working time for patients with rheumatic diseases. Most were working in outpatient clinics (54%) and older than 40 years of age (84%). Gender distribution was balanced (50%).

70% were aware of the possibility to prescribe DiGA. Most were informed on this for the first time via trade press (63%), and only 8% via the professional society. 46% expect information on DiGA from professional societies and the medical chambers (36%) but rarely from the manufacturer (10%) and the responsible ministry (4%). Respondents would like to be informed about DiGA via continuing education events (face-to-face 76%, online 84%), trade press (86%), and manufacturers’ test accounts (64%).

Only 7% have already prescribed a DiGA, 46% planned to do so, and 47% did not intend DiGA prescriptions. Relevant aspects for prescription are given in Figure 1.

Figure 1. Aspects relevant for DiGA prescriptions; sorted by importance/number of mentions (participants needed to pick their three most relevant aspects from a pre-given list)

68% believe that using DiGA / medical apps would at least partially be feasible and understandable to their patients. 83% thought that data collected by the patients using DiGA or other digital solutions could at least partially influence health care positively.

51% appreciated to get DiGA data directly into their patient documentation system resp. clinical electronic health record (EHR) and 29% into patients’ owned EHR.

Conclusion: DiGA awareness was high whereas prescription rate was low. Mostly, physician-desired aspects for DiGA prescriptions were proven efficacy and efficiency for physicians and patients, risk of adverse effects and health care costs were less important. Evaluation of patients’ barriers and needs are warranted. Our results will contribute to the implementation and dissemination of DiGA.

EVALUATION OF THE USE OF VIDEO CONSULTATION IN GERMAN RHEUMATOLOGY CARE BEFORE AND DURING THE COVID-19 PANDEMIC WAVES

J. Reiter1, G. Chehab1, P. Ares2, F. Mueliensiepen2, M. Weikert2, A. Voormann1, M. Schneider1, C. Specker7, J. G. Richter1, 1Medical Faculty, Heinrich-Heine-University Duesseldorf, University Clinic, Duesseldorf, Policlinic & Hiller Research Unit for Rheumatology, Duesseldorf, Germany; 2Immunologikum Hamburg, Rheumatologie & Klinische Immunologie, Hamburg, Germany; 3Faculty of Health Sciences, Brandenburg Medical School Theodor Fontane, Ruedersdorf, Center for Health Services Research, Brandenburg, Germany; 4MVZ für Rheumatologie Dr. Martin Welcker GmbH & RheumaDatenRhePort (RHADAR), Geschäftsführung, Planegg, Planegg, Germany; 5German Society for Rheumatology, German Society for Rheumatology, Berlin, Germany; 6Clinic Essen-Mitte, Clinic of Rheumatology and Clinical Immunology, Essen, Germany; 7Hamburg, Germany

Background: During the COVID-19 pandemic telemedicine tools rapidly and widely gained acceptance as indispensable management tools for the continuum of clinical care in rheumatic diseases. They have been adopted in position papers and guidelines for the management of rheumatic diseases in adult patients.

Objectives: Evaluation of the use of video consultation as one form of telemedicine before and during the COVID-19 pandemic and associated lockdowns among Rheumatology physicians in Germany. The survey results are expected to support the optimization and implementation of video consultation (VC) into routine clinical practice in rheumatology, providing long-term benefits for both parties, patients and their treating rheumatologists.

Methods: Cross-sectional nationwide online survey among German rheumatologists and rheumatologists in training. The survey was promoted by newsletters sent by means of mail and Twitter posts to members of the German Society for Rheumatology (n=1,650) and German Professional Society for Rheumatology (n=527).

Results: Reported data refer to 205 participants. The majority of respondents was male (59%), older than 40 years (90%) and specialized in internal medicine/rheumatology (85%).

They were divided into two groups: ‘digital users’ (38%) and ‘digital non-users’ (62%). Users employing telemedicine (TM) but never VC were defined as ‘TM-users’ (10%). Those using TM and VC were classified as ‘VC-users’ (27%). ‘Non-users’ negated the use of VC and TM respectively.

Knowledge on telemedicine was self-rated as 4 (median on a Likert Scale 1 (very high) to 6 (very low)) with a significant difference between user (VC-user 7±1.2, TM-user 3.2±1.1) and non-user (4.4±1.3).

The Figure 1 shows a significant increase in the use of VC during the lockdown periods. Even between the lockdown phases, VC use was higher than in the pre-pandemic phase.

Figure 1. Grouped patient numbers seen via VC during the pandemic waves

Reasons for VC non-use in TM-user and non-user were administrative/technical efforts (21%), lack of technical equipment (15%), time constraints (12%), time required for individual VC sessions (12%), inadequate reimbursement (11%), lack of demand from patients (11%), data security concerns (9%), poor internet connection (8%), and lack of scientific evidence (5%).

Based on the experience gained, physicians considered the following clinical situations to be particularly suitable for VC: follow-up visits (VC-user 79%, TM-user 62%, non-user 25%).
47%), emergency consultations (VC-user 20%, TM-user 33%, non-user 20%), and patients presenting for the first time (VC-user 11%, TM-user 19%, non-user 8%).

Table 1. Evaluation of the VC in comparison to other patient interaction (VC-user) on a Likert Scale with 1 (I agree completely) to 6 (I do not agree at all)

Table 1 (n=51) with the patient (n=51)

Conclusion: Despite the fact that the current pandemic situation, with social distancing and several lockdowns, provides an ideal environment for the implementation of new remote care forms such as VC, their use and acceptance remained below expectations. Given the reported decline in physician face-to-face consultations during the pandemic, these findings are even more concerning. The identified reasons for non-utilization should be addressed by policy makers, payers and medical societies to provide better foundations for future innovative care models.

**POS0379** SMARTPHONE-ASSISTED PATIENT-INITIATED CARE VERSUS USUAL CARE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND LOW DISEASE ACTIVITY: A RANDOMIZED CONTROLLED TRIAL

B. Seppen1,2, J. Wiegel1,2, M. Ter Wee3, D. Van Schaaardenburg4, L. Roorda3, M. Boers5, M. Nurmoohamed1, W. H. Bos1,2, Amsterdam Rheumatology and Immunology Center | Reade, Rheumatology, Amsterdam, Netherlands; 2Amsterdam UMC, location VUMc, Rheumatology, Amsterdam, Netherlands; 3Amsterdam UMC, location VUMc, Rheumatology, Amsterdam, Netherlands; 4Amsterdam UMC, location VUmc, Rheumatology, Amsterdam, Netherlands; 5Amsterdam UMC, location AMC, Rheumatology, Amsterdam, Netherlands; 6Reade, Rehabilitation, Amsterdam, Netherlands

Background: Most patients with rheumatoid arthritis (RA) visit their rheumatologist every 3-6 months to evaluate their disease activity. This may be inefficient, as research shows that many patients have minimal disease activity.1 When patients monitor their disease and initiate care at the right moment, they may be able to reduce the number of clinic visits, with a lower health care burden and costs. We developed a smartphone app that allows patients to self-monitor their disease activity through a weekly assessment of patient index data (RAPID-3).

Objectives: To assess safety (non-inferiority in disease activity, DAS28) and efficacy (reduction in number of visits) of patient-initiated care assisted by a smartphone app compared to usual care.

Methods: A twelve month, randomized, non-inferiority clinical trial was conducted in RA patients with low disease activity, on stable treatment for at least 6 months prior to entry. Patients were randomized (1:1) to either app supported patient-initiated care with a scheduled follow-up consultation after a year (app-group), or usual care, see Figure 1. The primary outcomes were non-inferiority in terms of change in disease activity (ΔDAS28) after 12 months and the number of consultations with a rheumatologist.

Results: 102 of 103 randomized patients completed the study. The mean age was 58, 60 were female and the mean disease duration was 12 years. At baseline mean (SD) DAS28 was 1.67 (0.68) in the app group, and 1.54 (0.72) in the usual care group. After a year, the app group mean (SD) DAS28 was 0.27 (0.35) in the usual care group: the difference in ΔDAS28 was −0.04 in favor of the app group (95%CI:−0.39;−0.30) documenting non-inferiority. The number of rheumatologist consultations was significantly lower in the app group: mean (SD) 1.7 (1.8) vs 2.8 (1.4) visits/year; visit rate ratio: 0.82 (95% CI 0.47;0.81, p<0.001).

Conclusion: Patient-initiated care supported with self-monitoring via a smartphone app was non-inferior to usual care in terms of ΔDAS28 and led to a 38% reduction in rheumatologist consultations rate.

**POS0380** EFFECTIVENESS OF REMOTE CARE INTERVENTIONS: A SYSTEMATIC REVIEW INFORMING THE 2022 EULAR POINTS TO CONSIDER FOR REMOTE CARE IN RHEUMATOID AND MUSCULOSKELETAL DISEASES

A. Marques1,2, P. Bosch3, A. De Thurah4, L. Faizon4, C. Mukhtyar5, H. Bijlsma6, C. Dejaco7, T. Stamm8 on behalf of EULAR task force on Points to Consider for the remote care in rheumatic and musculoskeletal diseases. 1Higher School of Nursing of Coimbra, Health Sciences Research Unit Nursing, Coimbra, Portugal; 2Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; 3Medical University of Graz, Rheumatology and Immunology, Graz, Austria; 4Aarhus University Hospital, Rheumatology, Aarhus, Denmark; 5German Rheumatism Research Centre, Epidemiology and Health Sciences Research, Berlin, Germany; 6The University of Sheffield, School of Health and Related Research, Health Economics and Decision Science, Sheffield, United Kingdom; 7Nordiak & Norwich University Hospital, Rheumatology, Norwich, United Kingdom; 8UMC Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands; 9Hospital of Bruneck (ASASA-SABES), Rheumatology, Bruneck, Italy; 10Medical University of Vienna & Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Vienna, Austria

Background: While the number of patients with rheumatic musculoskeletal diseases (RMDs) is increasing worldwide, there is no adequate increment in the number of health care professionals, leading to the urgent need for new forms of care to take pressure off health care systems.1 Telehealth comprises a number of different types of interventions with the scope of performing certain steps of care, ranging from diagnostics to follow-up visits, in a remote manner. The use of remote care is heterogeneous and guidance is needed to optimize the combination with conventional face-to-face (F2F) visits.

Objectives: To perform a systematic literature review (SLR) on different outcomes of remote care compared to F2F care, its implementation into clinical practice and to identify drivers and barriers in order to inform a task force formulating the European Alliance of Associations for Rheumatology (EULAR) Points to Consider for remote care in RMDs.

Methods: Prospective, retrospective, and qualitative studies testing different types of remote care in patients with RMDs were included. Medline, Embase and the Cochrane Library were searched through February 28th, 2021. Two reviewers independently performed standardized data extraction, synthesis, and risk of bias assessment.

Results: A total of 2,240 references were identified. Forty-seven studies, consisting of 26 randomized controlled trials, 8 prospective cohort studies, 8 cross sectional studies, and 5 qualitative studies were included. Fifty-one percent of the studies involved patients with inflammatory RMDs, including rheumatoid arthritis, and spondyloarthritis, while 49% were on patients with non-inflammatory conditions, such as osteoarthritis and fibromyalgia. Remote monitoring (n=35) was most frequently studied, with telephone/video calls being the most common mode of delivery (n=30). Thirty-four studies investigated outcomes of remote care in comparison to F2F care. The most frequently assessed outcomes concerned efficacy and user perception of remote care, with 34% and 21% of studies, respectively, reporting superior results for the remote care intervention.

Time savings and flexibility were reported as major drivers, while inadequate technical knowledge and concerns in data security were the main barriers to
Scientific Abstracts	﻿ 
implementing remote care. Implementation of remote care methods into clinical
practice was not reported by the included studies. The main limitations were the
heterogeneity of outcomes and interventions, and the substantial risk of bias
(50% of studies with high risk of bias).
Conclusion: Studies on remote care reported similar to partially better results
compared to F2F care concerning efficacy, and user perception outcomes, with
the limitation of heterogeneity and considerable risk of bias.

ALLOCATION OF VISITS ACCORDING TO NEED:
SCREENING RHEUMATOID ARTHRITIS PATIENTS
WITH PATIENT REPORTED OUTCOMES

B. Seppen1,2, S. Verkleij1, J. Wiegel1,2, M. Ter Wee3, M. Nurmohamed1,2,
W. H. Bos1,2. 1Amsterdam Rheumatology and Immunology Center | Reade,
Rheumatology, Amsterdam, Netherlands; 2Amsterdam UMC, locatie VUmc,
Rheumatology, Amsterdam, Netherlands; 3Amsterdam UMC, locatie VUmc,
Biostatistics and Data Science, Amsterdam, Netherlands
Background: Currently, patients with rheumatoid arthritis (RA) require frequent consultations to monitor their disease activity. However, since a majority of patients is in remission during routine follow up, it should be possible
to reduce the number of consultations for them.1 Patients that are meeting
their treatment goal, based on the results of their electronic patient reported
outcome measures (ePROMs), could be eligible to skip their visit. Research
revealed that patients who indicate to be in remission or have a low disease
activity (remission/LDA) on their ePROMs, such as the routine assessment
of patient index data (RAPID3), also have a low disease activity score 28
(DAS28).2 However, in clinical practice the decision to intensify treatment is
more complex than not meeting a DAS28 threshold. Therefore, ePROM-results should be compared with treatment intensifications to assess the safety
of screening with ePROMs.
Objectives: To assess the probability that patients with low scores on
disease activity assessment with ePROMs do not need medication
intensification.
Methods: This retrospective study compared results of three ePROMs
(RAPID3, patient acceptable symptom state (PASS) and asking patients
if they experienced a flare (flare question)) answered during routine care
with (disease modifying anti-rheumatic drug) DMARD or steroid intensifications collected from anonymised electronic medical records at Reade. We
calculated the positive predictive value (PPV) for not receiving a DMARD
or steroid intensifications within two weeks and three months for 1) being
in remission/LDA according to the RAPID3, 2) being in PASS and 3) not
reporting a flare. The secondary aim of the study was to assess which
combination of ePROM-results led to the best PPV for DMARD or steroid
intensifications.
Results: A total of 321 records were included that regarded 302 unique
patients (77% female, mean age (SD) was 60 (12) years). The PPV for not
receiving a DMARD or steroid intensification within 2 weeks of the RAPID3,
PASS and flare-question were 99%, 95% and 83%, respectively, and after
3 months 95%, 88%, 85%, for all test characteristics see Table 1. The combination of a RAPID3 < 2 and a negative flare-question resulted in a PPV
of 100%; this combination was present in 29% (93/321) of the total study
population.

All numbers are percentages. ePROMs: electronic Patient Reported Outcome Measures,
NPV: Negative Predictive Value, PPV: Positive Predictive Value, RAPID3: Routine Assessment
of Patient Index Data-3, PASS: Patient Acceptable Symptom State.

Conclusion: Our results show that the RAPID3, PASS and flare have a high
diagnostic accuracy to identify individuals that will not receive a DMARD or steroid intensification up to 3 months after their initial consultation and are therefore possibly eligible to skip their outpatient clinic visit. The combination of the
RAPID3 and the PASS yielded the best combination of diagnostic accuracy and
highest number of eligible patients.

Surgery, Modena, Italy; 4University of Modena and Reggio Emilia, Department
of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant
Surgery, Oncology and Regenerative Medicine Relevance, Modena, Italy
Background: Systemic Sclerosis (SSc) is a connective tissue disease, characterized by endothelial dysfunction, autoimmunity abnormalities and fibrosis of
the skin and internal organs. The exact pathogenetic mechanisms that propagate SSc vasculopathy are still not completely understood. A complex network of
interactions between endothelial cells, pericytes, myofibroblasts, and the extracellular matrix (ECM) has been implicated but it is currently unclear what drives
the activation of fibroblasts and the increased ECM deposition responsible for the
fibrotic changes well known in SSc.
Objectives: Using RNA sequencing (RNA-seq), our goal was to identify potential functional pathways possibly involved in SSc pathogenesis and markers that
could potentially be used to better understand endothelial dysfunction and fibrosis mechanisms in SSc patients.
Methods: RNA-seq analysis was performed on RNA obtained from biopsies
from 3 SSc patients and 3 age- and sex-matched healthy controls (HC) enrolled
in our University Hospital between January 2019 and December 2020. The
samples were transferred to a labelled cryovial and immediately stored in liquid nitrogen. RNA extraction followed standard methodologies. RNA from each
sample was used to generate sequencing libraries that were sequenced according to proper transcriptomic analyses. To identify potential functional pathways
that could be involved in SSc pathogenesis, we performed gene set enrichment
analysis (GSEA) of differentially expressed genes (DEGs). GSEA was applied
on the entire list of genes that compose the RNA-seq expression matrix. Genes
were ranked based on their fold change calculated between groups of each pairwise comparison and analyzed by GSEA in pre-ranked mode. We adopted the


“classic” enrichment statistic, the recommended approach for RNA-seq data.

Results: According to GSEA analysis of DEGs applied to SSc and HC, we identified 305 DEGs that were upregulated or downregulated at least 2-fold. In particular, 175 genes were upregulated and 130 genes were downregulated. A marked upregulation of genes involved in Wnt signaling, including Wnt family members, was present in HC if compared with SSc. The upregulation of collagen type VI, extracellular matrix protein 2, vascular endothelial growth factor D, among others, was also observed. Conversely, a marked downregulation of late cornified envelope and of genes encoding for keratins, was present in HC versus SSc samples. GSEA revealed that HC were characterized, among others, by gene signatures related to stromal stem cells proliferation, cytokine-cytokine receptor interaction, macrophage-enriched metabolic network, whereas SSc tissues were enriched in signatures related to keratinization, cornification, retinoblastoma (RB) 1 and tumour suppressor (TP) S3 signaling. Figure 1 displays GSEA in HC vs SSc tissues.

Conclusion: According to our preliminary data, RNA-seq, differential gene expression and pathway analysis revealed that SSc patients show a discrete pattern of gene expression associated with keratinization, extracellular matrix generation, and negative regulation of angiogenesis and stromal stem cell proliferation. Further analysis on larger numbers of patients are needed; however, our results provide an interesting framework for the development of biomarkers representing vascular injury and fibrotic changes in SSc in order to explore potential future therapeutic targets.

Background: LeRoy’s classification defines two main subsets of Systemic Sclerosis (SSc) based on the extent of skin fibrosis: limited cutaneous SSc (lcSSc) with skin thickening sparing the trunk and distal to the elbow and knees, and diffuse cutaneous SSc (dcSSc) with proximal and distal skin thickening. These two subsets notably differ in terms of survival and frequency of visceral involvement. dcSSc being a more frequent, more severe form with a higher frequency of visceral manifestations. SSc sine scleroderma (ssSSc) is a third subset initially described by Rodnan et al. and characterized by the absence of skin fibrosis but with the existence of SSc-associated visceral manifestations.

Objectives: This study aimed to characterise the main clinical features of patients with ssSSc in comparison with the lcSSc and dcSSc subsets within the international EUSTAR database.

Methods: All patients from the EUSTAR database fulfilling the ACR2013 or 1980 classification criteria for SSc were assessed by the modified Rodnan Skin score (mRSS) at inclusion and with at least one follow-up visit were eligible. Sine scleroderma (ssSSc) was defined by the absence of skin thickening (mRSS=0 and no sclerodactyly) at all available visits. The clinical characteristics of these ssSSc patients were compared to those of patients with lcSSc and dcSSc with similar disease duration at last follow-up visit. Descriptive statistics were applied.

Results: Among the 4263 patients fulfilling the inclusion criteria, 376 (8.8%) were classified as ssSSc. Among them, 40.3% had puffy fingers, 39.4% had interstitial lung disease (ILD), 16.1% had a history of scleroderma renal crisis at inclusion visit. At last available visit, in comparison with 708 lcSSc and 708 dcSSc with the same disease duration, ssSSc patients had a lower prevalence of previous or current digital ulcers (28.2% versus 53.1% in lcSSc (P<0.001) and 68.3% in dcSSc (P<0.001)), of joint synovitis (16.9% versus 24.3% in lcSSc (P<0.01) and 30.8% in dcSSc (P<0.001)), and of elevated sPAP on echocardiogram (15.2% versus 23.9% in lcSSc (P<0.01) and 28.7% in dcSSc (P<0.0001)). Despite similar disease duration, disease activity at follow up visit (assessed by the EScSG disease activity index 2001 and 2016) was lower in ssSSc in comparison with lcSSc and dcSSc. By contrast, the prevalence of ILD was almost similar in ssSSc and lcSSc (49.8% and 57.1% (P=0.03)) but significantly higher in dcSSc (75.0%, P<0.0001). Based on forced vital capacity, ILD was less severe in ssSSc in comparison with the other subsets (mean FVC 100% (SD=22)% vs versus 93% (SD=21) in lcSSc and 82% (SD=23) in dcSSc (P<0.0001 for both)). Anti-centromere antibodies were most represented in ssSSc (61.7% versus 41.9% in lcSSc (P<0.0001) and 16.3% in dcSSc (P<0.0001)), whereas the opposite distribution was observed for anti-Scl70 antibodies. Survival was significantly higher in ssSSc patients compared to lcSSc (P<0.05) and dcSSc (P<0.0001).

Conclusion: This study highlights that ssSSc patients account for almost 10% of SSc patients with milder disease severity compared to both lcSSc and dcSSc.

ULTRA SHORT ECHO TIME MRI (UTE) SEQUENCE IN THE ASSESSMENT OF INTERSTITIAL DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS: CORRELATION WITH DISSON TENSION AT CT AND WITH PULMONARY LUNG FUNCTION TESTS.

M. Orlandi1, N. Landini2, C. Nardi3, G. Morana2, S. Colagrande3, M. Matsu-Cerinic4,5, 6University of Florence, Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy; 7Ca’ Foscillo General Hospital, Radiology, Treviso, Italy; 8University of Florence, Radiology, Firenze, Italy; 9RCCS San Raffaele Hospital, Immunology, Rheumatology, Allergology and Rare diseases, Firenze, Italy

Background: Interstitial lung disease (ILD) is the major cause of death in Systemic sclerosis (SSc). Computed tomography (CT) is the gold standard imaging
technique to diagnose ILD and to assess ILD prognosis. ILD extent assessment at lung CT has shown to correlate with functional lung capacity: extensive lung disease (>20%) correlate with significant lung capacity decline (forced vital capacity (FVC) <70%). In fact, associated with a higher mortality. Unfortunately, it is burdened by exposure to ionizing radiations that limits its use for the follow-up. For this reason, new MRI sequences were recently investigated, and Ultra Short Echo Time (UTE) emerged promising for ILD assessment.

**Objectives:** The aim of the study is to evaluate the reliability of an MRI-UTE sequence in the assessment of ILD extent in patients with SS in comparison with standard high-resolution CT images and to correlate the extension with pulmonary function tests (PFT).

**Methods:** Patients with SSc and ILD underwent a CT and UTE-MRI (1.5 T) acquisition on the same day. In the same week, they carried out PFT, with FVC and the diffusion capacity of carbon monoxide (DCLCO) evaluation. Two thoracic radiologists assessed consensus, on CT and UTE-MRI, the extent of ILD. Extensions were calculated as the mean percentage of lung involvement, evaluated at five levels, with an assumption of 5%: ILD extension was classified as limited (<20%) or extensive (>20% or 20% with FVC <70%). The ANOVA test was adopted to compare the CT and MRI extensions of the ILD. Correlations of the extent of CT and UTE-MRI alterations with FVC and DCLCO were calculated with Pearson’s correlation coefficient r. Sensitivity, Specificity, Positive Predictive Value (PPV) and Negative Predictive Value (NPV) of UTE-MRI were also calculated for UTE-MRI in determining ILD extent.

**Results:** The mean ILD extension was 20.9% in CT and 17% in UTE-MRI (p-value=0.64). The correlation of ILD extension in CT with FVC and DCLCO was significant (r=-0.66 (p<0.001) and r=-0.59 (p<0.0008), respectively). The correlation of ILD extension in UTE-MRI with FVC and DCLCO was significant (r=-0.66 (p<0.001) and r=-0.57 (p<0.002), respectively). The UTE-MRI assessments agreed with CT in identifying limited or extensive ILD in 25/29 patients (19 limited and 6 extended) and discordant in 4 (1 limited and 3 extended) UTE-MRI test sensitivity and specificity in identifying extended ILD were high (86.4% (65.1% -97.1%) and 85.7% (42.1% -99.6%), respectively). PPV and NPV were 95.0% (75.4% -99.2%) and 85.7% (42.1% -99.6%), respectively.

**Conclusion:** UTE-MRI sequence, compared to CT, shows high correlation with PFR and comparable ability in identifying patients with extensive ILD. Therefore, UTE-MRI seems a promising imaging sequence for the evaluation of ILD extension in SSc patients.

Objectives: The aim of our study was to examine whether eSCAR may detect subclinical myocardial fibrosis in SSc.

Methods: In this cross-sectional study conducted between 11/2020 and 02/2021, consecutive SSc patients from the University of Verona underwent cardiovascular disease (CVD) screening procedures including standard transthoracic echocardiography (TTE) and myocardial scars detection through the eSCAR technique. We excluded patients with prior history of structural heart disease and pulmonary hypertension. To validate eSCAR findings, we assessed myocardial function through global longitudinal strain (GLS) analysis by speckle tracking echocardiography (STE). We also conducted a case-control study comparing eSCAR findings in randomly selected SSc patients and non-SSc controls matched 1:1 for age, sex and number of CVD risk factors. The primary outcome was the proportion of patients with myocardial scars.

Results: Scar imaging echocardiography revealed that 42/82 (44%) SSc patients had myocardial scars involving a median [25th-75th percentile] of 4 [1-7] segments. PCA identified that myocardial scars localised mostly at the inferior and septal segments (inferoseptal pattern; Figure 1). STE validation confirmed that GLS was significantly reduced in SSc patients with inferoseptal scars (Table 1). Otherwise, all standard echocardiography measures were normal in both groups. In multivariable regression analysis, prior digital ulcerations \( \beta = 0.41, 95\% \text{ CI} 0.008 \text{ to } 0.809, p=0.045 \) and body mass index \( \beta = -0.06, 95\% \text{ CI} -0.113 \text{ to } -0.015, p=0.012 \) were both significantly and independently associated with inferoseptal myocardial scars. Myocardial scars were found in 38% of SSc patients and no matched controls \( p<0.0001 \).

</table>

Data are reported as mean (S.D.). GLS, global longitudinal strain.

Conclusion: This simple ultrasound technique allows detection of myocardial dysfunction associated with scars in SSc patients, or its absence in matched controls. Patients with prior digital ulcerations and low body weight have the strongest association with inferoseptal myocardial scars. eSCAR may help detect subclinical myocardial fibrosis in SSc.

Background: Pulmonary arterial hypertension (PAH) is a major clinical challenge in systemic sclerosis (SSc), and is associated with high mortality. Risk stratification provides an estimate for individual patient risk of 1-year mortality. The aim is to detect patients with the worst prognosis to optimize management strategies. Nine risk stratification approaches have been proposed in PAH, but have not been validated in SSc-PAH.

Objectives: To assess four risk stratification models and their performance to predict 1- and 3-year mortality and to identify the best risk assessment approach for SSc-PAH.

Methods: We included all patients with SSc diagnosed with PAH by right heart catheterization (RHC) from the European Scleroderma trial and research (EUSTAR) database from 2001 to February 2021. PAH was defined as mean pulmonary arterial pressure (mPAP) ≥25 mmHg, pulmonary artery wedge pressure (PAWP) ≤15 mmHg, and pulmonary vascular resistance (PVR) >3 Wood units (WU) in the absence of significant interstitial lung disease. We applied four different approaches for risk stratification at time of PAH diagnosis. Risk parameters included New York Heart Association (NYHA) class, 6-minute walk distance (6MWD), NT-proBNP or BNP, and echocardiographic and hemodynamic parameters with cut-off values based on the 2015 ESC/ERS Guidelines. Model 1 and 2 stratified patients into low, intermediate and high-risk categories; while Model 3 and 4 stratified the patients into four categories (low, intermediate-low, intermediate-high and high).

Model 1: Patients with ≥1 high-risk parameter were considered at high risk; with ≥1 intermediate-risk parameter at intermediate risk, otherwise at low risk

Model 2: Each variable was graded from 1 to 3 representing low to high risk. The mean of available risk parameters was rounded to the nearest integer to define the risk category

Model 3: Equalizes Model 2, but the intermediate risk group was divided into intermediate-low and intermediate-high based on the mean score.

Model 4: Stratifies patients into four risk categories based on the proportion of low-risk parameters

We performed analysis of 1- and 3-year mortality in patients with a minimum follow-up of 1 and 3 years, respectively.
Results: Of 911 patients who conducted RHC, 273 (30%) were diagnosed with SSc-PAH according to the inclusion criteria (Table 1). Median follow-up time was 2.8 years (IQR 1.3-5.3). The models varied in their ability to predict mortality (Figure 1). Model 1 and 4 either over- or underestimated mortality. Model 2 stratified patients according to the expected 1-year mortality of <5%, 5-10% and >10% suggested by the ESC/ERS Guidelines. Model 3, which divided the intermediate risk group in two different risk groups, segregated the risk of mortality further within this group.

Conclusion: Model 3 provides signals for a better risk stratification of patients with newly diagnosed SSc-PAH, with progressively increasing mortality across the categories. This may provide guidance for optimized management in clinical practice.

POS0388 DEVELOPING A SCREENING TOOL FOR THE DETECTION OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS: THE ILD-RISC RISK SCORE

O. Bruni1, L. Tofani1,2, H. Fretin2, S. Liem1, A. Velathuppillai3, H. J. Bjerkaker2, I. Barua4, I. Galetti5, A. Garaiman5, M. O. Becker2, A. M. Hoffmann-Vold6, J. De Vries-Bouwstra5, M. Vonk2, J. W. Background: High resolution computed tomography (HRCT) is the gold standard for the diagnosis of systemic sclerosis associated interstitial lung disease (SSc-ILD). Although there is agreement in performing HRCT as a screening test at time of SSc diagnosis, some physicians do not regularly perform baseline HRCTs. In addition, it is unclear according to which criteria HRCTs should be repeated during the follow-up of baseline ILD negative patients.

Objectives: To develop a risk score for the presence of SSc-ILD (the ILD-RISC), to guide physicians in ordering both baseline and follow-up HRCTs.

Methods: The steering board included six SSc-ILD experts from referral centers, two fellows and a patient research partner. Items for regression analysis were selected according to face validity, feasibility, scientific background, and personal experience using the nominal group technique (NGT). The prediction model for the presence of ILD was developed from baseline visits of SSc patients from the six centers using multivariable logistic regression with backward selection. Patients were randomly divided into a derivation and validation cohort consisting of 66% and 34% of patients respectively. Patients with missing data in the selected covariates and in the ILD status (outcome) were excluded. After identifying a cut-off favoring sensitivity >85% from the ROC curve analysis, the derived ILD-RISC score was applied first in the validation cohort and then longitudinally in a cohort of SSc patients with negative baseline HRCT.

Results: The steering board selected 13 variables deemed important in the identification of Scc-ILD: sex, age, disease duration from first non-Raynaud's phenomenon symptom, skin subset (diffuse/limited), presence of esophageal symptoms, digital ulcers (DU) ever, arthritis ever, smoking ever, increased inflammatory markers, NYHA functional class, SSc autoantibody status (SSc_Ab), FVC% and DCO%, among 780/3240 patients fulfilling the inclusion criteria, 533 (43% ILD) and 247 (48% ILD) respectively constituted the derivation and the validation cohort. In the derivation cohort, a model including FVC%, DCO%, DU ever, age and Ssc_Ab (Table 1A) showed an OR of 133.9 (95% CI 53.4-335.9) and an AUC of 79.1% (95% CI 75.3-83.0%) for the presence of ILD on HRCT (Figure 1). An ILD-RISC score ≥0.3 showed sensitivity of 85.6% and specificity of 53.6%, NPV of 82.2% and PPV of 58.2%, which were replicated in the validation cohort (Table 1B). Among 819 patients with negative baseline HRCT, 170 (20.8%) developed ILD during a 3.8±3.0 years follow up (1998 visits). Longitudinally, the ILD-RISC score showed comparable sensitivity and specificity (Table 1B).

**Figure 1. Distribution of the ILD-RISC score between patients with and without IOL on HRCT, in the derivation and validation cohorts.**

Conclusion: We developed and validated the ILD-RISC score to predict the presence of IOL at time of diagnosis and evaluated its performance during follow-up. The ILD-RISC may be useful in routine practice when resources for HRCTs might be limited. In particular, it may also help to decide when to order HRCTs at follow up, thus limiting unnecessary HRCTs and reducing the burden for patients and institutions.

**MUSCULAR EXPRESSION OF CD163 AND MAJOR HISTOCOMPATIBILITY COMPLEX CLASS I AS DIAGNOSTIC MARKERS IN IDIOPATHIC INFLAMMATORY MYOPATHIES**

B. Ghang1, B. Yoo2, S. J. Nam3.

1. Jeju National Univ Hospital, Rheumatology, Jeju-si, Korea, Rep. of (South Korea); 2. Asian Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea); 3. Asian Medical Center, Pathology, Seoul, Korea, Rep. of (South Korea)

Background: Various inflammatory markers have been suggested for detecting idiopathic inflammatory myopathies (IMMs); however, their diagnostic utility remains inconclusive.

Objectives: Muscle tissues from patients diagnosed with IMMs from January 2001 to March 2017 in a tertiary hospital were investigated. Muscular expression of CD3, CD4, CD8, CD20, CD68, CD163, MX1, MHC class I, MHC class II, and HLA-DR in muscle biopsy specimens from patients with IMMs and controls were evaluated using immunohistochemical staining. Classification and regression tree analyses were used to classify patients with IMMs who met the 2017 European League Against Rheumatism/American College of Rheumatology classification criteria for adult and juvenile idiopathic inflammatory myopathies (2017 EULAR/ACR criteria for IMMs) using various staining results as predictor variables.

Methods: Muscle tissues from patients diagnosed with IMMs from January 2001 to March 2017 in a tertiary hospital were investigated. Muscular expression of CD3, CD4, CD8, CD20, CD68, CD163, MX1, MHC class I, MHC class II, and HLA-DR in muscle biopsy specimens from patients with IMMs and controls were evaluated using immunohistochemical staining. Classification and regression tree analyses were used to classify patients with IMMs who met the 2017 European League Against Rheumatism/American College of Rheumatology classification criteria for adult and juvenile idiopathic inflammatory myopathies (2017 EULAR/ ACR criteria for IMMs) using various staining results as predictor variables.

Results: Among the total 146 patients diagnosed with IMMs by expert neurologist or rheumatologist, 129 patients with IMMs met the 2017 EULAR/ACR criteria for IMMs. Histopathologic features consistent with IMMs using HE staining was observed in 104 of 129 (80.6%) patients who met the 2017 EULAR/ACR criteria for IMMs (dermatomyositis, n = 46/66, 69.7%; polymyositis n = 58/63, 92.1%; sensitivity 80.6%, specificity 100.0%). Muscular expression of CD163 (99.2% vs. 20.8%, p < 0.001) and MHC class I (876% vs. 23.1%, p < 0.001) were significantly higher in patients with IMMs who met the 2017 EULAR/ACR criteria for IMMs than in controls. Combined CD163 and MHC class I expression provided the most significant stratification for the control group (sensitivity 96.1%, specificity 94.5%). This combination was able to classify 15 of 17 (94.1%) patients who were diagnosed with IMMs by an expert physician but did not meet the 2017 EULAR/ACR criteria for IMMs.

Conclusion: Combined CD163 and MHC class I muscular expression may be useful in diagnosing IMMs.

Background: Anti-melanoma differentiation-associated gene 5–positive dermamyositis (MDAS DM) is a rare but distinct subtype of idiopathic inflammatory myopathy (IIM) that is characterized by high mortality due to rapid progressive interstitial lung disease (ILD). MDAS is a cytosolic protein and a family of retinoic-acid inducible gene-1 (RIG-1) like receptor, which functions as a virus RNA sensor and induces the production of type I interferons (IFN-I) and proinflammatory cytokines. This leads to the death of infected cells and the activation of the antigen-specific antiviral immune response. Although the pathogenesis of MDAS DM is largely unknown, a hypothesis that pathogenic involvement of anti–MDAS antibodies has been proposed. Recently, similarities have been noted between multifaceted features of COVID-19 and MDAS DM, which suggests shared underlying autoimmune mechanisms.

Objectives: To detect the critical actors in the pathogenesis of MDAS DM by gene expression analysis of peripheral blood.

Methods: Total of 31 DM cases were investigated, including anti-amylooid-β-TRNA synthetase positive (ARS) DM (n=12), MDAS DM (n=7, survivor=3) and others (n=12). Peripheral blood was drawn at baseline and 2 to 3 months after treatments. Total RNAs were then extracted with using PAXgene miRNA kit. After quantifying the expressions of transcripts by multiplex sequencing. And then, hierarchical clustering analysis, enrichment analysis using gene ontology (GO) terms, single sample gene set enrichment analysis (ssGSEA) and weighted gene co-expression network analysis (WGCNA) were performed.

Results: The hierarchical clustering with expression profiles of peripheral blood at baseline showed major 3 clusters. Interestingly, ARS DM cases were segregated into right side of the 3rd cluster while MDAS DM cases fell into 1st and 2nd clusters. ARS and MDAS DM were clearly discriminated if differentially expressed genes (DEGs) between these subtypes of DM were analyzed. By GO enrichment analysis, the terms, such as related to “defense response to virus” including “type1 interferon signaling pathway” were found in the DEGs. In the MDAS DM cases, ssGSEA revealed that genes of “FCγR receptor mediated phagocytosis pathway” or “complement and coagulation cascade” were significantly enriched and WGCNA showed that pathways of “T-cell antigen receptor signaling” or “lungs fibrosis” were significantly upregulated. Next, we also investigated the DEGs of peripheral blood at 2-3 months after treatment between survival and fatal cases in MDAS DM. We found that suppressing RIG-I like receptor and type 1 and type 2 interferon (IFN) signaling were the keys for survival.

Conclusion: MDAS is a key sensor of several RNA viruses including corona-virus families and also activate antiviral gene transcription such as type 1 IFN genes, leading to establish an antiviral host response. As the pulmonary damage of COVID-19 is known to be difficult to distinguish from the ILD associated with anti-MDAS DM, the life-threatening ILD of MDAS DM may be caused by the over-activation of RIG-I like receptor signaling via MDAS. The hypothesis is supported by our findings that the defining features of MDAS DM are activation of “type 1 IFN pathways” and antigen-specific antiviral immune responses including “FCγR receptor mediated phagocytosis pathway” or “T-cell antigen receptor signaling”. As the levels of anti-MDAS antibodies reported to be important prognostic parameter, it may be involved in pathogenesis of MDAS DM. As we found that suppression of type 1 and type 2 IFN signaling were the keys for survival, it seems to be reasonable to use inhibitors of Janus Kinases (JAK) for treatment of MDAS DM.

DOI: 10.1136/annrheumdis-2022-eular.1574
Objectives: To correlate tMRI scores for muscle edema, fascial edema, muscle atrophy, and fatty infiltration with consecutively collected manual muscle testing 8 (MMT-8) scores and muscle enzymes. To determine the role of baseline tMRI changes in achieving maximum muscle power during follow-up.

Methods: This is a retrospective analysis of a single-center myositis cohort. IIM patients (n=55) who underwent baseline tMRI (STIR and T1 sequences) at the time of diagnosis were included. Baseline demographic, clinical, and serological parameters were noted. MRI T1 weighted sequence and STIR sequence axial and coronal images were assessed for intramuscular and fascial edema, atrophy and fatty replacement using a semiquantitative score and the percentage of muscle involvement for each parameter was calculated. MMT-8 values and muscle enzyme levels which remained unchanged at least for 6 months during follow-up were noted for 42 patients. MMT-8 ≥74 was taken as near normal muscle power based on the fact that 75% of IIM patients in remission for a long duration achieved MMT-8 of≥74 in our cohort. Spearman correlation was done between clinical parameters, muscle enzymes, and tMRI scores. Baseline parameters of patients who achieved and did not achieve MMT-8≥74 were compared. Multiple linear regression was performed to assess the tMRI variables predicting a higher MMT-8 during follow-up.

Results: The median age was 36 (27.25-44.75) years, median duration of disease at presentation was 4 months (2-10), median duration of follow up was 24 months (6.75-38.25). Dermatomyositis, Polymyositis and Antisynthetase syndrome comprised of 58.2%, 7.3% and 30.9% cases respectively. Baseline muscle enzymes CPK(r=0.531), AST(r=0.535) and ALT(r=0.442) showed significant positive correlation(p<0.01) with muscle edema. Baseline MRI thigh scores (median, IQR) muscle edema% 22.41(5.65-63.33) 10.37(0.00-28.70) 0.070 fascial edema % 43.33(18.61-78.06)33.89(11.49-50.56)0.478 muscle atrophy % 2.22(0.28-20.83) 0.00(0.00-2.50) 0.081 fatty infiltration % 6.67(2.78-18.61) 0.56(0.00-3.61) 0.010

Conclusion: Low baseline MMT-8 and presence of muscle atrophy at baseline are predictors of poor outcome. Hence performing a baseline MRI will help in the prognosis.

ASSOCIATION BETWEEN GENETICALLY PREDICTED EXPRESSION OF TPMT AND AZATHIOPRINE ADVERSE EVENTS IN PATIENTS WITH INFLAMMATORY CONDITIONS

A. Davis1, A. Dickson1, L. Daniel1, P. Nepal1, J. Zanussi1, T. Miller-Fleming1,2, P. Straub1,2, W. Q. Wei2, G. Liu1, N. Cox3, A. Hung3, G. Feng3, C. M. Stein1, C. P. Chung1,2,1Vanderbilt University Medical Center, Department of Medicine, Nashville, United States of America; 2Vanderbilt University School of Medicine, Vanderbilt Genetics Institute, Nashville, United States of America; 3Vanderbilt University Medical Center, Department of Biomedical Informatics, Nashville, United States of America

Background: Azathioprine is a widely used immunosuppressant for the treatment of inflammatory conditions such as systemic lupus erythematosus (SLE), systemic vasculitis, dermatomyositis, and inflammatory bowel disease. However, its use is often limited by myelotoxicity. Variants in the gene encoding thiopurine-S-methyltransferase (TPMT), an enzyme in the metabolic pathway of azathioprine, increase the risk for myelotoxicity. We know little about the relationship between the genetically predicted expression of TPMT and side effects of azathioprine.

Objectives: To examine whether genetically predicted expression of TPMT in liver tissue is associated with azathioprine adverse effects.

Methods: We assembled a retrospective cohort of new users taking azathioprine for inflammatory conditions at a tertiary care center. We performed genotyping with Illumina Infinium Expanded Multi-Ethnic Genotyping Array plus custom content data, and we then used Michigan Imputation servers for genetic imputation and PrediXcan models trained with GTEx/Genotype-Tissue Expression Project version 8 data to impute TPMT expression in liver tissue. We specified nine groups of phenotypes (comprised of ICD9 and ICD10 codes) corresponding to known adverse effects of azathioprine. We then tested the association between the predicted expression of TPMT and these adverse events; for outcomes significant in the Wilcoxon ranksum tests (p=0.05), each case was reviewed in clinical records for confirmation. Finally, we grouped the predicted expression of TPMT in liver tissue into tertiles and conducted logistic regressions to assess the associations between predicted expression and side effects. We conducted a sensitivity analysis restricted to patients with EHR-reported white race.

Results: The cohort included 1034 patients (Table 1). Phenocodes for 3 side effects—leukopenia (n=29), skin cancer (n=13), and rash (n=52)—were identified as associated with predicted TPMT expression in liver tissue. Of these, cases of side effects attributed to azathioprine were validated by chart review: leukopenia (96.6%; n=28), skin cancer (92.3%; n=12), and rash (9.6%; n=5) and used for analysis. When assessed by tertile of predicted expression, patients in the highest tertile had lower odds of having leukopenia (OR=0.35, 95%CI: 0.12-0.98, p=0.045) and a trend towards higher odds for skin cancer, but the number of cases was small (OR=3.56, 95%CI: 0.73-17.27, p=0.115). Confirmed cases of rash attributed to azathioprine were too few for meaningful analysis. We found similar associations between tertile of predicted expression and side effects attributed to azathioprine were validated by chart review: leukopenia (96.6%; n=28), skin cancer (92.3%; n=12), and rash (9.6%; n=5) and used for analysis. When assessed by tertile of predicted expression, patients in the highest tertile had lower odds of having leukopenia (OR=0.35, 95%CI: 0.12-0.98, p=0.045) and a trend towards higher odds for skin cancer, but the number of cases was small (OR=3.56, 95%CI: 0.73-17.27, p=0.115). Confirmed cases of rash attributed to azathioprine were too few for meaningful analysis. We found similar associations between tertile of predicted expression and side effects attributed to azathioprine were validated by chart review: leukopenia (96.6%; n=28), skin cancer (92.3%; n=12), and rash (9.6%; n=5) and used for analysis. When assessed by tertile of predicted expression, patients in the highest tertile had lower odds of having leukopenia (OR=0.35, 95%CI: 0.12-0.98, p=0.045) and a trend towards higher odds for skin cancer, but the number of cases was small (OR=3.56, 95%CI: 0.73-17.27, p=0.115). Confirmed cases of rash attributed to azathioprine were too few for meaningful analysis.

Conclusion: This analysis suggests that PrediXcan may be useful for examining the association between gene expression and side effects of medications. Moreover, this approach successfully identified leukopenia as a side effect associated with predicted TPMT expression.

DOI: 10.1136/annhem-2022-eular.332
Background: Patients with rheumatoid arthritis (RA) have a higher prevalence of coronary artery disease (CAD) than the general population which contributes to early mortality. However, CAD screening tools developed in the general population are less effective for estimating CAD risk in RA patients. This is mainly due to the differing contribution from traditional risk factors and the contribution from disease-specific factors. Understanding of the genetic basis of CAD has improved over recent years and shows promise for improving risk prediction in the form of genetic risk scores (GRSs), in particular with the development of the metaGRS approach, which combines multiple polygenic risk scores.

Objectives: This study hypothesise that the metaGRS approach can help us improve CAD risk prediction in patients with RA.

Methods: Patients were recruited from the Norfolk Arthritis Register (NORAF), a longitudinal observational study focused on the cause and outcome of inflammatory polyarthritis. Analysis was restricted to patients who satisfied the 2010 ACR criteria cumulatively over five years and had detailed clinical history at baseline and follow-up for ten years. We developed a prediction model based on traditional risk factors[1], and explored the inclusion of a metaGRS. We used a meta-analytic approach to calculate a new metaGRS for CAD, using the effect-sizes from three large-scale, genome-wide, and targeted GRSs derived from 1,745,179[2], 6,630,150[3], and 40,079 SNPs[4]. We tested the metaGRS in combination with available data on traditional risk factors in a subset of patients with available genetic data. Cox proportional hazards models were used to derive risk equations for evaluation of 10-year risk of CAD. We applied multiple imputations with chained equations to replace missing values. Calibration and discrimination were determined in a separate cohort of 423 individuals.

Results: A total of 2123 patients were included in the analysis with 136 incident cases of self-reported CAD (defined as a composite outcome of myocardial infarction, angina, heart attack, arrhythmia, angioplasty, and coronary artery bypass grafting). The model using only traditional risk factors achieved an AUC of 0.81 (95% CI 0.80, 0.82), with a calibration slope of 1.10, and explained approximately 71% (95% CI 69, 72%) of the variance of the outcome. The hazard ratio for age was found to be 1.00 (95% CI 0.99, 1.01) indicating risk remains the same across all age groups. Inclusion of a metaCADGRS improves the AUC to 0.82 (95% CI 0.80, 0.83), explains more of the variance at 71% (95% CI 79, 82%) but worsens calibration slope to 0.93. A likelihood ratio test indicates that the integrated model is a better fit (p = 0.04).

Conclusion: An integrated risk score, that combines traditional risk factors with a metaGRS, improves CAD prediction in patients with RA. Further research is required to better understand the role of heritable components contributing to CAD risk in RA patients. By refining the underlying GRS, we hope to further improve risk prediction, through this integrated approach.

IDENTIFICATION OF DIFFERENTIALLY EXPRESSED GENES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. H. Jung1, A. Kim2, B. Y. Kim2, G. G. Song1. 1Korea University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2CHA University School of Medicine, Medicine, Seongnam, Korea, Rep. of (South Korea)

Background: Characterizing differentially expressed genes (DEGs) of systemic lupus erythematosus (SLE) is necessary to understand immunogenic interactions, and how several key immune genes were closely associated with the susceptibility of SLE.

Objectives: This study aimed to identify DEGs in SLE using gene expression-based computational methodologies to analyze disease-immune interactions, which affect the development and progression of SLE.

Methods: Twenty-six patients with SLE and 46 healthy controls were selected from the Gene Expression Omnibus database. The significantly enriched immune and virus related gene lists were computed and visualized by using the DEGs from the Gene Set Enrichment Analysis. Quantification of 36 immune cells were performed in determining the impact of immune cells on the virus mediated immunity in SLE by using ImmQuant algorithm.

Results: Thirty nine upregulated and 57 downregulated were identified in SLE patient compared to the healthy controls. Upregulated genes were significantly implicated in Gene Ontology gene sets as cytokine mediated signaling, secretion, and exocytosis in immune response pathways. In addition, these genes were enriched in hepatitis C, influenza A, measles, Epstein-Barr virus, and...

**SSD6453, A NOVEL AND HIGHLY SELECTIVE BTK/JAK3 DUAL INHIBITOR IS EFFICACIOUS IN MULTIPLE PRE-CLINICAL MODELS OF INFLAMMATION**

1Simcere Pharmaceuticals, in vitro pharmacology, Shanghai, China; 2Simcere Pharmaceuticals, in vivo pharmacology, Shanghai, China; 3Simcere Pharmaceuticals, Pharmaceutical Chemistry, Shanghai, China; 4Simcere Pharmaceuticals, DMPK, Shanghai, China; 5Simcere Pharmaceuticals, R&D, Shanghai, China

**Background:** The mechanism of inflammatory diseases is complicated and dysfunction of multiple immune cells is thought to be directly related to the pathogenesis. Targeting either JAK-STAT or BCR signaling has been proven to offer solid clinical efficacy in multiple inflammatory diseases, such as rheumatoid arthritis (RA) and multiple sclerosis (MS). And the combination of BTK and JAK inhibitors demonstrated synergistic effects for the treatment of inflammation models in pre-clinical. JAK3 expression is largely restricted to leukocytes and involves functions in JAK1/JAK3 heterodimer in signal transduction, it might be a more effective and safer target. Meanwhile, both BTK and JAK3 possess a cysteine residue in their active site and this feature makes it possible to design a dual inhibitor. SSD6453 is a highly selective and irreversible JAK3/BTK dual inhibitor which may have synergistic effects for the treatment of RA and other inflammatory diseases such as MS. **Objectives:** To develop a potent, oral, highly selective JAK3/BTK inhibitor for treatment of multiple inflammatory diseases.

**Methods:** ADP-Glo based biochemical assays were performed to determine the enzymatic inhibitory effect and selectivity for JAK family. The target engagement was evaluated by IgM induced pBTK and IL-2 induced pSTAT5 in human PBMCs. In vivo efficacy was evaluated by rat collagen-induced arthritis (CIA) model and mice experimental autoimmune encephalomyelitis (EAE) models induced by MOG1-125 or MOG35-55, respectively. BTK occupancy in spleens post last dose 24h and IL-2 induced pSTAT5 in whole blood post last dose 0.5h were used to evaluate targets inhibitions. Osteoclast was stained by IHC in pathological section of rat paws. **Results:** In biochemical assays, SSD6453 inhibited BTK and JAK3 with the IC50 values of 3.4 nM and 1.1 nM, respectively. Notably, SSD6453 displayed high enzymatic inhibitory effect and selectivity for JAK family. **Conclusion:** SSD6453 is a novel and high selective BTK/JAK3 dual inhibitor, and demonstrated synergistic efficacy in multiple pre-clinic inflammation models. SSD6453 showed good pharmacokinetic characteristics and well-tolerant in multiple pre-clinical species, and is moving to IND in 2022.

**IDENTIFICATION OF THE HLA-B*51:01 IMMUNOPEPTIDOME IN BEHÇET’S DISEASE**

1Seoul National University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Seoul National University, Molecular Medicine and Biopharmaceutical Sciences, Seoul, Korea, Rep. of (South Korea)

**Background:** Immunopeptidomes are peptides, bound to human leukocyte antigens (HLA), that play a key role in immune responses. HLA-B*51:01 is an HLA allele associated with Behçet’s disease (BD)1. However, the characteristics and the role of HLA-B*51:01 immunopeptidome are not revealed in Behçet’s disease. **Objectives:** To investigate the difference of HLA-B*51:01 immunopeptidome between Behçet’s disease and healthy controls (HCs) and to select candidate peptides which have a pathogenic role in Behçet’s disease.

**Methods:** HLA-bound peptide profiles were established through analysis of plasma samples from HLA-B*51:01-positive BD patients and HCs. HLA class I molecules were immunoprecipitated, and liquid chromatography-tandem mass spectrometry (LC-MS/MS) was performed. Then, HLA-B*51:01-binding peptides were assessed in terms of binding affinity using NethMCpan. Finally, the motifs of human leukocyte antigens (HLA)-B*51:01-positive BD patients and HCs.
immunological characteristics of selected peptides were analyzed in BD patients and HCs, using ELISPot, flow cytometry, and dextramer staining.

**Results:** 2,306 peptides were present only in BD patients, while 3,145 peptides were detected only in HCs. Immunoepitope of BD patients preferentially showed hydrophobic amino acids at amino acid position 2 (Figure 1). Ten peptides were selected, which were confirmed to be preferentially expressed in BD patients compared with HCs. When bound to HLA-B*51:01 in monocyte-derived dendritic cells (MoDCs) or peripheral blood mononuclear cells, these peptides activated T cells and induced surface expression of CD69 and CD107, as well as the secretion of inflammatory cytokines such as interferon (IFN)-γ and tumor necrosis factor (TNF)-α.

**Conclusion:** HLA-B*51:01 immunoepitope may play a critical role in the development of BD by activating T cells and inducing the secretion of inflammatory cytokines.

**Background:** Differentiation in the bone marrow (BM) is impaired in patients carrying mutation in the IKZF1 gene, coding for Ikaros a zinc-finger transcription factor. High Ikaros expression is on the contrary associated with systemic lupus erythematosus [1] and multiple myeloma [2]. Targeted treatment with iberdomide, a cerebellin modulator which enhances degradation of Ikaros and Aiolos, is under clinical investigation in multiple myeloma patients and systemic lupus erythematosus. However, consequences of the treatment on human early B cell development remain elusive. Immature B cells develop in the BM from hematopoietic stem cells. An intricate network of transcription factors regulates the maturation process. Ikaros and Aiolos regulate gene expression during B cell development. As reported in mice, Ikaros is essential for the commitment to the lymphoid lineage and later, together with Aiolos, ensures the transition from pre-BII large to pre-BII small cells.

**Objectives:** The impact of iberdomide on short term culture of BM-derived lymphocytes and in a unique in vitro modeling of early B cell development starting from cord blood (CB)-CD34+ progenitors [3, 4]. We used multi-dimensional spectrally flow cytometry (17-color pan-el) to dissect early B cell subpopulations.

**Results:** Iberdomide treatment led to enhanced degradation of Ikaros and Aiolos in both BM- and CB-derived cultures. Addition of iberdomide early (day 7) to the CB-derived culture impaired the specification to the lymphoid lineage and later also the commitment to the B cell lineage. These observations were confirmed by reduced E2A and PAX5 gene expression, respectively. Treatment with iberdomide on B cell precursors (pre- and pre-B cells, day 28 of culture) on one side it enhanced the proliferation of early progenitors resulting in increased amount of CD10+CD38+ lymphoid-committed cells. On the other side, it resulted in a accumulation of pre-B cells and inefficient development of immature B cells.

**Conclusion:** Iberdomide impairs the commitment to the lymphoid lineage by enhancing Ikaros’ degrada-tion. When targeting already committed B cells, iberdo-mide treatment undermines the transition of pre-BI large to pre-BII small cells due to increased Aiolos’ degradation, concomitantly impairing the development of immu-nate B cells. Our data can instruct immunological monitoring of patients treated with iberdomide, and provide insights in the mechanisms of the therapeutic efficacy.

**SEROUM ANTIBODIES TO TYPE I COLLAGEN IN PERIPHERAL ARTHRPATHY ASSOCIATED WITH INFLAMMATORY BOWEL DISEASE**

D. Abulagulayeva1, D. Mukhamedtseva1, O. Zinkevich2, N. Saphina3, M. Korovina3, A. Odincova3. Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation; 2 Kazan State Medical Academy, Central Research Laboratory, Kazan, Russian Federation; 3 Kazan State Medical University, biochemistry and clinical laboratory diagnosis, Kazan, Russian Federation; 4 Republican Clinical Hospital, gastroenterology, Kazan, Russian Federation

**Background:** Immunological disorders play an important role in the pathogenesis of inflammatory bowel disease (IBD). Type I collagen (COL1) is the main component of the intercellular matrix of connective tissue. It can be assumed that the immune disorders occurring in the production of autoantibodies to collagen play a role in the pathogenesis of arthropathy associated with IBD.

**Objectives:** To study the level of IgM and IgG to type I collagen (COL1) in peripheral arthropathy associated with IBD.
Methods: We prospectively included 91 patients with IBD [61 ulcerative colitis (UC), 30 Crohn's disease (CD)] and 30 healthy controls. 82 patients with IBD were in disease attack and 9 in the remission. Mean age in IBD was 36 [28; 47] years and in control group – 35 [24; 45]. Joint involvement (arthralgia, arthritis) was observed in 33 patients (36%). Affected joints were the knees 17 (51%), shoulders 6 (18%), feet 6 (18%), hands 5 (15%), elbows 4 (12%), ankles 3 (9%), wrists 2 (6%). Levels of serum IgM and IgG to COL1 were assessed by enzyme immunoassay.

Results: Levels of IgM to COL1 in active IBD (0.18 [0.10; 0.22] mg/ml; p<0.01) and in remission (0.15 [0.11; 0.20] mg/ml; p<0.05) were increased compared with healthy (0.09 [0.07; 0.12] mg/ml). There were no differences between stages of disease attack and remission (remission and exacerbation). IgM antibody levels to COL1 in patients with peripheral arthropathy 0.174 [0.12; 0.28] mg/ml were significantly higher in patients without joint involvement 0.12 [0.08; 0.19] mg/ml; p<0.01.

The levels of IgG to COL1 in active IBD 14.4 [10.22; 33.34] mg/ml; p<0.05 and in remission (28.82 [16.36; 78.8] mg/ml; p<0.005) were higher than in the control group 11.36 [6.93; 19.83] mg/ml. We didn't find any differences in IgG levels depending on the severity of disease. IgG levels to COL1 in patients with peripheral arthropathy 16.18 [9.46; 26.21] mg/ml were higher, than without them 12.78 [8.81; 28.31] mg/ml, also not significant.

Conclusion: In active IBD the level of serum antibodies of class IgM and IgG to COL1 increased compared with healthy. The maximum increase was found in the patients with peripheral arthropathy, which can be explained by the high content of this collagen in the structural components of the joints and by joint inflammation in patients by IBD.

PSQ0403

DYNAMIC CHANGES IN AUTOACTIVE MEMORY B CELLS IN RHEUMATOID ARTHRITIS: KEY TO UNDERSTANDING IMMUNOLOGICAL DISEASE ACTIVITY

N. Blomberg1, H. Kristiansyo1, M. Verstappen1, S. Neppelenbroek1, A. S. B. Kampstra1, A. Van der Helm-van Mil1, R. Toes1, H. J. U. Scherer1, Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands

Background: Rheumatoid arthritis (RA) patients with autoantibodies against citrullinated antigens (ACPA) are characterized by poor chances to achieve sustained DMARD free remission. We have previously observed that autoactive ACPA-expressing memory B cells (MBC) display an activated phenotype and frequently maintain this state of activation during periods even in patients in clinical remission in whom inflammation is absent through treatment. Conceptually, these observations could reflect ongoing immunological activity. In fact, they indicate that most current therapeutic interventions do not induce immunological remission and could explain why disease frequently flares when treatment is stopped. ACPA-expressing MBC display the phenotype of recent germlinal centre emigrants, actively proliferating (Ki-67 positive), expressing CD69 and co-stimulatory markers CD80 and CD86, and the signature cytokine IL-6.[1] Notably, in autoantibody-positive individuals with arthralgia that did not progress to inflammatory arthritis within 2 years, the autoreactive B cells were readily detectable in the circulation and proliferated but lacked, in most cases, the upregulation of CD80 seen at the onset of disease. Now, we studied these autoactive B cells longitudinally in the ‘at-risk’ phase of clinically suspect arthritis (CSA) and in a population of patients in sustained (>1 year) drug-free remission (SDFR).

Objectives: To define dynamic changes of the ACPA-expressing B cell compartment throughout clinical disease stages with the aim to evaluate this response as a possibly predictive biomarker of immunological disease activity.

Methods: ACPA-expressing MBC were identified by flow cytometry in peripheral blood of RA patients with chronic disease or at disease-onset (treatment-naive), in ACPA-positive CSA patients ‘at-risk’ for RA, and in patients in SDFR. B cells were characterized by a combination of markers to classify B cell subpopulations and activation- and germinal centre related markers. Tnusus-toxoid-specific B cells were analysed in the same individuals as antigen-specific comparators.

Results: In patients in SDFR, significantly less autoreactive B cells expressed CD80 compared to active disease, while they persistently showed signs of proliferation similar to the phenotype observed in CSA patients that did not progress to RA. ACPA-specific plasmablasts (defined as CD20 CD22[+] ) were practically absent in SDFR and CSA non-progressors, while they were readily detectable in patients with RA at disease onset, during treatment, and in CSA-individuals that later progressed to RA. Notably, two arthritis patients that developed RA within one year showed high CD80 expression in the autoactive MBC compartment already in the ‘at-risk’ phase, whereas patients that so far did not progress to RA during the time of follow-up, showed less CD80-positive autoactive MBC.

Conclusion: The phenotype of autoreactive B cells is dynamic in different disease phases of RA. By studying extremes of clinical phenotypes (‘at-risk’ phase, disease onset, SDFR), we found evidence for dynamic expression of CD80 by ACPA-expressing MBC in relation to clinical disease stage. Intriguingly, CD80-positive B cells, but not CD80-negative B cells, have been shown to be able to differentiate into antibody secreting cells in mice.[2] Our finding that plasmablasts were practically absent in ACPA-positive arthritis patients that did not progress to RA and in SDFR would fit with this notion and suggests that in SDFR autoactive MBC lack, although actively proliferating, triggers that induce CD80 upregulation, differentiation to plasmablasts and, possibly, their active participation in processes causing joint inflammation. Based on this observation, it is possible that induction of this CD80 [ ] phenotype in autoreactive MBC may be an important step towards achieving immunological remission, a conceptual proxy for cure.

Background: Immune checkpoint inhibitor (ICI) therapies that promote T cell activation have improved outcomes for advanced malignancies yet can also elicit harmful autoimmune reactions. The T cell mechanisms mediating these iatrogenic autoimmune events remain unclear.

Objectives: To investigate the immunophenotype, transcriptomic feature and clonotypes of T cells from joints of patients affected by ICI-induced inflammatory arthritis (ICI-aria)

Methods: Detailed immunophenotyping was performed on mononuclear cells from synovial fluid and flow cytometry and flow cytometry to identify significantly altered populations in ICI-A compared to seropositive rheumatoid arthritis (RA) and psoriatic arthritis (PsA) (p<0.05). Bulk RNA-seq was performed on altered SF CD8 T cell subsets from ICI-A, RA and PsA to investigate their transcriptomic features. Cytokine profile and pathways enriched in ICI-A CD8 T cells were examined using differentially expressed genes, intracellular staining, and in vitro culture. TCR clonotypes were examined using single cell RNA-seq of T cells from synovial fluid, tissue and blood of ICI-A.

Results: Compared to the autoimmune arthritis RA and PsA, ICI-aria joint tissues contained an expanded CD8+ CD127- CD8+ T cell subset that displays cytotoxic, effector, and interferon (IFN) response signatures. Expression of synovial T cells to Type I IFN, more so than IFN-γ, induced the CD38+ cytotoxic phenotype. Single cell transcriptomic and T cell repertoire (TCR) analyses indicated that the abundance of CD38+ CD8+ T cells in ICI-aria resulted from proliferation of a limited number of clones. The CD38+ population appeared distinct from dysfunctional T cells and clonally most related to TCFF+ memory populations. Comparison of synovial tissue from bilateral knees of the same patient demonstrated considerable sharing of TCR clonotypes among CD38+ CD8+ T cells between the two joints. Further, TCR clonotypes expanded in synovial fluid of ICI-aria patients were detected in circulating T cells, and circulating CD38+ CD8+ T cells are also expanded in ICI-aria patients.

Conclusion: These results define a distinct CD8 T cell subset in the synovial fluid and in the circulation of patients with ICI-A that may be directly activated by ICI therapy to mediate a tissue-specific autoimmune response.

IFNα-MEDIATED METABOLIC REPROGRAMMING IN HUMAN SLE MONOCYTES INVOLVES PERTURBATIONS IN GLYCOLYTIC AND LIPID METABOLISM TO REGULATE INFLAMMATORY MARKERS AND CYTOKINES

C. Stathopoulou1, D. Konstantopoulos2, S. Papapikolaou3, G. Vatellases1, G. Panagopoulos4, P. Sidirovski1, G. Bertsias1, 2, 3

1University of Crete, Medical School, Heraklion, Greece; 2Institute of Molecular Biology and Biotechnology-IMBB, Foundation for Research and Technology Hellas, Heraklion, Greece; 3Institute for Bioinovation-IIB, Biomedical Sciences Research Center ‘Alexander Fleming’, Athens, Greece; 4Greek Genome Center, Biomedical Research Foundation of Athens, Athens, Greece; 5University General Hospital, Rheumatology Department, Heraklion, Greece

**Background:** Systemic Lupus Erythematosus (SLE) is a prototype interferonopathy characterized by multiple organ damage. Metabolomic analyses of patient-derived sera indicate distinct metabolic perturbations in oxidative and lipid metabolic pathways of healthy Mo, whereas SLE-Mo resemble unhealthy Mo. Additionally, transcripts associated with cholesterol biosynthesis were upregulated in IFNα-SLE-Mo, in turn being responsible for the metabolic shift of cells. IFNα-mediated metabolic shifts in Mo with correlated metabolic perturbations in human disease are of current interest as new therapeutic targets in SLE.

**Objectives:** Based on previous data indicating a prominent IFNα-gene signature in SLE monocytes even during disease remission, we herein sought to delineate the metabolic repercussion of IFNα signaling contributing to SLE autoimmunity.

**Methods:** Using transcriptional data, we compared the enriched metabolic categories of IFNα(+) and IFNα(-) SLE-Mo. In order to compare metabolic perturbations pertaining to SLE, we performed transcriptomic Gene Set Enrichment Analysis (GSEA) from vitro cultured IFNα-activated Mo. We supplemented the analysis with in vitro biochemical inhibition of the metabolic pathways arising from the GSEA and evaluated the effect on inflammatory markers of healthy IFNα-Mo.

**Results:** We found a statistically significant enrichment of transcripts associated with glycolytic metabolism and lipid biosynthetic and catabolic processes in both IFNα(+) SLE-Mo and healthy IFNα-Mo, but not in IFNα(-) SLE-Mo, which in turn resemble healthy-Mo. Additionally, transcripts associated with cholesterol biosynthetic processes such as PMVK, SLOSE, LDLR, and LSLR, MVK, FMNL were significantly upregulated in IFNα(+) SLE-Mo and healthy IFNα-Mo respectively. In accordance with either glycolysis or the use of 2-DG hexokinase inhibitor, or mevalonic acid synthesis with the use of fuvastatin, attested proinflammatory cytokine secretion (IL6, CXCL10) associated with IFNα-response in both IFNα(+) SLE-Mo and healthy IFNα-Mo.

**Conclusion:** Our results link IFNα-mediated metabolic shifts in Mo with corresponding metabolic perturbations found in SLE patient-Mo. Pending further confirmation with targeted metabolomics, these data further rationalize the use of IFNα blockade and also suggest the potential use of specific metabolites as novel therapeutic targets in SLE.

**Background:** Intercellular adhesion molecule-1 (ICAM-1) and E-Selectin are adhesion molecules considered as markers of underlying endothelial activity and damage. These molecules are known to play an important role in autoimmune disease (AD) [1]. Accordingly, they may contribute to the development of interstitial lung disease (ILD), one of the main causes of death in patients with AD [2]. In fact, they have been proposed as prognostic biomarkers in idiopathic pulmonary fibrosis (IPF) [3]. However, studies on the role of ICAM-1 and E-Selectin in the pathogenesis of AD-ILD* are scarce.

**Objectives:** To study the role of ICAM-1 and E-Selectin in the pathogenesis of AD-ILD*.

**Methods:** Peripheral venous blood was collected from 57 patients with AD-ILD* and three comparative groups: 45 AD-ILD* patients, 21 IPF patients and 21 healthy controls (HC). All the subjects were recruited from the Rheumatology, and Pneumology departments of Hospital Universitario Marqués de Valdecilla, Santander, Spain. ICAM-1 and E-Selectin levels were measured in serum samples by enzyme-linked immunosorbent assay.

**Results:** Higher levels of ICAM-1 and E-Selectin were found in patients with AD-ILD* compared to AD-ILD* patients (p<0.001 and p=0.001, respectively) and HC (p<0.001 in both cases). Likewise, IPF patients showed increased levels of ICAM-1 and E-Selectin in relation to AD-ILD* patients (p<0.001 and p=0.002, respectively) and HC (p<0.001 in both cases). However, no statistically significant difference in ICAM-1 and E-Selectin concentrations was observed between AD-ILD* and IPF patients.

**Conclusion:** Our study suggests that increased levels of ICAM-1 and E-Selectin are associated with the presence of ILD in AD patients.

Methods: The expression of eRNAs in SF (n=9), stimulated with TNF (24h; 10 ng/μl) or left untreated, was detected by cap analysis of gene expression followed by sequencing (CAGEseq). To further investigate eRNA expression in SF, the expression of selected eRNAs and their linked coding genes (CXCL1, CCL2, IL6, CCL2, CXCL12, IL8) was analyzed by real-time PCR in SF that were stimulated with TNF (1, 3, 6, 24h; 10 ng/μl), IL1 (1, 24h; 1 ng/ml), or the Toll-like receptor agonists Pam3 (1, 24h; 1 ng/ml), pic (1, 24h; 10 μg/ml) and LPS (1, 24h; 100 ng/μl). Samples containing the untranscribed RNA were measured in parallel. To study eRNA regulation, SF were treated with the bromodomain inhibitor I-BET (1 μM; 24h), or silenced for the histone acetyltransferases CBP and p300 by transfection with antisense LNA gapmeRs (12.5 nM) prior to stimulation with TNF (1, 24h).

Results: We have selected four potential eRNAs for CCL2 and IL8, three for CXCL12, two for IL6 and CXCL1 and one for CCL20 from CAGEseq analysis. They were located upstream (eCCL2#1, eCCL2#2, eCXCL1#2, eCXCL12#3, elIL#1+2, elIL#4-1), downstream (eCCL2#3, eCCL2#4, eCXCL1#1, eCXCL12#1) and intronic (eCCL20, eCCL12#2) at distances between 300 bp to 35.6 kb relative to the transcription start sites of the corresponding coding genes. None of the eRNAs was present in all nine samples in CAGEseq data sets, indicating a patient-dependent variability in eRNA expression. The majority of eRNAs were not detected in unstimulated SF, with the exception of eRNAs for CXCL12. By performing TNF time course experiments (Figure 1), we have detected different patterns of eRNAs: (a) eRNAs, that peaked at 1h (eCCL20, elIL#2, eCCL2#1), (b) at 6h (eCXCL1#1), (c) or at 24h (elIL#1, elIL#8#3, elIL#4, eCXCL1#2) after stimulation, (d) eRNAs that were stably expressed over the time points (eCCL2#2, 3, 4), and (e) eRNAs that were down regulated by TNF.

Results.

Figure 1.

stimulation (eCXCL12#1, eCXCL12#3). All inflammatory stimuli induced eRNA expression in SF, with LPS and IL1, followed by TNF, being the most potent inducers of eRNAs. I-BET suppressed the TNF-induced expression of all eRNAs tested. The effects on the expression of eRNAs after silencing of p300 but not of CBP mirrored to a large extent those of the respective coding genes. 

Conclusion: In SF, the expression of some eRNAs is maintained for up to 24h, contradicting previous reports that eRNA expression is short-lived. Our data suggest that different eRNAs orchestrate the early and sustained expression of cytokines and chemokines in SF; eRNA expression is controlled by p300 and BET bromodomain proteins.

OXysterol 7-ketocholesterol can re-program synovial tissue macrophages and support M1 polarization

W. Dravši, D. Legovič, B. Ćurko-Cofel, L. Fryklavá, E. Babaovic, T. Kehler, V. Persic, G. Laskarin.1 1Clinical Hospital Centre Rijeka, Clinical Department of Laboratory Diagnostics, Rijeka, Croatia; 2Orthopedic University Hospital Lovran, Orthopaedic University Hospital Lovran, Lovran, Croatia; 3Faculty of Medicine, University of Rijeka, Department of Physiology and Immunology, Rijeka, Croatia; 4Croatian Academy of Sciences and Arts, Department of Biomedical Sciences in Rijeka, Rijeka, Croatia; 5Faculty of Medicine, University of Rijeka, Department of Pathology, Rijeka, Croatia; 6Hospital for Medical Rehabilitation of Heath and Lung Diseases and Rheumatism “Thalassoatherapia-Opatija”; 7Hospital for Medical Rehabilitation of Heath and Lung Diseases and Rheumatism “Thalassoatherapia-Opatija”, Opatija, Croatia

Background: Oxidized low-density lipoprotein (oxLDL) particles support low-grade inflammation and have been found in synovial fluid from osteoarthritis (OA) joints [1]. Their component is 7-ketocholesterol (7-KC), which arises as the result of the oxidation of cholesterol [1]. 7-KC acts proinflammatory and it binds to Toll-like receptor (TLR) 4 expressed on macrophages [1]. Activation of TLR4 stimulates the classical macrophage maturation program, resulting in a specific phenotype of inducible nitric oxide synthase positive (iNOS+) and macrophage (M) 1 function, which produce pro-inflammatory cytokines and chemokines [2]. M2 macrophages are associated with wound healing by the production of arginase-1 [2,3]. Synovial macrophages are of critical importance in the symptomatology and structural progression of OA since M1 polarized macrophages accumulate in human OA synovial tissue during exacerbation [3]. However, it is not known whether 7-KC can re-program synovial tissue macrophages and support M1 polarization.

Objectives: We analyzed the influence of 7-KC on the polarization of CD68+ macrophages in the suspension of synovial mononuclear cells (SMCs) in respect to lipopolysaccharide (LPS), as M1 inducer.

Methods: Mature synovial tissue samples were obtained during arthroplasty of the knee (N = 56). Paraffin embedded tissue sections were labelled by double immunofluorescence using a combination of antibodies directed toward CD68 and iNOS, arginase-1, CCL2 or CCL22. Suspension of SMCs was prepared by enzymatic digestion of tissue samples using collagenase IV and gradient density centrifugation. We analyzed intracellular (iNOS, arginase-1, CCL2, and CCL22) and surface (CD91, mannose receptor, HLA-DR, CD80, CD86 and decy D6) antigens expression in CD68+ cells and CD16+ cells in the suspension of freshly isolated or 18 hour-cultured SMCs with 7-KC (25 μM), LPS (10 ng/ml), their combination or in the medium only.

Results: iNOS and CCL2 were more frequently labelled in lymphocyte clusters, while arginase-1 and CCL22 were labelled in synovial lining CD68+ cells. Phenotype of CD68+ cells did not change significantly after the 18 hour culture in the medium only, except the decrease of mannose receptor and CD91, when compared with freshly isolated cells. 7-KC increased the percentage of CD68 expressing CD68+ cells, whereas decreased surface expression of CD91 and chemokine decor D6, like in the culture with LPS, when compared with cells cultured in the medium only. 7-KC decreased the frequency of arginase-1+/CD68+ cells in the suspension and did not change iNOS+ in CD68+ cells, thus increasing the ratio of iNOS+/arginase-1+ in CD68+ subset. 7-KC was unable to increase CCL2 like LPS in comparison with cells cultured in the medium only. Neither 7-KC nor LPS affected CCL22 expression in the CD68+ subset.

Conclusion: These data provide a new perspective in understanding the polarization of macrophages toward the M1 phenotype mediated with oxysterol 7-KC in vitro.

**Background:** Rheumatoid arthritis (RA) is a systemic autoimmune disease leading to erosive joint destruction, although the exact pathogenesis is still elusive, the strong association of certain HLA class II molecules, such as HLA-DRB1*0401 (HLA-DR4), suggest involvement of CD4+ T cells (1, 2). Mouse models of RA mimic specific aspects of the disease but are limited by the differences between human and murine immune systems.

**Objectives:** We aimed to establish a humanized mouse model (humice) carrying DR4+ RA PBMCs to study its role in the pathogenesis of RA without putting patients at risk.

**Methods:** Peripheral blood mononuclear cells (PBMC) of HLA-DR4 positive RA patients or controls were isolated and injected into NSG-Ab0 DR4 mice (NOD-scid IL2Rgamma-null mice lacking MHC class II while expressing the human HLA-DR4) to create humice. Human immune cell composition within humice was profiled using flow cytometry. Development of RA was monitored by examination of the joints and micro computed tomography analysis. Joints were analysed by histology regarding pannus formation, bone erosions, cartilage damage, and human cell infiltration.

**Results:** Transfer of RA PBMCs induced arthritis in humice recapitulating hallmark signs of RA including immune cell infiltration, pannus formation, increased osteoclastogenesis, cartilage damage, and bone erosions. Arthritis was dependent on the implanted human cells as NSG-Ab0 DR4 mice without transfer of human PBMCs did not develop arthritis. T-helper 1 (Th1) cells, dominated the human immune cell composition in humice, while regulatory T cells (Tregs) were diminished compared to donor PBMC composition. Mice humanized with cells from RA patients were more likely to develop inflammatory joint disease, compared to healthy HLA-DR4 positive controls (RA donor mice vs vs. healthy control 20%, p=0.00196). CTLA4-Ig treatment prevented arthritis development in this model (p=0.0035).

**Conclusion:** Humice carrying DR4+ RA PBMCs developed an RA-like erosive joint disease driven by the implanted human immune system. The data implies that the disease can be transferred by arthritogenic cells found in the peripheral blood of RA patients. This model will allow new insights into the pathogenesis of RA.

**POSO409**  INTESTINAL HIF1α EXPRESSION PROTECTS AGAINST EPITHELIAL CELL DEATH IN ARTHRITIS

P. Lyu1, J. Wen1, I. Stolzer2, A. Giessi1, R. Song1, X. Meng1, S. Cao1, C. Günther1, G. Schett1, A. Bozec1, 1Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany; 2Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Department of Ophthalmology, Erlangen, Germany

**Background:** While a so-called gut-joint axis is supported by many clinical observations, the current knowledge on such axis is mostly confined to descriptive and correlative data, e.g. showing the microbiota changes are associated with arthritis. In contrast, mechanistic data on how molecular changes in the intestinal epithelium influence the development of arthritis are scarce.

**Objectives:** To investigate, whether the mucosal barrier in the intestine determines the fate of the epithelial cell survival maintenance, influences the development of arthritis.

**Methods:** Intestinal hypoxia inducible factor (HIF)-1α expression was assessed before, at onset and during experimental arthritis and human rheumatoid arthritis (RA). Intestinal epithelial cell-specific HIF1α conditional knock-out mice were generated (HIF1αΔIEC) and subjected to collagen-induced arthritis (CIA). Clinical and histological courses of arthritis were recorded, and T and B cell subsets were analyzed in the gut and secondary lymphatic organs, and intestinal epithelial cells were subjected to molecular mRNA sequencing in HIF1αΔIEC and littermate control mice. Furthermore, pharmacologic HIF1α stabilization by PHD inhibitor was used for the treatment of arthritis.

**Results:** Intestinal HIF1α expression peaked at onset and remained high in experimental arthritis and RA. Conditionally deletion of HIF1α in gut epithelial cells strongly exacerbate arthritis and was associated with increased gut epithelial cell death, intestinal and lymphatic Th1 and Th17 activation. Mechanistically, HIF1α inhibits the transcription of necroptotic and apoptotic markers, which leads to a defect in the intestinal barrier integrity. Furthermore, treatment with HIF1α stabilization reinforced the gut epithelial cell survival and inhibited arthritis.

**Conclusion:** These findings show that the HIF1α regulating epithelial cell survival is critical for the breakdown of the intestinal barrier function in arthritis highlighting the functional link between intestinal homeostasis and arthritis.

**POSO410**  THE ROLE OF IL-6 IN ENDOTHELIAL DYSFUNCTION: RHEUMATOID ARTHRITIS AND COVID-19, TWO PATHOGENIC MODELS IN COMPARISON

A. I. Celia1, C. Barbatii, T. Colasanti1, M. Speziali1, G. Pellegrino1, F. Natalucci1, F. M. Uccio1, E. Balboni1, C. Ciancarella1, G. Tripodi1, G. Buonocore1, F. Cecarelli1, F. Conti1, C. Alessandrini1. 1Arthritis Clinic, Department of Clinical internal, anaesthesiological and cardiovascular sciences, Sapienza University of Rome, Rome, Italy

**Background:** Rheumatoid arthritis (RA) is the most common systemic autoimmune disease that primarily affects joints but is also often characterized by extra-articular involvement. Cardiovascular diseases are the most important causes of sudden death in these patients, which present a risk of developing cardiovascular events increased by 48%. The causes of increased cardiovascular risk are several and not completely understood, but recent evidence supports the key role of endothelial dysfunction in pathogenesis. In this complex scenario, it is known that IL-6 receptors are present at the endothelial level and can be activated leading to endothelial dysfunction. SARS-CoV-2 is a coronavirus responsible for the disease called COVID-19. COVID-19 2019 (COVID-19) characterized by clinical manifestations ranging from a flu-like syndrome up to severe lung damage associated with systemic hyper cytokine syndrome that can lead to multiple organ failure and death. Therefore, both RA and COVID-19 are associated with an increased pro-thrombotic and cardiovascular risk and IL-6 might be crucial in the pathophysiological mechanisms of both diseases.

**Objectives:** The main hypothesis of this study was to evaluate the possible role of IL-6 as a promoter of endothelial dysfunction in RA and COVID-19.

**Methods:** In vitro experiments were conducted on the endothelial cell line EA.hy926. Cells were treated for 24 h with fetal bovine serum (FBS), a pool of RA patients' sera or a pool of COVID-19 patients' sera. The expression levels of adhesion molecules (VCAM-1/CD-106, ICAM-1/CD-54, P-Selectine/CD-62, E-selectine/CD-62l), apoptosis were analyzed using cytofluorimetric technique. In addition, we observed increased levels of both p62 and LC3 proteins after both rheumatoid arthritis and COVID-19 patients' sera treatment. The expression levels of IL-6, IL-10, IL-22, and the Mann-Whitney test for paired samples. P<0.05 values were considered statistically significant.

**Results:** EA. hy926 cells, when treated with both RA and COVID-19 patients' sera, showed increased levels of activation molecules and apoptosis compared to FBS treated cells. In addition, we observed increased levels of both p62 and LC3 proteins after both rheumatoid arthritis and COVID-19 patients' sera treatment. All these findings were reversible in the presence of TCZ. The results are presented in Figure 1.
Background: Optimal dosing of methotrexate (MTX) in rheumatoid arthritis (RA) remains challenging. To this end, monitoring of intracellular MTX polyglutamates (MTX-PGs) in red blood cells (RBCs) has been investigated as a potential marker of MTX (non-)response, with contradictory results. As enucleated, non-proliferative cells, mature RBCs lack regulated folate metabolism and are devoid of folylpolyglutamate synthetase (FPGS) activity catalyzing the conversion of MTX to MTX-PGs. Therefore, it has been argued that analysis of MTX-PG in immune-effector cells, represented by peripheral blood mononuclear cells (PBMCs), would be more relevant. However, no prospective study has been performed measuring MTX-PG levels in PBMCs nor in comparison with RBCs.

Objectives: To investigate the pharmacokinetics of MTX-PG accumulation in RBCs and PBMCs in newly diagnosed RA patients in the early phase of MTX treatment.

Methods: In a clinical prospective cohort study (Methotrexate Monitoring (NTR7149)), RA patients were administered MTX op to 25 mg/week, as described before. (1) At 1, 2, 3 and 6 months after start of therapy, blood was collected and RBCs were isolated by centrifugation and PBMCs after Ficoll density gradient centrifugation. MTX-PG\(n\) concentrations in these cells were analyzed using a UPLC-MS/MS method with including custom-made stable isotopes of MTX-PG\(n\) as internal standards. (2) UPLC-MS/MS measurements for MTX-PG\(n\) were performed with a Waters Acquity BEH C18 column coupled to an AB Sciex 6500+ with the ESI operating on the positive mode. MTX dosing and concomitant treatments were in conformity with clinical practice. (3) Results: 46 consecutive patients were included in this study; 76% female, mean age: 57.8 years, mean baseline DAS28-ESR: 3.5, as described before. (1) Mean dosage was 10.5 mg (SD: 1.5) at baseline, 16.3 mg (2.5) at month 1, 22.7 mg (4.5) at month 2, 19.5 mg (6.3) at month 3 and 19.1 mg (6.2) at month 6. MTX-PG accumulation in PBMCs and RBCs revealed a disparate profile in both MTX-PG distribution and absolute accumulation levels (Figure 1A). Remarkably, MTX-PG distribution in PBMCs was mainly composed of MTX-PG1 (58%), and to a lesser extent MTX-PG2 (27%) and MTX-PG3 (15%). Longer chain MTX-PG\(n\) were also detectable in PBMCs, but at lower levels (mean: 4.0–6.7 nmol/10^6 cells) than MTX-PG\(1\). Moreover, this MTX-PG distribution profile in PBMCs remained constant over a MTX therapy period of 6 months (Figure 1A). The RBC MTX-PG accumulation profile shows mainly MTX-PG1 and lower levels of MTX-PG2-5 at 1 month after the start of therapy. After 3 months of therapy, MTX-PG1 is the main PG-moiety with also MTX-PG2 being detected. This profile is largely similar after 6 months of therapy. With respect to total intracellular MTX-PG\(1-6\) accumulation, PBMCs had significantly (p<0.001) 10-20-fold higher levels than RBCs at all analyzed time points (Figure 1A/B). Total MTX-PG\(1-6\) levels in RBCs and PBMCs at all time points were weakly correlated (r=0.41, p<0.01) (Figure 1C).

Conclusion: Our data showed that treatment with RA and CoViD-19 patients' sera increase the activation and death of endothelial cells in vitro. The increased level of cells death is possibly due to a block of autophagy. The reversibility of the process after blocking IL-6 with TCZ co-treatment confirms the hypothesis that IL-6 can play a key role in the pathogenesis of endothelial damage in patients with RA and CoViD-19.

Figure 1. Figures show the adhesion molecules levels (A), apoptosis levels (B), p62 and LC3II levels (C), in all experimental conditions. FBS 10% (cells treated with FBS at 10% concentration), S AR (cells treated with a pool of RA patients' sera); S Covid (cells treated with a pool of CoViD-19 patients' sera); FBS 10%+toci (cells co-treated with FBS at 10% concentration and TCZ); S AR+toci (cells co-treated with a pool of RA patients' sera and TCZ); S Covid+toci (cells co-treated with a pool of CoViD-19 patients' sera and TCZ).

Figure 1. Individual MTX-PG concentrations in PBMCs (A) and RBCs (B) during the first 6 months of MTX administration (note the different scaling of the y-axes). At 6 months, 36 patients were still on MTX treatment. Panel (C): Spearman's correlation plot of total MTX-PGs in RBCs versus PBMCs of all time points.

The disparate MTX-PG accumulation and distribution profiles in PBMCs versus RBCs of RA patients may be associated with the shorter life span of PBMCs and the low FPGS activity in RBCs. (4) No significant relation between MTX-PGs and DAS28 was found (data not shown).

Conclusion: This study shows that in newly diagnosed RA patients starting MTX therapy, MTX-PG concentrations in PBMCs are significantly 10-20-fold higher than in RBCs over a period of 6 months, with a disparate MTX-PG distribution profile in PBMCs (highest: MTX-PG1,) than RBCs (highest: MTX-PG3.).

Methods: A mouse model of pulmonary fibrosis was induced by intratracheal injection of bleomycin (BLM)[2]. Model mice were randomly assigned to receive Sodium carboxymethyl cellulose (CMC) or different concentrations of IGU. HE staining and immunohistochemical staining were performed to observe the therapeutic effects of IGU on mouse fibrosis. TGF-β1 induced A549 EMT cell model was utilized to investigate the effects of IGU on EMT in vitro[3]. NLRP3 inflammasome was activated by the co-stimulation of TGF-β1+LPS+ATP (TLA) to evaluate the effects of IGU in vitro[4].

Results: We found that IGU resulted in favorable therapeutic outcomes by affecting the inflammation infiltration (Figure 1A) and collagen deposition (Figure 1B). Immunohistochemical results showed that IGU downregulated the levels of α-SM and NLRP3. Additionally, the markers of BLM-mediated EMT (Figure 1C) phenotype and NLRP3-activated (Figure 1D) phenotype in the lung were also attenuated after IGU administration. In vitro experiments, the results confirmed its anti-EMT effects of reducing the expression of interstitial proteins Vimentin and α-SMA and restoring the content of epithelial protein E-cadherin. Besides, IGU could inhibit NLRP3 activation by downregulating NLRP3 related marker proteins, reducing the secretion of IL-1β, and attenuating caspase-1 activity. We then found that IGU anti-EMT and anti-NLRP3 effect was accompanied by decreased ROS production.

Conclusion: IGU can inhibit the EMT process and NLRP3 inflammasome activation, reduce ROS production to ameliorate pulmonary fibrosis, which may provide new insights into the further application of IGU in Interstitial pulmonary fibrosis.

Objectives: To investigate the role of GaR-9 as a biomarker for disease severity in treatment naïve patients with early RA and to study aspects of Gal-9 effects on inflammatory RA FLS.

Methods: Soluble plasma Gal-9 was measured in patients with newly diagnosed, treatment-naive RA (n = 98) and in Healthy (HC) (n = 48) (Table 1). Over a 2-year period patients were randomized to either MTX alone or MTX and anti-TNF antibody treatments. Serial measurements of disease activity (DAS28CRP) were collected to evaluate the disease course. In another cohort of patients with established RA, plasma and synovial fluid samples were also examined for Gal-9 (n = 18). Table 1. Synovial fluid mononuclear cells (SFMC) from established RA patients were used to harvest RA FLS (n=7). Osteoarthritis FLS were used as disease controls and obtained from patients with knee OA undergoing joint replacement surgery (n = 5). Monocultures of synovial fluid derived FLS (SF-FLS) (n=6) and autologous co-cultures of SF-FLS and peripheral blood mononuclear cells (PBMC) were established (n=7) and subsequently analyzed by flow cytometry, MITT assay, and ELISA. In vitro, cultures were treated with a neutralizing anti-Gal-9 antibody.

Patient characteristics. Data are expressed as median with IQR range unless otherwise indicated.

Results: Patients with early and established RA had increased plasma levels of Gal-9 compared with HC (P < 0.05) (Table 1) and levels of Gal-9 correlated positively with swollen joint counts at baseline (rho = 0.344, P < 0.05). The levels remained unaffected by treatment with MTX alone or by a combination of MTX and anti-TNF antibodies. Gal-9 levels were markedly elevated in the synovial fluid of chronic RA patients compared with the corresponding plasma samples (P < 0.05) (Table 1). In vitro, a neutralizing Gal-9 antibody mediated a 40% decrease in MCP-1 secretion (P < 0.05) and a 30% decrease in IL-6 secretion (P < 0.05) in RA FLS mononucleates. In OA FLS, addition of anti-Gal-9 antibodies comparably decreased the production of both MCP-1 (P < 0.05) and IL-6 (P < 0.05). The changes in cytokine production were not attributable to reduction in the fraction of inflammatory FLS (CD34/PDPN+THY1), decreased viability or proliferation. We further investigated if the effect of neutralizing Gal-9 persisted in co-cultures between FLS and activated T cells. Also in vitro using neutralization of Gal-9, mediated a 40% reduction in both MCP-1 and IL-6 (P < 0.05, P < 0.05). Conclusion: Pretreatment plasma Gal-9 levels in patients with newly diagnosed RA were increased and correlated with baseline clinical disease activity but remained elevated during goal directed synovitis suppressive therapy. In addition, in vitro neutralization of Gal-9 decreased MCP-1 and IL-6 production in a subset of FLS linked to RA pathology. Collectively, these findings indicate that Gal-9 overexpression is a co-player in the causation of acute and persistent RA synovitis by enhancing pro-inflammatory FLS pathways.

23% of RA patients positive for 0-4 epitopes, 36% for 5-10 epitopes, and 41% for >10 epitopes (p=0.02). The one ICI-A patient who was also RF positive had 12 positive ACPA epitopes. There was no significant difference in the number of ACPA epitopes in ICI-A patients who were smokers vs. nonsmokers, RA-like vs. PMR-like, or who received ICI combination vs. ICI monotherapy. In the 3 ICI-A patients with synovial fluid samples, SF ACPA was not demonstrated.

a Other cancer types in ICI-A patients included urothelial carcinoma (n=2), non-small cell lung cancer (n=2), and head and neck cancer (n=1).

**Conclusion:** ICI-A patients had lower ACPA titers and targeted fewer ACPA epitopes than early RA patients. It remains to be determined if ICI-A represents an accelerated model of RA pathogenesis with ICI triggering an early transition from pre-clinical to clinical disease. This would require sequential sampling and analysis.

**DIFFERENTIAL MiRNA EXPRESSION AND ENDOTHELIAL CELL FUNCTION IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS**

Q. Tyman1, C. Cunningham1, M. Hanlon1, A. Floudas1, M. Canavan1, U. Fearon1, D. Veale1, Trinity Biomedical Sciences Institute, Molecular Rheumatology, School of Medicine, Dublin, Ireland; 2St.Vincent’s University Hospital, and University College Dublin, Centre for Arthritis and Rheumatic Disease, Dublin, Ireland

**Background:** Rheumatoid arthritis (RA) and Psoriatic arthritis (PsA) constitute forms of inflammatory arthritis (IA) characterised by enhanced angiogenesis, immune cell infiltration, and generation of a hypoxic microenvironment leading to an invasive synovial pannus that results in bone and cartilage destruction. However, significant differences in circulating biomarkers in addition to disease pathogenesis at the clinical, immunological, cellular, and molecular levels have been identified that differentiate the two pathotypes.

**Objectives:** The aim of this study was to examine circulating miRNA as cellular biomarkers that can distinguish RA form PsA and to evaluate the potential implication for disease pathogenesis. Furthermore, this study aimed to examine the differential effect of the joint microenvironment on endothelial cell (EC) function in both RA and PsA.

**Methods:** RA, PsA and healthy controls (HC) were recruited from St. Vincent’s University Hospital, and serum was collected. Multiplex analysis of 88 serum miRNAs was performed using the FirePlex miRNA Immunology-V2 panel (FirePlex Biochrks Inc). Receiver operator characteristic (ROC) curves were generated to determine specificity and sensitivity of specific miRNAs whilst DNA intelligent analysis (DIANA)-mirPath and STRING software were used to analyse pathways targeted by the dysregulated miRNAs. Additionally, human umbilical vein endothelial cells (HUVEC) were cultured with RA and PsA synovial fluid (SF). Angiogenesis, invasion, and cellular adhesion were quantified by Matrigel tube formation assays, wound healing assays, and adhesion assays. Real-time cellular bioenergetics was analysed in HUVEC in response to RA and PsA SF using the Seahorse XF96 Analysers.

**Results:** 7 miRNAs; miR-126-3p, miR-29b-3p, miR-22-3p, miR-223-3p, miR-320a, let-7g-5e, and let-7g-5p (allp<0.01), were significantly elevated in RA
Denmark

ovial fluid, the panel was able to identify podoplanin+/CD90+/FAPa+ synovial fibroblasts previously linked with joint inflammation. The panel was, furthermore, able to identify a podoplanin+/CD90+/HLA-DR+ population in the immortalized synovial fibroblasts.

Conclusion: The optimized flow cytometry panel presented here enables researchers to identify synovial fibroblasts subsets which have been linked with disease traits in rheumatoid arthritis. This panel could therefore both be useful as a supplement to transcriptomic data and as a primary interrogation tool when investigating fibroblast subsets and cell function on a protein level.

POS0420

A 10-COLOR FLOW CYTOMETRIC PANEL FOR IDENTIFYING SYNOVIAL FIBROBLAST SUBSETS IN RHEUMATOID ARTHRITIS

S. Lomholt1, T. W. Kragstrup1,2.1 Aarhus University, Department of Biomedicine, Aarhus, Denmark; 2Silkeborg Regional Hospital, Diagnostic Center, Silkeborg, Denmark

Background: Synovial fibroblasts are key players in the disease pathology of rheumatoid arthritis and specific fibroblast subsets have been linked to joint inflammation and joint destruction[1]. These synovial fibroblasts can be cultured from both the easily obtained synovial fluid or the more time-consuming synovial biopsy or resection. Recently, cultured synovial fibroblasts from synovial fluid where confirmed to possess a similar phenotype to that of the synovial fibroblast podoplanin+/CD90+/HLA-DR+ subset from biopsies.[2]

The present advancement in our knowledge of synovial fibroblasts have been spearheaded through bulk and single cell RNA transcriptionics. Expensive techniques that may require supplementary identification of phenotype clusters and cell function on protein level.

Objectives: The objective of this work was to plan, optimise and test a multi-color flow cytometry panel for identification of known synovial fibroblast subsets linked to arthritis pathology. The primary focus was well established markers; podoplanin, CD90, CD55, HLA-DR, CD24 and fibroblast activation protein alpha (FAPA).

Methods: Several cell types were used in optimizing the panel. The majority of antibody titration was conducted on immortalized synovial fibroblasts from a patient with rheumatoid arthritis. Exclusion markers such as CD45 (blood leukocytes), CD34 (endothelial and monocytes/macrophages) were titrated on synovial fluid mononuclear cells and peripheral blood mononuclear cells. Finally, full panel testing on synovial fibroblasts cultured from synovial fluid was compared with immortalized synovial fibroblasts. All tests were carried out on a commercially available flow cytometer with 4-lasers (405, 488, 561 and 637nm) and 27 detectors.

Results: Several panel iterations were tested during the optimization process. Two markers, cadherin-11 and receptor activator of nuclear factor kappa-b ligand, were abandoned after testing different antibody clones for staining and several detaching solutions on fibroblasts prior to staining. Initial compensation issues were overcome by rearranging fluorochromes and using cells as CD90 compensation controls.

The final flow cytometry panel contained 10 markers; podoplanin, CD90, CD55, CD34, HLA-DR, FAPA, CD45, CD31, complement C3a receptor and a viability marker. Final testing on synovial fibroblasts cultured from synovial fluid yielded an acceptable viability > 90%. Within the synovial fibroblasts cultured from synovial fluid, the panel was able to identify podoplanin+/CD90+/FAPA+ synovial fibroblasts previously linked with joint inflammation. The panel was, furthermore, able to identify a podoplanin+/CD90+/HLA-DR+ population in the immortalized synovial fibroblasts.

Conclusion: The optimized flow cytometry panel presented here enables researchers to identify synovial fibroblasts subsets which have been linked with disease traits in rheumatoid arthritis. This panel could therefore both be useful as a supplement to transcriptomic data and as a primary interrogation tool when investigating fibroblast subsets and cell function on a protein level.

POS0422

A HISTORY OF CHLAMYDIAE INFECTION IN RHEUMATOID ARTHRITIS DEVELOPMENT

C. Lamachia1, R. Aymon1, B. Gilbert1, O. Studer1, K. Lauper1, A. Finckh1. Geneva University Hospital, Rheumatology, Geneva, Switzerland

Background: Current hypotheses for the ethiopathogenesis of rheumatoid arthritis (RA) postulate an infectious agent initiating autoimmunity, which is thought to be at the mucosal level. Chlamydiae infections have been previously associated to development of an acute inflammatory arthritis, which can become chronic in some patients. Chlamydia trachomatis was detected in synovial fluid and tissue of RA patients, at least in early disease, suggesting that this organism could be involved in initiating RA onset, at least in a subset of patients.

Objectives: To investigate the association between Chlamydiae infection and the development of autoimmunity and pre-clinical manifestations associated with RA.

Methods: This study was performed in an ongoing prospective study of individuals genetically at risk of developing RA, namely first-degree relatives of RA patients (RA-FDR). Individuals without clinical evidence of RA

serum compared to both PsA patients and HC, with ROC curve analysis demonstrating the predictive accuracy with which each miRNA differentiated between RA and PsA (all p<0.05). Biplot analysis further identified that three miRNAs, miR-21-3p, miR-22-3p, and miR-223-3p, demonstrated the greatest separation between RA and PsA (all p<0.05). DIANA and STRING analysis identified the P13K-Akt pathway as being the primary target of these 3 miRNAs with specific gene targets involved in this pathway including factors importantly associated with endothelial cell migration, proliferation, invasion, and angiogenesis. Next, we examined the effect of the joint microenvironment on endothelial cell function and demonstrated that PsA SF significantly enhanced EC tube formation (p<0.05) and EC leukocyte adhesion (p<0.05), with RASF only significantly inducing EC leukocyte adhesion. Finally, metabolic analysis of endothelial cells demonstrated that PsA SF significantly induced baseline glycolysis (p<0.05), baseline OCR (p<0.05), maximal respiratory capacity (p<0.05) and spare respiratory capacity (p<0.05), with no effect observed for RA SF.

Conclusion: Circulating miRNAs may be valuable as diagnostic biomarkers that can distinguish RA from PsA. Additionally, the joint microenvironment induces EC function and metabolic capacity, with these effects more pronounced in response to PsA SF compared to RA SF.

are enrolled, and assessed yearly, clinically and biologically. We included all RA-FDRs who responded to a Chlamydiae infection questionnaire, and the exposure of interest was self-reported Chlamydiae infection. The primary outcome was autoimmunity associated with RA (seropositivity) defined by the presence of anti-citrullinated peptide antibodies (ACPA) and/or rheumatoid factors (RF) at the last visit. Seropositive inflammatory arthritis at the last visit was a secondary outcome. We used logistic regression to analyze univari- able and multivariable associations, adjusting for age and gender as potential confounders.

Results: A total of 1254 RA-FDRs were analyzed, of which 168 (13.4%) had developed seropositivity. The prevalence of self-reported Chlamydia infection was significantly higher in seropositive individuals as compared to controls (179% versus 9.8%, P < 0.01 (Table 1). A significant association between the self-reported history of Chlamydiae infection and the seropositivity was observed in both univariate and multivariate analyses (OR = 2.00, 95% CI: 1.27-3.09; OR = 1.91, 95% CI: 1.20-2.95, respectively). A sub-group of 48 RA-FDRs (4%) presented inflammatory arthritis in conjunction with seropositivity. This sub-group, considered at highest risk for RA, reported significantly more often prior infections with Chlamydiae than the negative subgroup (20.8% versus 10.5%, P < 0.05). The ORs for the association of self-reported history of Chlamydiae infection and inflammatory arthritis coupled to RA-associated autoimmunity were 2.23 (95% CI: 1.03-4.43, P < 0.01, univariate analysis) and 1.91 (95% CI: 0.88-3.82, P = 0.08, multivariate analysis).

Table 1. A potential association between a self-reported history of Chlamydiae infection and RA development

1Logistic regression model adjusting for age and gender. 2Seropositive inflammatory arthritis was defined by being either: seropositive RA; seropositive “arthritis” (defined by at least one swollen joint at physical examination); seropositive with MSUS (musculoskeletal ultrasound) inflammatory activity. 

Conclusion: Our results suggest that a history of Chlamydiae infection may be a risk factor for the development of RA in a subset of individuals at genetic risk for the disease. Serological analyses to assess the prevalence of antibodies to Ch. trachomatis major outer membrane protein (MOMP) are under way to confirm these preliminary data.

POS0423 CYCLIC CITRULLINATED PEPTIDE APAMTER TREATMENT ATTENUATES COLLAGEN INDUCED ARTHRITIS

S. Khatri1, J. Hansen1, N. Pedersen1, S. Gram-Nielsen2, A. Mendes3, I. Chronakis1, U. Keiding1, B. Réth1, M. H. Clausen1,5, T. W. Kragstrup5,6, K. Astakhova1,5,6,11, Technical University of Denmark, Chemistry, Lyngby, Denmark; 2Technical University of Denmark, Health Technology, Lyngby, Denmark; 3Technical University of Denmark, Food, Lyngby, Denmark; 4Karolinska Institutet and Karolinska University Hospital, Department of Medicine/Solna, Solna, Sweden; 5IBIO TECH A/S, R&D, Copenhagen, Denmark; 6Aarhus University, Biomedicine, Aarhus, Denmark

Background: Anti-citrullinated peptide antibodies (ACPA) appear 10–15 years before the diagnosis of rheumatoid arthritis (RA) and are associated with a more severe disease course. In previous work, we rationally designed and screened ACPA-binding peptide aptamer sequences in silico and constructed a nanoparticle with chitosan and hyaluronic acid (1). A development- al stage version of this nanoparticle was able to reduce disease activity in the collagen-induced arthritis (CIA) and the serum transfer arthritis mouse models (2).

Objectives: Here, we investigated the effect and potential toxicity of three different versions of the aptamer nanoparticle (loading of 20%, 10% and 5% aptamer, respectively) in the CIA rat model.

Methods: Wistar rats (males and females) were given a single intravenous dose (100 mg/kg) of type II collagen in PBS in the tail vein. The dosing was repeated three times with one day interval, followed by blood sample collection at day 7 after the initial collagen injection. To evaluate route of administration and dosing, we injected a single intravenous and subcutaneous dose (2.5 mg/kg) of aptamer-nanoparticles (A/N ratio 20%) in PBS in the tail vein/abdomen, and plasma concentration-time profiles were followed for 2 days after dosing with weekly blood sampling. To evaluate organ uptake, rats were given a single intravenous and subcutaneous dose (2.5 mg/kg) of aptamer-nanoparticles and nanoparticle controls without aptamer or PBS alone in the abdomen. The procedure was repeated once after 24 hours. Blood and urine samples were taken once a week. A group of 10 animals was sacrificed every week over a three-week period, and the organs were processed. To examine efficacy, rats were given a single subcutaneous dose (2.5 mg/kg) of aptamer-nanoparticles and nanoparticle controls without aptamer or PBS alone in the abdomen. The procedure was repeated once a week over a course of three weeks. Weight, joint measurement, blood, and urine samples were taken once a week. Paw swelling was measured on a weekly basis. In the plasma samples we measured CPEP2 and anti-collagen II by enzyme linked immunosorbent assay (ELISA).

Results: Using a rather high dose of collagen (100 mg/kg) via an intrave- nous administration route, ACPA was measurable in all CIA rats with rapid development of RA in 82% of the included animals. Intravenous administra- tion resulted in an immediate high plasma concentration post injection, which decreased rapidly to low levels. The s.c. administration route gave a steady, long-term aptamer release with a maximum availability 8 hours post-injection. After three aptamer-nanoparticle doses (2.5 mg/kg; either 20%, 10% or 5% aptamer), we observed a dose-dependent reduction in swollen joint count for the aptamer-nanoparticle treated groups (10 rats in each group) compared with the healthy control group (10 rats) (P-value = 2.1E-6). We observed decreased ACPA IgG levels in the rats treated with aptamer-nanoparticle. The decrease in ACPA levels correlated with the aptamer-nanoparticle having higher loading. Anti-collagen II IgG levels slightly increased towards the end of the study.

Conclusion: We developed and tested a novel peptide aptamer-based drug can- didate for seropositive rheumatoid arthritis in CIA rats. Over a 3-week course of treatment with subcutaneous administration of aptamer-nanoparticles, joint swelling was decreased during treatment, and completely reversed at the end of the observation period. The reduction of joint swelling was associated with decreased levels of ACPA in the blood.

Disclosure of Interests: D. Liu1, Y. Li2, Xi’an No.5 Hospital, Department of Rheumatology and Immunology, Xi’an, China; Xi’an No.5 Hospital, Department of Rheumatology and Immunology, Xi’an, China
Background: Rheumatoid arthritis (RA) is a prevalent common autoimmune disease characterized by chronic inflammation of the joint and synovial hyperplasia and progressive destruction of articular cartilage and bone, which seriously influences a patient’s quality of life. Interleukin-25 belongs to the IL-17 cytokine family newly identified. IL-25 is widely produced between tissues, and IL-25 is reported to play an anti-inflammatory role in autoimmune and inflammatory diseases through the downregulation of Th1 and Th17 cell responses[1]. However, the exact role of IL-25 in the pathogenesis of RA remains to be elucidated.

Objectives: Set up CIA model to evaluate IL-25 influence in RA disease. Determine the molecular mechanism of IL-25 how to regulate IL-17A, ROR-γt, and Th17.

Methods: ① Male DBA/1 mice (n=12) were induced with immunized intradermally twice with type II collagen (2 mg/ml) emulsified in Complete Freund’s adjuvant orIncomplete Freund’s adjuvant containing by tail intravenous injection. CIA model mouse was constructed. CIA were then divided into two groups, for the use of PBS (n=6) and IL-25 (0.5μg, n=6) respectively, and followed daily. After 42 days, mice were sacrificed and collected articular tissues, proceed pathological staining and pathological score of arthritis. ② Male DBA/1 mice were immunized with CII to induce arthritis and consecutively received rMIL-25 (1 μg/mice) or PBS for 5 days beginning from day 1 after the second immunization with CII, and the incidence of arthritis was calculated. Spleen CD4+ T cells were isolated from CIA mice using Mouse CD4+ T Cell Isolation Kit. Cells were stimulated with plate-bound anti-CD3 (5 μg/ml) plus anti-CD28 (2 μg/ml) in the presence or absence of recombinant mouse (rm) IL-25 (100 ng/ml) for 24 h. In some cases, control IgG (10 μg/ml) were added to the cultures. The expression of IL-17A were examined using ELISA assay and ROR-γt mRNA in the cells were measured by real-time quantitative qPCR.

Results: In vivo studies indicated that, the RA incidence and symptoms of arthritis in IL-25-treated mice were significantly decreased compared with PBS controls. Histopathologic examination showed that the knee joints of IL-25-treated mice with CIA exhibited a significant reduction in synovial hyperplasia, cartilage damage and bone erosion compared with PBS controls. The serum levels of IL-17A in IL-25-treated mice were markedly reduced compared with those in WT mice. RT-qPCR also demonstrated that the transcript levels of IL-17A and ROR-γt were decreased in the Spleen of IL-25-treated mice.

Conclusion: Systemic injection of IL-25 can reduce the onset of arthritis and joint injury in CIA mice. IL-25 can inhibit Th17 cells of CIA mice, and its target is to regulate IL-17 cytokines and Expression of ROR-γt mRNA. CIA protection is mediated by the inhibition of Th17 by IL-25.

METABOLIC ALTERATIONS IN ACTIVATED FIBROBLAST-LIKE SYNOVIOCYTES FROM NON-INFLAMED SUBJECTS - MIMICKING EARLY STAGE OF RHEUMATOID ARTHRITIS

Y. Zhang1,2, A. Nguyen1, A. Rudin1, C. Maglio1,2,3, Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation research, Gothenburg, Sweden; 1University of Gothenburg, Wallenberg Center for Molecular and Translational Medicine, Gothenburg, Sweden; 3Region Västra Götaland, Sahlgrenska University Hospital, Rheumatology Clinic, Gothenburg, Sweden

Background: Proliferative cells, such as inflamed cells, depend on altered metabolic pathways to support their active proliferation. Synovial samples from patients with rheumatoid arthritis (RA) show reprogramming of different metabolic pathways such as glucose and glutamine metabolism [1]. However, it is unknown which metabolic pathways are altered in the early phases of RA pathogenesis, when non-inflamed fibroblast-like synoviocytes (FLS) are activated to a pro-inflammatory state. Our group has created an in-vitro cell model using FLS from subjects without inflammatory arthritis (non-inflamed FLS) after activation with adiponectin and tumour necrosis factor (TNF) to mimic the early stage of RA [2].

Objectives: We aim to determine if the stimulation of non-inflamed FLS upregulates the expression of key enzymes involved in glucose and glutamine metabolism and how the inhibition of those enzymes affects FLS activation.

Methods: FLS (passage 8-8) were isolated from synovial tissues of patients without inflammatory arthritis or osteoarthritis who underwent diagnostic arthroscopy due to a previous injury. FLS were cultured in DMEM medium (high glucose and GlutaMAX) containing 10% FBS and stimulated by known FLS-activators, i.e. TNF, interleukin 1 beta (IL-1β), and adiponectin. For the inhibition experiments, cells were pre-treated with 25 mM 2-DG or 300 mM CB-839 for 4 hours before stimulation. Expressions of the enzymes were measured by western blot in whole-cell lysates and IL-6 was measured using ELISA in cell culture supernatants at 24 hours after stimulation. Cell proliferation was determined using MTT assay after 48 hours of stimulation.

Results: First, we compared the expression of hexokinase 2 (HK2), glutaminase C (GAC), and PFKFB3 in non-inflamed FLS before and after activation with adiponectin, TNF, and IL-1β. Expression of HK2 and GAC were upregulated in adiponectin- and TNF-activated FLS compared to unstimulated FLS. PFKFB3 was not affected by any of the stimuli. IL-1β did not affect the expression of the analysed enzymes (Figure 1A-C). As IL-1β did not affect the expression of metabolic enzymes, we continued stimulation only with adiponectin and TNF. TNF but not adiponectin significantly enhanced the proliferation of FLS without inhibition (Figure 1D). However, FLS proliferation was significantly reduced by pre-treatment with 2-DG, a glycolysis inhibitor, in unstimulated as well as TNF- and adiponectin-stimulated cells. CB-839, a glutaminase inhibitor, did not affect the proliferation of FLS (Figure 1D). Both TNF and adiponectin significantly upregulated the production of IL-6 in FLS. Pre-treatment with 2-DG significantly reduced the production of IL-6. CB-839 pre-treatment significantly reduced the production of IL-6 only in unstimulated FLS (Figure 1E).

Conclusion: Our results show that the expression of key enzymes regulating metabolic pathways can be enhanced by adiponectin and TNF in non-inflamed FLS. Moreover, we also show that inhibition of specific metabolic pathways can affect FLS activation differently depending on the cytokine stimulation. These results provide a deeper understanding of metabolic reprogramming in FLS in early RA.

BRD3 REGulates THE INFLAMMATORY AND STRESS RESPONSE IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

M. Maciukiewicz1,2,3, L. Mose1, K. Krosel1, T. Seifritz3, M. Tomsic4, B. Maurer1,2, O. Distler1, C. Ospelt1, K. Klein1,2, University Hospital Bern, Department of Rheumatology and Immunology, Bern, Switzerland; 1University of Bern, Department of BioMedical Research, Bern, Switzerland; 2University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland; 3University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia

Background: Small molecule inhibitors targeting members of the bromodomain and extra-terminal (BET) protein family (BRD2, BRD3, BRD4) have anti-inflammatory properties in rheumatoid arthritis (RA). BET proteins are readers of acetylated histone side chains and activators of transcription. BRD3 is an under-studied member of BET proteins.

Disclosure of Interests: None declared.

Objectives: To analyse individual functions of BET proteins and mechanisms underlying BET inhibition in RA synovial fibroblasts (SF).

Methods: The expression of BRD2, BRD3, and BRD4 was silenced by lentiviral transduction followed by TNF stimulation (10 ng/ml, 24h). Silencing was confirmed by Western blotting. Transcriptomes were determined by RNA-seq (Illumina NovaSeq 6000, n=3). Pathway enrichment analysis for KEGG and Reactome databases was conducted with significantly affected genes (a fold change > 1.5, FDR < 0.05). SF were treated with I-BET (1 µM) and TNF (10 ng/ml, 24h). Autophagy was evaluated by Western blotting using the conversion of LC3B as a marker (n=9). I-BET-induced global changes on post-translational histone modifications were analysed by mass spectrometry (Mod Spec, Active Motif; n=2; 120h protocol) and Western blotting (H3K27ac, H3K18ac, total acH3; n=7; 24h and 120h protocol). For this purpose, SF were stimulated with I-BET (1 µM) for 24h, and either co-stimulated with TNF (24h protocol), or washed with PBS, followed by a 24h stimulation with TNF 120h after the I-BET treatment (120h protocol).

Results: Silencing of BRD2 and BRD4 in SF was in contrast to silencing of BRD3, associated with high levels of cell death, and therefore not analyzed further. We detected 257 and 324 differentially expressed genes (DEG) that were affected by BRD3 silencing in unstimulated and TNF-stimulated SF, respectively. 105 DEG overlapped between the two groups. DEG were enriched in inflammatory pathways such as "TNF signaling pathway", "rheumatoid arthritis", " Toll-like receptor cascades", "MAPK signaling pathway", "IL-17 signaling pathway" and "signaling by interleukins". Furthermore, pathway enrichment analysis suggested a role for BRD3 in different stress-associated pathways, including "DNA repair", "chaperone mediated autophagy", "cellular responses to stress", and "autophagy". In line with the pathway enrichment analysis, I-BET induced levels of LC3B-II in unstimulated (4.3 fold, p=0.07) and TNF-stimulated (2.9 fold, p=0.07) SF, indicating a role of BET proteins in the regulation of autophagy. To further study the mechanisms underlying I-BET-mediated suppression of gene expression, we analyzed potential effects of I-BET on histone modifications. Mod Spec analysis indicated that I-BET induced profound changes in chromatin modifications, with a global reduction of acetylation on different histone side modifications. We confirmed some of these differences in independent samples. I-BET treatment reduced mean TNF-induced levels of total acH3 by 25.2% (120h; p=0.0303), of H3K18ac by 35.3% (24h; p=0.0028) and by 29.3% (120h; p=0.0373) and of H3K9ac by 41.7% (120h; p=0.0587).

Conclusion: BRD3 acts as an upstream regulatory factor that integrates the response to inflammatory stimuli and stress conditions in SF. Our data suggest that BET inhibitors do not only prevent the reading of acetylated histone side chains, but also directly affect the chromatin structure, in particular by downregulating BRD3, associated with high levels of cell death, and therefore not analyzed further. In addition, BET inhibitors do not only prevent the reading of acetylated histone side chains, but also directly affect the chromatin structure, in particular by downregulating BRD3, associated with high levels of cell death, and therefore not analyzed further.

Disclosure of Interests: Malgorzata Maciukiewicz: None declared, Larissa Moser: None declared, Monika Krosel: None declared, Tanja Seifritz: None declared, Matija Tomsic: None declared, Brita Maurer Speakers bureau: Boehringer-Ingelheim, Consultant of: Novartis, Boehringer Ingelheim, Janssen-Cilag, Grant/research support from: AbbVie, Protagene, Novartis Biomedical Research and Innovation Infrastructure, funded by the Operational Programme "Competitiveness, Entrepreneurship and Innovation" (NSRF 2014-2020) and co-financed by Greece and the European Union (European Regional Development Fund).

Objectives: We investigated the presence on the surface of RA-MPs of antigens derived from post-translationally modified proteins (citrullinated peptides and carbamylated peptides). We assumed that these specific antigens carried on the surface of RA-MPs could participate in RA pathogenetic process.

Methods: We enrolled 20 RA patients naïve for biological therapy fulfilling the 2010 American College of Rheumatology RA criteria and 20 healthy controls (HC), matched for age and sex. For each patient, laboratory and clinical data were recorded and clinical indexes were measured. TJC, SJC, CDAI, VAS pain, CDAI, SDAI, DAS28. A fasting blood sample, obtained from RA patients and HC, was centrifugated in order to obtain platelet-poor plasma (PPP), rich in MPs. Thereafter, MPs in RA patients and HC were measured using nanoparticle tracking analysis. Later on, MPs were incubated with unconjugated anti-citrullinated/carbamylated proteins antibodies and processed by flow cytometry and western blot to evaluate the surface expression of citrullinated/carbamylated antigens.

Results: Nanoparticle tracking analysis revealed a significant increase of number of MPs in RA compared to HC. Moreover, densitometric analysis showed a significant higher expression of citrullinated antigens on MPs’ surface in RA than controls (p < 0.0001), while no substantial difference was found in the expression of carbamylated antigens. The data obtained were confirmed with the western blot which identified the cytoskeletal protein vimentin, the cytoplasmatic glycylcytic enzyme alpha-enolase1 and type II collagen as the main citrullinated and carbamylated proteins carried by MPs. Finally, a relevant correlation between the expression of citrullinated and carbamylated antigens and disease activity was found (Figure 1).

Conclusion: The results of this study confirm an important role of MPs in the pathogenesis of RA not only as markers of disease activity but also as possible inducers of autoimmunity.

Disclosure of Interests: None declared.

Figure 1. The figure shows: (A) concentration of MPs in RA patients and HC (nanoparticle tracking analysis); (B) expression of citrullinated and carbamylated antigens on MPs’ surface in RA patients (flow cytometry analysis); (C) expression of citrullinated antigens in RA patients and HC and correlation between expression of citrullinated and carbamylated antigens on MPs’ surface in RA patients and DAS28, CDAI, SDAI; (D) cytoskeletal protein vimentin, cytoplasmatic glycylcytic enzyme alpha-enolase1 and collagen type II (western blot).
Background: Accumulating evidence suggests that poor mental health is one of the most common comorbidities of both rheumatoid arthritis (RA) and osteoarthritis (OA) [1]. Even if underpinning RA and OA are different genetic, structural, mechanical, and immunologic pathways involved in their pathogenesis, poor mental health, and joint involvement are intertwined and negatively affect their mutual course by contributing to global disability. Thus, new insights into mechanisms that link these disorders are needed to identify new actionable biomarkers to drive more personalized therapeutic strategies. Amidst potential mediators, extracellular vesicles (EVs) play a central role in terms of communication between cells, they cross the blood-brain barrier and based on their cargo can affect the recipient cell function [2].

Objectives: To isolate EVs from synovial fluid (SF) in RA and OA patients and to evaluate if and how these EVs can alter in vitro synaptic transmission of murine hippocampal neurons.

Methods: In this cross-sectional pilot study, consecutive adult RA and primary OA who were referred to the Rheumatology Unit for aspiration of joint effusion were enrolled. Demographic and clinical variables and mental health rating scales were collected. Discarded SF were collected and EVs were isolated and analyzed by Malvern NanoSight NS300 system to obtain information on their number and size. Afterwards, DIV14 cultured wild-type hippocampal neurons were exposed for two hours to OA- and RA-EVs at low and high concentration EVs. Thus, miniature excitatory and inhibitory postsynaptic currents (mEPSCs and mIPSCs), which reflects glutamatergic and GABA-ergic activity respectively, were examined by exploiting patch-clamp recordings in the whole-cell configuration. Frequency and amplitude were analyzed to evaluate potential changes at the presynaptic or postsynaptic compartment. Mann Whitney test was used to compare two different samples.

Results: Eight RA patients (7 female, mean age 57 yrs), and 5 primary OA (4 female, mean age 60 yrs) were recruited for SF aspiration. The mean VAS pain was 7.25 in RA and 6.5 in OA. No statistically significant differences were found between the two groups in mean rating scale scores although patients affected by RA had more severe depressive symptoms (Montgomery Asberg Depression Rating Scale -MADRS- means scores: 16.57) with respect OA group (MADRS mean scores: 10). The Nanoparticle tracking analysis showed that RA-EVs were significantly more in number compared to OA-EVs (Figure 1 A), mimicking more inflammation, while no significant difference in size was observed. Analysis of miniature events revealed the occurrence of two different changes. High concentration of OA-EVs has led to an increased amplitude of excitatory events, meaning OA-EVs at low and high concentration EVs. Thus, miniature excitatory and inhibitory postsynaptic currents (mEPSCs and mIPSCs), which reflects glutamatergic and GABA-ergic activity respectively, were examined by exploiting patch-clamp recordings in the whole-cell configuration. Frequency and amplitude were analyzed to evaluate potential changes at the presynaptic or postsynaptic compartment. Mann Whitney test was used to compare two different samples.

Discussion: Our results suggest that SF-derived EVs from OA and RA patients lead to different specific changes of neurotransmission, with different concentration needed to alter neuronal spontaneous activity in post-synaptic and pre-synaptic compartment, respectively. EVs may provide insight into the pathogenesis of joint-brain communication in RA and OA, unraveling specific pathways thus allowing targeted therapies for neuropsychiatric involvement.

PGDF-BB, TNF-α, and LT-β REGULATE FOLLICULAR DENDRITIC CELL DEVELOPMENT IN THE RHEUMATOID SYNOVION

M. Elshish1, R. El Sayed1, N. Ay2, E. Prediletto1, R. Hands2, L. Fossati-Jimack1, M. Bombardieri1, M. Lewis3, C. Pitzalis1.

1Experimental Medicine and Rheumatology, William Harvey Research Institute - Barts and The London School of Medicine and Dentistry - Queen Mary University of London, London, United Kingdom

Background: Follicular dendritic cells (FDCs) fundamentally contribute to the formation of synovial ectopic lymphoid-like structures in rheumatoid arthritis (RA) which is associated with poor clinical prognosis. Despite this critical role in RA pathogenesis, FDC development in the RA synovion has not been fully elucidated.

Objectives: To investigate the role of TNF-α/LT-β and PGDF-BB in the ontogeny of RA synovial FDCs and the differentiation of lymphoid and fibroid RA synovions.

Methods: RA Synovial tissues were obtained from the Pathobiology of Early Arthritis Cohort (PEAC) of the Centre for Experimental Medicine and Rheumatology of Queen Mary University of London. RNA-Seq analysis and confocal imaging of early and late FDC differentiation markers were carried out and the stromal cell subsets were sorted by flow cytometry. The stromal cell subsets were treated with TNF-α/LT-β and/or PGDF-BB and the expression of FDC differentiation genes was assessed by qPCR. Germinal centre reactions were setup in vitro using TNF-α/LT-β activated stromal cells, and antibody production by naive human B cells stimulated with anti IgM was measured by ELISA.

Results: Our results indicate that PGDF-BB induces the FDC marker CNA.42 on NG2+ uSMA+ type-1 pericytes, stimulates THY-1 and uSMA gene expression, and strongly correlates with fibroid synovits using RNA-Seq analysis. On the other hand, TNF-α/LT-β downregulate PGDFFr-β, THY-1, uSMA; induce CD21, FcγRIIB expression, and significantly correlate with lymphoid synovial phenotype. Ultrastructural examination of antigen trapping on TNF-α/LT-β-activated RA synovial fibroblasts (RASFs) showed periodically retained surface antigens and these fibroblasts were able to induce T cell independent B cell activation in vitro germinal centre reactions. The transition from an early PGDFFr-β+ pre FDCs to a late TNF-α/LT-β- responsive mature FDCs is promoted by PGDF-BB. PGDF-BB induces TNF-α/r expression in RASFs and facilitates B cell recruitment via pericyte CXCL13 expression and stromal cell migration.

Conclusion: To the best of our knowledge, this is the first report describing the crosstalks between PGDF-BB and TNF-α/LT-β in FDC development in the rheumatoid synovion and its association with the evolution of lymphoid and fibroid synovits. Selective targeting of this interplay could inhibit FDC differentiation and potentially ameliorate RA in clinically severe and drug-resistant patients.

Disclosure of Interests: None declared.

MDCS IN THE INFLAMMATORY JOINT OF SKG MICE HAVE BOTH T CELL SUPPRESSIVE ABILITY AND OSTEOCLAST DIFFERENTIATION POTENTIAL

1Kobe University, Rheumatology and clinical Immunology, Chuo-Ku, Kobe, Hyogo, Japan; 2University of California, San Diego, Department of Medicine, San Diego, California, United States of America; 3Kobe University, Rheumatology and clinical Immunology, Chuo-Ku, Kobe, Hyogo, Japan.

Background: Myeloid-derived suppressor cells (MDCs) are heterogeneous immature myeloid cells with suppressive functions (1). It is known that MDCs are expanded in inflammatory sites after migrating from bone marrow (BM) or spleen. Rheumatoid arthritis (RA) is an autoimmune disease characterized as polyarthritis. Although previous reports indicate that MDCs are increased in BM
and spleen of arthritis model mice, detailed analysis of MDSCs in inflammatory joints is limited.

Objectives: The purpose of this study is to characterize the MDSCs in the joints of autoimmune arthritis.

Methods: We isolated CD11b+Gr1+ cells as MDSCs from joints (Jo-MDSCs), bone marrow (BM-MDSCs) and spleen (Sp-MDSCs) of arthritis-induced SKG mice, and investigated differential expressed genes (DEGs) among MDSCs from three tissues by microarray expression analysis. Furthermore, we analyzed the suppressive function of each MDSCs by investigating the effect of them on T cell-proliferation and the osteoclast differentiation of each MDSCs stimulated by M-CSF and RANKL.

Results: Microarray analysis revealed that Jo-MDSCs highly expressed immunosuppressive DEGs (Pdl1, Arg1, Eg2 and Egr3) compared to BM MDSCs or Sp MDSCs. In addition, Jo-MDSCs highly expressed NF-κB non-canonical pathway DEGs (Nkb2 and Relb), which are related to osteoclast differentiation. BM-MDSCs differentiated into osteoclasts but didn’t suppress T cell-proliferation and Sp-MDSCs suppressed T cell-proliferation but didn’t differentiate into osteoclasts. On the other hand, Jo-MDSCs was found to have both functions: T cell suppression and osteoclast differentiation potential.

Conclusion: Jo-MDSCs have a strong inhibitory effect on T cell proliferation and have the ability osteoclast differentiation potential.

POTENTIAL THERAPEUTIC EFFECTS OF NARINGENIN ON RA THROUGH SUPPRESSING P2X7R/NLRP3 MEDIATED PYROPTOSIS BY TARGETING ESR

H. Wang1, Y. Zhang1. 1Qilu Hospital, Department of Clinical Laboratory, Jinan, China

Background: Naringenin (NAR), a partial agonist on estrogen receptor, is naturally occurring flavonoids in grapes and grapefruits. We previously reported that NAR in patients with Rheumatoid arthritis (RA) have changed significantly [1]. However, the role and mechanism of action of NAR in RA remain unclear.

Objectives: This study aimed to determine the roles and mechanisms of NAR on RA and provides a basis for NAR to become a potential therapeutic agent for RA.

Methods: This study employed bovine type II collagen-induced arthritis (CIA) rats, in vitro mononuclear cells (MNCs) as models to explore the potential therapeutic effects and mechanisms of NAR on RA.

Results: Rats following NAR injections showed significantly alleviated CIA, while the proportion of NK cells decreased. After CIA rats were injected with both NAR and NK cells, the rats remained joint inflammation. NAR decreased the proportion of NK cells in RA MNCs. However, NAR did not directly affect the NK cell activation and their cytokine production. NAR suppress pyroptosis in THP-1 cells (Figure 1). The NAR activate the ESR1 in macroage. NAR significantly increased histone deacetylase 1 gene (HDAC1) activation in macroage. NAR significantly increased P2X7R expression and decreased NLRP3 expression in macroage.

Conclusion: NAR has therapeutic effects for CIA and RA through suppressing P2X7R/NLRP3 mediated pyroptosis by targeting ESR.

POS0434

A NOVEL TARGET FOR TREATMENT OF INFLAMMATORY JOINT DISEASES

S. Lindquist1,2, H. Persson3, A. Roos3, L. Lundberg3, O. Hernel1,2, 1Umeå University, Clinical Sciences, Pediatrics, Umeå, Sweden; 2Lipum AB, Drug Discovery and Development Platform, Uppsala, Sweden; 3SciLifeLab, Drug Discovery and Development Platform, Uppsala, Sweden

Background: A significant number of patients with inflammatory joint disorders do not respond or experience a waning effect to currently available pharmaceuticals, which emphasizes a high medical need for new efficacious drugs operating through novel targets and modes of action. One unexplored novel target is Bile Salt-Stimulated Lipase (BSSL). We have shown that patients with rheumatoid arthritis (RA), psoriasis arthritis (PsA), and juvenile idiopathic arthritis (JIA) have increased BSSL plasma levels compared to healthy controls, and that these levels correlate with disease activity scores. Moreover, conventional BSSL knockout mice are protected from developing disease in several recognized in vivo arthritis models and antibodies targeting BSSL prevent or mitigate arthritis in rodent models.

Figure 1. Effect of NAR on RA in vitro and in vivo. A The chemical structures of NAR and Estrogen. B Flow cytometry assay of NK cells in MNCs with treatment of NAR. C The morphology of THP-1 cells with treatment of NAR. D Joint inflammation of CIA rats with treatment of NAR and NK cells. E The expression level of pyroptosis-related protein was tested by western blot (WB). F Pattern diagram explaining therapy mechanism of NAR to RA.
We have further shown that BSSL is secreted from activated granulocytes, binds to monocytes and stimulates their migration in vitro. With that knowledge, we developed a humanized anti-BSSL antibody (SOL-116) that blocks BSSL from binding to monocytes and we are now evaluating SOL-116 as candidate drug for treatment of chronic inflammatory joint diseases, including RA, PsA and JIA in man.

**Objectives:** The aim of the present study was to characterize SOL-116’s biological activity in vitro and verify the therapeutic efficacy in the pristane induced arthritis (PIA) rat model.

**Methods:** The affinity of SOL-116 to human, mouse and rat BSSL was measured by surface plasmon resonance biosensor technology. The epitope on human BSSL was mapped by hydrogen deuterium exchange mass spectrometry (HDX-MS) and confirmed by crystallization of SOL-116 Fab-fragments with human BSSL. For efficacy evaluation, arthritis was induced in DA rats by administration of pristane. SOL-116 at three different doses (10, 30 and 90 mg/kg) or vehicle control were administered subcutaneously on day 5, 10 and 15 after disease induction. Disease activity was evaluated daily from day 7 in a blinded fashion using a macroscopic scoring system of the four limbs. To gain knowledge about the mechanism of action, the effect of SOL-116 on BSSL induced cell migration was evaluated using a transwell migration assay.

**Results:** SOL-116 binds to human, mouse, and rat BSSL, although a single amino acid deviation in the BSSL epitope results in approximately 80-fold lower affinity to rodent compared to human BSSL protein. In the efficacy validation study, treatment with highest dose SOL-116 (90 mg/kg) significantly mitigated disease severity in the PIA rats (Figure 1A). The relatively high doses of SOL-116 were chosen to compensate the low affinity for rat BSSL. A decrease in disease severity was also seen with SOL-116 at 30 mg/kg and 10 mg/kg, indicating a dose response, albeit not statistically significant. The plasma concentration of SOL-116 at day 19 correlated significantly to the arthritis score (Figure 1B). Mechanistic studies show that BSSL stimulates migration of CD14+ monocytes, and that SOL-116 prevents this effect in a dose dependent manner.

**Conclusion:** The present study verifies that BSSL plays an important role in inflammation and that SOL-116 is a promising biologic drug candidate for novel treatment of chronic inflammatory joint diseases.

**Acknowledgements:** The authors are grateful to Mrs. Eva-Lotta Andersson for excellent technical assistance.

**POS0435 IMPACT OF COMBINATION THERAPY WITH CDSDMARDS ON THE EFFECTIVENESS OF BIOLOGIC OR TARGETED SYNTHETIC DMARDS IN A REAL-LIFE SETTING: RESULTS FROM THE SWISS RHEUMATOID ARTHRITIS REGISTER (SCQM-RA)**

B. Gilbert, D. Longin, E. Nham, D. Courvoisier, K. Lauper, C. Laedermann, F. Muller, A. Finckh, Geneva University Hospitals, Division of Rheumatology, Geneva, Switzerland; Centre for Musculoskeletal Research University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; Eli Lilly (Suisse) SA, Vernier, Switzerland; Kantonsspital, Division of Rheumatology, Aarau, Switzerland

**Background:** Management guidelines of RA suggest to administer biological or targeted synthetic DMARD (b/tsDMARD) in combination with conventional synthetic DMARD (csDMARD). Limited data exists about the impact of such csDMARD combination therapy (co-therapy) in real life settings, in particular for baricitinib use compared to other types of b/tsDMARD.

**Objectives:** To assess the impact of concomitant csDMARD prescription on b/tsDMARD maintenance, in a real-world setting.

**Methods:** This is a nested cohort study within the Swiss registry of RA patients (Swiss Clinical Quality Management (SCQM-RA)), of treatment courses with bDMARDs or baricitinib (BARI) initiated between 2017-09-01 and 2020-06-01, with at least one follow-up visit. We compared the time-to-drug-discontinuation (drug maintenance), as a measure of drug effectiveness of b/tsDMARDs, with or without csDMARD co-therapy. Our exposure of interest was the impact of csDMARD co-therapy compared to monotherapy in 3 categories of b/tsDMARDs: baricitinib (BARI), TNFi inhibitors (TNFi) and other modes of action bDMARDs (OMA). Co-therapy was defined as receiving at least one csDMARD during at least 40% of the b/tsDMARD treatment courses (TC) duration. Baseline characteristics were compared using t-tests or χ². Survival Kaplan-Meier curves, with Log-rank test, were used to assess time-to-discontinuation. Cox models were applied to obtain adjusted hazard ratios (HR) using age, BMI, corticosteroid treatment, CDAI score, disease duration, smoking, line of therapy, seropositivity, gender as covariates. Missing baseline CDAI values were imputed using linear model with quadratic regression time.

**Results:** 1065 TC were included (273 BARI, 319 OMA, 473 TNFi), about half of which were initiated with csDMARD co-therapy (Table 1). In the co-therapy groups, csDMARD were taken on average 98% of the TC duration. Methotrexate was the most prescribed csDMARD (Table 1). Even after adjustment, we found no difference in drug maintenance with and without concomitant csDMARD in the BARI group (crude p = 0.67; HR co-therapy 2.17, 95% CI [0.61;7.77], p = 0.16) and in the TNFi group (crude p = 0.13; HR co-therapy 1.24, 95% CI [0.56;2.74], p = 0.60). Adjusted drug maintenance with or without csDMARD was also similar in the OMA group, despite non-adjusted p-value in favor of monotherapy (Figure 1) (crude p = 0.007; HR co-therapy 0.66, 95% CI [0.25;1.80], p = 0.39).

**Conclusion:** Our data suggest that drug maintenance of BARI, OMA and TNFi, were not significantly modified by concomitant csDMARD therapy.

**RESULTS:**

Cartilage degradation activity in SKG mice

- *Control* (untreated): Normal cartilage structure, no visible signs of degradation.
- *TNFα* + *ZyA*: Severe cartilage erosion, with visible loss of cartilage matrix.
- *ZyA*: Mild cartilage erosion.

**DISCUSSION:**

The results indicate that TNFα inactivation can significantly reduce cartilage degradation in SKG mice, demonstrating the potential efficacy of anti-TNFα strategies in RA-ILD treatment.

**CONCLUSION:**

The study highlights the importance of TNFα in RA-ILD and suggests that targeted anti-TNFα therapies may offer significant therapeutic benefits for this condition.
the concentration of inflammatory factors. Double luciferase reporter gene detection and rip detection confirmed mir-654-5p and Interaction between Circ_0003972.

PO5439
STROMAL B-CELL Crosstalk PROMOTES THE ESTABLISHMENT OF SYNOVIAL B CELL NICHEL THROUGH THE SELECTION, ACTIVATION OF NATURALLY OCCURRING EBV+ B CELLS

M. Caliste1, E. Prediletto1, E. Consiero1, L. Jagemann1, C. Pitzalis2, M. Bombardieri1, William Harvey Research Institute, Experimental Medicine & Rheumatology, London, United Kingdom.

Background: Rheumatoid Arthritis (RA) is characterized by the formation of ectopic lymphoid structures (ELS) in the synovial tissue, which can promote B cells activation and local production of autoantibodies. B cells exert an essential role in RA immunopathogenesis, as demonstrated by therapeutic effects of Rituximab (1). We previously showed that ELS in the RA joints frequently accumulate Epstein Barr virus (EBV)-infected B cells displaying evidence of both latent (LMP2A) and early lytic viral reactivation in locally differentiated plasma cells (PCs)(2). RA synovial fibroblasts (SFs) can sustain B cells activation, proliferation and maturation into high affinity antibodies producing cells, mimicking B cells physiological differentiation in germinal centres (3). Whether RASFs can also promote preferential selection of naturally-occurring EBV+ B cells is currently unknown.

Objective: Here, we aim to a) demonstrate SFs role in EBV+ B cells selection b) phenotypically characterize B cells after co-culture with SFs c) dissect the molecular mechanisms behind the B cells SFs crosstalk.

Methods: Long-term in vitro B cells SFs co-cultures have been established, followed by phenotypical characterization of B cells in flowcytometry. Supernatant were then screened by ELISA at different timepoints, to measure IgG, IgM and IgA production. EBV infection status on B cells were analysed by qRT-PCR after gDNA extraction. Single cells RNA sequencing was finally performed at 28 days of co-culture.

RESULTS: Preliminary results confirmed RASFs role in sustaining B cells activation and maturation, showing B cells survival up to 90 days, production of IgG and an increased IgG/IgM ratio overtime. Interestingly, we identified a particular B cells phenotype occurring in long term in vitro co-cultures, characterized by CD38 expression and the subdivision into two functional subsets, CD58+/CD23high and CD58+CD23low. These two subpopulations - previously described by Megyola et al. in in vitro EBV infected B cells - are characterized by two different functional states: an highly proliferating (CD58+/CD23high) population and an IL-6 producers (CD58+CD23low) one(4). We also observed that RASFs preferentially support EBV+ clones expansion, showing a preferential expression of EBV markers in CD58+CD23low cells. The high proliferation rate of these B cells allowed – on a specific experiment - the establishment of a cell line, named

Disclose of Interests: None declared.
“Carejavi,” that we are currently employing as tool for functional investigation of RASFs primed EBV+ B-cells. Finally, the transcriptomic analysis revealed the selection of a relatively small number of clonotype at the VDJ analysis at the end of co-culture. In addition, we observed the upregulation of genes related to GC formation (such as EB13, LTA and LTβ), B cells proliferation (mi67) and viral oncosogenic transformation (MYC).

Conclusion: Here, we demonstrated that RA SFs not only support B cells maturation and activation in local autoantibodies producing cells, but they are also able to preferentially induce selection and proliferation of EBV+ clones, characterized by a peculiar expression of CD56 and CD23. The molecular mechanisms behind this phenomenon are currently under investigation.

POS0440 THE ANALYSIS OF THE INFLAMMATORY PROTEOME IN RHEUMATOID ARTHRITIS IDENTIFIES COMMON SIGNATURES ASSOCIATED WITH THE CLINICAL RESPONSE TO DMARDS AND TNFI THERAPIES

Background: Tyrosine kinases receptors MerTK and Axl have been implicated in the pathogenesis of several autoimmune diseases. Despite sharing significant structural homology and having common ligands, Axl and MerTK have distinct features and biological functions [1]. A growing body of evidence suggests that both Axl and MerTK play a crucial role in Rheumatoid Arthritis (RA) pathogenesis and progression and may be exploited as novel therapeutic targets [2]. However, numerous unanswered questions remain to be addressed.

OBJECTIVES:
1. To define common and distinct gene-partners of Axl/MerTK and quantify their expression in RA synovial tissue.
2. To assess the co-expression of Axl/MerTK by synovial cells.
3. To outline the longitudinal variation in Axl/MerTK expression upon treatment intervention.

Methods: Synovial tissue samples were collected by US-guided synovial biopsy from: i. Patients with early (<12 months) RA DMARDs/steroid-naïve (n=87); and ii. RA patients who failed the first-line biologic with TNF-inhibitors (TNFi) before and 16 weeks after receiving either Rituximab (RTX) or Tocilizumab (TOC) (n=164) [3]. Gene expression was obtained by bulk RNAseq performed on an Illumina HiSeq2500 platform. Axl/MerTK-modules were defined using STRING networks and the module expression determined by the mean z-score of regularized log transformed expression for all genes in the set. Axl, MerTK, CD55, CD90, CD68 protein expression was analysed by protein expression in immunofluorescence staining.

Results: Using STRING network analysis, we defined an Axl- and a MerTK-module composed of 31 predicted gene-partners of either Axl or MerTK. Thirteen genes were common to both modules and included the ligands Gas6 and ProteinS, and EGFR. Conversely, eighteen genes were uniquely present in the Axl-module (e.g., PIK3-family, IFG1R, IFNAR1 and STAT3) or the MerTK-module (e.g., Galectin3 and TULP; recently discovered MerTK ligands, FCGRA1/CD64, PTTP1 and MEGF10). Axl/MerTK-modules quantified in the early-arthritis treatment-naïve RNAseq dataset showed a significant negative correlation with the synovitis score (Axl r=-0.33, p=0.0152; MerTK r=-0.23, p=0.0003). There were twelve log transformed gene expression differences of the Lining showed notable heterogeneity between patients: they could express either Axl or MerTK alone, or co-express both. Axl was also present in most CD55+ Lining Fibroblast-Like-Cells (FLS) but not by CD90+ Sublining FLS while MerTK, as expected, was restricted to macrophages, including intra-aggregate tingible-body-macrophages. To define Axl and MerTK vary depending on disease stage and treatment exposure, we quantified their gene expression in active RA patients inadequately responding to TNFi, prior and 16 weeks after starting second-line biologic (RTX or TOC) [3]. Differently from the early-arthritis cohort, MerTK was significantly up-regulated in synovia characterised by higher degree of tissue inflammation (lympho-myeloid > diffuse-myeloid > pauci-immune, p<0.0001) and significantly positively correlated with several cytokines’ genes such as TNF, IL-6, CCL5 and IL-10. MerTK expression was dependent on clinical response to RTX but not TOC as assessed by EULAR response (dAS28CRP, good vs none/mod, FDRresp 0.048). Conversely, Axl expression compared with Cluster 2 (C2), where a signature of 16 chemokines was significantly enriched (CCL-3, -4, -10, -23, CXCL1, CXCL-10, -11, -5, -6, -9; MCP-1, -3, -4). Clinically, 25% of the non-responders’ patients was included in C2, while 75% was located in C1, suggesting that a prominent circulating chemokines profile prior therapy is associated with a poor clinical outcome. These data were similarly observed in patients before receiving DMARDs, where a signature of upregulated chemokines and pro-inflammatory mediators characterised a cluster with a high % of non-responding patients.

Conclusion: A pro-inflammatory signature, where chemokines are predominatiely up-regulated in the serum of RA patients before therapy, is associated with a poor clinical outcome. This newly identified signature, which deserves a more in-depth analysis, might be clinically useful guiding precision medicine and novel therapeutic approaches.

GLPG4399: SELECTIVE SIK3 INHIBITION AS A NOVEL MODE OF ACTION FOR THE TREATMENT OF INFAMMATORY ARTHRITIC DISEASES (PRECLINICAL)

S. Lavazais,1 A. Pereira-Fernandes,2 C. Delachamaë,1 C. Jagerschmid1, M. Drennan,2 D. Merciris1, C. Peixoto1, M. Borgonovi1, N. Desroy,2 D. Amantini,1 S. De Vos,2 K. Nys2, Galapagos, SASU, Romainville, France; Galapagos, NV, Mechelen, Belgium.

Background: SIK3 is a serine/threonine kinase implicated in inflammatory pathways and contributing to the generation of IFN-γ and TNFα in peripheral blood. In the present study, we investigated the effect of GLPG4399, a selective SIK3 inhibitor, on human synovial tissue biopsies (ST) from patients with inflammatory arthritis.

Methods: Freshly digested ST tissue was assayed for IL-12 and IFN-γ protein production. ST cells were isolated by enzymatic digestion and then stained for multiple populations, demonstrating differential endocytosis associated with a shift in their metabolic profile. In addition, freshly digested ST cell suspensions were subjected to an optimized assay to evaluate endocytosis in multiple populations simultaneously without the need for cell sorting. Briefly, digested cells were incubated at 4°C (passive endocytosis) or 37°C (active endocytosis) in the presence of OxPhos inhibitors and then stained for multiple populations, demonstrating differential endocytosis.

Results: GLPG4399 was shown to be a SIK3 inhibitor with high selectivity against a panel of 370 kinases. The wide effect of SIK3 inhibition on key immune cell types was demonstrated by GLPG4399’s reduction of pro-inflammatory cytokines produced by monocytes, macrophages, dendritic cells, B and T lymphocytes. Immune phenotypic assays and in a lipopolysaccharide (LPS)-stimulated human whole blood assay by measuring the production of inflammatory cytokines. In vivo target engagement was evaluated in an acute LPS-stimulated cytokine release mouse model by measuring plasma tumour necrosis factor (TNF) levels. The therapeutic efficacy of GLPG4399 was evaluated in vivo in collagen-induced arthritis (CIA) and IL-23-induced psoriatic arthritis mouse models by assessing disease activity endpoints.

Conclusion: Our preclinical findings demonstrate the strong immunomodulatory effect of SIK3 inhibition in arthritis-relevant immune cell assays and highlight the significant preclinical efficacy of GLPG4399 in two experimental arthritis mouse models. The novel mechanisms of action of GLPG4399 represents a promising approach for the treatment of arthritis.

POS0443 INSIDE THE JOINT OF INFLAMMATORY ARTHRITIS PATIENTS: HANDLING AND PROCESSING OF SYNOVIAL TISSUE BIOPSYs FOR HIGH THROUGHPUT ANALYSIS

A. Floudas1,2, A. Gorman,2 N. Neto,3 M. Monaghan,3 Z. Elliott,2 U. Fearon,1,2 V. Marzocco1,2 1 Trinity Biomedical Sciences Institute, Molecular Rheumatology, Dublin, Ireland; 2 EULAR Centre of excellence, Centre for Arthritis and Rheumatic Diseases, St Vincent’s University Hospital, Dublin, Ireland; 3 Trinity Biomedical Sciences Institute, Trinity Centre for Biomedical Engineering, Dublin, Ireland

Background: Inflammatory arthritis (IA) is a chronic systemic autoimmune disease whose etiology is unknown, which afflicts the joints. While studies on immune cell populations in peripheral blood have been informative regarding potential immune cell dysfunction and possible patient stratification, there are considerable limitations in identifying the early events that lead to synovial inflammation. The joint, as the site of inflammation and the local microenvironment, exhibit unique characteristics that contribute to disease pathogenesis.

The limited availability of synovial tissue (ST) biopsies is a key incentive for the utilisation of high-throughput techniques in order to maximise information gain.

Objectives: This work aims to provide an overview of key methods and novel techniques that are used in the handling, processing and analysis of ST biopsies and the potential synergy between these techniques.

Methods: We describe the utilisation of high dimensionality flow cytometric analysis, single cell RNA sequencing, ex vivo functional assays, including T cell activation, endocytosis and two-photon fluorescent lifetime imaging microscopy (FLIM).

Results: When comparing different methods for ST cell suspension generation we observed that the combination of mechanical and enzymatic digestion resulted in the release of considerably higher numbers of total viable cells when compared to mechanical digestion alone, although consideration should be taken in the cleaving of extracellular markers, like CD27. We next compared two different cryopreservation methods that to that of freshly digested ST and observed similar viability and frequency of immune cells. Functional characterisation of ST cells can be challenging due to the high number of cells required for analysis, herein, we utilised the above protocols to establish ST viable cell suspensions and optimised different experimental approaches for phenotypic functional characterisation. To investigate the functional consequence of OxPhos inhibition on ST T-cell polyfunctionality, ex-vivo ST cell suspensions from IA patients were stimulated with PMA/ionomycin in the presence/absence of FCPP followed by metabolic profile characterisation via FLIM and high dimensionality flow-cytometric analysis for T cell-derived cytokines. Treatment with FCPP resulted in a decreased in T-cell polyfunctionality specifically in co-expression of TNF-α, IL-2, IFN-γ, IL-17A. -GM-CSF, an effect associated with a shift in their metabolic profile. In addition, freshly digested ST cell suspensions were subjected to an optimized assay to evaluate endocytosis in multiple populations simultaneously without the need for cell sorting. Briefly, digested cells were incubated in parallel at 4°C (passive endocytosis) and 37°C (active endocytosis) with DQ OVA (Ovalbumin). ST cells were then stained for multiple populations, demonstrating differential endocytosis capacity across pathotypes and disease controls. Finally, utilisation of novel bioinformatics analysis of RNAseq a data showed differential gene expression and pathway enrichment involved in IA pathogenesis and allowed for the comparison of cell specific enrichment scores and transcription factor usage based on pathotype and gender.

Conclusion: The introduction of new powerful techniques in the study of ST inflammation brings new challenges and significant opportunities. These approaches will accelerate our path towards understanding of the mechanisms involved in the pathogenesis of IA and lead to the identification of new avenues of therapeutic intervention.

Acknowledgements: We would like to thank all the patients who consented to be involved in this study.

PROFILING OF CIRCULATING MiRNAs IN DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS

J. Baloun1,2, A. Pekacova1,2, H. Mann1,2, J. Vencovsky2,4, K. Pavelek2,4, L. Šenolt1,2, 1Institute of rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic, 11st Faculty of Medicine of Charles University, Department of Rheumatology, Prague, Czech Republic, 2Institute of rheumatology, Inpatient department, Prague, Czech Republic, 3Institute of rheumatology, Research Center, Prague, Czech Republic

**Background:** Biologic (b-) and targeted synthetic (ts-) disease-modifying anti-rheumatic drugs (DMARDs) have brought significant progress in the treatment of rheumatoid arthritis (RA), but a significant proportion of RA patients still remain symptomatic despite treatment according to current recommendations. These patients have recently been defined as “difficult-to-treat (D2T)” RA (1). There is evidence that miRNA expression may play a role in the diagnosis and therapy of RA (2).

**Objectives:** In a retrospective study, we analyzed patients’ blood samples prior to b-/ts-DMARD treatment and profiled circulating miRNAs to predict the development of D2T-RA.

**Methods:** A total of 36 patients fulfilling the EULAR definition of D2T-RA (1) (mean age 59.1±10.7 yrs, 78% females), 36 patients with RA in sustained clinical remission on b-/ts-DMARDs at two consecutive examinations 12 yrs apart (mean age 66.3±9.6 yrs, 78% females), and 36 healthy controls (mean age 61.1±7.7 yrs, 68% females) were included in the study. Blood samples were collected before initiation of b-/ts-DMARD. We profiled circulating miRNAs using the sequencing approach and differential expression analysis was performed using DESeq2 algorithm.

**Results:** The massive parallel sequencing of circulating miRNAs detected 814 quantifiable miRNAs and DESeq2 algorithm revealed 35 miRNAs with differential concentrations in patients who developed D2T-RA compared to patients with RA who achieved sustained remission or healthy controls. Out of these miRNAs, miR-16-5p (1.5x) and miR-451a (2.1x) were downregulated and miR-126-3p (1.4x) was upregulated in D2T RA patients compared to controls. In addition, miR-101-3p (1.5x) was downregulated in D2T RA compared to RA patients. Except for miR-101-3p, these miRNAs have been previously associated with RA and might predict development of D2T disease prior to initiation of b-/ts-DMARD therapy.

**Conclusion:** We found four miRNAs as potential biomarkers differentiating patients who are at risk to develop difficult-to-treat disease compared to patients who have a chance of sustained remission even before initiation of biologic or targeted synthetic DMARDs. Further studies with larger sample size are needed to validate these data.

**POS0445**

DISSECTING THE ROLE OF PLATELET FUNCTION IN INFLAMMATORY ARTHRITIS

D. Kimpel1, K. Kannan1, 1University of Virginia, Rheumatology & Immunology, Charlottesville, United States of America, 2University of Arkansas, Medicine, Little Rock, United States of America

**Background:** Inflammatory autoimmune diseases such as rheumatoid arthritis (RA) show an increase in atherosclerotic cardiovascular disease, and are commonly associated with an increase in platelet counts. Thus, platelets fill a central role in the tenet: Inflammation begets coagulation, and coagulation begets inflammation. We have previously reported that induction of arthritis by the Streptococcal cell wall component peptidoglycan polysaccharide (PGPS) results in increased platelet numbers, aggregation, activation, and increased expression of P-selectin (CD62-P) and of the costimulatory molecule CD40. These platelets are also more sensitive to stimuli such as ADP and thrombin, which induce dense granule release of serotonin and aggregation. We have also described increased P-selectin expression limited to the joints in mice with acute arthritis. Platelets, generally considered elements of the hemostatic system, are underestimated for their pro-inflammatory potential.

**Objectives:** To further understand the role of platelets in inflammatory arthritis, and distinguish their biochemical and adhesive features we set out to characterize the impact of modulating platelet activity in acute and chronic rodent models of arthritis.

**Methods:** Chronic inflammatory arthritis was induced in Lewis rats by a single i.p. injection of PGPS which results in an early phase non-T cell dependent arthritis, and a chronic T cell dependent phase after day 10. An acute inflammatory arthritis was induced in Balb/c mice by the same method. Joint scoring and volume measurement were carried out daily to determine an arthritis severity score. The role of platelets on PGPS arthritis was assessed using a) depletion of platelets using periodic intraperitoneal (IP) anti-platelet antibody, b) blockade of the integrin GPIb/IIIa with the monoclonal antibody (mAb) abciximab to inhibit activation and aggregation via vWF and fibrinogen. In the acute murine arthritis models, we previously described expression of CD62-P in joints and on platelets, the CD62-P knockout mice had no significant difference in arthritis severity. Conversely treatment of wild-type mice with the anti-CD41 to block GPIb resulted in suppression of the arthritis.

**Conclusion:** Platelet depletion had a dramatic impact on both acute and chronic phases of inflammatory arthritis, which is not unexpected given that platelets carry an array of pro-inflammatory and procoagulant mediators including IL-1, chemokines, vWF, and fibrinogen, as well as an array of adhesion molecules for binding to endothelium, leukocytes, and to other platelets. The increase in chronic arthritis severity despite inhibiting platelet aggregation by blockade of GPIb/IIIa was unexpected, but may have been due to increased platelet-endothelial binding or platelet-leukocyte aggregation thus exacerbating the chronic T cell phase. Lack of CD62-P appeared to have no influence on acute phase arthritis development. Interestingly anti-CD41, which blocks one part of the GPIb/IIIa integrin, was effective at ameliorating arthritis in the murine model. Platelets play an often underappreciated role in inflammatory processes, but understanding the mechanisms will require further description of the complex nature of these cellular elements which have dual inflammatory and hemostatic roles.

ARP23 AS A LASP1 INTERACTION PARTNER REGULATES CELL-TO-CELL CONTACT FORMATION OF FIBROBLAST-LIKE SYNOVIOCYTES IN RA

D. Beckmann1, A. Krause2, U. Hansen1, H. Kiener2, J. Kremerskothen2, H. Ravenstät3, T. Pap1, A. Korb-Pap1, 1University Hospital Muenster, Institute of Musculoskeletal Medicine, Muenster, Germany; 2Medical University of Vienna, Department of Medicine III, Division of Rheumatology, Vienna, Austria; 3University Hospital of Muenster, Department of Nephrology and Rheumatology, Internal Medicine D, Muenster, Germany

**Background:** In rheumatoid arthritis (RA), fibroblast-like synoviocytes (FLS) undergo a stable transformation resulting in an aggressive phenotype mediating cartilage damage by increased levels of adhesion molecules. In this context, Lasp1 and the Arp2/3 complex are of interest because they modulate actin organization and focal adhesion turnover.

**Objectives:** In this study, the effects of Arp2/3 on cadherin-11 mediated cell-to-cell contact formation have been investigated using the arthritic hTNFtg mouse model.

**Methods:** Expression levels of Lasp1 and Arp2/3 protein complex were investigated in synovial tissue of wild type (wt) and hTNFtg hind paws by immunohistochemistry. Primary FLS were analyzed, respectively and co-immunoprecipitation experiments were performed. In addition, Lasp1+/− mice were interbred with hTNFtg animals and offspring were evaluated for disease progression and joint destruction. To further study the role of Arp2/3 in the function of the cadherin-11 adhesion complex, the effects of an Arp2/3 inhibitor (CK666) on cell-to-cell contact formation in FLS derived from hTNFtg and Lasp1−/− mice were assessed for severity of arthritis, and d) wild-type mice were pre-treated with a single ip injection of anti-CD41 (GPIb) antibody.

**Results:** Depletion of platelets in rats during the PGPS treatment resulted in amelioration of both the early and chronic phases of disease. We previously demonstrated that TNF is elevated in this model following PGPS injection, so for comparison animals were treated with infliximab, a monoclonal antibody to TNF, with equivalent suppression of both acute and chronic phases of disease. Abciximab, targeting the dual function adhesion and signaling molecule GPIb/IIIa, did not decrease arthritis, and in fact increased the severity of the chronic phase of arthritis. In the acute murine model, despite the previously described expression of CD62-P in joints and on platelets, the CD62-P knockout mice had no significant difference in arthritis severity. Conversely treatment of wild-type mice with the anti-CD41 to block GPIb resulted in suppression of the arthritis.

**Disclosure of Interests:** Don Kimpel Speakers bureau: GSK, Consultant of: Auria, Krishna Kannan: None declared.

**DOI:** 10.1136/annrheumdis-2022-eular.4673
Results: upregulated Lasp1 levels were found in synovial tissue and FLS of hTNFtg compared to wt mice. Assays showed that Arp2/3 is part of the adhesion junction (AJ) machinery in FLS although Arp2/3 expression levels were not changed between the genotypes. In vivo evaluation of lasp1+ hTNFtg mice revealed a milder arthritis score, less cartilage degradation and reduced FLS attachment to articular cartilage compared to hTNFtg mice. In vitro, the loss of Lasp1 led to clear alterations in AJ arrangement indicated by altered β-catenin pattern. As expected, β-catenin expression was mainly located at adhesion sites between adjacent cells. In hTNFtg FLS, these structures were characterized by a zipper-like pattern. In contrast, these structures were disrupted in lasp1+ hTNFtg FLS. Interestingly, CK666 induced zipper-like structures in hTNFtg FLS comparable to the pattern found in lasp1+ hTNFtg cells. Furthermore, lasp1+ hTNFtg FLS showed decreased Src phosphorylation following PDGF stimulation in comparison to hTNFtg FLS.

Conclusion: Lasp1 represents an interesting target involved in RA-caused joint destruction, because its loss results in significantly reduced cartilage destruction and altered FLS contacts mediated by Arp2/3.

POS0447 TREATMENT WITH UPADACITINIB IN RA PATIENTS FOR WHICH BIOLOGIC THERAPY FAILED

L. Robles Kirkegaard1, E. Rubio Romero1, P. León1, Servicio Andaluz Salud, Hospital Universitario Virgen del Roció, Sevilla, Spain

Background: Upadacitinib is a JAK inhibitor recently approved for rheumatoid arthritis treatment with promising results in its studies for severe moderate RA for which conventional therapies failed.

Objectives: To study and describe the evolution of patients diagnosed with RA and treated with Upadacitinib who had inadequate response to biological therapy in association or not with DMARDS and GC for 6 months.

Methods: A population of 23 patients (19 of them female) with RA on treatment with Upadacitinib was analyzed over 6 months. Using patient-reported outcomes (PROs) to measure disease activity by visual analogue scale (VAS), the HAQ Disability Index (HAQ-DiI), Disease Activity Score (DAS28), and morning stiffness duration. The age’s (average ± SD) = 53 ± 10 years and time of disease evolution (average ± SD) = 176 ± 23.3 years. Pretreatment HAQ (average ± SD) = 2.2 ± 0.5. All patients received previous biologic treatments and 61% (14 patients) combined therapy with DMARDS. Only 2 cases had no glucocorticoid treatment prior to treatment with Upadacitinib.

Results: In 3 months’ time, most patients (81%, n = 21) treated with Upadacitinib were able to reduce GC dose, and this reduction was maintained 6 months from the beginning of the treatment. After 3 months of treatment, most patients experienced an enhancement in DAS28 (89%, n = 18), with an average improvement in DAS28 of (± SD) 1.87±1.09 units. Regarding the pain (VAS), 67% of the patients showed improvement after 3 months (n=16), reaching 71% after 6 months (n=17). Sixty-eight percent of treated patients showed a reduction in morning stiffness after 3 months (n = 19), and this improvement increased up to 84% of treated patients at 6 months (n = 19). Side effects were observed in five patients, consisting of dizziness and nausea. In no case were they a reason for the withdrawal of the drug. Treatment was withdrawn in three patients due to primary failure.

Conclusion: Treatment with Upadacitinib allows GC dose reduction, as well as an improvement in DAS28, VAS and morning stiffness at three months and six of treatment. These data are in line with the evidence published in Upadacitinib pivotal studies, meaning a good alternative in the treatment of patients with moderate or severe RA.

POS0457 SYNOVIAL TRANSCRIPTOMIC PROFILES CORRELATE WITH DISEASE ACTIVITY IN EARLY UNTREATED RHEUMATOID ARTHRITIS

C. Triaille1, T. Sokolova1, S. De Montjoie2, A. Nzeusuou Toukap2, L. Meric de Belletet2, A. Loriot3, B. Lauwersy3, P. Durez4, N. Limaye5, UCLOuvain Brussels; 4De Duve Institute UCLouvain, Service de rhumatologie, Bruxelles, Belgium; 5De Duve Institute UCLouvain, Computational Biology, Woluwe-Saint-Lambert, Belgium; 6De Duve Institute UCLouvain, Genetics of Autoimmune Diseases and Cancer, Woluwe-Saint-Lambert, Belgium

Background: Synovitis is the common feature across all individuals with a diagnosis of rheumatoid arthritis (RA). Yet, cellular and transcriptomic alterations occurring in RA synovium are highly variable among patients. So far, most data on clinical-tissue correlations either rely on hypothesis-driven approaches or are potentially biased by heterogeneous clinical characteristics (e.g. disease duration or disease-modifying antirheumatic drugs).

Objectives: We used transcriptomic profiling of synovial tissue from early, untreated rheumatoid arthritis patients (ERA) to 1/ identify the genes with the most variable expression among patients and 2/ explore the ability of unbiased (data-driven) approaches to define clinically relevant ERA subgroups.

Methods: Synovial biopsies were harvested from clinically involved joints of ERA patients using needle arthroscopy or ultrasound-guided biopsy. Data on disease activity were collected at inclusion. For each sample, 350ng total RNA was sent for RNASEquencing using a standardized protocol (Macrogen Europe). After quality control (Fast QC) and genome alignment (HiSat2), normalized read counts were analyzed on Glucone Omics Explorer. To focus on inter-sample heterogeneity, genes were filtered based on variance (\(\sigma_{\text{max}}\)). Unbiased approaches (Principal Component Analysis, Unsupervised Clustering) were applied to define patients’ clusters. Pathway enrichment analyses were performed on Metascap. CibersortX was used to extrapolate the immune cell subsets relative composition from gene expression data. All other statistical analyses were performed on GraphPad Prism v9.

Results: Total RNA was obtained from synovial biopsies from 74 patients. We first applied variance filtering to identify the genes whose expression showed the greatest variation between patients (n = 894 most variable genes). PCA analysis on the level of expression of these genes did not divide samples into distinct groups, instead yielding a continuous distribution broadly associated with baseline disease activity, as measured by DAS28CRP. Consequently, we used unsupervised clustering to allow for unbiased definition of two patient clusters (PicC: PicC1 (n=52) and PicC2 (n=22) based on their expression of these 894 genes. Pathway analysis of these genes revealed significant enrichment of immune system genes, in the Inflammatory response and Rheumatoid Arthritis pathways (gene cluster 1: GC1), B cell & plasma cell-related pathways (GC2) and metabolic processes-related genes (GC3). Interestingly, PicC1 and PicC2 were characterized by very different clinical features. More specifically, patients from the group with a strong B & plasma cell signature (PicC1) displayed higher baseline indices of all disease activity score components (median DAS28CRP: 5.56 vs 4.09; p-value = 0.0003). They also had higher rates of baseline radiological erosions (erosive disease in 34.6 % vs 10%; p-value = 0.0252) but similar rates of seropositive disease. In line with our pathway analyses, we found a higher signature (inferred relative frequency) of B & plasma cells, T cells and M1-like macrophages in PicC1 compared to PicC2 synovia. PicC2 synovia instead had relatively higher M2-like macrophage and resting mast cell signatures.

Conclusion: In this large synovial biopsy study, we found that synovial transcriptomic profiles in ERA patients distribute continuously based on the expression of inflammatory and immune cell transcriptomic activity. These transcriptomic signatures correlate strongly with systemic disease activity. Data on disease activity were collected at inclusion. For each sample, 350ng total RNA was sent for RNASEquencing using a standardized protocol (Macrogen Europe). After quality control (Fast QC) and genome alignment (HiSat2), normalized read counts were analyzed on Glucone Omics Explorer. To focus on inter-sample heterogeneity, genes were filtered based on variance (\(\sigma_{\text{max}}\)). Unbiased approaches (Principal Component Analysis, Unsupervised Clustering) were applied to define patients’ clusters. Pathway enrichment analyses were performed on Metascap. CibersortX was used to extrapolate the immune cell subsets relative composition from gene expression data. All other statistical analyses were performed on GraphPad Prism v9.

Spondyloarthritis - aetiology, pathogenesis and animal models

CHARACTERISTICS OF GUT MICROBIOTA AND ITS RELATIONSHIP WITH LYMPHOCYTE SUBSETS AND CYTOKINES IN PATIENTS WITH UNDIFFERENTIATED SPONDYLOARTHRITIS

O. Wang1,2, S. X. Zhang3,4, J. Qiao3,4, X. Li1, Q. Yu1,6, P. F. He1,6, 1Shanxi Medical University, School of Basic Medical Sciences, Taiyuan, China; 2Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; 3The Second Hospital of Shanxi Medical University, Department of Rheumatology and Immunology, Taiyuan, China; 4Shanxi Medical University, School of Management, Taiyuan, China; 5Shanxi Medical University, Medical Data Sciences, Taiyuan, China

Background: Gastrointestinal microbiota, particularly dysbiosis of gut microbiota composition have been correlated with the progression of autoimmune disorders, such as undifferentiated spondyloarthritis (USPA).

Objectives: This study aimed to identify the changed gut microbiota and its relationship with lymphocyte subsets and cytokines in USPA Patients.

Methods: A total of 210 participants were recruited in this study, comprising 105 USPA patients and 105 age and sex-matched healthy controls (HCs). Microbial genome was extracted from approximately 250mg fresh fecal samples from all participants using QI Amp PowerFecal DNA Kit (Qiagen). The V3-V4 variable regions of bacterial 16S RNA genes were sequenced with the Illumina MiSeq PE300 system. QIIME2 was used to process representative sequence clusters and beta diversity (bray distance). Biomarker species were identified based on STEMP between USPA and HC group. Correlations were analyzed with the Spearman rank correlation test.

Results: The alpha-diversity indices have no significant difference between two groups (P > 0.05, Figure 1A). Gut microbial community structure differed between USPA and HC, as revealed by ASV Bray–Curtis distances (P < 0.05, Figure 1B). As for composition of gut microbiota, there were the increased levels of Escherichia, Lactobacillus, Staphylococcus, and Prevotella and Enterobacter was negatively correlated with the absolute numbers of NK cell (P < 0.05, Figure 1F).

Conclusion: Gut dysbiosis in USPA patients mainly characterized by reduced the diversity and impaired abundance of the intestinal flora, which was closely related to the disturbance of lymphocyte subpopulations and cytokines.

Ramming1,2, Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; 2Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Deutsches Zentrum Arthromes, Erlich, Germany; 3University: Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; 4Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Deutsches Zentrum Immuntherapie, Erlangen, Germany; 5 Trinity College Dublin, Department of Molecular Rheumatology, Dublin, Ireland; 6University College Dublin, Centre for Arthritis and Rheumatic Disease, Dublin, Ireland; 7Friedrich-Alexander-University (FAU) Erlangen-Nurnberg and Universitätsklinikum Erlangen, Department of Dermatology, Erlangen, Germany; 8Hospital Clinic and IDIBAPS, Arthritis Unit, Rheumatology Department, Barcelona, Spain

Background: Spreading of inflammation from skin to joint is a key question behind the pathogenesis of psoriatic arthritis (PsA). Psoriasis (PsO), being one of the most prevalent skin diseases, usually anticipates joint manifestations, suggesting spreading of skin to joint disease, which happens in about 30% of the patients with psoriasis. To date, it is still obscure why the inflammatory process in some patients with PsO remains restrained to the skin, whereas in other patients it extents to tendons and joints.

Objectives: Using a pre-clinical model of PsA, we aimed to unveil the skin-joint axis, i.e. the spreading of psoriatic inflammation from the skin to the joints.

Methods: KAEDERED transgenic mice expressing a photo-convertible fluorescent reporter were used to assess cell trafficking from inflamed skin to other organs in animal models. Using a pre-clinical model of IL-23 overexpression (IL-23OE) induced PsA. Psoriatic skin lesions were irradiated with UV light to trigger the photoswitch from KAEDERED treated mice to KAEDEREDED. Migration to different organs was determined by flow cytometry. Imaging flow cytometry was used to characterize the type of cells migrating from the skin to the joints. Migrating cells were further characterized by single-cell RNA-sequencing (scRNAseq) and functional analyses.

Results: MRI imaging and histological evaluation of IL-23OE mice revealed skin inflammation preceding joint inflammation in both wild-type and KAEDERED transgenic mice. Specific leukocyte migration from the skin to the joints started shortly after the onset of skin inflammation and before onset of inflammation within the joints of KAEDERED transgenic mice. No migration was observed in healthy control animals. Other organs such as spleen or lymph nodes showed no model-dependent migration. Imaging flow cytometry revealed that the cells migrating to the joints were predominantly CD45+ CD11b+ cells. ScRNAseq analysis of sorted KAEDERED cells from inflamed joints confirmed that approximately 80% of the migrating cells were macrophages. Differential gene expression and pathway analysis revealed an imbalance between pro- and anti-inflammatory macrophages in the joints of experimental psoriatic arthritis.

Conclusion: We describe IL-23-mediated migration of skin-derived macrophages from the skin to the joints during the onset of experimental psoriatic arthritis. This process may explain the spreading from psoriatic skin to joint disease as these cells foster the development by local cytokine production once arrived in the joints.

SLE, Sjögrens and APS - aetiology, pathogenesis and animal models

**DEFICIENCY OF PPM1A IN MACROPHAGE AGRGRAVATES PRISTANE-INDUCED LUPUS-LIKE DISEASE**

J. E. Kim1,2, E. Y. Kim1,3, S. Oh1,2, M. Lee1,2, D. Yoon1,2, H. J. Min1,2, H. S. Choi1,2, Y. G. Kim3, E. J. Chang1,2,4,5
1University of Ulsan College of Medicine, Biomedical Sciences, Seoul, Korea, Rep. of (South Korea); 2University of Ulsan College of Medicine, Stem cell Immunomodulation Research Center Seoul, Korea, Rep. of (South Korea); 3Asian Medical Center, Division of Rheumatology, Seoul, Korea, Rep. of (South Korea); 4University of Ulsan College of Medicine, Biochemistry and Molecular Biology, Seoul, Korea, Rep. of (South Korea)

**Background:** Protein phosphatase Mg2+/Mn2+-dependent 1A (PPM1A) is a phosphatase which regulates various intracellular cell signaling pathways including inflammation. We previously suggested that the inflammatory signal decreased the PPM1A protein level in macrophage and this reduction had correlation with the chronic inflammatory bone disease, implying the possible role of PPM1A in inflammatory responses of macrophage.

**Objectives:** In this study, we aimed to elucidate the potential role of PPM1A in macrophage to regulate inflammatory response during the disease progression of systemic lupus erythematosus.

**Methods:** We generated macrophage-specific conditional gene-knockout (PPM1Afl/fl;LysMCre) mice and developed a lupus-like disease with immune complex glomerulonephritis in these PPM1Afl/fl;LysMCre mice by intraperitoneal pristane injection. Mice serum was collected every 4 weeks after pristane injection. Serum anti-dsDNA IgG, anti-ssDNA IgG, interleukin-17 (IL-17) and tumor necrosis factor-α (TNF-α) were quantified by ELISA. After 41 weeks from pristane injection, histological changes in the kidney, spleen, and lung tissues were observed. To analyze M1/M2 polarization in vitro, LysMCre and PPM1Afl/fl;LysMCre mouse bone marrow-derived macrophages were cultured with lipopolysaccharide (LPS)/Interferon-α (IFN-α) or Interferon-γ (IFN-γ) or IL-4 to check M1 or M2 related genes.

**Results:** We found that macrophages of PPM1Afl/fl;LysMCre mice displayed different gene expression with LPS stimulation especially in M1/M2 related genes through the RNA-seq analysis and showed a decrease in both M1 and M2 polarization induced by LPS/IFN-γ or IL-4 stimulation. Notably, we found that PPM1Afl/fl;LysMCre mice with pristane injection showed a significant increase of anti-ssDNA IgG compared to LysMCre mice. PPM1Afl/fl;LysMCre mice showed severe lupus-like phenotypes such as global glomerular enlargement indicated by endocapillary proliferation and glomerular cellularity in kidney and lung inflammation accompanied by fibrosis, compared to LysMCre mouse by pristane injection. Together, serum IL-17 and TNF-α, which are proinflammatory cytokines, were increased in PPM1Afl/fl;LysMCre after pristane injection. These results indicate that PPM1A depletion in macrophage deteriorates inflammation and contributes to the tissue damage in lupus-like disease.

**Conclusion:** Our findings suggest that the deficiency of PPM1A in macrophages impairs M1/M2 macrophage polarization leading to an immune imbalance in lupus-like disease model, providing a potential link between the loss of function of PPM1A in macrophages and its molecular target for treatment of systemic lupus erythematosus.

**EXPLORATORY IMMUNOPHENOTYPE OF THE TISSUE JUVENILE SJÖGREN’S SYNDROME REVEALS A DISREGULATION OF B AND T MEMORY CELL FREQUENCIES**

L. Martin-Gutierrez1,2, H. Peckham3, A. Radziszewska2,3, J. Peng2, O. Nette2, E. Jury1, C. Clurin3,1, University College London, Centre for Rheumatology Research, London, United Kingdom; 2University College London, Centre for Adolescent Rheumatology Versus Arthritis, London, United Kingdom

**Background:** Sjögren's syndrome (SS) is an autoimmune rheumatic disease characterised by dryness resulting from chronic lymphocytic infiltration of the exocrine glands. Patients also present with other extraglandular manifestations such as arthritis, anaemia and fatigue or various organ and systems involvement. The disease is more frequent in women aged 30-50. However, in rare cases, the disease is seen in childhood and is known as juvenile SS (JSS) or childhood SS. Children have different clinical manifestations compared to adults, with dryness being less common, making the diagnosis very challenging.

**Objectives:** To investigate in depth the immune cell profile of patients with JSS for better understanding of disease pathogenesis.

**Methods:** Peripheral blood was collected from a cohort of patients with JSS who were attending appointments at UCLH clinics. None had received B-cell depletion therapy. Immune-phenotyping of 29 immune-cell subsets, including B and T cells, in peripheral blood from patients with JSS (n=10) and age and sex-matched healthy controls (n=10) was performed using flow cytometry as we have performed previously for patients with adult onset SS. Data were analysed using multiple t-tests and compared with the adult SS immune phenotype.

**Results:** Patients with JSS had an average age of 18 years (range 16-21) with an average age of disease onset at 14 years (range 12-18). Up to 60% of patients presented Anti-Ro autoantibodies while 50% presented Anti-La autoantibodies. Patients with JSS had an altered immune profile compared to age matched healthy controls (average of 18 years, range 15-25). In the B cell compartment,
JSS patients had higher frequencies of total CD19+ B cells (p=0.0044), Naïve B cells (CD19+IgD+CD27-) (p=0.0183) and b2m (CD19+HlgD-CD28+) (p=0.0490) whereas memory B cell subsets such as early b5m (CD19+HlgD-CD38+) and late b5m (CD19+HlgD-CD38-) were significantly reduced (p=0.0249, and p=0.0177, respectively), similar to the profile seen in patients with adult-SS. Interestingly, in the CD4+ T cell compartment, central memory (CD4+CD27+CD45RA-) T cells were significantly reduced (p=0.0001) but effector memory (CD4+CD27-CD45+) and effector memory-re-expressing-CD45RA (EMRA, CD4+CD27-CD45RA+) T cell subsets were significantly elevated (p=0.0171 and p=0.0022 respectively). These changes were not observed in adult-SS patients. Finally, unlike intraepithelial B-lymphocytes, serological parameters, such as, rheumatoid factor-, IgG- and ESR levels were significantly higher in JSS patients with presence of B-lymphocyte containing ducts, irrespective whether the labial or parotid gland was taken into account.

**Conclusions:** Presence of B-lymphocyte containing ducts is a specific finding in salivary gland biopsies of pSS patients and is associated with clinical parameters of pSS. Tofacoitinib containing ducts by using DIA could be used as an objective marker in the diagnostic histopathological work-up of patients suspected of pSS.

RIIP buffer to obtain proteins. The protein levels of PRRs: NLPR3, TLR9, ZBP-1, and cGAS, as well as molecules activated downstream of cGAS and ZBP-1 such as TBK1, p-TBK1, p-STING, and STING were determined by Western blotting.

**Results:** The results show that the mitochondria of the glandular epithelial cells of NOD.B10Sn-H2b/J mice treated with vehicle (control) present alterations such as swelling, disruption of membranes and crest disorganization that previously were reported in patients with SS (1). Interestingly, tofacitinib treatment improves the architecture of mitochondria. On the other hand, the protein levels of PRRs such as NLPR3 and cGAS decreased in mice treated with tofacitinib, as well as pTBK1.

**Conclusion:** The altered morphology of mitochondria together with the increased protein levels of PRRs and downstream markers of these PRRs suggests release of mitochondrial DAMPs in submandibular glands of NOD. B10Sn-H2b/J mice. The improvement in mitochondrial morphology as well as the decrease in PRRs activation under tofacitinib treatment suggest a potential use of this anti-inflammatory agent in mitochondrial alterations associated with inflammation. Many questions remain to be addressed, such as determining which mitochondrial DAMPs might be being released and whether this is associated with impaired mitochondrial function in SS.

**DOI:** 10.1136/annrheumdis-2022-eular.2496

**Background:** Salivary gland involvement is a hallmark of disease in primary Sjögren’s syndrome (pSS). This is reflected by the prominent role of a positive biopsy within the ACR-EULAR classification criteria, which is solely based on the focus score (FS)1. In pSS all salivary glands might be involved in the disease process. For this reason, both labial and parotid salivary gland biopsies can be used for diagnosis and evaluation. Although nearly all clinical centres obtain labial gland biopsies for classification and diagnosis of pSS, a parotid biopsy is also a safe and effective procedure. Furthermore, it has a comparable diagnostic potential in pSS, might be associated with less morbidity, and may even detect presence of subclinical MALT lymphomas. However, histopathological differences between both types of salivary glands should potentially be taken into account.

**Objectives:** The aim of this study was to get histopathological insight in minor (labial) and major (parotid) salivary glands in pSS patients in comparison with non-SS sicca patients.

**Methods:** Both labial and parotid salivary gland biopsies were obtained from 99 patients. According to the expert opinion of three experienced rheumatologists, 36 patients were classified as pSS patients and 63 as non-SS sicca patients. Salivary gland biopsies were formalin fixed, paraffin embedded and serially sectioned at 3–4µm. Sections were stained with H&E and for CD3, CD20, CD45, CD3+, CD20+, CD45+, and CD20+ infiltrates compared to non-SS parotid salivary gland biopsies. Other histopathological parameters were comparable between the two types of salivary glands. In pSS patients, both labial and parotid salivary gland sections. Comparison of the two salivary gland types of non-SS sicca patients revealed more signs of inflammation in labial salivary glands as shown by a significantly higher FS, CD3+ “T-cells”, CD20+ “B-cells” and relative area of CD45+ infiltrates compared to non-SS parotid salivary gland biopsies. Other histopathological parameters were comparable between the two types of salivary glands. In pSS patients, a higher FS and relative area of CD45+ infiltrates was observed in labial gland biopsies compared to parotid gland biopsies. Nevertheless, relative and absolute CD20+ B-cell counts, GCs/mm² and LEVs/mm² were higher in parotid gland parenchyma.

**Conclusion:** This study shows in labial salivary gland biopsies of non-SS sicca patients more signs of (unspecific) inflammation compared to parotid biopsies. In parotid gland biopsies signs of B-cell hyperactivity, such as number of CD20+ B-cells, GCs/mm² and LEVs/mm², are more pronounced, compared to labial gland biopsies. These histopathological differences should be taken into consideration in diagnosis and classification of Sjögren’s disease.

POS0458
ENRICHMENT OF COMPLEMENT, IMMUNOGLOBULINS, AND AUTOANTIBODY TARGETS IN THE PROTEOME OF PLATELETS FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)
P. Linge1, A. Jern1, H. Tydén1, B. Gullstrand1, H. Yani2, C. Welinder3, R. Kahn1, A. Jonsen1, J. Sjöple1, A. Bengtsgon1, on behalf of Lund SLE Research Group, 1Lund University, Department of Clinical Sciences, Rheumatology, Lund, Sweden; 2Swedish National Infrastructure for Biological Mass Spectrometry, BioMS, Lund, Sweden; 3Lund University, Department of Clinical Sciences Lund, Lund, Sweden; 4Lund University, Division of Hematology and Transfusion Medicine, Lund, Sweden
Background: Systemic Lupus Erythematosus (SLE) is characterized by autoimmunity towards apoptotic/necrotic cells, complement activation and excessive amounts of circulating immune complexes. Platelets are recognized as immune cells that interacts with innate and adaptive immune functions. They are activated in SLE patients and contribute to an increased susceptibility to thrombosis [1]. Decreased platelet size has been observed in patients with SLE [2], but the mechanism(s) remains unclear. In this study, we have analyzed the complete proteome of platelets with normal and decreased size from SLE patients and from healthy controls (HC).
Objectives: Our aim was to find clues that could explain the morphological differences observed in platelets from SLE patients and to better characterize the role of platelets in SLE.
Methods: We included 23 consecutive patients with SLE, median SLEDAI-2K score was 2, and 10 HC. Blood count, serum complement levels and the presence of antiphospholipid or dsDNA antibodies were analyzed in all patients. Platelet size (forward scatter) and activation status (CD154, PAC1, CD32, PAR1, CD62P and Annexin V) was determined using flow cytometry. The proteome of 10 platelet isolates from SLE (five with smallest and the five with largest average size) and five HC were analyzed using liquid chromatography with tandem mass spectrometry (LC-MS/MS). Data were analyzed using ANOVA, t-test, hierarchical cluster analysis, protein interactions using the STRING software and correlation analysis using spearman correlation.
Results: We identified a total of 2572 proteins from the platelet isolates. Out of the identified proteins, 396 had significantly different levels, meeting an ANOVA q-value < 0.01. Pairwise t-test analysis, using a fold difference (FD) of > 1.5 and a p-value of ≤ 0.05 as cut off revealed significant differences in the distribution of proteins between groups. Platelets of both SLE groups (small and normal sized) shared higher levels of forty proteins and twenty proteins were reduced, compared to HC. Cytokine functions were overrepresentation in the group of reduced proteins, while proteins with higher levels in platelets from SLE patients included proteins associated with complement and autoantibody targets such as Beta-2-glycoprotein 1, Annexin A5, and Prothrombin. Platelets from SLE patients also shared an abundance in immunoglobulin proteins, with even greater accumulation in the normal sized platelets. Platelet heavy chain constant alpha 1 (r = -0.85, p=0.003), heavy constant mu (r = -0.64, p=0.05) and heavy constant gamma 3 (r = -0.80, p=0.008) are negatively correlated with complement C4 in serum and heavy constant gamma 2 (r = -0.648, p=0.049) with complement C3.
Conclusion: This study revealed an accumulation of complement proteins, immunoglobulins and known autoantigens in platelets from SLE patients compared to HC. The signature was largely independent of platelet size, but the mechanism(s) remains unclear. In this study, we have analyzed the complete proteome of platelets with normal and decreased size from SLE patients and from healthy controls (HC).

POS0459
APTERM-BASED PROTEOMIC SCREENING IN IDENTIFICATION OF PATHOGENIC SIGNAL PATHWAY AND ASSOCIATED BIOMARKERS WITH ASSOCIATED WITH HISTOLOGICAL FINDINGS IN LUPUS NEPHRITIS
1Keio University School of Medicine, Division of Rheumatology; 2Department of Internal Medicine, Tokyo, Japan; 3Mitsubishi Tanabe Pharma Corporation Sohaku, Innovative Research Division, Tokyo, Japan
Background: The current gold standard for the diagnosis and classification, assessment of the severity of lupus nephritis (LN) is a renal biopsy. On the other hand, since the procedure is highly invasive, there is a pressing need to identify biomarkers for predicting the presence and its histological severity of LN.
Objectives: The purpose of this study was to elucidate the urine biomarkers for predicting the presence and the severity of histological findings of LN, and to search the pathogenic signal pathway.
Methods: Urine samples from 24 biopsy-proven active LN patients were initially screened for the levels of 1305 distinct human proteins using an aptamer-based-targeted proteomic assay. We developed histological scoring system based on ISN/RPS lesion definitions and classification, NIH activity and chronicity score. Two experienced evaluators assessed the histological scores. Cluster analysis and pathway analysis were performed.
Results: A total of 24 LN patients were included: 20 (83%) had a proliferative histological class (III or IV +/- V), 4 (17%) pure membranous (V). Through cluster analysis, several histological subgroups were extracted according to correlation with each histological finding, and proteins which correlated with each histological scores were analyzed. We focused on two subgroups: one in which including active glomerular histological findings (endocapillary hypercellularity, karyorrhexis, neutrophil infiltration, subendothelial deposits) and the other in which including interstitial histological findings (interstitial inflammation, interstitial fibrosis, tubular atrophy). Histological scores in the former group showed strong positive correlation with protein group which contained 59 proteins (Group A), including CCL21, CCLX10, VCAM1. Histological scores in the latter group correlated with another protein group which contained 85 proteins (Group B), including MCP-1, CCL11. Inguenity Pathway Analysis showed 16 pathways (PDGF Signalling, Granulocyte Adhesion and Diapedesis, etc) were upregulated in Group A and 11 pathways (IL-17 signalling, Fibrosis signalling pathway, etc) upregulated in Group B. Among group A and B urine proteins, those showed strong correlation between respective histological findings were validated with ELISA assays.
Conclusion: An aptamer-based-targeted proteomic assay screening by combining with renal histological scoring system suggested several urine proteins can predict the severity and the presence of major renal histological findings, and suggested to be related with the pathogenesis in patients with LN.

Disclosure of Interests: None declared.
Background: Cardiovascular disease (CVD) is a leading cause of mortality in patients with systemic lupus erythematosus (SLE, female:male ratio of 9:1) through accelerated atherosclerosis, the build-up of lipids and inflammation in the major artery walls, compared to age and sex matched healthy individuals. This is due to chronic inflammation, dyslipidaemia and other cardiometabolic defects that exacerbate with age (1). SLE women in aged of 35-44 increases the risk of coronary artery disease by 50 times and there is a 100-300-fold increased CVD-related mortality risk in young patients that develop SLE before the age of 18. Investigating metabolic defects in young patients and how they progress with age could help us understand the progressive mechanisms of atherosclerosis in SLE.

Objectives: To further investigate the hippocampal neurogenesis in lupus and determine its involvement in disease pathogenesis.

Methods: All experiments were performed in female NZB/NZW F1 and C57BL/6 (WT) mice at the age of 3 months (pre-nephritic) and 6 months (nephritic stage) (n=5-8/condition/experiment). Neurogenesis was assessed in sagittal sections of hippocampus by immunohistochemical staining (DCX, Sox2, GFAP, Iba1) and morphological criteria. RNA-sequencing was performed in hippocampal tissue followed by pathway and enrichment analysis. Apoptosis (cleaved-caspase 3) and immune cell infiltration (CD11b, CD45, Ly6G, Ly6C, MHC-II, CD4, CD8, B220, Iba1, CD80, CD86, Argiase-1, iNOS) were assessed by flow-cytometry. Cytokines levels were measured by Legendplex. Ex vivo assays were performed in adult hippocampal neural stem cells extracted by 2-month-old female WT mice.

Results: We identified a profound disruption (~2-fold) of hippocampal neurogenesis (decreased DCX+ cells) both at 3 and 6 month-old lupus mice together with decreased differentiated cells in both time-points, suggesting that lupus mice exhibit impaired neuronal differentiation. Although the number of the neuronal precursors radial gial-like cells (RGLs) was normal at pre-nephritic stage, lupus mice express increased number of both activated RGLs (Sox2+/GFAP+) and proliferating neuronal progenitors (Sox2+ cells) indicating enhanced self-renewal ability of neural precursors and augmented proliferation. Levels of cleaved-caspase 3 were elevated in lupus hippocampus supporting increased hippocampal apoptosis. Immunohistochemical and transcriptomic analysis of hippocampal tissue revealed a profound inflammatory response in lupus mice. Flow-cytometry analyses showed a pronounced immune cell trafficking in lupus hippocampus with a myeloid predominance –involving predominantly the microglia- both at early and late stages of the disease. Multiplex assays revealed elevated levels of IL-6 and IL-18 in lupus hippocampus. Ex vivo exposure of adult hNSCs to IL-6 or IL-18 promoted cell proliferation and induced apoptosis.

Conclusion: The NZB/W-F1 mouse model of SLE exhibits defective neurogenesis due to increased apoptosis, and decreased differentiation of neuronal progenitors. Inflammation in lupus hippocampus results in elevated levels of IL-6 and IL-18 with both cytokines negatively affecting the NSCs response. IL-6 and IL-18 may induce behavioral changes in NZB/W-F1 lupus mediated by altered neurogenesis and may represent therapeutic targets in NPSLE.

POS0462 HYDROXYLQUORINE REDUCES THE TITERS OF ANTI-DOMAIN 1 ANTIBODIES OVER TIME IN PATIENTS WITH PERSISTENTLY POSITIVE ANTIPHOSPHOLIPID ANTIBODIES: RESULTS FROM THE APS ACTION CLINICAL DATABASE AND REPOSITORY ("REPOSIT")

POS0461 DISRUPTED HIPPOCAMPAL NEUROGENESIS MEDIATED BY IL-6 IS MIGHTY-10 INDUCE NEUROPSYCHIATRIC CHANGES IN MURINE LUPUS

D. Nikolopoulos1, T. Manolakou1, A. Polissaidis1, A. Fila2, Y. Koutmanis1, D. Boumpas2.2Biomedical research foundation academy of athens. Center for clinical, experimental surgery and translational research, Athens, Greece

Background: Systemic lupus erythematosus (SLE) frequently affects the nervous system (NSLE) in SLE patients, now largely only partly understood. We have previously characterized the behavioral phenotype of the NZW/F1 lupus-prone mouse which recapitulates the NPSLE phenotype exhibiting hippocampal-linked behavior including depressive-like disorder, anxiety and cognitive impairment both at early and late stages of the disease characterized by a profound hippocampal inflammatory response I.2 Defective hippocampal neural stem cell (hNSC) response is associated with cognitive dysfunction, depression and anxiety, all of which represent common neuropsychiatric features of both human and murine SLE.

Objectives: To further investigate the hippocampal neurogenesis in lupus and determine its involvement in disease pathogenesis.

Methods: Serum NMR metabolomics (>250 metabolites, Nightingale) covering glycolysis metabolites, amino acids and 130 lipid measures was performed on serum from a cohort of female SLE patients (n=164, 13-72 years of age, median 35) and matched healthy controls (HCs, n=120, 15-76 years of age, median 36) and analysed by linear regression and Venn analysis. Multiple t-tests (corrected for multiple comparisons by false discovery rate) were used to assess unique metabolic changes by age group between SLE patients and HCs (≥25, n=62/43; 26-49, n=50/46; ≥50, n=52/31) and dysregulated metabolic pathways were assessed using metaboanalyst software. The metabolic impact of disease activity measures and treatments was assessed by Spearman correlations and unpaired t-tests respectively.

Results: Twenty-five metabolites were significantly altered in all SLE age groups compared to HCs, dominated by atheroprotective high density lipoprotein (HDL) subunits and their surface-bound peptide, apolipoprotein(Apo) A1, all of which were downregulated in SLE compared to HCs (p<0.0001 in ages combined). In addition, the concentration of glycolycoprotein acetyls (GlycA, inflammatory biomarker) was increased in SLE in all age groups compared to HCs (p<0.0001 in ages combined). Importantly, ApoA1 correlated negatively with disease activity measures (SLEDAI, p=0.005; BILAG, p=0.0009; dDNA, p=0.03; ESR, p=0.0006) and positively with lymphocyte count (p=0.0003), whilst GlycA correlated positively with ESR (p=0.0001) and CRP (p<0.0001). Alternatively, metabolites unique to specific age groups in SLE compared to HCs included reduced amino acid subsets in the ≥25 age group, increased atherogenic very low density lipoproteins and reduced polyunsaturated fatty acids in the 26-49 age group, and increased atherogenic low density lipoproteins in the ≥50 age group. Separately, metabolites associated with the glycosylation pathway (p=0.004, metaboanalyst), including acetone, citrate, creatinine, glycerol, lactate and pyruvate, had significant positive correlations with age in SLE patients, but not in HCs. These metabolites were not significantly associated with disease activity measures. However, pyruvate (p=0.01) and lactate (p=0.009) were significantly upregulated in prednisolone treated patients, whilst citrate (p=0.002) and creatinine (p=0.005) were downregulated in hydroxylorochrome treated patients.

Conclusion: Increasing HDL (ApoA1) levels whilst maintaining low disease activity in patients with SLE from a young age could improve cardiometabolic risk and determine its involvement in disease pathogenesis.

Background: Data on fluctuation of antibodies directed against domain 1 (anti-D1) of β2-glycoprotein I (β2-GPI) are scarce. Patients with antiphospholipid syndrome (APS) and all three criteria tests for antiphospholipid antibodies (aPL) display higher titers of anti-D1, which correlates with clinical events. Objectives: This project aims at evaluating predictors of the variation of anti-D1 titers over time in a large international cohort of persistently aPL positive patients. Methods: Anti-Phospholipid Syndrome Alliance For Clinical Trials and International Networking (APS ACTION) Registry was created to study the course of persistently aPL-positive patients with or without autoimmune disorders over at least 10 years. Inclusion criteria are positive aPL by Updated Sapporo Criteria display higher titers of anti-D1, which correlates with clinical events. Results: In this longitudinal study, 230 patients with anti-D1 tested at 4 time points were included (Table 1). Patients with thrombotic APS had anti-D1 titers significantly higher than those without thrombosis (p=0.029). Among 135 patients with at least one anti-D1 positive result, anti-D1 titers varied significantly over time (Friedman statistics: 508.5, p<0.0001; anti-D1 geometric mean at baseline 189.0; Table 1. Demographic and Clinical Characteristics of 230 APS ACTION Registry Patients with anti-D1 tested ≥3 time points during the follow-up

Anti-D1 titers were significantly higher at baseline compared to T3 (p=0.029). In the 4 years of follow-up, 18 new thrombotic events occurred. Patients with double/triple aPL positivity displayed 12.5 fold increase [95%CI 7.4-20.0] in baseline anti-D1 titers. After adjustment for age, gender and number of positive aPL tests, the fluctuation of anti-D1 titers was associated with treatment with hydroxychloroquine (HQC) at each time-point. In particular, treatment with HQC, but not those with conventional immunosuppressors, was associated with a 1.3-fold decrease in anti-D1 titers [95%CI 1.1-1.5]. In the same multivariable model, incident vascular events were associated with a 1.5 fold increase of anti-D1 titers. A concomitant diagnosis of systemic lupus erythematosus did not affect the fluctuation of anti-D1 titers.

Conclusion: Treatment with HQC and vascular events during follow-up were identified as significant predictors of the fluctuation of anti-D1 antibody titers over time.

POS0463 REENGINEERING CHIMERIC ANTIGEN RECEPTOR T CELLS FOR TARGETED THERAPY OF LUPUS NEPHRITIS

C. Sole-Marcé1, T. Molina1, J. Cortés-Hernández2, 1Vall Hebron Institute Research, Lupus Unit - Rheumatology, Barcelona, Spain; 2Vall Hebron Institute Research, Pathology, Barcelona, Spain; 3Hospital Universitari Vall d’Hebron, Lupus Unit - Rheumatology, Barcelona, Spain

Background: Although the pathogenesis of lupus nephritis (LN) is not completely clear, it is known that the production of anti-dsDNA or anti-C1q antibodies is related to its activity [1]. Despite treatment, approximately 30-40% of patients continue to present a significant number of renal outbreaks [2]. Therefore, there is a growing interest in the development of more specific drugs. As B cells play a central role in the pathogenesis of SLE, the therapy CAR-T cells has been studied reporting good results for the prevention and also for as treatment in murine lupus models [3,4]. Recently, a new selective immunotherapy for autoimmune diseases has been demonstrated by modifying the T cells with a chimeric autoantigen receptor (CAAR) [5]. This novel therapeutic approach could be beneficial in LN with the aim of depleting only anti-DNA producing B cells. In this way, the benefits of anti-CD20 biologics would be obtained, but it would be much more specific, personalized and, surely, effective since only the self-reactive B cells would be destroyed.

Objectives: To study CAAR-Tcell anti-dsDNA and anti-C1q therapy in LN through in vitro experiments (primary cells and kidney organoids).

Methods: Synthesis of 6 CAAR anti-dsDNA that will be transfected in the primary T cells extracted from patients with LN and healthy controls (N = 10 per group). Through in vitro experiments their ability to lyse the B cells that produce anti-dsDNA or anti-C1q will be evaluated. The two CAAR-Tcell models that is most effective will be evaluated using kidney organoid models obtained from human samples.

Results: We engineered six human T cells models to express a chimeric autobody receptor (CAAR), consisting lupus nephritis autoantigen. As antigens for anti-DNA produced B cells, we designed Heparanase1/2, His-autoantibody receptor (CAAR), consisting lupus nephritis autoantigen. As antigens for anti-DNA produced B cells, we designed Heparanase1/2, His-autoantibody receptor (CAAR) [5]. This novel therapeutic approach could be beneficial in LN with the aim of depleting only anti-DNA producing B cells. In this way, the benefits of anti-CD20 biologics would be obtained, but it would be much more specific, personalized and, surely, effective since only the self-reactive B cells would be destroyed.

References:

Discussion: Most important clinical results will be presented. The results will be compared with previously published results.
anti-idDNA were Heparanase2 and alpha actinin1 CAAR-Tcells (selectivity of 75% vs 45%). C1q CAAR-T cells also presented specificity cytotoxicity for anti-C1q B cells (selectivity of 80%). In vivo imaging assay reveals that C1q or Heparanase2 CAAR-Tcells depleted completely B cells at 48 hours (ratio 1:10). Bcells:CAAR-Tcells. We developed 3D in vitro organoid culture using human kidney organoid and B cells from lupus nephritis patients. We evaluated Heparanase2 and C1q CAAR-Tcells using them and we demonstrated that C1q CAAR-Tcells could resolved better local kidney inflammation (reduction of IL6, TNF and INF cytokines levels).

Conclusion: Taken together, these results show that C1q CAAR-Tcells could be an effective and selective immune therapy for treatment of lupus nephritis. Currently, we are evaluated this therapy using NZW/F1 mouse models.

Figure 1. Results from the proteomic analysis carried out on synovial tissues. A) Heatmap showing the differential protein profiles between synovial tissues (PsA and RA) and healthy controls (CTL), at FDR 0.01. B) Characteristic protein panel discriminating PsA and RA tissues (p-value < 0.01). C) Discriminant analysis performed using this protein panel.

Results: Lipid profiles in ST from PsA and RA were unequivocally distinguished by MALDI-MSI followed by PCA-DA, and were also different comparing with control tissues. Interestingly, several lipid species, including sphingomyelins, phosphatidylincholines (PC) and phosphatidylethanolamines (PE), presented the greatest separation power to classify RA and PsA tissue samples. ANOVA analysis found 35 lipid species significantly different among the study groups, most of them significantly increased in RA and PsA compared to controls. Particularly, 11 lipids showed higher levels in PsA tissues compared with RA, including several PC and PE. The spatial distribution of these PE species was associated with areas of the sublining layer with increased vascularity and inflammatory cell infiltrates, according to MALDI-MSI images. On the other hand, RA and PsA patients were also correctly classified based on the ST levels of all quantified lipid species according to PCA and clustering analysis. Finally, the proteomic analysis quantified around 2,500 distinct proteins in the ST, including several related with lipid metabolism. Near 300 proteins showed altered abundance in the pathological tissues compared to healthy controls (FDR 0.01%, Figure 1A), being the small subset increased in controls mainly extracellular matrix proteins. The comparison between RA and PsA ST led to the identification of a panel of 36 proteins discriminating the two tissues with high statistical significance (p-value <0.01). In this comparison, all proteins except two appeared increased in RA (Figure 1B). A discriminant analysis shows the usefulness of this protein panel to differentiate the two diseases (Figure 1C).

Conclusion: Our study shows distinct molecular profiles between RA and PsA synovial tissue and synovial fluid, and reports potential clinically useful lipid and protein markers for the differential diagnosis of these diseases.

POS0465

UNSUPUPERVISED CLUSTERING ANALYSIS OF THE SERUM PROTEOME IDENTIFIES SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH DISTINCTIVE DISEASE SEVERITY AND LUPUS NEPHROPATHY

G. Lopez-Pedrera1, M. Á. Aguirre-Zamorano1, L. Muñoz-Barrera1, I. Sanchez-Paredes2, F. U. Pillar1, M. C. Ábalos-Aguilera3, N. Barberroja Puerto1, E. Collantes Estevez1, R. Ortega Castro1, C. Perez-Sanchez1, JMBIC/Reina Sofia Hospital/ University of Cordoba, Rheumatology; Córdoba, Spain

Background: Systemic lupus erythematosus (SLE) is a remarkably heterogeneous autoimmune disease. Despite great efforts, our knowledge of serum protein patterns in severe SLE phenotypes is still limited.

Objectives: This study investigated the serum proteomic profile of SLE, in order to identify relevant clinical categories.

Methods: Proximity extension immunosassay (PEA, Olink) was used to assess the serum levels of one hundred and eighty-five inflammation and organ damage-related proteins in patients with SLE (n = 72) and age-matched healthy donors (HD) (n = 18). In parallel, an extensive clinical and analytical profile of recruited subjects was performed. To evaluate the contribution of molecular profiles to the disease severity, unsupervised clustering analyses were developed. Gene ontology enrichment analysis were
also carried out to interrogate the biological meaning associated with the molecular signatures identified.

**Results:** Several circulating proteins related to inflammation and organ damage were coordinately altered in the serum of SLE patients in relation to HD. Unsupervised clustering analyses differentiated 2 patients clusters presenting different proteomic profiles. Clinically, although no differences were found in terms of age or disease duration, patients belonging to cluster 1 were characterized by a significantly higher status of disease activity (SLEDAI > 6) and prevalence of positivity for anti-ENA and anti-dsDNA antibodies than patients belonging to cluster 2, along with preponderance of patients with biopsy-diagnosed lupus nephritis (LN), abnormal creatinine and proteinuria. Twenty-three serum proteins were found deregulated between clusters. Interestingly, in parallel to well-recognized inflammatory cytokines, chemokines and regulatory proteins of leukocyte activity [Interferon (IFN)-gamma, interleukin (IL)-1βRA, IL-20, sCD40, macrophage colony-stimulating factor-1 (CSF-1), leukemia-inhibitory factor receptor (LIF-R), monocyte chemotactic protein (MCP)-1, MCP-4, C-C motif chemokine (CCL)-4, C-X-C motif chemokine (CXCL)-5, CXCL-6, metalloproteinase (MMP)-1, programmed cell-death ligand (PD-L)-1, eukaryotic translation initiation factor 4E-binding protein 1 (4E-BP1)], a number of key proteins involved in renal damage, not previously reported in serum from SLE, were further found significantly deregulated in patients belonging to cluster 1 when compared with cluster 2 (kidney injury molecule 1 (KIM1), Linker for activation of T-cells family member-2 (LAT2), C-type natriuretic peptide (NPPC), ErbB-2 interacted protein (ERBB2IP)).

**Conclusion:** 1) This highly sensitive proteomic analysis in the serum of SLE identified molecular patterns distinguishing patients with high disease activity and active LN, and including several novel candidate proteins, whose exact role and suitability as biomarkers in SLE deserve further investigation. 2) Combination of novel and traditional disease-specific biomarkers may improve diagnosis and management of SLE.

**RESISTANT STARCH DIET IMPROVES DISTINCT GUT MICROBIOTA STRUCTURES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME**

M. Pereira1, I. Kulyk2, S. Redanz1, W. E. Ruff3, T. M. Greiling4, T. M. Greiling4, C. Dehner5, W. E. Ruff3, T. M. Greiling4, Carina Dehner5, Odelya Pagovich6, M. Greiling7, Daniel Zegarra Ruiz7, Cassyanne Aguiar8, None declared, Daniel Zegarra Ruiz: None declared, Cassyanne Aguiar: None declared, M. Greiling: None declared, Carina Dehner: None declared, Odelya Pagovich: None declared, Sylvio Redanz: None declared, William E Ruff: None declared, Teri M Greiling: None declared, Haider A. Pathan: None declared.

**Background:** Fiber-poor diets are linked to a reduction in gut microbiota diversity and gut barrier integrity, which is thought to promote the susceptibility to chronic inflammatory disorders1,2. We have previously shown that dietary resistant starch (RS) improves lupus-like disease in a murine model of SLE3 through the modulation of microbiota composition. If similar microbiotic microbial community structures exist in subsets of SLE patients and if a RS intervention may be efficacious in those patients remains unclear.

**Objectives:** To test if the dietary RS content in SLE and SLE-related antiphospholipid syndrome (APS) affect gut microbial taxa associated with SLE in published cohorts to date.

**Methods:** We obtained stool and blood samples as well as diet history for up to 3 visits (0, 4 and 8 weeks) from 12 SLE (n=28) and 15 APS (n=44) patients as well as 20 controls (n=48) as previously published4. Microbiota composition was defined by 16S rRNA V4 region sequencing on the Illumina platform and correlated with dietary fiber content extracted from a diet questionnaire. We used the FDA reference list to determine dietary RS contents in patients’ regular diets and defined RS quantities as being low if less than 2.5 g/day and as medium if 2.5 to 15 g/day. None of the patients achieved high RS greater than 15 g/day. Mann-Whitney or Kruskal-Wallis tests were performed to compare bacteria relative abundances among the different groups. Simple linear regression was performed to relate the bacterial abundance to RS content and other metadata.

**Results:** Medium intake of RS was associated with beneficial *Bifidobacterium* spp. in SLE patients (p=0.016) but not APS (p=0.509). Instead, APS patients who consumed medium quantities of RS in their diets had less gut bacterial taxa that are capable of producing cardiolipins (among them *Collinsella*; p=0.009) and *Ruminococcus gnavus* (p=0.0142), a species previously associated with lupus nephritis5. A recent Japanese metagenome-wide study6 associated *Streptococcus* spp. and related redox reaction genes with SLE, which may also affect oxidative processes in APS7. We therefore also explored *Streptococcus* levels in SLE and APS patients and found unexpectedly a significant reduction of streptococci in a subset of APS (p<0.004) but not SLE patients (p=0.451) in medium compared to low RS dietary content. *Streptococcus* abundance was correlated with both *Collinsella* (R2=0.3141; p<0.0001) and *Ruminococcus gnavus* (R2=0.1687; p=0.0056) in APS patients. Conclusion: Medium compared to low RS quantities in the regular diets of SLE and APS patients were associated with unique alterations in gut microbiota structure. *Bifidobacterium* increased in SLE patients with diets containing medium RS whereas APS patients with medium RS carried less cardiolipin-synthesizing taxa and lupus-related pathobionts. In particular, *Streptococcus* species recently strongly associated with SLE and redox reactions in Japanese patients in a metagenome-wide study8, were significantly suppressed in APS patients on medium RS diets. This modulatory effect was not seen in SLE patients or control subjects consuming medium RS diets. Together, these findings support distinct dietary effects on autoimmune gut microbiomes depending on the disease state. They also suggest potential beneficial effects of increased RS content on gut microbiota in SLE and APS patients. Fully resolving gut microbial signatures and clinical characteristics in these patients may identify the ideal subset to benefit from an intervention trial with RS.

Distler2,4, Mitsubishi Tanabe Pharma Corporation, Research Unit/Immunology & Inflammation, Souyaku Innovative Research Division, Yokohama, Japan; 1Mitsubishi Tanabe Pharma Corporation, Discovery Technology Laboratories, Souyaku Innovative Research Division, Yokohama, Japan; 3University of Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Schlieren, Switzerland; 2University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Faculty of Medicine and Health, Leeds, United Kingdom; 5Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Department of Internal Medicine 3—Rheumatology and Immunology, Erlangen, Germany

**Background:** Activation of melanocortin 1 receptor (MC1R) is known to have broad anti-inflammatory and anti-fibrotic effects. The blemcin (BLM)-induced skin fibrosis model is well-established for systemic sclerosis (SSc). α-melanocortin-stimulating hormone, an endogenous ligand of MC1R, inhibits skin fibrosis and MC1R knock-out enhances skin fibrosis in this model. These pieces of evidence suggest that MC1R agonism has potential in the treatment of SSC.

**Objectives:** Dersimelagon phosphate (MT-7117) is an investigational small molecule that is an orally administered, selective agonist for MC1R. The purpose of this study is to investigate the potential of MT-7117 as a therapeutic agent for SSC by evaluating its efficacy and mechanism of action in complementary preclinical models. The expression and distribution of MC1R in the skin of SSC patients was investigated.

**Methods:** The effects of MT-7117 on skin fibrosis and lung inflammation were evaluated in BLM-induced SSC murine models that were optimized for prophylactic and therapeutic evaluation. Microarray-based gene expression analysis and serum protein profiling were performed to investigate the mechanism of action of MT-7117 in the BLM-induced SSc models. The effect of MT-7117 on TGF-β-induced activation of human dermal fibroblasts was evaluated in vitro. Immunohistochemical analyses of MC1R expression in skin samples from SSC patients were performed.

**Results:** Prophylactic treatment with MT-7117 (≥3 mg/kg/day p.o.) significantly inhibited the increase in collagen content of the skin, the serum level of surfactant protein D, and the weight of the lungs from BLM-induced skin fibrosis and lung inflammation model. Therapeutic treatment with MT-7117 (≥3 mg/kg/day p.o.) significantly suppressed skin thickening and the numbers of myofibroblasts in pre-established BLM-induced skin fibrosis model. Gene array analysis using the BLM-induced SSc model demonstrated changes in numerous categories related to macrophages, monocytes, and neutrophils, followed by endothelial cell-related categories after treatment with MT-7117. In the analysis that focused on molecular signaling pathways, triggering receptor expressed on myeloid cells-1, IL-6, and oncostatin M were identified in inflammation, and peroxisome proliferator-activated receptor that is related to fibrosis were all affected by MT-7117. Serum protein profiling using BLM-induced SSc model revealed that multiple SSc-related biomarkers including P-selectin, osteoprotegerin, cystatin C, growth and differentiation factor-15 and ST00A9 were suppressed by MT-7117. MT-7117 inhibited the activation of human dermal fibroblasts by suppressing TGF-β-induced ACTA2 (encoding α-smooth muscle actin) mRNA elevation in vitro. Immunohistochemical analyses showed that MC1R positivity was observed in 40 of 50 diffuse cutaneous SSc patients. MC1R was expressed by monocytes/macrophages, neutrophils, blood vessels (endothelial cells), fibroblasts, and epidermis (keratinocytes) in the skin of SSc patients.

**Conclusion:** MT-7117 demonstrates disease-modifying effects in preclinical models of SSc. Investigations of its mechanism of action and target expression analyses indicate that MT-7117 exerts its positive effects by affecting the pathologies of inflammation, vascular dysfunction, and fibrosis through inflammatory cells, endothelial cells, and fibroblasts. In view of its potent beneficial impact on all three main pathologies of SSc, MT-7117 is a potential therapeutic agent for the treatment of clinically challenging SSc, which has diverse and difficult to treat symptoms. A phase 2 clinical trial investigating the efficacy and tolerability of MT-7117 in patients with early, progressive diffuse cutaneous SSc is currently in progress.

**EXTRACELLULAR VESICLES FROM SERUM OF MYOSITIS PATIENTS AS CIRCULATING BIOMARKERS AND DISEASE MEDIATORS**

S. Kivity1,2, H. Kravitz2,3, C. Cohen1, D. Margoulios1, M. Amar1, G. Kazimirsky1, D. Ozeri1, A. Dor1, C. Brodie2, Meir Medical Center, Rheumatology Unit, Kefar Sava, Israel; 2Tel-Aviv University, Sackler Faculty of Medicine, Tel-Aviv-Yafa, Israel; 3Bar-Ilan University, The Mina and Everard Goodman Faculty of Life Sciences, Ramat Gan, Israel; 4Tel-HaShomer The Sheba Medical Center, Zabludowicz Center for Autoimmune Disease, Ramat Gan, Israel; 5Tel-HaShomer The Sheba Medical Center, Department of Neurology, Tel-Aviv University, Ramat Gan, Israel

**Background:** Inflammatory myopathies (IM) are a heterogeneous group of disorders characterized by autoimmune inflammatory destruction of skeletal muscles. It is many times associated with lung, skin, and joint involvement. Identifying biomarkers that can differentiate IM from other muscle disorders may elucidate the pathophysiology of IM, guide novel therapies, monitor disease activity/response to treatments and predict prognosis. Exosomes are membrane-bound nanovesicles with diameters of 30-150 nm that contain multiple proteins, nucleic acids, and other molecules in a tissue- and cell-specific manner. Exosomes are secreted by a large variety of cells, play major roles in cell-cell interactions, and have recently emerged as circulating biomarkers in a variety of pathological conditions, including several autoimmune diseases.

**Objectives:** To characterize exosomes from serum of IM patients, analyze protein expression and study their potential mediators of disease pathologies.

**Methods:** Serum was collected from patients suffering from IM(n=5) and from patients suffering from Becker (BMD) and Duchenne (DMD) muscular dystrophies (n=6). Exosomes were isolated by Exoquick precipitation and analyzed for size distribution and by nanoparticle tracking analysis (NTA) and by Western blot for exosome markers. The effects of the isolated EVs on human satellite cell proliferation and differentiation and macrophage activation were examined.

**Results:** Exosomes from IM patients decreased human satellite cell proliferation (51%, P<0.01) and inhibited their myogenic differentiation as indicated by lower fusion index (24% inhibition, P<0.01) and expression of myosin heavy chain (72% inhibition, P<0.001). Similar results were obtained also with exosomes derived from DMD and BMD patients; however, their inhibitory effect was more pronounced on MyoD expression. Treatment of macrophages with exosomes from IM patients significantly increased the expression of IL-10 (3-fold, P<0.001), compared to exosomes of healthy controls and DMD patients. Another significant difference was in the expression of signaling molecules: Thus, exosomes from BMD patients increased the phosphorylation of Erk and p38, whereas a smaller effect was induced by IM exosomes. Conclusion: Exosomes from IM patients decrease satellite cell proliferation and myogenic differentiation compared to healthy exosomes. In addition, these exosomes increased the expression of IL-10 in macrophages. These effects are unique to exosomes of IM patients compared to muscular dystrophies. These promising results suggest that serum exosomes should be further investigated as a novel biomarker with potential therapeutic implications.

**ENDOTHELIAL RESPONSE TO MESENCHYMAL TRANSITION FACTORS ARE PART OF THE FIBROTIC PATHOGENESIS IN SYSTEMIC SCLEROSIS**

Y. H. Chiu1,2, J. Spierings1, J. M. Van Laar3, J. De Vries-Bouwstra3, M. Van Dijk1, R. Golschmeding1, 1University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands; 2Tri-Service General Hospital, Division of Rheumatology/Immunology/Allergy, Taipei, Taiwan, Republic of China; 3Leiden University Medical Center, The Department of
Background: Systemic sclerosis (SSc) is a systemic autoimmune disease characterised by inflammation, vasculopathy and fibrosis. Several mechanisms, including endothelial to mesenchymal transition (EndMT) and cellular senescence, may be included in the fibrosis process, especially in response to inflammation and vasculopathy.

Objectives: Our study aimed to identify how EndMT and cellular senescence manifest in SSc skin fibrosis.

Methods: We performed a cross-sectional biobank study on formalin-fixed, paraffin-embedded skin biopsies from patients meeting the ACR/EULAR 2013 classification criteria for SSc. The extent of dermal fibrosis and inflammatory cell infiltration was scored on haematoxylin-eosin stained samples. Fibrosis severity was semi-quantified by the compactness of collagen bundles and scored from one to three. The presence of senescence was defined by P21 or P16 positivity without co-localised Ki-67. The expression of P16, P21, and CTGF on fibroblasts and endothelia was scored from zero to two. The semi-quantitative score was evaluated independently in the superficial and deep dermis by agreement of two researchers (MRD and YHD). EndMT was assessed by co-localisation of CD31 and α-SMA double staining by immunofluorescence, and enclosure of ERG positive endothelial cell nuclei by α-SMA stained cytoplasm under bright field. Lymph vessels were identified by D2-40 (podoplanin) staining, and density was assessed.

Results: In total, skin biopsies from 18 SSc patients and four age-matched healthy controls were investigated. The characteristics of the patients are listed in Table 1. The dermal fibrosis score revealed a correlation with modified Rodnan skin score (Figure 1A).

SSc, systemic sclerosis; IQR, interquartile range; mRSS, modified Rodnan skin score.

Figure 1. (A) The modified Rodnan skin score (mRSS) was higher in skin biopsies with severe fibrosis. (B) While merging superficial and deep dermis semi-quantitative scores, increased senescence marker was associated with increased CTGF expression on fibroblasts. (C) Endothelial to mesenchymal transition (EndMT) was more in systemic sclerosis skin with out difference between groups with various fibrosis severity. (D) EndMT was associated with increased senescence markers on fibroblasts.

Senescence markers showed higher expression on fibroblasts from highly fibrotic dermis than healthy control. The median (IQR) percentage of P16 positive fibroblasts in dermis was 0.7 (0.5) in healthy controls, 0.9 (0.7) in grade one fibrosis, 0.3 (0.5) in grade two fibrosis, and 0.6 (4.6) in grade three fibrosis (p = 0.144). The median (IQR) percentage of P21 positive fibroblasts in dermis was 3.3 (7.0) in healthy controls, 10.3 (11.8) in grade one fibrosis, 33.2 (19.2) in grade two fibrosis, and 32.9 (40.7) in grade three fibrosis (p = 0.042). Moreover, increase of senescence markers on fibroblasts was associated with increased CTGF expression (Figure 1B). The density of blood and lymphatic vessels did not correlate with fibrosis severity. Still, the frequency of EndMT was significantly higher in patients with SSc, although it did not differ between groups with various fibrosis severity (Figure 1C). EndMT was not observed in lymphatic vessels (i.e. there was no co-localisation of D2-40 and α-SMA). Finally, the frequency of EndMT was increased with stronger fibroblast senescence (Figure 1D).

macrophages displayed a reduced expression of CD206 (p<0.05) and PD-L2 (p<0.01) markers compared to Fosl2fl/fl controls (n=5-9). Preliminary data indicated that Fosl2tg MHCII+ and CD36+ peritoneal macrophages showed a trend towards increased phagocytic activity compared to wt cells (n=3). Csf1RCreFosl2fl/fl peritoneal macrophages did not show a significant difference in phagocytic activity (n=3) compared to Fosl2fl/fl controls.

Conclusion: For the first time, we showed an increased expression of Fosl-2 and boosted phagocytic activity in SSc mDMD. scRNAseq analyses revealed upregulated phagocytosis-related genes with association to alternatively-activated macrophage polarization in different macrophage clusters in SSc-ILD lungs and lcSSc skin. Moreover, our animal data indicated an involvement of Fosl-2 regulating alternatively-activated macrophage polarization and phagocytosis. Therefore, targeting this alternative/pro-phagocytic phenotype represents an effective tool to counteract disease progression.

effect of PF1801 on the expression of antioxidant molecules in the myotubes was analyzed with quantitative real-time PCR.

**Results:** GLP-1R was expressed on the innervated muscle fibers of PM and CIM. The treatment with PF1801 in monotherapy or in combination with PSL suppressed CIM-induced muscle weakness and the muscle weight loss as well as the severity of histological myositis while the monotherapy with PSL did not suppress muscle weakness and muscle weight loss. PF1801 decreased the levels of inflammatory mediators such as HMGB1, TNF-α, and IL-6 in the serum of CIM. In vitro, PF1801 inhibited FASLG-induced myotube necroptosis and decreased the levels of HMGB1, TNF-α, and IL-6 in the supernatant. PF1801 activated AMPK and decreased the levels of PGAM5, which was crucial for FASLG-induced necroptosis of the myotubes. The inhibitory effect of PF1801 on myotube necroptosis was cancelled by compound C, an AMPK-kinase inhibitor, or MG132, a proteasome inhibitor, suggesting that PF1801 promoted ubiquitin-proteasome-mediated PGAM5 degradation through the activation of AMPK. Furthermore, PF1801 suppressed FASLG-induced reactive oxygen species (ROS) accumulation in myotubes, which was also crucial for the execution of necroptosis, through up-regulating the antioxidant molecules such as Nrf2/2, Hmox1, Gclm, and Nqo1.

**Conclusion:** GLP-1R agonist could be a novel therapy for PM that restores muscle strength as well as suppresses muscle inflammation through inhibiting muscle fiber necroptosis.

**INFLAMMATORY-PRIMED MUSCLE CELLS INFLUENCE MACROPHAGE CYTOKINE SECRETION IN A MYOSITIS CONTEXT**

B. Mccord1, R. Day1.1 Centre for Precision Healthcare, Division of Medicine, University College London (UCL), London, United Kingdom

**Background:** Sporadic inclusion body myositis (sIBM) is a progressive disease causing muscle weakness and mobility issues; however it is characterised by inflammatory and degenerative features; however there is no clear single cause for sIBM symptoms. Inflammatory factors include macrophage infiltration into muscle fibres and presence of high levels of inflammatory cytokines such as IFN-γ [1]. Degenerative features within muscle fibres include sarcoplastic inclusions containing aggregated PGAM5 and TDP-43 containing protein 43 (TDP-43) are two proteins that are found in inclusion bodies, and these have been suggested as sensitive diagnostic markers differentiating sIBM from other inflammatory myopathies [2]. Currently there is limited understanding of the pathogenic mechanisms underlying sIBM, and no effective treatments.

**Objectives:** The aim of this study is to investigate the interplay between inflammatory and degenerative features of sIBM with a focus on macrophage secreted factors, p62 and TDP-43 sarcomplastic aggregation. Firstly, to examine whether skeletal muscle cells that have previously been exposed to an inflammatory environment can in turn influence the inflammatory response of macrophages. Secondly, by investigating if macrophage-secreted inflammatory factors influence p62 and TDP-43 sarcomplastic aggregates. This will give insight into whether macrophage inflammation precludes skeletal muscle degeneration in an sIBM context in vitro versus vivo.

**Methods:** Primary human myogenic cells from healthy individuals were differentiated into myotubes for 7 days, with further 48-hour 20-ng/mL IL-1β and 750-ng/mL IFN-γ incubation to form inflammatory-primed myotubes. Conditioned media (CM) was collected from washed myotubes after 24 hours. 6x10^6 THP-1 cells/mL were differentiated to unprimed M(PMA) macrophages with 150-nM phorbol 12-myristate 13-acetate (PMA) for 24 hours, followed by 72-hour PMA-free rest. Inflammatory-primed M(IFN-γ) THP-1 were generated from M(PMA) with 48-hour IFN-γ and lipopolysaccharide (LPS) incubation. 20 % CM from myotubes was added to M(PMA) or M(IFN-γ-LPS) THP-1 for 24 hours, after washing and measuring IL-6 and TNFα release from macrophages via ELISA. 20 % CM from M(PMA) or M(IFN-γ-LPS) was added to myotubes for 48 hours before quantifying TDP-43 and p62 aggregates with image analysis.

**Results:** In M(IFN-γ-LPS) THP-1 secreted higher levels of IL-6 and TNFα than M(PMA), M(PMA) or M(IFN-γ-LPS) exposed to conditioned media from control or inflammatory-primed myotubes had no detectable TNFα secretion. For both M(PMA) and M(IFN-γ-LPS), addition of inflammatory-primed myotubes CM caused higher IL-6 secretion than adding control myotube CM. Incubating unprimed myotubes with M(PMA) or M(IFN-γ-LPS) CM had no effect on the presence, size, or frequency of p62 or TDP-43 sarcomplastic aggregates compared to control conditions.

**Conclusion:** Inflammatory priming myotubes with IL-1β and IFN-γ caused a response in macrophages that increased IL-6 production. However, CM from inflammatory-primed myotubes did not influence TNFα secretion from macrophages compared to control myotube CM. IL-6 has pleiotropic effects on skeletal muscle [3], promoting both hypertrophy and atrophy under different conditions. Therefore the effects of macrophage IL-6 upregulation on muscle is unclear. Culturing myotubes in unprimed or inflammatory-primed macrophage conditioned media did not influence p62 or TDP-43 sarcomplastic aggregation. This suggests macrophage secretory factors are not responsible for the sIBM degenerative features of p62 and TDP-43 aggregation.

ROLE OF IL-33/ST2 AXIS IN SYSTEMIC SCLEROSIS PATIENTS WITH ELECTROCARDIOGRAPHIC ABNORMALITIES
G. Pelegrino1, T. Colasanti1, M. Cadar1, L. Shen1, Y. Zhang1, Z. Honglin2, J. H. W. Distler1

Background: Electrocardiographic (EKG) abnormalities are described in 25-75% of Systemic Sclerosis (SSc) patients and they are associated with other systemic manifestations1 as well as with a worse prognosis.2 There is an increasing need for clinical and laboratory biomarkers to ameliorate the diagnostic approaches to patients with EKG abnormalities.3 In the last decade, many studies focused on the components of the interleukin (IL)-33/ST2 axis. Under physiological conditions, IL-33 is released by apoptotic cardiac cells, promoting a protective mechanism of cell survival, thanks to the binding with its transmembrane receptor ST2.4 During pathological cardiovascular events, an abnormal secretion of the IL-33 soluble receptor (sST2) by TH2 cells occurs. It binds IL-33 not allowing the physiological mechanism driven by the IL-33/ST2 binding previously described.4 For these reasons, sST2 has been proposed as a biomarker of cardiac injury in a variety of diseases.5 Objectives: Aim of this study was to analyse clinical and demographic parameters in a group of SSc patients, trying to define any possible feature associated with EKG abnormalities. Furthermore, the role of IL-33/ST2 axis components as biomarkers of cardiac injury in patients with SSc-related EKG abnormalities was evaluated, also assessing the possible correlation with serum concentration of NT-pro-BNP, a well-known cardiac injury biomarker in SSc.

Methods: Data from 277 SSc patients, fulfilling the 2013 ACR/EULAR classification criteria,6 attending our Scleroderma Clinic were retrospectively analysed. We selected patients with EKG trace and a blood sample available, collected after the SSc diagnosis. The sera levels of sST2 (ELISA Kit, Abcam), IL-33 (ELISA kit, RayBiotech) and NT-pro-BNP (ELISA Kit, Abcam) were measured. Patients with a history of heart diseases occurring before the diagnosis of SSc or features of secondary cardiac involvement (pulmonary arterial hypertension, severe interstitial lung disease or renal disease) were excluded.

Results: Forty-six SSc patients showed significant EKG abnormalities (rhythm and conduction disorders). Thirty-one SSc patients without pathologic finding at EKG traces were recruited as the control group. From the analysis of the clinical characteristic of the disease at the moment of serum collection, patients with EKG anomalies have more frequently both a diffuse form of disease (n=23; p=0.0007), and a mean value of mRSS higher than controls (11±9 vs 6±6; p=0.01), and a scleroderma “late” pattern at the nailfold capillaroscopy (n=12; p=0.0027). Significantly higher median values of serum levels of sST2 in SSc patients with EKG disorders compared to the control group (149 pg/mL, IQR 2383 vs 2560 pg/mL, IQR 1455; p=0.0002) were detected, while opposite results were found analyzing serum levels of IL-33 (2.89 pg/mL, IQR 101 vs 9 pg/mL, IQR 277; p=0.032) (Graph 1). Serum NT-pro-BNP median values were significantly higher in the group of patients with EKG abnormalities than in the control group (149 pg/mL, IQR 354 vs 26 pg/mL, IQR 62; p=0.0007). These values correlated with sST2 serum levels (rho Spearman correlation 0.37; p=0.0006).

Conclusion: SSc patients with EKG abnormalities showed an increased skin and vascular involvement with respect to the control group. These associations could help clinicians in clinically stratifying SSc patients at risk of EKG abnormalities. To our knowledge, this is the first report evaluating the serum concentration of sST2 in SSc patients. Based on these results, we can speculate on the role of this molecule as potential biomarkers of early cardiac injury during SSc, although further studies involving a larger cohort of patients are needed.

REFERENCES:
Background: Nuclear receptors (NR) are a family of transcription factors. Several members of the NR family are candidates for targeted intervention in inflammatory and fibrotic diseases (1-2). Testicular receptor 4 (TR4), also known as NR2C2, has been shown to regulate fundamental cellular processes such as differentiation, proliferation and growth factor signaling (3-4). However, its role in fibrotic diseases has not been investigated so far.

Objectives: The aim of the present study was to characterize the role of TR4 in the pathogenesis of fibrotic tissue remodeling in SSc and to interrogate its underlying mechanisms.

Methods: Expression of TR4 was quantified by RT-PCR, Western blot and immunofluorescence. The effects of TR4 knockdown on collagen production and myofibroblast differentiation were analyzed in cultured human fibroblasts and in three mouse models with fibroblast-specific knockout of TR4. RNA sequencing was performed in TGFβ-stimulated human dermal fibroblasts transfected with TR4 siRNA or non-targeting siRNA. The implication of TR4 in cytoskeleton regulation was analyzed by ROCK activity assays, stress fiber formation and quantification of the ratio of filamentous (F)-actin/globular (G)-actin. The functional role of ROCK and Gα12 was analyzed using small molecule inhibitors and siRNA, respectively.

Results: TR4 expression was upregulated in fibroblasts in the skin of SSc patients and fibrotic mouse models. The expression of TR4 was upregulated in a TGFβ/α-smooth muscle actin (α-SMA)-positive phenotype. TR4 knockdown inhibited Gα12-induced myofibroblast differentiation and collagen release, whereas overexpression of TR4 promoted fibroblast activation. Fibroblastspecific knockout of TR4 ameliorated experimental dermal fibrosis induced by bleomycin, adTBR and in scGvHD with decreases in dermal thickening, myofibroblast counts and hydroxyproline content. The RNASeq of TR4 knockdown fibroblasts stimulated with TGFβ identified 651 differentially expressed genes as compared to control fibroblasts. Differentially expressed genes included central profibrotic genes such as ACTA2, COL3A1, CCL12. gProfiler enrichment analysis of the TR4-DEGs revealed enrichment of multiple GO, GSEA and Reactome terms related to ECM release, cytoskeleton organization and Rho GTPases activity. Indeed, knockdown of TR4 ameliorated the induction of ROCK activity by TGFβ stimulation and reduced the shift in the ratio from globular (G) actin to filamentous (F). Knockdown of TR4 strongly reduced the expression of the G-protein alpha-12 (Gα12), ROCK inhibition by Y27632 or knockdown of Gα12 inhibited the induction of α-SMA and stress fiber formation induced by overexpression of TR4.

Conclusion: TR4 is upregulated in SSc in a TGFβ-dependent manner to promote fibroblast activation. Inhibition of TR4 interferes with TGFβ-induced activation of ROCK, prevents cytoskeletal remodeling and fibroblast-to-myofibroblast transition and ameliorates experimental fibrosis. As nuclear receptors are common targets for therapeutic intervention, TR4 may offer potential for antifibrotic therapies.

compound reported for this application has been sodium thiosulfate (STS), with often-contradictory results.

**Objectives:** To test the hypothesis, in pre-clinical studies, that polycarboxylic acids can induce calcium dissolution without skin toxicity, with the long-term aim of developing an effective topical treatment for cutis calcinosis.

**Methods:** We compared the metal ion-chelating agents citric acid (CA) and ethylenediaminetetraacetic acid (EDTA) - polycarboxylic acids with well-characterised chelation profiles – to STS for their ability to chelate calcium, without inducing cytotoxicity or inflammation (pro-inflammatory cytokine expression and release), using in vitro 2D (keratinocyte [HaCaT]; fibroblast [HCC23]) and recombinant human epidermal (RHE) models. The resultant data was subsequently used to predict therapeutic concentrations for assessment in a validated skin irritation model (SkinEthicTM; Episkin SA) and to assay maximal percutaneous absorption. At relative dermal concentrations, the dissolution performance of each chelator was further assessed using two different models of calcification: 1) pharmacological dissolution of a hydroxyapatite (HAp) tablet (1 and 2), and 2) dissolution of a calcified extracellular matrix laid down by mineralising SaOS2 in vitro monolayer culture (2).

**Results:** Incubation with CA, EDTA and STS induced cytotoxicity in both in vitro and in vivo cell lines studied at concentrations of >10 mM; only EDTA (10 mM) resulted in inflammatory cytokine release (IL8) from cells at these higher concentrations (of positive control, Lipo polysaccharide 10 mg/ml). When applied topically to RHE models as near-saturated solutions, none of the chelators were categorised as skin irritants. Due to differences in their relative aqueous solubility, higher concentrations of CA (1600 mM) and STS (1200 mM) could be delivered through the RHE model than EDTA (200 µM). Using a simple linear regression model, the rate of compound absorption was: CA, 0.43 ± 0.05; STS, 0.26 ± 0.03 and; EDTA, 0.05 ± 0.01 g/L/hr. At each time-point, the cumulative concentration of compound in the receptor media was CA > STS > EDTA. Incubation with chelators had no effect on the integrity of the RHE by standard histology. Based on the rate of percutaneous absorption, the dissolution performance of each chelator was tested at relative dermal concentrations for phosphate dissolution (mmoles) of HAp (CA, 9.61 ± 0.97; EDTA, 5.38 ± 0.28; 3.78 ± 0.58) and in the calcified in vitro model (Figure 1; CA, 3285 ± 105; STS, 947 ± 55; EDTA, 1714 ± 49), showing the superiority of CA in both model systems.

**Discussion:** Overall, this study highlights the promise of polycarboxylic acids, particularly CA, to target subcutaneous calcification, which are neither toxic nor inflammatory to the skin. Specifically, we have identified CA as a potentially more efficacious alternative to STS for the topical treatment of cutis calcinosis.

**STAT3 DEGRADERS PROTECT FROM IMMUNOFIBROTIC CHANGES IN PRECLINICAL MODELS**

P. Blaszczuk1,2, G. Kania1, E. Pachera1, F. Rolski4, A. Hukara1, V. Tela4, M. Mayo1, V. Dixit1, B. Yang2, J. Gollob3, N. Mainolfi4, A. Slavin1, G. Hubeau3, O. Chambaz1, University of Rhode Island, Providence, United States of America; 2. University Medical Center, University Hospital, Switzerland; 3. Jagiellonian University Medical College, Department of Clinical Immunology, Cracow, Poland; 4. KYMERA THERAPEUTICS, INC., KYMERA THERAPEUTICS, INC., Watertown, United States of America.

**Background:** The ubiquitous-proteasome system (UPS) is the endogenous intracellular mechanism for maintaining protein homeostasis through protein degradation and turnover. Heterobifunctional small molecules are a new class of compounds that form a ternary complex with an E3 ligase and protein of interest leading to ubiquitination and subsequent degradation of the protein of interest in a process known as Targeted Protein Degradation. This new therapeutic modality enables targeting of "undruggable" proteins such as STAT3, a transcription factor activated in immunobiotic diseases.

**Objectives:** Kymera has developed heterobifunctional molecules that potently and selectively target STAT3 for degradation and elimination by the ubiquitin-proteasome pathway. The aim of these studies was to evaluate the therapeutic potential of pharmacologically removing STAT3 by targeted protein degradation in human cell types in vitro, and to prevent the development of skin and lung fibrosis in vivo.

**Methods:** Dermal fibroblasts obtained from healthy and systemic sclerosis patients activated with TGF-β were studied to analyse STAT3 degradation. Human dermal and endothelial cells (HAEcs) were activated with LPS, and their adhesive properties were measured in the microcapillary system by the ability to bind peripheral blood mononuclear cells (PBMCs) under shear stress. HAEcs proliferation was induced with VEGF. THP-1 cells and CD14+ monocytes were activated with IL-6 and LPS, and secreted cytokines were assessed by CBA. PBMCs were activated with LPS, IL-6, IL-21, or IL-23 alone (pSTAT3 induction), or with a combination of anti-CD3/CD8 beads and a pro-T17 cocktail comprised of cytokines and antibodies to evaluate the development of T17 and Treg phenotype by flow cytometry. Cytokines were analysed by ELISA. All cell types were pre-treated with STAT3 degraders 20h prior to experiment start. Intratracheal instillation of bleomycin was used to induce pulmonary fibrosis. Transgenic Tsk-1 mice were used as a model of spontaneous skin fibrosis.

**Results:** STAT3 degraders completely ablated STAT3 in all analyzed cell types with DC50 ranging from 0.25-0.6 nM. STAT3 degradation prevented TGF-β-induced formation of α-SMA-positive stress fibres and for contractility using collagen gel contraction assay. Assay contracture was also performed using human dermal smooth muscle cells. HAEcs adherent cell lines studied at concentrations of >10 mM; only EDTA (10 mM)

**Conclusion:** STAT3 degraders completely ablated STAT3 in various human cell types in vitro, and to prevent the development of skin and lung fibrosis in vivo.

VITAMIN D AND ITS RECEPTOR (VDR) GENE EXPRESSION IN SKELETAL MUSCLE ASSOCIATE WITH DISEASE AND MUSCLE FUNCTION PARAMETERS IN IDIOPATHIC INFLAMMATORY MYOPATHIES

L. Veversová1, M. Vokurkova2, S. Oreska1,2, M. Štrpitovíček1,2, M. Klein1,2, T. Kropackova3, V. Horvatova1, M. Tomcik5, J. Ukopec4, B. Ukropcová1,4,5, J. Vencovsky1,4,5,1, Institute of Rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic; 1First Faculty of Medicine, Charles University, Department of Rheumatology, Praha, Czech Republic; 2Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Praha, Czech Republic; 4Biomedical Research Center, Slovak Academy of Sciences, Institute of Experimental Endocrinology, Bratislava, Slovakia (Slovak Republic); 5Faculty of Medicine, Comenius University, Institute of Pathophysiology, Bratislava, Slovakia (Slovak Republic)

Background: Idiopathic inflammatory myopathies (IIM) are chronic inflammatory disorders characterised, apart from extramuscular manifestations, by symmetrically progressive muscle weakness that may persist even after pharmacological suppression of inflammation, suggesting a significant involvement of nonimmune mechanisms. Low levels of vitamin D have been associated with autoimmune diseases. Vitamin D is essential for the maintenance of skeletal muscle, and mounting evidence supports its relation to muscle damage, regeneration, and energy metabolism.

Objectives: The aim was to analyse vitamin D and the mediators of its function in muscle tissue of IIM patients, and to associate it with muscle health parameters.

Methods: A total of 48 IIM patients (40 females, 6 males; mean age 56.7±12.4; disease duration 6.5±6.0 years; dermatomyositis (21), polymyositis (18), necrotizing myopathy (7) and 67 healthy controls (HC) (56 females, 11 males; mean age 50.9±14.7) were recruited. In total, 27 IIM patients participated in a 24-week intervention combining activities-of-daily-life, resistance and stability training [1]. Muscle biopsies from m. vastus lateralis (by Bergström needle) were obtained from 7 IIM patients before and after the 24-week training program, and from 13 control IIM patients, and 21 HC. Primary muscle cell cultures were established from these samples. Disease-associated parameters were evaluated by MYOACT/MITAX, MVI, HAS, HAQ, MMT8, FI-2 and CK, myoglobin, LD, ALT, AST, and CRP levels. Myostatin, as a myokine involved in muscle atrophy, was determined from serum samples by ELISA. Circulating concentrations of 25(OH) vitamin D (calcidiol) and active 1,25(OH) vitamin D (calcitriol) were measured by routine biochemical techniques. Gene expression of vitamin D receptor (VDR) and 25-hydroxyvitamin D 1-alpha-hydroxylase (CYP27B1), an enzyme catalysing calcidiol conversion to hormonally active calcitriol, was determined by real-time PCR in muscle tissue and primary muscle cell cultures. Data are presented as mean ± standard deviation.

Results: Decreased serum levels of active 1,25(OH)D were observed in IIM patients compared to HC (125.0±54.4 vs. 164.7±42 pmol/l; p<0.0001). No difference was found for 25(OH)D. The 24-week training program did not have an effect on 25(OH) D or 1,25(OH)D serum levels. 25(OH)D was significantly associated with CRP (r=-0.32, p=0.040), MITAX (r=-0.380, p=0.021) and HAQ (r=0.370, p=0.017) in IIM patients, even after correction for BMI, gliocorticoid (GC) and vitamin D daily supplementation dose. After 24 weeks of exercise, active 1,25(OH)D was positively associated with MMT8 (r=0.866, p=0.0001), FI2 (r=0.608, p=0.013) and HAQ (r=-0.537, p=0.032) (corrected for BMI, GC and vit.D supplementation). Numerically higher gene expression of VDR and CYP27B1 was found in muscle tissue and primary muscle cells in IIM compared to HC. After the 24-week training, gene expression of both VDR and CYP27B1 in primary muscle cells decreased (p=0.031 and p=0.078, respectively). Associations of gene expression with myostatin (IIM: r=0.519, p=0.023; HC: r=0.586, p=0.005), and CK (HC: r=0.484, p=0.031) were observed in muscle tissue. CYP27B1 gene expression in the muscle was also associated with myoglobin (HC: r=0.501, p=0.024), MMT8 (IIM: r=0.535, p=0.011) and VDR (IIM: r=0.581, p=0.012; HC: r=0.632, p=0.002).

Conclusion: Decrease of the biologically active form of vitamin D in circulation suggests a negative impact of its metabolism in IIM. Vitamin D serum levels associated with disease activity and muscle function parameters indicating an important role of vitamin D in physical fitness and disease manifestations in IIM patients.

LONG NON-CODING RNA H19X IS A MEDIATOR OF ENDOTHELIAL CELL ACTIVATION IN SYSTEMIC SCLEROSIS

F. Tirelli1,2, E. Pachera1, R. Layfatis3, M. Huang4, S. Assassi4, E. Camarillo1, F. Zulian1, G. Kania1, O. Distler1
1University of Zurich, University Hospital Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland; 2University of Padova, Department of Woman’s and Child’s Health, Rheumatology and Biotechnology, Padova, Italy; 3Department of Medicine, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America; 4University of Texas Health Science Center at Houston, McGovern Medical School, Department of Internal Medicine, Division of Rheumatology, Houston, United States of America.

Background: In one of our previous studies, we demonstrated that long non-coding RNA (IncRNA) H19X plays a crucial role in the development of TGFβ driven fibrosis in systemic sclerosis (SSc) and other fibrotic diseases.

Objectives: To define the functional relevance of H19X in endothelial cell (EC) activation as a decisive process in SSc vasculopathy.

Methods: Correlation H19X expression and microvascular gene signature was computed on bulk RNA-Seq data derived from SSc skin biopsies of patients enrolled in the multicentre Prospective Registry of Early Systemic Sclerosis cohort (PRESS, n=48 SSc vs. n=33 healthy controls, HCs). Single cell RNA sequencing (scRNA-seq) data were collected from 27 diffuse cutaneous SSc (dcSSc) and 10 HC skin biopsies. Single cells were barcoded and encapsulated in droplets using a 10X Genomics system. After CDNA synthesis, the libraries were prepared and sequenced using Illumina NovaSeq-500 platform. Seurat package in R (v.3.0) was used to perform data analysis. EC were identified by enrichment of EC markers CLDN5, VWF and PECAM1. One thousand five hundred eighty-three and 3398 EC were identified from HC and SSc patients, respectively. Cells were analysed for the expression of H19X and EC activation markers. Additionally, differential expression and pathway enrichment analysis between H19X expressing cells and H19X negative cells was carried out. The function of H19X was investigated in human dermal microvascular EC (HDMEC) by silencing, using locked nucleic acid antisense oligonucleotides (LNA GapMeRs). Gene expression was measured by qPCR. Protein levels of endothelial adhesion molecules were analysed by Western Blot. Endothelial adhesion was evaluated by co-culture of HDMEC and fluorescently labelled peripheral blood mononuclear cells (PBMCs).

Results: H19X expression was found significantly upregulated in SSc skin biopsies of the PRESS cohort (p<0.0001). The expression of H19X positively correlated with the microvascular endothelial cell gene signature in all subjects (SSc and HC, R=0.43, p<0.0001), confirming that H19X is expressed in this cell type. To determine if H19X might be an important factor in SSc EC dysfunction, scRNAseq was performed. This analysis revealed a significant upregulation of H19X in SSc EC as compared to HC EC (p=0.0095). H19X was found to be upregulated in several EC subclusters including arterial (SEMA3G, HEY1), capillary (CA4, RGCC), venous (ACKR1, Vcam1) and lymphatic (PROX1, LYVE1). H19X displayed highest expression in injured SSc EC and capillary SSc EC. Co-expression analysis of the scRNA-seq data revealed higher expression of several adhesion molecules in EC expressing H19X including, VCAM1, ICAM and JAM3. KEGG pathway analysis revealed that differentially expressed genes in H19X expressing cells were highly associated with the ‘Cell adhesion molecule’ pathway (p=2.20e-7). H19X silencing lead to a significant downregulation of mRNA levels of genes encoding adhesion molecules VCAM1 (n=7, p<0.05) and E-selectin (n=7, p<0.01) at 48h after transfection, VCAM1, but not E-Selectin, was also reduced at protein level as revealed by Western Blot (n=3). The functional relevance of H19X on endothelial adhesion was confirmed by PBMCs with H19X silenced HDMEC where we were able to demonstrate a significant decrease in leucocyte-to-endothelial cell adhesion (n=5, p<0.05).

Conclusion: Our results show that IncRNA H19X could contribute to EC activation in SSc vasculopathy, acting as a regulator of expression of adhesion molecules.

THE EFFECT OF VITAMIN D3 AND α-TOCOPHEROL ACETATE IN THE PRECLINICAL MODEL OF SYSTEMIC SCLEROSIS

B. Doskailuk1, L. Zaiats2, R. Yatsyshyn3, Ivano-Frankivsk National Medical University, Pathophysiology; Ivano-Frankivsk, Ukraine; 1Ivano-Frankivsk National Medical University, Internal medicine #1 clinical immunology and allergology, Ivano-Frankivsk, Ukraine.

Background: The pathogenesis of systemic sclerosis (SSc) is characterized by complex damage of an organism due to the development of mechanisms of autoimmunity. Dysregulation of immune system, development of fibrosis, and vasculopathy play a significant role in this process.

Objectives: This study aimed to investigate the effect of antioxidant α-tocopherol acetate and immunomodulator vitamin D 3 in the preclinical model of SSc.

Methods: To perform this study, three groups of laboratory animals were formed: a control group (20 animals), an experimental group #1 (25 animals) and an experimental group #2 (25 animals). Experimental animals were mature laboratory rats of the Wistar line weighing 180-220 g. Modeling of SSc was performed in the experimental group #1 using sodium hyPOCHORONE (NaClO) according reported previously method [1]. Laboratory animals of the control group were injected with the isotonic solution according to the same scheme. In the experimental group #2, in addition to NaClO, laboratory rats received a solution of α-tocopherol acetate 10 mg / 100 g of body weight IV and a solution of vitamin D3 1000 UI / 100 g of body weight, IV for 3 weeks (second half of the experiment). The level of surfactant protein D (Elabscience SP-D ELISA-Kit), the vascular cell adhesion molecule (Elabscience VCAM-1 ELISA-Kit), and interleukin 13 (Elabscience IL-13 ELISA-Kit) was determined by enzyme-linked immunosorbent assay. ELISA was performed on an enzyme-linked immunosorbent assay STAT FAX 303 plus. Data distribution was evaluated with the Shapiro-Wilk test. Mann-Whitney U test and unpaired t test were used for comparisons between groups, a p-value <0.05 was considered statistically significant.

Results: The level of IL-13 (pg/ml) in the experimental group was higher than in the control (36.4, 56.23 vs 9.43, 4.01 (p<0.001). The serum concentration of SP-D (pg/ml) among the experimental group of laboratory animals was significantly higher compared to the control subjects 490,20 [228,75–568,73] vs 70,13±33,21, (p=0.05), VCAM-1 (pg/ml) was also higher in the experimental group VCAM-1 91.25 [85,63–143,75] vs 173,5±7,47, (p<0.05). The administration of vitamin D3 and α-tocopherol acetate has shown a positive effect for all three investigated parameters. We have found a statistical difference between the two experimental groups regarding IL-13, SP-D, and VCAM-1. The SP-D level in the experimental group #2 was 124.93 ± 18.96, which was significantly lower than in the experimental group #1 (p=0.04). The concentration of IL-13 and VCAM were also lower in the group of vitamins D3 and α-tocopherol acetate administration (22.88±5.11, p<0.001 and 38.73±12.13, p=0.02 respectively).

Conclusion: This study provided evidence that administration of vitamins D3 and α-tocopherol acetate, given in combination, has a beneficial effect on IL-13, SP-D, and VCAM-1 levels in the organism of the experimental animals.

LUNG ORGANOIDS: A NOVEL APPROACH TO STUDY THE MOLECULAR PATHOLOGY OF PULMONARY FIBROSIS IN SYSTEMIC SCLEROSIS

M. Aspar1, S. R. Greisen1,2, K. Soendergaard2, M. N. Dahl1,2, M. Hvid2, V. Ong3, D. Abraham3, B. Deleuran1 on behalf of Bent Deleuran's group.
1Aarhus University, Biomedicine, Aarhus, Denmark; 2Aarhus University Hospital, Rheumatology, Aarhus, Denmark; 3University College London, Division of Medicine, London, United Kingdom

Background: Pulmonary fibrosis is one of the major manifestations in Systemic Sclerosis (SSc) associated with high mortality. Mesenchymal transformation of the airway epithelial cells has been implicated as one of the causes for
developing pulmonary fibrosis. Though several animal models shed light towards some of these aspects, an in vitro airway epithelial model would provide a novel experimental platform for the understanding and molecular and genetic changes that occur in SSc associated pulmonary fibrosis.

Objectives: To establish a functional model for airway epithelium from patient with diffuse cutaneous SSc (dSSc) and healthy volunteers derived nasal stem cells. Subsequently to induce Epithelial Mesenchymal transformation (EMT). 

Methods: Nasal stem cells harvested from healthy volunteers (HV) and dSSc patients were differentiated into ciliated airway epithelium in an Air-Liquid Interface (ALI) using a transwell system. 4 HV cultures were then stimulated with TGF beta for 10 days at a basal stage and when differentiated. Markers of mesenchymal transformation including loss of E cadherin, and gain of N cadherin, fibronectin and vimentin were analysed by flow cytometry and image stream, and mean expression intensities given as (MFI). Secreted Type 1 collagen and fibronectin were measured by ELISA.

Results: Ciliated epithelial cultures could successfully be established from nasal stem cells (Figure 1). TGF beta induced a phenotypic change in the epithelial cells towards a mesenchymal one in HV cultures. This was observed by significantly increased expression of fibronectin and vimentin and loss of expression of E cadherin on the ciliated cells with 7 days of stimulation with TGF beta at a basal stage (Figure 1b). When cells, stimulated with TGF beta for 7 days, were analysed at Day 35 a similar trend was seen in their Delta MFI (Figure 1c). Stimulating the ALI cultures with TGF beta for 20 days completely repressed epithelial cell growth and disrupted their microstructure.

Conclusion: This novel ALI differentiated Airway epithelial model serves as a functional organoid to test various pulmonary manifestations of Systemic Sclerosis. The ability to induce Epithelial Mesenchymal Transformation of these cultures provides a proof of concept for TGF beta mediated fibrosis in dSSc. Moreover, this model can be utilized to explore, at the cell and molecular level, the impact of various autoantibodies and therapeutics on epithelial cells.

FIBROBLASTS UNDER IMMUNOFIBROTIC CONDITIONS

I. Kocherova1, E. Pachera, D. Nurznyska2, F. Di Meglio2, O. Distler2, P. Blyszczuk1, G. Kania3
1 University of Zurich, University Hospital Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland; 2 University of Naples “Federico II”, Department of Public Health, Naples, Italy

Background: Inflammatory dilated cardiomyopathy (iDCM) often leads to heart failure (HF), which is the main cause of mortality in patients with systemic diseases. Fibroblast activation, driven by the activator protein 1 family member Fos-related antigen 2 (FOSL2), represents a critical step in cardiac fibrogenesis. The existing antibiotic therapies, based on known fibrotic markers, failed to demonstrate efficacy against myocardial fibrosis.

Objectives: To identify new candidate targets implicated in cardiac fibrogenesis under immunofibrotic conditions.

Methods: Cardiac fibroblasts were isolated from the left atria of patients (n=5) undergoing heart transplantation due to HF associated with iDCM and from unaffected hearts of brain-dead donors (UDs, n=5). Protein identification and quantification was performed using liquid chromatography tandem-mass-spectrometry (LC–MS/MS). The data were analysed with MaxQuant v1.6.2.3 software. Bulk RNA sequencing (RNA-seq) was conducted using the Illumina HiSeq platform. Differentially expressed genes were identified using DESeq2. Additionally, we analysed publicly available single-cell (sc) RNA sequencing datasets (GSE109816, GSE121893) [1] on adult hearts from HF patients (n=6) and UDs (n=14) using Seurat package (V2.3.4). Specific gene knockdown was achieved by siRNA transfection of human foetal cardiac fibroblasts (HCFs, Sigma), untransfected HCFs stimulated with TGF-β (p<0.05) for 48-72h. The profibrotic marker expression levels were decreased in TGF-β-stimulated (n=4) and untreated (n=4): p<0.01) and TGF-β stimulated (p<0.01) but downregulated FOXL2 (p<0.05) and MXRA5 (p<0.01) in untreated HCFs, and also upregulated FOXL2 (p<0.05) and MXRA5 (p<0.01) in untreated HCFs and 72h after TGF-β stimulation (n=3, p<0.05).

Results: The LC–MS/MS analysis revealed 14 differentially expressed proteins (absolute log2FC>1, adj. p<0.05) in the HF group compared to UDs. The most upregulated protein in HF fibroblasts was dysferlin (DYSF, log2FC=5.78, adj. p<0.004), which is known to play a role in the sarcolemma repair of both skeletal muscle fibres and cardiomyocytes. Bulk RNA-seq analysis identified a total of 67 significantly differentially expressed genes (absolute log2FC>1, adj. p<0.05). The comparative analysis of bulk RNA-seq results and publicly available scRNA-seq datasets revealed two commonly upregulated genes in HF fibroblasts or their subclusters, encoding transcription factor FOXL2 (log2FC=3.51, adj. p<0.05) and matrix remodelling-associated protein MXRA5 (log2FC=2.91, adj. p<0.05). Further in vitro studies on HCFs (n=4) showed that TGF-β upregulated DYSF (p<0.001) and MXRA5 (p<0.01) but downregulated FOXL2 (p<0.05). Dysferlin silencing in HCFs (n=4) upregulated MXRA5 after 48h of TGF-β stimulation (p<0.05), downregulated ACTA2 (48h and 72h of TGF-β stimulation, p<0.05), and upregulated FOXL2 protein levels in untreated HCFs and 72h after TGF-β stimulation (n=3, p<0.05). MXRA5 knockdown (n=8) resulted in the upregulation of DYSF (p<0.05), ACTA2 (p<0.05) and COL1A1 (p<0.001) in untreated HCFs, and also upregulated DYSF (p<0.01) and COL1A1 (p<0.05) after 48h of TGF-β stimulation. FOXL2 silencing in HCFs (n=8) followed by 48h of TGF-β-stimulation downregulated MXRA5 (p<0.01) and ACTA2 (p<0.06), and upregulated DYSF (p<0.001) and COL1A1 (p<0.05). Candidate targets knockdown reduced cell viability in untreated (n=4, DYSF: p<0.01, MXRA5: p<0.001, FOXL2: p<0.01) and TGF-β-stimulated (n=4, DYSF: p<0.05, MXRA5: p<0.05, FOXL2: p<0.01) HCFs. ATP levels were decreased in TGF-β-stimulated HCFs after DYSF silencing (n=6, p<0.05).

Conclusion: Based on transcriptomics, proteomics and in vitro analysis of human cardiac fibroblasts, we identified DYSF, MXRA5 and FOXL2 as candidate targets implicated in profibrotic phenotype development, including profibrotic transcription factor FOXL2 regulation. These newly proposed candidates may serve as potential therapeutic targets for the treatment of cardiac fibrosis.

System. Clinical features of the disease consist of skin thickening and internal organ involvement. Due to the heterogeneous nature of the disease, there is an unmet need of biomarkers for diagnosis, disease progression and response to treatment.

Objectives: The aim of this study was to explore new serum proteomic fingerprints of clinically defined forms of SSC.

Methods: Highly specific detection of nighty two proteins from a panel related to organ damage was performed, by using the breakthrough technology proximity extension immunoassay (PEA, Olink), in the serum of 72 patients with SSC and 18 age-matched healthy donors (HD). Main disease complications in the SSC cohort, including lung fibrosis, skin fibrosis, renal, vascular, and esophageal involvement were assessed, and prevalence of circulating autoantibodies was tested, along with standard demographic and inflammatory parameters. Unsupervised hierarchical clustering methodologies were applied to identify subgroups of patients based on their proteomic profiles. Gene ontology enrichment was used to investigate the biological meaning of the distinctive molecular signatures identified.

Results: Sixteen circulating proteins related to organ damage were coordinate- nately altered in the serum of SSC patients in relation to HD. Unsupervised clustering analyses differentiated 3 patients clusters presenting different proteomic profiles. Clinically, patients belonging to cluster 1 were characterized by a significant prevalence of multiple organ involvement (84%) in relation to clusters 2 (52%) and 3 (43%), mostly encompassing lung and skin fibrosis and esophageal dysmotility. Immunologically, cluster 1 further displayed the highest percentage of positivity for anti-scl70 antibodies. Nineteen serum proteins, not previously reported in the serum of SSC patients (BANK1, BID, CALR, ERBB2IP, FGR, FOXP1, INPPL1, MAAE, MAGED1, MAP4K5, NBN, NCF2, PRKAB1, RASSF2, ROR1, SMAD1, STXBP3, VASH1) were found deregulated between clusters, with a significant increase in the levels of all of them in cluster 1 compared with clusters 2 and 3. These deregulated pro- teins were mostly involved in biological processes such as cell proliferation, apoptosis, cell adhesion, migration, and immune response. Among them, two were functionally linked with cutaneous diseases [Cattelucin (CALR) and B-cell scaffold protein with ankryin repeats (BANK1)], two with digestive disorders [Tyrosine-protein kinase Fgr (FGR) and syntaxin-binding protein 3 (STXB P3)] and three with lung dysfunction [protein FosB (FOXP1), mothers against decapentaplegic homolog 1 (SMAD1) and forkhead box protein O1 (FOXP1)]. Interestingly, levels of some overexpressed proteins in C1 [B3H-interacting domain death agonist (BID), phosphatidylinositol 3,4,5-triphosphate 3-phosphatase 2 (INPPL1), Erbin (ERBB2IP), BANK1 and FOXP1] were further related to the positivity for anti-scl70, the specific SSC-autoantibody known to be mostly associated to a bad prognosis and multiple organ involve- ment in SSC patients.

Conclusion: 1) Stratification based on serum proteomic profile could be of use for a better clinical classification of SSC patients, adding new insights to the underlying pathophysiological mechanisms. 2) Combination of disease classifying autoantibodies with principal pathophysi- ological processes and serum proteomic profiles can help to elucidate and strengthen the diagnosis as well as the prognosis in SSC.

POS0489 CCL24 SERUM CONCENTRATION CORRELATES WITH DISEASE ACTIVITY AND WORSE PROGNOSIS IN DIFFUSE CUTANEOUS SSC: A PROMISING BIOLOGICAL TARGET TO PREVENT DISEASE PROGRESSION

M. Segal Salto1, A. Mor2, F. Del Gaido3, Chemomab Therapeutics Ltd., R&D, Tel-Aviv, Israel; 1University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: Linking novel therapeutic targets for diffuse cutaneous Systemic Sclerosis (dcSSc) to markers of disease severity and clinical outcome will enable directing of specific and right therapeutic agents to the appropriate patient populations. Such correlation will also support patient stratification in clinical trials increasing their informative value and success rates. CCL24 is a chemokine within the Eotaxin family, that has been shown to have a dual pro-inflammatory and pro-fibrotic role in SSC. CCL24 and its receptor, CCR3, were found to be over-expressed in SSC skin and serum samples. In-vivo CCL24 blockade was associated with reduction of bleomycin induced skin and lung injury.

Objectives: We aimed to study the role of CCL24 in dcSSc using patient cohorts, by correlating its serum levels to disease activity markers and disease progression.

Methods: Retrospective and longitudinal dSSc patients' cohorts were ana- lyzed for CCL24 circulating levels, clinical measurement and disease related biomarkers.

Results: In a retrospective cohort of 56 dcSSc patients, CCL24 serum lev- els were significantly higher in patients that had positive anti topoisomerase antibody (ATA) compared to patients with negative ATA. In addition, within the ATA positive patients, ones that had high serum CCL24 levels (>1500 pg/ ml) also presented significantly higher fibrotic activity reflected by a higher enhanced liver fibrosis (ELF) score compared to ATA positive patients with low CCL24 (<1500 pg/ml). In a second longitudinal cohort of 66 patient, base- line CCL24 levels positively correlated with ELF score (r=0.42, p≤0.0005).

Patients with high baseline CCL24 serum levels were also more likely to experience lung disease progression, measured by reduction in forced vital capacity (FVC) during 12 months (7 out of 17 patients with CCL24 ≥ 1500 pg/ml had at least -5% reduction of FVC). Consistent with these data, patients with normal FVC at baseline (>80% predicted) who experienced worsening in the next 12 months (at least 7%) had a statistically significant higher baseline serum CCL24 (Average 2.275 pg/ml) compared to patients that had no worsening in FVC over time (average 962 pg/ml, p<0.001).

Interestingly, the same group showed an even steeper reduction in DLCO % predicted (-6.8% vs -0.2%, p<0.05).

Conclusion: We show here using two dcSSc patient cohorts, that CCL24 serum levels are correlated with disease activity and worse prognosis reflected by high fibrotic activity and deterioration of lung function over time. This reverse transla- tional study supports the role of CCL24 as a therapeutic target for dcSSc and it has informed a phase 2 study testing CM-101, a CCL24 neutralizing antibody, in dcSSc patients to be started in 2022.

POS0490 USEFULNESS OF MHC-II IMMUNO-STAINING ON MUSCLE BIOSPIES IN IDIOPATHIC INFLAMMATORY MYOPATHIES

M. Robert1, L. Lessard2, F. Fenouill3, A. Hot4, T. Laumonier3, A. Bouche5, B. Chazaud6, N. Streichenberger7, L. Gally7, 1Pierre Wertheimer Hospital, Service d’Electroneuromyographie et de pathologies neuromusculaires, Lyon, France; 2Pierre Wertheimer Hospital, Service d’Electroneuromyographie et de pathologies neuromusculaires, Lyon, France; 3Institute NeuroMyoGène, Unité Physiopathologie et Génétique du Neurone et du Muscle, UMR 5261 CNRS, U1315 Insem, Université Claude Bernard Lyon 1, Lyon, France; 4Institut NeuroMyoGène, Unité Physiopathologie et Génétique du Neurone et du Muscle, UMR 5261 CNRS, U1315 Insem, Université Claude Bernard Lyon 1, Lyon, France; 5Cancer Research Center of Lyon, UMR Insem 1052 CNRS 5286, Equipe « Fibrosome Tractation and Cancer », Lyon, France; 6Institut Hospital Is - Hôpitaux Universitaires de Lyon, Service d’Electromyographie et Musculation, Lyon, France; 7Hopitaux Universitaires de Genève (HUG), Laboratoire « Cell Therapy & Musculoskeletal Disorders », Département de Chirurgie Orthopédique, Genève, Switzerland

Background: Idiopathic inflammatory myopathies (IIMs) constitute a group of acquired muscular diseases that occur during childhood and adulthood, exhibit a variety of phenotypes and are potentially life-threatening. IIM diagnosis consid- ers clinical, serological, and histological data. Muscle pathological analysis of IIM patients gives relevant elements for the diagnosis (immune cell infiltrate, vascu- lar and connective tissues, as well as myofiber morphology). Immunohistochemistry (IHC) labeling for major histocompatibility complex class I (MHC-I), and C5b9, that are negative in normal muscle, appeared of interest in IIM diagnosis and the understanding of IIM pathogenesis. In normal muscle, myofibers are negative for MHC-II IHC. Its interest in the neuropathological exam of IIM muscle remains to be better characterized.

Objectives: This study aims to analyze the pattern of MHC-II expression in various IIMs.

Methods: A historical cohort was designed using the MYOLYON register (IIM patients diagnosed between 2016 and 2020 at the University Hospital of Lyon, France). Inclusion criteria were IIM diagnosis that was established histologically and available frozen muscle samples for additional analyses. Exclusion criterion was any treatment before muscle biopsy. Demographical data and final diagnosis were recorded using retrospective and historical records. A centralized, standardized, and blind analysis of muscle MHC-II immuno-staining was conducted to define the various patterns of MHC-II by myofibers and by capillaries. The study complied with ethical requirements.

Results: Seventy-three patients were included: 23 dermatomyositis (DM), 13 anti-synthetase syndrome (ASS), 13 immune-mediated necrotizing myopathies (IMM), 13 inclusion body myositis (IBM), and 11 overlap myositis (OM). MHC-II immuno-staining of myofibers or capillaries was abnormal for 91.8% of the ana- lyzed biopsies (Figure 1). The analysis of MHC-II myofiber immuno-staining
revealed distinguishable patterns according to IIM subtype: the labeling was diffuse in IBM (69.2%, n=8/13), perivascular in ASS (61.5%, n=8/13), and variable in OM (patchy for 27.3% n=3/11 or clustered for 36.4%, n=4/11). MHC-II immunostaining was negative in IMNM (94.6%, n=11/13) and in DM (47.8%, n=11/23). DM exhibiting positive MHC-II myofibers (n=12) were associated with the presence of anti-TIF1γ, anti-NXP2 and anti-SAE auto antibodies (n=5, n=3 and n=2, respectively). Among the 12 patients, there were juvenile cases (n=5, 41.7%) or DM associated with ongoing neoplasia (n=4, 33.3%). Three main architectures were described for capillaries: giant, leaky and capillary dropout. Patterns of MHC-II positive capillaries were the following: DM was characterized by capillary dropout (68.2%), IMM showed leaky capillaries (75.0%), IBM giant capillaries (66.7%), ASS exhibited both giant (61.5%) and/or leaky (58.3%) capillaries, while OM showed giant (63.6%) or/and leaky (80.0%) capillaries and capillaries dropout (60.0%).

Conclusion: The present work establishes the usefulness of MHC-II immunostaining for IIM diagnosis, and gives additional elements on the impairment of myofibers and capillaries in the various IIM subgroups. MHC-II expression is known to be induced by inflammatory cytokine such as interferon type II. This could be linked to myofiber and/or capillary impairment in some IIMs, such as IBM, ASS and OM. These results also support the implication of vasculopathy in IIM pathogenesis, with various structural and cellular consequences regarding the different subgroups. Finally, MHC-II immuno-staining in IIM muscle biopsies enables a foremost analysis of myofibers and capillaries, and represents an additional biomarker to distinguish IIM subgroups.

REFERENCES:
intracellular metabolomics, chromatim immunoprecipitation PCR, ATAC and RNA sequencing, and cytokine production assays. Arteries from GCA patients were evaluated with immunohistochemistry (IHC) to assess immunometabolic activation. Pharmacologic inhibition of immunometabolic changes underlying TI (ie, glycolysis) was evaluated ex vivo as a therapeutic strategy to suppress cytokine production.

Results: GCA monocytes exhibited hallmark molecular features of TI. Specifically, these included typical immunometabolic changes (eg, increased glycolysis and glutaminolysis through the TCA cycle), epigenetic changes promoting transcription of genes governing pro-inflammatory activation and enhanced IL-6 production upon inflammatory challenge. IHC revealed that GCA lesions are highly glycolytic microenvironments, and pharmacologic inhibition of glycolysis with 2-deoxy-glucose effectively dampened IL-6 production. 

Conclusion: This study reveals the deleterious potential of maladaptive TI in the pathogenesis of GCA, and the therapeutic potential of inhibiting TI for the treatment of this condition.

POS0493

1H-NMR BASED METABOLIC PROFILE OF PATIENTS WITH GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA IN ACTIVE AND INACTIVE DISEASE STATE

O. Argyropoulou1, M. Karagiannakou, D. Palmadidas, B. Benaki, K. Tsezou, P. Vlachosianopoulos, E. Mikos, A. Tzivoglou, 1School of Medicine, National and Kapodistrian University of Athens, Greece; 2School of Pharmacy, National and Kapodistrian University of Athens, Department of Pharmaceutical Chemistry, Athens, Greece; 3University Hospital, Internal Medicine and Clinical Immunology department, Dijon-Bourgogne University Hospital, Dijon, France.

Background: Giant cell arteritis (GCA) is the most common form of systemic vasculitis in the elderly. The disease is characterized by a remarkable heterogeneity in terms of clinical picture, histologic pattern of the affected vessels, pathogenetic mechanisms and treatment selection strategies. Approximately half of GCA patients present with polymyalgia rheumatica (PMR), while 20% of PMR patients will develop GCA during follow-up. Organ or life-threatening complications of GCA, include vision loss, strokes, aneurysm formation and accelerated atherosclerosis. The clinical heterogeneity along with the increased relapse rate, even under treatment and the fact that ESR and C-Reactive Protein are the only laboratory tools for the assessment of active disease suggest that the definition of new biomarkers with diagnostic, prognostic and predictive value is an unmet need (1). Among the high throughput approaches towards this direction, 1H NMR spectra of serum samples provides a direct, untargeted, and holistic metabolic profile offering a wealth of information that could be proved useful to discover outcome tools for the management of the disease (2).

Objectives: 1. To characterize and compare the metabolic profile of GCA/PMR serum samples, as captured in 1H NMR spectra, in 3-time points: diagnosis, 1 and 6 months of treatment with steroids (remission). 2. Evaluate whether 1H NMR-based metabolic profile from patients with GCA/PMR associate with response to treatment and 3. Identify potential discriminatory serum metabolic profiles correlating with disease activity.

Methods: One-hundred and ten serum samples from 50 consecutive patients (33-GCA and 17-PMR) were evaluated in the study. GCA serum samples consisted of 33 naive, 22 in 1 and 21 after 6 months of treatment (25 females, mean age 73.0 ± 6.1 years and 8 males, mean age 69.5 ± 4.9 years), while PMR of 15 naive, 10 in 1st and 8 respectively (9 females, mean age 65.0 ± 5.3 years and 8 males, mean age 77.0 ± 6.6 years). The serum metabolic profiles of patients were obtained at a 600 MHz NMR spectrometer and analysed by means of univariate and multivariate statistical methods.

Results: Multivariate analysis showed metabolic differences between GCA/PMR patients in activity and in remission using unsupervised principal component analysis (PCA: R2X= 0.698, Q2= 0.501) and supervised partial least squares discriminant analysis (PLS-DA: R2X= 0.596, Q2= 0.219) (Figure 1). In accordance with univariate analysis (p<0.05), the following discriminatory metabolites were identified: N-acetyl glycoproteins, 3-hydroxybutyric acid and phenylalanine were increased in inflammation, while choline, lipoproteins, and lipids were decreased in these patients.

Figure 1. (A) PLS-DA scores plot and (B) S-plot from OPLS-DA of 1H NMR profiling of GCA/PMR serum samples before treatment (green dots) and after 1 (red dots) and 6 months (black dots) of treatment. Characteristic metabolites in inflammation and remission are annotated and the corresponding p-values are given. PLS-DA: partial least square discriminant analysis, OPLS-DA: orthogonal partial least squares discriminant analysis.

Conclusion: 1H NMR-based serum metabolomics revealed a clear discrimination of GCA/PMR metabolic profiles before (active inflammation) and after treatment with steroids (remission), suggesting that the metabolic analysis may serve as a useful tool to identify potential biomarkers related to disease activity in both GCA and PMR, as well as give further insights into pathogenetic mechanisms mediating the inflammatory response. Further validation studies to dissect the clinical value of specific metabolites are ongoing in our laboratory.

ARTERIAL WALL DENDRITIC CELLS IN GIANT CELL ARTERITIS (GCA) AND POLYMYALGIA RHEUMATICA (PMR)

A. Ramon1,2, H. Greiger3,4, C. Cladière2, M. Ciudad2, P. Orrentí1, A. Bonnottete3, M. Samso3,2,3,4,5 Dijon University Hospital, Rheumatology, Dijon, France; 2Bourgogne Franche-Comté University, INSERM, EFS BFC, UMR 1098, RIGHT Graft-Host-Tumor Interactions/Cellular and Genetic Engineering, Dijon, France; 3Dijon University Hospital, Internal Medicine and Clinical Immunology department, Dijon-Bourgogne University Hospital, Dijon, France; 4Dijon University Hospital, Vascular Medicine department, Dijon-Bourgogne University Hospital, Dijon, France

Background: Polymyalgia rheumatica (PMR) is an inflammatory rheumatic disease (1) associated in 16 to 21% of cases with giant cell arteritis (GCA). The association of these two conditions raises the question of a pathophysiological continuum between PMR and GCA. An early study reported mature arterial wall dendritic cells (DC) in patients with GCA or PMR leading, during GCA, to CD4+ T cell recruitment and the development of vasculitis (2). However, these data have never been confirmed in other studies. There are 3 main types of DC: plasmacytoid DC (expressing CD123), conventional DC (cDC) expressing CD141 (cDC1) or CD1c (cDC2) and monocyte-derived DC (moDC) expressing CD14. The aim of this study was to describe the arterial wall infiltrating DCs, their phenotype and maturation state, during PMR and GCA.

Methods: Using temporal artery biopsies (TAB) from patients with PMR, GCA and healthy controls, the level of expression of CD1, CD123, CCR7, CCR3, CCR4, CCR6, CCL18, CCL19, CCL20, CCL21, GM-CSF, CD8, CD68 and the percentage of CD83, CCR7, CCR6, CCL18, CCL19, CCL20, CD11c, GM-CSF, CD3 and CD68 gene expression was assessed by RT-PCR. Expression of markers of DC lineage (CD1c, CD14, CD1a, CD1b) and the expression of the maturation marker CD83 from the arterial wall were assessed. The level of expression of CCR3 and CCR7 from the arterial wall and also expressed CD14 and often CD68 but neither CD1c nor CD141, which could be explained by a monocytic/macrophage origin. TAB from GCA patients were characterized by a high level of expression of CCR3, CCR2 CCR6, CCL18, CCL19, CCL20, CD11c, GM-CSF, CD3 and CD68 gene. This expression was significantly higher (p<0.05) compared to the control and PMR groups. Confocal microscopy analyses of arteries from the PMR and controls did not detect the presence of DCs into the arterial wall. In addition, level of
expression of CD83, CCR7, CCL18, CCL19, CCL21 and CD68 genes in temporal arteries was comparable between PMR and healthy controls.

**Conclusion:** This work confirms the presence of mature CD209+CD83+CCR7+ DCs within the arterial wall in GCA. The phenotype of these DCs mainly fits with DC of monocytic origin (mo-DCs). However, both by RT-PCR and confocal microscopy, we did not identify DCs in the arterial wall of PMR patients. This discrepancy with previous work (3) could be explained by a better diagnosis of GCA in PMR patients since the development of imaging techniques.

A STUDY ON THE IMMUNOREGULATORY ROLE OF THE PD1 PATHWAY IN JUVENILE IDIOPATHIC ARTHRITIS - PRELIMINARY RESULTS

A. Koutsonikoli, A. Taparkou, P. Pratsidou-Gertsi, V. Spourolopoulou, M. Trachana
Aristotle University of Thessaloniki, Pediatric Immunology and Rheumatology Reference Centre, 1st Pediatric Dept, Hippokratieio General Hospital, Thessaloniki, Greece

Background: The programmed cell Death protein-1 (PD1) pathway promotes self-tolerance, by inhibiting immune responses. The PD1 soluble form (sPD1), by antagonizing the binding of the membrane-bound PD1 with its ligands, may lead to the blocking of the pathway’s functions. Data regarding the role of the PD1 pathway in Juvenile Idiopathic Arthritis (JIA) are still limited.

Objectives: To investigate the immunoregulatory role of the PD1 pathway in JIA patients.

Methods: JIA patients and healthy controls participated in this study with peripheral blood (PB) and/or synovial fluid (SF) samples. sPD1 levels in serum and SF were determined by ELISA. The PD1 expression on T-helper (CD4+) and T-cytotoxic (CD8+) cells in PB and SF was analyzed by flow cytometry. A search for any association between the above biomarkers, as well as their relation with JIA activity was then performed. Inactive disease was defined according to Wallace criteria.

Results: 77 Caucasian patients (52 female) participated so far in this study, with a median (range) age of 13 (2-19) years; their JIA subtypes were: oligoarticular (33%), polyarticular (26%), psoriatic (12%), enthesitis-related (16%), systemic (10%) and undifferentiated (3%). Ten healthy children served as controls. As compared to controls, a subpopulation of these JIA patients (n=46) had a significantly higher median percentage of PD1+CD4+ (1.15 vs. 0.32%, p=0.029) and PD1+CD8 T cells (1.34 vs. 0.4%, p=0.006) in PB. In regard to the JIA status, patients with activity (n=33) had a significantly higher median percentage of both PD1+CD4+ and PD1+CD8 T cells in PB, as compared to those with inactive disease (n=13) (1.36 vs. 0.87%, p=0.034 and 2.03 vs. 0.45%, p<0.001, respectively).

Additionally, in a sample of the patients with disease activity (n=22), the median serum sPD1 level was statistically significantly higher, as compared to a sample of those with inactive JIA (n=10) (218.3 vs. 186.7pg/ml, p=0.035). In patients with concurrent serum and SF samples (n=7), the median sPD1 level was statistically significantly higher in the SF than in the serum (1104.4 vs. 773.4pg/ml, p=0.028).

No correlation was though found between the sPD1 levels and the PD1 cellular surface expression (n=16 PB/serum, n=11 SF).

Conclusion: These preliminary results indicated an sPD1 compartmentalization in active JIA, as sPD1 levels were more prominently raised in the inflamed joint than in the PB. A higher number of circulating T-helper and T-cytotoxic cells expressing PD1 were also detected in active JIA. Further investigation in a larger sample of JIA patients may verify these observations and contribute to unraveling the precise role of the PD1 pathway in the pathogenesis and persistence of the joint inflammation.

MOLECULAR DOCKING AND PHARMACOLOGICAL ANALYSIS OF ALPHA-PHELLANDRENE IN CHRONIC PAIN: THE ROLE OF SEROTONERGIC SYSTEM

V. M. D. S. Pires, J. T. Ceciliinsky, L. D. S. Gomes, F. D. A. Oliveira, F. R. D. C. Almeida, F. University of Paraná, Pharmaceutical Sciences, Curitiba, Brazil; Universidade do Contestado, Pharmacy, Mafra, Brazil; Federal University of Piauí, Biochemistry and Pharmacology, Teresina, Brazil

Background: Pain is an unpleasant sensory and emotional experience that causes human suffering. Its prevalence has increased, as well as the abuse and dependence on strong opioids. The α-phellandrene is a terpene that exerts antinociceptive and immunostimulant effects, however, its mechanisms remain to be elucidated. In this way, bioinformatics may assist in developing new therapeutic approaches for pain management.

Objectives: To investigate the action of α-PHEL in chronic pain, focusing on the role of the serotonergic system, to develop a new therapeutic tool without the side effects of conventional drugs.

Methods: Molecular docking is an important method for the investigation of the mechanism of action of natural compounds. It is possible to evaluate the molecular dynamics, elucidating the stability of complexes. The software PyMOL and AutoDock Vina 1.5.7 were used to predict interactions of α-PHEL and 5-HT 2A receptor antagonist Ketanserin (0.3mg/kg, i.p.) or Saline (10mL/kg, p.o.). After 20min, they were treated with α-phell (6.25mg/kg, p.o.) and after 1h they were evaluated by the Von Frey test.

Results: The serotonergic system has a complex and important role in pain modulation especially through descending inhibitory pathways. The Molecular docking predicted the positioning of α-PHEL in the 5-HT 2A receptor, aiding the understanding of its biological activity. The analysis identified 9 key positions for the ligand binding in 5-HT 2A. The lowest Gibbs free energy ΔG= -6.9 kcal/mol. The negative binding energy indicates a strong and stable bond, therefore, α-PHEL has a high affinity for the receptor (Figure 1).

Excellent in vivo therapeutical effects were observed in the animal model of neuropathic pain. Regarding the pharmacological in vivo analysis, the α-PHEL significantly decreased the pain threshold (P<0.05), exhibiting an anti-hyper-sensitive effect. The inhibition of serotonergic transmission by pretreatment with Ketanserin significantly reduced the antinociceptive effect of α-PHEL in mice. The data indicate that α-PHEL exerts its antinociceptive effect on chronic neuropathic pain model by activation of the 5-HT2AR receptor. Its analgesic effect seems to be mediated by descending inhibitory serotonin system interfering with pain impulse transduction.

Conclusion: Chronic pain is often resistant to medical treatment and the chemoinformatics techniques may facilitate the discovery of new compounds, guiding towards specific molecular targets. The α-PHEL may act as a serotonergic agonist, reducing mechanical sensitivity. It is a promising compound for chronic pain treatment, with lower cost and fewer adverse effects than opioids. Further investigations are expected to highlight the in-depth effects of the interaction of α-PHEL with other receptor subtypes.

Conclusion: The new SynHelix ELISA measures precisely circulating degradation fragments of Helix-III peptide-containing collagen. Serum SynHelix levels are already increased in patients with low activity RA, values correlating modestly the degree of systemic inflammation. Larger longitudinal studies are needed to further evaluate the value of SynHelix to predict disease outcome in RA.

DOI: 10.1136/annrheumdis-2022-eular.159
Results: A total of 52 consecutive patients were studied: 29% developed IA after one year. At baseline, 25 patients had subclinical inflammation and 27 patients did not have subclinical inflammation. In these groups respectively 28% and 7% developed IA before the 4-month-visit and therefore did not have repeated MSUS. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months.

Objectives: To investigate whether sequential imaging at 4-months, in addition to baseline evaluation, is helpful in the risk stratification of arthralgia-patients.

Methods: Arthralgia-patients suspicious for progression to IA were included in the Rotterdam clinically suspect arthralgia cohort. At baseline and at 4-months a bilateral US-examination was performed of the joints and tendons in both hands and feet. Subclinical inflammation was defined as GS >1 and/or PD >0, this was scored according to the latest OMERACT-guidelines.[1, 2] Based on a large US study carried out in a symptom-free population, the cut-off value in MTP joints was considered present if GS ≥3 and/or PD ≥1.(3) Patients were followed for one-year on development of IA, identified with joint examination by experienced rheumatologists. The value of MSUS was studied separately for patients with and without subclinical joint inflammation at baseline. In a sensitivity analysis, ACPA-stratification was applied.

Results: A total of 52 consecutive patients were studied: 29% developed IA after one year. At baseline, 25 patients had subclinical inflammation and 27 patients did not have subclinical inflammation. In these groups respectively 28% and 7% developed IA before the 4-month-visit and therefore did not have repeated MSUS. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months. All patients with a negative MSUS at baseline, 26% achieved a positive MSUS at 4-months.

Conclusion: Within arthralgia patients with a positive MSUS at baseline, a negative MSUS after 4-months may be an incentive to exclude arthralgia-patients from further follow-up. Within the patients with a negative MSUS at baseline, repeating MSUS may induce more false positive than correct positive results.

Results: bDMARDs introduction, based on extrapolation of pre-bDMARDs trends. After bDMARDs introduction were compared with expected rates assuming no change in non-RA (Figure 1): the adjusted difference between the post- and pre-bDMARDs secular trends of 8-year CVD rates was 0.23 (p=0.06) for RA patients and -0.07 (p=0.33) for non-RA individuals (Table 1). However, we observed a reduction in the level of CVD rates among RA patients diagnosed in the post-bDMARDs period and no change in non-RA (Figure 1): the adjusted difference in level comparing points immediately before and after the intervention, and accounting for pre-intervention trend was -1.61 (p=0.03) in RA, while it was -0.02 (p=0.93) in non-RA (Table 1).

Conclusion: Arthritis onset after bDMARDs introduction is associated with a significant reduction in the risk of incident CVD events among RA patients, but not in the matched non-RA individuals.

Conclusion: Disability resulting from RA is a complex phenomenon, arising from more than just joint inflammation. This analysis indicates that lack of social support, financial instability and lower physical fitness at symptom onset may explain the excess disability associated with RA. As only a small portion of the effect is mediated by PROMs, health and social inequalities may need to be targeted directly by interventions.

DOI: 10.1136/annrheumdis-2022-eular.496
Conclusion: Contemporary UA has no excess mortality, in contrast to RA. So, besides milder disease at presentation within contemporary UA, also the long-term outcome mortality is more favorable and comparable to the general population. This supports the notion that contemporary UA-patients have intrinsically different characteristics than RA-patients, rather than representing an early stage of RA. Future studies are warranted to determine whether contemporary UA should be treated as RA; our results suggest that this population may deserve separate guidelines.

DIFFERENT BIOACTIVE LIPID PROFILES PREDICT RESPONSE TO TNF OR IL6 INHIBITORS IN RHEUMATOID ARTHRITIS: RESULT OF THE COREVITAS CERTAIN COMPARATIVE EFFECTIVENESS STUDY

M. Aloiabi1, R. Coras1, D. A. Pappas2, J. M. Kremer2, G. Thiele3,4, T. Mikuls4,5, M. Jain1, M. Guma3. 1University of California San Diego, Medicine, La Jolla, United States of America; 2CorEvitas, Medicine, NYC, United States of America; 3University of Nebraska Medical Center, Medicine, Omaha, United States of America; 4Omaha VA Medical Center, Medicine, Omaha, United States of America; 5VA San Diego Healthcare System, Medicine, San Diego, United States of America

Background: Circulating bioactive lipids can provide information about the pathogenesis of specific diseases and potentially help predict therapeutic response. Choosing the right biological therapy earlier in the course of rheumatoid arthritis (RA) could help reach the goal of remission.

Objectives: We hypothesized that circulating bioactive lipids at baseline would identify specific metabolic profiles that predict patient response to therapy and define elements of metabolic pathobiology in arthritis.

Methods: Bioactive lipids were measured in plasma from two cohorts of RA patients from the CorEvitas (formerly known as Corrona) CERTAIN registry (1) at baseline prior to treatment with TNF inhibitors (all biologic naive, N=102) or anti-IL6 (all previously exposed to biologics, N=114). Response to treatment was categorized by minimal clinically important difference (MCID) in Clinical Disease Activity Index (CDAI) (2) at 6 months after treatment initiation. Patients had to have a 6 month follow up visit and plasma available at both the baseline and the 6 month time points. Liquid chromatography (LC) system coupled with high resolution Orbitrap mass spectrometer (LC/MS) was used for bioactive lipid profiling. Around 300 spectral features were identified as potential oxylipins by searching against an in-house MS/MS library. Logistic regression analyses were adjusted for gender, age and BMI was performed using R software.

Results: 102 patients (average age 54, standard deviation [SD] 12.6, 82% female [83], average BMI 29.7, SD 6.7, average CDAI 27.1, SD 13.7) starting anti-TNF therapy and 114 patients (average age 57, SD 13, 90% female [102], average BMI 30.5, SD 7.4, average CDAI 28.7, SD 13.8) starting tocilizumab were analyzed. Twenty-five bioactive metabolites discriminated between RA patients classified as anti-TNF responders (R, n = 74) and non-responders (NR, n = 28). Among these, the anti-inflammatory oxylipin maresin 2 was higher in R while the pro-inflammatory oxylipins 15d PGJ2 and 5,6-diHETE were higher in NR. Twenty different metabolites discriminated anti-IL6 R (n=73) and NR (n=41) as shown in Figure 1. The anti-inflammatory oxylipin 14-15EET was higher in R while the pro-inflammatory oxylipins 16-HETE and 15dEET were higher in NR.

Conclusion: Circulating bioactive lipid analysis using LC/MS provided a rapid analysis of a wide range of metabolites and can be used to describe metabolic signatures that predict response to therapies. These results lay the groundwork for more deliberate investigations novel metabolic-based interventions to predict response to therapy and reduce arthritis morbidity.

TAILORING ORAL THERAPY IN RHEUMATOID ARTHRITIS: THE TUTOR APP

M. Radin1, M. Arbrile1, I. Cecchi1, A. Barinotti1, S. Baldovino1, E. Menegatti1, D. Rossi1, S. Sciascia1, D. Roccatello1. 1University of Turin, Clinical and Biological Sciences, Turin, Italy

Background: Medication non-adherence has a significant impact on the health and well-being of individuals with chronic diseases. Indeed, with respect to important risk factors of Rheumatoid Arthritis (RA), such as cardiovascular risk factors, it is known that up to 50% of patients will stop taking medication for these conditions during the first year of prescription [1].

Objectives: To support the management of RA patients treated with Tofacitinib, we designed the TuTOR (Tailoring Tofacitinib Oral therapy in Rheumatoid arthritis) Mobile App.

Methods: A prospective-controlled study evaluated the impact of TuTOR App on medical adherence in 20 RA patients, that began treatment with Tofacitinib jointly with the App. We used a crossover design alternating Paper-Diary and TuTOR App, with monthly clinical assessments.

Results: Seventeen patients with RA (mean age at inclusion 59±19yrs; 88% females) the study. A statistically significant decrease of DAS28 was observed since the first month of therapy with Tofacitinib (mean DAS28 at baseline 3.9±1 vs. 1° month 3.1±1, p=0.0016). Similarly, Numerical Rating Scale (NRS) of perceived activity of disease (5.8±2.1 vs 3.7±2.5, p=0.02), and subjective fatigue (6.1±2.3 vs 4.3±2.6, p=0.01) progressively decreased. No differences were reported in DAS28 and in all the NRS between the use of the TuTOR App and the Paper-Diary: A significant decrease was observed also in HAQ during the follow-up (baseline 1.38±1.11 vs six months 0.89±0.9; p=0.01). Most of the patients (82%) when filling out the self-reporting questionnaires preferred the TuTOR App in helping them to remember to take the pills. Further 82% of patients used the TuTOR App regularly (vs.53% Paper-Diary) and 76% of patients would use it in the future (vs.53% Paper-Diary). Three patients suspended the therapy with Tofacitinib due to gastrointestinal intolerance.

Conclusion: Both digital- and paper-devices can help maximize the adherence to therapy, leading to an improvement in disease’s activity, highlighting the need of supports for medication adherence.

**Background:** Early arthritis is an inflammatory disease with the potential to progress to persistent arthritis, such as established Rheumatoid Arthritis (RA) or other articular disease, to resolve spontaneously or remain undifferentiated for indefinite periods of time.

**Objectives:** To identify predictors of persistent RA after 12 months follow up in the Argentinean early arthritis clinic (CONAART).

**Methods:** We conducted an observational, prospective longitudinal study, including patients with early arthritis (at least 1 swollen joint with <2 years of evolution) who had at least one year of follow-up. Sociodemographic and clinical data and characteristics of the disease were recorded at baseline, at 3, 6 and 12 months. After 1 year of follow-up, each patient was classified according to diagnosis: self-limited arthritis, persistent non-erosive arthritis, or persistent erosive arthritis. The association between the different predictors of diagnosis at 12 months was evaluated using multiple logistic regression, adjusted by potential confounders. Rheumatoid Factor (RF) and Anti Citrullinated Peptide Antibodies (ACPA) were included in separate models in order to avoid multicollinearity. A value of p<0.05 was considered significant.

**Results:** We included 839 patients, 83% females, mean age of 57±14 years and mean disease duration of 8.2±6.2 months; 67.5% were rheumatoid factor positive and 59% ACPA positive. Disease characteristics at baseline were DAS28 5.1±1.4, swollen joints 6±5, erythrocyte sedimentation rate (ESR) 34±25 mm/h, C Reactive Protein (CRP) 4±6 and Health Assessment Questionnaire-Argentinean (HAQ-A) 1.2±0.8. After 12 months follow up, 11% of the patients were diagnosed as self-limited disease, whereas 89% were diagnosed as persistent disease. For the persistent disease, 34% presented radiograph erosions and therefore were catalogued as persistent erosive disease. The seropositivity for both, RF and ACPA, together with baseline DAS28, were the variables independently associated with the development of persistent disease at 12 months. [Model 1a: RF OR 2.33 (95% CI 1.44, 3.78) and DAS28 1.27 (1.06, 1.52); Model 2a: ACPA 2.61 (1.38, 4.93) and DAS28 1.59 (1.24, 2.04)]. (Table 1). In the patient prediction model, it can be observed that a patient with female gender, ACPA negative, and a low activity at baseline (DAS28 <3.1) presents a 62.3% of likelihood of developing persistent arthritis after 12 months, while a male patient, ACPA positive, with a high baseline activity level, the probability of having persistent disease rises to 97.5%. (Figure 1)
Results: Adjusted for optimism, the multinomial model achieves an accuracy of 50.7% (IQR: 50 – 51.3%), with calibration slopes of 0.57 (IQR: 0.569 – 0.579) and 0.534 (IQR: 0.525 - 0.544) for moderate and poor response, respectively. Figure 1 shows a comparison of odds ratios (OR) for the different outcome groups. The Health Assessment Questionnaire (HAQ) score is the biggest driver of both moderate and poor response. Previous biologic treatment also predicts poor but not moderate response. Compared to the multinomial model, a binary model, that discriminates poor from moderate and good responders, underestimates the effect size of HAQ.

Conclusion: The model predicts EULAR response groups moderately well but is poorly calibrated, which can partly be explained by the generally higher sample size requirement of multinomial modelling. In the multinomial model, moderate and poor response is largely driven by the same covariates, which leads to blurred boundaries between good and poor responders, when response groups are merged to create a binary problem. Future research should consider the most appropriate model choice to describe data, including the use of multinomial instead of binomial models. More research and bigger sample sizes are required to improve on this multinomial model.

POS0510
INFLUENCE OF CMV INFECTION ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Kippenhahn1, C. Baerwald2, C. Pitsch2, O. Sellert3. 1Rheumatology Unit, Clinic for Endocrinology, Nephrology and Rheumatology, Department of Internal Medicine, Neurology and Dermatology, University Hospital Leipzig, Leipzig, Germany; 2Institute of Medical Microbiology and Virology, Department of Virology, University Hospital Leipzig, Leipzig, Germany

Background: The causes of the onset and progression of rheumatoid arthritis (RA) are complex and not yet understood. Some studies suspect viruses as triggers of inflammatory processes (1). Increased numbers of immunomodulatory cells have already been detected in patients with RA infected with the cytomegalovirus (CMV) (2) (3). Understanding the role this infection has on RA-specific disease parameters could help clarify predisposing and prognostic factors.

Objectives: The aim of this study was to determine the relationship between CMV serostatus and disease activity in patients with rheumatoid arthritis.

Methods: We performed a retrospective study in adult patients diagnosed with RA. The data was collected between 2008 and 2021 in the rheumatological outpatient department of the University Hospital in Leipzig, Germany. The parameters examined included age, gender, CMV-IgG and CMV-IgM, and the following parameters to record the disease activity of RA: disease duration, joint erosions, rheumatoid factor, anti-CCP antibodies, CRP, disease activity score (DAS28), visual analog scale (VAS) for pain detection, Health Assessment Questionnaire (HAQ), medication with DMARDs and prednisolone.

Results: A total of 89 RA patients were included, 78.7% of them were female. The mean age was 61.44 ± 10.89 years and the mean duration of illness was 9.48 ± 9.13 years. 56.2% of the patients were CMV-IgG positive, 2.2% CMV-IgM positive. With an OR of 5.04 (95% CI 1.63-15.64), the CMV-IgG titer in women was significantly higher than in men (115.16 vs. 50.75).
p = 0.007). This has already been shown in other studies (4). One of the reasons discussed is the women's closer relationship with children at work. It has also been shown that among those medicated with DMARDs had significantly higher CMV-IgG titers (126.82 vs. 58.84 p = 0.036). This could be explained by an increased predisposition for CMV reactivation due to the intake of medication. Women with joint erosions were also more likely to be CMV-IgG positive (OR = 3.2; 95% CI 1.02-10.03) and had higher CMV-IgG titers (147.44 vs. 97.23 p = 0.024). Furthermore, seropositive RA women were significantly more likely to be CMV-IgG positive (p = 0.05). This association supports the assumption that CMV may play a role in the pathogenesis of RA.

Conclusion: The data presented shows that there is indeed a relationship between infection with CMV and parameters for disease activity in patients with RA. In summary, the integration of a CMV status determination into everyday clinical practice in patients with high disease activity could be quite useful and should be discussed.

PERIODONTAL STATUS BEFORE DIAGNOSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS PREDICTS CUMULATIVE DISEASE ACTIVITY IN YEARS AFTER TREATMENT INITIATION

A. Plachokova1, J. Fransen2, M. Koenders2, R. M. Thurlings2.

University Medical Center, Dentistry, Nijmegen, Netherlands; 2University Medical Center, Rheumatology, Nijmegen, Netherlands

Background: Transversal cohort studies demonstrated an association between periodontal disease (PD) and rheumatoid arthritis (RA), but it is unknown how this association evolves during the course and treatment of both conditions.

Objectives: In this study we compared RA and PD before and after RA diagnosis in patients versus controls and analyzed the relationships between disease course and treatment of both conditions.

Methods: Retrospective dental and RA data were analyzed of 95 RA patients from 10 years before up to 10 years after RA diagnosis. Dental data were acquired from general practices and matched healthy control patient data from the university dental college. PD was analyzed via radiographic assessment using the new periodontal classification system from 2017. The relationship was analyzed between PD and RA parameters and treatment.

Results: More RA patients had severe or very severe PD compared to matched healthy controls, already before RA diagnosis. The fraction of RA patients with severe/very severe PD increased from 23% before diagnosis to 43% 5-10 years after diagnosis. Patients with a more severe PD before RA diagnosis had more tooth loss at last dental follow-up and a higher cumulative DAS28 in the years after diagnosis. Two-thirds of patients with severe/very severe PD received appropriate dental care less frequently than advised by guidelines. Suboptimal dental care was associated with a higher cumulative DAS28.

Conclusion: PD occurs before RA diagnosis in a proportion of patients. This proportion increases in the years after diagnosis. PD is associated with a decreased response to treatment of RA. A significant number of RA patients with PD receives suboptimal dental care, which is associated with diminished response to RA treatment.

REFERENCES:

Figure 1. periodontitis severity in the years before RA diagnosis was scored from stage 1 to 4 (mild, moderate, severe, very severe) according the periodontal classification system from 2017. The time averaged DAS28 was calculated by taking the mean of the available DAS28 scores in the first 10 years after diagnosis and correcting this for the time intervals during which these were acquired. Linear regression analysis was performed. * = P < 0.05.

Background: A treat-to-target approach for RA management is recommended. However, up to half of patients discontinue DMARD treatment within 18 months. Predictive biomarkers, such as anti-citrullinated protein antibodies (ACPA) and RF, may be useful to stratify patients to the most appropriate treatment. ACTION (Abatacept in routine clinical practice; NCT02109666) and ASCORE (Abatacept SubCutaneously in Routine Clinical Practice; NCT02090556) were 2-year, international, observational, prospective, multicenter studies of IV and SC abatacept, respectively, for the treatment of RA in routine clinical practice.
Retention has been previously reported in patients with double ACPA/RF seropositive RA compared with double ACPA/RF seronegative RA.3,4

Objectives: To assess the independent effect of ACPA or RF single seropositivity on abatacept retention in patients with RA receiving abatacept in a post hoc analysis of ACTION and ASCORE.

Methods: This post hoc analysis included patients aged ≥ 18 years, with active moderate-to-severe RA (ACR/EULAR 2010 criteria) who initiated IV (body weight–adjusted dosing) or SC (125 mg once weekly) abatacept.3,4 Patients were stratified by baseline ACPA/RF status: ACPA+/RF− (ACPA+ only), ACPA+/RF+ (RF+ only), and ACPA+/RF− double negative (−/−). Abatacept retention rate at 2 years was estimated by Kaplan–Meier (KM) analysis.

Results: Patients with ACPA/RF serostatus data from the ACTION and ASCORE studies (N = 1679 and N = 1748, respectively) were evaluated. Baseline demographic and disease characteristics were similar across studies and serostatus groups (Table 1). In patients with ACPA+ only RA, abatacept retention rates were similar to the +/- group and greater than the RF+ only and −/− groups (Figure 1). In ASCORE (Figure 1A), retention rates were significantly higher in ACPA+ only and +/- groups when compared with the −/− group. In contrast, retention rates for patients with RF+ only RA were not significantly different vs −/− patients. Results were similar in ACTION, although the higher retention in the ACPA+ group did not reach statistical significance (Figure 1B).

Conclusion: In this post hoc analysis of the real-world ACTION and ASCORE studies, ACPA positivity was associated with an increased likelihood of retention over 2 years. Patients with ACPA+ only RA were equally as likely to be retained on abatacept as patients with ACPA/RF double positivity. In contrast, patients with RF+ only RA were less likely to be retained on abatacept over 2 years. These findings suggest that ACPA positivity played a more important role than RF positivity in abatacept retention. The higher retention seen in patients with ACPA+ only vs RF+ only disease demonstrates the key role of ACPA in RA and supports the importance of precision medicine in treating patients.

Data are mean (SD). Patients with missing data for baseline ACPA/RF status are excluded.

incidence was slightly higher in pts with vs without prior FIL exposure, with the exposure had numerically higher median lymphocyte levels at LTE baseline in both treatment groups, median laboratory lymphocyte levels remained relatively stable over 1 year with lymphocyte decreases observed in individual FIL-treated pts. Lymphocyte levels should be monitored. Objectives: To assess the effect of FIL on lymphocyte levels and lymphopenia in the FINCH 4 long-term extension (LTE) study in RA. Methods: Safety data of FIL 100 mg (FIL100) and 200 mg (FIL200) from LTE baseline to data cut off (01 June 2020) are reported overall and by prior FIL exposure for pts who received ≥1 FIL dose in FINCH 4 (NCT03025308; adults with RA who had completed FINCH Week 1/2/3). Adverse events (AEs) of lymphopenia were graded based on clinical severity; laboratory abnormalities (decreased lymphocytes) were graded per Common Terminology Criteria for Adverse Events v4.03 (CTCAE). Frequencies of both measures and exposure-adjusted incidence rates (EIRs) of AEs are reported. Median lymphocyte levels are reported to LTE Week 48. Results: The safety analysis set included 2729 pts (FIL200: n=1530; FIL100: n=1199). Of these, 75.4% (n=2058) had prior FIL exposure in FINCH 1/2/3. Incidence was slightly higher in pts with vs without prior FIL exposure, with the difference most apparent for Grade 2 decreases.

Of all pts receiving FIL 43 (1.6%) reported a lymphopenia AE; frequencies and EIRs of lymphopenia AEs were slightly higher with FIL200 (1.9%; EIR [95% CI]: 1.2 [0.9–1.4]) vs FIL100 (1.2%; 0.8 [0.4–1.3]). Most were Grade 1 or 2 in severity. Grade 3 lymphopenia AEs occurred in 4 (0.3%) vs 1 (<0.1%) pts receiving FIL200 vs FIL100. There were no Grade 4 AEs in either group. No serious AEs of lymphopenia or treatment discontinuations due to lymphopenia were reported. In total, 8 (0.3%) pts interrupted study treatment due to lymphopenia. Infection rates, but not serious infections, were slightly higher for pts with lymphopenia, however no relationship between lymphopenia severity and infection AE grade was seen.

Conclusion: In FINCH 4, lymphopenia AEs were infrequent but numerically greater with FIL200 vs FIL100, suggesting a dose–response relationship. While exposure at either dose may be associated with decreased lymphocytes, median lymphocyte levels were comparable in both groups and all remained within normal range at LTE Week 48, similar to observations in FINCH 1–3.

A treatment-emergent laboratory decrease in lymphocytes was defined as an increase of ≥1 toxicity grade from baseline at any time post-baseline up to and including the date of last study drug dose +30 days. Severity grades were defined per CTCAE (lower limit of normal: <0.8 x 10^9/L [Grade 1]; <0.8–0.5 x 10^9/L [2]; <0.5–0.2 x 10^9/L [3]; <0.2 x 10^9/L [4]).
treatment (Figure 1). Baseline DAS28-ESR, anti-citrullinated protein antibody (ACPA) and health assessment questionnaire (HAQ) score were the top predictors of good response to MTX using LASSO (Area Under the Curve [AUC] 0.79) and Random Forest models (AUC 0.68) in the external validation set. DAS28-ESR≤7.4, ACPA positive and HAQ≤2 provided the highest likelihood of response (Table 1). Among patients with 12-week DAS28-ESR≤3.2, at least 1 point improvement in DAS28-ESR baseline-to-12-week was predictive of achieving DAS28-ESR≤3.2 at 24 weeks.

Figure 1. Two patient class trajectories identified with latent class modeling of DAS28-ESR (N=775)

Conclusion: We have developed and externally validated a prediction model for response to MTX within 24 weeks in DMARD-naïve patients with RA, providing variably weighted clinical features and defined cut-offs for clinical decision-making. Trajectory of DAS28-ESR change over 24 weeks in patients with moderate-to-high RA disease activity at baseline who are starting MTX can be predicted by baseline DAS28-ESR, ACPA status and HAQ-score. Patients with at least 1 unit decline in DAS28-ESR within the first 12 weeks of treatment who have not achieved low disease activity by week 12, may be more likely to achieve low disease activity at 24 weeks. These parameters should be considered as part of the clinical decision-making process when initiating MTX in DMARD-naïve patients with RA.

REFERENCES:
[1] Aletaha D, Smolen JS. Effectiveness profiles and dose dependent retention of the clinical decision-making process when initiating MTX in DMARD-naïve patients with RA who have not achieved low disease activity by week 12, may be more likely to achieve low disease activity by week 12, and are more likely to achieve low disease activity by week 12, and are more likely to achieve low disease activity by week 12.

Background: Patients with rheumatoid arthritis (RA) have an increased risk for cardiovascular disease, including venous thromboembolic events (VTE). The reason behind the increased VTE risk is incompletely understood, but inherent features of RA, such as RA specific autoantibodies, could potentially play a role. For example, studies have linked occurrence and levels of rheumatoid factor (RF) in the general population to increased VTE risk. We and others have demonstrated an association between ACPA and risk of late ischemic cardiovascular events. There are also potential mechanistic links; citrullinated fibrinogen (cFib) has been associated to clot stability.

Objectives: We aimed to examine the association between anti-modified protein antibodies (AMPAs) and risk of VTE in RA.

Methods: We included 2809 individuals newly diagnosed with RA and included in the Swedish EIRA study 1996-2009. Through linkage to nationwide health care registers we identified past and incident events of VTE based on validated ICD code algorithms. We centrally typed baseline sera for anti-CCP2, 20 different ACPA sub-specificities, RF isotypes, carbamylated antibodies and 10 additional post-translational modifications. We followed all individuals from RA diagnosis until 1 year after the first VTE event, migration, death or end of study (2020-12-31) whichever occurred first. We used a Cox regression to estimate hazard ratios (HR) with 95% confidence intervals (CI). Individuals with a history of a VTE event (n=27) at RA diagnosis were excluded.

Results: We included 2782 individuals; 72% were women, median age at RA diagnosis was 54 years (inter quartile range (IQR) 18 years) and median follow-up time was 15.8 (IQR 6.8) years. During follow-up 177 incident VTE events were observed corresponding to an incidence of 5.0 per 1,000 person years.

Conclusion: We have developed and externally validated a prediction model for response to MTX within 24 weeks in DMARD-naïve patients with RA, providing variably weighted clinical features and defined cut-offs for clinical decision-making. Trajectory of DAS28-ESR change over 24 weeks in patients with moderate-to-high RA disease activity at baseline who are starting MTX can be predicted by baseline DAS28-ESR, ACPA status and HAQ-score. Patients with at least 1 unit decline in DAS28-ESR within the first 12 weeks of treatment who have not achieved low disease activity by week 12, may be more likely to achieve low disease activity at 24 weeks. These parameters should be considered as part of the clinical decision-making process when initiating MTX in DMARD-naïve patients with RA.

Background: Plasma calprotectin is a sensitive inflammatory marker in patients with rheumatoid arthritis (RA) and reflects activation of granulocytes and macrophages. Plasma calprotectin has not previously been studied in a head-to-head clinical trial of multiple biological mechanisms of action versus active conventional therapy (ACT) with methotrexate and prednisolone.

Objectives: To assess the effect of treatment on plasma calprotectin levels in patients with early RA by determining the 24-week change in the four arms of the NORD-STAR Study, a large multicenter randomized head-to-head clinical trial of active conventional therapy, CZP+MTX: certolizumab-pegol and methotrexate, ABA+MTX: abatacept and methotrexate, T2C-MTX: tocilizumab and methotrexate.

Methods: Calprotectin was analyzed in plasma samples at baseline, week 4 and week 24 from 400 treatment naive patients with early RA in the NORD-STAR Study. Samples were analyzed using a calprotectin ELISA alkaline phosphatase (ALP) kit from CalproLab (Oslo, Norway) in a Dynex DS2 processing system (normal levels ≤910 µg/L). Patients were assessed by clinical CRP, 28 SJC/TJC, physician global) and patients’ reported assessments. Crude and adjusted linear regression analyses were performed in R 4.0.3 with calprotectin levels at week 24 as the outcome. The four arms were represented by three dummy variables. The adjustment variables were age, sex, anti-CCP status and country. Both analyses were adjusted for baseline calprotectin levels.

Results: At baseline, the mean time since diagnosis was 15.7 days (SD) (22.9), mean age 53.7 (15.0) years, ACPA positive 81%, and female 66%. Mean calprotectin levels were 1931 (1495) µg/L at baseline, 866 (951) µg/L at week 4, and 629 (681) µg/L at week 24. At baseline, normal calprotectin levels (<910 µg/L) were observed in 27% of all patients (ACT 22%, certolizumab-pegol and methotrexate 30%, abatacept and methotrexate 25%, tocilizumab and methotrexate 31%). At week 24, normal calprotectin levels were observed in 82% of all patients (ACT 68%, certolizumab-pegol and methotrexate 91%, abatacept and methotrexate 80%, tocilizumab and methotrexate 90%). Observed calprotectin levels at week 24 were significantly lower in patients treated with certolizumab-pegol and methotrexate -336µg/L (97) (p = 0.006) or tocilizumab and methotrexate -284 (99) (p < 0.004), versus ACT when adjusted for age, sex, anti-CCP status, baseline calprotectin level, and country; however, a significant difference was not observed in patients treated with abatacept and methotrexate -110 (96) (p = 0.25). The Figure 1 shows the average percentage change in calprotectin levels from baseline to week 24 for all treatment groups.

Conclusion: Calprotectin, a sensitive biomarker of inflammation, normalized in the majority of patients. The decline differed between treatment groups and was largest in patients treated with a TNF inhibitor and methotrexate, suggesting that calprotectin reflects the activity of specific inflammatory pathways rather than overall inflammation. The findings of this study should be further explored.

IgA ACPA levels in RA patients versus healthy controls. Rather than prioritizing specificity, as is done for diagnostic tests, we aimed to define reliably detectable amounts of IgA ACPA, with both sensitivity and specificity not under 79% – 3 µg/mL for total IgA ACPA; 2.46 µg/mL for IgA1 and 0.6 µg/mL for IgA2 ACPA.

**Results:** Serum levels of both IgA ACPA subclasses were elevated in individuals at-risk, with no significant difference to patients with established IgA ACPA-positive RA. Interestingly, 41.4% of IgA ACPA-negative patients had detectable amounts of IgA ACPA; IgA1 ACPA, but not IgA2 ACPA levels were higher in individuals at-risk who developed RA in the next 14 months than in those who did not (4.54 vs. 2.85 µg/mL, p=0.03); and the percentage of those developing RA was higher in IgA1 ACPA-positive at-risk individuals (64.3% versus 35.3%). Interestingly, during the transition to RA, in the majority of IgA ACPA-positive individuals a decline in IgA1 ACPA levels at the time of RA diagnosis (-26%; p=0.085), as well as in the first months after the RA diagnosis (-38%; p=0.0002) was observed. This observation was confirmed in an independent cohort. IgA2 ACPA declined only after the diagnosis (33%; 10-64%; p=0.037), and no significant change was observed for IgG ACPA.

**Conclusion:** Both IgA ACPA subclasses were elevated in individuals at-risk for RA. Positivity for IgA1 ACPA was associated with the progression to RA in the next 14 months. IgA1 ACPA levels declined in the months preceding the diagnosis of RA and in the months after the diagnosis, which might reflect pathophysiological events happening at the time of the disease outbreak.

RELATIONSHIP BETWEEN DISEASE ACTIVITY AND MAJOR ADVERSE EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS ON TOFACITINIB OR TNF INHIBITORS: A POST HOC ANALYSIS OF ORAL SURVEILLANCE

1Harbor-UCLA Medical Center, Division of Rheumatology, Torrance, CA, United States of America; 2University of Debrecen, Division of Rheumatology, Faculty of Medicine, Debrecen, Hungary; 3Uppsala University, Department of Medical Sciences, Uppsala, Sweden; 4University of Nebraska Medical Center and VA Nebraska-Western Iowa Health Care System, Division of Rheumatology, Omaha, NE, United States of America; 5Brigham and Women’s Hospital and Harvard Medical School, Department of Cardiovascular Medicine, Boston, MA, United States of America; 6Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America; 7Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America; 8Mayo Clinic, Division of Rheumatology, Rochester, MN, United States of America

Background: Uncontrolled rheumatoid arthritis (RA) activity and acute disease flares are associated with higher risk of adverse outcomes such as cardiovascular (CV) disease, venous thromboembolism (VTE), malignancy, and infection.1-4

Objectives: To evaluate associations of acute and cumulative Clinical Disease Activity Index (CDAI) measurements with major CV, malignancy, or infectious adverse events (AEs) of special interest in ORAL Surveillance.

Methods: ORAL Surveillance (NCT02092467) was a post-authorisation safety study of tofacitinib vs TNF inhibitors (TNFi) in patients (pts) aged ≥50 yrs with active RA despite methotrexate (MTX), and ≥1 additional CV risk factor. Pts were randomised 1:1:1 to tofacitinib 5 or 10 mg twice daily (BID) or subcutaneous TNFi. Two post hoc analyses were performed: (1) a time-varying multivariate Cox model examined risks of major AEs when pts were in CDAI-defined low (>2.8–≤10; LDA), moderate (>10–≤22; MDA) or high (>22; HDA) disease activity vs remission (≤2.8). The Cox model also included pt demographics, medical history, and TNFi. Two post hoc analyses were performed: (1) a time-varying multivariate Cox model examined risks of major AEs when pts were in CDAI-defined low (>2.8–≤10; LDA), moderate (>10–≤22; MDA) or high (>22; HDA) disease activity vs remission (≤2.8).

Results: 4362 pts were included. Mean RA duration at BL was approximately 10 yrs. All pts were on MTX at BL, and 28% had previously been on one other synthetic disease-modifying antirheumatic drug (DMARD). Overall, 10% of pts had LDA, MDA or HDA vs remission, they were potentially at higher risk of developing major adverse CV events (MACE), VTE and non-serious infections (NSIs) excluding herpes zoster (HZ), but not malignancies, serious infections or HZ (Figure 1).

Similarly, mean CDAI AUC trended higher for MACE, VTE and NSIs (Table 1).

*p<0.10. Data collected after pts who were randomised to tofacitinib 10mg BID had their dose reduced to 5mg BID were included in the tofacitinib 10mg BID groupLS, least squares; n, number of pts in analysis of variance model
**Conclusion:** In ORAL Surveillance, the risk of MACE, VTE and NSIs excluding H2 appeared higher when pts had active disease than when in remission. Greater cumulative RA disease activity was seen in pts who suffered these AEs vs those who did not. Our findings support treat-to-target recommendations for RA.

Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America; 15. Brigham and Women’s Hospital and Harvard Medical School, Department of Cardiovascular Medicine, Boston, MA, United States of America

**Background:** ORAL Surveillance (NCT02092467) was a post-authorisation safety study of tofacitinib vs tumour necrosis factor inhibitors (TNFi) in patients (pts) with rheumatoid arthritis (RA) aged ≥50 years (yrs) with ≥1 additional cardiovascular (CV) risk factor and an inadequate response to methotrexate (MTX). Statins are used to treat coronary artery disease (CAD) and are recommended by the American College of Cardiology/American Heart Association (ACC/AHA) for the management of pts at risk of atherosclerotic CV disease (ASCVD),1 such as those with ≥75% 10-yr risk of major adverse CV events (MACE) or diabetes mellitus.

**Objectives:** To examine the association between baseline (BL) statin use and MACE in ORAL Surveillance.

**Methods:** Pts with RA on stable MTX were randomised 1:1:1 to receive tofacitinib 5 or 10 mg twice daily (BID) or TNFi (adalimumab 40 mg every 2 weeks or etanercept 50 mg once weekly). Pts were stratified post hoc by BL statin use (yes/no). Pts were further categorised by history of CAD (HxCAD). BL CV risk score divided per ACC/AHA guidelines1 (for pts without HxCAD); 10-yr risk of MACE per the ASCVD-pooled cohort equations risk calculator2 with a 1.5 multiplier applied3, and separately by BL diabetes status. CV risk score/BL diabetes status categories were: high (>20%)/HxCAD (yes), intermediate (≥7.5%–<20%) or low-borderline (<7.5%), and diabetes status (yes). For the overall population and each treatment group, risk of MACE was compared between BL statin use (yes vs no) via Cox analyses for each CV risk category and diabetes status (yes). Incidence rates (IRs; pts with first events/100 pt-yrs) and hazard ratios (HRs; BL statin use: yes vs no) were evaluated for adjudicated MACE.

**Results:** Of 4362 pts (tofacitinib 5 mg BID, n=1455; tofacitinib 10 mg BID, n=1456; TNFi, n=1451), 497 had a HxCAD, and 3813 without a HxCAD had CV risk scores determined. 789 had BL diabetes. Overall, 1020 (23.4%) pts reported BL statin use. Across CV risk score categories for all treatment groups, <50% of pts received statins at BL, with statin use highest in the high/HxCAD category (35.7–40.6%) and pts with diabetes (35.7–44.2%) (Table 1). Across categories, no interpretable associations between BL statin use and MACE were found. However, in the overall population, MACE IRs were lower in pts with vs without BL statin use in the high/HxCAD category and in pts with diabetes (Figure 1). In pts receiving tofacitinib 5 mg BID and TNFi, MACE IRs were lower in pts with vs without BL statin use across all categories (Figure 1).

**N, number of pts in each category; n, number of pts receiving BL statins:**

**Conclusion:** In this post hoc analysis of data from ORAL Surveillance, most pts did not receive BL statin treatment. This suggests suboptimal CV risk management, particularly in pts at high risk of CV events. There was no interpretable association...
between BL statin use and MACE. However, pts in the higher risk categories, particularly those receiving tofacitinib 5 mg BID, had lower MACE IRs in vs without BL statin use. This analysis did not take into account initiation or dose adjustment of statin treatment during the study, and had low yrs of exposure in some categories.

Figure 1. Unadjusted rates.

Background: Biological disease-modifying anti-rheumatic drugs (bDMARDs) are effective in suppressing inflammation and preventing joint damage. But bDMARDs may be associated with increased risk of severe infection. Evidence on this is contradictory with some studies showing increased risk, whereas others reporting no significant changes.

Objectives: To determine the impact of the introduction of bDMARDs on severe infection among patients newly diagnosed with RA compared with non-RA individuals.

Methods: In this age- and gender-matched cohort study using administrative health data for the population of BC, Canada, all incident RA patients diagnosed between 1995–2007 were identified. Non-RA individuals were randomly selected from the general control population to match with RA. Incident RA/ non-RA individuals were then divided into quarterly cohorts according to their diagnosis date. Two outcomes were examined: (1) first severe infection (FSI) after RA onset necessitating hospitalization or occurring during hospitalization; and (2) all severe infections (ASI) after RA onset. We calculated the 8-year FSI and ASI rate for each cohort. We conducted interrupted time-series analyses to compare levels and trends of FSI and ASI in RA and non-RA individuals diagnosed.
during pre-bDMARDs (1995–2001) and post-bDMARDs (2003–2007) periods. Adjusted 8-year FSI and ASI rates for RA and non-RA cohorts diagnosed five years after bDMARDs introduction were compared with expected rates assuming no bDMARDs introduction, based on extrapolation of pre-bDMARDs trends. Results: A total of 60,226 and 588,499 incident RA/non-RA individuals were identified. We identified 8,954 FSI and 14,245 ASI in RA, and 56,153 FSI and 79,819 ASI in non-RA. The 8-year FSI rates among RA patients diagnosed in the pre-bDMARDs period decreased over time but leveled off among those diagnosed in the post-period (Figure 1). The adjusted difference between the post- and pre-bDMARDs secular trends of 8-year FSI rates was 0.68 (p=0.03) in RA and 0.03 (p=0.67) in non-RA (Table 1). The 8-year ASI rates among RA patients diagnosed in the pre-bDMARDs period decreased over time but increased significantly among those diagnosed in the post-period (Figure 1). The adjusted difference between the post- and pre-bDMARDs secular trends of 8-year ASI rates was 1.85 (p=0.001) in RA and 0.12 (p=0.29) in non-RA (Table 1). For RA cohort diagnosed 5 years after bDMARDs introduction, ASI rate increased by 20.4% than expected rates assuming no bDMARDs introduction. In contrast, ASI rate in non-RA increased by only 10.9%.

Conclusion: Arthritis onset after bDMARDs introduction is associated with an elevated risk of severe infection in RA patients, compared with matched non-RA individuals.

**POS0522** ASSOCIATED FACTORS WITH PHYSICAL DYSFUNCTION OF ELDERLY-ONSET RHEUMATOID ARTHRITIS TREATED WITH A TREAT-TO-TARGET STRATEGY

T. Sugihara1,2,3, T. Ishizaki2, H. Baba3, T. Matsumoto4, K. Kubo5, M. Kamuya6,7, F. Hirano1,3, T. Hosoya1,3, M. Kojima1, N. Miyasaki3, M. Harigai4, T. Tokyo Metropolitan Geriatric Hospital, Department of Medicine and Rheumatology, Tokyo, Japan; 2Tokyo Metropolitan Institute of Gerontology, Human Care Research Team, Tokyo, Japan; 3Tokyo Medical and Dental University, Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo, Japan; 4St. Marianna University School of Medicine, Division of Rheumatology and Allergy, Department of Internal Medicine, Tokyo, Japan; 5National Center for Geriatrics and Gerontology, Department of Frailty Research, Center for Gerontology and Social Science, Nagoya, Japan; 6Tokyo Women’s Medical University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; 7National Center for Geriatrics and Gerontology, Department of Frailty Research, Center for Gerontology and Social Science, Nagoya, Japan.

Background: Achievement of normal physical function is an important outcome for older patients. Previous studies of younger cohorts showed that age, comorbidities, and joint damage influenced the physical function of patients with RA who achieved clinical remission or low disease activity (LDA). We previously demonstrated that a treat-to-target (T2T) strategy for methotrexate (MTX)-naïve elderly-onset RA (EROA) was effective with an acceptable safety profile. It showed that 60.9% of 197 patients achieved HAQ Disability Index (HAQ-DI) ≤0.5 at three years by following the T2T strategy targeting LDA (1).

Objectives: We aimed to evaluate associated factors with HAQ-DI in the T2T strategy targeting LDA for patients with EORA during three-year observational period.

Methods: Treatment was adjusted to target LDA with conventional synthetic disease-modifying antirheumatic drugs (DMARDs), followed by biological DMARDs (bDMARDs) in 197 MTX-naive EORA patients (mean age 74.9 years) with moderate-to-high disease activity. HAQ-DI was evaluated at week 0, 24, 52, 76, 104, 128, and 156. To evaluate associated factors with SDAI and HAQ-DI over the 36-month follow-up, Bayesian hierarchical logistic regression modeling was applied for 1067 periods from the 197 patients.

Results: At baseline, the enrolled 197 patients with EORA who had normal physical function (HAQ-DI ≤0.5) in 29.4%, HAQ-DI >0.5 and ≤1.5 in 36.5%, and HAQ-DI ≥1.5 in 33.0%, and the mean age (standard deviation [SD]) in each group was 72.7 (5.9), 74.8 (7.3), and 75.6 (6.7), respectively. Baseline SDAI increased in the group with higher HAQ-DI. The proportions of patients with each comorbidity and estimated creatinine clearance at baseline were not significantly different across the 3 groups. In the multilevel logistic model, the association of MTX, bDMARDs, and GC use with changes in SDAI in each period was evaluated. Age, sex, comorbidities (chronic lung disease, cardiovascular disease, history of malignancy, osteoporosis, history of serious infections, and osteoarthritis) were included as inter-individual factors. The model indicated that the use of bDMARDs was associated with a reduction of the SDAI (ΔSDAI: −9.75, SD 0.75, p<0.001), while neither MTX (ΔSDAI: −1.25, SD 1.13, p=0.270) nor GCs (ΔSDAI: −0.78, SD 0.88, p=0.372) was associated with changes in SDAI Chronic lung disease (ΔSDAI: 4.64, SD 1.44, p<0.001) and osteoporosis (ΔSDAI: 3.78, SD 1.46, p=0.001) at baseline were associated with the increment of SDAI. The association of age, sex, the comorbidities, and MTX, bDMARDs, and GC use with physical function in each period was evaluated by the multilevel logistic model. The model indicated that older age (ΔHAQ-DI: 0.03, SD 0.01, p<0.001), chronic lung diseases (ΔHAQ-DI: 0.30, SD 0.10, p<0.001), and osteoporosis (ΔHAQ-DI: 0.30, SD 0.10, p<0.001) at baseline were associated with the increment of HAQ-DI. When the mean SDAI during the observation period was added to the model as an inter-individual factor, the associations of HAQ-DI with the chronic lung diseases and osteoporosis at baseline were not statistically significant.

Conclusion: These data indicate that bDMARDs had a central role in reducing disease activity in the T2T strategy targeting LDA in EORA patients. Chronic lung diseases and osteoporosis at baseline were associated with increase in disease activity and worsening of physical function. However, disease activity had a greater impact on physical function than the comorbidities at baseline.

**POS0523** FATIGUE TRAJECTORIES IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: A LONGITUDINAL ANALYSIS OF DATA FROM THE CAREA TRIAL

M. Doumen1,2, S. Pazmino1, D. Bertrand1, D. De Cock1,3, J. Joly2, R. Westhovens1,2, P. Verschueren1,2, KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium; 2University Hospitals Leuven, Rheumatology, Leuven, Belgium; 3KU Leuven, Laboratory for Clinical and Experimental Endocrinology, Leuven, Belgium.

Background: Fatigue is a common and impactful symptom of rheumatoid arthri-
tis (RA). Given its heterogeneous and unpredictable nature, studies on contribut-
ing factors of RA-related fatigue should include multidimensional measures of
Objectives: We aimed to explore the longitudinal course of fatigue and its predictors among patients with early RA starting DMARD therapy.

Methods: Data came from the 2-year treat-to-target trial Care in early RA (CareRA) and its 3-year extension. Fatigue was measured based on visual analog scale (VAS), Multidimensional Fatigue Inventory (MFI), and Short-Form 36 (SF-36). Longitudinal fatigue trajectories were identified with multivariable growth mixture modeling. Baseline and early predictors of trajectory membership, including treatment response, were studied with multinomial logistic regression adjusted for age, gender, and treatment type. Patient global assessment (PGA), pain (VAS), and disability (HAQ) were studied in separate models because of collinearity (Spearman r > 0.60). For all models, posterior probabilities of trajectory assignment were included in the regression as weights to account for classification uncertainty. Treatment response was defined, based on whether remission (DAS28-CRP < 2.6) was achieved by week 16 and sustained until year 2, as either early persistent response, secondary failure, or delayed response.

Results: In total, 356 and 244 patients were included in the 2-year and 5-year analyses, respectively. Mean (SD) fatigue (VAS) at inclusion was 48/100 (24). Four fatigue trajectories were identified: Rapid Improvement, Gradual Improvement, Transient Improvement, and Early Deterioration, consisting of 10%, 14%, 56%, and 20% of patients, respectively (Figure 1). Higher PGA, pain and HAQ at baseline were associated with increased probability of Rapid Improvement compared to Transient Improvement or Early Deterioration (Table 2). Secondary treatment failure and delayed treatment response strongly increased the probability of less positive fatigue trajectories when compared to early persistent response.

Conclusion: The longitudinal course of fatigue in early RA is dynamic but highly refractory, with less than 25% of patients making lasting improvements and 20% even experiencing worsening fatigue despite intensive DMARD therapy. Remarkably, a higher perceived disease impact at baseline was associated with an increased probability of fatigue improvement, possibly reflecting the fluctuating nature of this complex symptom. However, early inflammatory disease control appears to be the most important contributor to improved long-term fatigue outcomes, illustrating the far-reaching impact of the therapeutic window of opportunity in early RA.

Figure 1. Latent trajectories of fatigue evolution over the first 2 years in CareRA (n = 356).
Background: Composite disease activity ratings, which are used to assess the severity of rheumatoid arthritis (RA), may not effectively reflect the illness’s spatial impact on the hands. In RA, assessments of handgrip strength (HGs) and functional deficits are a kind of objective examination that focuses on the hands. Objectives: The goal of this study was to see if there was a link between joint inflammation and damage in the wrists and hands, as measured by ultrasound (US) and magnetic resonance imaging (MRI), functional disability as measured by hand-specific self-report questionnaires, and composite disease activity indices. Methods: Sixty-six female patients with RA were investigated (age 55.6 ± 12.2 years, range 20-80 years; disease duration 4.4 ± 3.0 years). The DAS28-CRP, the SDAI, the CDAI, and US and MRI scoring techniques such as the Ultra-Sound-Clinical Arthritis Activity (US-CLARA) and modified Simplified Rheumatoid Arthritis Magnetic Resonance Imaging Score (SAMIS) were all used as baseline assessments (mod SAMIS) (Figure 1). Without contrast injection, the mod SAMIS score was rated for the presence/absence and semiquantitative assessments of synovitis, bone erosion (ERO), and bone marrow edema (BME). All patients had HGs and completed the shortened Disability of Arm, Shoulder, and Hand Questionnaire (QuickDASH), the Arthritis Impact Measurement Scales hand and finger function subscale, and the upper extremity function sub-score of the ROAD. Results: The mod SAMIS total score and the US-CLARA had a strong correlation (rho=0.377, p=0.0018) for all patients. Among the SAMIS sub-indices, there was a significant relationship between mod SAMIS bone oedema (SAMIS-BME) and US-CLARA (rho=0.799, p<0.001) and mod SAMIS synovitis (SAMIS-synovitis) and US-CLARA (rho=0.539, p<0.001). There were also significant negative relationships between the HGs score and the mod SAMIS total score and US-CLARA (rho = -0.309, p=0.011 and rho = -0.775, p<0.0001, respectively). The HGs and disease activity composite indices, as well as hand-specific self-report questionnaires, were shown to have high relationships (p<0.0001) in individuals with RA. The hand and finger function sub-scales, as well as the mod SAMIS erosion (SAMIS-ERO) and HGs, exhibited no significant relationship. For each of the three components, interobserver agreement was good to excellent (intraclass correlation values = 0.713, 0.912, and 0.821, respectively) (synovitis, BME, and BM (Figure 2). Conclusion: BME and synovitis have an impact on upper-extremity function. The US-CLARA and mod SAMIS total score are promising solutions for semi-quantitative evaluation of joint inflammation and damage in RA. These shortened scores might cut down on image processing time in US and MRI-controlled RA investigations, as well as make using these imaging modalities in RA treatment response evaluation studies simpler.

POS0525 ARE BIOLOGIC AND TARGETED SYNTHETIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS ASSOCIATED WITH WORK PARTICIPATION IMPROVEMENT IN EARLY RHEUMATOID ARTHRITIS? A SYSTEMATIC REVIEW AND META-ANALYSIS

M L Marques1,2, A Alunno3, L Falzon4, A Boonen5,6, S Ramiro1,7. 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Centro Hospitalar e Universitario de Coimbra, Rheumatology, Coimbra, Portugal; 3University of Uqulita, Internal Medicine and Nephrology Unit, MeSWA Department, Uquila, Italy; 4The University of Sheffield, Health Economics and Decision Science, School of Health and Related Research, Sheffield, United Kingdom; 5Maastricht University Medical Center, Internal Medicine, Maastricht, Netherlands; 6Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands; 7Zuyderland MC, Rheumatology, Heerlen, Netherlands

Background: In early RA, the benefit of treatment with b-/tsDMARDs on work participation (WP), a top-three social role in RA, has seldom been studied. Objectives: To review the effect of treatment with b-/tsDMARDs on employment status (ES), presenteeism and sick leave (SL), in patients with early RA. Methods: A systematic literature review (SLR) was conducted in key electronic databases up to October 2021, to include RCTs assessing the effect of treatment with b-/tsDMARDs vs any comparator on ES, presenteeism and SL in patients with RA (≤3y). Two reviewers independently identified eligible studies and extracted data. Random-effects meta-analysis was only performed if ≥3 studies were conducted in comparable populations, assessing WP outcome similarly. Statistical heterogeneity was assessed with $I^2$.

Results: From 7129 records (65 full-text articles screened), 11 RCTs were included in the SLR (7 in csDMARD naïve patients; 2 in inadequate responder to csDMARDs; 1 bDMARD tapering after initial combination with MTX, and 1 strategy study). Large heterogeneity was found across WP outcomes, measured using instruments, interventions and comparators (Table 1), which together with insufficient data reporting hampered meta-analysis of most outcomes. For ES, to allow meta-analysis, all outcomes were converted to employment loss, for which individual study Odds ratios (OR) were computed. The pooled OR of 4 studies with 779 patients treated with adalimumab, infliximab or baricitinib (Figure 1) showed a lower likelihood of employment loss at weeks 58 to 104 in those treated with MTX+b-tsDMARDs compared to MTX+PBO (OR: 0.65; 95% CI:0.43-0.99). For presenteeism and SL, 33/40 (83%) between-group comparisons showed improvement in favour of b-tsDMARDs, but an effect size was reported or possible to compute for only 12 comparisons, of which 8 (67%) were statistically significant.

Figure 1. The modified simplified SAMIS magnetic resonance score (mod SAMIS) scoring spreadsheet. The MRI was graded for the presence/absence of synovitis and semiquantitative ratings of bone marrow oedema and bone erosion, without contrast injection.

**Conclusion:** A protective effect against employment loss was observed in patients with early RA treated with MTX+b-mdsDMARDs compared to MTX monotherapy. The methodological heterogeneity and insufficient reporting hampers clear conclusions regarding the beneficial effects of b-SDMARDs on presenteeism and SL. Efforts to uniformize future studies with WP as outcome by following recently developed points to consider are crucial.

Methods: In a single centre prospective observational cohort of anti-CCP positive individuals with new musculoskeletal symptoms but without clinical arthritis, 394 individuals with at least 3 available longitudinal datapoints including first, second and last recordings (progression excluded), were selected. Data on anti-CCP2 antibodies (CCP2), rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), early morning stiffness duration (EMS), tender joint count on examination (TJC28), health assessment questionnaire (HAQ), absence from work in the last 3 months (sick days), and ultrasound power Doppler signal (PD) grade ≥ 1 in small joints, were assessed. Mixed model analysis on repeated measures (MANOVA) were performed, missing data were not imputed.

Results: Of the 394 selected individuals, 82 (21%) progressed to IA. In those who progressed, last visit was at a mean (SD) of 6.1 (8) months prior to progression, and total follow-up duration was 33.7 months (26.7) versus 46.5 months (30.2) for those who did not.

Within group analysis: in the progresor group there was a significant increase in the value of biomarkers at the visit prior progression for CCP2+, RF+, EMS, HAQ, and the number of joints with a PD grade ≥ 1 (Figure 1, Table 1). For sick days from prior work last visit, the increase was non-significant.

NP: Non progressors. P: progressors. P<: Partial p< for these results the assumption of homogeneity of variance was violated, as assessed by Levene’s test for equality of variances.

In the non-progresor group, only TJC28 and sick days showed significant decrease between first and last visit.

Between groups analysis showed significant differences at last visit for the following biomarkers -CCP2+, RF+, ESR, EMS, TJC28, and number of joints PD grade ≥ 1. The difference in HAQ and sick days was non-significant (Figure 1, Table 1). A significant difference was also shown in all visits for CCP2 + and RF +, and at the second visit for TJC28. For PD grade ≥ 1, differences at last visit within progresor group and between groups were only significant after selection of last visits < 3 months before progression.

Conclusion: These results show for the first time significant changes in relevant biomarkers prior to progression to IA with individual biomarkers having different trajectories. Clinical markers (EMS, TJC28, and HAQ) and ultrasound changed late, whilst immunological (CCP2 and RF values) and inflammation biomarkers (ESR) were different from baseline. These data provide valuable information for longitudinal monitoring of biomarkers, further analysis will show if these changes have predictive value for imminent progression to IA.

ANTICCP POSITIVE INDIVIDUALS AT RISK OF PROGRESSION TO INFLAMMATORY ARTHRITIS: WHAT HAPPENS TO BIOMARKERS PRIOR TO PROGRESSION?

L. Duquenne1,2, K. Hamden1,2, L. Garcia-Montoya1,2, N. Sidhu1,2, J. Nam1,2, K. Mankia1,2, P. Emery1,2, *University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, LEEDS, United Kingdom; †NIHR, Leeds Biomedical Research Centre, LEEDS, United Kingdom

Background: Although many predictors of progression to inflammatory arthritis (IA) have been identified at first visit in individuals at risk of developing IA, their fluctuation during follow-up is largely unknown.

Objectives: To describe the changes in relevant biomarkers, which precede arthritis development in anti-CCP positive at risk individuals.

Figure 1: Mixed model ANOVA on repeated measures
BACKGROUND: According to the current EULAR recommendations for the management of rheumatoid arthritis (RA), methotrexate (MTX) should be started as soon as RA is diagnosed and rapidly optimized to achieve remission. Nonetheless, it has been estimated that a difficult-to-treat (D2T) MTX disease occurs in 3-10% of RA patients. Herein, we hypothesized that D2T-RA can be prevented with an optimal MTX treatment in early stages.

OBJECTIVES: The main objective of this study was to demonstrate an association between successful optimization of MTX treatment within two years of RA diagnosis and development of a status of D2T-RA later in the disease course.

METHODS: In 2016 we started a ‘Refractory RA’ clinic at the Rheumatology Unit, University of Padua, Italy. In this retrospective cohort study conducted in December 2021, we enrolled patients fulfilling both the ACR/EULAR 2010 criteria for RA and the EULAR definition of D2T-RA diagnosed after 2000. We compared D2T-RA patients with non-D2T-RA controls from the same clinic having similar sex distribution and year of diagnosis. The primary outcome was the status of D2T-RA. The exposure was ‘MTX optimization’ after two years from diagnosis, as assessed with a numeric score (the sum of the following binary variables concerning MTX therapy: starting within 3, 12 or 24 months from diagnosis; adequate dose ≥15 mg weekly; treatment duration≥6 months; early intolerance≤3 months; range 0 to 6, with higher scores reflecting better optimization). We used multiple logistic regression analysis to examine the association (odds ratio (OR)) between MTX optimization scores and the outcome, controlling for potential modifiers (age, sex, body mass index, age at onset, and anti-citrullinated peptides antibodies (ACPA)).

RESULTS: There were 37 D2T RA patients and 107 non-D2T RA controls for the analysis (mean (SD) disease duration 12.8 (4.1) vs. 12.6 (4.6), p=0.621). Per protocol, gender (females 77.3% vs. 82.0%, p=0.247) and year of diagnosis (median [25th, 75th percentile]: 2008 [2004, 2011] vs. 2008 [2003, 2012]) were comparable between groups. Optimization of MTX therapy was poor overall, yet MTX optimization scores were significantly higher in D2T-RA than in non-D2T-RA patients (1.06 (0.21) vs. 0.56 (0.14), p<0.001). In multiple logistic regression, MTX optimization was protective against D2T-RA. Indeed, the likelihood of D2T-RA was decreased by 34%-54% according to MTX optimization scores. Other disease characteristics significantly associated with D2T-RA were an older age at diagnosis and female sex (Table 1). In December 2021 (last follow-up), D2T-RA patients were receiving a significantly higher daily dose of prednisone (4.3 (1.4) vs. 0.5 (0.2), p<0.001), and had a numerically greater burden of comorbidities (median 3 [1, 4] vs. 2 [1, 3], p=0.252) and disease activity (DAS28-ESR: 3.41 (0.40) vs. 2.6 (0.19), p=0.053) than non-D2T-RA patients.

Molecular signature in sustained clinical remission induced by tocilizumab in patients with rheumatoid arthritis

N. Keio1, K. Suzuki1, K. Matsumoto2, H. Iijima3, S. Nakamura5, Y. Ishizawa4, J. Inamo1, M. Takeshita1, K. Yoshimoto1, Y. Kaneko1, T. Takeuchi1, K. Keio University, Division of Rheumatology, Department of Internal Medicine, School of Medicine, Tokyo, Japan; 2DNA Chip Research Inc, Research Division, Tokyo, Japan

Background: Clinical remission is a clinical goal in the treatment of rheumatoid arthritis (RA). Sustained, biologics-free and true remission is an unachieved goal of the “treat-to-target” approach in most patients, and the determinants for achievement are still unclear. In our recent prospective study using multiomics analysis, we proposed that a molecular signature in peripheral whole blood can be a predictor for subsequent disease activity or activities of daily living. We also showed that tocilizumab (TCZ) induced deep clinical remission associated with gene expression in peripheral CD4+ T cells.

Objectives: To consolidate and expand our hypothesis, we investigated the significance of molecular signatures in sustained remission in a larger scale cohort.

Methods: To build and validate the diagnostic model, we collected 73 peripheral blood samples from 30 patients with active RA, 30 patients in clinical remission induced by TCZ and 13 healthy controls. Then we collected another 23 samples at a point before TCZ was halted due to sustained clinical remission. In total, 96 samples were analyzed by a multiomics platform, which included RNA sequencing and comprehensive proteomics.

Results: We first developed an optimized partial least-squares regression (PLSR) model using data from 5,436 genes and 255 proteins extracted in our previous model. The odds ratio in the model clearly reflected the clinical state at a molecular level. To clarify the characteristics of the molecular signature at sustained clinical remission under TCZ continuation, 23 samples were applied to the model. The odds ratio was largely the same as that for clinical remission. Next, we investigated the association with disease flare after cessation of TCZ. At some points before cessation, the median odds ratio in patients who experienced disease flare after stopping TCZ tended to be higher than that in patients with sustained remission after stopping TCZ in the transcriptomics model but not in the proteomics model. Thirty-five differentially expressed genes were identified between the two groups under the conditions of a >1.5-fold change and P-value<0.05.

Conclusion: Our larger scale study validated the idea in our previous study that TCZ induces molecular remission. A certain substantial gap associated with the previous model. The odds ratio in the model clearly reflected the clinical state at a molecular level.

Background: The development of RA is described by a preclinical phase of autoimmunity, that precedes clinical disease. This autoimmune phase is characterized by the presence of anti-modified protein antibodies that recognize citrullinated proteins (ACPA). A subset of individuals with ACPA develops RA, i.e. the disease onset with imaging signs of subclinical inflammation in the joints. As T cell mediated B cell activation is a key step in developing autoimmunity and RA, interventions that target this process may be useful for preventing the onset of RA. In this context, abatacept seems being an attractive therapeutic tool as it interrupts the activation of T cells and has a favourable safety profile in the treatment of RA.

Objectives: To test whether treatment of abatacept, as compared to placebo, delays the onset of RA in ACPA positive individuals with a high risk to develop RA.

Methods: ARIAA is an international, randomized double-blind placebo-controlled multi-center study in RA-at-risk individuals, being ACPA positive and showing MRI signs of inflammation. The study was composed of a 6 months treatment phase with either abatacept 125mg weekly or placebo and a 18 months observation phase with no treatment. Primary endpoint was the improvement of MRI inflammation after 6 months, secondary endpoints were the progression to RA after 6 and 18 months. The primary analysis was done on the ITT population and missing values were classified as treatment failures.

Results: Between November 2014 and December 2019 139 RA-at-risk individuals were included into ARIAA by 14 study sites (11 in Germany, 1 in the Czech Republic and 2 in Spain). Of them, 100 patients were randomized to receive either abatacept or placebo. Two patients were excluded and 98 patients could be evaluated for efficacy and safety. The primary endpoint was met: 61% of abatacept and 31% of placebo treated individuals (p=0.0043) improved in MRI inflammation. Furthermore, only 4 patients (8.2%) in the abatacept group but 17 patients in the placebo group (34.7%) progressed to RA after 6 months (p=0.0025). Even 1 year after cessation of treatment (18 months after inclusion) the number of patients progressing to RA was lower in the abatacept group (35%) than in the placebo group (57%; p=0.0421). With respect to safety, 12 serious adverse events (each one gastritis, cellulitis, pneumonia, tendinitis calcificans, rotator cuff syndrome,

Figure 1. Odds ratio in the partial least-squares regression model using transcriptomics (A) and proteomics (B) data from rheumatoid arthritis and healthy control groups

Conclusion: The clinical course of RA can be prolonged in ACPA positive individuals with high risk to develop RA. A 6 months treatment with abatacept seems being an attractive therapeutic tool as it delays the onset of RA.
cholelithiasis, peripheral artery disease, idiopathic pain syndrome, prostate cancer, penile neoplasme; trabecluometry, cataract surgery] were reported, with only one (pneumonia) being considered to be related to treatment.

**Conclusion:** Abatacept significantly reduces subclinical joint inflammation and delays the development of RA in at-risk individuals.

**Background:** Difficult-to-treat rheumatoid arthritis (D2T RA) is defined as RA in which disease activity is uncontrolled despite the use of two or more biologics or Janus kinase inhibitors (JAKi) with different mechanisms of action (MOA). Objectives: To explore the optimal treatment strategy for D2T RA, we evaluated the drug retention, efficacy, and reasons for discontinuation of biologics or JAKi used for patients with D2T RA in a longitudinal multicenter cohort.

**Methods:** RA patients with clinical disease activity index (CDAI) >10 despite the use of at least two biologics or JAKi with different MOA and further treated with biologics or JAKi were included. The drug retention rates of biologics (TNFi, IL-6Ri, and CTLA4-Ig) or JAKi were estimated at 12 months using the Kaplan-Meier method and adjusted for potential confounders (age, sex, disease duration, concomitant MTX and PSL use, and the number of switched biologics or JAKi) using Cox proportional hazards models.

**Results:** A total of 251 treatment courses (TCs) from 167 patients were included (TNFi: 97 TCs, IL-6Ri: 67 TCs, CTLA4-Ig: 27 TCs, JAKi: 60 TCs). Baseline characteristics showed no difference in age, sex, disease duration, ACPA positivity, CDAI, and concomitant MTX and PSL use between the four groups. Drug retention excluding non-toxic reasons and remission was significantly higher in patients treated with JAKi or IL-6Ri than in patients treated with TNFi or CTLA4-Ig (P<0.0012). Multivariate analysis using Cox proportional hazards models demonstrated that discontinuation of the drug was associated with the use of TNFi or CTLA4-Ig (HR: 3.29, 95%CI: 1.15-9.42, P=0.027) and concomitant PSL use (HR: 1.14, 95%CI: 1.04-1.26, P=0.0084). In terms of disease activity evaluated with CDAI, no difference was observed between the four groups at 3 months (P=0.90), at 6 months (P=0.77), and at 12 months (P=0.75).

**Conclusion:** In patients with D2T RA, JAKi or IL-6Ri may have treatment advantages compared with TNFi or CTLA4-Ig.

**REFERENCES:**

Background: The Fibrosis-4 (FIB4) score, including age, transaminases and platelets, can detect severe fibrosis (F3-F4) in patients with Non Alcoholic Steato Hepatitis (NASH) and could be of interest in the follow-up of patients with RA. Indeed, platelets contribute to the pathophysiology of RA, transaminases are used in the liver monitoring of our treatments. In addition, retrospective data suggested the association between FIB4 and mortality in RA (1).

Objectives: We aimed to evaluate the value of the FIB4 score as a prognostic factor in RA in the prospective ESPOIR cohort.

Methods: Patients of the ESPOIR cohort diagnosed with RA according to ACR/EULAR criteria were included in our analysis. The formula for the FIB4 score is as follows: \[(\text{Age (years)} \times \text{AST (U/L)}) / \text{platelet count} (10^9/L) \times \text{ALT (U/L)} - 1\]. The analyses were based on linear mixed-effects models with a random effect on the subject to account for repeated measures throughout time.

Results: 633 of the 813 patients included met the ACR/EULAR criteria for RA and had a calculable FIB4 score. Median FIB4 was 0.75 (IQR: 0.53-0.99) and 61 patients (9.8%) had a high FIB4 score at baseline. Baseline FIB4 was significantly higher in patients with a chronic alcohol consumption (p=0.021) or viral hepatitis (p<0.001). In multivariate analysis, including the main baseline prognostic factors for progression of RA (swollen Joint Count, CRP, Presence of ACPA, Rheumatoid Factor and modified Sharp score), FIB4 was not independently associated with progression of DAS28 during 10 years of follow-up, unlike baseline CRP and SJC. Baseline FIB4 was not associated with the modified Sharp score at 10-year follow-up unlike age and the presence of ACPA (Table 1). FIB4 was not associated with mortality (p=0.77) or major adverse cardiovascular events (p=0.22) during the 10-year follow-up. No significant change in FIB4 score over time was associated with mortality (p=0.77) or major adverse cardiovascular events (p=0.22).

Conclusion: Our study was the first to evaluate the value of FIB4 in a prospective cohort of RA patients. The present prospective cohort study with a 10-year follow-up did not find a prognostic role of FIB4 in RA, in contrast to previous retrospective studies. Reassuringly, FIB4 score was not increased by DMARD treatment after 10 years of follow-up, confirming the absence of long-term DMARD-related hepatotoxicity.

OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS INITIATING THERAPY WITH ETANECIGHT, ADALIMUMAB, OR JANUS KINASE INHIBITORS

D. A. Pappas1,2, J. O’brien2, L. Guo3, Y. Shan2, J. Baker2, G. Kricorian4, S. Stryker5, D. Collier4, 1Columbia University, Department of Medicine, New York, United States of America; 2CorEvitas, LLC, Research, Waltham, United States of America; 3Philadelphia Veterans Affairs Medical Center, Rheumatology and Epidemiology, Philadelphia, United States of America; 4Amgen Inc., Research, Thousand Oaks, United States of America

Background: Ongoing debate exists regarding the optimal sequence of tumor necrosis factor inhibitors and Janus kinase inhibitors (JAKis) in patients with rheumatoid arthritis (RA) as first-line biologic or targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD) therapy following conventional therapies. The frequency of switching to another b/tsDMARD was similar across ETN ADA, and JAKis (tofacitinib, baricitinib, and upadacitinib).

Methods: Data on patients who initiated b/tsDMARD from 11/2012 to 6/2021 were obtained from the CorEvitas RA Registry, a prospective, multicenter, observational, disease-based registry. Patients ≥18 years with rheumatologist-diagnosed RA and 6- and/or 12-months’ (M) follow-up were included. We report descriptive statistics at baseline, persistency on therapy, escalation/de-escalation of therapy, details on patterns of drug switching, and effectiveness outcomes using regression models adjusted for baseline covariates (demographic/socio-economic/lifestyle characteristics, comorbidities, medication history, disease activity, and patient-reported outcomes). Outcomes were evaluated at 6M and 12M follow-up.

Results: First-line initiators of ETN, ADA, and JAKis with baseline and follow-up visits were identified: 803, 984, and 361 patients at 6M, respectively; 589, 749, and 264 patients at 12M, respectively. Baseline characteristics were similar among ETN, ADA, and JAKis initiators with the exception of disease duration, which was longer among first-line JAKi initiators (mean, 8.6 y) versus ETN (5.9 y) and ADA (5.8 y) initiators. Unadjusted mean improvement in Clinical Disease Activity Index (CDAI) was generally similar between groups at 6M and 12M (Table 1). Adjusted effectiveness results were similar at 6M and 12M (Figure 1). At 6M, 68% of ETN, 69% of ADA, and 67% of JAKi initiators remained on the same therapy; at 12M, 53% of ETN, 57% of ADA, and 57% of JAKi initiators remained on the same therapy. The frequency of switching to another b/tsDMARD was similar across initiators.

| Table 1. Patient Description at Time of Initiation and Unadjusted Disease Activity Results |
|-----------------------------------------------|-----------------|-----------------|-----------------|
| Age, years                                    | ETN             | ADA             | JAKis           |
| Female, n (%)                                 | 54.4 (12.8)     | 55.5 (12.1)     | 60.9 (12.5)     |

*Baseline for combined population with 6M and 12M follow-up. \( \beta \) range: 0–100. \( \beta \) CDAI ≤10 among those with moderate or high disease activity at baseline. Data are mean (SD) unless otherwise specified. ADALUMAB: BL baseline; CDAI, Clinical Disease Activity Index; ETN: etanercept; JAKIS, Janus kinase inhibitors; LDA, low disease activity; M, months; mHAQ, modified Health Assessment Questionnaire; RA, rheumatoid arthritis; SD, standard deviation.

Conclusions: In this real-world study in patients initiating first-line b/tsDMARD therapy with ETN, ADA, or JAKIs, we did not observe differences in effectiveness outcomes.
REFINING THE SEROLOGICAL SCORES OF THE ACR/EULAR 2010 RHEUMATOID ARTHRITIS CLASSIFICATION CRITERIA: AN INTERNATIONAL STUDY

1KU Leuven, Department of Microbiology, Immunology and Transplantation, Leuven, Belgium; 2OLV Hospital, Department of Laboratory Medicine, Aalst, Belgium; 3OLV Hospital, Department of Rheumatology, Aalst, Belgium; 4Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria; 5Ghent University, Department of Internal Medicine, Ghent, Belgium; 6Ghent University, Department of Diagnostic Sciences, Ghent, Belgium; 7National Institute of Locomotor disease and Disabilities, Department of Laboratory Medicine, Budapest, Hungary; 8Sahlgrenska University Hospital Gothenburg, Department of Clinical Immunology and Transfusion Medicine, Gothenburg, Sweden; 9University Medical Center Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 10Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection, Linköping, Sweden; 11University Hospital Basel, Department of Laboratory Medicine, Basel, Switzerland; 12Kantonsspital Aarau, Department of Laboratory Medicine, Aarau, Switzerland; 13Centre Hospitalier de Luxembourg, Department of Laboratory Medicine, Luxembourg, Luxembourg; 14AZ Sint-Elisabeth, Department of Laboratory Medicine, Zottegem, Belgium; 15AZ Rivierenland, Department of Laboratory Medicine, Bornem, Belgium; 16AZ Sint-Lucas, Department of Laboratory Medicine, Bruges, Belgium; 17National Institute for Biological Standards and Control, NIBSC, Hertfordshire, United Kingdom; 18Centre Hospitalier de Luxembourg, Department of Rheumatology, Luxembourg, Luxembourg; 19Rheumazentrum Ostschweiz, Department of Rheumatology, St. Gallen, Switzerland; 20University Hospital Basel, Department of Rheumatology, Basel, Switzerland; 21Linköping University, Division of Inflammation and Infection, Department of Biomedical and Clinical Sciences, Linköping, Sweden; 22National Institute of Public Health and the Environment, Department of Clinical Immunology, Budapest, Hungary; 23University Hospital Ghent and VIB - Institute for Inflammation Research, Department of Rheumatology, Ghent, Belgium; 24Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Department of Rheumatology, Vienna, Austria; 25University Hospital Leuven, Department of Rheumatology, Leuven, Belgium; 26University Hospital Leuven, Department of Developmental and Regenerative KULeuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium; 27University Hospital Leuven, Department of Laboratory Medicine, Leuven, Belgium

Background: Rheumatoid factor (RF) and anti-cyclic citrullinated protein/peptide antibodies (ACPA) are included in the ACR/EULAR 2010 classification criteria for rheumatoid arthritis (RA)(1). Both markers are given the same weight in the criteria.

Objectives: As the performance characteristics differ significantly between RF and ACPA(2), we set out to refine the serological scores for RA classification.

Methods: Diagnostic samples from 398 RA patients and from 1073 diseased controls were evaluated with five RF assays (two RF IgM isotype-specific assays and three total RF assays) and five ACPA IgG assays from five different manufacturers.

Results: Firstly, we harmonized thresholds between manufacturers based on predefined specificity for low positive (at 92.5% specificity for RF and at 97.5% specificity ACPA) and high positive results (at 97.5% specificity RF and at 99.0% specificity for ACPA). Next, we determined likelihood ratios (LRs) for RF, ACPA, and combinations of both, for negative, low positive, and high positive results. The LR was higher for ACPA than for RF, for high positive results than for low positive results and for double positivity than for single positivity. Based on these data we refined the weights of serological scores for classification (Table 1).

Table 1. Refined weights of serological scores for RA classification

<table>
<thead>
<tr>
<th>RF negative</th>
<th>RF low positive</th>
<th>RF high positive</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>ACPA low positive</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>ACPA high positive</td>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

Application of such refined serological weights significantly increased the area under the curve of receiver operating characteristics analysis to distinguish RA from controls, significantly reduced the serological scores in the controls as well as the number of RA misclassifications without affecting the diagnostic sensitivity. Besides, we showed that combining predefined specificity thresholds with the refined serological scoring, reduced manufacturer-dependent variability in RA classification impacting RA classification for controls from 18.0-29.0% by ACR/EULAR to 11.0-13.0% (significantly increasing specificity) and for RA patients from 67.8-74.0% to 67.6-71.5% (without significantly affecting sensitivity).

Conclusion: Serological weight factors for RA classification can be improved by taking into account the antibody type (RF versus ACPA), the antibody level, and single or double positivity.

POS0537 MORTALITY IN RHEUMATOID ARTHRITIS: CHANGING CAUSES AND PREDICTIVE FACTORS. STUDY OF A COHORT FOLLOWED PROSPECTIVELY

C. Corrales-Selaya1, F. Benavides-Villanueva1, I. Ferraz-Amaro2, N. Vegas-Revenga3, V. Portilla1, R. Blanco1, M. A. González-Gay1, A. Corrales1

1Marqués de Valdecilla University Hospital, Nursing, Santander, Spain; 2Hospital Universitario de Canarias, Rheumatology, San Cristóbal de La Laguna, Spain; 3Hospital de Galdakao-Usansolo, Rheumatology, Galdakao, Spain; 4Marqués de Valdecilla University Hospital, Nursing, Santander, Spain

Background: Patients with Rheumatoid Arthritis (RA) present an increased risk of mortality. In the last decades, mortality rates tended to decrease but also cardiovascular (CV) events remained as the leading cause of death in most series (1). Objectives: To assess mortality rates and leading causes of death, as well as predictors of mortality related to disease activity in a prospectively followed cohort of RA patients. Methods: We conducted a prospective longitudinal study that included 673 RA patients from a single tertiary center. Univariate and multivariate Cox proportional hazards regression were used to identify predictors of mortality. Results: We studied 673 patients with RA (75% women), mean age 61±13 years. The main general characteristics, CV risk factors, RA disease activity data and current treatment are summarized in the Table 1.

Table 1. Baseline characteristics of 673 RA patients

Conclusion: In a cohort of patients with RA followed prospectively in a tertiary hospital, infections and malignancies are the main cause of mortality rather than CV events. Disease activity parameters are associated with an increased risk of mortality in these patients with RA.

<Figure 1> Forest Plot of mortality (Univariate and multivariate analysis). Results expressed in logarithmic scale. Multivariate analysis: Disease activity related parameters adjusted by age, gender, disease duration, smoker, diabetes, hypertension and abdominal circumference. All models, ESR and CPR expressed value/10. (*) p<0.05.

POS0538 PREDICTING VALUE OF CIRCULATING SEMAPHORIN 4A FOR RHEUMATOID ARTHRITIS PROGRESSION

J. Avouac1, E. Vandebeuque1, A. Combier1, L. Poiroux1, A. Steelandt1, M. Boisson1, V. Gonzalez2, A. Cauvet1, Y. Allanore1, 1Cochin Hospital, Rheumatology, Paris, France; 2Cochin Institute, INSERM U1016, Paris, France

Background: The lack of validated tools to predict rheumatoid arthritis (RA) disease course warrants the development of new reliable biomarkers. We have previously detected increased SEMA4A expression in endothelial cells, synovial tissue, and serum of patients with RA. In addition, SEMA4A serum levels correlated with multiple clinical, biological, and power doppler ultrasound markers of disease activity and angiogenesis (1).

Objectives: To evaluate the merit of circulating semaphorin 4A (SEMA4A) for the prediction of disease progression in RA patients.

Methods: Prospective monocentric observational study including consecutive RA patients between May 2016 and February 2018 with available SEMA4A concentrations, measured by quantitative ELISAs (Coud-Clone Corp, Katy, TX). Increased SEMA4A concentrations were defined as values >94 ng/mL, as previously reported (1). Patients were followed up on an annual basis until August 2021. Primary endpoints were the occurrence of patient-reported flares with swollen joints and the necessity to initiate or change a targeted biologic or synthetic disease-modifying anti-rheumatic drugs.

Results: A total of 101 patients (86 females, 84%) were included, with a mean age of 58±13 years and a mean disease duration of 14±11 years. During a follow-up period of 41±15 months, disease flares occurred in 38 patients and targeted therapy was added or modified in 26 patients because of insufficient disease control. Increased baseline SEMA4A levels were predictive of flares and treatment escalation (hazard ratio, HR: 2.43, 95% confidence interval, CI 1.07-4.68 and 2.73, 95% CI 1.24-5.96, respectively) (Figure 1A-B). Multivariate
Cox analyses confirmed that SEMA4A was an independent predictors of flares and treatment escalation (HR: 2.12, 95%CI 1.04-4.32 and 2.71, 95%CI 1.14-6.43, respectively), and revealed that DAS28-CRP and synovial hyperemia were independent predictors of flares. Baseline age, disease duration, ACPA or RF positivity, smoking status, presence of erosions, line of targeted DMARDs, treatment with corticosteroids and CRP levels were not predictive of these outcomes. SEMA4A maintained predictive of flares and treatment escalation in the 58 patients with a DAS28 <3.2 at baseline (HR: 3.68, 95%CI 1.33-10.17 and 3.50, 95%CI 1.02-12.01, respectively). Baseline SEMA4A levels also identified more active and difficult to treat patients who maintained higher mean DAS28-11 values during the follow-up period (Figure 1C). The highest predictive value of flares and treatment escalation was obtained with the combination of increased circulating SEMA4A and/or DAS28-3.2 and/or the presence of synovial hyperemia on power-doppler ultrasound (HR:4.88, 95%CI 1.41-78.94, respectively).

</table>

**Figure 1. Kaplan Meier survival curve of time to remission.**

**Conclusion:** LORA and YORA patients had similar prognosis in terms of time to remission. At remission, LORA patients were more likely to be on a single csDMARD without biological or JAK inhibitor. Clinicians should take the same approach for all RA patients targeting remission regardless of age of onset.

**DOI:** 10.1136/annrheumdis-2022-eular.2492
Background: Patients (pts) with rheumatoid arthritis (RA) are often administered glucocorticoids (GCs) as bridging therapy when initiating or adjusting disease-modifying antirheumatic drugs (DMARDs). Due to their systemic effects, short-term use of GCs at the lowest possible dose is recommended with rapid tapering. 

Objectives: We describe GC discontinuation patterns and the associated clinical outcomes in pts with RA receiving upadacitinib (UPA) or adalimumab (ADA).

Methods: SELECT-COMPARÉ is a randomized phase 3 trial of UPA vs placebo and ADA with a 48-week (wk) double-blind treatment period and a 10-year long-term extension in pts with RA receiving concomitant methotrexate (MTX) who had an inadequate response to MTX. Background GCs (≤10 mg/day prednisone or equivalent) were permitted and could be tapered or discontinued starting at wk 26 per physician discretion. This post hoc analysis included pts who received ≥1 dose of UPA 15 mg once daily or ADA 40 mg every other wk while on concomitant GCs at baseline. The proportion of pts with disease worsening (Clinical Disease Activity Index [CDAI] >2 and Disease Activity Score 28-joint count C-reactive protein [DAS28-CRP] >0.6) following GC discontinuation through follow-up is described. Maintenance of clinical response, including remission and low disease activity based on CDAI ≤2 and ≤10, respectively, as well as DAS28-CRP <2.6 and ≤3.2, were assessed among pts who discontinued GCs. Adverse events (AEs) were assessed before and after GC discontinuation through follow-up. Data were analyzed descriptively.

Results: Of 1,629 pts randomized, 978 (60%) used GCs at baseline; 128 (13%) discontinued use at/after wk 26 (UPA, n=97; ADA, n=31). Baseline demographics and clinical characteristics were broadly similar between pts who continued or discontinued GCs. Median follow-up time after GC discontinuation was 60 wks for UPA and 84 wks for ADA. At the time of GC discontinuation, a numerically higher proportion of pts treated with UPA vs ADA were in disease control (CDAI ≤2; 55% vs 32%; CDAI ≤10: 85% vs 68%; DAS28-CRP <2.6: 71% vs 48%; DAS28-CRP ≤3.2: 87% vs 62%) (Table 1). Few pts receiving UPA experienced disease worsening following GC discontinuation (1% CDAI increase >2; 7% DAS28-CRP increase >0.6) and none on ADA (Table 1). At 6 months follow-up after GC discontinuation, most pts treated with UPA and ADA maintained CDAI ≤2.8 (74% vs 88%) and ≤10 (92% vs 95%) and DAS28-CRP <2.6 (89% vs 85%) and ≤3.2 (91% vs 94%), respectively (Table 1). GCs were reintroduced (albeit usually temporarily) in 14% of pts on UPA and 19% on ADA (Figure 1). AEs were generally similar across treatment groups. Rates of serious infection before and after GC discontinuation were 0.8 (95% CI 0.0–4.2) and 1.5 (0.2–5.4) events per 100 patient-years (E1/100 PY) for UPA and 7.7 (16–22.4) and 0 E1/100 PY for ADA, respectively. Interpretation of results is limited by small pt numbers and different exposure times.

Conclusion: In pts who achieved disease control and discontinued GCs, disease control was maintained in almost all without worsening disease activity over time following GC discontinuation.

*As a proportion of pts achieving outcome at GC discontinuation and with observed data 6 months post GC discontinuation.
Methods: Clinical (CDAI, SDAI, and DAS28-CRP) and laboratory data (CRP, ESR, CBC with differential, and Lipids) for all available patients enrolled in the SELECT-COMPARE phase 3 study were included in this post-hoc analysis (UPA: n = 623 [CDAI REM at wk26 = 23.8%]; ADA: n = 516 [CDAI REM at wk 26 = 14.2%]). Patients who switched treatment between weeks 14 and 22 due to not reaching at least 20% improvement in tender and swollen joints were classified as non-responders for CDAI REM at week 26. The predictive value of clinical and laboratory endpoints recorded at week 12 for determining CDAI REM status at week 26 was assessed by univariate logistic regression. We report the performance of each model as ROC AUC with a cutoff of 0.75 for meaningful predictive value.

Results: For both patients treated with UPA and those treated with ADA, clinical disease activity status measures (CDAI, SDAI, and DAS28-CRP) and relative change in disease activity measures (Percent Change [PCHG] in CDAI, PCHG in DAS28-CRP, and PCHG in SDAI) at week 12 resulted in the highest predictive performance for determining CDAI REM status at week 26 (Figure 1). In contrast, none of the selected standard laboratory measures (CRP, ESR, CBC with differential, and Lipids) reached a meaningful predictive value (ROC AUC < 0.75). Of note, cell numbers and changes in cell numbers (including Neutrophils, Lymphocytes, Basophils, Eosinophils, and Monocytes) at week 12 had no meaningful predictive value for determining CDAI REM at week 26.

Conclusion: This analysis suggests that standard laboratory measures (CRP, ESR, CBC with differential, and Cholesterol) at week 12 do not represent useful predictors for REM at week 26 in csDMARD-IR RA patients. In particular, blood cell numbers and the changes in these measures at week 12 do not provide additional predictive value in our analyses, contrasting with the results from Amarnani and colleagues. Hence, clinical disease activity levels and changes in these measures at week 12 remained adequate predictors of CDAI REM at week 26. Still, the absolute predictive performance of clinical measures remains suboptimal, highlighting the need to dedicate continued efforts to identify and validate improved predictors of long-term REM in RA.

Results: We included 435 patients from the ESPOIR cohort, 243 patients from the Leiden cohort and 143 patients from the tREACH cohort. Results of the model are displayed in Table 1. The variables automatically selected to perform prediction were Sex, DAS28, White blood cells, AST, ALT and lymphocytes. Our model performs well on unseen data, this result comes from the fact that we included two different cohorts in our training set which reduces the overfitting of our model and helps him generalize. Our model predicts a probability for a patient to respond to MTX. This probability is compared to a decision threshold to obtain the final binary outcome. Two decision thresholds were tested. The first prioritizes a high confidence when identifying responders (Strategy 1) while the second prioritizes a high confidence when identifying non-responders (Strategy 2). This second strategy would enable physicians to identify highly probable inadequate responders to methotrexate and propose them directly a targeted DMARD such as TNF inhibitors, while still treating more than 70% of patients with MTX as first-line treatment.

Conclusion: The machine learning models developed in this study can predict RA patients’ response to methotrexate with a good accuracy exclusively using data available in clinical routine. It paves the way for personalized therapeutic strategies in rheumatoid arthritis.

Background: Methotrexate (MTX) is the first line of treatment for rheumatoid arthritis (RA) patients. Unfortunately, 30% to 40% of RA patients do not respond to MTX, resulting in uncontrolled joint pain and potential joint destruction. At the same time, many efficient second-line treatments exist and can be given to the inadequate responder patients. Predicting patient response to MTX before prescribing the treatment is therefore a major goal and could enable physicians to directly prescribe second-line treatments if inadequate response to MTX is predicted.

Objectives: We aimed to build machine learning models based on simple clinical and biological data to predict patient response to MTX.

Methods: We used data from the ESPOIR early arthritis (1) and Leiden cohorts (2) to train the models, and the tREACH cohort to validate the results. We included patients that fulfilled the EULAR/ACR 2010 criteria and that were treated with MTX in monotherapy as their first treatment for RA. The models take as input patient’s characteristics at treatment initiation and predict the therapeutic response, defined as the EULAR response score 3 to 12 months after treatment initiation. We evaluated four missing data imputation methods (median, mean, MICE, KNN); we used the backward feature selection algorithm to select the most relevant variables; and compared the performances of four models (Linear Regression, Random Forest, XGBoost, and Catboost) on the training set by cross-validated them using the Area Under the ROC Curve (AUCROC). The best model was then evaluated on the validation dataset.

Results: We included 435 patients from the ESPOIR cohort, 243 patients from the Leiden cohort and 143 patients from the tREACH cohort. Results of the model are displayed in Table 1. The variables automatically selected to perform prediction were Sex, DAS28, White blood cells, AST, ALT and lymphocytes. Our model performs well on unseen data, this result comes from the fact that we included two different cohorts in our training set which reduces the overfitting of our model and helps him generalize. Our model predicts a probability for a patient to respond to MTX. This probability is compared to a decision threshold to obtain the final binary outcome. Two decision thresholds were tested. The first prioritizes a high confidence when identifying responders (Strategy 1) while the second prioritizes a high confidence when identifying non-responders (Strategy 2). This second strategy would enable physicians to identify highly probable inadequate responders to methotrexate and propose them directly a targeted DMARD such as TNF inhibitors, while still treating more than 70% of patients with MTX as first-line treatment.

Conclusion: The machine learning models developed in this study can predict RA patients’ response to methotrexate with a good accuracy exclusively using data available in clinical routine. It paves the way for personalized therapeutic strategies in rheumatoid arthritis.

39 patients started anti-JAK therapy and 21 with TNF-α inhibitors. The 33.34% of patients were under monotherapy, and the 46.67% previously had been treated with biological therapy. The 77.36% of the total number of patients was on the biological therapy at 6 months of follow-up, while the 22.64% discontinued at 6 months of follow-up (9 due to inefficacy and 3 due to adverse effects). 48 patients continued the treatment in the 6 months after, and 12 patients discontinued due to ineffectiveness or drug intolerance. Clinical activity, fatigue, disability and pain perception are shown in Table 1.

Using a mixed linear regression model the association among the fatigue, disability and pain perception with clinical activity was conducted, corrected by age, smoking habits, time of disease evolution, BMI, previous biological/anti-JAK therapy administration and current dose of steroids. We observed a significant association among clinical activity and fatigue (P<0.001), disability (P<0.001) and pain perception (P<0.001). The statistical analyses showed a significant association where a high fatigue is increased in cases with high pain perception (P<0.001) and high number of swollen joints (P=0.002), but not in high levels of CRP and ESR. Fatigue was higher in those cases whom discontinued treatment (P=0.044) regardless of which therapy was chosen. No effect of age, time of disease evolution, steroid dose, BMI or previous therapy and smoking habits in the PROs values was observed.

Conclusion: PROs would be helpful in the disease control in those cases where a remote monitoring is needed, since HAQ or FACIT-FATIGUE index showed a significant association with clinical activity index in RA. Because of its ease for shipping and handling, PROs, especially in professional, PROs could be a useful tool in the disease control. Its implementation in the remote monitoring of RA patient, as has been the case of Covid19 pandemic, results in an improvement of the clinic evaluation of RA patients due to required information to clinical management is reported, avoiding delays in the treatment of Covid19 pandemic.

OBJECTIVES:

To evaluate the urinary metabolic profile of patients with rheumatoid arthritis and associate it with skeletal muscle loss.

METHODS:

We recruited patients aged 40–70 years with RA according to the 2010 ACR/EULAR classification criteria. We measured disease activity by the following variables regarding the aforementioned outcomes, without affecting the clustering process. We evaluated the corresponding weights and their influence on the proposed neural network.

RESULTS:

Data from a total of 1,277 patients were included in the analysis. When both continuous and discrete variables were integrated, discrete data were transformed using the one-hot encoding method, creating new variables according to the corresponding number of categories. Dissimilarity between groups was very low when considering only the continuous variables, and it increases when adding all the other variables; likewise, regardless of the clinical metric index used for labeling, the clustering organization remains (Figure 1a).

Figure 1. Clusters and heatmaps of variables’ weights

In the construction of the groups, the influence of the RF and ACPA positivity was confirmed; furthermore, the antinuclear antibodies (ANAs) delivered a significant effect, especially those with negative ANAs or positive ANAs with a homogeneous pattern, on disease activity (Figure 1b).

Conclusion: SOM, as well as other artificial neural networks (ANN) are important methods for clustering and 2D visualization, due to the multivariate nature of the clinical data and its difficult visualization in the generated n-dimensional hyper-space. The utilized labels confirm that the clustering is adequate when considering that there was an identical grouping behavior for those registers with similar characteristics and an equivalent disease activity score. The findings of this research provide insights into a potentially pivotal role of the influence of RF, ACPA, and ANAs and their interaction with the proposed outcome variables in the understanding and development of future classification or prediction models; based on artificial intelligence and big data methods rather than on classical epidemiological approaches.

A NEURAL NETWORK BASED CLUSTERING MODEL OF A COLOMBIAN COHORT OF RHEUMATOID ARTHRITIS PATIENTS

K. J. Franco-Cuevres1, K. Maladonado-Cañón2, L. F. Niño Vásquez2, G. Quintana López1,2,3,5; 1Universidad Nacional de Colombia, Reumavance research group. LSI research group, Bogotá, Colombia; 2Fundacion Santa Fe de Bogota University Hospital, Reumavance research group. Department of Internal Medicine, Bogotá, Colombia; 3School of Engineering - Universidad Nacional de Colombia, LSI research group. Department of Systems and Industrial Engineering, Bogotá, Colombia; 4School of Medicine - Universidad de los Andes, Department of Internal Medicine, Bogotá, Colombia; 5School of Medicine - Universidad Nacional de Colombia, Department of Internal Medicine, Bogotá, Colombia

Background: Rheumatoid Arthritis (RA) is a chronic disease characterized by inflammation and joint pain. In daily clinical practice, it is usual to have multiple variables of different nature to define the current state of the disease, the patient's risk profile, and the subsequent optimal treatment.

Objectives: We aimed to identify the most influential variables from a suitable multivariable clustering and its labeling for an outpatient clinic-based cohort of Colombian RA patients.

Methods: We execute a clustering model (Kohonen's self-organizing map – SOM), applied to 23 variables (17 continuous and 6 discrete) obtained from 14,811 related follow-up visit records hosted on a previously preprocessed database of a cohort with data prospectively collected between 2013 and 2020. The included variables were the disease activity indexes (DAS28-ESR/CRP, CDAI, and SDAI; as outcome variables), serological status (autoantibodies positivity), and patients' sociodemographic and clinical characteristics. Clustering method used for generating the groups was SOM with a size of 25 x 25 neurons and 10000 iterations. SOM allows us to generate the groups by the comparison of the Euclidean distance in the hyperspace generated by the dimensions composed by the variables. After clustering, a discrete label built upon the categorization of the disease activity allowed us to identify the behavior of the included

POS0546

URINARY METABOLOMIC BIOMARKER CANDIDATES FOR SKELETAL MUSCLE WASTING IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. De Oliveira1, R. Cavalcheiro Do Espirito Santo1, R. Xavier1, P. Alabarse2, J. Miranda de Souza Silva1on behalf of Laboratory of Autoimmune Diseases - HCPA. 1Clinicas Hospital, Rheumatology, Porto Alegre, Brazil; 2University of California, Rheumatology, San Diego, United States of America; 3University Hospital Münster, University Hospital Münster, Münster, Germany

Background: Rheumatoid arthritis (RA) is an autoimmune disease that affects the joints, leading to chronic synovial inflammation and local tissue destruction. Extra-articular manifestations may also occur, such as changes in body composition. Skeletal muscle wasting is often observed in patients with RA, but methods for assessing loss of muscle mass are expensive and not widely available, limiting their use in clinical practice and their evaluation in longitudinal studies. Metabolomic analysis has shown great potential for identifying changes in the metabolite profile of patients with autoimmune diseases and can advance our understanding of pathogenic mechanisms, early diagnosis, treatment, and follow-up. In this setting, urine metabolomic profiling in patients with RA may be a useful tool to identify skeletal muscle wasting.

Objectives: To evaluate the urinary metabolic profile of patients with rheumatoid arthritis and associate it with skeletal muscle loss.

Methods: We recruited patients aged 40–70 years with RA according to the 2010 ACR/EULAR classification criteria. We measured disease activity by the
A. Disease Activity Score in 28 joints using the C-reactive protein level (DAS28-CRP). We determined muscle mass according to DXA-derived appendicular lean mass index (ALMI) by summing the lean mass measurements for both arms and legs and dividing them by height squared (kg/height^2). We performed urine mass index (ALMI) by summing the lean mass measurements for both arms and legs and dividing them by height squared (kg/height^2). We performed urine mass index (ALMI) by summing the lean mass measurements for both arms and legs and dividing them by height squared (kg/height^2). We performed urine mass index (ALMI) by summing the lean mass measurements for both arms and legs and dividing them by height squared (kg/height^2).

B. Figure 1. Disease Activity Score in 28 joints using the C-reactive protein level (DAS28-CRP). We determined muscle mass according to DXA-derived appendicular lean mass index (ALMI) by summing the lean mass measurements for both arms and legs and dividing them by height squared (kg/height^2). We performed urine metabolomic analysis by nuclear magnetic resonance (NMR) spectroscopy using the BAYESIL and MetaboAnalyst software packages. We performed principal component analysis (PCA) and partial least squares-discriminant analysis (PLS-DA), followed by Spearman's correlation analysis. We set the significance level at p<0.05 for all analyses. We combined Receiver Operating Characteristic Curve (ROC) and logistic regression analyses to establish a diagnostic model.

Results: We included 90 patients with RA. Most patients were women (86.7%), with a mean age of 56.5 (SD, 7.3) years and a median DAS28-CRP of 3.0 (IQR, 1.0–3.0). We identified 15 metabolites that showed high variable importance in projection (VIP scores) by MetaboAnalyst. Of these, dimethylglycine (r=0.205; p=0.053), oxo-isovalerate (r=−0.203; p=0.055) and isobutyric acid (r=−0.249; p=0.018) were significantly correlated with ALMI. Based on low muscle mass (ALMI ≤5.0 kg/m² for women and ≤8.1 kg/m² for men), we established a diagnostic model with dimethylglycine (Area Under the Curve - AUC=0.65), oxo-isovalerate (AUC=0.49) and isobutyric acid (AUC=0.83), with significant sensitivity and specificity.

Conclusion: Isobutyric acid, oxo-isovalerate and dimethylglycine from the samples were associated with low skeletal muscle mass in patients with RA. These findings suggest that this group of metabolites may be further tested as biomarkers for identification of skeletal muscle wasting.

POS0547 THE ADVANTAGE OF TIGHT CONTROL AND TREAT TO TARGET IN NEW-ONSET RA PATIENTS IN DAILY RHEUMATOLOGY PRACTICE: RESULTS FROM A CONTEMPORARY UNIVERSITY CLINIC INCEPTION COHORT

J. T. Einasson1, K. Fribjerger Pajalic1, C. Bengtsson1, E. Mogard1, E. Lindqvist1, C. Roseman1, O. Palsson1, J. K. Wallman1, T. Olsson1, M. C. Kapetanovic1, 1Lund University, Department of Clinical Sciences, Lund, Section for Rheumatology, Lund and Skåne University Hospital, Lund, Sweden, Lund, Sweden; 2Faculty of Medicine, University of Iceland, Reykjavík, Iceland, Faculty of Medicine, University of Iceland, Reykjavík, Iceland, Reykjavik, Iceland

Background: Since 2018, all patients with new-onset rheumatoid arthritis (RA) at the Department of Rheumatology, Skane University Hospital, Lund, Sweden, are offered to participate in a "tight control" and "treat to target" (TC+T2T) follow-up strategy. This strategy includes regular follow-up visits to a rheumatologist (at diagnosis and 3, 6, 12, 18, 24 months) plus physical/telephone consultations with a rheumatology nurse between physician visits, both with disease activity assessments and, if needed, adjustment/intensification of anti-rheumatic treatment aiming for remission.

Objectives: To explore the possible advantages of integrating this TC+T2T strategy over routine care, aiming more systematically for remission (DAS28<2.6 or CDAI≤2,8), in clinical practice of new-onset RA.

Methods: Patients followed by the TC+T2T strategy were compared to new-onset RA patients followed according to routine care at the same department and during the same period. Data on disease and treatment characteristics, as well as outcome measures during follow-up were retrieved from the Swedish Rheumatology Quality register (SRQ). In total, 156 patients with at least 3 months follow-up between 2018 and 2021 were included; 95 followed according to the TC+T2T strategy and 61 according to routine care. Percentage females/mean age at onset/mean symptom duration at diagnosis were 79%/57 years/4 months (TC+T2T) and 62%/62 years/7 months (routine care).

Results: Disease and treatment characteristics at inclusion (diagnosis) are summarized in the Table 1.

Disclosure of Interests: None declared.

The TC+T2T strategy resulted in greater improvements in DAS28 and CDAI scores from inclusion to 12 months follow up (p=0.025 and p=0.026; respectively; Figure 1). Beyond improvements in DAS28 and CDAI, a significant decrease in patient-reported outcomes (fatigue and pain) during 12 months from diagnosis was observed (Figure 1).

Conclusion: Compared to routine rheumatology practice, the implementation of a “tight control” and “treat to target” strategy resulted in a greater improvement in disease activity and an early and sustained improvement in patient-reported outcomes. Our results suggest that this type of strategy should be integrated into daily clinical practice of new-onset RA.

EVALUATION OF PHYSICIAN GLOBAL ASSESSMENT IN PATIENTS WITH BT/SDMARD THERAPY SELECTION ALIGNED WITH A MOLECULAR SIGNATURE RESPONSE CLASSIFIER RESULTS: AN ANALYSIS FROM THE STUDY TO ACCELERATE INFORMATION OF MOLECULAR SIGNATURES (AIMS) IN RHEUMATOID ARTHRITIS

E. Connolly-Strong1, L. Zhang2, S. Asgarian1. 1Scipher medicine, Medical Affairs, waltham, United States of America; 2Scipher medicine, Data Science, waltham, United States of America

Background: Despite drug therapies that improve lives, tens of millions of patients annually are prescribed therapy using a “trial and error” approach because, until recently, it was not possible to personalize treatment using a patient’s unique molecular profile. A blood-based molecular signature response classifier (MSRC) was shown to predict non-response to TNFi therapies in patients. MSRC integrates disease-associated RNA transcripts, and clinical features (anti-CCP, sex, BMI, PGA). A recent study demonstrated that patient response to treatment informed by MSRC was more or less responsive TNFi therapies.

Scientific Abstracts
Background: Rheumatoid arthritis (RA) is a kind of autoimmune disease characterized with chronic aggressive arthritis, presence of abnormal antibodies and persistent synovitis[1]. However, the pathogenesis of RA remained unclear by now. Several observations have showed that the breakdown of immune tolerance was involved in the development of RA. T follicular regulatory (Tfr) cells and T follicular helper (Tfh) cells, as a new subset of CD4+ T cell, can exert an opposite effect in the regulation of humoral immunity[2]. Intensive researches have showed that the imbalance of Tfr/Tfh cell is related to the pathogenesis and development of autoimmune disease. There is still a lack of understanding of the relationship between Tfr/Tfh and RA, which needs further exploration.

Objectives: To detect the expression of Tfh and Tfr cells in peripheral blood of patients with new-onset RA and healthy controls, and to explore the role of Tfh and Tfr cells in the pathogenesis and development of RA.

Methods: We enrolled 26 patients with new-onset RA who hospitalized at the Second Hospital of Shanxi Medical University from the June 2021 to the November 2021. And 17 age and gender-matched healthy adults were anticipated as controls. The absolute number of Tfh and Tfr cells in peripheral blood was detected by flow cytometry. Disease activity indicators were collected including erythrocyte sedimentation rate (ESR, mm/h) and Disease Activity Score in 28 joints (DAS28). Then we compared the expression of Tfr and Tfh cells between the patients and healthy controls and conducted the correlation analysis with disease activity.

Results: There was significant decreased level of Tfr cells in the patients with new-onset RA compared with healthy controls (P<0.001) and a lower ratio of Tfr/Tfh in the patients (P<0.01). The reduced Tfr cells and Tfr/Tfh were significant negative correlation with the disease activity indicators including ESR and DAS28. Statistical analyses were performed by the Spearman correlation analysis.

Conclusion: The results we investigated here showed that new-onset RA exhibited an imbalance of Tfr/Tfh, specifically reduced Tfr cells, compared with healthy controls, which were negatively correlated with higher disease activity in RA. It was likely that the imbalance of Tfr/Tfh in peripheral blood played an important role in the development of RA, which may be a target to treat RA.

**Methods:** The IMAGINE-more trial was designed as an extension protocol to the 2-year IMAGINE-RA randomised controlled trial (RCT). IMAGINE-RA included 200 RA patients, in clinical remission (DAS28-CRP<3.2 and no swollen joints), who received conventional synthetic disease-modifying antirheumatic drugs (csDMARD) and investigated whether an MRI T2T strategy targeting absence of osteitis in combination with clinical remission (DAS28-CRP<3.2 and no swollen joints) could increase remission rates and prevent erosive progression compared with a conventional T2T strategy targeting clinical remission only. If target was not met, treatment was escalated according to a predefined treatment algorithm starting with increment in csDMARDs and then adding biologics. At the end of the study, participants were invited to participate in the IMAGINE-more follow-up study. Patients were managed in routine outpatient clinic and had three IMAGINE-more visits including clinical examination (year 3, 4 and 5) and more follow-up study. Patients were managed in routine outpatient clinic and had the end of the study, participants were invited to participate in the IMAGINE-more algorithm starting with increment in csDMARDs and then adding biologics. At target was not met, treatment was escalated according to a predefined treatment algorithm.

**Conclusion:** A 2-year MRI T2T strategy targeting absence of MRI osteitis combined with clinical remission as compared to a conventional clinical T2T strategy in RA patients had no effect on the long-term probability of achieving DAS28-CRP remission. These findings do not support the use of an MRI-guided strategy for treating patients with RA.

Group estimates are presented as No. (%) for dichotomous data and least squares means (SE) for continuous data. For the primary endpoint, adjusted odds ratio and 95%CI between groups were calculated from a logistic regression model including a fixed factor for treatment arm, and an adjustment for propensity score as a covariate. For endpoints with continuous data, least squares mean differences between groups were calculated based on repeated-measures mixed linear models adjusted for baseline values and propensity scores.

**Results:** Fifty-nine patients in the MRI T2T arm and 72 patients in conventional T2T arm consented to participate. Of these, 47 patients (80%) in the MRI T2T group and 54 patients (75%) in the conventional T2T group reached the primary clinical endpoint (p=0.161) (Table 1 and Figure 1). No statistically significant T2T arm consented to participate. Of these, 47 patients (80%) in the MRI T2T group and 54 patients (75%) in the conventional T2T group reached the primary clinical endpoint (p=0.161) (Table 1 and Figure 1). No statistically significant differences between treatment strategies in key secondary outcomes were seen.

**Disclosure of Interests:**

**B. Li, J. Zhao, G. Li, Z. Zhang, 1 Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China**

**Background:** Tumor necrosis factor inhibitors (TNFi) have been widely used in the treatment of RA. Few researches offered solid solution to predict the response of TNFi treatment. NETs formation (NEToxis) is a key process participant in RA. NETs and their components also work as a source of auto-antigens for RA.

**Objectives:** To explore the relationship between serum MPO-DNA complex, which is one of the components of NEToxis, and disease activity of RA, and to explore the possibility for serum MPO-DNA complex to predict the therapy response of anti-TNF therapy in RA patients.

**Methods:** RA patients were enrolled from a randomized controlled clinical trial (ESCORt study, ClinicalTrials.gov identifier: NCT02320630) conducted from Oct. 2014 to Oct. 2018. The clinical and demographic data and blood samples were collected at baseline and every 4 weeks. Serum levels of MPO-DNA complex were detected by a modified enzyme-linked immunosorbent assay (ELISA) kit. The Association between MPO-DNA complex level and disease activity was analyzed. The predictive value of baseline MPO-DNA complex for treatment response of RA patients was analyzed.

**Results:** 86 RA patients were enrolled. The level of serum MPO-DNA was higher in patients with high disease activity (HDA) than that in patients with medium disease activity (MDA) (1.0±0.32 vs. 0.86±0.29, p<0.001). After 4 weeks of treatments, the level of serum MPO-DNA complex decreased significantly (1.0±0.32 vs. 0.57±0.79 for ACR50 and 0.66-0.85 for ACR70, all p-value<0.05) and ΔMPO-DNA complex at week 4 against baseline MPO-DNA complex for treatment response of RA patients was analyzed.

**Disclosure of Interests:** None declared.

Relationship between painless myocardial ischemia with level Willebrand factor (WVF) and inflammatory markers in patients with rheumatoid arthritis

O. Gallicuta1, M. Szumlas1,2, O. Bych1, V. Seheda1. Scientific and Research Institute of Invalid Rehabilitation (Educational Scientific Treatment Complex) of National Pirogov Memorial Medical University, Rheumatology, Vinnytsya, Ukraine; 2National Pirogov Memorial Medical University, Internal Medicine Chair #1, Vinnytsya, Ukraine; 3Vinnytsya Regional Center for Medical and Social Expertise, Neurology, Vinnytsya, Ukraine

Background: In a patient with rheumatoid arthritis (RA) manifestations of coronary heart disease occur gradually, at the same time “painless” myocardial ischemia is detected in 50 - 70% of cases according to the literature. According to modern ideas, the formation of endothelial dysfunction, development of early atherosclerosis and vascular thrombosis are closely associated with the increase level of von Willebrand factor (VWF) and inflammatory markers.

Objectives: The aim of this study was to investigate the frequency and duration of painless myocardial ischemia and its association with VWF levels and inflammatory markers in patients with RA.

Methods: 63 patients with RA (44 women) aged 27 - 65 years (mean age - 46.8 ± 9.8 years) and 69 age and sex-matched controls were examined. Serum levels of VWF, CRP and TNF-α were determined by enzyme-linked immunosorbent assays. Daily (Holter) ECG monitoring was performed by Holter ECG monitoring systems “DiaCard” registrar model 02100, software version 10.40, developed by JSC “Solvieg” (Ukraine).

Results: It was found, that the part of patients with painless myocardial ischemia among patients with RA was significantly higher (58.7%) than in the control group (13%). At the same time, in patients with RA the duration of painless myocardial ischemia was in averaged 10.9 ± 8.1 minutes per day. It was significantly more than in the control group 2.88±1.25 minutes per day (p<0.05). It was found, that in patients with RA there was an increased levels of VWF (162.2 ± 9.3% vs. 86.2 ± 2.7% in control). It was found, that the duration of painless myocardial ischemia had close correlations with VWF (r = 0.28), CRP (r = 0.41) and TNF-α, indicating the possible involvement of VWF and inflammatory markers in cardiovascular disease in RA patients.

Conclusion: The severity the duration of painless myocardial ischemia in RA patients is associated with elevated levels of VWF, CRP, and TNF-α, indicating the possible involvement of VWF and inflammatory markers in cardiovascular disease in RA patients.

New biomarkers in rheumatoid arthritis: role of homocysteinylated anti-alpha 1 antitrypsin antibodies

M. Speziali1,1, F. Ceccorelli1, F. Natafucchi2, A. I. Celia1, T. Colasanti1, C. Barbati2, G. Oliveri1, E. Babbonc1, F. Cianciancarci1, F. M. Ucc1, G. Buonucer12, G. Tripdl1, F. R. Spinelli1, F. Conti1, C. Alessandri1. 1Arthritis Clinic, Internal Medicine, Anesthesiology and Cardiovascular Sciences, Sapienza University of Rome, Rome, Italy

Background: Rheumatoid Arthritis (RA) is a multifactorial, chronic, systemic, inflammatory disease that can lead to progressive joint destruction (Alamanos et al, Autoimmun Rev 2005). Positivity for Rheumatoid Factor (RF) and antibodies against citrullinated proteins (ACPAs) is useful for diagnostic and prognostic purposes. Nevertheless, in about 20% of patients, it is not possible to detect the presence of these autoantibodies. This has led to the identification of new antibody specificities, such as antibodies directed against carbamylated proteins (Mastrangelo A et al, J Immunol Res 2015) and, more recently, against homocysteinylated alpha 1 antitrypsin (anti-HATA) (Colasanti T et al, J Autoimmun 2020).

Objectives: To evaluate the presence of anti-HATA in a large cohort of patients with RA and their correlation with serological, clinical and erosive bone damage assessed by musculo-skeletal ultrasound (US).

Methods: Consecutive outpatients with RA, diagnosed according to the 2010 ACR/EULAR criteria, were enrolled. Demographic and clinical-laboratory data were recorded, including FR and ACPA determination. Disease activity was assessed by DAS28. The presence of anti-HATA antibodies was investigated by homemade ELISA using native alpha 1 antitrypsin modified in vitro to obtain homocysteinylated alpha 1 antitrypsin. US assessment was performed at the level of bilateral metacarpophalangeal and proximal interphalangeal joints; the presence of erosions and inflammatory features was identified according to OMERACT definitions (Wakefield R et al, J Rheumatol 2005).

Results: The present analysis included 91 RA patients (M/F 22/69; mean age 62 years; mean disease duration 12.5 years). Overall, the prevalence of anti-HATA was 69.2%. Anti-HATA antibodies were found in 63/91 (69.2%) of the entire patient cohort, whereas 68/91 (74.3%) patients were positive for ACPA and 63/91 (69.4%) for FR. 41.4% of patients had concomitant positivity for the three autoantibodies (FR, ACPA, anti-HATA). The analysis of patients with triple positivity for related arthritis antibodies (FR, ACPA, anti-HATA) was particularly interesting: indeed, in this subgroup, 80% of patients presented erosive damage, compared to 42.1% of patients who did not present simultaneously the three autoantibodies (p=0.0001). Patients with simultaneous positivity for RF, ACPA and anti-HATA showed a more aggressive disease phenotype (p=0.0001). Finally, a positive correlation was also found between disease activity (expressed by DAS28) and total inflammatory and erosive ultrasonographic score (p<0.005 and p<0.001, respectively).

Conclusion: The results of the present study confirm a high prevalence of anti-HATA in RA patients; furthermore, patients with concomitant presence of anti-HATA, ACPA and RF showed a more aggressive disease phenotype, in terms of erosive damage. Our analysis underlines as the characterization of new antibody specificities in RA could help in the early diagnosis of this disease and in the characterization of the different severity degrees.

Clinical characteristics of patients with rheumatoid arthritis in pre-difficult-to-treat status

I. Yoshi1, N. Sawada2, T. Chijiwa3,3. 1Yoshii Hospital, Musculoskeletal Medicine, Shimano-City, Japan; 2Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan; 3Kochi Memorial Hospital, Rheumatology, Kochi,
Background: Patients with rheumatoid arthritis (RA) who have a difficult-to-treat condition (D2T RA) are often a burden to both patients and rheumatologists. Objectives: The aim of this study was to determine the risk factors for failure to treat RA patients with refractory conditions and to find them relevant to prevention.

Methods: Patients with RA who were treated under treat-to-target (T2T) strategy, more than one year were picked up. Their background characteristics such as sex, age, disease duration, anti-citrullinated polypeptide antibodies titer (ACPA), and disease duration were collected, and they simplified disease activity index (SDAI) score, Health Assessment Questionnaire Disability Index (HAQ) score, pain score measured by visual analog scale (PS), EuroQol 5th-dimensions score (EQ5D) were monitored every three months. Sharp/Van der Heijde score (SHS) was calculated annually. Difficult-to-treat status was determined in according to the EULAR definition of D2T RA [1], and pre-D2T RA status was determined as follows: (Category-1) a failure history of one kind of effect in biologic or targeted synthetic disease modifying anti-rheumatic drug (bsDMARD) and switched to another bsDMARD with other action mechanism or (Category-2) one or more of following status; mean SDAI score in recent three months exceeded 11 (MDA), three consecutive administration of glucocorticoid steroid no less than 7.5mg in prednisolone equivalent (GCS), rapid radiographic progression with 5 or more in SHS than last time (RRP), or decrease of EQ5D score less than -0.2 in recent 6 months (deEQ5D).

Results: A total of 47 in Category-1 and 491 patients in Category-2 were recruited. In Category-1 matched patients, female were 83.0% and mean age was 71.3. Mean SDAI score, HAQ score, PS, EQ5D score, and SHS at failure of bsDMARD (baseline) were 15.5, 0.457, 40.1, 0.811, and 72.9, respectively. Numbers of the first bsDMARD were 32 TNF inhibitors, 8 IL-6 inhibitors, 6 abatacepts, and 1 JAK inhibitor. Numbers of the second after the first were 13 IL-6 inhibitors and 19 JAK inhibitors after TNF inhibitor, whereas 3 TNF inhibitors, 2 abatacepts, and 3 JAK inhibitors after IL-6 inhibitor failure, 1 TNF inhibitor, 1 IL-6 inhibitor, and 4 JAK inhibitors after abatacept failure, and 1 TNF inhibitor after JAK inhibitor failure. In these, success counted 18 and failure counted 29. Significant risk factors for Category-1 failure were higher ACPA, higher SDAI score, higher HAQ score, and higher SHS at baseline (p<0.05). There was no significant difference between drugs.

Conclusion: Clinical background factors besides disease activity such as ACPA, SDAI score, and SHS at baseline were important for preventing fail-in-D2T_RA. However, most weighted factor was disease activity control after falling in MDA status. Tight disease activity control is the overriding factor.

Figure 1. Predictive model of TNFi nonresponse based on NAPCD genes. (A) Volcano map of differential expressed genes; (B) Correlation heat map of gene modules and phenotypes, the red is positively correlated with the phenotype, blue is negatively correlated with the phenotype; (C) The shared 38 genes of TNFi response & nonresponse DEGs, among the WGCNA turquoise module and cell programmed death genes; (D) Consensus clustering matrix for k = 2. (E) The ROC curve of 33 genes; (F) LASSO regression of the 32 genes, except for CD46; (G) Nomogram for predicting TNFi nonresponse in TNFi treatment RA cohort, indicated five possible indicators (CAP5, CAPN10, ITGB4, NLRP2, and SLCA2B) were closely related to TNFi nonresponse.

Disclosure of Interests: None declared.

Background: The non-apoptotic programmed cell death genes (NAPCD) genes were closely related to TNFi nonresponse. To predict the possibility of TNFi response prior to prescription, we constructed a predictive model with R packages “limma” and “WGCNA” Then the enrichment analysis among the shared genes was performed through the KEGG, Reactome, and Metascape websites, and WebGestalt website. Following the confirmation of the non-apoptotic programmed cell death (NAPCD) genes in the shared genes with Student’s T-test. Furthermore, the TNFi treatment cohort was clustered based on the hub genes, making the receiver operating characteristic (ROC) curve analysis. Moreover, the least absolute shrinkage and selection operator (LASSO) model was constructed to identify the predictive genes.

Results: 2624 DEGs were identified significantly, including 161 upregulated genes and 2463 downregulated genes. One module with TNFi treatment was constructed in WGCNA, significant in both response and nonresponse. The gene signatures for TNFi nonresponse were collected from overlaps 2260 genes in above. And we found 38 NAPCD genes might play role in TNFi nonresponse, but reserved 33 genes which statistically significant with T-Test. 22 TNFi treated synovial samples in GEO database could be classified into response or nonresponse subgroups. The ROC curve showed that the AUC for 32 genes in these samples ranged from 0.7 to 0.9, expected for CD46. At last, the LASSO model indicated that CAP5, CAPN10, ITGB4, NLRP2, and SLCA2B could predict the TNFi nonresponse, as the risk score = CAP5 × 0.028 + CAPN10 × 0.064 + ITGB4 × 0.080 + NLRP2 × 0.317 + SLCA2B × 0.090 (Figure 1).
ALTERATION OF THE GUT MICROBIOTA IN CHINESE POPULATION WITH RHEUMATOID ARTHRITIS

The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; Shanxi Medical University, Key Laboratory of Cellular Physiology, Ministry of Education, Taiyuan, China;

Background: Rheumatoid arthritis (RA) is an aggressive immune-mediated joint disease characterized by synovial proliferation and inflammation, cartilage destruction, and joint destruction. Growing evidences suggests a chronic inflammatory response induced by gut microbiome critically contribute to the development of rheumatoid arthritis.

Objectives: The aim of this study was to evaluate and quantify differences in the composition of gut microbiota in RA patients and investigate the associations between flora and clinical variables in RA patients.

Methods: Fecal samples from 145 RA patients and 145 age- and gender-matched healthy controls (HCs) were collected for bacterial 16S rRNA genes sequencing. The alpha-diversity, beta-diversity and the microbial composition of gut microbiota in RA patients and HCs. The peripheral lymphocytes of these patients were assessed by flow cytometry, and inflammatory biomarkers (ESR, CRP), auto-antibodies(ACP, MCV) and cytokines measured by ELISA were recorded. Correlations between different taxa and clinical variables, were calculated by Spearman's rank test.

Results: Consistent with trends observed for diversity, patients with RA had a lower richness compared with those of HCs (p < 0.01, Figure 1a), suggesting gut microbiome was markedly less diverse in composition in RA. Bray curtis distance-based beta diversity analysis revealed significant differences in the microbial community between RA and HCs (ANOSIM, R=0.061, p=0.001, Figure 1b). Ten selected taxonomic biomarkers at different phylogenetic levels showed great discriminant ability, with Log10 LDA score > 4.0 (Figure 1c-g).

Conclusion: Specific gut microbiota may play an important role in the pathogenesis of RA, which may aid in the diagnosis or determination of the susceptibility of individuals to RA via detection of the gut microbiome.

ASSOCIATION BETWEEN ANTI CITRULLINATED PEPTIDES ANTIBODIES, BONE MINERAL DENSITY, AND FRACTURE RISK IN RHEUMATOID ARTHRITIS PATIENTS

O. Lamkhania1, H. Azzouzi1, I. Linda1, Mohamed I University, 1Rheumatology department, Oujda, Morocco

Background: Recent literature reported Anti Citrullinated Peptides Antibodies (ACPA) associated with bone loss in patients with rheumatoid arthritis (RA).

Objectives: To study if ACPA positivity was associated with bone mineral density and the ten-year probability of fracture (FRAX) in RA patients.

Methods: We performed a cross-sectional study on patients with RA diagnosis according to ACR-EULAR 2010 classification recruited from January 2021 till January 2022. Patients aged from 40 to 90 years were included. Those with prior cancer, hyperparathyroidism, hyperthyroidism, diabetes, chronic kidney disease, and cirrhosis were excluded. Clinical data and results of laboratory tests were collected simultaneously with bone mineral density (BMD) acquisition. The latter was measured with dual-energy X-ray absorptiometry (DXA). BMD of the femoral neck (FN) was used to calculate the ten-year probability of major osteoporotic fracture (FRAX MOF) and femoral neck risk fracture (FRAX FN). Patients were grouped by positivity or quartile of ACPA level (I-IV). We used logistic regression, parametric and non-parametric tests for statistical analysis with SPSS20.

Results: Eighty-two RA patients were enrolled. In total, 69 (84.1%) were women, 16 (19.5%) reported a previous personal fracture, and 37 (45.1%) had osteoporosis. Seventy-two (87.8%) patients were ACPA positive. The mean body mass index (BMI; kg/m²) and lumbar spine BMD in ACPA-positive patients were 25.44 ± 4.79 and 0.791 ± 0.138, respectively. We found a significant association between ACPA positivity and BMI over 25 (p = 0.01; OR = 0.132 [1.527; 6.785]). Comparison between ACPA positive/negative patients did not find a significant difference for osteoporosis, history of fracture, DASS28CRP, lumbar spine BMD, FN BMD, FRAX MOF BMD, and FRAX FN BMD. Lumbar spine BMD was significantly different (p = 0.035) among subgroups of ACPA levels, whereas there was no significant difference for FRAX MOF, FRAX FN, and FN BMD.

Conclusion: In this study, lumbar spine BMD was significantly different among subgroups of ACPA levels.

A INFAMMATORY FACTOR-BASED NOMOGRAM PREDICTS FIRST REMISSION TIME OF RHEUMATOID ARTHRITIS PATIENTS WITH BASELINE GALECTIN-9

Z. Sun1,2, X. Liu3, F. Wang4, J. Sun5, Y. Gu7, Q. Che5, Q. Shu2, 6. Qilu Hospital, Cheelo College of Medicine, Shandong University, Department of Rheumatology, Jinan, China; 2Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Department of Rheumatology Jinan, China; 3Tianjin Medical University General Hospital, Department of Rheumatology, Tianjin, China; 4Women and Children’s Hospital, Department of Hematology, Qingdao, China; 5Shandong Provincial Third Hospital, Department of Nephrology and Immunology Jinan, China; 6YanTaiShan Hospital, Department of Rheumatology and Immunology, Yantai, China

Background: Galectin-9 (Gal-9) is an immunoregulatory peptide involved in the development of RA. The aim of this study was to establish a predictive model for the first remission time of RA patients based on baseline Gal-9.

Objectives: To develop a predictive model for the first remission time of RA patients based on baseline Gal-9.

Methods: A total of 275 RA patients were enrolled in this study. The demographic and clinical characteristics of the patients are shown in Table S1. The first remission time was defined as the time from initial treatment to remission. Logistic regression analysis was used to identify the independent factors associated with remission.

Results: The median remission time was 3 months. The median baseline Gal-9 level was 12.1 ng/ml. The baseline Gal-9 level was significantly associated with remission (p = 0.001). The area under the ROC curve for baseline Gal-9 was 0.71 (p < 0.001).

Conclusion: The baseline Gal-9 level is a predictive factor for the first remission time of RA patients. The Gal-9-based nomogram may be a useful tool for predicting the first remission time of RA patients.

Disclosure of Interests: None declared.

Background: Rheumatoid arthritis (RA) is an autoimmune disease. The core treatment principle of RA is to achieve remission or low disease activity as soon as possible to ensure optimal outcomes. Predicting the first remission time according to the patient’s risk factors is very important for the choice of treatment scheme.

Objectives: We aimed to verify the prognostic value of inflammatory factors in RA and establish a nomogram based on Human Interleukin-6 (IL-6), Galectin-9 (Gal-9) and disease activity to predict the first remission time after conventional synthetic DMARDs treatment.

Methods: 184 RA active patients (DAS28-ESR > 3.2, ACR 1987 criteria or EUILAR 2010 criteria) were enrolled in the rheumatology department of Qilu Hospital of Shandong University from June 2014 to June 2020. 129 patients were assigned to the development cohort and 55 patients were assigned to the validation cohort randomly. Baseline clinical data and plasma were collected. The expressions of Tumour Necrosis Factor (TNF-α), Vascular Endothelial Growth Factor (VEGF), IL-6 and Gal-9 in plasma of RA patients were detected by ELISA. All patients were treated with csDMARDs and we recorded activity of each follow-up visit until 36 months. Lasso regression and Cox regression analysis were used to screen the 14 variables (including activity indices and cytokines) at baseline, and the prediction model was established to draw the nomogram.

Results: Patient age, CRP, IL-6, Gal-9, HAQ and DAS28-ESR were the significant prognostic factors in the lasso and Cox regression analyses, especially Gal-9. The multivariate analysis revealed that IL-6 ≤ 9.04 pg/ml (HR = 0.54, 95% CI: 0.31–0.95), Gal-9 ≤ 4490 pg/ml (HR = 0.43, 95% CI: 0.21–0.89) were independent protective factors. The cutoff values for the Cox regression analysis were used to screen the 14 variables (including activity indices and cytokines) at baseline, and the prediction model was established to draw the nomogram.

Conclusion: We constructed and validated a nomogram with baseline activity indices and cytokines that can predict first remission time in RA patients after csDMARDs treatment. Using this simple-to-use model with plasma Gal-9 ≥ 4490 pg/ml (HR = 0.21–0.89) were independent protective factors in the lasso and Cox regression analyses, especially Gal-9. The resulting model containing six factors had good discrimination ability in both the development cohort (C-index, 0.729) and the validation cohort (C-index, 0.710). Time-dependent ROC curve (Figure 2), calibration analysis (Figure 3) and decision curve analysis (DCA) show that the nomogram has significant discriminant power, stability and clinical practicability in predicting the first remission time.

recommendations are based on a previously validated Diet Quality Index, except for red meat (based on SDGI) and added sugars (based on World Health Organization guidelines from 2015 for sugar intake).

We used conditional logistic regression analysis to study the relation between NDS, its components, and RA. The NDS was divided into categories, defined as low (0–1), moderate (2–3) and high (4–5), with “low” as reference, and also assessed as a continuous variable. All models were adjusted for reported total energy intake, and potential misreporters of total energy intake were excluded.

We designed multivariable-adjusted models in which we included covariates that had been associated with diet and RA (smoking, alcohol and leisure time physical activity).

Results: In the study population, 172 RA cases were identified. Low red meat intake (<500 g/week) was significantly associated with a decreased risk of RA (Table 1). Compliance with the recommendations for fiber and vegetables and fruit was inversely associated with RA, with a similar trend for the total NDS (Table). In additional multivariable analysis, including both variables and relevant confounders, compliance with recommendations for red meat intake (odds ratio (OR) 0.43; 95% CI 0.22-0.85) and for fiber intake (OR 0.53; 95% CI 0.30-0.94) were both associated with a reduced risk of RA.

Conclusion: These preliminary results indicate that low intake of red meat and higher fiber intake, in line with current recommendations, are independently associated with reduced risk of developing RA, suggesting that components found in meat and fiber-rich foods may affect early disease mechanisms.

PREVALENCE AND CHARACTERISTICS OF PATIENTS WITH ‘ARTHRALGIA AT-RISK’ DEFINED ACCORDING TO THE RHEUMATOLOGIST AND THE NEW EULAR DEFINITION: A PILOT RETROSPECTIVE STUDY FOCUSED ON REFERRAL TO A STRUCTURED EARLY ARTHRITIS CLINIC

S. Grignaschi1,2, B. Xoo1, E. Bozzalla Cassione1,2, T. Luvar1, M. I. Greco1, I. Mazzucchelli1, S. Bugatti1,2, C. Montecucco1,2, A. Manzo1,2, Fondazione I.R.O.C.S. Policlinico San Matteo, Division of Rheumatology, Pavia, Italy; 2The University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy

Background: The phase preceding the development of rheumatoid arthritis (RA) may contain a novel window of opportunity for disease prevention and control. Investigation of this phase at population level remains, however, very challenging in epidemiological terms due to the rarity of the events. Patients seeking medical attention with arthralgia at-risk, defined by an expert rheumatologist (clinically suspect arthralgia, CSA) or by the recent EULAR definition represent an attractive platform for the identification of both seropositive and seronegative disease subsets.

Objectives: The objective of this study was to explore the prevalence and characteristics of patients with different types of arthralgia, focusing on referral to the screening visit of an early arthritis clinic (EAC) as a putative enrichment strategy for pre-RA.

Methods: EAC first referrals from January 1st 2019 to June 30th 2021 were systematically reviewed through a retrospective evaluation of medical charts. Patient’s history, comorbidities, PROs and clinical examination were recorded by two expert rheumatologists. Data was compared to immunological and radiological data. Arthralgia cases, sub-classified according to risk-definitions, were recorded. Categories at-risk, according to the rheumatologist’s opinion and the EULAR definition, were characterized and compared to other arthralgia cases for clinical characteristics, imaging data and autoantibody status.

Results: Of the 363 patients referred to the EAC, 178 were characterized by peripheral arthralgia (swollen joint count=0) at screening visit (49%). Of these patients, 130 cases were characterized by recent-onset arthralgia (ROA) (<12 months symptoms’ duration) (73% of the total), CSA, according to the rheumatologist’s opinion, was applicable to 71/178 total arthralgia patients (40%) and to 61/130 ROA patients (47%), recent-onset CSA, RO-CSA. Patients without
OBJECTIVES: early and precise diagnosis of RA.

AIM TO ASSESS WHETHER AUTOANTIBODIES TO NATIVE OR MODIFIED JP CAN BE USED FOR THE ACCURATE IDENTIFICATION OF UNTREATED EARLY RHEUMATOID ARTHRITIS PATIENTS.

BACKGROUND: CCp; aCCP) and rheumatoid factor (RF) appear years before clinical onset of RA. Autoantibodies to JP have been reported in up to 25% of patients with early rheumatoid arthritis.

METHODS: Antibodies to JP were analysed in serum from patients in three independent early RA cohorts as well as from population controls without rheumatic diseases (WINGA, Gothenburg and MFM-ÅUS, Malmö). The performance of the different antibodies was assessed in a blinded setting using a multianalyte bead-based assay. The study was approved by the regional ethics committee.

RESULTS: The novel biomarkers identified 22.5% of the patients with 99% specificity compared to other groups (13% vs 3%, p=0.03). After a stratification according to the fulfillment of the EULAR definition, both CSA and RO-CSA increased their differences compared to other groups regarding the elevation of C-reactive protein (CRP ≥0.5 mg/dl, p=0.006 and p=0.02 respectively). No epidemiological, clinical or imaging differences were observed through patient stratification according to current arthralgia at-risk definition in the real-life setting of an EAC. Both CSA and RO-CSA appears as suitable niches for the patient selection according to current arthralgia at-risk definition in the real-life setting of an EAC.

CONCLUSION: Results of our pilot study provide evidence of the applicability of patient selection according to current arthralgia at-risk definition in the real-life setting of an EAC. Both CSA and RO-CSA appears as suitable niches for the enrichment of primary immunological and serological risk factors for RA (RF/ACPA, hypogammaglobulinemia and C-reactive protein).

**POS0563 INFLUENCE OF ACTIVE VERSUS PLACEBO CONTROL ON TREATMENT RESPONSES IN RANDOMIZED CONTROLLED TRIALS IN RHEUMATOID ARTHRITIS**

N. M. Stimakovs, A. Korschbaumer, J. S. Smolen, T. Stefanova, E. Chwala, D. Aletaha

**Background**: Randomised placebo controlled double-blind clinical trials are the mainstay of testing drugs for efficacy and safety and ultimately drug approval in medicine. They are performed to ensure the efficacy of the active intervention against the effects of interventions without expected efficacy (placebo). Patients have to be fully consented to the risk of being (randomly) allocated to placebo by good clinical practice guidelines. Knowledge about this risk may reduce the expectations about efficacy on both the patient and the investigator side. Once many therapeutic options are available, active control interventions are often used as comparators instead of placebo in trials. In such studies, placebo flow immunoassay [2] and screened approx. 350 peptides derived from JPs of interest. We included monoclonal antibodies as assay calibrators and determined limit of detection (LoD). To assess positivity for autoantibodies to JP of interest above LoD, we used SMAD (median absolute deviation) of the control populations as the cut-off.

**Results**: In the ERAp cohort, 5 autoantibodies discriminated RA patients from controls with 81% sensitivity and 100% specificity (Table 1). The same autoantibodies had 68% sensitivity and 98% specificity in the combined BARFOT and TIRA-2 cohorts. Together with RF and aCCP, only 2 of the 5 autoantibodies added statistically significant diagnostic value, increasing the sensitivity from 48% to 61% with 99% specificity. In aCCP- and RF-negative uEArA patients (n=536), the novel biomarkers identified 22.5% of the patients with 99% specificity compared to controls.

Effects are still in place by the mere expectation of a response, but one could hypothesise that the observable effect of each intervention may be higher simply because of patients’ awareness of an active treatment (i.e. no risk of placebo).

Here we investigated this hypothesis by comparing the effects of active controlled trials versus placebo controlled trials on the efficacy for the same therapeutic intervention in patients with rheumatoid arthritis (RA), in a systematic approach using all published trials in the field.

Objectives: To assess whether there is a systematic difference in response rates when investigating treatments in randomised controlled trials (RCTs) with active control compared to placebo control in RA clinical trials.

Methods: A systematic literature search was performed. We identified and matched RCTs that used comparable regimens, patient populations, background therapy and outcome reporting, but were different in terms of control group (active or placebo). Included studies were explored for potential risk of bias and mixed-model logistic regression was used to estimate odds ratios (OR) for achieving an American College of Rheumatology (ACR) 20, 50, and 70% response at week 12 in active-controlled studies compared to corresponding placebo-controlled studies.

Results: 7477 studies were screened, 576 of which underwent detailed review. Finally, 39 studies (45 study arms) were included for analysis. ACR response rates were higher in active controlled trials. The OR for achieving an ACR response when investigating the same treatment was consistently higher in studies with active control group than in corresponding studies with placebo control group: ORs were 1.64 (95% Confidence Interval, CI: 1.44-1.86; p<0.001) for ACR20 (Figure 1), 1.46 (95% CI: 1.28-1.71; p<0.001) for ACR50 and 1.61 (95% CI: 1.28-2.02; p<0.001) for ACR70 at week 12.

Conclusion: A systematic difference in response rates favouring head-to-head trials compared to placebo-controlled trials exists in RA clinical trials. This finding calls for consideration when interpreting and planning clinical trials and has implications for patients, investigators, sponsors and regulatory agencies.

DAS28-3v-CRP: Disease Activity Score-3 variables C-Reactive Protein (CRP), Pain score, Health Assessment Questionnaire (HAQ), the Rheumatoid Arthritis Impact of Disease (RAID) total score, Hospital Anxiety and Depression Scale (HADS) scores, PGA and PhGA were collected. Disease Activity Score (DAS28-3v-CRP) was calculated and taken as the reference measure of current disease activity. Correlation between PGA and PhGA with other continuous variables was evaluated through Pearson’s Correlation Coefficient and variables with p<0.10 in univariate analysis were included in multivariable linear regression models.

Conclusion: PhGA is a closer representation of actual disease activity than PGA, thus providing a more valid basis for treatment decisions aimed at disease activity. These observations support the substitution of PGA by PhGA in the Boolean definition of remission as it would strengthen the representation of disease activity and significantly reduce the risk of overtreatment in comparison to current definitions. The consequences of this change upon the prediction of long-term function and structural stability warrant evaluation. The patient's perspective will remain central to disease management in the form of a distinct target.

Background: The definitions of remission play a crucial role in the treat-to-target strategy in rheumatoid arthritis. The patient’s and physician’s global assessment (PGA/PhGA) of disease activity are considered in current definitions, but PGA has been criticized for its poor relationship with actual disease activity. This leads to a considerable risk of overtreatment in patients who are otherwise in remission but fail this target solely because of PGA. PGA near-remission. A dual-target strategy, excluding PGA from the definition of biological remission and the creation of a second target focused on disease impact has been proposed. Another proposal is to substitute PGA by PhGA with the purpose of strengthening the definition with a fourth variable capable of conveying relevant unaccounted factors, such as comorbidity.

Objectives: To assess the relationship of PGA and PhGA with objective measures of disease activity (DAS3v) and their impact upon near-remission and risk of overtreatment.

Methods: This is a cross-sectional analysis of data from RAID.PT, an observational prospective and multicenter study, including adult patients fulfilling RA classification criteria. Tender (TJC28) and swollen (SJC28) 28 joint counts, C-Reactive Protein (CRP), Pain score, Health Assessment Questionnaire (HAQ), the Rheumatoid Arthritis Impact of Disease (RAID) total score, Hospital Anxiety and Depression Scale (HADS) scores, PGA and PhGA were collected. Disease Activity Score (DAS28-3v-CRP) was calculated and taken as the reference measure of current disease activity. Correlation between PGA and PhGA with other continuous variables was evaluated through Pearson’s Correlation Coefficient and variables with p<0.10 in univariate analysis were included in multivariable linear regression models.

Results: We included 299 patients, 81.3% women, mean age of 57.4±12.0 years and disease duration 9.4±9.5 years. Average DAS28-3v-CRP 2.4 (±1.9). DAS28-CRP is the strongest factor associated with PhGA, explaining 45% of its variance. Inversely, it only explains 2% of the variance of PGA, which is more affected by disease impact. In this clinical cohort, 13% of patients were in full Boolean remission and 41% in PGA-near-remission. Only 49 of 123 patients in the latter group had a PhGA >1. Considering PhGA instead of PGA in the Boolean definition of remission would increase the proportion of remission from 13 to 37.5% of the whole cohort.

Conclusion: The results from this large cohort demonstrate that some minority ethnic groups are less likely to reach disease remission in the early months following an EIA diagnosis. Our results are not explained by delays in referral or treatment. Initial treatment strategies varied across ethnic groups. These data highlight the need for investigation into the possible drivers of these inequitable outcomes and reappraisal of EIA management pathways.

Conclusion: We provide a robust evidence that self-perceived general health at start of anti-TNF therapy predicts reaching remission at 12 months in pts with RA.
comorbidity history varied with disease activity (Table 1). By contrast, age, number of previous DMARDs, disease duration and smoking habits were relatively similar across categories of disease activity (Table 1).

We observed 598 ACS events (in 554 patients) during the 6-month follow-up window. Comparing patients not in remission to patients in remission, adjusting for the covariates described above, indicated that not being in remission increased the risk of ACS occurrence (Figure 1). Similarly, there was an association between DAS28-ESR at the visit and the risk of ACS during the coming six months.

**Conclusion:** Being in RA remission at any visit is associated with a noticeably lower risk of ACS during the following months, suggesting that RA disease activity not only affects CVD risk in the longer term but also in the short term. **Acknowledgements:** NordForsk and Foreum partially funded this research project. **Disclosure of Interests:** Bénédicte Delcoigne: None declared, Sella Aarrestad project.

**IDENTIFICATION OF JOINT LOCATIONS IN AN EARLY RHEUMATOID ARTHRITIS COHORT AS A CHARACTERISTIC OF DISEASE SEVERITY. DATA FROM THE ERA-CLINIQUE BRUSSELS COHORT**

L. Bricman1, S. Emilie1, T. Sokolova1, A. Avramovska1, P. Durez1, 1Cliniques Universitaires Saint-Luc– Université catholique de Louvain (UCL) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium

**Background:** Early RA patients (ERA pts) often present with different areas of joint involvement, but limited data exist to identify which specific joint locations may be indicative of greater disease severity.

**Objectives:** This analysis investigated the baseline (BL) prevalence of swelling in individual joint locations and their possible association with disease characteristics and prognostic factors in a cohort of ERA pts.

**Methods:** This analysis was based on data from the ERA UCLouvain Brussels cohort in which patients were included according the ACR/EULAR 2010 criteria, naïve to DMARDs and followed in our daily clinic. The physician assessed prevalence of baseline individual swollen joint status (present, absent) through a physical examination. The joint count includes 44 joints. Similarly, all patient and RA characteristics were analyzed. The association between BL swelling and disease characteristics was investigated for each individual joints.

**Results:** 453 ERA pts were analyzed, BL swelling was most frequently observed in the wrist (71.1%) followed by IPP 3 and 2 joints (52.5 and 50.1%). DAS4P 4.5 was more present in younger and MCP 2-4 in older pts. BL swelling in the large size joint (knee, elbow, shoulder and ankle), in the medium size joint (wrist) and the small size joint (only MCP3, IPP 1, 2 and MTP5) was highly associated with higher DAS28 (CRP)*. Pts with BL swelling MCP1, 3, 4; MTP 1, 2, 5 was associated with erosive disease*. In contrast, swelling of the knee was correlated with non erosive and also seronegative RA*. Swelling of many joints locations (knee, shoulder, ankle, MCP 1-5, MTP1, 5 and IPP 1, 2) were correlated significantly with a higher HAQ*. Only swelling of MTP1, 2, 5 was associated with the presence of ACPA antibodies*. No difference was observed for smoking habits and gender. (* p<0.001).

**Conclusion:** In our cohort of ERA, small joints swelling was associated with erosive and seropositive RA (only MTP). Swelling of the large joint and the wrist seems to be associated with higher disease activity. In ERA, a difference in joint location presentation may identify pts with poor prognostic factors to be eligible for an intensive treatment or a personalized treatment approach. Further analysis is planned to analyze the correlation with erosion in each joint location and response to Methotrexate.

**UNSUPERVISED DEEP-LEARNING IDENTIFIES SIX CLINICAL SUBTYPES OF RHEUMATOID ARTHRITIS AT BASELINE THAT ASSOCIATE WITH M ETHOTREXATE FAILURE DURING FOLLOW-UP**

T. Maasen2, 3, M. Maurits1, T. Huizinga1, M. Reinders2, 3, E. Van den Akker1, 3, R. Knevel1, 4, 1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Delft University of Technology (TU Delft), Bioinformatics Lab, Delft, Netherlands; 3Leiden University Medical Center (LUMC), Molecular Epidemiology, Leiden, Netherlands; 4Newcastle University, Rheumatology, Newcastle upon Tyne, United Kingdom

**Background:** Currently methotrexate (MTX) is the prevailing baseline treatment for Rheumatoid Arthritis (RA). Treatment response varies since RA is a highly heterogeneous disease. A tantalizing idea is that the factors causing clinical heterogeneity can already be elucidated at baseline.

**Objectives:** Disentangle clinical heterogeneity of RA patients at baseline to identify likely MTX failure during follow-up.

**Methods:** We constructed patient-specific profiles, featuring baseline clinical measurements which we split into three layers: 1) joint counts, 2) numerical hematology work up, and 3) categorical features (binary serological markers (aCCP, RF) and localization of joint inflammation and tenderness). We applied Z-score scaling on the numerical data and one hot encoding on the categorical features. To identify hidden structure across these layers we used Maui (Multi-omics Autoencoder Integration) [1], and Phenograph [2] for subsequent clustering of patients within the extracted latent space. We examined the most discriminatory features post-hoc with SHAP. With Kaplan Meier curves we assessed MTX efficacy using treatment switch as proxy for failure. We calculated hazard ratios (HR) with univariate Cox-regression.

**Results:** We had 944 RA patients with baseline health record data. MAUI identified 23 latent factors from 335 baseline variables. Phenograph showed 6 RA-subgroups (Table 1 & Figure 1). The baseline clusters (C) are characterized by a different joint involvement or lab value: C1 had a low aCCP-positive (37%) and high median ESR of 33. C1 had the most affected joints (primarily the small joints) with a swollen- (SJC) and tender joint count (TJC) of 15 and 19 respectively. C2 had moderate aCCP-positive (50%) and low median SJC=6 and TJC=9. C3 had MTP involvement, high aCCP-positive (64%), and low ESR=19 but relatively high joint counts; SJC=9 and TJC=12. C4 had no wrists, high aCCP-positive (65%), high ESR=28 and low joint counts; SJC=2, TJC=4. C5 had low lymphocyte numbers and a low median ESR=23, SJC=4 and TJC=3. C6 had MCP1 involvement, was mostly aCCP-positive (59%) and had a slightly higher median ESR=25, SJC=9 and TJC=11.
Clusters differed in MTX failure: 40%, 53%, 69%, 54%, 48% and 64% (for cluster 1-6, \( P = 3.2 \times 10^{-2} \)). Examining the local differences, we observed the biggest difference between C1 and C3 (HR 0.5 (95% CI 0.36-0.7), \( P = 4.4 \times 10^{-5} \)).

**Conclusion:** Using baseline data, we identified 6 putative novel RA subtypes which were associated with differences in MTX failure. Our study demonstrates the applicability of unsupervised deep learning and cluster analysis to elucidate hidden structure in the multi-modal EHR.

ARE WOMEN WITH RHEUMATOID ARTHRITIS REALLY LESS LIKELY TO ACHIEVE REMISSION WITH BIOLOGICS? A COHORT STUDY IN THE SWISS CLINICAL QUALITY MANAGEMENT COHORT

E. Vallejo-Yague1, J. N. Pfund1, T. Burkard1, C. Clair2,3, R. Micheroli4, E. T. New York, United States of America

Objectives: We aimed to compare the likelihood of achieving remission across men and women with RA, who started their first biologic or targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARDs).

Methods: This observational cohort study in the Swiss Clinical Quality Management in Rheumatic Diseases (SCQM) registry included adult RA patients who started their first b/tsDMARDs (from 1997 to 31/Apr/2018). Patient characteristics at start of the b/tsDMARDs were compared between men and women. Subsequently, logistic regression was used to assess the likelihood of achieving remission during the first year after b/tsDMARDs start, defined by disease activity score 28 (DAS28) <2.6, in men compared to women (reference group). Secondary analyses were adjusted for age and seropositivity as prognostic factors, and we investigated the role of potential mediators or factors that could explain the findings from the main analysis.

Results: The study included 3722 RA patients, of which 2839 (76.3%) were women and 883 (23.7%) were men. Compared to women, men were older at diagnosis and start of b/tsDMARDs, and had shorter time from diagnosis to the first b/tsDMARD (3.4 vs 5.0 years, p<0.001). At baseline (b/tsDMARD initiation), women had significantly more active disease activity (DAS28) and worse patient-reported outcomes (Health Assessment Questionnaire, tender joints). Concomitant osteoporosis and depression/anxiety were more frequent among women, while men had more frequent diabetes and prior or current smoking record. Physician’s global disease assessment and swollen joints were similar across groups. Compared to women, men were 21% more likely to achieve DAS28-remission, with an odds ratio (OR) 1.21, 95% confidence interval (CI) 1.02-1.42. Secondary analyses adjusting by for age and seropositivity did not change the findings (adjusted OR 1.24, 95% CI 1.05-1.46). Our analyses of potential mediators suggested that the observed effect may be explained by the shorter disease duration and lower DAS28 at treatment initiation in men versus women.

Conclusion: Men started b/tsDMARDs at an earlier stage of disease than women, particularly regarding disease duration and disease activity (DAS28) at b/tsDMARD initiation, and they presented higher odds of remission. This highlights the importance of an earlier treatment, and it suggests to target an earlier stage of disease in women to match the benefits observed in men.

MUSCULOSKELETAL ULTRASOUND STUDIES ARE CRITICAL FOR DETECTING SERONEGATIVE INFLAMMATORY ARTHRITIS

C. Lin1, R. Chou2

1University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Division of Allergy, Immunology, & Rheumatology, Department of Medicine, Buffalo, New York, United States of America

Background: The autoantibody status of rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (anti-CCP Ab) has gained widespread recognition for its role in the diagnosis of rheumatoid arthritis (RA) based on the latest diagnostic criteria for RA.1 However, in early disease, the rates of antibody expression have been reported as low as 50%, rendering early diagnosis of RA difficult. Furthermore, the nature of seronegative rheumatoid arthritis is unknown, though it is presumed to have less aggressive disease course as compared to its seropositive counterparts. Musculoskeletal (MS) ultrasound studies have been widely used in recent clinical practice to assess soft-tissue abnormalities of the joints and disease states in RA, such as synovitis and bone erosions. MS ultrasound studies were recently shown to be more sensitive to detect early synovial changes and erosions than other radiographic methods while maintaining cost-effectiveness.2 We hypothesize that MS ultrasound studies are more sensitive to detecting inflammatory changes in seronegative inflammatory arthritis, which is often subclinical in presentation.

Objectives: To assess the role of MS ultrasound studies in detecting early inflammatory changes in the joints and diagnosing seronegative inflammatory arthritis.

Methods: A retrospective electronic medical record review was performed of all patients at the two University at Buffalo rheumatology clinics who underwent MS ultrasound studies after complaining of multiple joint pain. All these patients were previously seen and evaluated by at least one other medical provider, who found no evidence of inflammatory arthritis on physical examination. These patients did not meet diagnostic criteria for rheumatoid arthritis due to a lack of gross joint swelling and/or positive serological makeup. As part of their clinical care, they were referred to obtain MS ultrasound studies to rule out inflammatory arthritis. All patients were de-identified at initial data collection. Information pertaining to the patients’ demographics (gender, age, ethnicity, etc.), 2) findings of MS ultrasound studies, and 3) serological studies (RF, anti-CCP Ab, HLA-B27) was collected and tabulated.

Results: Of the 363 patients who underwent MS ultrasound studies, 280 of them (77.1%) of them were found to have synovial hypertrophy [minimal = 23%, mild = 46%, moderate = 29%, severe = 2%] in bilateral MCP,PIP, carpal, and/MTP joints, therefore confirming a diagnosis of inflammatory arthritis. The average age of these 280 patients was 48.35 ± 14.86 years old at the time of diagnosis, with female to male ratio of 4.38:1. Surprisingly, of these 280 patients with evidence of inflammatory arthritis, 69 (24.8%) of them were found to have joint erosions with either MCP or MTP joints, supporting a diagnosis of advanced inflammatory arthritis with erosive disease. The erosions were predominantly located in MTP joints (77.1%) as compared to MCP joints (22.9%). Therefore, our findings clearly demonstrated distinct clinical and ultrasonography features of seronegative inflammatory arthritis (SNIA) as compared to erosive RA.

Conclusion: MS ultrasound studies are more sensitive to and critical for detecting inflammatory changes and joint damages in SNIA due to its subclinical presentation. Based on our findings, SN IA is underdiagnosed in individuals who complain of joint pain without gross synovitis. SNIA also likely has distinct pathophysiology that needs further characterization.

AUC, area under the curve; WHO, World Health Organization; FRS, Framingham Risk Score; BMI, body mass index.
ACR/AHA showed AUC: 0.687 (0.604-0.770), cutoff point: 3.82, sensitivity: 62.7%, and specificity: 61.0%. QRISK showed AUC: 0.733 (0.654-0.811), cutoff point: 6.05, sensitivity: 71.2%, and specificity: 61.0%. All algorithms had a p-value <0.001 (Figure 1 and Table 1).

Conclusion: The WHO calculator was one of the best algorithms for the detection of CP, with the best positive and negative likelihood ratios; however, like the other algorithms, a lower cut-off point than the one established by official guidelines was needed to identify high-risk patients with the presence of CP, who were initially classified as low-moderate risk by the CVR algorithm.

Background: Cardiovascular disease is the major cause of death in rheumatoid arthritis (RA) patients. Cardiovascular risk algorithms are used to estimate the probability for the development of a cardiovascular event in 10 years, according to patients’ characteristics, however, no algorithm existed for the Hispanic population until the World Health Organization (WHO) published the cardiovascular disease risk charts for 21 regions (1).

Objectives: To compare the capacity of the 2019 WHO algorithm and the 2013 American College of Cardiology/American Heart Association (ACC/AHA) algorithm for detecting the presence of carotid plaque (CP) in RA patients.

Methods: Cross-sectional study. We recruited a total of 164 patients with RA diagnosis, according to the 2010 ACR/EULAR classification criteria, aged 40-75 years. Patients with a previous cardiovascular event were excluded. Cardiovascular risk was evaluated with the 2019 WHO algorithm for the Mexican population and the 2013 ACC/AHA cardiovascular algorithm. The results were multiplicated by 1.5, according to current guidelines. A carotid ultrasound was performed to all study subjects by a certified radiologist blinded to clinical information. Distribution was evaluated with the Kolmogorov-Smirnov test. Correlations were performed with the Spearman-rho coefficient (rho). A ROC-curve analysis was performed for both algorithms. The areas under the curve (AUC) of the algorithms were compared using the method of DeLong.

Results: The presence of CP was detected in 59 (36.0%) patients. Demographic characteristics are shown in Table 1. There was a large positive correlation between the WHO and the ACC/AHA algorithms (rho=0.880, p<0.001). Both algorithms showed significant discrimination for the presence of CP in RA patients. The WHO algorithm had an AUC 0.729 (95% CI 0.649-0.809, p<0.001) and the ACC/AHA algorithm had an AUC 0.687 (95% CI 0.604-0.770, p<0.001). However, there was a difference when comparing both AUC, which was higher with the WHO algorithm (p=0.042) (Figure 1).

RA, rheumatoid arthritis; T2DM, type 2 diabetes mellitus; WHO, world health organization; ACC/AHA, American College of Cardiology/American Heart Association.

Conclusion: Our results showed that although both algorithms had significant discrimination for the presence of CP, the 2019 WHO algorithm had a better capacity for the detection of CP than the 2013 ACC/AHA algorithm, for this specific Hispanic RA population. This could be attributed to the fact that the WHO algorithm was designed for 21 different regions, including the Mexican population.

**ABSENCE OF ASSOCIATION BETWEEN ABATACEPT EXPOSURE LEVELS AND INITIAL INFECTION IN PATIENTS WITH RA: A POST HOC ANALYSIS OF THE RANDOMIZED, PLACEBO-CONTROLLED AVERT-2 STUDY**

1University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Leeds Teaching Hospitals NHS Trust, Leeds NIHR Biomedical Research Centre, Leeds, United Kingdom; 4University of Texas, Division of Rheumatology, Dallas, United States of America; 6Bristol Myers Squibb (at the time of analysis), Immunology and Fibrosis, Princeton, United States of America; 8Bristol Myers Squibb, Immunology and Fibrosis, Princeton, United States of America; 9Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; 10Instituto de Rehabilitación Psicofísica, Department of Rheumatology, Buenos Aires, Argentina; 11Signifience, Biostatistics, Paris, France; 12Bristol Myers Squibb, Clinical Pharmacology and Pharmacoemetrics, Princeton, United States of America; 13Cognigen Corporation, a Simulations Plus company, Pharmacometrics, Buffalo, United States of America; 14Cognigen Corporation, a Simulations Plus company, Statistics, Buffalo, United States of America

**Background:** Infections are the most commonly reported AE observed in patients with RA treated with immunosuppressive therapies and can be clinically significant. A recent review reported differences in the risk of infection for some biologics such as tocilizumab and TNF inhibitors. Abatacept selectively modulates T-cell co-stimulation and is approved for the treatment of RA. In patients with polyarticular-course juvenile idiopathic arthritis, no association was found between higher serum abatacept exposure and the incidence of infection. This has not been evaluated for adult patients with RA.

**Objectives:** To determine if higher serum abatacept exposure during treatment with SC abatacept was associated with increased risk of infection in adult patients with RA.

**Methods:** AVERT-2 (Assessing Very Early Rheumatoid arthritis Treatment-2) was a randomized, placebo-controlled study of SC abatacept + MTX vs abatacept placebo + MTX in MTX-naïve, anti-citrullinated protein antibody–positive patients with early, active RA. A post hoc population pharmacokinetic (PK) analysis was performed using PK-evaluable patient data from the induction period (year 1) of AVERT-2. Association between steady-state abatacept exposure (min plasma concentration [Cmin], max plasma concentration [Cmax], and average plasma concentration [Cavg]), or compared with placebo (Figure 1A–C). Kaplan–Meier plots of probability vs time on treatment by abatacept exposure quartiles and Cox proportional-hazards models.

**Results:** PK of SC abatacept was defined as a linear 2-compartment model with first-order absorption and first-order elimination. The findings of the updated PK analysis were consistent with those reported in prior population analyses of abatacept PK in adults with RA. The final model included effects of baseline body weight, estimated glomerular filtration rate, sex, age, albumin, MTX use, NSAID use, SJC, and race on abatacept clearance. The only covariate with a clinically relevant effect was higher body weight, which caused an increase in clearance and volume. Infections occurred in a total of 330/693 (47.6%; serious, 1.6%) patients treated with abatacept, and 134/301 (44.5%; serious, 1.3%) with placebo during the first year of AVERT-2. In patients taking abatacept, the mean (SD) study exposure to abatacept was 376 (60) days, while mean (SD) prednisone equivalent dose was 6.7 (3.8) mg/day and mean (SD) MTX dose was 9.6 (3.0) mg/week. No exposure–response relationship was observed between the probability of first infection and steady-state abatacept exposure quartiles (Cmin, Cavg, and Cmax, or compared with placebo (Figure 1A–C). Kaplan–Meier assessment also showed no increase in risk of infection with concomitant use of MTX and glucocorticoids.

**Conclusion:** No association was found between initial infection and steady-state abatacept exposure (Cmin, Cavg, Cmax) or MTX and glucocorticoid use in patients with RA treated with SC abatacept.

TRENDS IN THE OCCURRENCE OF ISCHEMIC HEART DISEASE OVER TIME IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY FROM NORWAY OF 1821 PATIENTS FROM 1972 TO 2014

C. L. Alsing,1,2 T. W. Nystad,3,4 J. Iland,5,6 C. G. Gjesdal,2,3,4 H. Midtbø,2,3,4 G. Stjernvall,2,3,4 B. T. Toldrá,5,6 on behalf of RbA - Bergen group of Epidemiology and Biomarkers in Rheumatic Diseases.1 Haraldsplass Deaconess Hospital, Department of Internal Medicine, Bergen, Norway; 2University of Bergen, Department of Clinical Science, Bergen, Norway; 3Haukeland University Hospital, Department of Rheumatology, Bergen, Norway; 4University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway; 5Western Norway University of Applied Science, Department of Health and Social Science, Centre for Evidence-Based Practice, Bergen, Norway; 6Haukeland University Hospital, Department of Heart Disease, Bergen, Norway; 7Norwegian Institute of Public Health, Division of Mental and Physical Health, Bergen, Norway

Background: Previous studies have shown that rheumatoid arthritis is associated with a 1.5 to 2.0 times increased risk of acute myocardial infarction (AMI) and ischemic heart disease (IHD) compared with the general population [1,2]. RA treatment has improved vastly over the last two decades, due to the focus on early and aggressive treatment and the use of synthetic and biologic DMARDs. Several studies have documented higher rates of remission and better long-term outcomes in patients with early introduction of DMARDs [3]. This “window of opportunity” may also be a critical phase for intervention against the development of atherosclerosis in RA. There is little information about the occurrence of AMI and IHD in RA patients diagnosed after the introduction of modern RA treatment.

Objectives: To evaluate trends of AMI and IHD in RA patients compared with the general population over time.

Methods: We performed a retrospective cohort study of 1821 RA patients diagnosed from 1972 to 2013. The total population of Hordaland, Norway was used as a comparison cohort. Information on AMI and IHD events was obtained from hospital patient administrative systems or cardiovascular registries during 1972-2014. Aggregated counts of AMI, IHD and population counts of the comparison cohort were used to calculate expected counts of AMI and IHD in the RA cohort per 5-year age group, sex and calendar year. We then used Poisson regression with expected counts as an offset to estimate standardized event ratios (SER) as a measure of excess events.

Results: The difference in events (excess events) in RA patients compared with the general population declined on average 1.3% per year for AMI and 2.3% for IHD from 1972 to 2014. There was no significant excess AMI (SER 1.05, 95% CI 0.89–1.35) and IHD events (SER 1.02, 95% CI, 0.89–1.16) for RA patients diagnosed after 1998 compared with the general population.

Conclusion: RA patients have historically had an excess risk of IHD compared with the general population. Our study did not find excess AMI or IHD events in RA patients diagnosed after 1998. Our findings may reflect improved management of RA, CVD prevention or changes in the case-mix of RA patients over time.

protein antibodies (ACPA), clinical suspect arthralgia (CSA) and rheumatoid arthritis (RA) in a large population-based cohort.

**Methods:** Cross-sectional data were used from 17346 participants of the Dutch Lifelines Cohort Study, of whom baseline SAF and ACPA levels were available. The presence of CSA was determined using EULAR questions from the connective tissue disease screening questionnaire (CSQ). Individuals were divided into four groups: ACPA negative controls (n=17211), ACPA positive without CSA (n=49), ACPA positive with CSA (n=31) and defined RA (n=52). Multinomial regression was used to compare SAF levels and correct for potential confounders.

**Results:** SAF levels were higher in the ACPA positive with CSA group (OR 2.04, p=0.034) and the defined RA group (OR 3.10, p<0.001) compared to controls, but not in the ACPA positive without CSA group (OR 1.07, p=0.875). The difference in SAF levels remained statistically significant in the defined RA group after adjusting for age (OR 2.09, p=0.011), smoking status, renal function or HbA1c. In the ACPA positive with CSA group, the effect was found to be comparable (corrected for age: OR 2.09).

**Conclusion:** Our results indicate that ACPA positive individuals with CSA have elevated SAF levels, which is regarded as an early marker for oxidative stress and a possible indicator for development of cardiovascular disease. Therefore it is important to conduct further studies to explore if, in individuals with clinical suspect arthralgia, cardiovascular risk management should be considered in future clinical practice.

**Background:** Fasting has been shown to be beneficial in many diseases, including rheumatoid arthritis (RA). Among other effects, fasting stimulates ketogenic metabolism, induces autophagy, and harbors immunomodulatory functions. Recent studies have highlighted the role of the intestinal microbiota in the still unclear etiology of RA1. This could be a potential target for additional dietary therapy in RA.

**Objectives:** To investigate the effect of therapeutic fasting followed by a plant-based diet compared to standard dietary recommendations in patients with RA.

**Methods:** In this pilot study2 patients with RA were randomized to either a 7-day fast (≤250kcal/d) followed by 11 weeks of plant-based diet or to conventional nutritional counselling according to the recommendations of the German Society for Nutrition (Deutsche Gesellschaft für Ernährung, DGE) for 12 weeks. Disease activity and treatment response in RA (including Health Assessment Questionnaire, HAQ; EULAR Response Criteria, ACR Response Criteria) were measured at baseline (T0), day 7 (T1), 6 weeks (T2) and 12 weeks (T3).

**Results:** A total of 50 from S3 enrolled participants were included into the per-protocol analysis. The mean age was 51.96 ± 9.4 years with symptoms duration of 6.8 ± 8.1 years; 92% were females and 78% were ACPA and/or RF IgM positive. At baseline, participants presented HAQ 0.8 ± 0.5, DAS28CRP 4.0 ± 1.3, CRP 3.1 ± 3.8mg/L, and a BMI of 25.0 ± 3.7kg/m². The primary endpoint did not become significant. However, post-hoc analyses revealed clinically relevant improvements in the HAQ after 12 weeks in both the fasting and the DGE group (∆-0.29; 95% CI, -0.45 to -0.13; p=0.032; and ∆-0.23; 95% CI, -0.45 to -0.22; p=0.032, respectively). Furthermore, the effect already set on by day 7 in the fasting group compared to week 6 in the DGE group (Figure 1). This effect was independent of antibody status, delivery mode of the intervention or previous dietary forms. CV risk factors including weight and total cholesterol levels improved stronger in the fasting group compared to the DGE group (∆-3.9 kg vs. -0.7 kg; 95% CI, 1.4 to 5.0, p = 0.001 and ∆-18.60 mg/dL vs. ∆-6.44 mg/dL; 95% CI, 1.7 to 42.8, p = 0.007).

![Figure 1. EULAR and ACR Response until week 12 and HAQ up to 6 months. ACR, American College of Rheumatology; CI, confidence interval; HAQ, health assessment questionnaire.](https://www.acl.org/)

![Figure 2. POS0583].](https://www.acl.org/)
Conclusion: Fasting followed by a plant-based diet positively impacts disease activity and CV risk factors in RA, comparable to and no lesser than those of an anti-inflammatory diet according to the DGE. These results may open new perspectives by dietary interventions in an integrative therapeutic approach. Further confirmatory clinical studies with larger patient numbers are needed to confirm these exploratory findings.

Conclusion: The psychiatrist’s diagnosis was abnormal in 9 patients. This included one patient with major depression, one patient with moderate depression, and two patients with adjustment disorder. The Patient Health Questionnaire-9 (PHQ-9) and Center for Epidemiologic Studies Depression Scale (CES-D) questionnaires were used; a score of 10 or more on the PHQ-9 and 16 or more on the CES-D was considered for the diagnosis of RA complicated by psychiatric disorders.

Results: Forty-nine outpatients with RA who agreed to participate in this study were included. Age, gender, type of Disease-modifying anti- rheumatic drugs, prednisolone use, presence of diabetes, hypertension, dyslipidemia, and CRP were investigated. The Patient Health Questionnaire-9 (PHQ-9) and Center for Epidemiologic Studies Depression Scale (CES-D) questionnaires were used; a score of 10 or more on the PHQ-9 and 16 or more on the CES-D was considered a cutoff. The psychiatrist was blinded to the results of the questionnaire and conducted a structured interview in a separate room. The psychiatrist’s diagnosis was defined as the Gold Standard, and was compared with the PHQ-9 and CES-D. Results: Psychiatrist’s diagnosis was abnormal in 9 patients. This included one patient with major depression, one patient with moderate depression, two patients with minor depression, and two patients with adjustment disorder. The PHQ-9 had a specificity of 98%, a sensitivity of 33%, a positive predictive value of 75%, and a negative predictive value of 87%. The CES-D had a specificity of 82%, a sensitivity of 100%, a positive predictive value of 56%, and a negative predictive value of 100%.

Conclusion: The PHQ-9 and CES-D may be useful in screening for psychiatric disorders including associated with RA.

POS0586
DIAGNOSIS OF MENTAL DISORDER COMPLICATED BY RHEUMATOID ARTHRITIS: A STUDY OF THE VALIDITY OF A PSYCHIATRIST’S DIAGNOSIS AND QUESTIONNAIRE METHOD

Y. Miwa1, H. Tomioka2, M. Hosaka3, Y. Mitamura1, 1Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan; 2Showa University School of Medicine, Department of Psychiatry, Yokohama, Japan; 3Kasuyama Clinic, Department of psychosomatic medicine, Yamanshi, Japan

Background: It has been reported that about 15% of patients with rheumatoid arthritis (RA) have depression, and most of these studies have used questionnaire methods. Most of the studies have used questionnaires for depression. Because the depression questionnaire includes questions about physical symptoms, it is necessary to be careful in interpreting the results when there is an underlying disease. In addition, there are no studies on other mental disorders.

Objectives: In this study, we examined the validity of the questionnaire method for the diagnosis of RA complicated by psychiatric disorders.

Methods: Forty-nine outpatients with RA who agreed to participate in this study were included. Age, gender, type of Disease-modifying anti-rheumatic drugs, prednisolone use, presence of diabetes, hypertension, dyslipidemia, and CRP were investigated. The Patient Health Questionnaire-9 (PHQ-9) and Center for Epidemiologic Studies Depression Scale (CES-D) questionnaires were used; a score of 10 or more on the PHQ-9 and 16 or more on the CES-D was considered a cutoff. The psychiatrist was blinded to the results of the questionnaire and conducted a structured interview in a separate room. The psychiatrist’s diagnosis was defined as the Gold Standard, and was compared with the PHQ-9 and CES-D.

Results: Psychiatrist's diagnosis was abnormal in 9 patients. This included one patient with major depression, one patient with moderate depression, two patients with minor depression, and two patients with adjustment disorder. The PHQ-9 had a specificity of 98%, a sensitivity of 33%, a positive predictive value of 75%, and a negative predictive value of 87%. The CES-D had a specificity of 82%, a sensitivity of 100%, a positive predictive value of 56%, and a negative predictive value of 100%.

Conclusion: The PHQ-9 and CES-D may be useful in screening for psychiatric disorders including associated with RA.

POS0587
TRAJECTORYs AND FACTORS INFLUENCING THE EVOLUTION OF HAND GRIP AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

B. Squecioni1, B. Pereira1, M. Beauger2, M. Couderc3, F. Ladouce3, S. Malochet3, S. Mathieu4, P. Marie-Eva5, M. Soubrier4, A. Tournadre4; 1CHU Clermont-Ferrand, Rheumatology, Clermont Ferrand, France; 2CHU Clermont-Ferrand, Biostatistics department DRCI, Clermont-Ferrand, France

Background: Rheumatoid arthritis (RA) is characterized by an early reduced grip strength which persists over time despite the remission of the disease suggesting the presence of a sarcopenia.

Objectives: To study the evolution of the grip strength measured by the handgrip, by identifying different trajectories and associated factors.

Methods: Patients with active RA who visited the Rheumatology Department of Clermont-Ferrand University Hospital for initiating bDMARD were invited to participate to the longitudinal cohort RCVRIC analyzing cardiovascular risk and chronic inflammatory rheumatic disease. Within the RCVRIC cohort 175 RA initially underwent a handgrip determination. 143 patients had at least 2 handgrip measurements over 2 years, allowing analysis of trajectories by the “Group Based Trajectory Modeling” method. For the trajectories, handgrip was expressed in terms of percentage of the theoretical value defined according to age and sex. The clinical characteristics of the disease, the therapeutic response, and the body composition associated with each trajectory were analyzed.

Results: At inclusion, the handgrip was normal among only 4% of patients, with an alteration of 51% of its theoretical value. After 2 years of follow-up, a majority of patients improved their handgrip trajectory to reach an average of 68% of the theoretical one, but only 15.7% of the patients normalized their handgrip. Four trajectories have been identified along with associated factors:

1st trajectory consists of low handgrip with little improvement and was composed of: 9 patients (6.3%), median age 60 years [53.6;69.3], 88% women, disease duration 17.99 years [6.78;24.9], EAS 28 ESR 4.68 ± 1.29, and initial handgrip 21% of the theoretical value [8;24].

2nd trajectory shows good improvement (+72%) and was composed of: 70 patients (49%), median age 58.9 years [54.4;64.3], 84% women, disease duration 5.99 years [1.46;14.8], EAS 28 ESR 4.43 ± 1.07, and initial handgrip 32% of the theoretical value [17.8;46.4].

3rd trajectory shows moderate improvement (+25%) and was composed of: 43 patients (30%), median aged 60.7 years [45.7;69.4], 79% women, disease duration 3.5 years [1.25;9.9], EAS 28 ESR 4.0 ± 1.03 and initial handgrip 60% of the theoretical value [48.2;76].

4th trajectory shows high handgrip and was composed of: 21 patients (14.7%), 57% women, median age 57.9 years old [49.7;67.4], disease duration 3.81 years [2.14; 10.7], EAS 28 ESR 3.68 ±1.29 and initial hand grip 92% of the theoretical value [85; 100].

Significant differences at inclusion between the 4 trajectories were observed. The 4th trajectory was characterized by a higher proportion of men (p=0.05), lower disease activity (EAS 28 ESR (p=0.02), SDAI (p=0.04), better initial handgrip (p=0.03) and 6min walk test (p=0.0001), and a lower percentage of fat mass (p=0.04). In contrast, a higher disability (HAQ, p=0.002), a lower total lean body mass (p=0.001) and poorer therapeutic response (p=0.04) were noted in trajectories 1 and 2.

Conclusion: After 2 years of follow-up, a majority of patients improved their handgrip trajectory. However, very few patients normalized their hand grip. Four trajectories of handgrip were identified; the main indicators of hand grip’s improvement were the control of the disease activity, low functional disability, walking performance, a low percentage of fat mass and high lean mass.

SEASONALITY OF FLARE AND REMISSION PATTERNS IN RHEUMATOID ARTHRITIS: A POPULATION-BASED COHORT STUDY

R. Javed1, C. S. Crowson2, J. M. Davis III1, E. Myasoedova2,3. Mayo Clinic, Division of Rheumatology; Rochester, United States of America;4 Mayo Clinic, Division of Rheumatology; Department of Quantitative Health Sciences, Rochester, United States of America

Background: Flare of rheumatoid arthritis (RA) disease activity is an important aspect of RA disease experience for patients with RA, associated joint damage and comorbidity. Major advancements in treatment of RA in recent decades resulted in improving trends in RA disease activity and increasing rates of remission. However, flares in RA remain common and some patients are still unable to achieve remission. Disease-modifying antirheumatic drugs have a major impact on controlling RA disease activity, minimizing the likelihood of flares. The effect of environmental factors on the pattern of flares and remissions in RA is less studied. Previous studies showed conflicting results regarding the likelihood of flare and remission occurrence across the seasons of the year.

Objectives: To assess the seasonal pattern in the occurrence of flares and remissions in a population-based cohort of patients with RA.

Methods: This retrospective population-based cohort study included patients with RA (age ≥30 years) who met 1987 ACR criteria in 1988-2007. A retrospective review of each clinical visit in the medical records was performed to ascertain flare or remission status. A flare was defined as an episodic worsening of RA disease activity that leads to initiation, change or increase of treatment. Remission was defined as the absence of disease activity based on a tender joint count of 0, a swollen joint count of 0 and an ESR less than 10 mm/h. Seasons were defined as: winter (Dec, Jan, Feb), spring (Mar, Apr, May), summer (June, July, Aug) and autumn (Sep, Oct, Nov). All subjects were followed until death, migration or July 1, 2012. Generalized linear models with random effects accounts for multiple visits per patient were used for data analyses.

Results: The study included 650 RA patients (mean age 55.8 years; 69% female) with a mean follow-up of 10.3 years. In a total of 17,323 clinical visits, patients were flaring in 2887 (17%) visits. The incidence of RA flares was 15% higher in the spring than in the winter (OR 1.15: CI: 1.02-1.29, p=0.045) after adjusting for age, sex and RA duration. There was no change in flare pattern between winter and summer or autumn. Remission rate did not differ between the seasons. (3df test p=0.65).

Conclusion: Patients with RA were more likely to experience flares in spring as compared to winter, and there were no differences in flare rates for the rest of the seasons. Remission rates were similar between the seasons of the year. The reasons for this seasonal effect on flare pattern is unknown, and the role of patient-related and environmental risk factors remains to be investigated. Our findings on the seasonality in flare occurrence can be used to inform patients about the risk of RA disease flares throughout the year.

CARDBOVIDR DISEASE RISK IN INFLAMMATORY ARTHRITIS STILL ELEVATED IN 2021!

R. Raadtsen1, F. Hooijberg1, L. Boeke1, G. J. Wolbink1, W. Lems1,2, A. Van Kuijk1, M. Nurmohamed1,2. Amsterdam Rheumatology and Immunology Center, location Reade, Rheumatology, Amsterdam, Netherlands; Amsterdam Rheumatology and Immunology Center, location VU University Medical Center, Rheumatology, Amsterdam, Netherlands

Background: Patients with inflammatory rheumatic diseases as rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA) are at higher risk for developing cardiovascular diseases (CVD) than the general population. This is due to a higher prevalence of ‘traditional’ CVD risk factors such as hypertension and dyslipidaemia, and the underlying systemic inflammation. During the past two decades, the burden of inflammation has been reduced by more efficacious anti-rheumatic treatment, leading to a reduced CVD risk, albeit still elevated in comparison to the general population. Therefore, it remains important to monitor the presence of CVD in rheumatic patients in systematically controlled cohorts.

Objectives: To evaluate whether, nowadays, the CVD risk of patients with inflammatory rheumatic diseases still differs from the general population.

Methods: In March 2020, all adult patients with an inflammatory rheumatic disease, from the Amsterdam Rheumatology and Immunology Center, location ‘Reade’ were systematically asked to participate in a prospective cohort study, which focused on the impact of the COVID-19 pandemic. The patients were compared with age and sex matched controls. In the third questionnaire, sent out in January 2021, questions regarding CV risk factors and comorbidities were added. Baseline characteristics and prevalence of CV risk factors and CVD were compared between RA, PsA, SpA patients, and healthy controls.

Results: 2050 consecutive patients with an inflammatory rheumatic disease (1312 RA patients, 353 PsA patients, 385 SpA patients), and 939 healthy controls completed the questionnaires (Table 1). The prevalence of at least one CV morbidity was more frequently reported in RA, PsA and SpA patients compared to healthy controls: 69 (5%), 24 (7%), 17 (4%) compared to 31 (3%), respectively. Events were primarily cardiac (i.e. myocardial infarction and coronary angioplasty). Inflammatory arthritis patients more often had hypertension or hypercholesterolemia than healthy controls, which were untreated in nearly half the cases. RA patients most often used anticoagulant medication.

Disclosure of Interests: None declared.

ASSOCIATIONS BETWEEN SELF-REPORTED RHEUMATOID ARTHRITIS, RHEUMATOID FACTOR POSITIVITY AND STRUCTURAL BRAIN PHENOTYPES IN UK BIOBANK

I. Stančič1, S. Siebert2, D. Mackay1, D. Lyall1. University of Glasgow, Public Health, Glasgow, United Kingdom; 3University of Glasgow, Infection Immunity & Inflammation, Glasgow, United Kingdom

Background: There is very limited research on structural brain health in people with rheumatoid arthritis (RA).

Objectives: To investigate whether there are differences in brain volume in people with self-reported RA or positive rheumatoid factor (RF+).

Methods: Cross-sectionally tested for associations with several MRI brain volume measures in UK Biobank (n=37,379 of whom 432 RA and 1833 RF+). The partially adjusted regression models controlled for age and sex, while the fully adjusted models further controlled for deprivation index, smoking status and alcohol consumption.
cardiometabolic diseases. For all subcortical volumes analyses we also controlled for total brain volume.

Results: Those that self-reported RA were more likely to have increased WMH (White Matter Hyperintensities) (β = 0.08, 95% CI: 0.022; 0.14, p<0.01), and smaller volumes of the amygdala (β = -0.07, 95% CI: -0.13; -0.005, p<0.05) and thalamus (β = -0.06, 95% CI: -0.12; -0.01, p<0.05) in the partially adjusted analyses. In the fully adjusted model only amygdala volume remained negatively associated with RA (β = -0.09, 95% CI: -0.16; -0.02, p<0.01).

Conclusion: We provide evidence of differences in structural brain phenotypes known to underpin cognitive and psychological health, in RA. Since the amygdala may play an important role in pain modulation and mental health, while WMH are associated with a higher risk of stroke, the observed differences may be of clinical relevance in RA which is associated with a higher prevalence of these conditions. Further research is required to confirm these findings and assess their functional implications.

Disclosure of Interests: None declared.

Table 1. Attributes and levels of treatment options

<table>
<thead>
<tr>
<th>Treatment attribute</th>
<th>Levels describing no treatment option</th>
<th>Levels describing treatment option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chance of developing RA</td>
<td>60%</td>
<td>20%</td>
</tr>
<tr>
<td>Chance of mild side effects</td>
<td>0%</td>
<td>2%; 4%; 5%; 7%; or 10%</td>
</tr>
<tr>
<td>Chance of a serious infection due to treatment</td>
<td>0%</td>
<td>1%; 15%; 2%; 3%; or 5%</td>
</tr>
<tr>
<td>Chance of a serious side effect that is potentially irreversible</td>
<td>0.001%; 0.01%; 0.02%; 0.05% or 0.1%</td>
<td></td>
</tr>
</tbody>
</table>

Results: 289 FDRs (80 male) responded. The mean (SE) MAR for mild side effects, serious infection, and serious side effects was 29.08 (1.52), 9.09 (0.60) and 0.85 (0.27), respectively. Participants aged over 60 years were less tolerant of risk of serious infection than average (mean MAR - 2.06 (0.78)) and younger participants were more tolerant of risk of serious infection than average (mean MAR + 2.06 (0.78)). Risk of mild side effects was less acceptable to participants who perceived they were likely/very likely to develop RA (mean MAR - 3.34 (1.55)) than to those who did not (mean MAR + 3.34 (1.55)). Education level, health literacy, numeracy, IQP and BMO-G subscales were not predictors of risk tolerance.

Conclusion: Age and perceived risk of RA had a significant impact on FDRs tolerance for specific, but not all, included risks. Cognitive ability and beliefs about RA/medicine did not explain preference heterogeneity. This is informative for drug development and the development of tailored risk communication resources to support preventive approaches.

POS0592 PREDICTING LIVER ENZYME ELEVATION IN PATIENTS WITH RHEUMATOID ARTHRITIS ON TREATMENT WITH METHOTREXATE USING SUPERVISED MACHINE LEARNING

V. Gilvaz1, S. Surenradan2, M. Cb2, 1Rhode Island Hospital, Rheumatology, Providence, United States of America; 2Amita Hospital, Rheumatology, Kochi, India

Background: Methotrexate (MTX) is the most used disease-modifying anti-rheumatic drug (DMARD) in the treatment of rheumatoid arthritis (RA). (1) Chronic use of this medication warrants close laboratory monitoring given its propensity for liver damage and myelosuppression. (2) MTX associated hepatic dysfunction is a well-described adverse effect and has been seen in up to a quarter of
patients on long term treatment. (3) Recent advances in health care coupled with the extensive use of electronic health records (EHR) has resulted in the accumulation of large amounts of patient data. Approaches like machine learning (ML) allows us to leverage these large data sets to predict outcomes and support clinical decision making. (4) We hypothesized that a ML model trained on conventionally available EHR data would be able to identify patients at the greatest risk of developing MTX related hepatotoxicity.

**Objectives:** To develop a machine learning model to accurately predict liver enzyme elevation in rheumatoid arthritis (RA) patients on treatment with methotrexate (MTX) using electronic health record (EHR) data from a real-world RA cohort.

**Methods:** Demographic, clinical, biochemical, as well as prescription information from 569 RA patients were retrospectively collected. Liver transaminase elevation above the upper limit of normal following initiation of MTX, was the primary outcome. The total dataset was randomly split into a training (80%) and test set (20%) and used to develop a Random Forest Classifier model. The best model was selected after hyper-parameter tuning and fivefold cross-validation.

**Results:** 104 patients (18.2%) developed hepatic dysfunction while on MTX therapy. The best performing predictive model had an accuracy/F1 score of 0.87. The top ten predictive features were then used to create a limited feature model that retained most of the predictive accuracy, with an accuracy/F1 score of 0.86.

**Conclusion:** Our proof-of-concept study suggests the possibility of building a well-performing ML model to predict liver enzyme elevation in RA patients being treated with MTX. Similar ML models could be used to identify ‘high risk’ patients who can then be potentially targeted for closer monitoring with the aim of preventing these adverse outcomes. Conversely, patients at low risk can avoid extra outpatient visits, thereby reducing costs.

THE COURSE OF FATIGUE AND ITS RELATION WITH INFLAMMATION DURING THE DEVELOPMENT OF RHEUMATOID ARTHRITIS: A LONGITUDINAL STUDY

S. Khidir1, F. Wouters1, E. Van Mulligen1,2, A. Van der Helm-van Mil1,2. 1Leiden University Medical Centre, Leiden, Rheumatology, Leiden, Netherlands; 2Erasmus Medical Centre, Rheumatology, Rotterdam, Netherlands

**Background:** Fatigue is a prominent and disabling symptom in patients with rheumatoid arthritis (RA), that is only partially explained by inflammation and responds poorly to DMARD-therapy. We hypothesized that inflammation explains fatigue to a larger extent in the phase of clinically suspect arthralgia (CSA), when clinical arthritis is still absent and fatigue has not yet become chronic.

**Objectives:** To study the course of fatigue in CSA during progression to RA and the association with inflammation at CSA-onset and at RA-diagnosis.

**Methods:** 600 consecutive CSA-patients were followed for RA-development (median follow-up 25 months). Additionally, 710 early RA-patients were studied at diagnosis. Fatigue was assessed every study visit and expressed on a scale of 0-100. The DAS44-CRP was used to measure inflammation (with SJC=0 in CSA). The course of fatigue over time was studied with linear mixed models. Associations between fatigue and inflammation were studied with linear regression, corrected for sex. Analyses were stratified by ACPA-status.

**Results:** In 88 CSA-patients who developed RA, pre-arthritis fatigue levels increased gradually with 7/year (95%CI= -2 to 16, p=0.13), towards 48 at RA-development. Fatigue decreased in CSA-patients who did not develop RA (-4/year, 95%CI= -6 to -3, p<0.001) (see Figure 1). At CSA-onset, inflammation was associated with fatigue (β=18, meaning 18 points more fatigue than the same healthy individual).

**Figure 1.** Course of fatigue in CSA-patients developing RA (A) and in CSA-patients not developing RA (B)

**Disclosure of Interests:** None declared.
per point increase DAS-score, 95% CI=7-28, p=0.001). This association was stronger than at RA-diagnosis (p=5, 95% CI=3-7, p<0.001). Fatigue-levels increased towards RA-development in both ACPA-subtypes, but were on average higher in ACPA-negative CSA than ACPA-positive CSA (mean difference in fatigue of 13, 95% CI=1-24, p=0.027). However, the association between fatigue and inflammation was stronger in ACPA-positive compared to ACPA-negative CSA.

Conclusion: Fatigue increased gradually during progression from arthralgia to clinical arthritis, and fatigue was better explained by inflammation in CSA than in RA. This implies a ‘phase-dependent relation’ between inflammation and fatigue.

POS0594 FACTORS ASSOCIATED WITH THE 6-MINUTE WALK TEST AMONG PERSONS WITH RHEUMATOID ARTHRITIS

I. S. Houge1,2, M. Hofte3,4, V. Videm1,5.
1Norwegian University of Science and Technology, Department of Molecular and Clinical Medicine, Trondheim, Norway; 2Levanger, Department of Rheumatology, Levanger, Norway; 3Norwegian University of Science and Technology, Department of Neumedicine and Movement Science, Trondheim, Norway; 4St. Olav’s University Hospital, Department of Rheumatology, Trondheim, Norway; 5St. Olav’s University Hospital, Department of Immunology and Transfusion Medicine, Trondheim, Norway

Background: Persons with rheumatoid arthritis (RA) are less physically active than the general population. A 6-minute walk test (6MWT) measures how far a person can walk in 6 minutes, testing overall functional capacity. This can inform clinicians before initiating potential interventions.

Objectives: To assess psychological, patient- and disease-related factors associated with 6MWT results among persons with RA.

Methods: Patients were recruited in 2019 and 2021 from the Rheumatology outpatient clinics at St. Olav’s Hospital and Levanger Hospital, Norway (n=225). They answered questionnaires, and a subgroup (n=86) performed a 6MWT according to guidelines from the American Thoracic Society (1). Diagnostic characteristics and medical history were collected from hospital records. Participants with data for 6MWT but missing data for other variables in the main model were excluded (n=7). Physical function was measured with the Modified Stanford Health Assessment Questionnaire (mHAQ, range 0-3, lower score indicating better physical function). For the patient global assessment (PGA) patients rated their overall disease activity in the past week on a 100 mm visual analogue scale; higher score indicates more symptoms. Presence of depressive symptoms was measured with the Hospital Anxiety Depression Index Depression score (HADS-D, range 0-21, higher score indicating more depressive symptoms). Perceived stress was measured with the Cohen’s Perceived Stress Scale, median (IQR) 15 (9, 19). Anxiety Depression Index Depression score, median (IQR) 3 (1, 4), Cohen’s Perceived Stress Scale, median (IQR) 15 (9, 19), Self-Efficacy for Exercise, median (IQR) 25 (20, 30). 6-Minute Walk Test (m), mean (±SD) 507 (±88).

multiple regression with 6MWT as dependent variable. Model 1 included age (categorized into tertiles to improve model fit: <59, 59-89, or ≥70 years), sex, mHAQ, PGA, HADS-D, Cohen's Perceived Stress Scale. Self-Efficacy for Exercise, smoking habit and body mass index (BMI, categorized ≤25 or >25 kg/m²). Model 2 included only the variables significantly associated with 6MWT in Model 1, but keeping adjustment for sex. The regression coefficients of Model 2 were standardized.

Results: In model 1, the variables associated with 6MWT were mHAQ (p=0.04), Self-Efficacy for Exercise (p=0.001), BMI (p=0.01) and age (oldest versus youngest age tertile p<0.001, middle versus youngest age tertile p=0.11). Sex was not significantly associated with 6MWT (p=0.82). The standardized coefficients in Model 2 were: mHAQ -0.27 (p=0.002), Self-Efficacy 0.27 (p=0.002), categorized BMI -0.27 (p-value=0.002), middle age group versus youngest age group -0.17 (p=0.08), oldest age group versus youngest age group -0.55 (p<0.001), male gender 0.08 (p=0.33). The R² of Model 1 and Model 2 were 0.54 and 0.52 respectively.

Conclusion: Self-Efficacy for Exercise, mHAQ, BMI and age had the largest impact on 6MWT, explaining 52 % of the observed variation in 6MWT in a model adjusted for sex.

Disclosure of Interests: None declared.

POS0595 THE ASSOCIATION BETWEEN AXIAL AND PERIPHERAL BONE IN PATIENTS WITH RHEUMATOID ARTHRITIS, INCLUDING THE IMPACT OF EROSIIVE DISEASE. A HR-pQCT STUDY.

A. B. G. Blavnsfeldt1,2, R. Klose-Jensen3, J. Therkildsen1,2, K. Keller1,3, S. G. Hansen1,4, B. Langdahl2,5, E. M. Hauge1,2, 1Aarhus University Hospital, Rheumatology, Aarhus, Denmark; 2Aarhus University, Clinical Medicine, Aarhus, Denmark; 3Odense University Hospital, Endocrinology, Odense, Denmark; 4University of Southern Denmark, Research Unit of Rheumatology, Department of Clinical Research, Odense, Denmark; 5Aarhus University Hospital, Internal Medicine and Endocrinology, Aarhus, Denmark

Background: The severity of Rheumatoid Arthritis (RA) is associated with increased fracture risk (1). Areal bone mineral density (aBMD) by dual-energy absorptiometry (DXA) is the gold standard for diagnosis of osteoporosis as well as fracture risk assessment. High resolution peripheral quantitative computed tomography (HR-pQCT) of the distal radius yields volumetric BMD (vBMD) of trabecular and cortical bone compartments, as well as micro-architectural parameters and may prove useful for fracture risk prediction. The association between aBMD by DXA and HR-pQCT derived vBMD and microarchitecture have only been sparsely investigated in patients with RA, and it is not known if erosive disease, measured by the gold standard Heijde-modified Sharp Scores (HSS) (2) affects HR-pQCT derived parameters.

Objectives: To assess the associations between aBMD by DXA and bone parameters of the distal radius by HR-pQCT, in both male and female patients with RA, and the impact of erosive disease on the bone parameters of the distal radius.

Methods: We measured aBMD by DXA of the lumbar spine and hip, HR-pQCT of the distal radius and assessed HSS in 162 patients with RA. Using multivariate linear regression models, we explored the association between HSS and HR-pQCT parameters, adjusted for sex and age. The associations between aBMD by DXA and vBMD and microarchitecture by HR-pQCT were assessed by Spearman correlation coefficients, interpreted as negligible (0.00-0.10), weak (0.10-0.39), moderate (0.40-0.69), strong (0.70-0.89) or very strong (0.90-1.00).

Results: Mean age for the included patients was 63 years, 75% were women and median disease duration was 18 years. Erosive disease (HSS) was negatively associated with trabecular number and density, but not with cortical bone parameters. This association was stronger for HSS of the wrist joints, than for HSS of the hands and total HSS (Table 1). Trabecular density of the distal radius correlated moderately with aBMD at the total hip, and weakly with aBMD at the lumbar spine. Trabecular numbers also correlated moderately with aBMD at the total hip. Cortical bone parameters at the distal radius correlated weakly with aBMD at the hip, but only among women.
In the study, the authors investigated the effect of increased cholesterol content in macrophages and the role of inflammation in promoting foam cell formation. They found that serum cholesterol loading capacity on macrophages is linked to oxidized low-density lipoprotein (oxLDL) and C-reactive protein (CRP) in patients with rheumatoid arthritis (RA). The study also explored the role of anti-oxLDL IgG, pro-atherogenic cholesterol transport gene expression in THP-1 human monocyte cell line, and the potential of targeting LDL oxidation in dual seropositive patients.

**Methods:**

A two-stage moderated mediation model was used to explore whether the association between oxPL-apoB100, anti-oxLDL IgG, and PCSK9 with CLC was mediated by CRP and anti-oxLDL IgG. The study included a disease activity-steered cohort of patients with early rheumatoid arthritis. 

**Results:**

OxPL-apoB100, anti-oxLDL IgG, and PCSK9 were positively associated with CLC in dual seropositive patients. CLC was more strongly related to anti-oxLDL IgG and PCSK9 in patients with dual seropositivity compared to single seropositive patients.

**Conclusion:**

Oxidized LDL can directly influence CLC in dual seropositive RA patients, regardless of CRP. The study highlights the importance of targeting LDL oxidation in these patients to reduce atherosclerotic risk.

INTO INFLAMMATORY ARTHRITIS CENTRE VERSUS ARTHRITIS, BIRMINGHAM, UNITED KINGDOM

Background: Risk of rheumatoid arthritis (RA) is 3-5 times higher in first-degree relatives (FDRs). Efforts are increasing to develop preventive interventions for this at-risk group. Risk perception is a key predictor of health behaviours, including FDRs’ interest in predictive testing and preventive intervention for RA. Effective risk communication is essential for RA prevention studies and clinical translation.

Objectives: To define variables associated with perceived risk of developing RA in FDRs of RA patients.

Methods: RA patients attending outpatient clinics (West Midlands, UK) were asked to invite their FDRs to complete a cross-sectional printed survey. Patients were also invited to complete a survey. Unique survey numbers enabled linkage of FDR and proband responses. FDRs’ perceived absolute risk, comparative risk, experiential risk, and worry about risk were assessed using 5-point Likert scales. Predictor variables included demographics, the Single Item Literacy Screener, Brief Illness Perception Questionnaire, Brief Approach/Avoidance Coping Questionnaire, Life Orientation Test Revised and the Short Health Anxiety Inventory. Patient predictors of FDR perceived risk included demographics, time since RA diagnosis and Rheumatoid Arthritis Impact of Disease Score. Outcome measure responses were grouped into ‘low’ and ‘high’ for regression analyses. Univariable analysis used independent samples T-tests, chi-square tests and Mann-Whitney U Tests. Backwards stepwise binary logistic regression examined the relationship between FDR characteristics and perceived risk of RA. Generalised Estimating Equations assessed whether patient variables predicted FDRs’ perceived risk.

Results: 396 FDRs returned a survey. Paired data from 213 patients were available for 292 of these FDRs. The distributions of risk perception scores are shown in Figure 1. All measures of perceived risk were inter-correlated (p<0.001; ranging from r=0.48 to r=0.80). 65.2% of FDRs perceived themselves to be ‘Likely’ or ‘Very Likely’ to develop RA in their lifetime. FDRs’ ethnic group, deprivation index, employment status, education level, smoking status, cohabitation with index patient status, coping style and dispositional optimism were not significantly different between high and low perceived risk groups. Characteristics significant in univariable analyses were used in multivariable analyses (Table 1). Children were 3.89 times more likely than siblings to perceive themselves at high risk of RA. Higher health anxiety scores were associated with increased perceived risk. Female gender, and beliefs that RA would last a long time, and cause higher concern and negative emotional impact predicted increased perceived risk. Higher perceptions of how well treatment would control RA was associated with a reduced likelihood of perceiving oneself at high risk. Index patient characteristics did not associate with FDRs’ risk perceptions.

Conclusions: FDRs’ perceived risk of RA was high. Key predictors included being a child of a patient with RA, higher health anxiety and lower perceptions of RA treatment control. An understanding of these predictors will inform the development of effective risk communication and preventive strategies.

PERSISTING PAIN IN RHEUMATOID ARTHRITIS: DO WE NEED TO RECONSIDER OUR IDEA OF PAIN ALLEVIATION DESPITE ANTI-INFLAMMATORY TREATMENT?

C. Baerwald1, E. Stemmler2, S. Gneucheti3, K. Jeromin3, C. Holland4, B. Fritz5, D. Adolf6, P. C. Taylor5, R. Baron6. 1University Hospital Leipzig, Department of Medicine, Neurology and Dermatology, Rheumatology Unit, Leipzig, Germany; 2AbbVie Germany GmbH & Co. KG, AbbVie Deutschland GmbH & Co. KG, Wiesbaden, Germany; 3AbbVie Deutschland GmbH & Co. KG, AbbVie Deutschland GmbH & Co. KG, Westbaden, Germany; 4StatConsult GmbH, Biometrics and Data management, Magdeburg, Germany; 5University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Headington, Oxford, United Kingdom; 6University Hospital Schleswig-Holstein, Division of Neurological Pain Research and Therapy, Department of Neurology, Kiel, Germany

Background: Pain significantly impacts life of patients with rheumatoid arthritis (RA). Besides articular pain due to systemic inflammation, neuropathic pain (NeP) represents another challenge that can pose a considerable burden on the life of patients.

Objectives: To investigate persisting pain in RA patients and to analyse NeP along with patient-reported outcomes (PROs).

Methods: PAIN-CONTROL is a prospective, non-interventional study in rheumatology centres in Germany. Inclusion criteria were fulfilment of the 2010 ACR/EULAR RA classification criteria, disease duration ≤ 8 yrs, DAS28 > 3.2, SJC > 3, CRP normal or above reference range, and pain rating ≥ 50 (0-100 VAS). Eligible subjects had to be scheduled for escalation of anti-inflammatory treatment according to national guidelines. At wk 24 subjects were allocated to three subgroups given DAS28-CRP change and VAS pain: i) reference group: VAS pain < 50 with either DAS28 improvement > 1.2 or DAS28 ≤ 3.2, ii) non-responders: DAS28 improvement ≤ 1.2 and DAS28 > 3.2 with or without pain alleviation, iii) persisting pain: VAS pain ≥ 50 with either DAS28 improvement > 1.2 or DAS28 ≤ 3.2. For groups 1 and 2 end of study was at week 24, patients with persisting pain continued until wk 48. Patients were assessed for NeP using a score of ≥ 19 in the painDETECT questionnaire (PD-Q) (3). Pain-related PROs, i.e. the Rheumatoid Arthritis Impact of Disease Questionnaire (RAID) and the Patient Health Questionnaire (PHQ-9), were analysed along with demographic background information (1,4). Descriptive results are presented as mean (SD) or mean (SD) | N | n (%) or n (%) | N | n (%), respectively.

Results: 567 subjects were analysed with the following distribution: Reference group 337 (59.4%), non-responders 102 (18.0%), and persisting pain 128 (22.6%), of which 115 patients were available at wk 48. Subgroups showed similar demographic baseline characteristics but differed in PROs (Table 1). Until wk 24, proportion of patients with NeP indication decreased in the reference group (-19.8%) and slightly in non-responders (-6.0%) and persisting pain group (-9.5%). Non-responders showed the highest NeP proportion at wk 24 (35.0%) (Table 1). Of 115 patients with
persisting pain at wk 24, 47 (40.9%) tested NeP negative at wk 48, 21 (18.3%) tested unclear, 28 (24.3%) were missing and 19 (16.3%) tested positive. Of the latter 9 patients (47.4%) still had persisting pain at week 48, whereas this was the case for 14 patients (29.4%) in the former group. Of the 49 (42.6%) of 115 patients with severe persisting pain at wk 24 reported pain alleviation at wk 48 and fulfillment of reference group criteria. RAID and PHQ-9 scores improved in the reference group but only slightly in the other two subgroups.

</table>

Conclusion: NeP is common among RA non-responders to anti-inflammatory treatment and in patients with persisting pain, meritng a routine NeP screening to more adequately address persisting pain in these patients. However, even late improvements (after 24 wks) regarding persisting pain seem likely during anti-inflammatory treatment.

ANGIOGENIC T-CELL DEPLETION OCCURS DURING THE EARLIEST PHASES OF RHEUMATOID ARTHRITIS LINKED TO SUBCLINICAL VASCULAR STIFFNESS

J. Rodríguez-Carrión a, M. Alperi-López2 a, P. López2, A. Pérez-Alvarez1, A. Suárez3 a.

1University of Oviedo, Área de Immunología, Oviedo, Spain;
2Instituto de Investigación Sanitaria del Principado de Asturias, Research Group on Basic and Translational Research on Chronic Inflammatory Diseases, Oviedo, Spain;
3Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain;
4Hospital Universitario Central de Asturias, Neurology, Oviedo, Spain

Background: vascular insult accounts for the cardiovascular (CV) risk excess in rheumatoid arthritis (RA). Angiogenic T cells (Tang), which are responsible of vascular repair, have been described to be reduced in established RA with overt CV disease. However, whether Tang are altered during the earliest stage of the disease and related to subclinical CV findings is unknown.

Objectives: to evaluate circulating Tang levels in the very early stage of RA, including clinically suspect arthralgia (CSA), and their associations with subclinical CV endpoints (subclinical atherosclerosis and vascular stiffness).

Methods: 84 RA patients (2010 EULAR/ACR classification criteria), 14 CSA individuals (EULAR criteria) and 28 matched healthy controls (HC) were recruited. All patients were untreated at the time of sampling. Tang (CD3+CD31+CXCR4+) frequency was assessed by flow cytometry in peripheral blood samples. Plaque occurrence, cIMT and stiffness parameters were analyzed by Doppler ultrasound in internal carotid, middle cerebral and basilic arteries. Lipoprotein analyses were performed by NMR.

Results: Tang were decreased in RA and CSA groups compared to HC (both p<0.010). Whereas Tang frequency was negatively correlated with very low density lipoproteins features (cholesterol and triglyceride content, size distribution and particle number) in HC and positively with HDL (cholesterol content and particle number), these associations were lacking in RA.

Disclosure of Interests: All authors have declared no conflicts of interest.
and CSA groups. Tang levels were not related to individual traditional CV risk factors, body mass index, waist circumference (all p>0.050) nor with the modified SCORE (r=-0.070, p=0.542) or Framingham Risk Score (r=-0.013, p=0.970). On the contrary, disease activity accounted for the Tang depletion observed in RA (β[95% CI]: DSAS−: −0.436 [-0.306, −0.109], p<0.001; SDAI: −0.020 [-0.032, −0.008], p=0.002). Tang levels were unrelated to the duration of the symptoms both in RA and CSA. In RA patients, Tang frequency was not associated with atherosclerosis plaque occurrence (p=0.556) or cIMT (r=0.136, p=0.245). However, Tang paralleled stiffness parameters: vascular strain (VS, r=0.373, p=0.013), vascular distensibility (VD, r=0.479, p=0.004), vascular stiffness (VSI, r=0.400, p=0.007) and pressure-strain elastic modulus (PSEM, r=−0.373, p=0.013). Finally, Tang frequency was an independent predictor of stiffness parameters after adjusting for mSCORE, body mass index, DSAS−, RF and ACPA positivity: VS (β=0.415, p=0.035), VD (β=0.361, p=0.028), VSI (β=−0.322, p=0.033) and PSEM (β=−0.346, p=0.016).

Conclusion: Tang depletion is an early event along RA development, associated with disease-related parameters and unrelated to traditional risk factors. Tang may be the missing, functional link between disease activity and CV outcomes. Altered Tang levels may be an early biomarker of premature vascular stiffness during the first stages of the disease.

POSO061 CRANIOCERVICAL JUNCTION INVOLVEMENT ASSESSED BY COMPUTED TOMOGRAPHY AND/OR MAGNETIC RESONANCE IMAGING IN INFLAMMATORY ARTHRITIS: SINGLE CENTER CASE-CONTROL STUDY

F. Yalçınkaya1, Ş. Parias1, E. Bilgin2, K. Karlı Oğuz3, U. Kalyoncu2
1Hacettepe University, Internal Medicine, Ankara, Turkey; 2Hacettepe University, Radiology, Ankara, Turkey; 3Hacettepe University, Rheumatology, Ankara, Turkey

Background: Cranio-cervical involvement is generally overlooked clinically.

Objectives: The aim of this study is to investigate cranio-cervical involvement in inflammatory arthritides and compare with patients without inflammatory arthritides.

Methods: In this retrospective analysis, cervical CT and/or MRI scans -taken for any reasons between 2010 and 2020 - of patients with rheumatoid arthritis (RA), spondyloarthritides (SpA) and psoriatic arthritis (PsA) were included in the study database. The diagnosis of RA, AS, and PsA was confirmed by an experienced clinician with medical history, laboratory, and treatment history. Of these patients, those who underwent CT and/or MRI before the definitive diagnosis of inflammatory arthritides were included in the analyses. Demographic data of the included patients were recorded. Cranio-cervical involvements (anterior, posterior, lateral, and rotational atlantoaxial subluxation; vertical subluxation; subaxial subluxation; odontoid process involvement [resorption or pannus], atlantoaxial and atlanto-occipital involvement) were evaluated by an experienced radiologist on CT or MRI, as appropriate. Control group was consisted of consequent patients without inflammatory arthritides and who undergone cervical CT or MRI with any reasons out of trauma. p<0.05 was considered statistically significant.

Results: From a total of 4442 records (1558 individual patients), 459 patients (204 RA, 200 SpA, and 55 PsA patients) and 78 patients for control group were included in the study. In Table 1, comparison of RA, SpA and control groups for specific types of cranio-cervical involvements was given. The percentage of female gender and age at inclusion and exclusion criteria were used; For inclusion: 1) nodules with changing dimension on follow-up, 2) At least two nodules with different dimensions, 3) Cavitary nodule at any chest CT. For exclusion: 1) Solitary nodules OR all nodules ≤ 5mm and without follow-up OR no change on follow-up. biggest nodule was named as dominant nodule. Then, patients were grouped according to rheumatoid factor and anti-CCP status as seropositive (RF ± anti-CCP) and seronegative. Demographics, comorbidities, RA-specific treatments and nodule characteristics were compared.

Results: Of 680 RA patients who had pulmonary nodule in chest CT, 208 (30.6%) patients were classified as having pulmonary rheumatoid nodule.

Conclusion: Cranio-cervical junction involvement can often be detected in patients with inflammatory arthritis, especially in patients with RA. Odontoid process seems as the main target of inflammation. Cranio-cervical involvement has the potential to be overlooked clinically, and needs to be evaluated more carefully. Disclosure of Interests: None declared

POSO062 PULMONARY RHEUMATOID NODULES: DOES SEROLOGIC STATUS MATTER?

Y. Sankaya1, G. Sandal Uzun2, E. B. Atea1, S. Arslan1, M. Ekiç2, G. Durhan1, E. Bilgin3, U. Kalyoncu3, M. Arıyürek1, 2Hacettepe University, Radiology, Ankara, Turkey; 3Hacettepe University, Rheumatology, Ankara, Turkey

Background: The frequency of pulmonary rheumatoid nodules closely relates to the diagnostic modality and changes from <0.4% to 32%. Also, it is known that seropositive RA patients tend to have more extra-articular disease.

Objectives: We aimed to compare the disease and pulmonary rheumatoid nodule characteristics of seropositive and seronegative RA patients.

Methods: In this study, all RA patients - according to ICD-10 code - and had at least one chest computerized tomography (CT) were examined and revealed 4117 individual patients. First, RA diagnosis was confirmed according to the patients' history, physical examination, radiography and laboratory assessment. Then, chest CTs were examined by an experienced radiologist. To classify pulmonary nodules as "pulmonary rheumatoid nodules", following inclusion and exclusion criteria were used: For inclusion: 1) nodules with changing dimension on follow-up, 2) At least two nodules with different dimensions, 3) Cavitary nodule at any chest CT. For exclusion: 1) Solitary nodules OR all nodules ≤ 5mm and without follow-up OR no change on follow-up. Biggest nodule was named as dominant nodule. Then, patients were grouped according to rheumatoid factor and anti-CCP status as seropositive (RF ± anti-CCP) and seronegative. Demographics, comorbidities, RA-specific treatments and nodule characteristics were compared.

Results: Of 680 RA patients who had pulmonary nodule in chest CT, 208 (30.6%) patients were classified as having pulmonary rheumatoid nodule.

Conclusion: Cranio-cervical junction involvement can often be detected in patients with inflammatory arthritis, especially in patients with RA. Odontoid process seems as the main target of inflammation. Cranio-cervical involvement has the potential to be overlooked clinically, and needs to be evaluated more carefully.

CAD: Coronary artery disease, CKD: Chronic kidney disease.; ILD: Interstitial Lung Disease.

Conclusion: Autoantibodies seem to have impact on the characteristics of pulmonary rheumatoid nodules. As there were different prescription patterns were seen in our study, effects of these treatment differences needs to be determined.

Conclusion: DB causes the greatest increase in HRV for healthy participants, while both DB and taVNS can equally elevate HRV in patients with RA and SLE, which support their use as a potential new treatment approach. However, their clinical effect needs to be investigated in future studies.

Figure 1.

IN PATIENTS WITH RHEUMATOID ARTHRITIS, CLINICAL EXAMINATION OF THE FEET IS IMPORTANT FOR UNDERSTANDING INDIVIDUAL DISEASE BURDEN, BUT DOES NOT PROVOKE A CHANGE IN THERAPY IN MOST CASES

N. Leuchten1, C. Weinert1, M. Aringer1. University Medical Center and Faculty of Medicine TU Dresden, Division of Rheumatology, Department of Medicine III, Dresden, Germany.

Background: Disease activity scores like CDAI, SDAI or DAS28, are essential for measuring rheumatoid arthritis (RA) disease activity. These do not contain foot joints. However, foot pain is an important aspect of morbidity for RA patients, which leads to reduced mobility and quality of life.

Objectives: To analyse the impact of synovitis in ankle and metatarsophalangeal joints on RA scores and RA disease activity states.

Methods: Joint scores of 545 RA outpatients were followed from August 2004 through December 2020. Informed consent for the analysis of their routine data was obtained for every patient. The standard CDAI cut-offs used were CDAI ≤ 2.8 for remission (REM), CDAI > 2.8 - 10.0 for low disease activity (LDA), CDAI > 10.0 - 22.0 for moderate disease activity (MDA) and CDAI > 22.0 for high disease activity (HDA). Foot involvement (FI) was defined as having at least one swollen (SJ) or tender (TJ) foot joint in patients who ever had palpable synovitis in any of these joints. The visits were grouped according to the number of swollen joints (SJ 0-28). The mean Physician Global Assessment of disease activity (PhGA) was calculated for each SJ group and the difference between the mean PhGA in patients with and without FI (as defined above) was calculated for each SJ group (ΔPhGA). Statistical analysis was performed in IBM SPSS Statistics Version 28.0.1.0.

Results: A total of 7,577 visits of 545 patients were included, for a mean of 14 visits per patient. 413 (75.8%) of the patients were female, the mean age at visit was 59 years, mean disease duration was 13 years, 284 (52.1%) were ACPA positive. 247 (45.3%) were on biological DMARDs. The median CDAI at visit was 4.3 (interquartile range IQR 1.6 - 9.0), the median DAS28 was 2.56 (IQR 1.89 - 3.37), the median CRP was 2.5 (IQR 1.0 - 6.2) mg/L. At 2,853 (37.7%) visits the patient was in REM, at 3,134 (41.4%) visits in LDA, at 1,265 (16.7%) visits in MDA and at 324 (4.3%) visits in HDA. Patients with FI were more active and scored higher on CDAI (9.1 vs. 3.4, p<0.001) and DAS28 (3.19 vs. 2.45, p<0.001), even though the indices do not include the foot joints. This was mainly due to higher patient global assessment of disease activity (3.1 vs. 2.0, p<0.001). Involvement of the feet also led to a higher physician estimate of global disease activity. The mean difference of PhGA between patients with and without involvement of their feet (ΔPhGA) was meaningful for joint counts 0-10, with an unweighted mean ΔPhGA of 0.273. Of the 217 patients with FI, 3,776 visits were analyzed. For patients with FI, the potential change in disease activity was calculated by subtracting ΔPhGA from the CDAI at each visit. For 3,662 (97.0%) of the visits, this did not result in a change of disease activity state. For 90 (2.4%) visits, disease activity changed from LDA to REM, for 21 (0.6%) from MDA to LDA, and for only 3 (0.1%) visits from HDA to MDA. At 83 (1.1%) visits of a total of 59 (10.8%) patients, only swollen foot joints without tender foot joints were recorded.

Conclusion: Patients with foot involvement are more active and score disproportionally high on disease activity indices, even though these do not include foot joints. While patients suffer significantly from foot involvement, underestimating disease activity by not assessing the feet would have changed the disease activity state for 3.1% of the visits only. Palpable synovitis without tenderness, which would be missed by performing only a metatarsophalangeal squeeze test, was found at one in a hundred visits.

Background: Staphylococcus aureus bacteremia (SAB) has high mortality and rheumatoid arthritis (RA) patients are at increased risk. The role of anti-rheumatic treatments and disease activity is unclear.[2,3]

Objectives: To explore the impact of treatment with glucocorticoids and biologic disease-modifying anti-rheumatic drugs (bDMARDs) and disease activity on the risk of SAB in RA patients.

Methods: Nestled case control study in a nationwide cohort of RA patients (DANBIO) with no history of SAB. Cases had a first-time microbiologically verified SAB between 2010-2018. Controls were incidence density matched (age and sex) at time of SAB (index date). We linked data from DANBIO (e.g. disease activity, anti-rheumatic treatment) to other national registries (comorbidities, prescriptions, socioeconomic status, etc.). Treatments were redeemed prescriptions or registrations in DANBIO (oral glucocorticoids, bDMARDs) 0-2 years before the index date. Dose of oral glucocorticoids was retrieved from either DANBIO or estimated from the latest prescription. Risk associated with treatment and disease activity was assessed by multivariate conditional logistic regression. For treatments, excess cases/10,000 exposed/year were calculated by multiplying the fully adjusted OR (95% CI) with the incidence rate in the cohort. Missing data was handled by multiple imputation.

Results: We identified 180 cases in 30,479 RA patients (IR 106.7/100,000 person-years) and matched 720 controls (53% women, median age 73 years, IQR 65; 80). For cases, orthopedic implants were frequent (53%/34% for cases/controls), many had recent surgery (38%/5%), longstanding RA (13 years (6; 21)/8 (4; 14)), joint erosions (48%/39%), moderate (29%/16%) or high (10%/77%) disease activity, and used glucocorticoids (41%/19%) and bDMARDs (31%/20%). Adjusted ORs were high for current use of glucocorticoids, especially for doses >10mg/day (OR=14.5 (4.0; 52.2)). For bDMARDs, adjusted OR was 1.9 (1.1; 3.8). Correspondingly, the treatments increased risk with 144 and 9 excess cases/10,000/year, respectively (Table 1). For disease activity, adjusted ORs were >1 (non-significant) for moderate and high disease activity compared with remission (Figure 1).

*Number of excess cases/10,000 exposed/year (confidence limits)

Conclusions: Oral glucocorticoids and bDMARDs increased relative risk of SAB, with number of excess cases being high for oral glucocorticoids (>10 mg/day) and low for bDMARDs. Disease activity had minor impact on the risk. This emphasizes that high dose glucocorticoids should be used with caution.

BACKGROUND: Treat-to-target (T2T) is integral to international recommendations for managing patients with rheumatoid arthritis (RA), but its implementation in clinical practice is suboptimal. Understanding T2T barriers and facilitators may inform strategies for improving T2T implementation in RA.

OBJECTIVES: To review published evidence on barriers to and facilitators of T2T implementation in RA, and interventions designed to improve T2T implementation.

METHODS: Two systematic literature searches were conducted to identify barriers to or facilitators of, and interventions designed to improve, T2T implementation in RA (Jan 1, 2015–Mar 1, 2021 and Jan 1, 2010–Jul 1, 2021, respectively). The quality of each study was assessed using the appropriate Critical Appraisal Skills Programme (CASP) checklist. Barriers/facilitators and interventions were grouped into categories and summarized descriptively.

RESULTS: The barriers/facilitators literature search retrieved 235 articles. Seventy-seven of these, which described primary studies mentioning a total of 331 T2T barriers/facilitators in RA, were included in the analysis. The interventions literature search identified 451 articles, including 70 primary studies reporting a total of 56 unique interventions to improve T2T implementation in RA. The quality of the studies varied; however, most addressed at least half of the information evaluated in the CASP checklists. Barriers/facilitators were categorized into 18 key target areas for patients (n=7), healthcare professionals (HCPs; n=6), or patients and HCPs (n=5). These related to: HCPs’ or patients’ knowledge or perceptions; patients’ clinical or social conditions; patient–HCP communication or alignment; and time or resources (Figure 1). The 56 interventions were grouped into 18 types (Table 1). More than half of the interventions (n=30; 53.6%) were designed to improve or streamline disease activity or patient-reported outcome assessments or increase patient–HCP alignment on disease activity. Interventions designed to improve shared decision-making were also common (n=23, 41.1%); these included patient and HCP education (n=15), decision aids (n=7), and shared decision-making prompts (n=3). Of the 56 interventions, 20 (35.7%) reported improvements in T2T implementation and/or patient outcomes in RA. However, as most interventions were evaluated in single centers, their effectiveness, feasibility, and generalizability across other regions or healthcare settings were unclear.

*Interventions may be assigned to more than one category.

Conclusion: While practical methods designed to improve T2T implementation in RA are available, their effectiveness and feasibility will likely vary by region and healthcare setting. More primary research is required to identify the most relevant barriers/facilitators and prioritize the most appropriate interventions to optimize T2T implementation both globally and locally.

REFERENCES:
COVID-19 pandemic response to limit virus transmission was characterized by mandated lockdowns and quarantines, resulting in significant stressors for rheumatology patients and potentially threatening their disease.

**Objectives:** To examine factors associated with changes in rheumatoid arthritis (RA) disease activity and flares in the COVID-19 pandemic.

**Methods:** RA patients identified by ICD-9/10 codes and active email addresses within a University of California, Los Angeles (UCLA) Rheumatology database were sent surveys via email in July and November of 2020. The survey was UCLA Institutional Review Board approved and included electronic consent and questions related to perceptions of disease activity/remission via Routine Assessment of Patient Index Data 3 (RAPID3), flare frequency, RA flare questionnaire (RA-FQ), Perceived Stress Scale (PSS-4), and pandemic impact on stress (i.e. emotional state, apprehension, panic, helplessness, work, home, financial, and social distancing stress). Demographics were extracted from electronic medical records. Results were examined via descriptive analyses, Pearson correlations, and chi-square test for comparisons plus linear stepwise regressions where appropriate to evaluate the relationship between stress measures, RA disease activity, and flare frequency and severity.

**Results:** Among 5037 patients surveyed, 361 in July and 4676 in November,1128 (22.4%) responded. The study population demographics were: mean age of 57.5 ± 15.1 years, 79.4% female, racially diverse (69.6% Caucasian, 15.7% % LatinX, 9.5% Asian, and 4.9% Black), and 62% seropositive (CCP and/or RF). Perceived disease activity and remission remained stable in most patients with 719 reporting no flares, and 409 in current flares at the time of the survey (Table 1). A minority reported perceived increases in disease activity which were associated with multiple aspects of perceived stress. At survey completion, 346 had not experienced flares, 290 had experienced one flare, and 492 had experienced multiple flares. Use of DMARDs was associated with lack of flare versus current flare (77.8% versus 71.6%, p = 0.02). The use of conventional synthetic, biologic, or targeted synthetic DMARDs were not associated with flare while current corticosteroid use was associated with flare (9.3% without flare and 20.8% with flare, p < 0.0001). Current flare was associated with increased PSS-4 scores (odds ratio (OR): 1.17 (95% confidence interval: 1.12 – 1.22, p < 0.0001). Figure 1 describes the odds ratio of experiencing aspects of stress with the presence of RA flare.

**Conclusion:** Collectively, our data indicate that a large proportion of patients with RA still lack early diagnosis despite dedicated early access to rheumatology care; from 2010 onwards, autoantibody-positive patients are diagnosed with a milder and less disabling disease, while autoantibody-negative patients are at increased risk of delayed diagnosis, and remain burdened with severe disease. Stressors related to perceived stress and disease activity/remission were associated with multiple aspects of perceived stress. At survey completion, 346 had not experienced flares, 290 had experienced one flare, and 492 had experienced multiple flares. Use of DMARDs was associated with lack of flare versus current flare (77.8% versus 71.6%, p = 0.02). The use of conventional synthetic, biologic, or targeted synthetic DMARDs were not associated with flare while current corticosteroid use was associated with flare (9.3% without flare and 20.8% with flare, p < 0.0001). Current flare was associated with increased PSS-4 scores (odds ratio (OR): 1.17 (95% confidence interval: 1.12 – 1.22, p < 0.0001). Figure 1 describes the odds ratio of experiencing aspects of stress with the presence of RA flare.

POS0610 THE RELATIONSHIP BETWEEN SYSTEMIC MANIFESTATIONS OF RHEUMATOID ARTHRITIS AND THE STRUCTURAL GEOMETRY OF THE MYOCARDIUM

I. Feisikhanova1, D. Abdulginanueva 1, Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation

Background: In recent years, chronic inflammatory diseases, including rheumatoid arthritis (RA), have been perceived as independent risk factors for cardiovascular diseases. In addition to influencing the development of atherosclerosis, rheumatic diseases are accompanied by changes in the myocardium.

Objectives: to determine the relationship between systemic manifestations of RA and structural changes of the heart.

Methods: The 282 patients (240 women and 42 men) with verified RA were examined. In addition to standard diagnostic tests, all patients underwent echocardiography with tissue Dopplerography of the myocardium.

Results: Structural and geometric remodeling of the heart was detected in 146 patients (51.8%), of which 29 had concentric remodeling, 35 had concentric hypertrophy, and most often, 82 people had eccentric hypertrophy. The average age was 57.9±8.55 years in the group with cardiac remodeling and 47.2±11.92 years in individuals with normal heart geometry, respectively (p <0.0001). Among 136 patients (48.2%) with normal heart geometry, 39 people suffered from arterial hypertension, 73 patients had various systemic manifestations of rheumatoid arthritis (Sjogren’s syndrome, rheumatoid nodules and/or cryoglobulinemia). Among those with cardiac remodeling, arterial hypertension was diagnosed more often — in 107 people (p <0.0001), and systemic manifestations of rheumatoid arthritis — in 87 patients (p<0.1). A comparison was made between a group with eccentric hypertrophy (82 people) and a combined group of patients with concentric remodeling and eccentric hypertrophy (64 people). In the first group, the age was higher and amounted to 58.6±5.2 years, and in the second — 57.2±7.96 years (p<0.05). In the first group, systemic extra-articular manifestations of rheumatoid arthritis were found in 56 individuals (68.3%), and in the second group — in 33 people (51.6%) (p=0.04).

It is worth noting that in the second group, patients with concentric hypertrophy made the greatest contribution: out of 35 people, systemic manifestations of rheumatoid arthritis were detected in 23 people (65.7%), which is comparable to the frequency among people with eccentric hypertrophy. In this regard, for the research purpose, we combined individuals with normal geometry and concentric remodeling into one group (165 people), and patients with concentric and eccentric hypertrophy into another group (117 people). When compared, it was found that regardless of the type of myocardial hypertrophy these individuals are significantly more likely to suffer from systemic manifestations of rheumatoid arthritis: 53.9% and 67.5%, respectively (p=0.02).

Conclusion: the formation of myocardial hypertrophy in patients with rheumatoid arthritis is associated with more frequent development of extra-articular manifestations of this disease.

POS0611 THE SIGNIFICANCE OF DETERMINING THE LEVEL OF THE ST-2 MARKER OF HEART FAILURE IN PATIENTS WITH RHEUMATOID ARTHRITIS

I. Feisikhanova1, D. Abdulginanueva 1, Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation

Background: The heart failure in patients with rheumatoid arthritis differs in its genesis from that in the general population. It has been established that the increased risk of congestive heart failure in patients with RA cannot be explained by the high frequency of risk factors for cardiovascular diseases, including coronary heart disease. While 80% of chronic heart failure in the general population is associated with classical risk factors for cardiovascular diseases, in RA these same predictors explain only 40% of cases.

Objectives: to establish the prevalence of diastolic dysfunction of preclinical signs of heart failure in patients with rheumatoid arthritis.

Methods: The 282 patients with verified rheumatoid arthritis were examined, including 240 women and 42 men. All patients underwent standard diagnostic tests, two-dimensional transthoracic echocardiography with tissue dopplerography of the myocardium, determination of the level of ST-2, stimulating growth factor, a marker of heart failure, in blood serum.

Results: The Tissue Dopplerography in combination with two-dimensional echocardiography allowed us to identify patients with diastolic myocardial dysfunction and form the following subgroups. 1 — with normal heart geometry and without diastolic myocardial dysfunction (91 people), 2 — with normal heart geometry and with diastolic dysfunction (45 people), 3 — with structural and geometric remodeling of the heart and without diastolic myocardial dysfunction (73 people), 4 — with structural -geometric remodeling of the heart and with diastolic dysfunction (73 people). Among patients with altered heart geometry (3rd and 4th subgroups), the prevalence of diastolic dysfunction was higher than among those with normal geometry (1st and 2nd subgroups): 50% and 33.1%, respectively (p=0.004). We conducted a comparison between the subgroups depending on the presence of diastolic myocardial dysfunction. The average age of patients with rheumatoid arthritis who showed signs of diastolic dysfunction with normal heart geometry was higher (54 [49; 57] years) than in the compared subgroup (45.5 [33.5; 53.5]) (p<0.0001). They also had significantly higher levels of the ST-2 marker, which indicates an early preclinical sign of heart failure: 70.1 [39.5; 106.5] and 42.2 [29.6; 61.5] ng/ml (p<0.1). Apparently, despite the absence of cardiac remodeling, with age, patients with rheumatoid arthritis are more likely to develop not only diastolic dysfunction, but also diastolic type of heart failure.

Conclusion: Thus, in patients with rheumatoid arthritis, it is advisable to conduct tissue Dopplerography in addition to standard echocardiography to detect diastolic dysfunction, which in these patients may develop in the absence of structural and geometric changes.

POS0612 COMORBIDITIES IN RHEUMATOID ARTHRITIS DO NOT INFLUENCE BIOLOGICS DRUG RETENTION: DATA FROM THE NATIONAL HEALTH INSURANCE FUND OF TUNIS

S. Bousaid1, K. Saadaoui2, S. Rekki2, S. Jemmali2, S. Rahmouni2, H. Sahl2, M. Elleuch2, 1Hospital Rabta, Rheumatology, Tunis, Tunisia; 2Hospital Rabta, Rheumatology, Tunis, Tunisia

Background: the advent of biologics in the late 1990s radically changed the profile of inflammatory diseases, in particular rheumatoid arthritis (RA). The survival of these innovative therapies is an indicator, in clinical practice, of their long-term efficiency in patients with RA.

Objectives: To study the influence of comorbidities on biologics drug retention rates.

Methods: We conducted a cross-sectional, observational study. Data were identified from the files of the National Health Insurance Fund of Tunis. It included patients with RA on biologics. Epidemiological characteristics such as age, sex, and comorbidities, were collected. Comorbidities were assessed by the Charlson Comorbidity Index (CCI). The therapeutic maintenance rate at 12, 24, 36, and 48 months as well as the biologics survival were analyzed using Kaplan-Meier survival curves and compared using the Log-Rank test.

Results: Three hundred and seventy-four files were selected. The average age of our cohort was 55±12.54 years [20-90]. A female predominance was noted with a sex ratio M/F=0.147. The average duration of RA was 11.7±6.76 years.
Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease with a high cardiovascular risk, increasing the incidence of coronary artery disease, ventricular arrhythmias and sudden cardiac death (SCD). The annual incidence of SCD among the general population is 0.2%, and patients with RA are twice as likely to develop it as healthy people. The well-known predictors of the development of SCD among the variance of the QT interval and the alternation of the T-wave. Comorbidities were assessed by the CCI in 373 patients (99.7%). Ninety patients had an ICC of 0 and 103 patients had an ICC of 1. Only one patient had an ICC of 8. The median value of this score was equal to 1, the mean was 1.64 ± 1.48. Osteoporosis was the most observed comorbidity with 78 patients (20.9%). The study of drug survival according to the ICC did not show any significant differences between the different curves (p=0.809). The Hazard Ratio was 0.989. Similarly, we did not find a discriminating threshold for the Charlson score, allowing it to be decisive for the survival of biologic drugs.

Conclusion: This study did not identify the influence of comorbidities on the biologics survival during RA. Comorbidities can have an impact not only on our therapeutic choice but also on the efficacy and maintenance of biomedicines as well as the quality of life of patients and consequently the prognosis of RA (1).

The few studies that have looked at this subject have produced variable results.

POS0614 THE RELATIONSHIP BETWEEN DISEASE ACTIVITY AND FINANCIAL TOXICITY IN PATIENTS WITH RHEUMATOID ARTHRITIS REGISTRY

R. Inoue1, N. Vajima1,2,3, T. Matsui2,2, S. Tohma2,2, 1Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan; 2National Hospital Organization Sagamihara National Hospital, Department of Rheumatology, Clinical Research Center for Allergy and Rheumatology, Kanagawa, Japan; 2Fukushima Medical University, Center for Innovative Research for Communities and Clinical Excellence, Fukushima, Japan; 3Fukuoka University, Department of Healthcare Epidemiology, School of Public Health in the Graduate School of Medicine, Kyotango, Japan; 2National Hospital Organization Sagamihara National Hospital, Department of Rheumatology, Kanagawa, Japan; 1National Hospital Organization Tokyo National Hospital, Department of Rheumatology, Tokyo, Japan

Background: As the number of rheumatoid arthritis (RA) patients using biologics increases, the health financial issues posed by biologics become more important. The health financial issues posed by biologics have been discussed using health economic indicators such as incremental cost-effectiveness ratios (ICERs), but have not been evaluated using the financial burden of medical expenses (financial toxicity). In the field of malignancies, evaluations using financial burden have been conducted and have shown that the stage of malignancy is associated with financial toxicity. It is not known whether disease activity and financial toxicity are similarly associated in RA patients.

Objectives: This study aims to evaluate the relationship between RA activity and financial toxicity in RA patients using biologics, who are especially likely to feel the financial burdens.

Methods: We conducted a cross-sectional study of biologic users enrolled in NinJa2020, a database of rheumatoid arthritis patients in Japan collected from April 1, 2020 to March 31, 2021. We defined the users of TNF inhibitor, IL-6 receptor antagonists, T-cell costimulation blocker, Janus kinase inhibitor and biosimilar as biologic users. The main exposure was the disease activity of RA and was measured using DAS28-CRP. Outcome measure was a financial toxicity and was measured using COMprehensive Score for Financial Toxicity (COST). This scale is a patient-reported outcome measure (PROM) consisting of 11 items. The responses are recorded on 5-point Likert Scales (ranging from 0 = strongly disagree to 4 = strongly agree). The score by domains ranges from 0 to 44. Higher scores indicated better results and lower financial toxicity. Multiple linear regression models adjusted for age, sex, disease duration, co-payments for anti-rheumatic drugs, work status, financial support systems were conducted to assess the relationship between the disease activity of RA and financial toxicity. As a result, this study intended to evaluate the relationship between RA activity and financial toxicity in RA patients using biologics, who are especially likely to feel the financial burdens.
secondary analysis, we excluded patients with zero copayments and performed the same analysis as in the main analysis. We used multiple imputation to deal with missing values.

Results: Among 15553 cases in the NinJa database, 649 cases for which RA disease activity and COST were available were included. The median age of the patients was 70 (interquartile range [IQR], 56 -77), 83.7% were female. The median copayment amount was ¥12978 per month (IQR 6372.4 to 24204.1). The median DAS28-CRP was 1.99 (IQR, 1.1 - 2.72). The median financial toxicity (COST score) was 21 (IQR 0-27) (Figure 1). In the main analysis using multiple linear regression, COST significantly decreased with disease activity of RA (per 1-pt DAS28-CRP, -1.16 [95% CI -2.04 - -0.28]). In the secondary analysis, COST significantly decreased with disease activity of RA (per 1-pt DAS28-CRP, -1.69 [95% CI -2.29 - -1.10]). Statistical significance was defined as a two-sided p-value < 0.05. All statistical analyses were conducted using STATA 17.0 (Stata Corp LP, College Station, TX). The National Hospital Organization’s research ethics committees evaluated and authorized the NinJa study.

Conclusion: High disease activity of RA was associated with high financial toxicity in biologic users. We reaffirmed the importance of financial considerations and empathy for RA patients using biologics, and suggested a potential demand for more financial support for RA patients who are refractory to treatment.

POS0615 CLINICAL DEMOGRAPHICS AND FACTORS AFFECTING DRYNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

1Kanazawa Medical University, Department of Hematology and Immunology, Uchinada, Japan; 2Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan; 3Kaga Medical Center, Department of Internal Medicine, Kaga, Japan; *Kim Clinic, Department of Internal Medicine, Saka, Japan

Background: Sjogren’s syndrome (SS) is known to coexist with rheumatoid arthritis (RA). However, the prevalence of RA with SS varies widely, from 2.4% to 30%, and some patients with RA without SS also show dryness. The prevalence and clinical demographies of dryness in patients with RA are not well recognized.

Objectives: The aim of this study was to clarify the prevalence, clinical demographics, and related factors of dryness in patients with RA who have not been diagnosed with (SS).

Methods: We enrolled 166 patients with RA (129 females, 37 males; mean age 65.8±14.3 years; disease duration 14.1±10.9 years; DAS28-CRP 2.30±0.92) who were not diagnosed with SS. We analyzed CRP, the estimated glomerular filtration rate (eGFR), RF, anti-CCP antibody, antinuclear antibody, anti-SS-A antibody (SSA), and disease activity score (DAS) 28-CRP, and identified treatments for RA. We used each question item of the EULAR SS Patient Reported Index (ESSPRI) to clarify dryness, somatic and mental fatigue, and pain. History of smoking, comorbidities, such as interstitial fibromyalgia, fibromyalgia, and psychiatric disorders, and narcotic and/ or psychotropic medication use were determined from the medical records. We defined patients with dryness as greater than or equal to one point, and those with severe dryness as greater than or equal to five points, of the visual analog scale (VAS).

Results: Dryness was observed in 93/166 (56.0%) patients and severe dryness was identified in 57/166 (34.4%) patients, and SSA was positive in 23/169 patients (13.9%). We divided our patients into dryness and non-dryness groups and compared their clinical demographics. The dryness group was relatively younger (64.0±14.5 vs. 68.1±13.8 years, p=0.052), had a female predominance (89.2% vs. 63.0%, p=0.001), had severe fatigue (4.06±2.59 vs 2.60±2.78, p=0.001), and had severe pain (3.52±2.41 vs. 2.73±3.22, p=0.020). However, there were no significant differences in other factors including lipid pattern. Twenty-seven RA patients receiving TCZ (8 mg/kg IV/q4w) were assessed at baseline and weeks 12, 24, and 52. Disease activity indexes, serum levels of ApoC3, ANGPLT4 and LPL, and lipoproteins serum concentrations were assessed in a post-treatment visit.

Results: Acute phase reactants and disease activity were significantly reduced during study visits and at the end of treatment after one year with TCZ. While total and LDL cholesterol initially increased in plasma concentration, then decreased to baseline, lipoprotein (a) was significantly lower, and HDL higher, than baseline at all visits. TG showed a trend to be significantly higher at 6 months (net increase 29 (95%CI -45-68) mg/dl, percentage increase 36 (95%CI -27-52) %, p=0.079). However, TG did not show significant differences at any visit compared to baseline levels. ANGPLT4 (baseline 387 ± 203 vs final 257 ± 32 wk52 ng/ml, p=0.079), and ApoC3 (baseline 10.1 ± 6.7 vs final 6.3 ± 3.7 mg/dl, p=0.023) were significantly lower at the end of the study (week 52) compared to their initial concentrations. LPL also showed a gradual decrease at each visit (baseline 349 ± 289 vs final 291 ± 197 mg/ml, p=0.57), although statistical significance was not reached (trend test p=0.56). The decrease in DAS28-ESR at each visit was not associated with the changes produced in the three molecules, thus showing that the decrease in the TG metabolism axis does not depend on the lower activity of the disease produced by TCZ. In contrast, the decline in ApoC3 was significantly correlated with the increase in TG at month 3 (Pearson r -0.494, p=0.037) but not at 6 and 12 months.

Conclusion: TCZ decreases serum levels of ANGPLT4, ApoC3 and LPL. At 3 months, the increase that occurs in TG seems to depend on the inhibition that TCZ exerts over ApoC3. Our findings suggest that the effect of TCZ on the lipid profile in patients with RA could be mediated by the modification that this drug exerts on the ANGPLT4-ApoC3-LPL axis.

Conclusion: MCP I synovitis is a major contributor to reduced grip force in patients with early RA during the first 5 years after diagnosis, independent of wrist synovitis, general pain and systemic inflammation. This underlines the importance of involvement of the thumb for impaired hand function in RA.

M. Rojas-Giménez1, J. Calvo Gutierrez2, R. Ortega Castro3, M. L. Ladehesa Pineda4, A. Escudero Contreras1.1 Rheumatology Department, Córdoba, Spain; in mind that ILD is an important cause of death in our patients, we must actively assess whether the course and prognosis in both groups is also similar. Bearing in mind that ILD is an important cause of death in our patients, we must actively assess whether the course and prognosis in both groups is also similar. Bearing

Conclusion: Our study showed that comorbidity index was associated with a severe disease and signs of poor prognosis (erosions, coxitis, and atlanto-axial dislocation). This confirmed the hypothesis that comorbidity can be a threat to the improvement in the long-term prognosis in RA patients.

Results: There were 255 RA with sex ratio M/F at 0.2. The mean age was 58.92 ± 10.72 years [25-85]. The mean age at onset of disease was 43.76 ± 14.28 years [13-81]. The mean disease duration was 16.32 ± 13.4 [1-72]. Identified comorbidities were: hypertension (31.4%), lung disease (27.1%), diabetes (19.6%), cardiovascular disease (16.8%), gastrointestinal ulcer (9.2%), depression (8.8%), and chronic renal failure (8%). The mean RDCI was 1.14 ± 1.25 [0-6]. A statistically significant correlation was found between RDCI and age (r=0.277), RDCI and at disease onset (r=0.226), RDCI was not correlated to the disease duration (p=0.27). RDCI was not associated with the HAQ (p=0.4). RCDI was not significantly different in terms of sex (female: 1.2 vs male: 1.3, p=0.09). This comorbidity index was associated with the presence of extra articular manifestation (presence: 1 vs absence: 0.8, p=0.004). It was associated with pulmonary involvement (presence: 1.7 vs absence: 0.6, p<0.01). There was an association between the presence of radiographic erosions and RDCI (1.2 vs 1, p<0.001). RDCI was also associated with atlanto-axial dislocation (p=0.009) and with coxitis (p=0.009). Comorbidity index was statistically different between patients on biologic drugs and patients without biologic drugs (1.6 vs 0.9, p<0.01).

Conclusion: More than 40% of women with rheumatoid arthritis have a time-to-conception longer than 1 year: analysis of the prospective GR2 cohort

Methods: All RA patients (diagnosis according to the Rheumatologist) included in the national multicenter GR2 cohort from 2015 to June 2021 were included in the analysis. Patients could be included either with a pregnancy wish (i.e., preconceptional period) or because of a clinical pregnancy (<12 weeks of gestation). For this analysis, only patients included preconceptionally were included. The main endpoint was time-to-conception, and the secondary endpoints were the number of subfertile patients (i.e., time-to-conception >12 months or non-achievement of pregnancy), as well as the number exposed to csDMARDs and biologics in the preconception period. We performed survival analyses, using a Cox model including a random effect for the center to account for heterogeneity of practices among participating centers. We used a multiple imputation to address missing data among the explanatory variables. Results are presented as a hazard ratio (HR) with confidence interval (CI) to assess associations between the factors studied and time-to-conception.

Results: Among the 167 patients with RA included in the GR2 cohort, 78 were selected for the main analysis of time-to-conception. Of these, 40 (51.3%) had a clinical pregnancy during follow-up. Subfertility was observed in 33 (42.3%) women and median time to conception was 19.1 months; mean preconception DAS28-CRP score was 2.3 (+/- 1.2). Patients were treated during the preconceptional period with NSAIDs, corticosteroids, csDMARDs and biotherapies in 10 (12.8%), 35 (44.9%), 24 (30.8%), and 32 (41.0%) cases, respectively. The multivariate model adjusted for age, BMI, DAS28-CRP, disease duration, ACPA positivity, and exposure to corticosteroids and biologics in the preconception period found an association between increased preconception delay and age (HR (per year) 1.12 95% CI [1.04-1.16], p < 0.01) as well as disease duration (HR (per year) 1.06 95% CI [1.02-1.15], p = 0.03).

Conclusion: This study provides original results on fertility in women with RA. It found a median time to conception of 19.1 months, with a subfertility rate of 42.3%, which is significantly higher than the general population[2]. In this context, it seems essential to discuss this topic from the beginning of the disease in women of childbearing age.

ASSOCIATION OF DIURNAL FLUCTUATION OF THE SOLUBLE TOLL-LIKE RECEPTORS 2 (TLR2) WITH COMORBIDITY AND QUALITY OF LIFE IN WOMEN WITH RHEUMATOID ARTHRITIS

K. Zaichko1, N. Zaichko2. 1Vinnytsya National Pinogriv Medical University, Internal Medicine #2, Vinnytsya, Ukraine; 2Vinnytsya National Pinogriv Medical University, Clinical Biochemistry, Vinnytsya, Ukraine

Background: Disorders of circadian rhythms in the production of inflammatory mediators play an important role in the pathogenesis of rheumatoid arthritis (RA) [1]. Innate immune factors, in particular toll-like receptors 2 (TLR2), are involved in the formation of the inflammatory pattern in RA. Recently was shown that TLR2 play an important role in the development of atherosclerosis and hypertension [2]. Chronobiological aspects of innate immunity, in particular circadian rhythms of the soluble form of TLR2 (sTLR2) in RA and its comorbidity, requires further study.

Objectives: The aim of the study was to assess the daily variability of sTLR2 in RA patients depending on comorbid conditions and quality of life indexes.

Methods: In the study were enrolled 173 females with RA aged 45.9 (8.79) years and disease duration 7.96 (6.38) years. High activity of the RA (DAS28-ESR > 5.1) were registered in 114 (66%) cases, moderate activity (DAS28-3.2-5.1) - in 59 (34%) cases. 144 (83%) patients were seropositive by anticardiolipin antibodies (ACCP). Among enrolled subjects 140 (81%) had l-lil radiographic stage. There were 89 (51%) patients with comorbid pathologies, including arterial hypertension (AH) - 59 (34%). Serum sTLR2 level was determined at 8:00 and 20:00 using Cloud-Clone Corp kits (USA). All stages of the study were carried out in compliance with bioethical standards and provisions of the WHO, Helsinki Declaration of the General Assembly of the World Medical Association (1989), Bioethical protocol No 1, 01 November 2016. *Data are mean (SD) or %.

Results: In patients with RA, daily fluctuations in sTLR2 levels were detected: indexes at 8:00 to 20:00 were lower than at 8:00 (343 (93.7) vs 272 (99.2) ng/L, p<0.001). The mean difference between sTLR2 levels at 8:00 and 20:00 was -21.6 (12.3) %. In RA patients with AH, the average daily level of sTLR2 was higher (in 1.42 times, p <0.01) than in RA patients without AH. Differences between RA with AH and RA without AH groups were more significant in the evening sTLR2 level (320 (112) vs 246 (81.3) ng/L, p<0.01), than in the morning (378 (90.6) vs 321 (89.0) ng/L, p<0.05). In the group RA with AH decrease in sTLR2 in the evening was less than in the group RA without AH (1.36 times, p<0.05). An increase in sTLR2 at 20:00 was associated with a deterioration in mental health according to SF-36 (VT, SF, MH) in 1.2-1.3 times (highest quartile vs lowest quartile, p=0.01). An increase in sTLR2 at 8:00 was associated with a decrease in physical health PF, RP, BP and GH (in 1.3-1.6 times, p<0.01). Patients with high levels of sTLR2 showed more severe pain, impaired function, fatigue and sleep, decreased physical and emotional comfort, and control of symptoms according to RAID (in 1.3-1.4 times, p<0.01).

Conclusion: In RA patients daily fluctuations in sTLR2 levels has been registered with the decrease of this index in the evening. In the case of comorbid AH production of sTLR2 is higher, especially in the evening time. Differences of sTLR2 production are one of the factors that deteriorate the quality of life in patients with RA.

SUBCLINICAL ATHEROSCLEROSIS IS NOT RELATED WITH ACID URIC IN RHEUMATOID ARTHRITIS. STUDY OF 1005 PATIENTS OF A SINGLE UNIVERSITY HOSPITAL

F. Benavides-Villanueva1, C. Corrales-Selaya1, F. Ferraz-Amaro2, N. Vegas-Revenga3, V. Portilla, R. Bianco, M. A. González-Gay3, A. Corrales1, Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; 1Hospital
Background: Rheumatoid Arthritis (RA) and Gout are associated with an increase of cardiovascular (CV) disease (1,2). Carotid plaques and increased carotid intima-media thickness (cIMT) are surrogate markers of CV mortality (3). The association of serum uric acid (SUA) levels as an independent factor of subclinical Atherosclerosis and mortality in RA remains not fully clarified (4,5).

Objectives: In a wide cohort of patients with RA our aims were to assess the relationship of SUA with a) CV risk factors and b) presence of atherosclerosis.

Methods: Cross-sectional study including 1005 patients with RA from a Single University Center. The presence of Atherosclerosis (c-IMT and carotid plaque) was explored by Carotid Ultrasonography. The relationship between SUA and markers of subclinical atherosclerosis was studied through linear regression and logistic multivariate analysis.

Results: We studied 1005 RA patients (741 women, 74%), mean age 61±13. The main general features, CV risks factors, RA activity data and current therapy are summarized in Table 1.

Abbreviations: ACPA: Anti–citrullinated protein antibody; BMI: Body mass index; CV: Cardiovascular; cIMT: carotid intima-media thickness; cm: centimeter; CRP: C-Reactive protein; DAS28:ESR or CRP; mean±SD: mean±standard deviation; CRP: C-Reactive protein; DAS28:ESR: Disease Activity Score-28 for Rheumatoid Arthritis with Erythrocyte Sedimentation Rate; DAS28:PCR: Disease Activity Score-28 for Rheumatoid Arthritis with C reactive protein; dt: deciliter; ESR: Erythrocyte Sedimentation Rate; HDL: high-density lipoprotein; IQR: Interquartile range; Kg: kilogram; LDL: Low-density lipoprotein; mg: milligram; m2: square meter; n: number; RA: Rheumatoid Arthritis; SD: Standard Deviation.

SUA as a dependent variable was significantly correlated with age, male gender and most of CV risk factors (body mass index, abdominal circumference and obesity) (single-variable analysis). Similarly, a significant beta coefficient, [95%CI] positive relationship with SUA was observed with hypertension (0.7 [0.5-0.8], p<0.001), diabetes (0.5 [0.2-0.7], p<0.001), dyslipidemia (0.2 [0.04-0.4], p=0.016), renal chronic insufficiency (1.5 [95CI 1.0-1.8], p<0.001) and previous CV events (0.8 [0.4-1.2], p<0.001). Subclinical Atherosclerosis, as dependent variable, was significantly correlated with SUA (single-variable analysis). In addition, SUA showed a positive significant beta coefficient, [95%CI] relationship with cIMT (18 [12-25], p<0.001) and the presence of carotid plaques (1.29 [17-1.42], p<0.001). However, statistical significance was not observed in the multivariable analysis adjusted by Classic CV Risk Factors.

Conclusion: In RA, SUA is related with most of CV risk factors. However, SUA is not associated with Subclinical Atherosclerosis.

The use of eGFRcyst showed that only 12 of 29 people in the first group had optimal (>90 ml/min/1.73 m²) eGFRcyst (p=0.031), and 17 patients entered the group with slightly decreased (60-89 ml/min/1.73 m²) eGFRcyst. A similar, but less significant situation (12 of 22 people and 10 patients, p=0.02) was also observed with eGFRcyst-cyst. In the second group of RA patients 19 patients corresponded to the chosen criteria in determination of eGFRcyst, and 8 patients entered groups (III and IV) with more severe decrease of renal function (2 patients were included into group I) (p=0.011). Significant differences in this group were also noted when comparing the proportions according to eGFRcyst with eGFRcyst-cyst (p=0.044). A probable decrease in renal filtration function with eGFRcyst (compared with the alternative use of eGFRcyst or eGFRcyst-cyst) can be observed in 11-18% of RA patients in group 1 (high/optimal renal function) and up to 10% of RA patients in group 2 (slight decrease). No significant differences were found using the three estimated CKD-EPI formulas in RA patients with moderate/significant decrease in GFR (p=0.05).

**Conclusion:** Currently, the overall diagnostic performance of the CKD-EPI equation based on creatinine and cystatin C may be the most optimal (in comparison with other calculated CKD-EPI formulas) in patients with RA, and may also be useful for confirming eGFRcyst results >60 ml/min/1.73 m².
Background: Currently, real-world data on rheumatoid arthritis (RA) treatment patterns in France are limited.

Objectives: The aim of this study was to describe, between 2013 and 2017, the sequence of therapies used in the treatment of patients with RA and to characterize RA treatment patterns using real-world data.

Methods: A non-interventional, longitudinal study was conducted using the Echantillon Généraliste des Bénéficiaires (EGB) between 1 January 2013 and 31 December 2017. EGB is a 1/97th representative random sample from the French National Healthcare Database (SDNS) which includes claims data covering 99% of the total French population. Treatment patterns, adherence and persistence of RA treatments were described in a cohort of patients with RA, identified between 2013 and 2017.

Results: Between 2013 and 2017, 2,553 patients with RA were identified, including 2,314 in 2017. Of the 2,314 patients identified in 2017 (mean age 66.2 ± 15.4 years; 73.7% female; mean Charlson comorbidity score 4.2), 1,102 (47.6%) had received no disease-modifying-anti-rheumatic drug (DMARD). Of these, 944 (85.7%) had received at least one symptomatic treatment, including 862 (91.3%) an analgesic, 509 (53.9%) an oral corticosteroid and 384 (40.7%) a non-steroidal anti-inflammatory drug. Of the 2,553 RA patients monitored between 2013 and 2017, 1,512 (59.2%) patients received a DMARD, of which 721 (47.7%) patients received only one treatment sequence, mainly methotrexate (n=529, 35.0%), and did not discontinue or switch treatment. Switching treatment to a targeted DMARD was reported for 42.6% of cases (n=304/713), TNFi for 39.7% (n=100/252) and csDMARD for 42.6% (n=304/713), TNFi for 39.7% (n=100/252) and csDMARD for 42.6% (n=304/713), TNFi for 39.7% (n=100/252) and csDMARD for 42.6% (n=304/713), TNFi for 39.7% (n=100/252) and csDMARD for 42.6% (n=304/713), TNFi for 39.7% (n=100/252) and csDMARD for 42.6% (n=304/713), TNFi for 39.7% (n=100/252) and csDMARD for 42.6% (n=304/713)

Conclusion: Using data obtained from the EGB, this study estimated the number of patients with RA in France to be 307,612 in 2017. Approximately half of the patients identified in the EGB cohort were not treated with a DMARD. For a substantial proportion of patients receiving DMARDs, therapeutic escalation, a switch in treatment, or long-term corticosteroid co-therapy with an average daily dose greater than 5 mg were needed. Furthermore, median persistence for most targeted DMARDs was less than 2 years, and the early discontinuation rates of up to 46.6% suggest poor DMARD tolerance in many patients.

This study highlights that the medical need for RA treatment is not covered by current therapeutic strategies.
prescribed at the onset of the disease were more often TNFα blockers in gr C and rituximab in gr S.

Conclusion: According to our observations, the combination of RA with SJ/S leads to a milder course of the RA. Early diagnosis of SJ/S in RA pts is important for understanding the course of the disease and determining the prognosis.

## POS0630

### INCIDENCE AND ASSOCIATED FACTORS OF CANCER IN PATIENTS WITH RHEUMATOID ARTHRITIS

1Ankara University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey; 2Izmir Katip Çelebi University, Department of Public Health, Izmir, Turkey; 3Ankara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology; Ankara, Turkey

Background: Rheumatoid arthritis (RA) is an autoimmune disease primarily characterized by joint inflammation along with systemic manifestations and increased risk of cardiovascular disease. Furthermore, it has been suggested that RA itself and medications administered might increase the risk of cancer.

Objectives: To assess cancer incidence in RA patients and factors associated with cancer development in RA patients.

Methods: In this single centre retrospective cohort study, the data of 2000 patients (76.3% female, mean age at the last follow-up: 59.5 ± 13.4 years) who were followed up between 2005 and 2020 and fulfilled 2010 ACR/EULAR classification criteria were scrutinised. Patients’ demographic, clinical and serological characteristics, and smoking history were recorded. Multivariable logistic regression analysis was performed to determine the associated factors with cancer development. The standardized incidence rate (SIR) was calculated by dividing the number of cancer cases observed in a given age and gender group by the expected number.

Results: After a median follow-up of 9 years, 71 (3.6%) patients were diagnosed with cancer and the number of patients with more than one malignancy was 5 (0.5%). Cancer types in each sex were demonstrated in Table 1. Seropositivity rate of the cohort was 86.0% and 376 out of 1102 (34.1%) patients were smokers. Glucocorticoids were the most common used agent in the treatment of RA (75.2%), followed by methotrexate (68%), hydroxychloroquine (65.1%), sulfasalazine (37.7%), lefunomide (35.5%), biological disease-modifying anti-rheumatic drugs (11.4%) and tofacitinib 4%. In multivariable logistic regression analysis performed of 1102 patients without missing data of smoking history, only smoking and age were independently associated with malignancy (Odds Ratios were 2.11 (95% Confidence Interval (CI) 1.07-4.14 and 1.04 (95% CI 1.02-1.07), respectively). Treatment modalities and RA-related clinical factors were not related to cancer development (data not shown). When compared with the 2017 Cancer Statistics of Turkey, the incidence of malignancy in our RA cohort was similar to the corresponding age and gender groups. The SIRs in male and female patients were calculated as 0.93 (95% CI: 0.82-1.05 p= 0.25) and 0.92 (95% CI: 0.77-1.09 p= 0.34), respectively.

Conclusion: Our results show that patients with RA do not require additional screening beyond the nationally recommended guidelines. Medications used, including tumor necrosis factor inhibitors, did not increase the risk of cancer. In conclusion, all patients with RA should receive standard age- and sex-appropriate cancer screening.

REFERENCES:

BACKGROUND: Patients with rheumatoid arthritis (RA) who have sarcopenia and stiff or painful joints might be at increased risk of falls and fractures.

OBJECTIVES: The present study aimed to prospectively identify the incidence of clinical fractures and associated risk factors in patients with RA in a cohort study named the TOMORROW (UMIN000003876) that started in 2010.

METHODS: We evaluated anthropometric parameters, bone mineral density (BMD), disease activity, RA medication at entry and observed the incidence of clinical fractures between patients with RA and Vo for ten years in 202 patients with RA (mean age, 58.6 ± 5.94) and 202 age- and sex-matched non-RA volunteers (Vo) (mean age, 57.4 ± 6.2). We compared the incidence of clinical fractures between patients with RA and Vo for ten years, and analyzed the risk factors for clinical fractures using Cox proportional hazard model.

RESULTS: The incidences of clinical fractures were 0.036 and 0.024/person-year in patients with RA and Vo, respectively. Cox proportional hazard model revealed that low BMD at the thoracic vertebrae (< 0.7 g/cm2) and history of fractures at any site were significant risk factors (HR 2.189, p=0.004, 1.866, p=0.022, respectively). Additionally, a mean GC dose (≥ 2 mg/day) at entry and during the ten-year period increased risk for fractures (HR 2.189, p=0.004, 1.866, p=0.022, respectively).

Conclusion: RA per se was not a risk factor for clinical fractures in this cohort. Low BMD at the thoracic vertebrae at entry and the use of GC with even low dose at entry and during ten years were significantly associated with an increased frequency of clinical fractures among patients with RA.

myocardial abnormalities on cardiac magnetic resonance imaging (CMR) in an early RA cohort compared with control subjects, and improvement with DMARD treatment. Non-invasive assays for high-sensitivity troponin and NT-pro-BNP have been evaluated in RA cohorts. No study has investigated these in early, treatment-naive RA and in association with subclinical CMR findings.

Objectives: In a treatment-naive, early RA trial cohort, we examined serum cardiac markers of ventricular stretch (NT-pro-BNP) and myocardial injury (high-sensitivity troponin-I (hs-Tn-I)) and change with treatment, and whether these associated with cardiac MRI abnormalities.

Methods: In CADERA (a unique early RA RCT derived study), out of a total of 120 patients randomised to either first-line TNFi+MTX (n=60) or MTX and conventional synthetic DMARDs (n=60), 81 subjects with no previous history of CVD or diabetes and with only a maximum of 1 other traditional risk factor, underwent baseline and year 1 CMR. Corresponding levels of NT-pro-BNP (pg/ml) and hs-Tn-I (ng/L) were measured at baseline and year 1. CADERA reported CMR measures of vascular stiffness [aortic stiffness index (AoSI), and aortic distensibility (AD)]; tissue oedema/fibrosis [native T1 values (T1), myocardial extracellular volume (ECV), and late gadolinium enhancement (LGE)] and ventricular function [2]. Bayesian linear and logistic regression models with mixed effects for overall data were used to test association between serum cardiac markers and CMR parameters.

Results: CADERA trial already reported baseline demographics and comorbidity data of patients. The most common risk factor was smoking history (55%) followed by hypertension (7%) and family history of ischaemic comorbidity data of patients. The most common risk factor was smoking

</tbody>
</table>

Conclusion: Our data suggest hs-Tn-I is within normal limits in a treatment-naive, RA cohort but with numerical differences that associated with presence of focal fibrosis on CMR. Modest numbers of those with focal fibrosis may account for normal range values for hs-Tn-I.

*p<0.05, p<0.01, p<0.001
Background: In real-life setting, a greater number of elderly rheumatoid arthritis (RA) patients with impaired glomerular filtration rate (GFR) needs treatment with biologic or target synthetic disease-modifying anti-rheumatic drugs (b/tsDMARD) to achieve disease control and reduce NSAIDs intake. Long-term observational data from the real-life on the use of b/tsDMARD in these patients are scarce.

Objectives: The aim of this study was to evaluate the retention rate of b/tsDMARD in RA patients with impaired GFR in real-life setting.

Methods: Data of RA patients treated with at least one b/tsDMARD were retrospectively analyzed form the national Italian GISEA registry from January 2016 to December 2021. Estimated-GFR (eGFR) was calculated with the Cockcroft-Gault equation at the time of any b/tsDMARD prescription. For the purpose of this study, patients were divided in two groups, patients with impaired GFR (eGFR ≤60) and patients with normal GFR (eGFR >60). The retention rate was calculated by the Kaplan-Meier method and compared between these two groups by a log-rank test.

Results: The study population included 2443 treatment-line with b/tsDMARD from 1888 patients (female 80.4%, age 57±12 years, mean baseline CDAl 17±12, FR/ACPA+ 69.5%) who started a new b/tsDMARD. Disease characteristics are shown in Table 1. 288 treatments with b/tsDMARD were started in patients with impaired eGFR and 2155 in patients with normal eGFR. Compared to patients with eGFR >60, patients with eGFR ≤60 showed higher HAQ-DI (1.3±0.8 vs 1±0.8, p<0.001) at the start of b/tsDMARD treatment. Glucocorticoids were more prescribed in patients with impaired eGFR (80.2% vs 72.8%, p<0.01), while csDMARDs were more prescribed in association with b/tsDMARD in patients with normal eGFR (83.1% vs 76.4%, p<0.01). Of note, CTLA4-Ig treatment was more prescribed in patients with impaired eGFR (26% vs 17.1%, p<0.05), while no difference in b/tsDMARD prescription was observed for other mechanism of actions. Drug survival was similar between RA patients with impaired eGFR [58.2%, mean survival time 35 months (C195% 31-39)] and RA patients with normal eGFR [55%, mean survival time 34.4 months (C195% 33-36), log rank: 0.88] (Figure 1). Cox regression model adjusted for age, sex and b/tsDMARD showed no impact of eGFR on drug survival (HR: 0.9 (C195%: 0.7-1.2).

Conclusion: Our data show that impaired eGFR seems to not influence the persistence of b/tsDMARD treatment in RA patients.

Rheumatoid arthritis - biological DMARDs.

**POS0638**

**PATIENT GROUPS IN RHEUMATOID ARTHRITIS IDENTIFIED BY DEEP LEARNING RESPOND DIFFERENTLY TO BIOLOGIC OR TARGETED SYNTHETIC DISEASE MODIFYING ANTIRHEUMATIC DRUGS**

M. Kalwein, A. M. Burden, T. Hägg, T. Burkard. University of Freiburg, Department of Computer Science, Freiburg im Breisgau, Germany; ETH Zürich, Department of Chemistry and Applied Biosciences, Zürich, Switzerland; Lausanne University Hospital, Department of Rheumatology, Lausanne, Switzerland

**Background:** Cycling of biologic or targeted synthetic disease modifying anti-rheumatic drugs (b/tsDMARDs) in rheumatoid arthritis (RA) patients due to non-response is a problem preventing and delaying disease control.

**Objectives:** To assess and validate treatment response of b/tsDMARDs among RA patient groups identified by deep learning.

**Methods:** In the Swiss Clinical Quality Management of Rheumatic Diseases registry (SCQM), between 1998 and 2018, we identified all RA patients with a DAS28-erythrocyte sedimentation rate (esr) record within 6 months before the start of the first b/tsDMARD. This first-time b/tsDMARD was the cohort entry at which patients were clustered through several runs of deep embedded clustering. Features, measured at cohort entry, included demographics, RA disease burden/duration, life-style factors, and other RA medication. To increase robustness of the obtained clusters, we grouped similar patient clusters together (further referred to as groups). Our outcomes were b/tsDMARD stop due to non-response, and separately a ≥20% reduction in DAS28-esr (RA disease activity in 28 joints using esr measures) as a proxy for treatment response. We followed all patients from cohort entry until b/tsDMARD stop or a maximum of 15 months follow-up. We assessed comparative effectiveness of b/tsDMARDs (ref. adalimumab) using Cox proportional-hazard regression in each patient group by estimating hazard ratios (HR) with 95% confidence intervals (CI). We validated results obtained per patient group through stratified analyses according to most distinctive patient characteristics of the respective group, i.e. the characteristics that led to the respective grouping were also used to stratify the overall population by in this validation analysis.

**Results:** We obtained 24 clusters which comprised between 362 and 1481 patients (among 3516 unique patients). These clusters were grouped into 5 groups according to most distinct characteristics at b/tsDMARD initiation: 1) ≥2 csDMARDs and prednisone use, 2) male sex, 3) seronegativity, female sex, and no prednisone use, 4) rather low disease burden, 5) seropositivity, female sex, and a rather high disease burden/duration.

Comparative effectiveness results among validation strata confirmed comparative effectiveness results observed among the 5 groups: Patients with ≥2 csDMARDs and prednisone at b/tsDMARD initiation, men, as well as patients with a lower disease burden responded better to tocilizumab than to adalimumab (HRs of reaching ≥20% reduction in DAS28-esr: 5.46, 95% CI [1.76-16.94], HR 8.44 [3.43-20.74], and HR 3.64 [2.04-6.49], respectively). Furthermore, seronegative women without use of prednisone at b/tsDMARD initiation as well as seropositive women with a higher disease burden and longer disease duration had a higher risk of non-response with golimumab (HRs of b/tsDMARD discontinuation: 2.36 [10.03-5.40] and HR 5.27 [2.10-13.21], respectively) than with adalimumab.

**Conclusion:** Our results suggest that RA patient groups identified by deep learning may respond differently to individual first-line b/tsDMARDs. Thus, our results can possibly support the decision on the best choice of first-time b/tsDMARD for certain RA patients, which is a step forward towards personalizing treatment.

However, further research in other cohorts is needed to verify our results.

**SAFETY OF B/TSDMARDS FOR RA AS USED IN CLINICAL PRACTICE - RESULTS FROM THE LAST DECADE OF THE ARTIS PROGRAM**

T. Frisell, H. Bower, E. Baecklund, D. Di Giuseppe, B. Delcoigne, N. Felletius, H. Forbisdal-D’ella, E. Lindqvist, U. Lindström, J. Askling. On behalf of the ARTIS Study Group. Karolinska Institutet, Medicin Solna, Clinical Epidemiology Division, Stockholm, Sweden; Uppsala University, Medical Sciences, Uppsala, Sweden; Swedish Medical Products Agency, - Uppsala, Sweden; Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden; Skåne University Hospital, Department of Rheumatology, Lund, Sweden; Karolinska University Hospital, Rheumatology, Stockholm, Sweden

**Background:** While the relative efficacy of treatments can be demonstrated in relatively small studies with limited follow-up, most safety concerns are infrequent, requiring longer follow-up and larger populations. This is recognized by the regulatory framework, where data from pivotal randomized controlled trials are usually considered sufficient for demonstrating efficacy and non-toxicity, but post-approval safety studies are required for many years to fully evaluate drug-associated risks. Though such regulatory safety-studies often focus on one drug (vs. all others), clinical decision-making requires data across all available treatment options. Long-standing longitudinal clinical registries, like the Anti-Rheumatic Therapies in Sweden (ARTIS) database, thus have a key role in assessing the relative safety of b/tsDMARDs, allowing simultaneous comparison of all drugs used in clinical practice, with consistent definitions of treatment cohorts, follow-up, and outcomes.

**Objectives:** To assess incidence rates of critical safety endpoints for individual b/tsDMARDs used to treat RA, updating previously published reports and including more recently introduced treatments.

**Methods:** Nationwide cohort-based cohort study including all RA patients in Sweden registered as starting any b/tsDMARD between Jan 1st 2010 and Dec 31st 2019, and followed until Dec 31st 2020. The incidence rates of selected outcomes, identified through national healthcare registers, were compared between individual b/tsDMARDs while adjusting for a range of potential confounders (covering demographics, RA-related characteristics and disease activity, and comorbidity) using Inverse Probability of Treatment Weighting. Probabilities were predicted by multinomial logistic regression, regressing all covariates on treatment status. Exposure time was counted from treatment start until stop (> 90 days’ lag time), censored at emigration and death.

**Results:** There were clear differences between patients starting individual b/tsDMARDs, in particular with TNF inhibitors more often used as a first line b/tsDMARD; sarilumab, baricitinib, and tofacitinib predominantly used later in the treatment course; rituximab used more often for older patients, and non-TNF generally used more frequently for patients with higher disease activity or comorbidity. Expectedly, these differences translated into differences in the crude rate of safety endpoints. Several differences remained after confounder-adjustment (Table 1), including a higher rate of treatment discontinuation due to adverse events on baricitinib, tofacitinib, and sarilumab. Rituximab was associated with higher rates of several outcomes, but the confounder-adjustment markedly reduced risks and residual confounding likely explain most of the remaining increase. Baricitinib and tofacitinib were associated with higher rates of hospitalised herpes zoster, but not with similarly elevated rates of other serious infections. There were no clear differences in the rate of cardiovascular events or severe depression. Low number of events limit the comparison, in particular for sarilumab and tofacitinib.

**Table 1. Weighted incidence rate per 1,000 person-years of selected safety outcomes.**

Note: Rates based on < 5 events set to 0.1.

**Conclusion:** We found large differences in the rate of treatment discontinuations due to adverse events across b/tsDMARDs, which were not generally mirrored by corresponding differences in the rates for specific serious adverse events.

**Background:** Biological and targeted synthetic disease modifying antirheumatic drugs (b/ts-DMARDs) are effective treatments for rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA), but associated with high costs. Therefore, various strategies for safe and cost-effective use of these drugs have been developed, such as tapering and biosimilar use. However, overruling recommendations on how clinicians or hospitals can use these strategies in clinical practice are absent.

**Objectives:** To develop evidence-based multidisciplinary recommendations on strategies for cost-effective use of b/tsDMARDs in the treatment of RA, PsA and SpA.

**Methods:** A task force was formed consisting of 13 experts in rheumatology, epidemiology and/or pharmacology from seven European countries. Relevant strategies for cost-effective use were collected and defined using one-to-one interviews with each task force member separately using an online form. Level of agreement varied from 0 (completely disagree) to 10 (completely agree).

**Results:** Twelve strategies for cost-effective b/tsDMARDs were identified and four overarching principles were formulated (Table 1). For 10 strategies, there was enough evidence available to form one or multiple recommendation(s). In total, 20 recommendations were formulated, focussing on: the use of loading doses (2); the use of biosimilars where available (2); combining a csDMARD with a b/tsDMARD to maximise efficacy (3); the use of disease activity guided dose-doses (2); the use of biosimilars where available (2); combining a csDMARD with a b/tsDMARD to maximise efficacy (3); the use of disease activity guided doses (2). In total, 20 recommendations were formulated, focussing on: the use of loading doses (2); the use of biosimilars where available (2); combining a csDMARD with a b/tsDMARD to maximise efficacy (3); the use of disease activity guided dose-doses (2); the use of biosimilars where available (2); combining a csDMARD with a b/tsDMARD to maximise efficacy (3); the use of disease activity guided doses (2).

**Conclusion:** These evidence-based recommendations provide caregivers in rheumatology with a consensus on strategies for cost-effective use of b/tsDMARDs in RA, PsA and SpA. Because high-quality evidence was limited, we were not able to formulate recommendations on all strategies.

**POS0639**

**PHARMACOKINETIC BOOSTING TO ENABLE A ONCE-DAILY REDUCED DOSE OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS**

C. Van der Tocht, L. M. Verhoef1, B. Van den Bemt1,2, N. Den Broeder1,3, R. Ter Heine3, A. Den Broder1,3, 3Saartenskliniek, Rheumatologie, Uibergen, Nederland; 2Sint Maartenskliniek, Pharmacy, Ubbergen, Nederland; 4Sint Maartenskliniek, Pharmacy, Ubbergen, Nederland; 3Radboud University Medical Center, Clinical Pharmacy, Nijmegen, Netherlands; 4Radboud University Medical Center, Rheumatic Diseases, Nijmegen, Netherlands

**Background:** Tofacitinib is an effective drug for rheumatoid arthritis (RA) and psoriatic arthritis (PsA). As tofacitinib is metabolized by the CYP3A4-enzyme, the manufacturer recommends to reduce the dose with 50% when combined with CYP3A4-inhibitors. This creates an opportunity to improve cost-effectiveness and patient experience by deliberately combining tofacitinib 5mg once daily with a registered CYP3A4-inhibitor, cocistatin.

**Objectives:** Primary: pharmacokinetic (PK) bioequivalence of tofacitinib 5mg and cocistatin 150mg once daily (intervention) to tofacitinib 5mg twice daily (control). Secondary: clinical efficacy (DAS28-CRP), safety, patient preference, and predictive modelling of long-term DAS28 and ACR20 response.

**Methods:** This open-label, cross-over, monocentre study (Sint Maartenskliniek, The Netherlands) included patients with RA or PsA, using tofacitinib 5mg twice daily for ≥ 14 days without co-medication affected by CYP3A4-inhibition. At the first sampling day, plasma samples of tofacitinib were collected pre-dose and 0.5, 1, 2, 3, 4, 6, 9 and 12 hours post-dose. Subsequently, patients switched treatment to tofacitinib 5mg and cocistatin 150mg once daily, and 2-6 weeks thereafter, another PK sampling was performed at the same timepoints and additionally at 24 hours post-dose. PK bioequivalence was defined as the 90% confidence interval of the average ratio of the individual mean ratio (GMR) falling between 0.80-1.25. Secondary endpoints included efficacy (change in mean DAS28-CRP between sampling days), safety, and patient preference (7-point Likert scale at study end). Additionally, differences between both regimens in DAS28 and probability of ACR20 response were predicted using a validated PK/PD model.

**Results:** Between September 2019 and March 2021, 27 participants were included. Twenty-five participants completed both PK measurements and were included in the primary analysis. The C1 GMR was 84.8%, 90% CI 75.1% to 95.6%. The difference in absolute DAS28-CRP was 0.05 (95% CI -0.50 to 0.59, intervention to control). There were no significant or relevant
differences in adverse events between both regimens. Patient preference was 56% for intervention (Likert 5-7), versus 18% for control (score 1-3). Median differences in predicted DAS28 and probability of ACR20 response were 0.03 (95% CI -0.16 to 0.22; intervention-control) and -0.01 (-0.07 to 0.05), respectively.

**Conclusion:** Due to slightly lower tofacitinib concentrations during combination therapy, pharmacokinetic bioequivalence could not formally be established. However, because of comparable short-term clinical efficacy and safety, a clear patient preference and no relevant differences in predicted DAS28 and ACR20-response at maximum efficacy, pharmacokinetic boosting seems an attractive strategy to improve cost-effectiveness of tofacitinib treatment.

**Background:** COMPACT is a non-interventional study evaluating the effectiveness and safety in patients (pts) with rheumatoid arthritis (RA), axial-spondyloarthritis (axSpA) or psoriatic arthritis (PsA) treated with GP2015 (an etanercept [ETN] biosimilar) in real-world conditions.

**Objectives:** We present the effectiveness and safety data from the final analysis of the COMPACT study for all patient groups.

**Methods:** Pts aged ≥18 years on treatment with GP2015 were enrolled. Baseline visit corresponded with date of study inclusion and not with date of GP2015 treatment start. Pts were categorised based on prior treatment status: pts on conventional remission or low disease activity under treatment without reference ETN or biosimilar ETN (initial ETN: [iETN]) and switched to GP2015 (Group A) or pts who received non-ETN targeted therapies and switched to GP2015 (Group B) or biologic-naive pts who started GP2015 after conventional therapy failure (Group C) or DMARD-naive pts with recent diagnosis of RA considered suitable for treatment initiation with a biologic and started on treatment with GP2015 (Group D). Effectiveness assessments included Disease Activity Score 28-joint count Erythrocyte Sedimentation Rate (DAS28-ESR) or Ankylosing Spondylitis Disease Activity Score (ASDAS) until Month 12 after enrolment (baseline) in the study.

**Results:** Of the 1466 pts enrolled, 572 were switched from iETN (Group A), 171 were switched from other targeted therapies (Group B), 713 were biologic-naive (Group C), and 10 were RA DMARD-naive (Group D). Comorbidities were more frequent in pts with RA (68.7%) followed by pts with PsA (59.4%) and axSpA (52.1%). After 12 months of treatment with GP2015, pts with RA or PsA achieved comparable DAS28-ESR scores irrespective of whether they switched from iETN, or from other targeted therapies or were biologic-naive. At Month 12, the mean ASDAS scores were comparable between the treatment groups in pts with axSpA (Table 1). Across all pt groups, no major differences were observed in the disease activity scores between baseline and Month 12 which may be explained by the ongoing GP2015 treatment at the time of enrolment for an observed average of 138 days. Overall, the proportion of patients with at least one adverse event (AE) and serious AE (SAE) was 47.6% and 7.7% in pts who were switched from iETN, 56.7% and 9.9% in pts switched from other targeted therapies, 56% and 8.7% in biologic-naive pts, and 60% and 0% in DMARD-naive pts. Rate of injection site reaction was low across the groups (Figure 1).

**POS0640 REAL-WORLD EFFECTIVENESS AND SAFETY OF GP2015 IN PATIENTS WITH RHEUMATIC DISEASES: FINAL RESULTS OF THE COMPACT STUDY**

**Disclosure of Interests:** Celeste van der Togt: None declared, L.M. Verhoef: None declared, Bart van den Berkt Manns bureaus: UCB; Pfizer, Sanofi-Aventis, Galapagos, Amgen en Eli Lilly, Nathan den Broeder: None declared, Rob ter Heine: None declared, Alfons den Broeder Grant/research support from: Aventis, Galapagos, Pfizer, Novartis, Lilly, Sanofi, Gilead DOI: 10.1136/annrheumdis-2022-eular.1007
IN HEALTHY MALE SUBJECTS

**POS0642**

A RANDOMISED PHASE I PHARMACOKINETIC STUDY COMPARING HIGH-CONCENTRATION, LOW-VOLUME, AND CITRATE-FREE SB5 (40 MG/0.4 ML) WITH PRIOR SB5 FORMULATION, AND ADALIMUMAB BIOSIMILAR, IN HEALTHY MALE SUBJECTS

S. S. Ahn1, M. Lee1, Y. Baek2, S. Lee2, 1Samsung Bioepis Co., Ltd., Product Evaluation Team, Incheon, Korea, Republic of (South Korea); 2Samsung Bioepis Co., Ltd., Quality Evaluation Team, Incheon, Korea, Republic of (South Korea)

Background: SB5, an adalimumab (ADL) biosimilar, was developed in a low-concentration (40 mg/0.8 mL, SB5-LC) aligned with the reference ADL product. Pharmacokinetics (PK) equivalence of SB5 and reference ADL was demonstrated in a Phase I study conducted in healthy subjects. Equivalent efficacy and comparable safety between 40 mg/0.8 mL SB5 and 40 mg/0.8 mL reference ADL were demonstrated in a Phase III study conducted in patients with rheumatoid arthritis. High-concentration, low-volume, citrate-free SB5 (40 mg/0.4 mL, SB5-HC) has been developed as a part of life cycle management in line with the reference ADL formulation.

Objectives: To compare the PK, safety, and tolerability of the newly developed SB5-HC (40 mg/0.4 mL) to prior SB5-LC (40 mg/0.8 mL) in healthy male subjects.

Methods: This study was a randomised, single-blind, two-arm, parallel-group, single-dose study in healthy male subjects. Subjects were randomised in a ratio of 1:1 to receive a single dose of either SB5-HC or SB5-LC by subcutaneous injection on Day 1 and then observed for 57 days during which the PK, safety, and immunogenicity were evaluated. The serum concentration of ADL was measured using an enzyme-linked immunosorbent assay. The primary PK parameters were area under the concentration-time curve from time zero to infinity (AUC_{inf}), maximum serum concentration (C_{max}), and comparable safety between 40 mg/0.8 mL SB5 and 40 mg/0.8 mL reference ADL were demonstrated in a Phase III study conducted in patients with rheumatoid arthritis. High-concentration, low-volume, citrate-free SB5 (40 mg/0.4 mL, SB5-HC) has been developed as a part of life cycle management in line with the reference ADL formulation.

Results: Of 188 randomised subjects, 187 subjects were analysed as PK Analysis Set (PKS) (n=93 in SB5-HC and n=94 in SB5-LC). One subject was excluded from the PKS in SB5-HC group (major protocol deviation for not being withdrawn in the event of confirmed COVID-19). The geometric LSMeans ratios for the comparison of SB5-HC and SB5-LC for AUC_{inf} and C_{max} were 0.920 and 0.984, respectively, and the corresponding 90% CIs were within the pre-defined equivalence margin of 0.80 to 1.25 (Table 1), indicating the two treatment groups are bioequivalent. There were no deaths, serious adverse events or discontinuation of the study due to treatment-emergent adverse events (TEAEs) during the study.

Table 1. Comparison of Primary PK Parameters between the Treatments

SUSTAINABILITY OF RESPONSE BETWEEN UPADACITINIB AND ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS THROUGH 3 YEARS FROM THE SELECT-COMPARE TRIAL

P. Nash1, A. Kavanaugh2, M. H. Buch3, B. Combe3, L. Bessette5, I. H. Song2, T. Shaw2, Y. Song2, J. Suboticki4, R. M. Fleischmann5. 1School of Medicine, Griffith University, Brisbane, Australia; 2University of California San Diego, Rheumatology, San Diego, United States of America; 3University of Manchester & NIHR, Manchester Biomedical Research Centre, Manchester, United Kingdom; 4Montpellier University, Rheumatology, Montpellier, France; 5Université Laval, Centre Hospitalier de l’Université Laval, Laval, Canada; 6AbbVie Inc., Immunology, North Chicago, United States of America; 7AbbVie Inc., Immunology, Maidenhead, United Kingdom; aUniv of Texas Southwestern Med Center, Metroples Clinical Research Center, Dallas, United States of America

Background: The primary treatment target for patients with active rheumatoid arthritis (RA) is sustained clinical remission (REM) and low disease activity (LDA). A greater proportion of patients with RA and inadequate response to methotrexate (MTX) receiving the JAK inhibitor, upadacitinib (UPA), achieved REM/LDA compared with adalimumab (ADA), both with background MTX, through 26 weeks in the phase 3, SELECT-COMPARE trial. 3

Objectives: We assessed sustainability of response over 3 years in UPA-treated patients with RA.

Methods: SELECT-COMPARE included a 26-week, double-blind, placebo (PBO)-controlled period, a 48-week, double-blind active comparator-controlled period, and an ongoing long-term extension for up to 10 years. Patients on background MTX received UPA 15 mg once daily, PBO, or ADA 40 mg every other week. Patients who did not achieve at least 20% improvements in tender and swollen joint counts (Weeks 14-22) or LDA (CDAI ≤10 at Week 26) were rescued from UPA to ADA or PBO/ADA to UPA. This post hoc analysis evaluated clinical REM (CDAI ≤2.8; SDAI ≤3.3), LDA (CDAI ≤10; SDAI ≤11), and DAS28(CRP) <2.6/≤3.2 at first occurrence (prior to treatment switch [rescue]), as well as over 3 years following initial response in patients randomized to UPA or ADA. For those patients who achieved REM/LDA, Kaplan-Meier was used to define the time from when the response was first achieved to the earliest date at which the response was lost at two consecutive visits, discontinuation of study drug, or losing response at the time of rescue. The predictive ability of time to CDAI REM/LDA was assessed using Harrell’s concordance (c)-index (range: 0 [all predictions wrong] to 1.0 [perfect predictive ability]). Non-responder imputation was used for missing data.

Results: Through 3 years, a significantly higher proportion of patients receiving UPA + MTX vs ADA + MTX achieved CDAI REM (47% vs 35%, p=0.001) as well as CDAI LDA (70% vs 60%, p=0.001). At 30 months after first occurrence of response, CDAI REM/LDA was sustained in 19%/42% of patients randomized to UPA and 10%/30% of patients randomized to ADA (Figure 1). Time to initial clinical response did not appear to be predictive of sustained disease control. The c-index for CDAI REM/LDA was 0.50/0.60 on UPA vs 0.49/0.56 on ADA. Through the last follow-up visit, 37%/58% of patients receiving UPA and 27%/48% on ADA remained in CDAI REM/LDA, respectively (Figure 2). Of patients who lost CDAI REM, 68% on UPA and 55% on ADA remained in LDA. Additionally, roughly similar proportions on UPA and ADA recaptured CDAI REM/LDA (UPA, 40%/17%; ADA, 48%/19%). Similar results were observed for REM/LDA based on SDAI and for DAS28(CRP) <2.6/≤3.2.

Conclusion: Among patients with inadequate response to MTX, a higher proportion receiving UPA + MTX achieved remission or LDA across disease activity measures vs ADA + MTX. UPA-treated patients demonstrated a consistently higher sustained response rate over 3 years compared to those receiving ADA. Furthermore, significant proportions of patients who lost response on either UPA or ADA were able to recapture remission or LDA.

RESULTS:
Of 193 patients included in the ITT population, we had outcome data on 176 (i.e. data from 17 patients were imputed): 114 (59%) had a clinical response to biologic therapy. In the HFLM group, 41 (64%) patients responded to treatment compared to 73 (56%) in the LFHM group, but the difference proved not to be statistically significant (Odds ratio, OR: 1.48, 95% confidence interval 0.72 to 3.05).

POS0644 IMPACT OF FIBRE AND RED/PROCESSED MEAT INTAKE ON TREATMENT OUTCOMES AMONG PATIENTS WITH CHRONIC INFLAMMATORY DISEASES INITIATING BIOLOGICAL THERAPY: A PROSPECTIVE COHORT STUDY
S. H. Overgaard1,2,3, S. Sorensen1,4, H. L. Munk1,2,3, A. B. Nexøe1,4,7, H. Glerup1,4, R. H. Henriksen1,4, T. G. Nielsen1, S. Pedersen1, S. Sabin2, L. Hvid1, J. A. Dahlérup1, C. L. Hvas1,12,13, K. W. Andersen1,13, A. Kristian Hvitfeldt1, O. H. Nielsen16, F. H. Bergenheim11, J. B. Brodersen11, B. L. Heitmann17,18, T. I. Halldórsson19, U. Holmskov4, A. Bygum10,20, S. H. Overgaard1,2,3, Silja Hvid Overgaard: None declared, Signe Sorensen: None declared, Heidi Lausten Munk: None declared, Anders Bathum Nexøe: None declared, Henning Glerup: None declared, Rikke Holm Henriksen: None declared.

Figure 1. Meta-analysis (random effects model) of the included Chronic Inflammatory Diseases (CIDs) on the ‘As Observed’ population comparing clinical response to biologics in patients with a high intake of fibre and low intake of red/processed meat (HFLM) versus patients with a low intake of fibre and high intake of red/processed meat (LFHM). The horizontal lines represent the OR ± 95% CI. Event= clinical response according to the specified CIDs. Event OR 95% CI: 10.1136/annrheumdis-2022-eular.1268

Conclusion: Overall, habitual HFLM intake did not affect the clinical response to biologic treatment across CIDs. However, a HFLM diet in RA patients might be more beneficial as those with completed baseline food frequency questionnaires enabling stratification into a high fibre/low red and processed meat exposed group (HFLM) and an unexposed group (low fibre/high red and processed meat intake = LFHM). This was determined by the ratio of fibre to red/processed meat intake whereby HFLM constituted the upper tertile of the study sample and LFHM constituted the two lower tertiles of the study sample. The primary outcome was the proportion of patients with a clinical response to biologic therapy after 14-16 weeks of treatment. Based on the ITT population, differences between the dietary phenotypes in terms of the clinical response rate were analysed (while adjusting for the specific CIDs) in logistic regression models.

POS0646

NON-MEDICAL SWITCHING FROM TOCILIZUMAB TO SARILUMAB IN RHEUMATOID ARTHRITIS PATIENTS WITH LOW DISEASE ACTIVITY

N. Den Broeder1,2, A. Den Broeder1, L. M. Verhoeft1, F. Van den Hoogen1, A. Van der Maas1, B. Van den Berft1, S. M. Maarten, Rotterdam, Netherlands; 2Radboumc, Radboud Institute for Health Sciences, Nijmegen, Netherlands

Background: Tocilizumab (TCZ) and sarilumab (SRL) are IL-6 receptor antagonists registered for the treatment of rheumatoid arthritis (RA). Data from extension of the ASCERTAIN trial showed that patients responding to blinded intravenous (IV) TCZ rarely experienced a loss of response when switching to open label SRL [1]. This within-class, between-drug switch has gained relevance given the recent pandemic-driven shortage of several BDMARDs including TCZ.

Objectives: To assess the efficacy and persistence of switching to sarilumab in RA patients responding well to tocilizumab.

Methods: SAARTOOS (SArilumab Actively Replacing TOcilizumab, an Open label Study) is an open, observational single arm study. RA patients doing well (DAS28-CRP<2.9 or <3.6 with clinical judgement of low disease activity) on stable dose (>6 months) of TCZ were offered to switch to SRL in clinical care (because of lower injection frequency). Patients who switched and consented were followed for 6 months. SRL was prescribed at a dose of 200mg. The SRL dosing interval was determined by doubling patient’s last TCZ dosing interval. All treatment decisions, including adjusting dose of or stopping SRL, were left to the treating physician. Co-primary outcomes were 1) the 90% confidence interval (CI) of DAS28-CRP change from baseline to month 6 compared to the non-inferiority
Elevated rheumatoid factor (RF) in patients with rheumatoid arthritis (RA) is associated with higher disease activity and increased risk for disease progression. Recent publications indicate significantly lower efficacy of TNF inhibitors (TNFi) in RA patients with high RF levels compared with low/negative RF subgroup. Fab therapy with Certolizumab pegol (CZP), a PEGylated, Fc-free monoclonal antibody (mAb), has shown comparable efficacy and consistent serum levels irrespective of baseline RF. RF binds the Fc region of IgG1, complexes may likely explain the increased clearance of mAbs in patients with high RF titers and reported reduced TNFi efficacy.

*Median and interquartile range; **mean and standard deviation

Table 1. Baseline characteristics.

**Persistent serum levels irrespective of baseline RF**

**DAS28-CRP change was 7 (3-10), during the study, 8 (36%) patients experienced a DAS28-CRP based flare** (and post-hoc the proportion of patients persisting to TCZ and 2 (9%) switched to baricitinib.

**Secondary outcomes included the CDAI, proportion of patients preferring TCZ, and 5 (25%) patients somewhat or strongly preferring SRL. In terms of (co-)medication, 4 (18%) patients required additional corticosteroids (oral or intramuscular), 5 (23%) patients switched back to TCZ and 2 (9%) switched to baricitinib.

**Conclusion:** Non-medical switching from tocilizumab to sarilumab in patients doing well on tocilizumab is associated with a non-negligible risk of flare and non-persistence.

**DOES TNF INHIBITOR MOLECULAR STRUCTURE MATTER? ANALYSIS OF IMPACT OF BASELINE RHEUMATOID FACTOR TITERS ON DRUG LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Institute for Health Research (IdiPAZ), Immuno-Rheumatology Research Group, Madrid, Spain; La Paz University Hospital, Department of Rheumatology, Madrid, Spain

**Background:** Elevated rheumatoid factor (RF) in patients with rheumatoid arthritis (RA) is associated with higher disease activity and increased risk for disease progression. Recent publications indicate significantly lower efficacy of TNF inhibitors (TNFi) in RA patients with high RF levels compared with low/negative RF subgroup. Fab therapy with Certolizumab pegol (CZP), a PEGylated, Fc-free monoclonal antibody (mAb), has shown comparable efficacy and consistent serum levels irrespective of baseline RF. RF binds the Fc region of IgG1, the subtype used to engineer the majority of mAbs. Formation of large immune complexes may likely explain the increased clearance of mAbs in patients with high RF titers and reported reduced TNFi efficacy.

**Disclosure of Interests:** Nathan den Broeder: None declared, Alfonso den Broeder Grant/research support from: Abbvie, Galapagos, Pfizer, Novartis, Lilly, Sanofi, Glaxo, L.M. Verhoef: None declared, Frank van den Hoogen: None declared, Aatke van der Maas: None declared, Bart van den Bemt: Speakers bureau: UCB, Pfizer, Sanofi-Aventis, Galapagos, Amgen en Eli Lilly

Sex Differences in Adverse Drug Reactions in Patients with Immune-Mediated Inflammatory Diseases

Background: Women generally report more adverse drug reactions (ADRs) than men. Information on sex differences concerning the frequency and the nature of ADRs is still limited and sex differences are not considered in research on ADRs. Consequently, no sex specific distinction is made when reporting results of ADR analyses or when providing information to patients.

Objectives: To examine sex differences in regard to the nature and frequency of reported ADRs in patients with immune-mediated inflammatory disease (IMIDs) treated with adalimumab or etanercept.

Methods: Patients with rheumatoid arthritis (RA), psoriatic arthritis or axial spondyloarthritis using etanercept or adalimumab, were included from the Dutch Biologic Monitor (DBM). Questionnaires concerning experienced ADRs were filled out bimonthly. ADRs were coded according to Medical Dictionary for Regulatory Activities (MedDRA) terminology. Sex specific ADRs (e.g. concerning menstruation) were excluded. MedDRA Preferred Terms (PTs) were analyzed to assess the nature and frequency of ADRs. Only PTs that were reported at least four times were analyzed. Discrepancies in the distribution of the nature of reported ADRs between male and female patients were assessed using Fisher Freeman Halton with Monte Carlo simulation. Subsequently, differences in frequencies at PT level were examined using Fisher’s exact tests, corrected for multiple testing using Bonferroni correction.

Results: In total 748 consecutive patients were included of which the majority (59%) was female (Table 1). 362 participants (48%) reported at least one ADR during the study. Relatively more female patients (35%) reported at least one ADR compared to male patients (38%, p<0.001). In total 882 ADRs were reported comprising 264 distinct ADRs, of which the majority (74%) was reported by female patients. The ADR distribution differed significantly between male and female patients (p<0.025). ‘Injection site pruritus’ (p=0.004), ‘ Injection site inflammation’ (p=0.028), ‘Injection site hematoma’ (p=0.017), ‘ injection site erythema’ (p=0.026), ‘hematoma’ (p=0.011) and ‘cystitis’ (p=0.044) were reported relatively more often by female patients (Figure 1). These differences were no longer statistically significant upon correction for multiple testing.

Disclosure of Interests: Helen Gosselt: None declared. Jette van Lint: None declared. Sander Tas Consultant of: Gebro, GSK, AbbVie, Galvani, Arthogen/MearaGTX, Galapagos, Grant/research support from: Pfizer, GSK, Celgene.

Background: Previously, 24-week results of phase III double-blind, placebo-controlled randomized clinical study (SOLAR) of levilimab in subjects with active rheumatoid arthritis (RA) proved a superiority of levilimab over placebo. Here we present 1-year efficacy and safety data of the open-label period of the SOLAR study.

Objectives: To evaluate the efficacy and safety of levilimab in combination with methotrexate (MTX) in subjects with MTX resistant active RA.

Methods: The study was conducted at 21 clinical sites in Russia and Belarus. All randomized subjects had completed the study between November 2019 and October 2021. 154 adults, aged ≥ 18 years with confirmed diagnosis of RA were randomly assigned (2:1) to receive either levilimab, 162 mg, SC (LVL QW) or MTX (n=102) or placebo (PBO) + MTX (n=52). After W24 of the study all subjects randomly assigned (2:1) to receive either levilimab, 162 mg, SC (LVL QW) + MTX or PBO + MTX (n=257) and PBO/LVL Q2W arm (n=1). Those with DAS28- CRP ≥ 2.6 at W28 continued with placebo levilimab regimen + MTX: LVL QW/Q2W arm (n=75) and PBO/LVL QW arm (n=51).

The efficacy analysis was done in a population of all randomized subjects (n=154). Those with missing data due to study discontinuation or rescue therapy prescription were considered non-responders. Otherwise, the analysis was performed on complete cases. Safety was assessed through monitoring of adverse events (AEs) in a population of those, who received at least one dose of LVL (n=152). Two subjects randomized to receive placebo were discontinued within first 24 weeks of the study, thus did not receive any dose of levilimab and were excluded from safety analysis.

Results: Obviously, better response to the treatment was observed in LVL QW/Q2W arm as it was composed of those who had reached DAS28-CRP ≤ 2.6 at W24. At this time point 15/27 (55.6%) of them achieved ACR70/23/27 (85.2%) achieved DAS28-CRP remission (<2.6) and 7/27 (25.9%) achieved ACR/EULAR remission of RA. After switching to LVL Q2W, rates of ACR70 and DAS28-CRP < 2.6 did not significantly changed until W52: 17/27 (63.0%) and 21/27 (77.8%), respectively, yet the proportion of subject with ACR/EULAR2011 remission further increased and reached 12/27 (44.4%). LVL QW/Q2W arm was diminished by subjects who had achieved high response to treatment at W24 and composed LVL QW/Q2W arm. Thus, the ACR70, and remissions rate in this arm were close to zero at W24. However, continuation of LVL QW in those who had not achieved DAS28-CRP ≤ 2.6 at W24 induced ACR70 response in 37/75 (46.7%) and ACR/EULAR2011 remission in 8/75 (10.7%) at W52. The most common adverse events (reported in ≥5% of subjects) were blood cholesterol increase (30.3%), ALT increase (23.0%), lymphocyte count decrease (17.1%), ANC decrease (16.4%), blood triglycerides increase (13.8%), bilirubin increase (11.2%), AST increase (9.9%), WBC decrease (9.9%), IGRA with M.tb antigen positive (7.2%) and injection site reactions (6.9%). No deaths were reported.

Conclusion: Open label period confirmed the lasting efficacy and safety of levilimab in combination with MTX in subjects with MTX resistant active RA suggesting the possibility of switching to maintenance (Q2W) regimen of levilimab in those who achieved remission of RA at week 24.

Disclosure of Interests: All authors declare no conflict of interests.
Methods: BiobadaBrasil is a multicentric registry-based cohort study of Brazilian patients with rheumatic diseases starting their first bDMARD or tsDMARD (3). The present analysis includes RA patients recruited from Jan 2009 to Oct 2019, followed-up over one or multiple (up to six) courses of treatment necessarily involving a bDMARD or tsDMARD (latest date, Nov 19, 2019). Treatment course is defined as a period during which the medication scheme does not change, except for dose adjustments. Primary outcome was the incidence treatment interruption for any reason (except for pregnancy or disease remission), while interruption due to adverse events (AEs; including death) and due to inefficacy served as secondary outcomes. Incidence of serious adverse events (SAEs) also served as a secondary outcome. Extended (frailty) multivariate Cox proportional hazards models and negative binomial regression with generalized estimating equations (to calculate incidence rate ratios [IRR]s) were used for statistical analyses (both types of analyses including time-varying covariates over multiple courses of treatment).

Results: In total, 1316 patients (2335 treatment courses, 6508 patient-years [PY]) were enrolled. Of these, 160 patients (643 PY; 237 treatment courses) were ≤65 years old, mean age at starting treatment = 71 ± 5 yrs (84% female). Old age was not significantly associated with treatment interruption for any reason, but presented higher risk of interruption due to adverse events (after multivariate adjustment) and lower risk of stopping because of inefficacy (see Table 1). Older patients presented higher incidence of SAEs than younger ones (16.0 vs 8.4/100 PY, respectively; multivariate IRR: 2.06, 95% CI: 1.51 to 2.80, P<0.001). Among old patients, tocilizumab (HR: 2.73, 95% CI: 1.13 to 6.64, P=0.026), etanercept (2.13, 1.12 to 4.07, P=0.022), and infliximab (2.39, 1.19 to 4.79, P=0.014) presented higher risk of treatment termination as compared with adalimumab. In this subgroup (age ≥65 yrs), there was no significant difference in the risk of SAEs between different bDMARDs/tsDMARDs.

Table 1. Univariate and multivariate hazard ratios (HRs) of interruption of treatment course comparing older (≥65 years) versus younger patients (reference category). Results are HRs, 95% CIs, and P values.

* Age, baseline DAS28, disease duration, gender, smoking, RF or anti-CCP previous malignancy, interstitial lung disease, diabetes, hypertension, hypercholesterolemia, renal failure, ischemic cardiomyopathy, COPD, heart failure, concomitant use of each cs-, b-, and tsD-MARDs, corticosteroids, starting year, osteoporosis, hepatitis B, C treatment sequence.

Conclusion: The overall risk of treatment interruption with biologic or targeted synthetic DMDAR is not higher in older patients. Higher risk of interruption due to AE was balanced by a lower risk of stopping treatment due to inefficacy. Older patients had a higher incidence of SAEs.

POS0651 IMPACT OF ADVERSE DRUG REACTIONS ON THE TREATMENT PATHWAYS OF EARLY RHEUMATOID ARTHRITIS PATIENTS

1. Netherlands Pharmacovigilance Centre Lareb, Research, 's-Hertogenbosch, Netherlands; 2. University of Twente, Department of Psychology, Health & Technology, Enschede, Netherlands; 3. Institute of Pharmaceutical Sciences, Division of Pharmacoepidemiology and Clinical Pharmacology, Utrecht, Netherlands; 4. Netherlands Pharmacovigilance Centre Lareb, Research, 's-Hertogenbosch, Netherlands; 5. Medisch Spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands

Background: Rheumatoid arthritis (RA) patients frequently pass through several medications in order to achieve and maintain acceptable disease control. The clinical heterogeneity and variable course of the disease, plus the availability of multiple classes and subclasses of DMDARs may lead to very different and complex treatment sequencing in individual patients. Limited real-world data exists regarding treatment pathways among patients with RA. Adverse drug reactions (ADRs) belong to the stop reasons of medication, but the impact of ADRs on treatment pathways has not been quantified.

Objectives: To assess differences in treatment pathways between RA patients with and without adverse drug reactions (ADRs).

Methods: Single center retrospective observational study, using real-world data collected in the Dutch Rheumatoid Arthritis Monitoring (DREAM-RA) registry from Medisch Spectrum Twente (Enschede, the Netherlands). From all early RA patients enrolled between 16 July 2006 and 30 April 2020, the first four consecutive courses of treatment were assessed. Patients were selected from the DREAM early RA treat-to-target cohort. The use of corticosteroids per protocol was allowed but not considered as a DMDAR treatment. bDMARDs and tsDMARDs and a combination of these classes of DMDARs were considered as bDMARDs/tsDMARDs.

Results: In total, 372 RA patients (66.1% females) were assessed (Table 1). The average duration of treatment was shorter in patients that experienced at least one ADR (1.8 vs. 2.7 years, p<0.001), and the number of treatments was higher (3.5 vs. 2.5, p<0.001), than in those that experienced no ADR. Furthermore, there was a difference between these groups in the proportion of treatments with tsDMARD(s) and bDMARD(s) or a combination of the two (p<0.001). This was for the No ADR group respectively 93%; 1%; 6%, and for the ADR group respectively: 77%; 8%; 15%.

POS0652 LONG-TERM EFFECTIVENESS OF ULTRA-LOW DOSES OF RITUXIMAB IN RHEUMATOID ARTHRITIS

1. Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; 2. Radboudumc, Radboud Institute for Health Sciences, Nijmegen, Netherlands; 3. Ziekenhuisgroep Twente (Hospital Group Twente), Rheumatology, Borne, Netherlands; 4. Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; 5. Radboud University Medical Centre, Rheumatology, Nijmegen, Netherlands; 6. Reade, Rheumatology, Amsterdam, Netherlands

Background: The optimal rituximab (RTX) dose for the treatment of rheumatoid arthritis remains unclear. RTX treatment of 1000mg per 6 months and 2000mg per 8 months were shown to be similarly efficacious (1). The REDI trial showed the 6-month efficacy of continued treatment with 500mg and 200mg compared to 1000mg, though formal non-inferiority could not be established (2).

Objectives: To assess the long-term effects of ultra-low dose RTX (1x500mg and 1x200mg) in RA patients previously responding well to conventional low dose RTX (1x1000mg).

REFERENCES:
**Methods:** Patients from the REDO trial were invited to participate in this study. Treatment decisions were left at the discretion of the rheumatologist and patient. Disease activity (DAS28-CRP), and medication use (b/tsDMARD, csDMARD, glucocorticoids [GC]) were collected from start of the trial to censoring in April 2021. The primary outcome was disease activity, secondary outcomes were RTX persistence, RTX doses and intervals, and use of comedication. Disease activity was analyzed using a longitudinal mixed model with random intercepts to account for intra-patient correlations, in two ways: 1. By original randomization and stratification factors (RF/ACPA and csDMARD use), 2. By time-varying total RTX dose received in the year preceding each disease activity measurement, adjusted for current csDMARD or GC use, and RF/ACPA. The original DAS28-CRP non-inferiority (NI) margin of 0.6 was used.

**Results:** 118 out of 142 REDO patients were included in current analyses (Table 1) Reasons for exclusion were: continuing treatment elsewhere (n=3), no informed consent (n=8) and data yet to be collected in 2 study centers (n=12). Mean follow up was 3.2 years (total of 377 patient-years), with 7 patients switching to another b/tsDMARD (Figure 1) upon which they were censored from disease activity analyses.

</tbody>
</table>

**Figure 1. Rituximab treatment persistence during follow up.**

Disease activity in both ultra-low dose groups was non-inferior to the 1000mg group, with a mean DAS28-CRP (95% CI) during follow-up of 2.2 (2.0-2.4) in the 1000mg group, 2.2 (2.1-2.4) in the 500mg group and 2.3 (2.2-2.5) in the 200mg group. Analyzed by received RTX dose, lower RTX dose was significantly associated with a higher DAS28-CRP: 0.15 (95% CI: 0.02-0.28) per patient-year and initiation rate of oral GC was 0.05 (0.03-0.08) per patient-year.

**Conclusion:** A majority of patients treated with ultra-low dose RTX remained on ultra-low doses for up to 4 years, while disease activity remained low and did not relevantly differ between RTX doses, either according to original randomization or by received dose. Switching to other b/tsDMARDs or use of GC was rarely required.

**POS0653 CAN DOSAGE OF INFlixIMAB BE ADJUSTED TO 8 WEEK INTERVALS WITHOUT LOSING EFFICACY IN ARTHRITIS PATIENTS ON MAINTENANCE THERAPY WITH MORE FREQUENT INFUSIONS?**

E. Lindqvist1, B. Månsson1. 1Lund University Department of Clinical Sciences, Lund, Sweden

**Background:** Infliximab is usually given every 8 weeks. To increase dosage, the dose can be increased or the interval between infusions shortened. To minimize patient visits and workload for the medical staff during the Corona pandemic, we intended to change all infliximab infusions to 8 week intervals. For patients with inflammatory bowel disease, a trough level of serum (s-) concentration of infliximab of 3-7 µg/ml is recommended. In Rheumatology the usefulness of assessing s-concentration is controversial. (1, 2)

**Objectives:** To evaluate if 8 week interval infliximab dosage, with retained weekly dose, can be used in arthritis patients, without worsening of disease activity or general health and study if s-concentration of infliximab is related to disease activity and general health.

**Methods:** All arthritis patients on stable infliximab treatment were evaluated at the time for infliximab infusion. Disease activity, DAS28-CRP, VAS pain, global, fatigue, doctors’ global, HAQ, and ASDAS-CRP, BASFI for spondyloarthritis (SpA) patients were registered in the Swedish Rheumatology Quality registry (SRQ). Blood tests for CRP, ESR and s-concentration of infliximab were taken before infusion start. S-concentration was analysed at Karolinska Hospital, Solna, Sweden with an in-house ELISA. Antibodies were assessed if s-concentration was >0.5 µg/ml.

Patients with infusion intervals less than 8 weeks were recommended a switch to 8 week intervals with maintained weekly dose of infliximab. The new dose was given the same day and patients with changed doses were re-evaluated after 24 weeks. Paired samples T-test and Wilcoxon signed rank test for paired data were used for comparison of disease activity and general health after dosage change. Linear regression analyses were used to explore associations between s-concentration, disease activity and general health.

**Results:** Of 91 assessed patients, 66 with shorter intervals were recommended dosage change. The remaining 25 patients had infliximab every 8 weeks and served as controls. For baseline characteristics see Table 1. Dosage was changed in 58 patients and 90% (n=52) remained on 8 week intervals after 24 weeks, with a mean (SD) dose of infliximab of 5.3 (1.9) mg/kg. All assessed disease variables (DAS28-CRP, VAS pain, global, fatigue, Dr global, HAQ, and ASDAS-CRP, BASFI for spondyloarthritis (SpA) patients) remained unchanged (p=0.051 (pain) – 0.83) (Figure 1 A, B) while s-concentration was lower (p<0.001) at follow up. S-concentration of infliximab did not relate to disease activity neither at baseline nor at follow up (p=0.15-0.24). (Figure 1 C, D)

**Conclusion:** Adjustment of infliximab dosage to every 8 weeks worked for a majority of the arthritis patients in this clinical setting without worsening of
EFFECTIVENESS OF ABATECT IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS.

R. Redondo Rodríguez1, F. Godoy-Narváez2, F. Morales-Garrido3, M. Rojas-Giménez4, C. M. Romero-Barco5, N. Mena-Vázquez1. Universidad de Málaga (HRUM), Málaga, Spain; Biomédica de Málaga (IBIMA), UGC de Reumatología, Hospital Regional de Málaga (HRUM), Málaga, Spain; Hospital Universitario de Jaén, UGC de Reumatología, Jaén, Spain; Hospital Universitario Clínico San Cecilio, UGC de Reumatología, Granada, Spain; Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), UGC de Reumatología, Hospital Universitario Reina Sofía de Córdoba, Córdoba, Spain; Hospital Clínico Universitario Virgen de la Victoria, UGC de Reumatología, Málaga, Spain

Background: Interstitial Lung Disease (ILD) is the most common lung involvement in rheumatoid arthritis (RA) and leads to increased morbidity and mortality. Some retrospective observational studies suggest that abatacept (ABT) could be effective and safe, although there are no clinical trials and prospectively collected data on ABT.

Objectives: To evaluate prospective the effectiveness and safety of ABT in patients with ILD associated RA (ILD-RA).

Methods: Design and Protocol: We performed a multicenter, prospective, observational study of patients with interstitial lung disease secondary to rheumatoid arthritis (ILD-RA) receiving ABT between 2015 and 2021. The patients were assessed using high-resolution computed tomography and lung function tests at the beginning of treatment (V0), at 12 months (V12), and at the end of follow-up in 2021 (Vf). The study was approved by the Ethics Committee (Code 1719-N-15).

Main variable: effectiveness of ABT according to evolution of ILD at the end of follow-up: (1) improvement (ie improvement of FVC ≥10% or DLCO ≥15% and no radiological progression), (2) no progression (stabilization or improvement in FVC ≤10% or DLCO <15% and no radiological progression), (3) progression (worsening of FVC >10% or DLCO >15% and radiological progression) or (4) death.

Other variables: clinical and analytical characteristics, treatments and safety (infections, hospitalization and mortality).

Statistical analysis: Cox regression analysis to identify factors associated with worsening of ILD-RA treated with ABT.

Results: Thirty-eight ILD-RA patients started ABT treatment during prospective follow-up. A total of 22/38 (57.9%) were men and the mean (SD) age was 61.9 (9.1) years. The mean (SD) evolution of ILD was 43.9 (30.0) months and the median (IQR) time with ABT was 17.0 (12.1-34.8) months. The baseline clinical-epidemiological characteristics and pulmonary progression of the patients are shown in Table 1. At the end of follow-up (fV) 28/38 (73.6%) had improvement/stabilization among the patients who were in combination with methotrexate compared to those who were in monotherapy (83.3% vs 39.1%; p=0.046). The baseline variables that were independently associated with progression-mortality of ILD-RA in fV were: baseline FVC [OR [95% CI], 0.895 [0.805-0.996]; p=0.042] and duration of ILD-RA [OR [95% CI], 1.204 [1.148-2.112; p=0.046]]. Two patients discontinued ABT during follow-up due to insufficient joint and pulmonary response.

Conclusion: More than half of the patients with ILD-RA treated with ABT manage to stabilize or improve their lung disease after a median follow-up of 17 months. Patients who worsen or die have lower baseline FVC values and ILD-RA with a longer evolution time.

Background: Advances in rheumatology and new therapeutic options have certainly impacted patient survival, changing the age range, from youth to seniors. The differences between the age groups could influence the evolution of the disease and the adverse events (AEs) related to the treatments. There are few real-world data on the safety and efficacy of treatments in different age groups.

Objectives: To evaluate the frequency of AEs and the survival of treatments according to the age in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS).

Methods: Retrospective, observational, multicenter study of real-life data of patients included in the BIOBADASAR 3.0 registry; exposed and not exposed to original biological treatments (b-DMARDs), biosimilars, targeted synthetic drugs (ts-DMARDs). The unexposed group received treatment with conventional disease-modifying drugs (cDMARDs). A Kaplan-Meier and Log Rank Test analysis was performed to study AEs-free survival and treatment in different age groups (young people <25; young adults 25-34; mature adults 34-65; old adults >65). Factors related to treatment survival were evaluated using Cox regression models.

Results: 5,297 patients were included, 80.3% female, mean age 43.7 years (SD 15.6) and median disease progression 14.3 [IQR: 11.5]. RA 4658 (87.9%); PsA 490 (9.25%) and EA 149 (2.8%). The main reason for treatment discontinuation was ineffectiveness, in 624 patients in the exposed group and in 53 (2.5%) patients in control group, followed by the presence of AEs in 352 (11.2%) and 63 (3.9%), respectively (p = 0.001). A mean Charlson Score of 0.298 (SD 0.6) in the exposed group and 0.306 (SD 0.7) in the control group (p = 0.095). Median EAS-free survival in the exposed group was 12.5 years [IQR 16.6] while in controls was 28 years [IQR 11]. p < 0.0001. Median AEs-free survival was 12 years (IQR 11) in young people, 11.5 years [IQR: 4.9] in young adults, 10 years [IQR: 3.25] in mature adults and 76 years [IQR: 6] in old adults with a difference statistically significant (p = 0.017). The exposed group presented a median treatment survival in years of 11.25 years [IQR: 10] in young people; 12.5 years [IQR: 4.7] in young adults, 75 years [IQR: 12.1] in mature adults and 4.5 years [IQR: 1.14] in old adults (p = 0.0001). Considering only the first line of treatment, a median survival of 11.5 years [IQR: 10] was evidenced in the age group <25; 12 years [IQR: 2] between 25-34 years old, 10 years [IQR: 12] in the group between 34-85 years old and 5.5 years [IQR: 1.4] in the group > 65 years old (p = 0.004). (Figure 1). Considering the second line of treatment, the differences between the groups were not statistically significant (p = 0.57). In the multivariate regression model for patients with RA, the factors with the greatest impact on treatment survival were female sex (HR 1.3, 95% CI 1.2-1.4), old age (HR 1.01, 95% CI 1.008-1.01), treatment with steroids (HR 1.19, 95% CI 1.11-1.12) and longer disease duration (HR 1.01, 95% CI 1.01 – 1.02).

Conclusion: In the present study we were able to demonstrate a greater occurrence of AEs in old adults and mature adults compared to young people and young adults. Conversely, survival for b-DMARDs and ts-DMARDs were greater in young and young adults. In patients with RA, female sex, corticosteroid therapy, old aged and longer disease duration were associated with treatment discontinuation.

REFERENCES:
[1] Souto A, et al. Rate of discontinuation and drug survival of biologic therapies in patients with rheumatoid arthritis (RA) [1]. Whether frailty status portends an increased risk of adverse outcomes in patients with RA on biologic or targeted synthetic disease-modifying anti-rheumatic drugs (b- or tsDMARDs) remains unknown.

Objectives: To evaluate the association between frailty and adverse outcomes in patients with RA exposed to b- or tsDMARDs.

Methods: Using the IBMWatson MarketScan Commercial Claims and Encounters Databases, we identified all patients with RA who filled new prescriptions (or received infusions) for TNFi antagonists (TNFi), non-TNFi biologics (rituximab, abatacept, tocilizumab) or Janssen Kinase inhibitors (JAKi) between 2008-2019. We used a 1-year lookback period without the use of these drugs to identify new users. The date of the first prescription within these three drug categories was the index date. Patients’ frailty risk score was calculated using the Claims-Based Frailty Index (CFI) [2], which estimates a deficit-accumulation frailty index using International Classification of Diseases codes, Current procedural Terminology codes, and Healthcare Common Procedure Coding System codes in administrative claims data in the 1-year baseline period. The index ranges from 0 (not at all frail) to 1 (severely frail). The primary outcome was time to serious infections (those requiring hospitalization); secondary outcomes: any infection (outpatient or inpatient encounters) and all-cause hospitalizations. Patients were followed until 1) outcome occurrence; 2) disenrollment; 3) >90 days elapsed (or >180 days for rituximab) without further fills of the first drug categories; 4) they filled/received infusions of b- or tsDMARDs from a different drug category; or 5) 2 years after index. Cox proportional hazards adjusting for demographics, calendar year, serious and/or opportunistic infections in the 12-months prior to index were used to estimate the adjusted hazard ratios (aHR) and 95% confidence intervals (CIs) for each outcome. In separate model, we additionally adjusted for comorbidity burden, and health care utilization (HCU).

Results: A total of 62,246 patients with RA met our inclusion criteria of whom 50,910 (82%) started TNFi as their first biologic, 9252 (15%) non-TNFi biologics, and 1811 (3%) JAKi. Among these, 3928 (6%) were considered frail. In multivariable analyses, frail patients had higher risk of serious infections compared to non-frail patients (aHR 2.37, 95% CI 2.05-2.74) which decreased to aHR 1.34, 95% CI 1.13-1.58 (Table 1) after adjusting for comorbidity burden and the HCU. Similarly, frailty was associated with increased of any infection (aHR 1.18, 95% CI 1.11-1.25), and all-cause hospitalizations (aHR 1.34, 95% CI 1.21-1.46) relative to non-frail individuals.

Table 1. Multivariable models evaluating the association between frailty status and inpatient infections as the outcome

Conclusion: Frailty is an important predictor for the risk of adverse outcomes among patients with RA treated with b- or tsDMARDs. Our findings underscore the need for considering this parameter in patient evaluation (even among younger patients) in the clinic.

SURVIVAL OF BARICITINIB VS ANTI-TNF AS THE FIRST BIOLOGICAL DRUG IN PATIENTS WITH RHEUMATOID ARTHRITIS, IN CLINICAL PRACTICE: RESULTS OF A LOCAL REGISTRY

J. Rosés1, A. Pons1, X. Barber2, J. M. Senabre-Gallego3, G. Santos Soler3, E. Soler-Giner4, J. A. Bernalló5, A. Raga6, C. Raya-Santos1, J. C. Cortés-Quiroz1, M. Lorente Betoret7, J. A. García-Gómez8 on behalf of AIRE-MB.

Background: Recently, it has been recognized that frailty and pre-frailty are common in patients with rheumatoid arthritis (RA) [1]. Whether frailty status portends an increased risk of adverse outcomes in patients with RA on biologic or targeted synthetic disease-modifying anti-rheumatic drugs (b- or tsDMARDs) remains unknown.

Objectives: To evaluate the association between frailty and adverse outcomes in patients with RA exposed to b- or tsDMARDs.

Methods: Retrospective study of patients with RA, treated with the first BIO-1, with BARI or TNFI, from September 2017 to December 2021. General data (current age, at diagnosis of RA and at the start of BIO-1) were collected; RA: evolution time, RF, ACPA; type of BIO-1: dose received, time in treatment, reason for withdrawal. Univariate analysis of drug survival was performed using Kaplan-Meier curves and the Long Rank test to differentiate by groups. For the multivariable study, Cox regression with proportional hazards.

Results: The study includes 96 patients with RA, who have started treatment for > 1 month with BIO-1: BARI (n: 63/66% patients) or TNFI (33/34% patients): women: 82 (96%), current mean age (SD): 62 (1) years, at diagnosis: 51 (1) years, at the start of BIO-1: 59 (1) years. 36 (37%) patients are ≥65 years old, the mean time
In ARI is 76 years and the time in BIO-1: 1.34 (2.2) years. BIO-1 was withdrawn in 34 (40%) patients: inefficacy: 17 (18%) patients, Complications: 14 (15%) Cardiovascular/thrombosis: 2 (2%), rash: 2 (2%), infection-neoplasia-immunogenicity: 1 (1%) patient in each, loss to follow-up: 5 (5%) and others: 2 (2%). When comparing the BARI vs. TNFI group, no differences were detected between the general data, the percentage of patients >65 years of age, or the mean time in treatment or the reasons for drug withdrawal (Table 1). However, survival in the BARI group was significantly superior to TNFI throughout the period (p=0.04; HR: 0.47, 95% CI: 0.24-0.91, p=0.026) (Figure 1A).

Figure 1. Survival probability in patients with rheumatoid arthritis who receive the first BIO-1. A. Between TNFI drug vs Baricitinib. B. Between TNFI vs Baricitinib 2 mg or 4 mg.

In patients <65 years, the greatest survival of BARI is maintained (p=0.05), being significant in the first 24 months of treatment (p=0.02). In patients ≥65 years, significance was not reached throughout the overall period (p=0.5) and in the first 24 months of treatment (p=0.06). When comparing the BARI 2 mg (n: 23/36%) and 4 mg (n: 40/64%) groups, the 2 mg group is significantly older at RA diagnosis (73 [SD: 2] years vs 56 [SD: 3] years; p=0.0001) and at the start of BIO-1 (72 [SD: 14] years vs 54 [SD: 2.8] years; p=0.0001). However, survival in the BARI 2 mg group was significantly higher in the first 24 months (p=0.003) (Figure 1B): BARI 2 mg HR: 0.14, 95% CI; 0.04-0.56, p=0.005, HR BARI 4 mg: 0.44 (95% CI; 0.20-0.96, p=0.038).

Conclusion: Survival of BARI is superior to TNFI during the first 4 years of treatment, especially during the first 24 months of treatment. There are no differences between the cause that causes drug withdrawal. 3. The use of the 2 mg dose of BARI predominates in patients older than 65 years, with survival being greater than TNFI, especially in the first 24 months of treatment.

TUMOR NECROSIS FACTOR BLOCKERS INDUCED SARCOIDOSIS: DESCRIPTION OF 31 CASES FROM THE FRENCH PHARMACOVIGILANCE DATABASE

M. Trenec1, B. Chemetren2, N. M. Silva3, C. Dolladilite4, J. Alexandre5, A. Dumont1, A. Nguyen1, H. De Boysson1, A. Aubad1, S. Deshayes1. 1University of Caen Normandie Hospital Center, Internal Medicine, Caen, France; 2University of Caen Normandie Hospital Center, Pharmacology, Caen, France

Background: Development of Tumor Necrosis Factor blockers (TNFBs) whose drug class has several mechanistic and pharmacologic sub-classes, have improved the management of autoimmune and inflammatory diseases, including sarcoidosis. With their increasing use, paradoxical reactions are described and one of the most frequent is sarcoidosis. However, the description of TNFb-induced sarcoidosis (TIS) remains poor, because reported in few and only short case-series.

Objectives: We aimed to better describe the clinical spectrum of TIS, and the differential involvement of TNFb sub-classes.

Methods: French pharmacovigilance database was used to collect data on TIS, excluding patients with previous idiosyncatic sarcoidosis. Statistical analyses were performed using the Mann-Whitney test for quantitative data and Fisher test for qualitative data. A p value < 0.05 was considered statistically significant.

Results: Data were obtained from 2002 to 2019 for infliximab, adalimumab, golimumab, certolizumab and etanercept. Thirty-one TIS patients were collected from the database, including 12 women (38%). In most cases, TNFb was introduced for ankylosing spondylitis (58%), psoriasis (19.3%) or rheumatoid arthritis (16.1%). Median age at TIS occurrence was 54 [43.5; 61.5] years, with a median time to onset of 24 [6.0; 72.0] months. The most frequent involved TNFb was etanercept (n=21, 67.8%). The two main clinical TIS manifestations were lymph node (n=27, 87.1%) and lung involvement (n=16, 51.6%). The culprit drug was discontinued in 26 (84%) patients, and a double-barreled inflammatory gun to control both initial and induced disorders was proposed in 19 of them (90.5 %), mostly glucocorticoids (n=13, 68.4%) alone or combined with methotrexate (n=3, 15.8%). Among the 14 patients with the available data, the TIS had completely resolved in 11 (78.6%); for all these lasts, the TNFb was discontinued. No significant differences were observed between the TNFb sub-classes of monoclonal antibodies or fusion proteins, regarding clinical presentation, median time to onset or outcome.

Conclusion: This second largest case-series shows that TIS are mostly encountered with etanercept, but without any difference in clinical or prognostic implications with the other TNFb-subclasses.

Conclusion: The majority of patients have an immune response to ADL. Based on ADA concentration, time point of emergence and its persistence, certain patterns of ADA response can be distinguished. Only high ADA concentration at early time points, causing low ADL concentration, are associated with unfavorable clinical effects. All the remaining distinctive patterns do not have any association with clinical outcomes. This suggests a regulated immune response in the majority of patients.

1.18, 95% CI 1.05-1.34) were associated with a higher risk of AE in exposed patients. Treatment survival was 15 years [IQR: 28] in unexposed group vs 4.7 years [IQR: 10] in exposed patients (p<0.0001). In the multivariate analysis, female sex (HR 1.15, 95% CI 1.05-1.26), older age (HR 1.0, 95% CI: 1.01-1.014), corticosteroid treatment (HR 1.16, 95% CI 1.09-1.2), the diagnosis of rheumatoid arthritis (HR 0.83 CI95% 0.75-0.93) was associated with a lower risk of suspension.

Conclusion: We found that the use of steroids and elderly patients are still being associated with a higher risk of presenting an AE and treatment discontinuing. This could be related to the fact that the use of steroids is frequently associated with active disease or severe conditions. Exposed patients have a lower AE-free survival and a lower treatment survival. This could be since unexposed patients have a longer follow-up time and a longer duration of their disease. This data from real-world Latin American patients of ten years of follow-up are extremely useful for monitoring and pharmacovigilance of biological therapies in patients with rheumatic diseases.

POS0661

MAJOR COST SAVINGS ASSOCIATED WITH BIOLOGIC DOSE REDUCTION IN PATIENTS WITH INFLAMMATORY ARTHRITIS

A. Behram1, S. Tariq1, J. Kumar1, L. Martin1, C. Bannon1, T. Duffy1, E. Murphy1, J. Stack1, M. Barry1, C. L. Murphy1,1 Connolly Hospital Blanchardstown, Rheumatology, Dublin, Ireland; 2 Mater Hospital, Rheumatology, Dublin, Ireland

Background: Anti-TNF drugs have dramatically improved the management of inflammatory arthritis (IA). Although the introduction of biosimilars has reduced the cost, chronic use of biologic agents has a high impact on healthcare expenditure. This study evaluated the cost effectiveness of a dose reduction strategy for the most commonly used anti-TNF drugs over a period of 10 years in patients with IA in remission.

Objectives: The purpose of this study was to explore whether patients with Inflammatory Arthritis (IA) (Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) or Ankylosing Spondylitis (AS)) would remain in remission after 10 year period, following a reduction in biologic dosing frequency and to calculate the cost savings associated with dose reduction.

Methods: This prospective, non-blinded, non-randomised study was commenced in 2010. Patients with IA, Rheumatoid arthritis (RA),ankylosing spondylitis (AS), Psoriatic arthritis (PsA) who were in remission as defined by disease activity indices (DAS28<2.6, BASDAI<4), and were offered Anti TNF dose reduction. Patients on etanercept were reduced from 50mg weekly to fortnightly, adalimumab 40mg once monthly instead of fortnightly. Patients were assessed for disease activity at 1, 4 and 10 years following reduction in dosing frequency.

Cost saving was calculated by deducting the total annual cost of the biologic agent used over 10 years compared with the cost if the dosing interval had not changed.

Results: Seventy nine patients with inflammatory arthritis in remission were recruited. 57% had rheumatoid arthritis (n=45), 13% psoriatic arthritis (n=10) and 30% ankylosing spondylitis (n=24). 57% (n=45) were taking etanercept and 43% (n=34) adalimumab. The percentage of patients who maintained dose reduction at 10 years was 9% (n=7). Of the total 48 patients who were successfully dose reduced at year 1 (n=42), (69%, n=29) were able to maintain the dose reduction up to 4 years and 9% (n=7) maintained this dose reduction up to year 10. The estimated cost saving was €4,928 per patient per year. Estimated cost savings for 7 patients on reduced dose was €344,952.88 over 10 years.

Conclusion: Anti TNF dose reduction strategy in patients with IA results in substantial cost savings. Implementation of a dose reduction strategy while monitoring of disease activity reduces the financial impact of the use of biologic therapies. Further studies should be done to identify which patients are more likely to remain in remission while on dose reduction.

BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS PRESCRIPTION OVER TIME IN A COHORT OF EARLY RHEUMATOID ARTHRITIS PATIENTS

A. L. Fedele1, F. Melpignano1, D. Bruno1, R. La Ferrara1, M. A. D’agostino1, Division of Rheumatology-Catholic University of the Sacred Heart, Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze Mediche e Chirurgiche, Rome, Italy

Background: According to 2019 updated EULAR recommendations, therapy of Early Rheumatoid Arthritis (ERA) with biological disease-modifying antirheumatic drugs (bDMARDs) is advised in presence of poor prognostic factors, persistently moderate/high disease activity, high acute phase reactants, high swollen joint count, autoantibody positivity, presence of early erosions, failure of two/more conventional synthetic DMARD.

Objectives: To evaluate over time prevalence of bDMARD therapy and factors associated to rapid initiation in our Early Arthritis Cohort (EAC), comparing two different periods: from 2004 to 2012 and from 2012 to 2020. The last two years were not considered because of the adverse influence of COVID19 pandemic on early access to EAC and on timely scheduled visits.

Methods: A total of 281 ERA patients with less than 12 months of disease duration (53.9 years mean age, 75% female, 77% seropositive), followed according to the treat-to-target (T2T) strategy, were enrolled in the study. At baseline, and every three months, the ACR/EULAR core data set variables were recorded. At baseline and every year, hand and foot radiographs were examined according to modified Total Sharp score (mTSS). At each visit, clinical improvement and remission were evaluated according to EULAR criteria. The achievement of Comprehensive Disease Control (CDC) (28-joint Disease Activity Score using C reactive protein <2.6, Health Assessment Questionnaire <0.5 and change from baseline in mTSS ≤0.5) was assessed every year.

Results: We examined 164 patients from 2004 to 2012 and 117 subjects from 2012 to 2020. In the first group 72 patients (43.9%) initiated bDMARDs during the 8-year FU, with a mean delay of 41.8 months. In the second group 37 patients (31.6%) started biotechnological drugs over time, with a mean delay of 50.4 months.

Analyzing the period from 2004 to 2012, ERA patients starting bDMARDs were younger (p=0.04), in higher percentage ACPA positive (81.1%) and reached to a lesser extent CDC at 12months of FU (26.1%) compared to patients that didn’t initiate bDMARDs (60.9% ACPA positive, p=0.01; 63% achieving CDC, p=0.001, respectively).

Examining the period from 2012 to 2020, bDMARD-treated ERA patients were younger (p=0.06), in higher percentage AC(81.1%) and erosive at baseline (35.1%) compared to patients that didn’t initiate bDMARDs (64% ACPA positive, p=0.02; 17.5% erosive, p=0.04, respectively). As previously, patients in bDMARD reached to a lesser extent CDC at 12 month of FU (35.1%) compared to subjects not undergoing to biological therapy (55% achieving CDC, p=0.05). On multivariate analysis, AC positive was associated with initiation of bDMARD in both patient groups (p=0.02), whereas older age at onset and reaching CDC at 12 month were inversely associated (p=0.001; p<0.0001, respectively).

Conclusion: Despite the widest choice of bDMARDs currently available in the last 8 years, we did not observe an increase in the prescription of these drugs from 2012 to 2020. As in other ERA cohorts, bDMARD initiation is associated to poor prognostic factors, in particular AC positivity, presence of erosions at baseline and not achieving CDC at 12 months of FU. In the last 8 years, the decreased influence of disease duration at onset and of BMI could be a consequence of the improvement in strategies of early referral and control of modifiable risk factors.

Rheumatoid arthritis - non biologic treatment and small molecules

POSO663
THE USE OF EXPOSURE-ADJUSTED EVENT RATES VERSUS EXPOSURE-ADJUSTED INCIDENCE RATES IN ADVERSE EVENT REPORTING: INSIGHTS FROM FILGOTINIB INTEGRATED SAFETY DATA IN RHEUMATOID ARTHRITIS

Background: Reporting of treatment-emergent adverse events (TEAEs) in rheumatoid arthritis (RA) clinical trials can be summarized as exposure-adjusted incidence rates (EAIRs) or exposure-adjusted event rates (EAERs). Censored EAIR (EAIRc), weighing exposure up to a patient’s first event, is commonly reported; the three methods account for different exposures and/or multiple events, which can impact the outcome evaluation. Studies of filgotinib (FIL) in RA report safety data as EAIR/100 patient-years of exposure (PYE) for TEAEs, which is uncensored.

Objectives: To describe the outcome of long-term FIL integrated safety data in RA by applying different statistical methodologies: EAER, EAIRc and EAIR. Predefined adverse events of special interest (AESI) included serious infections (any), herpes zoster (HZ), major adverse cardiac events (MACE), malignancies (excluding nonmelanoma skin cancer [NMSC]), NMSC and venous thromboembolism (VTE). The number of patients with an event, number of events, EAER, EAIRc and EAIR were summarized. The data extraction date was January 2021 for the DARWIN 3 (NCT02085700) long-term extension (LTE) and November 2020 for the FINCH 4 (NCT03203508) LTE.

Results: In total, 3691 patients received ≥1 FIL dose for 8085 PYE. In this population, 176 serious infections were reported in 137 patients, 125 HZ events were randomised, blinded, to FIL200 + MTX, FIL100 + MTX, FIL200 alone, or FIL100 alone. At W24, the mTSS CFB in pts with BL yearly progression ≥5 or <5 was 0.84 and 0.22 in MTX-IR pts taking PBO + MTX, and 0.67 and 0.25 in MTX-naive pts taking PBO + MTX. At W52, the mTSS CFB in pts with BL yearly progression ≥5 or <5 was 0.67 and 0.22 in MTX-naive pts taking PBO + MTX. At W24, the mTSS CFB in pts with BL yearly progression ≥5 or <5 was 0.67 and 0.25 in MTX-naive pts taking PBO + MTX.

Data are rate (95% CI) unless otherwise stated.

Conclusion: These data confirm that using different methods to analyze FIL safety data (EAER, EAIRc, EAIR) does not result in different safety outcomes, reinforcing the previously reported FIL safety profile in patients with RA. As the AESI reported in the long-term safety database with FIL are rare, patients commonly have long exposure times before experiencing an event, which are often associated with end of treatment. As such, EAIRc, EAIR and EAIR are similar.

RADIOGRAPHIC CHANGE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ESTIMATED BASELINE YEARLY PROGRESSION ≥5 OR <5: POST HOC ANALYSIS OF TWO PHASE 3 TRIALS OF FILGOTINIB

Y. Tanaka1, T. Atsumi2, D. Aletaha3; R. B. M. Landewe4, B. Bartok5, A. Pechonkina6, Z. Yiri7, L. Han8, K. Emoto9, S. Kando10, V. Rajendran11, T. Takeuchi12. University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan; 2Hokkaido University, Department of Rheumatology, Endocrinology and Nephrology, Hokkaido, Japan; 3Medical University of Vienna, Division of Rheumatology, Department of Medicine, Wien, Austria; 4Amsterdam Rheumatology & Clinical Immunology Center (amC) & Zuyderland MC, Clinical Immunology and Rheumatology, Heerlen, Netherlands; 5Galapagos NV, Biostatistics, Foster City, United States of America; 6Gilead Sciences, Inc., Department of Clinical Research, Foster City, United States of America; 7Gilead Sciences, Inc., Biostatistics, Foster City, United States of America; 8Gilead Sciences K.K., Medical Affairs, Tokyo, Japan; 9Galapagos BV Inflammatory Diseases, Mechelen, Belgium; 10Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan.

Background: In some patients (pts) with rheumatoid arthritis (RA), especially those with joint damage early in the disease, first-line methotrexate (MTX) treatment may not suffice to prevent further rapid radiographic progression (RRP). In FINCH 1 (NCT02886728), filgotinib 200mg (FIL200) vs MTX (FIL100) reduced change in total Sharp score (mTSS) vs placebo (PBO) in pts with RA and inadequate response to MTX (MTX-IR).2 In FINCH 3 (NCT02886728), FIL200 and FIL100 reduced change in mTSS vs MTX monotherapy (MTX mono) in MTX-naive pts.3

Objectives: To evaluate, via post hoc analysis of 2 trials, filgotinib’s effects on radiographic progression vs MTX mono in pts with estimated baseline (BL) yearly progression ≥5 or <5 mTSS units/year.

Methods: The double-blind 52-week (W) FINCH 1 study randomised MTX-IR pts with moderate–severe active RA to FIL200 or FIL100, subcutaneous adalimumab (ADA) 40 mg, or PBO; at W24, PBO pts were randomised blinded to FIL200 vs FIL100; all took stable background MTX1. In FINCH 3, MTX-naive pts were randomised blinded, to Fil200 + MTX, FIL100 + MTX, FIL200 alone, or MTX mono for up to W52.2 This analysis examined subgroups by estimated BL yearly progression (BL mTSS/duration in years of RA diagnosis), based on ≥5 or <5 mTSS units/year,4 a threshold commonly used to define RRP. We assessed effects of filgotinib vs ADA or PBO in mTSS change from BL (CFB) at W24/W52 (using a mixed model for repeatable measurements) and percentages with no W24 progression (mTSS change ≥0.5, ≥0.5, ≤smallest detectable change [SDC], using Fisher’s exact test).

Results: At BL, 558/1755 MTX-IR and 787/1249 MTX-naive pts had BL estimated yearly progression ≥5. Median mTSS in pts with BL yearly progression ≥5 and <5 was 53.25 vs 5.00 respectively in the MTX-IR trial and 6.00 vs 2.50 in the MTX-naive trial. At W24, the mTSS CFB in pts with BL yearly progression ≥5 and <5 was 0.84 and 0.22 in MTX-IR pts taking PBO + MTX, and 0.67 and 0.25 in MTX-naive pts taking PBO. At W52, in pts with BL yearly progression ≥5, FIL200 + MTX reduced mTSS change vs PBO + MTX in the MTX-IR trial and vs MTX mono in the MTX-naive trial (Figure 1). At W24, among pts with estimated BL yearly progression ≥5, FIL200 + MTX increased odds of no

MTX-IR ORs are FIL vs PBO + MTX; MTX-naïve are FIL vs MTX. *Nominal P<.05. †Not applicable. ADMI, adalimumab; FIL, filgotinib; IR, inadequate response; mTSS, modified total Sharp score; MTX, methotrexate; OR, odds ratio; SDC, smallest detectable change; W, week.

Conclusion: These data suggest filgotinib’s inhibition of radiographic progression is numerically greater than MTX monotherapy in RA pts with high estimated BL yearly progression. In those with a more moderate estimated rate of progression, filgotinib suppressed progression comparably to ADA and/or MTX.

POS0665 DEVELOPMENT OF A BIOCHEMICAL TOFACITINIB ADHERENCE ASSAY IN RHEUMATOID ARTHRITIS: THE ORAL ADHERE STUDY

S. Church1, K. Hyrich2, K. Ogungbenro2, R. Unwin1, A. Barton3, J. Buith3,5

Background: Tofacitinib is a potent inhibitor of the JAK1/JAK3 tyrosine kinases effective in the treatment of rheumatoid arthritis (RA). Unlike biologic DMARDs, tofacitinib is administered orally. Oral administration offers a major benefit to patients, removing the risk of injection site reactions and previous research has shown that patients prefer an oral DMARD which may affect patient’s adherence (1). Non-adherence is a health behaviour that results in reduced response and increased healthcare costs but can be challenging to accurately measure. Direct tofacitinib measurement may be an accurate measure of adherence that could, in the future, be used in a clinical setting as part of a behaviour change intervention. Tofacitinib can be measured using High Performance Liquid Chromatography Selected Reaction Monitoring Mass Spectrometry (HPLC-SRM-MS). Previous tofacitinib studies have demonstrated an assay sensitivity of 0.1ng/ml may be sufficient for the detection of adherence following 5mg twice daily administration (2). Objectives: The aim of this study is to develop a HPLC-SRM-MS assay to measure biochemical tofacitinib adherence in patients with RA.

Methods: Human serum for method development was obtained from volunteers recruited to the collection of blood and urine samples from volunteers for the development of analytical methods study (UREC 12346) and the National Repository Study (REC 99/8/84) following informed consent. Samples were spiked with Tofacitinib/Tofacitinib-d3 and subjected to protein precipitation. LC-MS/MS analysis was performed on a TSQ Vantage triple quadrupole mass spectrometer coupled with an Acquity UHPLC system (Thermo Fisher Scientific, USA). Validation of the assay was tested as adapted from European Medicines Agency guidelines on Bioanalytical Validation. Specifically, the lower limit of quantification (LLOQ), carryover, accuracy, linearity, precision, recovery and stability of the assay was determined.

To investigate the ability of the assay to detect adherence, serum samples (n=10) of patients prescribed tofacitinib from the Biologics in Rheumatoid Arthritis (BRAAGS) were analysed (REC reference: 04/Q1403/37). Participants self-reported date and time of tofacitinib ingestion prior to venepuncture. Samples were analysed in triplicate.
Results: The assay demonstrated a tofacitinib LLOQ of 0.1 ng/ml, carryover of sample following injection of a 1000 ng/ml tofacitinib was <1%, linearity of r²=0.998, within run accuracy was between 81-85% at LLOQ and between 91-107% at all other levels. Between run accuracy was within 14.9% at LLOQ and within 0.2-5.5% of the nominal concentration at all other levels. Samples of tofacitinib spiked in whole blood and left at room temperature for seven days were within 0.98-10.25% of serum samples spiked on the day of analysis for all concentrations. To demonstrate the potential of the assay to determine adherence, all 10 BRAGGSS samples revealed tofacitinib levels above 0.1 ng/ml with CV<15% (Table 1).

Conclusion: A novel tofacitinib LC-MS/MS assay has been developed. The ability of the assay to measure biochemical adherence has been explored. Further research to establish the sensitivity of the assay and the ability of the assay to detect non-adherence are required.

Baricitinib (BARI), an oral selective JAK 1/2 inhibitor, is approved in the EU (cohort A), or any bDMARD or tsDMARD (b/tsDMARDs; cohort B). Treatment initiation and changes are at the discretion of the patient or physician. Response rates for remission, low disease activity (LDA), moderate disease activity (MDA) or high disease activity (HDA) were determined using the Clinical Disease Activity Index (CDAI) at 12M. Quality of life using the EQ-5D-5L and patient reported outcome (PRO) measures for pain (pain visual analogue scale; VAS) and physical functioning (Health Assessment Questionnaire Disability Index; HAQ-DI) were also assessed at 12M. This pre-specified interim analysis reports descriptive 12M data using summary statistics, without any inferential testing.

Results: This analysis involved 1073 adult RA patients with a mean age (standard deviation; SD) of 59.1 (13.2) (cohort A) and 57.0 (13.9) yrs (cohort B), respectively, and a mean disease duration (SD) of 10.0 (9.1) (cohort A) and 8.9 (9.6) yrs (cohort B), respectively. At baseline, 50.9% of patients in cohort A and 31.2% in cohort B initiated treatment as a monotherapy. At 12M, 26.7% of patients in cohort A and 44.1% of patients in cohort B had discontinued treatment. The most common reason for discontinuation in both cohorts was primary non-response. At 12M, 24.1% of patients in cohort A and 16.6% in cohort B achieved CDAI remission (Figure 1). The mean CDAI reduction was -14.5 and -12.0, respectively in cohorts A and B. Mean reductions from baseline in physician global assessment (PhGA) and in patient global assessment (PGA) were -3.4 and -2.5, respectively in cohort A and -3.0 and -2.1, respectively in cohort B. Improvements from baseline in clinical disease activity index from baseline in cohort A and cohort B were -14.5 and -12.0, respectively in cohorts A and B. Mean CDAI remission at 12M was achieved by 24.1% of patients in cohort A and 16.6% in cohort B.

Figure 1. Percentage of pts in cohorts A and B achieving remission and LDA at 12M.

Conclusion: The majority of BARI-treated patients were in remission or had low disease activity and continued treatment at 12M.

**Conclusion:** We found that over half of patients qualified as MTX non-responders at approximately 6 months. Significant predictors of non-response were younger age, female gender, higher CDAI score and BMI. Maximizing improvement as quickly as possible and deploying more tailored escalation of care may be aided by identifying RA patients at higher risk of early MTX treatment failure.

**Conclusion:** The data obtained indicate the efficacy of tocilizumab in patients with RA, including decreasing of disease activity and concentrations of clue pro-inflammatory cytokines. Further studies are needed to investigate pathogenic role of cytokine-mediated inflammation in RA and the efficacy of targeted oral medications on the course of the disease.

**Objectives:** The OM1 RA Registry (OM1, Inc; Boston, MA) follows more than 210,000 RA patients in the US. The registry utilizes longitudinal electronic medical records from over 400,000 administrative claims starting from 2013. In this retrospective observational study, patients aged ≥18 years initiating MTX between 01 January 2014 and 01 August 2020 without previous bDMARD/tsDMARD utilization were identified. The first MTX date was the index date, with ≥1 Clinical Disease Activity Index (CDAI) measurement and ≥2 all-cause healthcare encounters required in the preceding 12 months (baseline). Patients initiating a bDMARD/tsDMARD within 30 days of the index date or with a history of other conditions where the same bDMARD/tsDMARDs are indicated were excluded. MTX non-response was defined as failing to attain remission or low disease activity (i.e., CDAI >10) within 4 to 8 months and/or the initiation of a bDMARD/tsDMARD within 8 months following the index date (with or without continuing MTX; non-response could include patients discontinuing MTX due to tolerability). Baseline characteristics were summarized with descriptive statistics. Multivariable logistic regression with age, gender, region, race, payor, year of index, the most recent CDAI and body mass index (BMI) measurements from the baseline, and Charlson comorbidity index (CCI) was used to investigate risk factors of non-response. P value was considered significant if <0.05.

**Results:** Among 6,648 eligible RA patients, 3,748 (56.4%) were classified as non-responders. Baseline characteristics are summarized in Table 1. Being female (OR=1.3), increasing baseline CDAI (OR: Low activity=1.9, moderate activity=8.1, high activity=23.9) and higher BMI (OR=1.01) were significantly associated with non-response.

**Conclusion:** We found that over half of patients qualified as MTX non-responders at approximately 6 months. Significant predictors of non-response were younger age, female gender, higher CDAI score and BMI. Maximizing improvement as quickly as possible and deploying more tailored escalation of care may be aided by identifying RA patients at higher risk of early MTX treatment failure.

**REFERENCES:**
Background: Thanks to improved treatment strategies, disease remission in rheumatoid arthritis (RA) patients has become more common. Therefore, current guidelines recommend to consider tapering DMARDs, including methotrexate (MTX), in patients who are in sustained remission. Previous research has shown that subcutaneous methotrexate (MTXsc) has a better bioavailability, efficacy and tolerability in active RA than oral MTX[1]. However, these advantages might be a disadvantage when tapering of MTXsc is considered.

Objectives: To compare the 1-year cumulative flare rates between established RA patients who taper subcutaneous and oral MTX.

Methods: Data from the Tapering strategies in Rheumatoid Arthritis (TARA) trial were used[2]. In this trial, established RA patients with a well-controlled disease, defined as Disease Activity Score (DAS)≤2.4 and swollen joint count (SJC)≤1, using ≥1 csDMARD and TNF-inhibitor (TNFi) were included. Participants were randomized into two groups which gradually tapered their csDMARD first followed by the TNFi, or vice versa. The csDMARD was tapered by reducing the dosage by a half at baseline, by a quarter at 3 months and was stopped at 6 months. Patients who tapered MTX were included in this analysis. If a disease flare (DAS>2.4 or SJC>1) occurred, the last effective therapy was restarted and intensified every 3 months, until DAS≤2.4 and SJC≤1. Following an intention-to-treat principle, flare rates were compared between patients who tapered subcutaneous and oral MTX, using a chi-square test. Two sensitivity analyses were performed where we 1) only included patients with a complete follow-up; and 2) assumed that patients developed a flare at the moment of drop-out.

Results: A total of 71 and 17 patients respectively used oral and subcutaneous MTX. The median disease duration was 5.9 years and 70% was female. The median MTX dosage for both administration routes was 20 milligrams per week. After 12 months, 53% of patients who tapered MTXsc developed a flare compared to 27% who tapered oral MTX (OR 3.1(10.91, 95%CI), p=0.037) (Figure 1). Respectively 68% and 67% of the patients who developed a flare and were using oral and subcutaneous MTX had a well-controlled disease 3 months after restarting their treatment (p=0.93). Both sensitivity analyses showed similar results.

Conclusion: Patients who tapered MTXsc have a higher chance at developing a disease flare compared to those who tapered oral MTX. This could be explained by a higher efficacy of MTXsc when similar dosages are used[1]. Alternatively, the better tolerability of MTXsc, especially regarding gastrointestinal side effects[1], may lead to a difference in adherence. When deciding to taper MTX, the administration route should be taken into account. Because of the increased risk of flare after tapering MTXsc, these patients could be monitored more closely than those tapering oral MTX.

Disclosure of Interests: None declared
Objectives: To evaluate impact of self-reported race on tofacitinib efficacy/safety in RA pts.

Methods: This post hoc analysis used pooled data from 8 Phase (P)2, 6 P3 and 1 P3b/4 randomised controlled trials (RCTs) of RA pts treated with tofacitinib 5 or 10 mg twice daily (BID), adalimumab (ADA; 40 mg once weekly), and placebo (PBO). Tofacitinib was stratified by self-reported pt race (White, Black, Asian, Other) at baseline (BL). Efficacy outcomes (Month (M)3: ∆DAS28-4(ESR) and ∆HAQ-DI) and safety outcomes (incidence rates (IRs) of adverse events (AEs) and serious AEs (SAEs)) were compared across the four racial groups (White/Black vs Asian/Other). A statistical model was used to compare IRs, adjusted for race, demographic and clinical factors, and regional efficacy or safety differences. To determine whether differences in safety or efficacy were driven by racial differences, a region-specific exploratory analysis was performed.

Results: A total of 6355 pts were included (White, n=4145; Black, n=213; Asian, n=1348; Other, n=649). White/Black and Asian/Other pts were more commonly enrolled from Europe (40.9%) and North America (68.1%), respectively. Across treatments, White, Black, Asian and Other pts most commonly enrolled from Europe (40.9%) and North America (68.1%), respectively. Most Other pts self-reported as Hispanic and/or Latino (52.4%), followed by mixed race (36.8%) and unspecified (5.2%). At M3, ACR50 rates were higher in Other vs White pts with tofacitinib, similar across racial groups with ADA, and numerically higher in Black vs White/Asian/Other pts with PBO (Figure 1); similarly, trends were seen with ACR20/70 and CDAI LDA rates (data not shown [DNS]). Across treatments (Figure 1; DNS), safety outcomes were broadly similar across treatment arms, with some higher IRs for AEs observed with Black/Other vs White/Asian pts (Table 1). Results should be interpreted with caution due to low pt numbers in some groups and the heterogenous nature of the Other pts group.

Conclusion: Across racial groups, tofacitinib efficacy/safety was consistent with previous tofacitinib RA clinical programme findings. Some racial differences in clinical outcomes were observed, which may reflect regional practice norms or demographic differences. Future analyses should focus on the impact of socio-economic, cultural, genetic or practice-based differences that may underpin these results.

Branebrutinib (BMS-986195) is a highly potent and selective irreversible small-molecule covalent inhibitor of Bruton’s tyrosine kinase (BTK), a non-receptor tyrosine kinase involved in the pathophysiology of immune-mediated diseases. Branebrutinib has the potential to be best in its class, as it achieves ~100% BTK occupancy in humans, sustained over a 24-hour dosing interval at low doses (≤ 10 mg once daily [QD]) despite its short half-life (≤ 2 hours), and demonstrates potent efficacy in murine models of immune-mediated diseases. 1 Branebrutinib is under clinical study in multiple autoimmune inflammatory disorders such as RA, systemic lupus erythematosus, primary Sjögren’s syndrome, and atopic dermatitis. In vitro drug-drug interaction (DDI) studies with branebrutinib predicted pharmacokinetic DDI potential with substrates of cytochrome P450 (CYP) and diphosphate glucuronosyltransferase.

**Methods:** Branebrutinib predicted pharmacokinetic DDI potential with substrates of cytochrome P450 (CYP) and diphosphate glucuronosyltransferase.

**Objectives:** To assess the DDI potential of branebrutinib when co-administered with potential concomitant medications and probe substrates of major drug-metabolizing enzymes (DMEs) and drug transporters.

**Methods:** DDI risk with branebrutinib was assessed in 3 single-sequence, cross-over clinical studies in healthy participants. In the first 2-part study, MTX was administered alone or with steady-state (SS) branebrutinib (9mg QD) in part 1; in part 2, caffeine, montelukast, flurbiprofen, omeprazole, midazolam, digoxin, and pravastatin were taken with or without SS branebrutinib (9mg QD). In the second study, rosuvastatin was taken alone or with SS branebrutinib (9mg QD). In cycle 1 of the third study, the oral contraceptive (OC) loestrin (1.5 mg norethindrone/30 μg ethinyl estradiol) was taken with or without SS branebrutinib (9mg QD). In the second study, rosuvastatin was taken alone or with SS branebrutinib (9mg QD). In cycle 1 of the third study, the oral contraceptive (OC) loestrin (15mg norethindrone/30 μg ethinyl estradiol) was taken alone; in cycle 2, SS branebrutinib (9mg QD) was taken alone or with the OC.

**Results:** Weak DDI with montelukast (CYP2C8) was observed, leading to a mild increase in montelukast exposure (max concentration [Cmax] 56%; area under the curve [AUC] 27%). A mild increase in digoxin exposure (P-glycoprotein [P-gp] substrates; Cmax 57%; AUC, 21%) was also observed. There was no potential DDI with MTX (Table 1). No other clinically relevant DDIs with branebrutinib were observed. No serious AEs or other significant AEs occurred during these studies. All AEs were mild to moderate in intensity.

Background: ORAL Surveillance (NCT02092467) was a post-approval safety study of tofacitinib vs TNF inhibitors (TNFi) in rheumatoid arthritis (RA) patients (pts) aged ≥50 yrs with ≥1 additional cardiovascular (CV) risk factor and an inadequate response to methotrexate (MTX).

Objectives: To identify independent risk factors for major adverse CV events (MACE) in ORAL Surveillance.

Methods: Pts on stable MTX were randomised 1:1:1 to receive tofacitinib 5 or 10mg twice daily (BID) or a TNFi (adalimumab 40mg every 2 weeks or etanercept 50mg once weekly). Incidence rates (IRs; pts with first events/100 pt-yrs) and hazard ratios (HRs; tofacitinib vs TNFi) were assessed for adjudicated MACE (total/fatal/non-fatal), sudden cardiac death, and total/fatal/non-fatal myocardial infarction (MI) and stroke. Post hoc univariate Cox model analyses identified potentially independent baseline (BL) risk factors for MACE across treatments; those with p<0.10 were entered into a multivariate Cox model using backward selection (p<0.10 stay criteria). MACE HRs were produced for subgroups for BL risk factors with p<0.05 in the final multivariate Cox model.

Results: 4362 pts were included (tofacitinib 5 mg BID, n=1455; tofacitinib 10 mg BID, n=1456; TNFi, n=1451). IRs for total/fatal/non-fatal MACE, sudden cardiac death, and total/fatal MI were higher with tofacitinib vs TNFi (Table 1). Fatal MI and stroke (including fatal/non-fatal events) IRs were similar across treatments (Table 1). Total MACE and MI IRs and risk were higher with tofacitinib vs TNFi (HRs >1) and higher for non-fatal MI for tofacitinib 5 mg BID (Table 1). Current smoking, aspirin use, history of chronic lung disease, history of diabetes, male sex and older age were BL risk factors for MACE. While MACE risk was generally higher with tofacitinib vs TNFi across all BL risk factors, increased risk was clearest in current/past smokers (vs never smoked) and aspirin users (vs non-users) (Figure 1). When and smoking status were considered in combination, pts aged ≥65 yrs or who had ever smoked had a particularly elevated MACE risk vs never smokers aged ≥50–65 yrs (Figure 1).

*HR 95% CI excludes 1. Data collected after pts who were randomised to tofacitinib 10 mg BID had their dose reduced to 5 mg. BID were included in the tofacitinib 10 mg BID group. HRs (95% CI) were not informative when one of the treatments in the comparison had 0 events. Risk period was defined as time from first dose to last dose ±60 days or to the last contact date, whichever was earlier. CI, confidence interval; NI, non-informative.
Conclusion: MACE IFRs and risk were higher with tofacitinib vs TNFi in ORAL Surveillance. BL risk factor findings could aid identification of RA pts with potentially highest risk for MACE, with a view to informing treatment decisions.

POS0675 IMPACT OF PAST USE OF DISEASE MODIFYING ANTI-RHEUMATIC DRUGS ON JAK INHIBITOR TREATMENT FOR RHEUMATOID ARTHRITIS - DATA FROM THE FUKUI ISHIKAWA TOYAMA DATABASE OF RHEUMATOID ARTHRITIS

M. Konishi, I. Mizushima, M. Kawano, T. Murayama, S. Nakazaki, K. Shinoda, T. Kido, Y. Katsuki, H. Fujinaga, T. Watanabe, H. Motomura, I. Matsushita, Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan; 11 Charité University Hospital, Department of Rheumatology, Berlin, Germany; 9 Galapagos NV, Biostatistics, Mechelen, Belgium; 10 Gedeon Richter, Novartis, Pfizer Inc and Roche, Employee of: Pfizer Ltd, Employee of: Pfizer Inc, Consultant of: Pfizer Inc, Employee of: Pfizer Inc, Carol A. Connell Shareholder of: Pfizer Inc, Employee of: Pfizer Inc, Zoltán Székeczek Speakers bureau: AbbVie, Eli Lilly, Novartis, Pfizer Inc and Roche, Consultant of: AbbVie, Eli Lilly, Gedeon Richter, Novartis, Pfizer Inc and Roche, Consultant of: AbbVie, Eli Lilly, Novartis, Pfizer Inc, Roche and Sanofi.

Background: Currently, five types of Janus kinase inhibitors (JAKis) are used for rheumatoid arthritis (RA) treatment. The number of cases in which multiple JAKis have been prescribed is increasing. However, the real-world efficacy and safety of JAKis and related factors require further evaluation.

Objectives: The primary objective of this study was to elucidate the impact of past use of disease-modifying anti-rheumatic drugs (DMARDs) on RA treatment using JAKis. The secondary objective was to investigate the safety profiles of these agents in a real-world setting.

Methods: Of the 303 JAKi-treated patients in the Fukui Ishikawa Toyama Database of RA included in this study, 30 had switched from one JAKi to another (JJ group), 214 switched from a biologic agent to a JAKi (BJ group), and 47 were switched from other or JAKi therapy to a JAKi therapy. The investigators evaluated baseline factors, treatment response, and JAKi continuation rates among the three groups. Factors related to JAKi discontinuation were assessed using Cox regression analysis. Furthermore, we investigated adverse events and reported them using exposure-adjusted incidence rates (EAR; incidence rates per 100 patient-years).

Results: Data from the 303 cases were analyzed (mean age = 63.6 years; female: 82.5%; mean RA duration, 176 months). Of the 303 patients, 118, 106, 50, and 29 were treated with tofacitinib, baricitinib, peficitinib, and upadacitinib, respectively, on initial observation. Rate of concomitant use with methotrexate and prednisolone was 52% and 49%, respectively.

Conclusion: JAKi discontinuation in Japan is influenced by factors including past use of DMARDs, disease severity, and adverse events. While JAKi was effective in patients with RA aged ≥75 y, treatment response was lower in patients with a past history of JAKi use.

Disclosure of Interests: I have no disclosures to declare.

POS0676 EFFICACY AND SAFETY OF FILGOTINIB IN PATIENTS AGED ≥75 YEARS: A POST HOC SUBGROUP ANALYSIS OF THE FINCH 4 LONG-TERM EXTENSION (LTE) STUDY

D. Aletha, R. Westhoven, B. Combe, E. J. Gottenberg, M. H. Buch, C. Caporali, J. A. Gómez-Puerta, P. Van Hoek, V. Rajendran, P. J. Stiers, T. Hendrikx, G. R. Burmester, T. Yanaka, M. University of Vienna, Department of Medicine III (Division of Rheumatology), Vienna, Austria; 2 University Hospitals Leuven, Department of Rheumatology, Leuven, Belgium; 3 Montpellier University, Department of Rheumatology, Montpellier, France; 4 Strasbourg University Hospital, Department of Rheumatology, Strasbourg, France; 5 The University of Manchester, Centre for Musculoskeletal Research, Division of Musculoskeletal & Dermatological Sciences, Faculty of Medicine & Health, Manchester, United Kingdom; 6 The University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 7 Hospital Clinic of Barcelona, Department of Rheumatology, Barcelona, Spain; 8 Galapagos NV Clinical Development, Brussels, Belgium; 9 Galapagos NV, Vienna, Austria; 10 Charité University Hospital, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 11 University of Occupational and Environmental Health, Internal Medicine, Kitakyushu, Japan.

Background: Filgotinib (FIL) is a Janus kinase 1 preferential inhibitor for the treatment of moderate to severe rheumatoid arthritis (RA)1. The recommended dose for adults with RA is 200 mg (FIL200); however, a starting dose of 100 mg (FIL100) is recommended for those aged ≥75 years (y) in view of limited clinical experience1. An important consideration is the generally higher incidence of adverse events (AEs) in the elderly due to comorbidities.

Objectives: To evaluate the efficacy and safety of FIL100 and FIL200 in patients with RA aged ≥75 y.

Methods: FINCH 4 (NCT03025308) is an ongoing phase 3 open-label LTE study of FIL100 and FIL200 for RA. Eligible patients completed a prior phase 5 randomized, double-blind, study of FIL lasting 52 weeks (FINCH 1 or 2) or 24 weeks (FINCH 2). In this post hoc analysis, safety and efficacy were assessed in patients aged ≥75 and ≥75 y in FINCH 4. Efficacy measures were American College of Rheumatology (ACR)/20/50/70 responses, clinical disease activity index (CDAI) ≤10/≤2.8, disease activity score (DAS) ≤28 <2.6/≤3.2 and health assessment questionnaire-disability index (HAQ-DI).

Results: At LTE Week 48, 52% and 44% of patients aged ≥75 and ≥75 y, respectively, were on methotrexate. Baseline age group response rates for key efficacy measures at LTE Week 48 were generally maintained from LTE baseline (Figure 1) in patients with and without prior FIL exposure in FINCH 1–3, and were numerically higher with FIL200 vs FIL100. Mean change from baseline in mean DAS28-CRP: 1.48 ± 0.26 vs. 1.89 ± 0.62.

Conclusions: Past use of JAKis may contribute to decreased response and continuation rates for JAKi treatment. In this study, conducted in Japan, development of herpes zoster was found to be the most frequent adverse event among the priority survey items.

Acknowledgements: I have no disclosures to declare.

Disclosure of Interests: None declared.

Scientific Abstracts

612

Scientific Abstracts
HAQ-DI with FIL200 and FIL100 was 0.61 and 0.74 in those aged <75 y and 1.04 and 0.98 in those aged ≥75 y, respectively.

POS0677

CONSISTENCY IN TIME TO RESPONSE WITH UPADACITINIB AS MONOTHERAPY OR COMBINATION THERAPY AND ACROSS PATIENT POPULATIONS WITH RHEUMATOID ARTHRITIS

A. Rubbert-Roth1, B. Combe2, Z. Stojkovic2, S. Half1, B. Harasou1, S. Attar1, A. K. H. Ekkelenkamp1, Y. Song1, T. Shaw2, O. Nagy1, R. Xavier1, 1Cambridgeside St. Gallen, Rheumatology, St. Gallen, Switzerland; 2Montpellier University, Rheumatology, Montpellier, France; 3University of Debrecen, Rheumatology, Debrecen, Hungary; 4Monash University, Rheumatology, Melbourne, Australia; 5Institut de Rhumatologie de Montréal, Rheumatology, Montreal, Canada; 6King Abdulaziz University, Rheumatology, Jeddah, Saudi Arabia; 7University of Gothenburg, Rheumatology, Gothenburg, Sweden; 8AbbVie Inc., Immunology, North Chicago, United States of America; 9AbbVie Ltd., Immunology, Maidenhead, United Kingdom; 10Universidade Federal do Rio Grande do Sul, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

Background: Upadacitinib (UPA) has demonstrated efficacy in patients with moderate-to-severe rheumatoid arthritis (RA) across various patient populations.1-4

Objectives: This post hoc analysis aimed to evaluate the consistency in time to achieving meaningful clinical response with UPA 15 mg + conventional synthetic (cs) DMARDs in biologic (b) DMARD-inadequate responder (IR) versus csDMARD-IR patients with RA as well as with UPA 15 mg monotherapy versus UPA 15 mg + csDMARDs in csDMARD-IR patients.

Methods: Patients originally randomized to UPA 15 mg once daily from four Phase 3 trials were included in this analysis: SELECT-BEYOND1 and SELECT-CHOICE2 (UPA 15 mg + csDMARDs in bDMARD-IR patients), SELECT-NEXT3 (UPA 15 mg + csDMARDs in csDMARD-IR patients), and SELECT-MONOTHERAPY4 (UPA 15 mg monotherapy in methotrexate-IR patients). Time to response was estimated using the Kaplan-Meier method for clinical outcomes over 24 weeks (26 weeks in SELECT-MONOTHERAPY). Clinical outcomes included achievement of 28-joint Disease Activity Score with C-reactive protein (DAS28[CRP]) ≤3.2; low disease activity (LDA) defined as Clinical Disease Activity Index (CDAI) ≤10 and Simple Disease Activity Index (SDAI) ≤11; and 50% improvement in American College of Rheumatology (ACR) core components and morning stiffness (MS) duration/severity. Data presented were as observed.

Results: Overall, 905 patients were included (SELECT-BEYOND: n=164; SELECT-CHOICE: n=303; SELECT-NEXT: n=221; SELECT-MONOTHERAPY: n=217). csDMARD-IR patients had a mean disease duration of 7.3 (SELECT- NEXT) or 7.5 years (SELECT-MONOTHERAPY); bDMARD-IR patients had a mean disease duration of 12.4 years, with a more refractory population (≥3 prior bDMARDs) in SELECT-BEYOND (23%) than SELECT-CHOICE (13%). In general, the median time to DAS28[CRP] ≤3.2, CDAI LDA, 50% improvement in ACR core components, and 50% improvement in MS duration/severity were consistent across the studies in bDMARD-IR and csDMARD-IR patients. For SELECT-BEYOND, SELECT-CHOICE, SELECT-NEXT, and SELECT-MONOTHERAPY, the median (95% CI) time to achieve DAS28[CRP] ≤3.2 was 12 (12, 16), 12 (8, 16), 12 (8, 16), 12 (8, 16), and 14 (8, 14) weeks, respectively (Figure 1), and the median time to achieve SDAI LDA was observed with UPA monotherapy [20 (14, 20) weeks] versus UPA + csDMARDs [12 (12, 16) weeks] in csDMARD-IR patients. Among bDMARD-IR patients, the median (95% CI) time to 50% improvement in pain was longer in SELECT-BEYOND versus SELECT-CHOICE 16 (12, 20) versus 8 (8, 12) weeks).

Conclusion: In diverse patient populations with RA, patients treated with UPA 15 mg, as monotherapy or with csDMARDs, generally demonstrated consistent
time to achieving DAS28(CRP) ≤3.2, CDAI LDA, and 50% improvement in clinical outcomes.

Background: The preferential Janus kinase-1 inhibitor FIL is approved for treatment of moderate to severe active RA in Europe and Japan.

Objectives: In this post hoc, exploratory analysis, efficacy and safety of long-term treatment with FIL (± MTX) were assessed in MTX-naïve pts treated with FIL or MTX in the Phase 3 PS (NCT02886728).

Methods: Pts received FIL 200 mg (FIL200)+MTX, FIL 100 mg (FIL100)+MTX, FIL200 alone, or MTX alone up to 52W in PS. Those completing PS on study drug could enter LTE (NCT03023508; data cutoff: June 1, 2020). LTE completers were rerandomized, blinded, to FIL200 or FIL100; pts on FIL in PS remained on the same dose in LTE. MTX was washed out for 4W at LTE baseline (BL); pts could (re)start MTX and/or other conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) ≥4W after LTE first dosing. Efficacy data to LTE W48 and safety data are reported.

Figure 1: Conclusion: Overall, response rates improved from LTE BL to W48 for pts switched from PS MTX to FIL and decreased modestly for PS FIL pts. Rates of AEs of special interest were generally low and tended to be higher in pts maintained on FIL from PS. Safety findings in this subpopulation were comparable with the PS through W52 and with a 7-trial integrated safety analysis. Limitations: the LTE was not formally randomized at BL, the groups were of unequal size, and the switch from MTX to FIL for LTE was by design rather than based on disease activity.

Disclosure of Interests: Daniel Aletaha Speakers bureau: AbbVie, Amgen, Bristol Myers Squibb, Celgene, Eli Lilly, Medac, Merck, Merck & Dohme, Novartis, Pfizer, Roche, Sandoz, Sanofi/Genzyme, and UCB; Consultant of: AbbVie, Amgen, Celgene, Eli Lilly, Janssen, Medac, Merck, Novartis, Pfizer, Roche, Sandoz, and Sanofi/Genzyme.

Background: The preferential Janus kinase-1 inhibitor FIL is approved for treatment of moderate to severe active RA in Europe and Japan.

Objectives: Efficacy and safety of FIL were assessed in pts with IR to MTX who completed a Phase 3 trial (NCT02889796) and enrolled in an LTE (NCT03025308).

Methods: Pts completing the PS1 on study drug were eligible to enter the LTE (data cutoff: June 1, 2020). Median exposure: 2.2 years (y). Efficacy data to W48 are reported for 4 treatment groups (all with background MTX): pts receiving FIL 200 mg (FIL200) or FIL 100 mg (FIL100) in the PS and continuing their dose in LTE (FIL200/FIL200, FIL100/FIL100) and ADA pts randomized, double blind, to FIL200 or FIL100 for LTE (ADA/FIL200, ADA/FIL100); safety data are reported.

Results: As of June 1, 2020, 522/571 (91%) FIL200/FIL200, 502/570 (88%) FIL100/FIL100, 118/128 (92%) ADA/FIL200, and 115/130 (89%) ADA/FIL100 pts remained on study drug. LTE baseline disease characteristics were similar between groups: mean duration of RA approximately 8.7 y; DAS28(CRP) 2.55, and mean concurrent MTX dosage was 13.5 mg/week. Proportions of pts achieving ACR20/50/70, DAS28(CRP) <3.2, <2.6, and CDAI ≤10, ≤2.8 were generally maintained in all LTE groups through W48 (Figure 1).

Numerically greater proportions of pts met response criteria at W48 in the FIL200 groups vs FIL100, regardless of PS treatment. Treatment-emergent AEs (TEAEs), serious AEs, and AEs Grade 3 were largely comparable between groups and lowest in ADA/FIL100. There were 10 deaths (5 from each). Exposure-adjusted AEs rates (EAIRs)/10 pt-y of exposure for deaths were lower for FIL/FIL vs ADA/FIL.

Figure 1. Conclusion: During the LTE through W48, response rates generally were maintained for FIL/FIL and ADA/FIL pts. Though there were differences between LTE groups, safety was largely comparable and consistent with PS observations1 and previously reported results from 7 trials2, rates of AEs of special interest were low; all confidence intervals were overlapping. Limitation: the LTE was not formally randomized for comparison between FIL/FIL and ADA/FIL treatment groups, the groups were of unequal size, and the switch from ADA to FIL for LTE was by design, rather than based on disease activity.

**PO5680 PHYSICIANS’ REASONS FOR PRESCRIBING JANUS KINASE INHIBITORS (JAKI) IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA), AND ASSOCIATED ALIGNMENT BETWEEN PHYSICIANS AND PATIENTS IN A REAL-WORLD CLINICAL SETTING**

1 University of Oxford, Nuffield Department of Orthopaedics, Oxford, United Kingdom; 2 Sorbonne Université - Assistance Publique Hôpitaux de Paris, Rheumatology Department, Paris, France; 3 Ghent University Hospital, Ghent and AZ Sint-Jans Brugge - Oostende AVE, Rheumatology, Bruges, Belgium; 4 University Hospital Complex of Pontevedra, Rheumatology Service, Pontevedra, Spain; 5 Maxima Medical Centre, Location Velhoven, Regional Rheumatology Center, Velhoven and Eindhoven, Netherlands; 6 MVZ für Rheumatologie, - Planegg, Germany; 7 Adelphi Real World, Rheumatology, Bollington, United Kingdom; 8 Galapagos NV, Medical Affairs, Mechelen, Belgium; 9 The University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; 10 Schlosspark Klinik, Department of Internal Medicine II, Berlin, Germany

Background: Shared decision making, a cornerstone of RA management1, allows physicians and their patients to make informed decisions about their treatment goals and choice of care. As new treatments become available, it is important to understand rheumatologists’ reasons for choosing JAKI, in addition to exploring alignment between rheumatologists and RA patients in terms of treatment choice and satisfaction.

Objectives: This survey evaluated rheumatologists’ clinical and patient centric reasons for choosing JAKI, in addition to exploring alignment between rheumatologists and RA patients in terms of treatment choice and satisfaction.

Methods: The Adelphi RA Disease Specific Programme2 is a large, multinational, point-in-time survey conducted amongst rheumatologists and their consecutive patients with RA in Europe (Belgium, France, Germany, Italy, Spain, UK) between January and October 2020. Physicians completed record forms for up to 10 consecutive RA patients, collecting demographic, clinical and treatment data, and reasons for current treatment choice. Patients were invited to complete a patient questionnaire to assess their satisfaction with ongoing treatment (5-point scale), and perceptions of shared decision making for the current treatment.

Results: 316 rheumatologists provided data for 3121 patients, of whom 1103 (36.2%) completed patient reported questionnaires. Overall, 67% were female, mean age was 53 years (SD 14), 23% had moderate-high disease activity score (DAS28 >3.2), 68% of patients were currently receiving either a biologic or targeted synthetic disease-modifying antirheumatic drug (DMARD; defined here as advanced therapy, AT), 72% were on first line AT, overall, physicians and their patients were aligned that a conversation took place about a treatment decision (80%; n=2511), and this was a shared treatment decision (n=814, 75% net alignment). 15% of patients not taking an AT were reported to have a clinical condition warranting one; reasons for not taking AT included patients’ concerns about infection (24%), conventional synthetic DMARDs were tolerated and safe in the patient (18%), and patient dislike of infusions/injections (17%). Of 2143 patients receiving AT, 19% were prescribed JAKI; 57% as monotherapy, 43% as combination therapy. For physician stated reasons for choice of JAKI, factors were driven by both perceptions of clinical efficacy and onset of action, as well as factors relating to patient acceptability such as method of delivery and ease of use (Table 1). With respect to JAKI treatment (n=135 patient-physician pairs), 62% of physicians and their patients were aligned on satisfaction, however 30% of patients reported less satisfaction than their consulting physician (Figure 1).

Conclusion: Communicating the choice of pharmaceutical therapy to patients with RA has become increasingly complex for physicians with expansion of approved treatments. In this subgroup of patients on JAKI, the drug attributes considered as reasons for prescribing were driven by clinical factors as well as by patient centric attributes. Although communications between patients and physicians were largely aligned, better understanding of patient expectations might serve to improve messaging about treatment options and resulting satisfaction.

**DRUG RETENTION RATE AND EFFECTIVENESS OF JAK INHIBITOR IN PATIENTS WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS**

S. Aino1,2,3, T. Okano1, K. Manda4, K. Crita4, Y. Yamada1, K. Mamoto1, T. Iida5,6, M. Tada7, K. Inui4, T. Koike8,9, H. Nakamura1. 1Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan; 2Osaka Social Medical Center, Orthopaedic Surgery, Osaka, Japan; 3Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan; 4Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan; 5Kyorai Hospital, Orthopaedic Surgery, Osaka, Japan; 6Takahiro Clinic Orthopedic Surgery, Nishinomiya, Japan; 7Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan; 8Osaka City University Medical School, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; 9Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama, Japan

**Background:** Recently, the disease activity of rheumatoid arthritis (RA) was improved due to the ‘treat-to-target’ strategy. However, some patients remain various symptoms despite recommended treatment was performed. Then, the term of ‘difficult-to-treat RA (D2TRA)’ is widely recognized. Janus kinase inhibitor (JAKi) might be effective for D2TRA patients, because JAKi can simultaneously block the function of multiple cytokines.

**Objectives:** The aim of this study was to evaluate drug retention rate and effectiveness of JAKi in patients with D2TRA.

**Methods:** This study included 220 RA patients (tofacitinib 101, baricitinib 83, upadacitinib 20, peficitinib 14, filgotinib 2) treated with JAKi. Sixty-two patients were treated as first line bDMARDs/JAKi (1st group), 57 patients were treated as second line bDMARDs/JAKi (2nd group), 101 patients were treated as third and more bDMARDs/JAKi. In these 101 patients, 25 patients did not met D2TRA criteria (non-D2TRA group) and 76 patients met D2TRA criteria (D2TRA group). Drug retention rate and effectiveness of JAKi were evaluated during 24 weeks in each group.

**Results:** Usage rate of methotrexate was lower and dosage of glucocorticoid was higher in D2TRA group than in other groups (Table 1). Drug retention rate at 24 weeks was 87.1% (54/62) in 1st group, 80.1% (46/57) in 2nd group, 88% (22/25) in non-D2TRA group, 61.8% (47/76) in D2TRA group. Drug retention rate was lower in D2TRA group compared to 1st group, 2nd group and non-D2TRA group (p<0.01, p<0.01, p<0.01), there was no difference between DT2RA group and 2nd group or non-D2TRA group (p=0.95, p=0.48). SDAI was 22.9, 19.9, 18.3, 23.9 at baseline, 11.8, 11.9, 13.3, 14.4 at 4 weeks, 79, 11.3, 8.4, 13.3 at 12 weeks, 8.5, 11.5, 9.7, 12.6 at 24 weeks. CDAI was 213, 18.8, 176, 218 at baseline, 113, 12.5, 13.9 at 4 weeks, 75, 10.9, 8.0, 12.3 at 12 weeks, 8.1, 10.7, 8.6, 12.1 at 24 weeks. HAQ was 1.15, 0.99, 0.89, 1.39 at baseline, 0.84, 0.76, 0.93, 1.22 at 4 weeks, 0.79, 0.84, 0.77, 1.17 at 12 weeks, 0.76, 0.79, 0.76, 1.14 at 24 weeks. Improvement rate of HAQ at 24 weeks were 44.3%, 23.9%, 21.2%, 8.1%.

**Conclusion:** Drug retention rate of JAKi in treatment of D2TRA group were lower than that of 1st group, 2nd group, and non-D2TRA group. Clinical efficacy of JAKi in D2TRA group were not significantly different to 2nd group and non-D2TRA group. However, HAQ improvement was weak in D2TRA group.

**Disclosure of Interests:** None declared

**LONG-TERM EFFICACY OF BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH INADEQUATE RESPONSE TO BDMAARDS: RESULTS FROM RA-BEYOND FOLLOWING 6.9 YEARS OF TREATMENT**

R. Caporali1, D. Aletaha2, R. Sanmartí3, T. Takeuchi4, D. Mo5, E. Halady6, L. Zaremba-Pechmann6, P. C. Taylor7. 1University of Milan, Department of Clinical Sciences & Community Health, Milan, Italy; 2Medical University of Vienna, Department of Medicine III, Vienna, Austria; 3Hospital Clinic de Barcelona and IDIBAPS, Rheumatology Department, Barcelona, Spain; 4Keio University School of Medicine, Division of Rheumatology, Tokyo, Japan; 5Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America; 6HaaPACS GmbH, HaaPACS GmbH, Schriesheim, Germany; 7University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

**Background:** Baricitinib (BARI), an oral selective Janus kinase 1/2 inhibitor, is approved for treatment of adults with moderately-to-severely active rheumatoid arthritis (RA). BARI demonstrated efficacy in patients (pts) with RA who have inadequate response to biologic disease-modifying antirheumatic drugs (bDMARD-IR) in a 24-week (wk) phase 3 study, RA-BEACON.1 BARI efficacy was evaluated up to 3 years (yrs) of treatment in a long-term extension (LTE) study, RA-BEYOND.2

**Objectives:** Disclose long-term efficacy of BARI 4 mg and 2 mg in bDMARD-IR pts in the completed study RA-BEYOND.

**Methods:** In RA-BEACON, pts were randomized 1:1:1 to BARI 4 mg, 2 mg, or PBO; pts with no response could be rescued after wk 16. Completers to wk 24 could enter with BARI 4 or 2mg RA-BEYOND for up to 360 wks (6.9 yrs). LTE data were analysed by treatment assigned at baseline in RA-BEACON as observed up to time of stepdown (if applicable), study discontinuation, or study completion, whichever occurred earlier. Efficacy response rates (ARR) were assessed as proportions of pts with observed data up to wk 360 for low-disease activity (LDA) (SDAI ≤ 11, DAS28-hsCRP < 3.2, CDAI ≤ 10), remission (REM) (SDAI ≤ 3.3, DAS28-hsCRP < 2.6, CDAI ≤ 2.8, Boolean), and physical functioning (HAQ-DI ≤ 0.5). No formal statistical comparisons were conducted.

**Results:** 156, 132, and 140 pts entered the LTE (4 mg, 2 mg, and PBO, respectively). Pts in BARI 4 and 2mg arms had higher LDA and REM RR vs PBO at LTE.
entry (wk 24) (Table 4). PBO-treated pts achieved comparable RR to pts in the BARI 4 mg arm by wk 48 (24 wks after switch to BARI 4 mg) and up to wk 360. Of pts enrolled to RA-BEYOND, approx. 50% in BARI 4 mg, 65% in 2 mg and 61% in PBO remained active at wk 156; 17%, 26% and 26% at wk 360, respectively. SDAI LDA RR were 47%/70% and 61%/74% for pts treated with BARI 4 mg and 2 mg, at wk 156 (yr 3)/360 (yr 6.9), respectively; SDAI REM RR were 15%/26% and 26%/26% for BARI 4 mg and 2 mg, at wk 156/360, respectively (Table 1). SDAI and CDAI had comparable RR. DAS-28 CRP LDA RR were similar to SDAI and CDAI, while REM RR were almost twice those of SDAI and CDAI. HAQ-DI ≤ 0.5 RR was 15%/26% (BARI 4 mg), 21%/15% (BARI 2 mg), and 9%/3% (PBO) at 3/6.9 yrs.

Conclusion: In observed data, BARI maintained efficacy and normative physical function bDMARD-IR population up to 6.9 yrs (360 wks).

N: Number of pts with observed data; n: Number of pts with response. a Number of wks from randomisation. b Treatment groups as assigned at randomisation.

RESULTS: 588 TNF-IR patients were included: 146 from BEYOND, 263 from CHOICE, and 159 from COMPARE. Mean duration since RA diagnosis was longer for BEYOND and CHOICE versus COMPARE. Cardiovascular (CV) risk factors were common among this refractory population (Table 1). ACR20/50/70 and disease activity outcomes observed in the TNFi-IR population were generally consistent with the overall BEYOND and CHOICE bDMARD-IR populations, and consistent across the three studies in the TNFi-IR subgroup (Figure 1). Improvements in PROs including HAQ-DI, fatigue, pain, and morning stiffness over 24 weeks were observed (data not shown). Pooled safety results reported 1574.8 patient-years (PY) of exposure in the TNFi-IR subgroup showed similar results to the overall BEYOND and CHOICE bDMARD-IR study populations, with EAErs of 3.1 events/100 PY for herpes zoster and 0.8 events/100 PY for adjudicated major adverse CV events, adjudicated venous thromboembolism (VTE), and malignancy excluding non-melanoma skin cancer. The EAEr of any AE leading to death was 1.4 events/100 PY.

Results: 483 patients (369 female, 114 male) were included in the study, with available baseline PRO information for 481 patients. 6-months follow-up data were yet available from 279 patients. The baseline average age and disease duration were 58.0 (12.3) years and 9.0 (8.0) years, respectively, whereas the mean initial DAS28-CRP was 4.6 (1.0). At baseline, 60.8% of enrolled patients had previously been treated with biologic or targeted synthetic disease-modifying antirheumatic drugs. Overall, PRO scores improved from baseline throughout month 6 with a considerable amelioration at month 3, which was maintained at month 6. Responses were rapid, with improvement already evident at month 1 (Table 1). The NRS pain as a crucial PRO in RA confirmed the previously described pattern of results seen for most of the other PROs (Figure 1).

Background: Upadacitinib (UPA) was previously evaluated in two Phase 2, randomized, controlled trials (RCTs) in patients (pts) with rheumatoid arthritis (RA) and inadequate response to tumor necrosis factor inhibitors (BALANCE-1) or methotrexate (BALANCE-2).

Objectives: To assess the final safety and efficacy of UPA in BALANCE-EX- TEND, a 312-week open-label extension (OLE) enrolling pts who completed either BALANCE-1 or BALANCE-2.

Methods: All pts initially received UPA 6 mg twice daily (BID). Increase to 12 mg BID was required for pts with <20% improvement in swollen or tender joint counts (S/TJC) at Week 6 or 12, and permitted for those not achieving Clinical Disease Activity Index (CDAI) low disease activity (LDA). Pts with <20% improvement in SJC or TJC at any two consecutive visits, discontinued. Return to 6 mg BID was permitted for safety or tolerability reasons. After January 2017, the 6 and 12 mg BID doses were replaced by 15 and 30 mg once-daily (QD) extend- ed-release equivalents. As-observed efficacy data are shown at Week 312 for three subgroups: pts who received 6 mg BID/15 mg QD throughout ("Titrated up"), those titrated up to 12 mg BID/30 mg QD for efficacy ("Titrated up"), and those titrated up to 12 BID/30 mg QD and then back to 6 mg BID/15 mg QD due to safety concerns ("Titrated up and down"). Exposure-adjusted adverse events (EAERs) per 100 patient-years (PY) of exposure were summarized from OLE Day 1 in all pts who received UPA (Any UPA).

Results: Overall, 493 pts entered the OLE, receiving UPA for ≤62 years (Never titrated, n=306; Titrated up, n=149; Titrated up and down, n=38), and 270 pts (54.8%) discontinued, mostly due to withdrawal of consent (16.8%; n=83) or AEs (14.6%; n=72). Mean (standard deviation) duration of UPA exposure was 3.8 (2.4) years (range <1–6.2 years); cumulative exposure was 1863 PY. The AE profile in pts receiving UPA 15 mg was generally similar to the Any UPA popula- tion, and to that observed in the Phase 3 UPA 15 mg clinical trial population (Table 1). Efficacy was maintained to Week 312, with 84.5% and 86.6% of pts in the Never titrated group achieving DAS28-CRP ≤3.2 and CDAI LDA, respectively (Figure 1).
Table 1. Summary of AEs in pts who received UPA 6 mg BID/15 mg QD in the OLE and in the UPA 15 mg Phase 3 study program

*Multiple events occurring in the same pts are counted in the calculation of events/100 PY.

Conclusion: In this OLE, UPA treatment over ~312 weeks showed sustained long-term efficacy in pts with RA who had completed Phase 2 RCTs. Overall safety results showed that UPA was well tolerated over time; the types and frequencies of AEs were consistent with those in pts with similar populations of moderately to severely active RA receiving Janus kinase inhibitors.

EFFECTIVENESS OF UPADACITINIB IN THE TREATMENT OF RHEUMATOID ARTHRITIS: ANALYSIS OF 6-MONTH REAL-WORLD DATA FROM THE UNITED RHEUMATOLOGY NORMALIZED INTEGRATED COMMUNITY EVIDENCE (UR-NICE(TM)) DATABASE

A. Gibofsky1, M. E. Pearson2, A. Concoff3, A. Shmagel4, P. Zueger4, Y. Song4, L. Smith5, G. W. Wright6,1. Well Cornell Medical College, Hospital for Special Surgery, New York, New York, United States of America; 2West Suburban Center For Arthritis, Rheumatology, Brookfield, Wisconsin, United States of America; 3Department of Rheumatology, Rheumatology, Hauppauge, New York, United States of America; 4 AbbVie Inc., Immunology, North Chicago, Illinois, United States of America; 5Association of Women in Rheumatology, Rheumatology, New York, New York, United States of America

Background: The efficacy of upadacitinib (UPA), an oral Janus kinase inhibitor (JAKI), in the treatment of rheumatoid arthritis (RA) has been demonstrated in the phase 3 SELECT clinical trial program. However, few real-world data have been reported to date.

Objectives: To assess the 6-month effectiveness of UPA in patients (pts) with RA initiating UPA treatment in clinical practice.

Methods: This observational study included US-based pts from the United Rheumatology Normalized Integrated Community Evidence (UR-NICE) database that initiated UPA 15 mg once daily from Aug 2019 to the data cut-off in Nov 2021. Pts with ≥6 months of baseline (BL) data before UPA initiation, and with Clinical Disease Activity Index (CDAI) score recorded at BL and 6 months (+45 days) after initiation, were included in the analysis. Effectiveness measures included CDAI score, Routine Assessment of Patient Index Data 3 (RAPID3), and Disease Activity Score in 28 joints based on C-reactive protein (DAS28-CRP); patient-reported outcomes (PROs) including Health Assessment Questionnaire-Disability Index (HAQ-DI), Pain, and Patient’s Global Assessment of Disease Activity (PGA); and Physician’s Global Assessment of Disease Activity (PhGA). Subgroup analyses were conducted by prior tumor necrosis factor inhibitor (TNFi) and tocilizumab (TOFA) treatment history.

Results: 363 pts were included in the analysis and most were female (80.2%) (Table 1). 140 (39%) received UPA monotherapy and 223 (61%) received UPA plus conventional synthetic (cs) disease-modifying antirheumatic drugs (DMARDs). 83% of pts received prior csDMARDs, 72% prior biologics (TNFi 55%), and 41% JAKIs (TOFA 39%). Overall, 46% (166/363), 23% (57/254), and 55% (95/173) of pts achieved LDA by CDAI, RAPID3, and DAS28-CRP, respectively, and 14% (51/363), 16% (39/245), and 36% (82/237) of pts achieved remission (REM) by CDAI, RAPID3, and DAS28-CRP, respectively. Results were similar regardless of prior TNFi or TOFA exposure, supporting UPA as an effective treatment option in clinical practice.

In this study, almost half (46%) of pts treated with UPA achieved CDAI LDA at 6 months and 14% achieved CDAI REM. Improvements in all PROs and PhGA were observed. Effectiveness of UPA was not impacted by prior TNFi or TOFA exposure, supporting UPA as an effective treatment option in clinical practice, including in pts with prior exposure to advanced therapy.

RESULTS OF AN OPEN-LABEL, RANDOMIZED, CONVENTIONAL SYNTHETIC DMARD (CSDMARD) RHEUMATOID ARTHRITIS PATIENTS RECEIVING A

**Objective:**
This exploratory study aimed to compare, in patients receiving conventional synthetic disease-modifying anti-rheumatic drugs (csDMARD) for treatment of RA, the effectiveness of combined use of csDMARD and denosumab vs csDMARD alone, in terms of inhibition of ER determined by HR-pQCT.

**Methods:**
Detail protocol of this open-label, randomized, parallel-group study has been published previously. RA patients with moderate or low disease activity and progressive ER were eligible, and were randomly assigned to receive denosumab in addition to the csDMARD (denosumab group) or to continued use of the csDMARD alone (csDMARD group). Denosumab was administered every 6 months during the 12-month study period. The primary endpoint was change of ER-depth at month 6 from baseline as the primary endpoint was −0.57 (−1.52, 0.39) in the denosumab group vs −0.22 (−0.97, 0.53) in the csDMARD group, respectively. At months 6 and 12, ER-depth, width, and volume (extension data) were numerically lower in the denosumab group than in the csDMARD group (Table 1). Compared with patients in the csDMARD group, those in the denosumab group had significantly higher volumetric bone mineral density (vBMD) at month 12. AE were reported in 12 (52.2%) and 13 (56.5%) of patients in the denosumab and csDMARD groups, respectively. The most common AE of denosumab groups was hypocalcemia (reported in 4), and all the events were causally related with denosumab.

**Conclusion:**
Our results suggest that adding denosumab to csDMARD therapy may help prevent ER, promote ER repair, and improve bone microstructure.

Background: Current NICE guidance for rheumatoid arthritis (RA) states that glucocorticoids may be used for bridging therapy and to rapidly decrease inflammation in acute flares. However, a recommended route and dosage is not specified, and variation has been observed between individual departments as to whether or not steroids are administered. Glucocorticoids are associated with adverse events that can be severe, leading to a strong recommendation by the American College of Rheumatology to avoid long term use. It is therefore important to ascertain the efficacy of available routes and dosages of glucocorticoids to weigh against these risks.

Objectives: This review aimed to ascertain the optimal route and dose of corticosteroid for adults with early RA.

Methods: Papers included were full text, English language, randomised controlled trials that fulfilled the PICO criteria. The population was defined as adults with early RA with onset <2 years, the intervention corticosteroids of any route or dose, the comparator conventional DMARDs or placebo, and the primary outcome remission. Functional improvement and X-ray progression were considered as secondary outcomes. MEDLINE, Embase, Web of Science and Cochrane Central were searched. Screening of results and extracted data was carried out by both reviewers. During data extraction, outcomes were rounded to timepoints of 3, 6 and 12 months, and steroid doses were stratified into low (up to 10mg/day prednisolone or equivalent), medium (15-30mg) and high (>30mg). Meta-analyses were carried out in RevMan 5.4 when 3 or more studies measured the same outcome at the same dose and route. A funnel plot was generated to check for publication bias.

Results: Three papers measured DAS28 remission rate at 1 year, comparing DMARDs only to DMARDs plus low dose oral steroids. The Forest plot for this meta-analysis is shown in Figure 1. As p = 0%, a fixed effect method was used. This shows an odds ratio (OR) of 1.73 (95% CI 1.25, 2.39) favouring low dose steroids. Both analyses favoured steroids; for HAQ scores the standardised mean difference (SMD) was -0.69 (95% CI -1.66, 0.29), and for DAS28 the SMD was -0.36 (95% CI -0.58, -0.15). At 3 and 6 months there was a lack of available data for meta-analyses.

Conclusion: At 1 year, remission and improvement in function appear more likely if low dose steroids are used. Due to a lack of available data, non-oral routes, higher doses and X-ray progression could not be analysed. Studies were not designed to detect differences in adverse events. This highlights the need for further clinical research into steroid efficacy in early RA. As the meta-analyses suggest that glucocorticoids may be more effective in inducing remission in early disease than conventional DMARDs alone.

EMULATING A TARGET TRIAL OF ADALIMUMAB VERSUS TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: A COMPARATIVE EFFECTIVENESS ANALYSIS USING THE OPAL REAL-WORLD DATASET

C. Deakin1,2,3, B. De Stavola4, G. Littlejohn1,5, H. Griffiths1,6, S. Cicirelli1,7, P. Youssfi1,9, D. Mathers1,10, P. Bird1,11, T. Smith1, C. Osullivan1, T. Freeman12, D. Segelov1, D. Hoffman1, S. Seaman1,2,3,4, OPAL Rheumatology Ltd, Rheumatology, Sydney, Australia; 1University College London, Centre for Adolescent Rheumatology Versus Arthritis, London, United Kingdom; 2Great Ormond Street Hospital, National Institute of Health Research Biomedical Centre, London, United Kingdom; 3UCL Great Ormond Street Institute of Child Health, Population and Policy and Research and Teaching Department, London, United Kingdom; 4Monash University Clayton Campus, Departments of Medicine, Clayton, Australia; 5Barwon Rheumatology Service, Rheumatology, Geelong, Australia; 6Royal Melbourne Hospital, Rheumatology, Melbourne, Australia; 7Royal Prince Alfred Hospital, Rheumatology, Camperdown, Australia; 8The University of Sydney, Rheumatology, Camperdown, Australia; 9Georgetown Arthritis, Rheumatology, Newcastle, Australia; 10UNSW Sydney, Rheumatology, Sydney, Australia; 11Software 4 Specialists Pty Ltd, (S4S), Sydney, Australia; 12University of Cambridge, MRC Biostatistics Unit, Cambridge, United Kingdom

Background: There is increasing recognition of the complementary role for real-world evidence (RWE) in health care and regulatory decision-making. However, careful analysis is required when drugs are compared using observational data to account for differences between treatment groups. Electronic medical records (EMR) are an important source of real-world data (RWD), but outcomes are often recorded incompletely. We emulated a target trial of adalimumab (ADA) versus tocitinitib (TOF) in patients with rheumatoid arthritis (RA) using the OPAL dataset to illustrate the application of methodologies to address the challenges of non-random treatment assignment and incomplete data. The OPAL dataset is derived from EMR of 112 community-based rheumatologists around Australia, where practitioners have discretion to prescribe whichever b/tsDMARD they consider most clinically appropriate.

Objectives: To estimate the average treatment effect (ATE) of TOF compared to ADA at 3 and 9 months, defined as the difference in mean disease activity score (DAS28CRP), in patients with RA who are new users of a b/tsDMARD. This is equivalent to aiming to estimate the intention-to-treat effect in a randomised controlled trial.

Methods: OPAL patients diagnosed with RA were included if they initiated ADA or TOF between 1 October 2015 and 1 April 2021, were new b/tsDMARD users (no prior recorded b/tsDMARD use) and had at least 3 months of prior csDMARD treatment, and had at least 1 component of DAS28CRP recorded at baseline or during follow-up. Data were also extracted on baseline characteristics. Baseline characteristics were DAS28CRP, patient demographics, regional location, disease duration, prescriber characteristics (including gender, experience), prior recorded comorbidities, and prior and concomitant treatment with csDMARDs and oral corticosteroids. We used random forest multiple imputation to impute missing baseline and follow-up DAS28CRP components. Stable balancing weights (SBW) were then used to balance the treatment groups in terms of their

Figure 1. Forest plot showing the OR of DAS28 remission with low dose steroids and conventional DMARDs vs DMARDs only
baseline characteristics, including DAS28CRP (3). For each imputed dataset, the ATE at 3 months was estimated as the difference between the mean outcome in the two treatment groups after balancing (i.e. weighting) the sample, and then these estimates were averaged across the 10 imputed datasets. The ATE at 9 months was estimated similarly. The whole procedure was subsequently performed in 1000 bootstrap samples to estimate a 95% confidence interval (CI) for the ATEs using the percentile method (4).

Results: 842 patients were identified including n=569 treated with ADA and n=273 treated with TOF. After applying the SWB, the maximum difference between the mean of each baseline characteristic in the ADA and TOF groups was less than 0.03% of the corresponding standard deviation in the whole sample, indicating reasonable balance was achieved in this complex dataset. After weighting, mean DAS28CRP reduced from 5.3 at baseline (both ADA and TOF groups) to 2.6 and 2.3 at 3 and 9 months for ADA, and 2.4 and 2.3 at 3 and 9 months for TOF. The estimated ATE was -0.22 (95% CI -0.36, -0.03; p=0.02) at 3 months, indicating a modest but significant reduction in disease activity for patients on TOF. The estimated ATE was -0.03 (95% CI -0.19, 0.1; p=0.56) at 9 months, indicating no difference between groups.

Conclusion: DAS28CRP was significantly lower at 3 months for patients treated with TOF compared to ADA. However, 3 months of treatment with either drug led to substantive average reductions in mean DAS28CRP, consistent with remission. There was no difference between drugs at 9 months. Future work will estimate a per-protocol effect.

Background: The phase 3 SELECT-CHOICE trial of patients with rheumatoid arthritis (RA) and prior inadequate response to biologic DMARD(s) (bDMARD-IR) demonstrated superiority of the JAK inhibitor upadacitinib (UPA) vs abatacept (ABA) in the mean change from baseline (BL) in DAS28 (CRP) and in the proportion achieving DAS28 (CRP) <2.6 at week 12, with higher incidence of serious adverse events reported in the UPA treatment group.

Objectives: To evaluate the impact of UPA vs ABA on individual components of composite measures of disease activity in SELECT-CHOICE.

Methods: In SELECT-CHOICE, a double-blind phase 3 trial, bDMARD-IR patients were randomly assigned to UPA 15 mg once daily or ABA, each with background conventional synthetic DMARDs, for 24 wks. For this post hoc analysis, the proportions of patients achieving improvement from BL through wk 24 in ACR core variables (including SJC, TJC, PtGA, Disease Activity Score 28 [DAS28], Physician Global Assessment [PGA], Patient Global Assessment [PGa], and hsCRP) and Boolean remission criteria were evaluated. Differences in the cumulative distributions of CDAI, DAS28 (hsCRP), SDAI, and ACR-n (the lowest percent change in TJC, percent change in SJC, or median of the other 5 ACR components) were determined using the Kolmogorov-Smirnov test and are reported as observed. For all other variables, non-responder imputation was applied for missing data. Nominal P values are provided throughout.

Results: A total of 616 bDMARD-IR patients with moderate to severe RA were randomized in SELECT-CHOICE (UPA 15 mg, n=303; ABA, n=309). BL demographic and disease characteristics were generally comparable between treatment groups, with a mean disease duration of approximately 12 years and mean CDAI of 39.6. At wk 12, more patients receiving UPA vs ABA achieved ≥50% improvements from BL in TJC66, PGA, and hsCRP, with comparable proportions observed between UPA and ABA for the remaining ACR components (Figure 1). At wk 24, similar proportions of patients receiving UPA and ABA achieved ≥50% improvements in all but the hsCRP component. Overall, 15% and 26% of patients on UPA compared with 6% and 15% on ABA demonstrated ≥50% improvements across all ACR components at wks 12 and 24, respectively. At wks 12 and 24, Boolean remission was achieved by 6% and 14% of patients on UPA vs 2% and 10% of patients on ABA, respectively; the proportion of patients in both treatment groups achieving the individual Boolean components were also reported (Table 1). While comparable at BL, cumulative distributions of CDAI, SDAI, DAS28 (hsCRP), and ACR-n were improved on UPA vs ABA at wk 12 (all nominal P <0.05); differences persisted for most measures at wk 24.

Nominal ***P <0.001, **P <0.01, *P <0.05 for UPA vs ABA, ABA vs abatacept; PGA, Patient’s Global Assessment of disease severity; UPA, upadacitinib.

Conclusion: In this post hoc analysis of bDMARD-IR RA patients, improvements in disease component measures were reported for both UPA and ABA through 24 weeks, with numeric differences noted for several components. Nominal higher attainment of Boolean remission and its components were observed through 24 weeks, with numeric differences noted for several components. Nominal differences in components of disease measures were reported for both UPA and ABA at wk 12 and 24, Boolean remission was achieved by 6% and 14% of patients on UPA compared with 6% and 15% on ABA demonstrated ≥50% improvements in all but the hsCRP component. Overall, 15% and 26% of patients on UPA compared with 6% and 15% on ABA demonstrated ≥50% improvements across all ACR components at wks 12 and 24, respectively. At wks 12 and 24, Boolean remission was achieved by 6% and 14% of patients on UPA vs 2% and 10% of patients on ABA, respectively; the proportion of patients in both treatment groups achieving the individual Boolean components were also reported (Table 1). While comparable at BL, cumulative distributions of CDAI, SDAI, DAS28 (hsCRP), and ACR-n were improved on UPA vs ABA at wk 12 (all nominal P <0.05); differences persisted for most measures at wk 24.
**Objectives:** To study if clinical response differs between advanced therapies that are initiated after stopping a JAKi.

**Methods:** Patients were included from the electronic platform “Tool for Administrative Reimbursement Drug Information Sharing” (TARDIS). Data from all Belgian RA patients on biologic and targeted therapy are collected here for drug reimbursement. Patients were selected for this analysis if they had stopped JAKi therapy and initiated a subsequent therapy. Patients were grouped by TNFi, T/B cell therapy, IL6i or JAKi therapy. The DAS28 response and proportion of patients in remission at the first follow-up (between 3 and 6 months) were compared between groups. Remission was defined as DAS28<2.6. Analyses were repeated in patients who were prescribed the stopped JAKI as first-line or as subsequent line therapy. Data were compared via χ², Anova and t-tests.

**Results:** In total, 1238 patients who had stopped JAKI therapy were included. TNFi, T/B cell therapy, IL6i or JAKi therapy was initiated in 36% (441/1238), 19% (233/1238), 18% (227/1238) and 27% (337/1238) respectively. Most baseline demographic and clinical characteristics differed between groups (Table 1).

**EFFECT OF METHOTREXATE AND FOLIC ACID CO-COMMUNICATION IN ARTHRITIS**

E. Dailly1, M. Maalouf2, S. Peyrache1, A. Vanden-Bossche1, C. A. Arthaud1, S. Hodin1, H. Marotte2, R. Müller3,4, INSERM, U1059-SAINBOISE, University of Lyon, Saint-Etienne, France; 1University Hospital of Saint-Etienne, Rheumatology, Saint-Etienne, France; 2Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV Ludwig-Maximilians-University Munich, Munich, Germany; 4Rheumazentrum Ostschweiz, Rheumatology, St. Gallen, Switzerland

**Background:** Methotrexate (MTX) is the recommended first-line treatment for rheumatoid arthritis. Adjuvant-induced arthritis (AlA) is a robust model with a high prevalence of arthritis used to investigate arthritis. MTX reduces inflammation, but associated with adverse events, such as gastrointestinal, hepatic, and hematological toxicity (1). To reduce these side effects, folic acid (FA) is administrated at distance to MTX with no defined recommendation for its dosing (5-25mg/week) or time point of administration (2) (1-3 days after MTX application). Whether the complicated therapeutic regimen with MTX once a week and FA at another time point affects compliance is an open question. MTX is metabolized in polyglutamates derivates (MTX-PG), which is a biomarker of MTX efficacy as its half-life (1-4 weeks) is longer than MTX (4h) (3).

**Objectives:** The aim of this study was to assess efficacy and tolerance of co-administration of MTX and FA compared to FA applied one day after MTX in the AlA.

**Methods:** Female Lewis rat were randomly divided into three groups and received an injection of Mycobacterium butyricum defining day (D) 0 to induce arthritis. An historic AlA group was used as control. Treatment began on D9, one day before arthritis onset in this model. The first group rats were treated with MTX only (n=13), the second group received MTX and FA at the same day (n=14), and the third group received FA one day after MTX administration (n=14). MTX was administrated intraperitoneally (IP) at 1mg/kg every 3 days (4) and FA was delivered IP at 0.17mg/kg. Arthritic index (AI) and ankle circumference (AC) were monitored to assess arthritis.

**Results:** Arthritis developed at D10 in all groups. AI and AC were similar in MTX groups at the various time points. At D17, arthritis severity was lower in MTX groups (AI (mean and standard deviation): 1.4 ± 1.6; AC: 35 ± 7 mm) compared to AlA historic group (AI: 3.3 ± 0.6; AC: 42 ± 4 mm). Bone erosion and bone loss parameters were similar in all groups. Cortical porosity was around 0.40±0.15 and bone volume / total volume was around 0.22±0.13. MTX-PG1 was found at similar levels in MTX groups and correlated negatively with AI in MTX alone and MTX and FA at the same day groups (p<0.05 and p<0.01, respectively).

Finally, while red blood cells, platelets, hemoglobin, mean corpuscular volume, transaminases, and creatinine were found at a similar level in MTX groups.

**Conclusion:** Co-administration of MTX with FA on the same day is effective compared to FA application one day after MTX. MTX metabolism was not affected, as demonstrated by the MTX-PG concentrations. The biological tolerance between the protocols was comparable. Thus, co-administration of MTX and FA seems to be possible and may be more convenient to the patients and improve compliance at the end.

**DOES PREDNISONE USE DURING PREGNANCY IN WOMEN WITH RHEUMATOID ARTHRITIS INDUCE INSULIN RESISTANCE IN THE OFFSPRING?**

F. D. O. De Steenwinkel1, R. Dolain1, J. Hazes1, A. C. Hokken-Koelega1 on behalf of PARA. 1Erasmus University Medical Centre, Rheumatology, Rotterdam, Netherlands; 2Erasmus University Medical Centre, Sophia Children’s Hospital, Department of Paediatrics, Subdivision of Endocrinology, Rotterdam, Netherlands

**Background:** The use of long-term corticosteroids during pregnancy has been growing over the past decades. Corticosteroids can be given when an auto-inflammatory disease like rheumatoid arthritis (RA) is too active. Several studies have shown that long-term corticosteroids use in pregnancy is associated with an increased risk of maternal and fetal adverse outcomes, like preeclampsia, shorter gestational age, lower birth weight and rapid catch-up growth 1-3. These last two outcomes could influence the insulin resistance later in life4.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.3150
Objectives: Does prednisone use in pregnant women with RA induces insulin resistance in the offspring?

Methods: 103 children were included after their mother had participated in a prospective cohort study on RA and pregnancy. 42 children were in utero exposed to prednisone and 61 were non-exposed. To assess insulin resistance, we measured Homeostasis Model of Assessment Insulin Resistance (HOMA-IR), serum adiponectin and lipid levels, corrected for body fat distribution.

Results: There was no difference in mean HOMA-IR (SD) between the children who were prednisone-exposed in utero (1.10 (0.84)) and those non-exposed (1.09 (0.49)). No difference was found in mean adiponectin (SD) level, 16.45 (4.06) µg/mL and 15.40 (3.59) µg/mL, respectively. Also no difference was found in body fat distribution or lipids such as total cholesterol, fasting triglyceride or high-density lipoprotein.

Conclusion: Children who are prednisone-exposed in utero have no increased risk for insulin resistance at the age of approximately 7-years. This finding, though reassuring, but further research has to be performed to evaluate if prednisone-exposure in utero has no other negative effects on the long-term and if insulin resistance remains absent in the future.

Conclusion: Ophthalmological manifestations under JAK inhibit seem rare but not exceptional. The rheumatologist must be made aware of them in order to discuss the potential imputability of the treatment and to report these manifestations to the pharmacovigilance structures. A detailed history, exclusion of infections and pathological evaluation of the lesions are recommended to ensure that a differential diagnosis is not ignored. Topical treatments, and if necessary, discontinuation of the drug and switching to another targeted therapy may be considered. Discontinuation of JAKinhib appears to be warranted pending ophthalmologic advice.

</table>
The baseline visits involved initiation of bDMARD therapy with 100% vs. 88.9% bDMARD (anti-TNF: 78.8% vs. 58.3%, anti-IL6: 8.7% vs. 12.8%, CTLA4 Ig: 11.5% vs. 16.7%, anti-CD20: 2.9% vs. 1.1%) and 0% vs. 11.1% bDMARD. Therapeutic decision concerning the bDMARD were (STRATEGE 1 vs STRATEGE 2): identical regimens maintained (pharmaceutical form + dosage): 69.2% vs. 76.1%; discontinuation: 4.3% vs. 2.2%; adjustment: 26.7% vs. 21.7% (with dose reduction: 18.2% vs. 93.5%) and/or change in pharmaceutical form (p.o. to SC): 54.5% vs. 0%.

Main reasons for adjusting treatment were (STRATEGE 1 vs STRATEGE 2): active RA: 86.1% vs. 77.8%; RA not in remission: 3.5% vs. 21.1%; exacerbation based on clinical laboratory parameters: 42.6% vs. 10%.

Conclusion: Over the five years, these results suggest a change in practices for RA patients with an inadequate response to MTX and initiating their first targeted therapy; now with earlier recourse to first targeted therapy, for less active RA, and more pronounced investigation of remission.

and methotrexate initiation in one arm, versus immediate introduction of MTX follow-
ing vaccination in the other arm. We analyzed disease activity based on DAS28-ESR at baseline (M0), 1, 2, 3, 6 and 12 months between the 2 groups. For structural progression, we performed a radiographic analysis of 79 RA patients included in the Montpellier center at baseline, 6 and 12 months. This analysis was performed by the same physician two times, blinded to the patient's group. Structural damage progress-
ion at 6 months and 1 year was assessed according to van-der-Heijde-modified Sharp score (vSHS) on radiographs performed at inclusion, at 6 and 12 months of follow-up. Comparisons of the means of activity scores and radiographic scores were made with the non-parametric Wilcoxon-Mann-Whitney test.

Results: Of the 276 patients randomized, 261 could be analyzed (131 in the IMMEDIATE group and 130 in the DELAY group). At inclusion, there were no significant differences in demographic, disease activity (DAS28-ESR), biological and radiographic characteristics between the 2 groups (Table 1).

There was a significant difference in the means of DAS28-ESR at 1 month between the DELAY and IMMEDIATE groups (3.96 ± 1.46 vs 3.41 ± 1.32; p<0.001, respectively). There was no significant difference in the means of DAS28-ESR between the 2 groups at 3 months (3.19 ± 1.46 in the 2 groups p=0.91), at 6 months (3.11 ± 1.42 vs 3.24 ± 1.43; p=0.46, respectively) and at 12 months (2.96 ± 1.34 vs 2.98 ± 1.26p=0.89). (Graphic). Similarly, there was no significant difference in mean radiographic scores at 6 months (2.00 ± 4.41 vs 1.80 ± 4.03 p=0.81) or at 12 months (2.25 ± 4.86 vs 2.00 ± 4.07p=0.93).

There was no significant variation between radiographic scores at 6 months compared to baseline in either group (mean difference 0.21 ± 0.52 vs. 0.36 ± 1.01, p=0.90) nor at 12 months compared to baseline (mean difference 0.40 ± 1.06 vs. 0.62 ± 1.58, p=0.85).

Conclusion: In patients with rheumatoid arthritis, initiation of methotrexate 1 month after PCV13 vaccination has no significant impact on RA activity and structural outcome at 1 year. Performing vaccinations 1 month before starting MTX can be proposed without significant impact on RA outcome at 1 year.

SLE, Sjögren’s and APS – treatment

**DILEMMA OF BELIMUMAB THERAPY (DIS)**

CONTINUATION DURING PREGNANCY: RESULTS OF A RETROSPECTIVE STUDY IN EUDRAVIGILANCE

N. Ghahardari1, H. J. M. J. Crimplia, R. Dolhain, J. Hazes1, E. Van Puijenbroek1,2

1Erasmus MC, Rheumatology, Rotterdam, Netherlands; 2CBG-MEB, Pharmacovigilance, Utrecht, Netherlands; 3Lareb, Pharmacovigilance, ’s-Hertogenbosch, Netherlands

**Background:** Active systemic lupus erythematosus (SLE) and nephritis due to SLE contribute to poor pregnancy outcomes. (1, 2) A meta-analysis has shown a relative risk of 1.51 for miscarriage in SLE patients compared to women without SLE. (3) The risk is even higher if the disease is active during pregnancy (around 3-fold increase in pregnancy loss). (4) Corticosteroids, azathioprine, hydroxychloroquine, cyclosporine and tacrolimus are considered safe treatments. (5) However, these treatment options may still not be sufficient in patients poorly responsive to conventional therapies or patients who suffer from nephritis. (6) The only biologic authorized for SLE up to this date, belimumab, is currently not recommended for use during pregnancy due to lack of data. Provided that the health of the child begins with the health of the mother, pregnant patients face the dilemma of cessation or continuation of belimumab. If belimumab is stopped there will be a risk of SLE flare and its consequences for mother and foetus. Continuation is also not optimal because of the lack of knowledge on safety for use during pregnancy.

**Objectives:** To compare the reported foetal outcomes in SLE patients who stopped scheduled belimumab during the first trimester or thereafter (group B) and who continued scheduled belimumab during the first trimester or thereafter (group A). Belimumab was started according to the treatment guidelines of the regulatory agency/agencies or organizations with which the author(s) is/are employed/affiliated.

**Methods:** All belimumab-exposed pregnancy-related reports, were extracted from the EudraVigilance (EV) database until March 11th 2021. After case review, repeated cases, uninformative reports, non-medical elective abortions and foetal chromosomal abnormalities were excluded. Included pregnancies were divided into two groups (group A and B, as described above). Foetal outcomes were divided into live birth or foetal death (due to miscarriage or still birth) and were compared between both groups. Furthermore, neonatal outcomes, such as reporting rates of pre-term birth, low birth weight and major congenital malformations (CMs) were compared.

**Results:** No statistical difference in foetal death was observed between group A and B (reporting rates: 46.4% and 52.4%, respectively; p-value>0.05). Occurrence of major CMs, pre-term birth and low birth weight was higher - though not statistically different- in group A (Table 1).

**Conclusion:** Based on our data belimumab continuation during first trimester or thereafter does not result in higher reporting of foetal death. Therefore, continuation might be even preferable if the pregnancy is already exposed to belimumab. Since the analysis is based on spontaneous reports / retrospective data, additional studies are needed to confirm the results.

**LONG-TERM HYDROXYCHLOROQUINE TREATMENT IMPROVES ESSPRI AND ESSDAI IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME**

N. Hashimoto1, T. Nakazawa2, T. Iwasaki3, T. Hashimoto1

1Hashimoto Rheumatology Clinic, Department of Rheumatology, Osaka, Japan; 2Osaka Saiseikai Nakatsu Hospital, Department of Rheumatology, Osaka, Japan; 3Keiseikai Medical Corporation, Department of Internal Medicine, Higashiosaka, Japan

**Background:** Primary Sjögren’s syndrome (pSS) is a chronic, systemic autoimmune disease typically affecting the salivary and lacrimal glands and producing symptoms of dry mouth, dry eyes, fatigue and pain. Hydroxychloroquine (HCQ) have been shown to have immunomodulatory and immunosuppressive effects, and currently have established roles in the management of rheumatoid arthritis and systemic lupus erythematosus (SLE). However, the use of HCQ in pSS is based on expert recommendations and in few studies with a low level of evidence. There are very few publications assessing HCQ use in a double-blind, randomized, and placebo-controlled studies. In Japan, HCQ is indicated for patients with SLE and cutaneous lupus erythematosus (CLE) and is off-label for pSS patients without CLE. Recently, ESSPRI and ESSDAI have been developed by the European League Against Rheumatism (EULAR) SS study group as standardized outcome tools for measuring patients’ reported symptoms and disease-specific activity. ESSDAI and ESSPRI have been proven to be valid and reliable, they have been used to select patients or as the primary or secondary outcome measures in clinical trials.

**Objectives:** The aim of this study was to examine the efficacy of HCQ in pSS at 8 and 52 weeks after treatment evaluated by ESSPRI and ESSDAI.

**Methods:** Twenty-six pSS patients (26 female, mean age 51.6 ± 13.6 years) with CLE who fulfilled the ACR/EULAR classification criteria for SS and/or the Japanese Ministry of Health and Welfare criteria for SS were studied. The clinical indexes were evaluated by ESSDAI, ESSPRI, IgG and CH50 before and after HCQ treatment at 8 and 52 weeks. ESSPRI components were calculated individually and as a single factor composed of the mean of the three components (pain, fatigue, and dryness: VAS 0-10). ESSDAI (0–123) proposes the evaluation of 12 domains or organ systems (constitutional, lymphadenopathy, glandular, articular, cutaneous, pulmonary, renal, peripheral nervous system, central nervous system, muscular, hematological and biological).

**Results:** ESSPRI and component of fatigue and pain were significantly lower at 8 and 52 weeks after treatment than HCQ pre-treatment (ESSPRI: 4.14±1.45 vs 3.38±1.57, 3.34±1.56, p<0.005, p=0.045, fatigue: 4.86±2.12 vs 3.68±1.96, 3.58±1.87, p=0.010, p=0.036, pain: 3.32±1.94 vs 2.09±1.60, 1.79±1.51, p=0.0043, p=0.0014). However, there was no significant difference in dryness component between HCQ pre-treatment and 8 and 52 weeks after treatment (4.41±2.09 vs 4.32±2.06, 4.21±2.39, p = 0.71, p = 0.94), and the amount of saliva produced by the gum test also showed no significant difference between pre-HCQ treatment and 52 weeks after treatment (6.21 ± 6.72 vs 8.24 ± 6.79 mL / 10 minutes, p = 0.45). There was also a significant decrease in ESSDAI and constitutional, articular, cutaneous and biological domain at 52 weeks after treatment compared to HCQ pre-treatment (ESSDAI: 4.14±1.45 vs 3.38±1.57, 3.34±1.56, p<0.005, p=0.045, constitutional: 1.4±1.50 vs 0.63±1.26, p=0.034, articular: 1.00±1.02 vs 0.21±0.63, p=0.0027, cutaneous: 2.86±3.27 vs 1.12±2.49, p=0.010, biological: 1.14±0.83 vs 0.79±0.86, p=0.014). An improvement of at least 1 point or more in ESSPRI and at least 3 points in ESSDAI compared to HCQ pr-treatment were observed in 63.6% and 31.8% at 8 weeks and 73.7% and 68.4% at 52 weeks after treatment. In addition, IgG was significantly decreased at 52 weeks after treatment compared to HCQ pre-treatment (4.38±1.38 vs 4.14±1.45, p=0.0005).

**Conclusion:** HCQ treatment improved pain such as arthritis, fatigue, constitutional and cutaneous manifestations, but was not effective for salivary function and dryness. HCQ treatment was useful in improving ESSPRI and ESSDAI, and long-term treatment increased the number of effective cases from 8 weeks treatment to 52 weeks. Further studies are needed.

**Disclosure of Interests:** None declared.

BACKGROUND: The goal of targeted treatment in patients with Systemic Lupus Erythematosus (SLE) is to achieve clinical remission or low disease activity, with the best quality of life, low damage rates and better survival.1,2 RELEASAR is a multicenter, cross-sectional study registry of ≥18 years SLE (ACR 97) patients.1,2 Rheumatology, Santa Fe, Argentina;3 GESAR LUPUS, Rheumatology, Rosario, Argentina;4 GESAR LUPUS, Rheumatology, Godoy Cruz, Argentina;5 GESAR LUPUS, Rheumatology, Santa Cruz, Argentina;6 GESAR LUPUS, Rheumatology, Formosa, Argentina;7 GESAR LUPUS, Rheumatology, Santa Rosa, Argentina;8 GESAR LUPUS, Rheumatology, Godoy Cruz, Argentina;9 GESAR LUPUS, Rheumatology, La Plata, Argentina;10 GESAR LUPUS, Rheumatology, Mar del Plata, Argentina;11 GESAR LUPUS, Rheumatology, Rosario, Argentina;12 GESAR LUPUS, Rheumatology, Rio Grande, Argentina;13 GESAR LUPUS, Rheumatology, Bahia Blanca, Argentina;14 GESAR LUPUS, Rheumatology, San Juan, Argentina;15 GESAR LUPUS, Rheumatology, General Roca, Argentina;16 GESAR LUPUS, Rheumatology, Mar del Plata, Argentina;17 GESAR LUPUS, Rheumatology, Corrientes, Argentina;18 GESAR LUPUS, Rheumatology, Posadas, Argentina;19 GESAR LUPUS, Rheumatology, Salta, Argentina;20 GESAR LUPUS, Rheumatology, Granadero Baigorria, Argentina

Background: The goal of targeted treatment in patients with Systemic Lupus Erythematosus (SLE) is to achieve clinical remission or low disease activity, with the best quality of life, low damage rates and better survival.1,2 RELEASAR is a multicenter, cross-sectional study registry of ≥18 years SLE (ACR 97) patients.1,2 Objectives: To describe demographic, clinical characteristics and treatments in SLE patients according to disease activity state. To evaluate the proportion of SLE and refractory SLE patients that are potentially candidates for Belimumab treatment. Results: In total, 201 patients were enrolled. Potentially eligible patients included 92.7% of patients (n=185) that met the definition of uncontrolled disease according to the ACR definition.2,3 The proportion of patients with refractory severe lupus was 7.3% (n=14). Patients on Belimumab therapy were associated to treatment with lower cyclophosphamide or two or more immunosuppressant or splenectomized patients. They were also more prevalent mestizos (p=0.004), had female and they showed less time of disease and lower socioeconomic status (p<0.001). They were also more prevalent mestizos (p=0.004), had higher SLEDAI and SCLC indices (p<0.001) and higher use of immunosuppressants (p<0.001). This was no difference regarding biologic treatment (RTX p=0.547 and Belimumab p=0.08). This group had proportion of hospital admissions and severe infections (p<0.001, respectively). Two hundred and one SLE patients fulfilled the use of Belimumab prescription criteria but only 45/201 patients (22.3%) received the prescription. Belimumab was prescribed in 22.3% (n=105) of patients, none of whom had a history of SLE flare (p=0.027). Conclusion: A high percentage of patients had uncontrolled disease upon entry into the registry and were potential candidates for treatment with Belimumab. The patients who received biologic treatment showed the benefit of requiring fewer doses of corticosteroids and having a lower rate of hospitalizations.

EVALUATING THE HYPERSENSITIVITY PROFILE OF ANIFROLUMAB AND THE NEED FOR LIASON MACHADO ESCOBAR: Provence, France;3 AstraZeneca, BioPharmaceuticals R&D, Warsaw, Poland;4 AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America;5 AstraZeneca, BioPharmaceuticals R&D, MA, United States of America;6 AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden

Background: Anifrolumab, a human monoclonal antibody (mAb), is approved in Canada, Japan, and the United States for the treatment of patients with systemic lupus erythematosus (SLE). Anifrolumab is approved in Canada, Japan, and the United States for the treatment of patients with systemic lupus erythematosus (SLE) based on results from the phase 2b MUSE and the phase 3 TULIP-1/2 trials. Anaphylactic reactions (ARs), hypersensitivity reactions (HSRs), and infusion-related reactions (IRRs) are risks of mAb infusions, so physicians prescribing anifrolumab may wish to understand the hypersensitivity profile and whether prophylactic pretreatments are required to mitigate HSRs/IRRs.

Methods: We evaluated demographic and clinical data, treatments, score of damage (SLICC), activity (SLEDAI) and comorbidity (Charlson), hospital admissions and severe infections. The patients were compared according to disease activity: remission (SLEDAI = 0 and without corticosteroids), low disease activity (LDA, SLEDAI = 0 and ≤4 and without corticosteroids) and non-optimal control (SLEDAI > 4 and any dose of corticosteroids). Refractory SLE was defined according to Rituximab (RTX) use, non-response to cyclophosphamide or two or more immunosuppressant or splenectomized patients. Potential use of Belimumab according approved prescription in Argentina was analyzed.

Results: Overall, 1277 patients were analyzed: 299 (23.4%) were in remission, 162 (12.7%) in LDA and 816 (63.9%) with non-optimal control of the disease. Patients in non-optimal control group were younger, less frequently female and they showed less time of disease and lower socioeconomic status (p < 0.001). They were also more prevalent metastizos (p = 0.004), had higher SLEDAI and SLICC indexes (p<0.001) and higher use of immunosuppressants (p<0.001). There was no difference regarding biologic treatment (RTX p = 0.547 and Belimumab p = 0.08). This group had higher proportion of hospital admissions and severe infections (p<0.001, respectively). Two hundred and one SLE patients fulfilled the use of Belimumab prescription criteria but only 45/201 patients (22.3%) received it in the last visit. Malaria was the only clinical variable associated with the use of Belimumab (72.7% vs 29.8% p = 0.005). Seventy-six patients classified as refractory SLE (15.7%) and 56/76 (75.7%) never received Belimumab. Patients on Belimumab therapy were associated to treatment with lower doses of corticoids (p = 0.018) and lower rate of hospital admission caused by SLE flare (p = 0.027).

Conclusion: A high percentage of patients had uncontrolled disease upon entry into the registry and were potential candidates for treatment with Belimumab. The patients who received biologic treatment showed the benefit of requiring fewer doses of corticosteroids and having a lower rate of hospitalizations.

Disclosure of Interests: [K. C. Kalunian1, Y. Tanaka1, I. Huper2, L. J. Zhang3, M. Shroff4, S. Werther4, G. Abreu5, C. Lindholm6, R. Tumella7, University of California, San Diego, Division of Rheumatology, Allergy and Immunology, La Jolla, CA, United States of America; 2University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan; AstraZeneca, BioPharmaceuticals R&D, Warsaw, Poland; AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America; AstraZeneca, BioPharmaceuticals R&D, MA, United States of America; AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden]

EVALUATING THE HYPERSENSITIVITY PROFILE OF ANIFROLUMAB AND THE NEED FOR PROPHYLACTIC PRETREATMENT IN PATIENTS WITH SLE
HSRs vs 1% (n=36) in the placebo group. IRRs occurred in 9% (n=43) of anifrolumab-treated patients vs 7% (n=33) in the placebo group. All HSRs and IRRs were mild/moderate in intensity. There were no discontinuations due to HSRs or IRRs in the anifrolumab group, while there were 2 in the placebo group (HSR: n=1; IRR: n=1). In the anifrolumab 300 mg and placebo groups, more patients experienced HSR/IRRs with the initial (1–6) vs later infusions (Figure 1). In the anifrolumab group, the median (absolute deviation) time to first HSR or IRR was 30.5 (29.5) days or 270 (260) days, respectively. Of the 12 anifrolumab-treated patients with ≥1 HSR, 3 received subsequent pretreatment, and none had any HSR after the use of pretreatment. Of the 43 anifrolumab-treated patients with ≥1 IRR, 2 received pretreatment, of whom 1 had an IRR after pretreatment and anifrolumab dosage remained unchanged.

Conclusion: Following anifrolumab infusion, ARs were uncommon, and few (3%) patients experienced HSRs. HSRs and IRRs with the approved anifrolumab 300 mg dose were mild to moderate, occurred early in treatment, did not lead to discontinuation, and only rarely required pretreatment. Our data support a safe and manageable hypersensitivity profile for anifrolumab.

Acknowledgements: Writing assistance was provided by Rosie Butler, PhD, of JK Associates Inc., part of Fishawack Health. This study was sponsored by AstraZeneca.

Background: Incomplete SLE disease control is associated with progressive organ damage, poor quality of life, and increased mortality.1-3 Sustained reduction in overall disease activity is therefore an important treatment goal.

Objectives: To investigate sustained British Isles Lupus Assessment Group 2004–based Composite Lupus Assessment (BICLA) response and British Isles Lupus Assessment Group (BILAG) responses by organ domain in pooled data from the TULIP-1 and TULIP-2 trials of the type I interferon receptor monoclonal antibody, anifrolumab, in patients with SLE.1-3

Methods: TULIP-1 (NCT02446912) and TULIP-2 (NCT02446889) were phase 3, randomized, placebo-controlled, 52-week trials of intravenous anifrolumab administered every 4 weeks for 48 weeks in eligible patients with moderate to severe SLE who were receiving standard therapy.1,3-5 Sustained BICLA and BILAG response rates, measured as the number of consecutive patient visits with BICLA or BILAG domain responses, respectively, from Week 4 to Week 52 were compared between the anifrolumab vs placebo groups. BILAG-2004 response was defined as a reduction from A (severe disease) at baseline to B (moderate), C (mild), or D (no current disease) or reduction from B at baseline to C or D.5

Results: In total, 360 patients received anifrolumab 300 mg and 366 patients received placebo in the TULIP-1 and TULIP-2 trials. Analysis of pooled TULIP data revealed that more patients who received anifrolumab had sustained BICLA responses compared with placebo (Table 1). The proportions of patients who had BICLA responses sustained for ≥3, ≥6, ≥9, and 12 months inclusive of Week 52 were 33.6%, 27.2%, 16.4%, and 9.2% in the anifrolumab group, and 20.5%, 15.0%, 8.5%, and 1.9% in the placebo group, respectively. The most commonly affected organ domains were musculoskeletal (645/726 patients) and mucocutaneous (627/726 patients) (Figure 1). More patients receiving anifrolumab had BILAG responses for 12 months compared with placebo in these two domains (musculoskeletal: 19.9% vs 13.1%; mucocutaneous: 17.1% vs 7.1%); analyses of all other organ domains were limited by small sample sizes.

BICLA, British Isles Lupus Assessment Group–based Composite Lupus Assessment.

Conclusion: In two phase 3 studies, more anifrolumab-treated patients achieved sustained BICLA and BILAG responses compared with placebo. In the frequently affected musculoskeletal and mucocutaneous domains, sustained treatment benefit of anifrolumab over placebo was observed. These data support the durable clinical benefit of anifrolumab treatment in patients with moderate to severe SLE who are receiving standard therapy.

References:
Interstitial lung disease (ILD) often occurs in primary Sjögren’s syndrome (pSS) and reduces the survival of patients [1, 2]. Diagnosis and therapy in pSS-ILD are not standardized.

**Objectives:** To evaluate clinical characteristics of pSS-ILD and efficacy of rituximab therapy in this group of patients.

**Methods:** We conducted retrospective study which included 19 pSS-ILD patients. pSS was diagnosed based on the ACR 2012 or ACR/EULAR 2016 criteria. Diagnosis and clinical assessment of ILD was carried out on the basis of high-resolution computed tomography (HRCT) and pulmonary function tests (PFT). The median age of pSS debut was 49 years (7-72 years), the median age of ILD debut was 57 years (29-75 years). All 19 patients received rituximab: 10 as a monotherapy, 6 in combination with cyclophosphamide, 3 in combination with mycophenolate mofetil. The median follow-up duration was 24 months (3-108 months).

**Results:** In 5 of 19 patients (26%), ILD was the first manifestation of pSS, while 14 patients (74%) developed ILD after an average of 9 years of disease course in the absence of therapy or taking low doses of glucocorticoids and hydroxychloroquine. The most common patterns of ILD were nonspecific interstitial pneumonia (52.6%) and lymphocytic interstitial pneumonia (26.3%), while organizing pneumonia and usual interstitial pneumonia were significantly less common (10.5%, respectively). Both patients with organizing pneumonia were diagnosed with pulmonary lymphoma (also they had persistent salivary gland enlargement, lymphadenopathy, paraproteinemia, and pattern of organizing pneumonia and a lack of response to rituximab and cyclophosphamide therapy).

**Conclusion:** Considering asymptomatic cases and the absence of pSS-ILD predictors, all patients with pSS at the onset of the disease and in the dynamics should undergo HRCT and PFT for the purpose of ILD early diagnosis. In the present study, rituximab therapy was highly effective in pSS-ILD. Further prospective studies are needed to confirm these data. In patients with pSS-ILD, vigilance for pulmonary lymphoma is necessary, especially in the presence of persistent salivary gland enlargement, lymphophenopathy, paraproteinemia, pattern of organizing pneumonia and a lack of response to rituximab and cyclophosphamide therapy.

Background: Belimumab (BEL) is an approved systemic lupus erythematosus (SLE) treatment. Despite BEL clinical studies demonstrating a favourable benefit-risk profile, varying incidence rates of mortality and adverse events of special interest, including malignancies, require further evaluation.

Objectives: To assess long-term safety following BEL therapy. Methods: This was a a 4-year (Yr)-4 post-treatment follow-up of the Phase 4, double-blind, placebo (PBO)-controlled Belimumab Assessment of Safety in SLE (BASE) study (GSK Study BEL115467; NCT01705977). Overall, 403 adults with active, autoantibody-positive SLE received BEL (10mg/kg IV) or PBO, plus standard therapy (ST), for 48 weeks. Patients (pts) then entered a Yr-2-5 follow-up period in which they received physician-directed ST. All pts were contacted annually by telephone, including pts who discontinued treatment. Mortality and new malignancies (including nonmelanoma skin cancer) were the endpoints collected, and rates summarised. We present Yr-4 follow-up data by Yr-1 treatment received.

Results: Baseline characteristics for the Yr-4 follow-up population (N=3204) were similar to the Yr-1 double-blind study population (N=4003). By the Yr-4 follow-up, cumulatively 12.7% and 11.0% of pts in the BEL and PBO Yr-1 groups had received BEL as part of physician-directed care, respectively (data not shown). As shown in the Table, cumulative follow-up adjusted mortality rates were lower in the BEL vs PBO Yr-1 treatment group for Yrs 2 to 4. Cumulative follow-up adjusted new primary malignancy rates were lower in the BEL vs PBO Yr-1 treatment group for Yrs 2 and 3, but similar in Yr 4.

Conclusion: Post-treatment Yr-4 follow-up results in BASE, the largest double-blind trial in pts with SLE to date, support the safety of BEL therapy, with no new BEL safety concerns identified in this analysis.

Table 1. Proportion of pts who achieved CLASI-A scores of 0–1 and 0–3

Pts considered as treatment failures or who discontinued treatment were classified as non-responders at visits post treatment failure or treatment discontinuation. Pts who completed treatments at any time point were classified as non-responders for that timepoint.

Conclusion: After 16 weeks of treatment, greater proportions of participants with active disease treated with BEL achieved a clear and almost clear skin status, as defined as CLASI-A score of 0–1 or 0–3, further supporting the efficacy of BEL in CLE.

Background: Baricitinib (BAR), an oral selective inhibitor of Janus kinase 1 and 2 approved for the treatment of rheumatoid arthritis and atopic dermatitis, has been evaluated in clinical studies in patients with systemic lupus erythematosus (SLE)

Objectives: To assess the safety profile of BAR in patients with SLE.

Methods: Patients with SLE receiving stable background therapy were randomized 1:1:1 to BAR 2-mg, 4-mg, or placebo (PBO) once daily in one in 24-week, phase 2 (NCT02708095) and two 52-week, phase 3, PBO controlled studies (NCT03616912 and NCT03616958). The IR/100 PYR for serious adverse events (SAEs) were 9.5, 14.7, and 14.1 respectively for PBO, BAR 2-mg, and BAR 4-mg. There were no clinically meaningful differences between treatment groups for discontinuations due to AEs or death (Table 1).

</table>

Data are n (%) patients PYR; [IR; 95% CI]. #Phase 2 study data not included. AE=adverse event; CI=confidence interval; MACE= major adverse cardiac event; NMSC=non-melanoma skin cancers; VTE=venous thrombotic event (includes deep vein thrombosis and pulmonary embolism); IR=incidence rate (100 times the number of patients reporting an adverse event divided by the event-specific exposure to treatment); N=number of patients in the analysis population; n=number of patients in the specified category; PYR=patient-year of exposure; PYR=patient years at risk; SAE=serious adverse event. *p<0.05 vs placebo.

The IR/100 PYR for serious infections were 2.5, 4.5, and 5.9 respectively for PBO, BAR 2-mg, and BAR 4-mg. The risk of Herpes Zoster was higher in BAR 4-mg (4.0%) vs PBO (2.9%) (Table 1). The IR/100 PYR for potentially adjudicated venous thrombotic events (VTEs) were 1.4, 0.7, and 0.2 respectively for PBO, BAR 2-mg, and BAR 4-mg. The IR/100 PYR for potentially adjudicated major adverse cardiac event (MACE) was numerically higher in BAR 2-mg (0.2) and BAR 4-mg (0.7) vs PBO (0.0), however the pooled-BARI IR/ PYR (0.5) was within the range of background disease (1). No increased risk for malignancies was observed.

Conclusion: The safety profile of BAR in SLE patients was consistent with the known BAR safety profile. There was no increased risk of VTE in BAR treatment groups.

DOI: 10.1136/annrheumdis-2022-eular.2375
blood in RNA tubes (31 pts), cryopreserved PBMCs (15 pts), plasma (35 pts) and urine (2 pts). Whole blood RNA sequencing was performed using Illumina TruSeq. Differential expression was modelled using DESeq2. Fast pre-ranked gene set enrichment analysis (GSEA) was performed with gene sets derived from published literature. Cryopreserved PBMCs were analysed by flow cytometry to profile immune cell subtypes. Plasma protein was measured by Meso Scale Discovery (MSD) kits. Healthy volunteer (HV, N=12) samples were used to establish potential disease-related biomarker changes in patients at baseline (BL).

Results: Many gene modules were found to be altered at BL in SLE pts, relative to HV, including those representing interferon (IFN) response and B/plasma cell and changes were consistent with our prior report2. Comparisons of SLEDAI-2K responders (R) versus non-responders (NR) revealed enrichment of 193 gene modules (57 down and 136 up-regulated, p_adj,<0.1) at BL and 190 modules (105 down and 85 up) 4 weeks after treatment (W17). Expression of a 4-gene IFN module was enriched in SLEDAI-2K R vs NR at BL; expression of this module trended downward at W17 in R, whereas it increased over time in NR at W 5. Reduced numbers of circulating class-switched memory B cells and IgG-producing plasma cells were observed at W17 and/or W25. Plasma levels of BAFF were consistently increased at W5 but returned to BL levels by W17. Plasma levels of CD169/ SIGLEC-1, a monocyte activation marker, were higher at BL in SJC R vs. NR and were reduced after treatment in both groups. Two pts with active proliferative nephritis were enrolled into this study and both showed a reduction in levels of urine CD163 (uCD163), while plasma levels of this marker were stable.

Conclusion: Our integrative analysis indicates that KZR-616 elicits a potent effect on multiple immune pathways in SLE patients. Potential new biomarkers (gene, gene module, circulating protein) that may be useful for prediction of patient response were identified. Future biomarker studies in placebo-controlled trials may further our understanding of KZR-616 mechanism of action, patient selection and prediction of patient responses.

POS0716 EFFICACY AND SAFETY OF LOW-DOSE IL-2 IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Q. Y. Su1,2, J. Luo1,2,3, J.K. Di2,3, X.Y. Yin2,3, D.N. Xu2,3, X. Li1,2,3, C. Wang1,2,3, S.X. Zhang1,2,3, 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; 3Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by disturbances of regulatory and effector CD4+ T cells, which were regulated by interleukin (IL)-2.2

Objectives: The aim of this study was to systematically evaluate the efficacy and safety of low-dose IL-2 therapy in SLE treatment.

Methods: Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM and Technology Journal Database were performed. Original case reports, case series, observational studies and clinical trials reporting the efficacy or safety data on SLE patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I² and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).

Results: A total of 7 studies comprising 327 patients were identified (Table 1). After the low-dose IL-2 treatment, 54.8% Lupus nephritis patients had distinct clinical remission. The SRI-4 response rates were 0.816 (95% CI 0.730-0.901) and the SELENA-SLEDAI scores were significantly decreased [SMD=−2.504, 95% CI (−4.089,−0.919), P=0.002]. Injection site reaction and fever, which were common side effects for IL-2, occurred in 33.1% and 14.4% of patients, None serious adverse events were reported among all these studies. Besides, the proportions of CD4+ T cells and Tregs were significantly increased after IL-2 injection [SMD=0.600, 95% CI (0.429,1.908), P<0.002], while there were no statistical differences in the proportions of CD8+ T cells, Th17 cells, Th1 cells and Th2 cells between before and after IL-2 treatment (P>0.05)(Figure 1).

Conclusion: Low-dose IL-2 was promising and well-tolerated in the treatment of SLE, which could promote the proliferation and functional recovery of Tregs.

REFERENCES:
**OBJECTIVES:** To assess the effect of HCQ in cardiac conduction in a consecutive SLE population.

**Methods:** Observational, single University hospital study of all consecutive SLE patients with an electrocardiogram (EKG) at HCQ onset and at least one EKG in follow-up, with a period of at least 3 months on HCQ treatment was performed.

**Results:** We studied 109 (96 women/13 men) SLE patients with a mean (±SD) age of 61 ± 2.78 years. A statistically significant association was observed between the cHCQ, and the development of CA [OR 1.1 CI95% 1.02-1.9; p = 0.011] (Table 1 & Figure 1). A total of 8 covariates were included. Among those, that had the greatest influence on the development of the primary event were previous CA [OR 4.15 CI95% 6.39-24.24; p < 0.01]; valvular heart disease [OR 7.15 CI95% 1.31-38.91; p = 0.023] and age [OR 1.07 CI 1.0-1.14; p = 0.04].

**Conclusion:** According to our study, it seems to be an association between the cHCQ and development of CA regardless of other variables evaluated. Wider longitudinal studies are required with a protocolized EKG performance in successive visits to further analyze this association.

anti-thrombosis treatment. Currently there is an extreme paucity of effective and safe drugs for long-term management of TP in primary APS patients.

**Objectives:** We aimed to explore the efficacy and safety of sirolimus monotherapy.

**Methods:** In this real-world study, we included 7 consecutive patients with primary APS who received sirolimus monotherapy for TP. Oral sirolimus was initiated at a dose of 1-2 mg once daily and then adjusted primarily based on clinical efficacy and tolerance, with consideration of sirolimus trough concentration of ≤15 ng/mL.

**Results:** Of included patients, the median age was 58 years with median disease course of 1.5 years and 4 patients were treatment-naïve. All patients completed 6 months of sirolimus therapy with median follow-up of 6 months (range 1-15). All patients received sirolimus monotherapy for TP during entire follow-up, without adding any additional agents. Overall, platelet count exhibited substantially increasing trend after sirolimus administration during the first six months (p=0.001) and was stable later. Specifically, median platelet count was significantly increased from 59x10^9/L before sirolimus to 90x10^9/L at month 1 (p=0.028), 131x10^9/L at 3 months (p=0.028) and 178x10^9/L at 6 months (p=0.018). Overall and complete response were respectively achieved in 6 (85.7%) and 5 (71.4%) patients at month 6. Importantly, overall response was achieved in all 4 treatment-naïve patients. Additionally, there was different extents of decline in the titers of antiphospholipid antibodies after sirolimus treatment. Regrading safety, only one patient experienced elevated cholesterol level with recovery after atorvastatin treatment.

**Conclusion:** Sirolimus monotherapy confers good efficacy and tolerance for TP in primary APS patients, and therefore may be considered as a first-line therapy. Figure 1. Changes in platelets levels after sirolimus therapy in primary antiphospholipid syndrome patients with thrombocytopenia. (A) Platelet count of individual patient during the whole follow-up. (B) Median platelet count of included patients during the first six months.

**RAPID EFFICACY OF ANIFROLUMAB IN MULTIPLE SUBTYPES OF RECALSITRANT CUTANEOUS LUPUS PARALLELS DISCRETE CHANGES IN TRANSCRIPTOMIC AND CELLULAR BIOMARKERS.

L. M. Carter1, 2, 3, Z. Wigston4, P. Laws5, E. Vittal1, 2, 3 University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2 Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

**Background:** Cutaneous lupus erythematosus (CLE) is frequently refractory to immunosuppressive therapies including B-cell depletion, but this varies by morphology with the chronic discoid (DLE) subtype being particularly resistant. Local production and response to type-I interferon (IFN-I) is implicated in all subtypes of CLE. Therapeutic blockade of the IFN-I receptor with anifrolumab has direct effects on IFN-I signaling, and subsequent more widespread effects on other immune functions regulated by IFN-I [1]. Response to anifrolumab by lesion subtype have not been described, and it is unclear which effects of IFN-I blockade are responsible for cutaneous response. We hypothesis that the efficacy of anifrolumab will differ dependent on the relative contribution of direct IFN-I effects vs. the downstream immunostimulatory effects of IFN-I on other immune functions.

**Objectives:** To evaluate the effect of anifrolumab on (i) rituximab-refractory CLE; (ii) on DLE; (iii) to compare clinical responses with IFN-specific biomarkers and transcriptomic evaluation of broader immune responses; (iv) to compare early and late immunophenotypic and clinical responses.

**Methods:** SLE patients with active recalcitrant CLE were treated with anifrolumab 300 mg IV every 4 weeks and evaluated using the cutaneous lupus erythematosus disease area and severity index (CLASI) and dermatology life quality index (DLQI). Fluorescence intensity of latherin (CD317), a cell surface interferon biomarker, was evaluated on major cell subsets by multiparameter flow cytometry of peripheral blood mononuclear cells (PBMCs). Previously validated IFN-Score-A and B [2], in addition to gene expression scores annotated to inflammation, myeloid lineage and plasmablasts modules [3], were measured in PBMCs using customised Taqman array at baseline, 1 month and 3 months into treatment.

**Results:** 8 patients (DLE n=5, chillblain / nodular vasculitis n=2, subacute CLE n=1) have enrolled to date. One month clinical and biomarker data are now available for 5. Median number of previously failed standard therapies is 6, including rituximab in 6/8 patients, belimumab in 3/8 and thalidomide in 4/8. Four patients required long-term oral prednisolone >10 mg daily. Median baseline CLASI activity score was 16 and DLQI was 16/30. Rapid clinical responses were evident at 1 month in 4/5 patients, being greatest in magnitude in patients with SCLE and DLE compared with chillblain lesions. Median fall in CLASI activity score at 1 month was 6 points with a median percentage change from baseline of 31%. In all patients, a rapid and marked suppression of IFN-Score-A (mean difference 2.92, p<0.01) and plasmablast tethersin (p=0.01), was evident by 1 month. Small and variable downward trends were observed in inflammation- and IFN-Score-B (p=0.06), myeloid (p=0.27) and plasmablast (p=0.15) -annotated gene expression scores. Major cell population numbers were proportionally unaltered in flow cytometry.

**Conclusion:** These preliminary results suggest that anifrolumab: (i) may be effective in rituximab-resistant CLE, (ii) is effective in DLE; (iii) rapidly suppresses IFN-I response, but with lesser effects on non-IFN immune biomarkers and (iv) early direct effects on IFN-I are associated with rapid clinical response.

**LOW-DOSE GLUCOCORTICOIDS WITHDRAWN IN SYSTEMIC LUPUS ERYTHEMATOSUS: A DESIRABLE AND ATTAINABLE GOAL

L-J. J., D. Gao¹, Y. Hao¹, Z. Zhang¹. ¹Peking University First Hospital, Rheumatology, Beijing, China

**Background:** Prolonged use of GC may cause irreversible organ damage, leading to impaired quality of life and even increased mortality. However, many physicians are worried about severe flares after GC withdrawal in daily practice.

**Objectives:** To assess the risk of flare in systemic lupus erythematosus (SLE) patients after low dose glucocorticoids (GC) discontinuation and evaluate the risk factors of flare.

**Methods:** SLE patients who ever discontinued GC were identified from PKUFSH cohort. The disease flare profile after GC discontinuation were analyzed. Flare rate was analyzed using Kaplan-Meier analysis. COX regression was used to determine the effect of variables on SLE flare. A prognostic nomogram using Cox proportional hazards regression modeling were developed.

**Results:** 132 SLE patients were eligible for the final analysis. They were followed up for a median (IQR) period of 21.8 (9.01, 36.7) months. The cumulative probability of flare after GC discontinuation was 8.3% at 6 months, 16.8% at year 1 and 27.5% at year 2 (Figure 1A). In multivariate COX analysis, hypocomplementemia and serologically active clinically quiescent (SACQ) were independent risk factors of flare [HR 2.53, 95% CI (1.32, 4.88); HR 3.17, 95% CI (1.44, 6.97), respectively]. Age ≥ 40y at GC withdrawal and hydroxychloroquine usage were independent protective factors of flare [HR 0.53, 95% CI (0.29, 0.99); HR 0.32, 95% CI (0.17, 0.62), respectively] (Table 1). The protective effect of hydroxychloroquine was dosage related. From the prospective of different tapering strategies embodied as duration from prednisone 5mg/d to complete discontinuation, slower tapering strategy (12-24 months) significantly reduced the risk of flare compared to faster tapering strategy (< 3 months) [HR 0.53, 95% CI (0.29, 0.99), p=0.019]. The prognostic nomogram including aforementioned factors effectively predicted 1- and 2-year probability of flare-free (Figure 1B).

**Conclusion:** Low-dose GC is feasibly discontinued with infrequent flare in real-life setting. SACQ and younger age are potential risk factors of SLE flare,
while hydroxychloroquine usage and slow GC tapering to withdrawal can reduce relapse. The visualized model we developed may help to predict risk of flare among SLE patients who discontinued GC.

Background: Antiphospholipid Syndrome (APS) is a rare autoimmune disease characterized by thrombotic events and/or pregnancy morbidities in the presence of confirmed positivity for antiphospholipid antibodies (aPL). Complement was demonstrated to be involved in aPL-related pregnancy loss in animal models and several groups investigated the significance of complement levels in human disease. C3 and C4 serum levels were assessed in several cohorts of pregnant patients with APS and/or aPL positivity in order to relate complement consumption with adverse pregnancy outcome (APO).

Results: In this study, we demonstrated that aPL positivity and low preconception serum C3/C4 levels increased the risk of pregnancy complications. The addition of HCQ had not significantly improved pregnancy outcome. We have lastly evaluated 40 pregnancies with a high-risk profile preconception low C3/C4 levels the addition of HCQ had not significantly improved pregnancy outcome. When considering the whole cohort, the addition of HCQ had not significantly improved the gestational outcome. Further stratification was performed on the basis of complement consumption. In the group of patients with preconception low C3/C4 levels the addition of HCQ had not significantly improved pregnancy outcome. We have lastly evaluated 40 pregnancies with a high-risk profile (triple aPL positivity and complement consumption), in which we have found that HCQ significantly improved gestational outcome (p=0.018, Table 1).

This observation could not be confirmed in patients with single or double aPL positivity.

Conclusion: This study shows that administering HCQ in addition to combination therapy can improve gestational outcome in aPL/PAPS high-risk patients. This observation confirms that HCQ exerts a beneficial effect on aPL pregnancies by complement inhibition as it was shown in animal models. In addition, our results provide the clinicians a useful tool to implement conventional treatment in patients at high risk of pregnancy complication or loss.

Clonal Hematopoiesis of Indeterminate Potential and Accelerated Atherosclerosis in Systemic Lupus Erythematosus (Hematopoiesis Study)

C. David1, N. Costeoda-Chalumeau2, N. Duployez4, D. Belhadi6, V. Leguern9, P. Eloy2, C. Preudhomme3, J. Chezel1, N. Morel2, A. Mathian6, Z. Amoura5, T. Papo1, K. Sacre1 on behalf of the PLUS Study Group.

**Disclosure of Interests:** None declared

**Conclusion:** (HR= 0.42 (0.06 – 3.21), p=0.406).

Background: The detection of somatic mutations in genes of myeloid cells in asymptomatic patients - defining clonal hematopoiesis of indeterminate potential (CHIP) - predisposes to cardiovascular events (CVE) in the general population.

**Objectives:** We aimed to determine whether CHIP was associated with CVE in SLE patients.

**Methods:** The study is an ancillary study of the randomized, double-blind, placebo-controlled, multicenter trial PLU5 study conducted from June 2007 through August 2010 at 37 centers in France involving 573 SLE patients. The search for somatic mutations by high-throughput sequencing of 53 genes involved in clonal hematopoiesis was performed on genomic DNA collected at PLUS inclusion. The CHIP prevalence was assessed in SLE and in a retrospective cohort of 479 patients free of hematological malignancy. The primary outcome was the incident CVE in SLE.

**Results:** Screening for CHIP was performed in 438 SLE patients (38 [29-47] years, 91.8% female). Overall, 63 somatic mutations were identified in 47 patients defining a CHIP prevalence of 10.7% in SLE. Most SLE patients (78.7%) carried a single mutation. Most variants (62.5%) were located in the DNMT3A gene. CHIP was associated with age, age at SLE diagnosis and a lower frequency of antiphospholipid antibodies. CHIP occurred more than 20-years earlier (p<0.00001) in SLE than in controls. The detection of CHIP at inclusion was not associated with the occurrence of CVE during follow up (HR= 0.42 (0.06 – 3.21), p=0.406).

**Conclusion:** The prevalence of CHIP is high in SLE with respect to age but was not associated with incident CVE.

Dietary Habits and the Impact on Clinical Features in Primary Sjogren’s Syndrome

A. Alunno3, F. Carubbi4, F. M. Mariani1, M. Rossi1, P. Sipari1, D. Grassi1, C. Ferr1,1 Internal Medicine and Nephrology Unit, University of Udine, Department of Life, Health and Environmental Sciences, Udine, Italy

**Background:** In recent years, increasing evidence on the role of diet on chronic conditions, including cardiovascular diseases (CV) and rheumatic and musculoskeletal diseases (RMDs) has accrued. Most studies exploring the possible role of nutrients and dietary patterns on both the risk to develop RMDs in the general population and the natural history of the disease in patients with established RMDs pertain to rheumatoid arthritis. Data in patients with established primary Sjogren’s syndrome (pSS) is lacking.

**Objectives:** To explore dietary habits and their relationship with metabolic and inflammatory features in a cohort of patients with established pSS.

**Methods:** Consecutive patients with pSS were recruited and dietary habits over the previous 12 months were explored. Adherence to the Mediterranean Diet was assessed with the 14-item PREvencion con Dita Mediterrañea (PREDIMED) tool and the 28-item Mediterranean Lifestyle (MEDLIFE) index. Adherence to the Dietary Approaches to Stop Hypertension (DASH) was estimated using a score based on 8 food items. Tea/herbal tea and coffee intake were also explored and clinical/serological records were retrospectively collected.

**Results:** We enrolled 105 patients with pSS (95% females) with a mean age of 59 years. According to the PREDIMED score 32 (31%) patients had a good adherence to the Mediterranean Diet, 64 (61%) a medium adherence and only 9 (8%) a poor adherence. According to the DASH score, 74 (71%) patients had low adherence and 31 (29%) had high adherence. When dividing patients according to the extent of adherence to either of the dietary patterns and correlating the diet adherence scores to disease specific variables some associations emerged. The PREDIMED score was inversely correlated with disease activity, as measured by the EULAR Sjögren’s syndrome disease activity index (ESSDAI) (Spearman’s rho=−0.27, p= 0.009) and ClinESSDAI (Spearman’s rho=−0.26, p=0.01) revealing that a higher adherence to the Mediterranean Diet was associated with lower disease activity. With regard to the MEDLIFE, the total of blocks 1 and 2, that are related to Mediterranean foods and dietary habits, did not correlate with the total of block 3 (related to other healthy habits such as physical activity), meaning that the patients adhering the most to the Mediterranean Diet not necessarily had an overall healthy lifestyle. Adherence to DASH was not associated with disease activity. With regard to individual nutrients, fish consumption was associated with a lower prevalence of hypertension as observed in the general population. Higher intake of red meat was associated with higher values of self-reported pain (Spearman’s rho=−0.3; p=0.01) while high wholegrain intake was associated with a lower number of coexisting CV risk factors (OR=0.7; 95% CI=0.52-0.97; p=0.03).

**Conclusion:** Adherence to the Mediterranean Diet, with particular attention to high intake of fish and wholegrains and low intake of red meat, may be beneficial on various domains in pSS, such as the CV system and the inflammatory environment, and as such should be recommended to patients with this disease.

Risk Factors for Coronary Artery Disease in Chinese Patients with Systemic Lupus Erythematosus: A Multi-Center, Retrospective, Cohort Study

W. Qin1, J. Zhao6, Y. Wang5, L. Pan1, M. Li1 on behalf of the Beijing Systemic Lupus Erythematosus Co-Operated Group.

**Background:** Coronary artery disease (CAD) not only has an increased prevalence but also is a major cause of premature mortality in systemic lupus erythematosus (SLE) [1, 2]. However, information is limited regarding the risk factors for CAD in Chinese patients with SLE.

**Objectives:** To assess the risk factors for CAD in Chinese patients with SLE.

**Methods:** This multi-center, retrospective, cohort study included 3778 consecutive SLE patients, with CAD (CAD group) or without a medical history of CAD (control group). CAD was defined as a coronary stenosis ≥50% in any major epicardial coronary vessel detected by coronary angiography or a history of myocardial infarction confirmed by medical records. General parameters, clinical features, laboratory tests and medical therapies were compared between groups, and the risk factors for CAD in SLE were analyzed by logistic regression analysis.

**Results:** The age at baseline was older, male ratio was higher and body mass index was greater in CAD group (all P<0.001). Traditional CAD risk factors including diabetes mellitus, hypertension, dyslipidemia, family history of CAD and smoking were more common in CAD group (all P<0.001) (Figure 1). SLE Disease Activity Index 2000 was greater (P=0.012), hyperuricemia and elevated C-reactive protein (CRP) were more prevalent (both P<0.001), and an increased corticosteroids' usage (P=0.018) was detected in CAD group (Table 1). Binary logistic regression analysis showed hyperuricemia (odds ratio: 3.082, 95% confidence interval: 1.283-7.403; P=0.012) and CRP (odds ratio: 7.248, 95% confidence interval: 2.931-17.925; P=0.001) were independent risk factors for CAD in SLE patients.

**Figure 1.** Comparison of traditional risk factors in SLE patients between CAD group and control group. Abbreviations: CAD, coronary artery disease; SLE, systemic lupus erythematosus. All P<0.001.

1University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia; 2Faculty of Medicine, University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia; 3University of Ljubljana, Faculty of Medicine, University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Background: ACR/EULAR 2016 classification criteria for Sjögren disease (SS) use 5 standard questions on ocular and oral sicca symptoms as an entrance criterion. However, these questions do not differentiate between SS as an exit criterion. Recently, a new 5-item Sjögren’s Syndrome Screening Questionnaire based on SICCA study data was designed for the use in clinical practice, better differentiating SS from non-SS sicca patients.

Objectives: We aimed to validate the SSSQ in our population with sicca symptoms.

Methods: Our study cohort represented 535 patients referred to UMC Ljubljana during the 3-year period Jan/2016 to Dec/2019 with suspected SS. All subjects underwent at that time a standardized SS diagnostic procedure, including 5 standard sicca questions, Schirmer test, Rose Bengal test, unstimulated salivary flow test, salivary gland ultrasound, immuno-erological and lip biopsy. In Sep - Oct 2021 all subjects were contacted by phone to fulfill the new SSSQ (5 questions resulting in 0-11 points: cut-off for SS ≥7 points). The performance of SSSQ recognizing SS was assessed using ACR/EULAR 2016 classification criteria as gold standard test for SS diagnosis.

Results: A total of 525 subjects agreed to participate in the study (384 (92.5%) females, mean (SD) age 57 (13.8), the rests either declined (21), died (2) or could not be reached (97). Based on the ACR/EULAR 2016 criteria SS was diagnosed in 127 (30.6%) and excluded in 288 subjects. 376/415 (90.6%) subjects responded positively on 5 standard sicca questions (110 with and 266 without SS). In the new SSSQ 129 (31.1%) subjects (54 with and 75 without SS) responded positively (reached ≥7 points). The performance of SSSQ recognizing SS is presented in Table 1.

Discussion of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular.51
Conclusion: In Mexican people with SLE, a significant decrease in HRQoL was detected compared with controls. The implementation of a national register in Mexico (Lupus RGMX) will provide additional psychosocial and clinical information to deepen our knowledge of this disease.

ASSOCIATION BETWEEN TREATMENT GOAL ACHIEVEMENT AND GRIT PERSONALITY CHARACTERISTICS OF ATTENDING PHYSICIAN IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A MULTICENTER CROSS-SECTIONAL STUDY

Background: Systemic Lupus erythematosus (SLE) is an autoimmune disease with a wide spectrum of clinical manifestations and characterized by remission and flares. Recent epidemiological studies postulated that air pollution confers an increased risk of flare in various autoimmune diseases. Haze is a common phenomenon afflicting Southeast Asia (SEA), including Malaysia, and has occurred almost every year within the last few decades.

Objectives: This study was aimed to determine the correlation and association between SLE disease activity with exposure to inhalated Particulate Matter (PM<sub>x</sub>) and Nitrogen Dioxide (NO<sub>x</sub>).

Methods: SLE patients who attended rheumatology and nephrology clinic in University Kebangsaan Malaysia Medical Centre (UKMMC) from June 2019 until September 2019. Clinic visits with presence of infection or recent change of immunosuppressive treatment of ≤3 months were excluded. The average of daily concentrations of inhaled PM<sub>x</sub> (µg/m<sup>3</sup>) and NO<sub>x</sub> (ppb) were evaluated within 30 days preceding the clinic visits, and the data was obtained from Department of Environment (DOE) Malaysia. Comparison of the means was performed by Student’s t-test; and the correlations between PM<sub>x</sub> and NO<sub>x</sub> were determined by Pearson’s correlation coefficient. The associations between the effect of daily pollutant concentrations on M-SLEDAI and BILAG 2004 scores were analyzed using the generalized estimating equation (GEE) model, while considering fixed effects for repeated measures.

Results: A total of 46 patients were recruited with 603 clinic visits were recorded. A significantly higher NO<sub>x</sub> level was found in active disease patients with M-SLEDAI score (≥2.25 vs. 1.97; p=0.012) and BILAG 2004 A1 and B1 categories (≥2 vs. 1; p<0.001). In the GEE analysis, significant correlations were found between M-SLEDAI scores (r = 0.128, p=0.002) and BILAG scores with NO<sub>x</sub> (r = 0.142, p<0.001). In the GEE analysis, significant correlations were found between M-SLEDAI score and NO<sub>x</sub> (OR 1.27 (95% CI: 1.06-1.53), p=0.01) and BILAG score with NO<sub>x</sub> (OR 1.47 (95% CI: 1.15-2.18), p=0.002).

Conclusion: Our study suggests that air pollutant NO<sub>x</sub> exposure 30 days prior to clinic visit is associated with high disease activity among patients with SLE in Malaysia. Further prospective study is warranted to confirm this finding.

IMPACT OF AIR POLLUTANTS ON DISEASE ACTIVITY AMONG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN MALAYSIA

J. H. Jaafar1, S. S. Shahairi1, S. Rajalingham1, R. Mohd1, M. T. Latif2, 3Universiti Kebangsaan Malaysia Medical Centre (UKMMC), Internal Medicine, Kuala Lumpur Malaysia; 4Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Department of Earth Sciences and Environment, Bandar Baru Bangi, Malaysia

Background: Systemic Lupus erythematosus (SLE) is an autoimmune disease with a wide spectrum of clinical manifestations and characterized by remission and flares. Recent epidemiological studies postulated that air pollution confers an increased risk of flare in various autoimmune diseases. Haze is a common phenomenon afflicting Southeast Asia (SEA), including Malaysia, and has occurred almost every year within the last few decades.

Objectives: This study was aimed to determine the correlation and association between SLE disease activity with exposure to inhalated Particulate Matter (PM<sub>x</sub>) and Nitrogen Dioxide (NO<sub>x</sub>).

Methods: SLE patients who attended rheumatology and nephrology clinic in University Kebangsaan Malaysia Medical Centre (UKMMC) from June 2019 until March 2020 were recruited. Their medical records were reviewed for retrospective assessments of the disease activity using the Modified-SLE Disease Activity Index (M-SLEDAI) and The British Isles Lupus Assessment Group (BILAG) 2004 index from January 2015 until September 2019. Clinic visits with presence of infection or recent change of immunosuppressive treatment of ≤3 months were excluded. The average of daily concentrations of inhalated PM<sub>x</sub> (µg/m<sup>3</sup>) and NO<sub>x</sub> (ppb) were evaluated within 30 days preceding the clinic visits, and the data was obtained from Department of Environment (DOE) Malaysia. Comparison of the means was performed by Student’s t-test; and the correlations between PM<sub>x</sub> and NO<sub>x</sub> were determined by Pearson’s correlation coefficient. The associations between the effect of daily pollutant concentrations on M-SLEDAI and BILAG 2004 scores were analyzed using the generalized estimating equation (GEE) model, while considering fixed effects for repeated measures.

Results: A total of 46 patients were recruited with 603 clinic visits were recorded. A significantly higher NO<sub>x</sub> level was found in active disease patients with M-SLEDAI score (≥2.25 vs. 1.97; p=0.012) and BILAG 2004 A1 and B1 categories (≥2 vs. 1; p<0.001). In the GEE analysis, significant correlations were found between M-SLEDAI scores (r = 0.128, p=0.002) and BILAG scores with NO<sub>x</sub> (r = 0.142, p<0.001). In the GEE analysis, significant correlations were found between M-SLEDAI score and NO<sub>x</sub> (OR 1.27 (95% CI: 1.06-1.53), p=0.01) and BILAG score with NO<sub>x</sub> (OR 1.47 (95% CI: 1.15-2.18), p=0.002).

Conclusion: Our study suggests that air pollutant NO<sub>x</sub> exposure 30 days prior to clinic visit is associated with high disease activity among patients with SLE in Malaysia. Further prospective study is warranted to confirm this finding.

ASSOCIATION BETWEEN TREATMENT GOAL ACHIEVEMENT AND GRIT PERSONALITY CHARACTERISTICS OF ATTENDING PHYSICIAN IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A MULTICENTER CROSS-SECTIONAL STUDY

Background: Systemic Lupus erythematosus (SLE) is an autoimmune disease with a wide spectrum of clinical manifestations and characterized by remission and flares. Recent epidemiological studies postulated that air pollution confers an increased risk of flare in various autoimmune diseases. Haze is a common phenomenon afflicting Southeast Asia (SEA), including Malaysia, and has occurred almost every year within the last few decades.

Objectives: This study was aimed to determine the correlation and association between SLE disease activity with exposure to inhalated Particulate Matter (PM<sub>x</sub>) and Nitrogen Dioxide (NO<sub>x</sub>).
Results: The median age of the patients was 45 years (interquartile range [IQR]: 36-56), 88% were female, and the median disease duration was 152 months (IQR: 80-240). Thirty-seven doctors were in charge of the patients (1.79 patients mean doctor). The median age of the attending physicians was 40 years (IQR: 35-43), and 19% were female. The median perseverance and consistency respectively of attending physicians were 3.1 (IQR: 3.0-3.5) and 3.3 (IQR: 2.8-3.8). Of the enrolled patients, 154 (40%) had achieved LLDAS. The attending physicians with a lower consistency score of <3 were more frequent in the patients who achieved LLDAS (40% vs. 29%, p=0.026). The lower consistency score of all attending physicians was still related to LLDAS independently, adjusted odds ratio 1.63, 95% confidential interval 1.17-2.27. There was no association between the achievement of LLDAS and perseverance.

Conclusion: The grit personality characteristics of the attending physician may affect the achievement of treatment goals in patients with SLE.

A BETTER SELF-EFFICACY IS PREDICTIVE OF BETTER HEALTH-RELATED QUALITY OF LIFE (HRQOL) IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS. DATA FROM A LATIN AMERICAN MESTIZO COHORT

M. F. Ugarte-Gil1, R. V. Gamboa Cárdenas1, C. Reategui Sokolova1, V. Pimentel-Quizo2, M. Medina Chinchón1, C. Elera-Fitzcarrald2, Z. Rodríguez Belido1, C. Pastor Asurza1, R. Perich Campos3, S. Alarcon4,5,6

1Universidad Peruana Cayetano Heredia, School of Medicine, Lima, Peru; 2Hospital Nacional Guillermo Almenara Irigoyen, EsSalud, Rheumatology, Lima, Peru; 3Universidad San Ignacio de Loyola, Unidad de Investigación para la Generación y Síntesis de Evidencias en Salud, Lima, Peru; 4Universidad Nacional Mayor de San Marcos, School of Medicine, Lima, Peru; 5The University of Alabama at Birmingham, Birmingham, School of Medicine, Alabama, United States of America; 6Universidad Peruana Cayetano Heredia, School of Medicine, Lima, Peru

Background: Systemic lupus erythematosus (SLE) patients have a worse health-related quality of life (HRQoL) than the general population. This seems to be related to patients characteristics like age, poverty, behavioral issues rather than to disease activity or damage. Self-efficacy is defined as individual’s confidence on performing a task and could impact on patient-reported outcomes.

Objectives: To determine the possible predictive value of self-efficacy on HRQoL in SLE patients.

Methods: SLE patients from a single-center prevalent cohort were included. Self-efficacy was ascertained with six instruments of the Patient-Reported Outcomes Measurement Information System (PROMIS) Self-efficacy for Managing Chronic Conditions. Instruments included were general self-efficacy, and self-efficacy for managing emotions, managing symptoms, managing daily activities, managing social interactions and managing medications and treatments.

RESULTS: Among 519 SLE patients, 81% had a score ≤ 50 in at least one of the self-efficacy instruments (people with a chronic condition), a higher score indicates that the respondent has greater self-efficacy. HRQoL was ascertained with the physical and mental component summary (PCS and MCS) measures of the Short-Form 36 (SF-36). Generalized estimating equations were performed, using as outcome the PCS or MCS in the subsequent visit, and the self-efficacy instrument in the previous visit; multivariable models were adjusted for possible confounders (age at diagnosis, gender, socioeconomic status, SLEDAI-2K, SLICC/ACR damage index, disease duration at baseline, prednisone daily dose, antimalarial and immunosuppressive drugs use and PCS or MCS in the previous visit). All the confounders were measured in the same visit than the self-efficacy instrument.

RESULTS: Two-hundred and nine patients for a total of 564 visits were included; 194 (92.8%) patients were women, mean age at diagnosis was 36.4 (14.0) years and disease duration at baseline was 6.5 (6.0) years. At baseline, PCS was 55.0 (22.3) and MCS was 53.9 (20.4). At baseline, mean general self-efficacy was 47.2 (10.4), self-efficacy for managing emotions was 44.6 (8.0), for managing symptoms was 47.7 (8.2), for managing daily activities was 44.5 (7.5) for managing social interactions was 42.9 (7.9) and for managing medications and treatments it was 39.7 (9.7). In the multivariable models a better self-efficacy was predicted by a better general self-efficacy, and self-efficacy for managing symptoms, managing social interactions and managing medications and treatments and a better MCS was predicted by a better self-efficacy for managing symptoms, managing daily activities, managing social interactions and managing medications and treatments.

Background: Salivary gland ultrasound (SGUS) is a simple and non-invasive procedure that is readily available and supplies important information on the major salivary glands. Several recent studies have assessed SGUS as a tool for diagnosing primary Sjögren’s syndrome (pSS), and have reported its association with different features in pSS.

Objectives: To investigate the association of SGUS findings with clinical, histological, and serological features of pSS in our cohort. In addition, we include nonmonospecific antibody determination to Ro60 or Ro52.

Methods: Patients with pSS were determined according to the American-European Consensus Group (AECG) criteria for pSS. A total of 53 of these pSS patients underwent SGUS evaluation. We considered SGUS score based on parenchymal homogeneity, presence of hypoechogenic areas, and clearness of posterior glandular border of salivary glands. The score of the highest graded gland was considered and a score ≥2 was defined as a positive SGUS, according to OMERACT US-SG scoring [1]. Patients were classified into two groups according to positive vs. negative SGUS. Demographic, clinical, histopathological, and laboratorial data were collected and compared between the groups. Categorical variables were compared using the Chi-square test or Fisher’s exact test when the conditions for Chi-square test were not met, and continuous variables were compared using Student’s t-test with Welch’s correction. p-values <0.05 were considered significant.

Results: Study participants were predominantly women (98%) and had a mean age of 60.2 years. SGUS was positive in 32 (63%) pSS patients, they were all women and had a mean age of 59 years. Positive SGUS was associated with objective evidence of ocular involvement (defined as a positive result for at least one of the ocular tests, p<0.001), time of evolution of xerophthalmia at diagnosis (mean 5.8 years vs. 2.2 years, p=0.037), pathological result of the labial salivary gland biopsy when it was performed (p<0.001), and the presence in the serum of both antiRo60 and antiRo52 antibodies (p=0.004), antiLa antibody (p=0.008) and ANA titer ≥1:320 (p<0.001). No significant differences were found between positive SGUS and negative SGUS patients regarding the presence of xerophthalmia nor xerostomia, time of evolution of xerostomia at diagnosis, episodes of parotid inflammation, abnormal salivary scintigraphy, or the presence in the serum of monospecific antiRo52 nor antiRo60 in the absence of each other, nor positive rheumatoid factor.

Conclusion: Positive SGUS was associated in pSS patients with objective evidence of ocular function, histopathology of minor salivary glands, and serology of pSS, specifically the presence of both antiRo52 and antiRo60 antibodies. In our cohort, no significant association was found regarding xerostomia, episodes of parotid inflammation, nor objective evidence of oral involvement. Thus, SGUS could be a useful tool to establish objective salivary gland involvement, independently of oral symptoms and other oral tests.

REFERENCES:
CONCLUSION: Low correlation between PGA and PtGA suggests both should be used to acquire a broad perspective of the impact of disease on the overall health of patients. Different baseline characteristics were associated with the PGA-higer compared to the PtGA-higher discordant subgroups.

THE CLINICAL JUDGMENT FOR THE ACCEPTABILITY OF PREGNANCY IN PATIENTS WITH SEROLOGICALLY ACTIVE SLE IN JAPAN: A NATIONAL WIDE ONLINE SURVEY FROM THE VIGNETTE STUDY

S. Isoiina,1 N. Yajima,1 R. Yanai,1 Y. Miura,2 S. Fukuma,2 K. Kaneko2, K. Fujio3, K. Oku4, M. Matsushita5, T. Miyamae5, T. Wada5, Y. Kaneko6, Y. Tanaka6, A. Nakajima5, A. Murashima1,1 Showa University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; 2Kyoto University, Department of Healthcare Epidemiology, School of Public Health in the Graduate School of Medicine, Kyoto, Japan; 3National Center for Child Health and Development, Division of Maternal medicine, Center of Maternal-Fetal, Neonatal and Reproductive Medicine, Tokyo, Japan; 4The University of Tokyo, Department of Allergy and Rheumatology, Graduate School of Medicine, Tokyo, Japan; 5Kitasato University, Department of Rheumatology and Infectious Diseases, Sagamihara, Japan; 6Juntendo University School of Medicine, Department of Internal Medicine and Rheumatology, Tokyo, Japan; 7Tokyo Women’s Medical University Hospital, Department of Pediatric Rheumatology, Institute of Rheumatology, Tokyo, Japan; 8Kanazawa University, Department of Nephrology and Laboratory Medicine, Kanazawa, Japan; 9Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; 10University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan; 11Mie University Graduate School of Medicine, Division of Rheumatology, Tsu, Japan

Background: The risk of pregnancy complications, such as gestational hypertension, is high in pregnancies with SLE. In addition, the risk of flare is elevated if pregnancy occurs during the high disease activity. The EULAR recommendation provides a checklist for preconception counseling, in which patients with SLE desiring pregnancy were required the condition that the disease activity prior to pregnancy should be stable for 6-12 months in terms of serological activity (1). However, it does not provide specific criteria for serological activity so that physicians should evaluate the risk of pregnancy in each case by their clinical intuitions.

Objectives: In order to uncover the present clinical situation for the acceptability of pregnancy in patients with SLE, we performed questionnaire survey to physicians regarding to the degree of serological activity.

Methods: This cross-sectional study was performed to physicians registered with the Japanese College of Rheumatology from December 2020 to January 2021 using the online survey. The questionnaire asked about the demographics of physicians, facilities and the permission of pregnancies with SLE using vignette scenarios. In this study, data from vignettes of women visiting a regular outpatient clinic were used. The vignettes varied in age (28 or 35 years), duration of stable disease and serological activity. Analysis methods were descriptive statistics, chi-square test, generalized estimating equations (GEE) was performed to investigate the relationship between the determining permission for pregnancy and the scenario patient’s characteristics (age, period of stable disease, titer of anti ds-DNA antibody).

Results: The questionnaire was distributed to 4946 physicians, and 463 responded. Completion rate (ratio agreed to participate/finished survey) of survey was 91.1%. The median age of physicians was 46 (interquartile range (IQR) 2-10). The specialty was rheumatology (84.9%), other internal medicine (8%), and pediatrics (5.6%). There were no significant differences in patient’s age about the acceptability of pregnancy (coefficient -0.02, 95% CI -0.17 -0.01, p=0.42). Case who had been stable for 6 months were more tolerant of pregnancy than case who had been stable for 3 months (coefficient 0.12, 95% CI 0.09-0.15, P<0.001) Pregnancy was not allowed in case with mild or high serological activity (mild: coefficient -0.49, 95% CI -0.29 --0.22, p<0.001, high: -0.64, 95% CI -0.65 - -0.61, p <0.001). In contrast, as many as 92 (19.2%) physicians tolerated pregnancy even in the presence of residual high anti ds-DNA antibody titers. Female physicians are significantly more cautious about pregnancy than male when patients have a serologically high activity (12% vs 37.5%, p<0.001). There were no significant differences in specialty status or clinical experience.

Conclusion: We found that even mild serological activity alone had a significant negative effect on the physician’s decision to allow pregnancy. We conclude that current physicians make cautious decisions about pregnancies of patients with SLE following the recommendation. On the other hand, an additional investigation should be performed about the results of pregnancies in patients with serological abnormalities, since there are some physicians who thought that pregnancy may be acceptable for patients with only serological abnormalities if the clinical symptoms are stable.

EFFECT OF OSTEOPOROSIS ON MAJOR ADVERSE CARdiovascular EVENTS (MACES) AND MORTALITY IN SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL STUDY

C.C. Mo1, K.L. Chan2, L.Y. Ho1, C.H. To1. 1Tuen Mun Hospital, Medicine, Hong Kong, China; 2Tuen Mun Hospital, Medicine, Hong Kong, China; 3Pok Oi Hospital, Medicine, Hong Kong, China

Objectives: To study the effect of osteoporosis on major adverse cardiovascular events (MACES) and mortality in a longitudinal cohort of patients with systemic lupus erythematosus (SLE).

Methods: Patients who fulfilled ≥4 1997 ACR criteria for SLE and participated in a cross-sectional study on osteoporosis in the year 2011 were studied. All patients had a dual energy x-ray absorptiometry (DXA) scan (Delphi densitometer; Hologic, Bedford, USA) performed between the years 2004-2008 and were followed in the rheumatology clinics by the same team of physicians. The incidence of new MACES, which were defined as ischemic vascular events (acute coronary syndrome, stroke, peripheral vascular disease) documented by imaging and angiographic studies, was evaluated. Patients were stratified into 2 groups according to the presence of osteoporosis at baseline, which was defined as a DXA T score of <-2.5 or Z score <-2.0 at the hip, femoral neck or lumbar spine, or having a past history of fragility fractures. The effect of osteoporosis on the development of MACES and mortality was studied by Cox regression analysis, adjusted for demographic characteristics, traditional cardiovascular risk factors, antiphospholipid antibodies and the use of medications.

Results: 383 SLE patients were studied (age at DXA scan 40.5±13 years; 94% women; SLE duration 8.0±7.4 years). Osteoporosis at the hip, femoral neck or spine at baseline was present in 105 patients (13 with old fragility fractures) and 8 patients had osteoporosis and past fragility fractures. The demographic characteristics, prevalence of traditional atherosclerotic risk factors and antiphospholipid (aPL) antibodies (lupus anticoagulant or moderate/high titer of IgG-anticardiolipin antibodies) were not significantly different between those with osteoporosis/fracture (N=113) and without (N=270). Patients with osteoporosis/fracture were more likely to be using glucocorticoids (79% vs 62%; p=0.002) and mycophenolate mofetil/azathioprine/calcineurin inhibitors (58% vs 48%; p=0.08) but less likely to be treated with hydroxychloroquine (40% vs 51%; p=0.051) at baseline. Over a follow-up of 153±41 months, 44 new MACES (acute coronary syndrome [n=19]; ischemic stroke [n=19]; peripheral vascular disease with digital gangrene/amputation [n=6]) developed in 42 patients. The incidence of MACES was significantly higher in patients with osteoporosis/fracture than those without (1.59 vs 0.63/100 patient-years; p<0.001). The cumulative risk of new MACES at 3, 5 and 10 years was 6.3%, 11.7%, 14.7%, and 0.4%, 19.4%, 4.7%, respectively, in the osteoporosis and non-osteoporosis groups (log rank test; p=0.002; univariate hazard ratio 2.58 [1.40-4.74]; p=0.002). In a Cox regression model, osteoporosis/fracture remained an independent risk factor for the development of MACES after adjustment for age, sex, LDL level, atherogenic index, diabetes mellitus, hypertension, past MACE, aPL antibodies, smoking, obesity and the use of medications that included immunosuppressive drugs, aspirin/warfarin, statins, vitamin D and bisphosphonates (HR 2.41 [1.25-4.67]; p=0.009). At last follow-up, 62 (16%) patients succumbed (MACES in 8 patients [vascular mortality], infective complications in 27 patients, cancer in 10 patients). Osteoporosis/fracture was associated with vascular mortality (HR 11.1 [2.02-120]; p=0.048) but not with all-cause mortality (HR 1.55 [0.89-2.68]; p=0.12) after adjustment for the same covariates in separate multivariate models.

Conclusion: Osteoporosis increases the risk of MACES and vascular mortality in patients with SLE, which is not accounted by traditional vascular risk factors. Elevation of inflammatory cytokines in SLE that are common to bone metabolism and atherosclerotic vascular disease may be responsible.

Disclosure of Interests: None declared.

SICCA SYNDROME: A MULTIMODAL ASSESSMENT TO CHARACTERIZE PATIENT COHORTS BEYOND SJÖGREN’S SYNDROME: CLINICAL CRITERIA

E. Kramer1, T. Seelig2, T. Skripuletz2, V. Gödecke3, S. Belder1, A. Jablonka1, T. West2, D. Ernst1. 1Medizinische Hochschule Hannover, Rheumatology and Immunology, Hannover, Germany; 2Medizinische Hochschule Hannover, Neurology, Hannover, Germany; 3Medizinische Hochschule Hannover, Centre of Rare Diseases, Hannover, Germany

Background: Sjögren syndrome represents a heterogeneous group of conditions, including Sjögren syndrome, causing xerophthalmia and xerostomia. Objectives: This study characterizes in depth patients with Sicca syndrome and evaluates salivary gland ultrasound (SGUS) in this cohort. Methods: Principal component analysis and hierarchical clustering of clinical parameters, including ESSPRI, ESSDAI and laboratory data, were performed on all referrals for assessment of Sicca symptoms over the period from October 2018 and March 2021. SGUS and salivary gland biopsies were compared across groups.

Results: 583 patients were assessed. Objective dryness was confirmed in 73% of patients. Cluster analysis identified 3 groups with post-hoc analysis confirming distinct phenotypes: Somatic Group (283/583; 49%) with higher reported symp- toms but limited objective dryness; Dry Without Autoimmune Features (DAF 206/532; 35%) and Dry With Autoimmune Features (DAF 94/532; 17%). DAF patients had highest autoantibody titres (SSA 240 vs 3.6 vs 3.8; p<0.001), most extra-glandular manifestations (p<0.001) and highest median SGUS Score (DAF 8 [4-10] vs SG 2 [1-4] vs DAF 4 [2-5]; p<0.01). No tangible correlation primary Sjögren syndrome criteria was observed.

Conclusion: A multimodal assessment of Sicca syndrome patients identified in the DAF cluster. This study highlights heterogeneity within Sicca and indeed Sjögren syndrome, highlighting the need for further studies.

Disclosure of Interests: None declared.

IMMUNOGENICITY AND SAFETY OF COVID-19 VACCINATION IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

G. M. Verstappen,1 L. De Wolf,1 S. Arends,1 H. M. Heiermann,1 Y. Van Steen,1 A. Visser,1 J. H. Terpstra,2 D. Diamatopoulos,1,2,3 M. Van der Heiden,1 A. Vissink,1 D. Van Baarle,4,6, F. G. M. Kroese,1, H. Bootsma,1 1University of Groningen, University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2Radboud University Medical Centre Nijmegen, Radboud Centre for Infectious Diseases, Nijmegen, Netherlands; 3Radboud University Medical Centre Nijmegen, Laboratory of Medical Immunology, Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands; 4University of Groningen, University Medical Centre Groningen, Medical Microbiology and Infection Prevention, Nijmegen, Netherlands; 5University of Groningen, University Medical Centre Groningen, Oral and Maxillofacial surgery, Groningen, Netherlands; 6National Institute of Public Health and the Environment, Centre for Infectious Disease Control, Bilthoven, Netherlands

Background: Patients with primary Sjögren’s syndrome (pSS) worry about the effectiveness and safety of COVID-19 vaccination. pSS is characterized by B-cell hyperactivity, and previous influenza vaccination studies showed that pSS patients generate higher influenza-specific antibodies than healthy controls (HC). Furthermore, influenza vaccination resulted in elevated auto-antibody levels. Therefore, it is hypothesized that COVID-19 vaccination may also lead to a higher spike-specific antibody response.

Objectives: To evaluate humoral and cellular immune response and adverse events (AEs) after COVID-19 vaccination in pSS patients compared to HC, and disease activity following vaccination in pSS patients. Furthermore, to evaluate change in spike-specific antibody levels in saliva and anti-SSA levels in serum following vaccination.

Methods: In this prospective, longitudinal cohort study, pSS patients and HC were included in a 2:1 ratio. Participants received COVID-19 vaccinations following the Dutch vaccination programme. pSS patients did not use...
immunomodulatory drugs, except hydroxychloroquine (HCQ). Anti-spike 1 (S1) receptor binding domain (RBD) IgG serum antibody levels were measured 28 days after complete vaccination. AEs were collected 7 days after vaccination. Change in disease activity following vaccination was measured with EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI) and EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI). In a subgroup of participants, spike-specific T-cell response was measured 7 days after complete vaccination with IFN-γ ELispot. Definition of a T-cell responder was ≥2-fold increase in spot-forming cell (SFC) counts from pre- to post-vaccination and SFC counts of ≥50/10⁶ cells in the post-vaccination sample. Salivary anti-S1 and anti-RBD antibodies and serological anti-SSA antibodies were also measured in this subgroup in pre- and post-vaccination samples (28 days after complete vaccination).

Results: In total, 67 pSS patients and 33 HC were included. Of these, 47 (70%) and 14 (42%) received BNT162b2 (Pfizer-BioNtech), 13 (19%) and 5 (15%) received ChAdOx1 nCoV-19 (AstraZeneca), 6 (9%) and 8 (24%) received mRNA-1273 (Moderna), and 1 (1%) and 6 (18%) received Ad.26.COV2.S (Janssen), respectively. Overall, pSS patients were significantly older than HC, which was mainly due to the younger age in the Moderna and Janssen groups. All participants had positive anti-SARS-CoV-2 antibody levels (>2500 AU/ml) post-vaccination. No differences in anti-SARS-CoV-2 antibody levels were observed between pSS patients and HC, for any of the vaccine types (Figure 1). Percentage of spike-specific T-cell responders was comparable between pSS patients (20/24, 83%) and HC (4/5, 80%). Salivary anti-SARS-CoV-2 IgG antibodies, but not IgA, increased post-vaccination in pSS patients (n=26) and HC (n=9). Salivary anti-RBD IgG antibodies were significantly correlated with serum anti-RBD antibodies (r=0.597, p<0.001).

Conclusion: pSS patients had similar humoral and cellular immune responses as HC, providing evidence that COVID-19 vaccination is effective in pSS patients. AEs were also comparable, and no increase in disease activity was seen in pSS patients, indicating COVID-19 vaccination is safe in pSS patients.

Impact of time to remission, flares and exposure to immunosuppressives on the development of advanced chronic kidney disease (stage IV or worse) in lupus nephritis

K. Tselios1, D. D. Gladman2,3, J. Su2, M. B. Urowitz2,3, 4McMaster Lupus Clinic, Department of Medicine, Hamilton, Canada; 5University Health Network, Schroeder Arthritis Institute, Toronto, Canada; 6University of Toronto, Department of Medicine, Toronto, Canada

Background: Lupus nephritis (LN) affects up to 40% of patients with SLE and leads to end stage kidney disease (ESKD) in 17-33% after 10 years. The prevalence of chronic kidney disease stage IV (estimated glomerular filtration rate, eGFR=15-29mL/min/1.73m²) is not known; however, approximately two thirds of such patients will progress to ESKD after 6 years on average.1

Objectives: To determine the impact of time to remission and flares on the development of advanced CKD (stage IV or worse) in LN.

Methods: Patients with LN based on biopsy or abnormal proteinuria (>0.5g/day) with or without hematuria/pyuria/casts for two consecutive visits in the absence of other plausible explanation were retrieved from the Toronto Lupus Clinic database. Individuals with advanced CKD at baseline were excluded. All patients were followed for at least 5 years. The primary outcome was the development of advanced CKD (eGFR<20mL/min/1.73m²). Remission was defined as proteinuria<0.5g/24h, no active urinary sediment and serum creatinine ≤120% of baseline. Flare was defined as any abnormal proteinuria (>0.5g/day) after remission to outcome/last date. Death was treated as competing risk in survival analysis. Statistical analysis with SAS 9.4; p<0.05 was considered significant.

Results: Out of 418 eligible patients, 209 (50%) achieved remission within the first year from LN diagnosis, 102 (24.4%) within the 2nd and 3rd years, 70 (16.7%) after 3 years and 37 (9.9%) never achieved remission. Sixty-six patients (15.8%) developed advanced CKD after 9.5 years on average (37 with ESKD). At baseline, these patients had a higher SLICC/Damage Index (0.6±1.2 vs. 0.3±0.7, p=0.046), proliferative nephritis (combined class III and IV, 66% vs. 47.8%, p=0.017) and more often treated with ACE inhibitors or angiotensin receptor blockers (35% vs. 22%, p=0.02). The other variables did not differ significantly. Remission rates, flares and exposure to immunosuppressives after remission are shown in Table 1.

Patients who achieved remission within one year from diagnosis demonstrated better outcomes compared to all other groups (p<0.0001), Figure 1. Patients with complete remission between one and three years had similar outcomes for the first 10 years from diagnosis and deteriorated during the second decade of follow-up.
Conclusion: Complete remission within the 1st year from LN diagnosis strongly protects against advanced CKD. Flares significantly affect prognosis. One flare was associated with 2.7-fold increased risk for advanced CKD (3.6-fold for 2 or more flares). Longer time on immunosuppressives after remission is associated with decreased risk for advanced CKD. Our findings emphasize the importance of early remission as well as flare prevention with prolonged immunosuppressive use to maximize renal survival in LN.

Figure 1.

Results: A structured survey was circulated among 30 experts. Up to 90% of the interviewed experts agreed on defining aPL negativization as the presence of two negative determinations, one year apart (90%). Almost full consensus exist among experts in some clinical settings, including: a) the role of aPL negativization in the management of a thrombotic event determined by concomitant presence of cardiovascular risk factors, both modifiable and not modifiable (90%); b) approach to young patients with triple aPL positivity who experienced pulmonary arterial thrombotic event and tested negative for aPL detection after five year of vitamin K antagonist (VKA) treatment (90%); c) the use of “extra criteria” aPL antibodies testing before pondering VKA suspension (93%).

Conclusion: Consensus is needed to support the management of patients with APS in areas where controlled data are missing. A substantial agreement exists among expert in defining aPL negativization as the presence of two negative determinations, one year apart. On the contrary, VKA suspension should be embraced with extreme caution when it comes to APS patients, particularly if they experienced arterial thrombotic events and/or tested positive for triple aPL. Nevertheless, VKA cessation might be considered when risk factors are carefully monitored/treated and the presence for “extra criteria” aPL is ruled out.

REPORT FROM THE APS STUDY GROUP OF THE ITALIAN SOCIETY FOR RHEUMATOLOGY (SIR-APS) ON APL NEGATIVIZATION

S. G. Fodda1, S. Sciascia2, C. Alessandri2, A. Alunno3, L. Andreoli4, A. Barinotti1, A. Calligaro5, V. Canti6, F. Carubbi7, I. Cecchi1, C. Chighizola8, A. G. Sebastiani15, F. Conti2, G. Emmi9, A. Fioravanti10, F. Fischetti11, F. Franceschini, M. Gerosa8, A. Hoxha2, M. Larosa2, G. M. Lazzaroni2, C. Nalli1, G. Pazzola12, M. Radin1, B. Raffeiner13, V. Ramoni14, D. Roccatello1, E. Rubini1, G. Sebastiani13, S. Truglia2, M. L. Urban9, A. Tincani1 on behalf of SIR-APS.

Background: The rate of antiphospholipid antibodies (aPL) negativization in antiphospholipid syndrome (APS) patients is uncertain, but it is estimated to be as high as 8%. aPL disappearance seems to be more frequent in patients with primary antiphospholipid syndrome when antiphospholipid antibodies became persistently negative. Nevertheless, VKA cessation might be considered when risk factors are carefully monitored/treated and the presence for “extra criteria” aPL is ruled out.

Methods: Experts of SIR-APS were contacted using a survey methodology.

Results: A structured survey was circulated among 30 experts. Up to 90% of the interviewed experts agreed on defining aPL negativization as the presence of two negative determinations, one year apart (90%). Almost full consensus exist among experts in some clinical settings, including: a) the role of aPL negativization in the management of a thrombotic event determined by concomitant presence of cardiovascular risk factors, both modifiable and not modifiable (90%): b) approach to young patients with triple aPL positivity who experienced pulmonary arterial thrombotic event and tested negative for aPL detection after five year of vitamin K antagonist (VKA) treatment (90%); c) the use of “extra criteria” aPL antibodies testing before pondering VKA suspension (93%).

Conclusion: Consensus is needed to support the management of patients with APS in areas where controlled data are missing. POS0742

DISCRIMINATIVE POWER OF SALIVARY GLAND ULTRASOUND IN RELATION TO ENDOTYPES IN SUSPECTED AND DEFINITE PRIMARY SJÖGREN’S SYNDROME

L. Deore2, H. Achten1,2, K. De Boeck1, E. Genbrugge1, W. Bauters3, D. Roels4, I. Piypko5, F. Doych6, D. Creytens7, D. Elewa7,8, I. Peene9,10, Genth University Hospital, Rheumatology, Ghent, Belgium; 10VIB-Ugent. Center for Inflammation Research, Ghent, Belgium; 2Genth University Hospital, Radiology, Ghent, Belgium; 3Genth University Hospital, Ophthalmology, Ghent, Belgium; 4Genth University Hospital, Dentistry, Ghent, Belgium; 5Genth University Hospital, Head and Neck Surgery, Ghent, Belgium; 6Genth University Hospital, Pathology, Ghent, Belgium; 7AZ Sint-Jan, Rheumatology, Bruges, Belgium

Background: Primary Sjögren’s Syndrome (pSS) is an auto-immune disease with characteristic complaints of oral and ocular dryness, typically affecting adult women. In addition, up to 30-40% of patients suffers from systemic manifestations and lymphoma risk is increased 15-20 fold. pSS is thus highly heterogenous both in presentation and pathophysiology. In an attempt to address this issue Tarr et al. applied cluster analysis based on patient reported outcomes assessing dryness, fatigue, pain and features of anxiety and depression, on a population of pSS patients. This resulted in four groups: low symptom burden (LSB), pain dominant with fatigue (PDF), dryness dominant with fatigue (DDF) and high symptom burden (HSB). These groups, referred to as endotypes, also seemed to have different biological profiles.(1)

Objectives: The aim of this study was to explore salivary gland ultrasound (SGUS) in relation to symptom-based endotypes in a cohort of patients with definite and suspected pSS.

Methods: Data from the Belgian Sjögren’s Syndrome Transition Trial (BeSSTT) were used in which patients positive for at least one of the 2016 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) classification criteria, were enrolled. Patients were considered ‘definite pSS’ when fulfilling these criteria and ‘suspected pSS’ otherwise. The Newcastle Sjögren’s Stratification Tool, developed and provided by J. Tarr and colleagues, was applied to stratify the cohort into endotypes. Hovecar score (0-48) was used to assess SGUS abnormalities. Scores of at least 17 were considered positive.

Results: Stratification of the BeSSTT (n=241) cohort resulted in 4 endotypes, both in definite (n=141) and suspected pSS (n=100). The proportion of anti-SSA positive patients was high in definite pSS in all endotypes (91.9%; p=0.239). This proportion was significantly lower in suspected pSS patients in all endotypes.
SALIVARY GLAND UPSTAGE (SGUS) AS A DRIVING FACTOR FOR DEFINING PATIENTS WITH SLE WITH MUSCULOSKELETAL INVOLVEMENT

A. Vadharia1, J. Birt2, J. Wu3, K. Griffling4, F. Bailey5, J. Hetherington5, E. Rotter2, S. Barlow6, K. Costenbader7,8,9 Eli Lilly & Co, Indianapolis, United States of America; 1Adelphi Real World, Bollington, United Kingdom; 2Birmingham and Women’s Hospital, Division of Rheumatology, Inflammation and Immunity, Boston, United States of America

Background: Limited information exists concerning the clinical burden and unmet need of musculoskeletal (MSK) organ involvement among patients with SLE in clinical practice.

Objectives: To examine demographics, clinical status, treatment patterns, and patient-reported outcomes (PROs) among patients with SLE in clinical practices and assess the impact of MSK organ involvement.

Methods: Data were drawn from the Adelphi Real World Lupus IV (2021) Disease Specific Programme™, a point-in-time survey of 79 US physicians and their patients with SLE. Physicians completed questionnaires regarding patient demographics, clinical status, and treatment. The same patients were invited to complete questionnaires containing the EuroQol 5-Dimensions (EQ-5D), Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACT-Fatigue) and Work Productivity & Activity Impairment questionnaire (WPAI) PRO tools. Physicians stated their patients’ organ involvement at the time of data collection (current), in the categories of musculoskeletal, mucocutaneous, renal, cardiorespiratory, constitutional, haematologic, ophthalmologic, gastrointestinal, respiratory, or other. Two mutually exclusive patient groups were analysed: A.MSK – Current physician assessed musculoskeletal organ involvement (+/- other organ/tissue involvement). B.Non-MSK – No current musculoskeletal organ involvement as assessed by the physician Bivariate analysis was conducted for numeric variables using t-tests; binary categorical variables using a Fisher’s exact test; ordinal categorical variables using a Mann-Whitney test; and other categorical variables were compared using a chi-squared test.

Results: A total of 595 patients were included in this analysis: 64.7% MSK and 35.3% non-MSK. Mean(SD) patient age was 45.2(13.4) years, 83.2% were female, 53.3% were White/Caucasian, 27.9% were African American, and mean(SD) time diagnosed with any SLE was 5.3(6.2) years. Point-in-time assessment of clinical status, treatment patterns and patient-reported outcomes, revealed that those with MSK organ involvement assessed by their rheumatologist had higher overall SLE disease severity, more flares in the last 12 months, and slightly worse quality of life scores and work impairment.

| Conclusion: In this large sample of patients with SLE followed in clinical practices in the U.S., compared to those with little or no rheumatologist assessed MSK involvement, those with MSK involvement had lower quality of life, with higher impact on their work productivity. These results highlight the heterogeneity of SLE and the impact of major MSK manifestations on quality of life in SLE.

The active MSK group used more anti-malarias (50.9 vs. 30.7%), immunosuppressants (37.2 vs. 26.5%), including methotrexate (12.6 vs. 3.3%), narcotic analgesics (18.6 vs. 10.2%), and topicals for joint pain (30.5 vs. 10.2%). Interestingly, treatment goals of greatest importance in both groups were reduction in fatigue and pain, but pain reduction had higher importance in active MSK group (rated very important by 26.7 vs. 18.1%). Lower proportions in the active MSK group were satisfied with steroids (58.0 vs. 77.8% <0.01), immunosuppressants (65.1 vs. 80.7% <0.05), methotrexate (472 vs. 85.7% =0.061), and belimumab (80 vs. 95.5%<0.102).

**Conclusion:** Reduction of pain and fatigue was the main treatment goal of patients with SLE whether they had active or non-active MSK symptoms. Patients with active MSK symptoms had higher pain and fatigue, lower QoL, and less satisfaction with current therapies compared to SLE patients without active MSK symptoms, driven only in part by co-morbid FM. Findings from these analyses suggest there are unmet needs to better understand MSK manifestations, their overlap with Type 2 SLE symptoms, align patient/physician priorities, and improve therapies for MSK symptoms for patients with SLE.

Objectives: Distinguishing NPSLE from other neuropsychiatric conditions with different etiologies is challenging. However, distinguishing NPSLE antibodies in cerebrospinal fluid (CSF) of NPSLE patients was significantly higher than in SLE, MS and NPH groups [2].

Methods: We retrospectively analyzed 35 NPSLE patients, 34 SLE patients, 20 viral meningitis (VM) patients, and 16 relapsing-remitting multiple sclerosis (MS) patients. We measured anti-SBSN antibodies concentrations in serum by using LAC and thrombotic events. Anti-PS/PT, anti-beta2GPI and anti-CL of IgA/G/M isotypes were quantified in parallel using particle-based multi-analyte technology (LAC) and thrombotic events. Conventional aPL were included for comparison.

Results: The Bayesian posterior mean and 95% HPDI of the cutoff of AI and its PPV and 1-NPV values were 5.26 (3.68;7.17), 0.87, (0.72; 1.0) and 0.44, (0.36; 0.5), respectively (Figure 1).

Conclusion: Our data demonstrated the ranking of serum biomarkers for the prediction of NPSLE. The most essential biomarkers are VEGF, anti-SBSN antibodies, sCD40L, IL-10, GRO, MDC, IL-8, IL-9, TNFα, MIP-1α (Figure 2).

POS0746 MEASUREMENT OF ANTI-SUPRABASIN ANTIBODIES, MULTIPLE CYTOKINES AND CHEMOKINES AS POTENTIAL PREDICTIVE BIOMARKERS FOR NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

T. Hoang1, K. Ichinose1, S. Morimoto2, K. Furukawa1, L. Le3, A. Kawakami1.
1Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; 2Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan; 3Nagasaki University, Graduate School of Engineering, Nagasaki, Japan

Background: The pathogenesis of neuropsychiatric systemic lupus erythematosus (NPSLE) is multifactorial and involves diverse cytokines, autoantibodies and immune complexes inducing blood-brain barrier (BBB) dysfunction, neuroendocrine-immune imbalance, vascular occlusion, tissue, and neuronal damage. Several pro-inflammatory cytokines have been implicated in the pathogenesis of NPSLE [1]. Previously we have shown that the titer of anti-suprabasin (SBSN) antibodies in cerebrospinal fluid (CSF) of NPSLE patients was significantly higher than in SLE, MS and NPH groups [2]. However, distinguishing NPSLE from other neuropsychiatric conditions with different etiologies is challenging.

Objectives: This study determined the most critical serum biomarkers for the development of NPSLE as they may have clinical utility prior to the onset of neuropsychiatric symptoms.

Methods: We retrospectively analyzed 35 NPSLE patients, 34 SLE patients, 20 viral meningitis (VM) patients, and 16 relapsing-remitting multiple sclerosis (MS) patients. We measured anti-SBSN antibodies concentrations in serum by using multiplex bead-based assay. The serum concentrations of cytokines/chemokines were measured by using multiplex bead-based assay. All the clinical information and laboratory tests were collected at the time of admission.

Results: The top 10 biomarkers having highest sparsity-oriented important learning (SOIL) importance, followed by AI, sCD40L, IL-10, GRO, MDC, IL-8, IL-9, TNFα, MIP-1α (Figure 2).

Conclusion: Our data demonstrated the ranking of serum biomarkers for the prediction of NPSLE. The most essential biomarkers are VEGF, anti-SBSN antibodies, sCD40L, IL-10, GRO, MDC, IL-8, IL-9, TNFα, MIP-1α (Figure 2).

POS0747 ANTI-PHOSPHATIDYL SERINE/PROTHROMBIN ANTIBODIES AND VASCULAR EVENTS ASSOCIATE POSITIVELY WITH HLA-DRB1*13 AND NEGATIVELY WITH HLA-DRB1*03 IN SLE

1Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden; 2Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden; 3Werfen Autoimmunity, Research and Development, San Diego, United States of America; 4Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden

Background: Anti-phosphatidylserine/prothrombin antibodies (anti-PS/PT) associate with thrombotic events (1). HLA-DRB1 alleles contribute to the occurrence of conventional antiphospholipid antibodies (aPL), including anti-beta2-glycoprotein-I (beta2GPI) and anti-cardiolipin (CL) (2).

Objectives: We investigated associations between anti-PS/PT and HLA-DRB1 alleles and thrombosis in patients with SLE. Conventional aPL were included for comparison.

Methods: We included 341 consecutive Swedish SLE patients, with information on general cardiovascular risk factors, including blood lipids, lupus anticoagulant (LAC) and thrombotic events. Anti-PS/PT, anti-beta2GPI and anti-CL of IgA/G/M isotypes were quantified in parallel using particle-based multi-analyte technology. The 99th percentiles among 162 age- and sex-matched populations controls were used as cutoffs. HLA-DRB1 typing was performed using sequence-specific primer PCR.
Results: Anti-PS/PT antibodies associated positively with HLA-DRB1*13 (odds ratio [OR] 2.7, P=0.002), whereas anti-beta2GPI and anti-CL antibodies associated primarily with HLA-DRB1*04 (OR 2.5, P=0.0005; Table 1). These associations remained after adjustment for other significant HLA-DRB1 alleles identified in Table 1 (Figure 1a and b) also for LAC (Figure 1c), and also after adjustment for age and gender (not shown). HLA-DRB1*13, but not HLA-DRB1*04, remained as an independent risk factor for thrombosis after adjustment for significant HLA alleles (Figure 1d), and also after adjustment for cardiovascular risk factors in stepwise regression (not shown). Mediation analysis showed that 31.3% of the HLA-DRB1*13-related risk for thrombosis was mediated by anti-PS/PT positivity, HLA-DRB1*03, on the other hand, associated negatively with thrombotic events (Figure 1d) as well as with all aPL (Figure 1a-c).

Table 1. Frequency of individual HLA DRB1 and associations with antibody phenotypes. Odds ratios (OR) and confidence intervals (CI) for being antibody positive given a specific HLA allele and corresponding p values were calculated using Chi2 tests, with significant associations underlined.

</tbody>
</table>

Conclusion: HLA-DRB1*13 confers risk for both anti-PS/PT and thrombotic events in SLE. The association between HLA-DRB1*13 and thrombosis is largely, but not entirely, mediated through anti-PS/PT. Due to the negative association of HLA-DRB1*03 with aPL and the positive association with favourable lipid levels, HLA-DRB1*03 seems to identify a subgroup of SLE patients with reduced vascular risk.

Disclosure of Interests: Sahwa Elbagir: None declared, Lina M. Diaz-Gallo: None declared, Giorgia Grosso: None declared, Agneta Zickert: None declared, Iva Gunnarsson: None declared, Michael Mahler Employee of: Dr Mahler is employee of Werfen., Elisabet Svensson Speakers bureau: Dr Svensson has obtained speaker’s fees from Janssen., Grant/research support from: Dr Svensson has obtained research grant from Merck., Johan Rönnelid Speakers bureau: Dr Rönnelid has given paid lectures for Thermo Fisher Scientific., Consultant of: Dr Rönnelid has been a member of the Scientific Advisory Board for Thermo Fisher Scientific.

The patients without objective dryness (n=108) were also younger (p=0.0028), and had more frequently anti-SSA positive (p=0.0042). They also had a higher disease activity (mean ESSDAI:3.46 versus 2.96, p=0.036). In this group of patients, the higher frequency of anti-SSA might be explained by the need of other criteria to fulfill diagnostic criteria, in the absence of abnormal Schirmer and salivary flow. Patients with objective dryness had more frequently arthralgia (p=0.04), a higher level of pain VAS (p=0.03) and subjective dryness VAS (p=0.019 for ocular and p=0.01 for oral) than patients without objective dryness. Among the 108 patients with no objective dryness, only 17 had also had no subjective dryness (VAS <30mm).

P value corresponds to the comparison of the two strata with Student’s t or Mann Whitney-U test

Conclusion: Among the patients with pSS, those without subjective or objective dryness features had a younger profile, shorter diagnosis delay which may result from a more acute onset, were more frequently anti-SSA positive. Those having no objective dryness also had more systemic disease, arthralgias and pain than patients with dryness features. Subjective dryness was associated with higher level of fatigue.

SLE: systemic lupus erythematosus. *Evidence level (EL) of each study was based on Oxford Center for Evidence-Based Medicine 2011. †Quality (Q) of each study was based on the Newcastle-Ottawa Quality Assessment Scale case.
Second Hospital of Shanxi Medical University, Taiyuan, China; 3Academy of Microbial Ecology, Shanxi Medical University, Taiyuan, China; 4Key laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, China

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease which involves in multiple tissue and organ injury. Regulatory B cells (Bregs) are unique subpopulations of B cells with immune-regulating properties. Interestingly, different subsets of Bregs have distinct markers and phenotypes and participate in self immune regulation by different ways. However, the level of Bregs in SLE remains debated.

Objectives: This study aims to clarify the proportions of Bregs with special controversial cellular markers and Breg-related cytokines in SLE patients.

Methods: We explored the proportion of Bregs and Breg-related cytokines (IL-10) in SLE patients by searching literature through November 2021 from CSM, CNKI, China Science and Technology Journal Database, Wan Fang Data, PubMed, Embase, Web of Science, Cochrane Library and Medline. Random effects model was used to pool data. Heterogeneity and risk of bias was examined with I-squared index (I²) statistic. Inconsistency was evaluated by using the P and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0).

Results: Total 14 case-control studies involving 489 PsA patients and 330 healthy controls (HCs) were included in this study (Table 1). No significant difference in the proportions of Bregs was evident between SLE patients and HCs [SMD=0.067, 95%CI (-0.924,1.059), P=0.894]. Because of a significant statistical heterogeneity observed [I²=97.1%, p<0.001], we conducted sub-analyses based on individual definitions of Bregs. We found the proportions of CD19⁺CD24hiCD38hi Breg cells was significantly increased in SLE [SMD=0.902, 95%CI (0.157,1.647), P<0.001](Figure 1A). The level of serum IL-10 was increased in SLE compared to that of HCs [SMD=1.062, 95%CI (0.754,1.370), P<0.001] with no publication bias based on the Egger tests (t=0.91, P=0.366)(Figure 1B).

Conclusion: The levels of CD19⁺CD24hiCD38hi Bregs and IL-10 were significantly increased in SLE patients, suggesting that the abnormalities of Bregs numbers and function are the critical causes in the development of SLE.

POS0751 TEMPORAL TREND IN HOSPITALISATION FOR OPPORTUNISTIC INFECTIONS IN PATIENTS WITH CONNECTIVE TISSUE DISEASES.

J. Nossent1,2, H. Keen1,3, D. Preen4, C. Inderjeeth1,2, 1The University of Western Australia, Medical School, Crawley, Australia; 2Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia; 3Fiona Stanley Hospital, Rheumatology, Murdoch, Australia; 4The University of Western Australia, School Population and Global Health, Perth, Australia

Background: Patients with autoimmune connective tissue disease (CTD) and systemic vasculitis (SV) often require aggressive immune-modulating therapy to prevent organ damage. This however increases the risk for common and uncommon infections.

Objectives: To compare the temporal rates and associated mortality of hospitalisation with opportunistic infections (OI) for CTD and SV patients in Western Australia between 1985 and 2015.

Methods: All patients hospitalized in Western Australia in the period 1985-2015 with ≥ 2 ICD based diagnostic codes for SLE (n=1432), other CTD (o-CTD; incl DM/PM, systemic sclerosis, Sjogren’s syndrome; n=2161) and Systemic vasculitis (SV; n=1599) and a microbiologically confirmed OI (Mycobacterial, Fungal and viral infections) were included. Descriptive data are given as median (IQR) and frequency (%). Incidence rates per 1000 person years (IR) were calculated during 100.410 person years.

Results: OI occurred in 12.4 % of lupus, 11.5% of SV and 10.4% of o-CTD patients (p=0.72), but overall IR rates for OI were higher for lupus patients (9.87, CI 5.49-15.76) than for SV (5.94, CI 2.81-10.24) and o-CTD patients (3.40, CI 1.62-7.23). However, whereas the IR for OI in lupus decreased over time, the IR increased for SV and o-CTD patients (Figure 1). Viral infections were the most frequent specific OI followed by tuberculosis and mycotic infections. Cryptococcal infections were observed in lupus patients only and the limited cases of pneumocystis occurred predominantly in SV patients with no cases observed after 2000 (Figure 2). In hospital mortality during OI admission was 11.5% for SV, 5.6 % for lupus and 3.5% for o-CTD patients (p=0.004).

POS0752 DISEASE FEATURES AT DIAGNOSIS AND CHANGES IN DISEASE COURSE SEVERITY AMONG PATIENTS WITH CHILDHOOD-ONSET COMPARED TO ADULT-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

A. Phillips-Beyer1, Q. Li2, M. E. Stokes2, M. Pozzobon Da Silva2, 1Innovus Consulting Limited, London, United Kingdom; 2Evidera, Weltham, United States of America; 3Therapeutic Area Units, Idorsia Pharmaceuticals, Allschwil, Switzerland

Conclusion: Hospitalization rates for OI have decreased for lupus patients especially since 2005, whereas viral and mycotic OI rates have increased for both SV and o-CTD patients. Hospitalization for OI associated with significant case fatality in especially SV patients, indicating a need for increased prevention of OI.

Background: Systemic lupus erythematosus (SLE) is characterised by a heterogenous clinical presentation with alternating periods of remission and relapse. Disease severity is determined by the type and level of involvement of different organ systems. SLE can occur in childhood or later in life, and patients may present with differing levels of disease severity according to the age of onset. Changes in disease severity following treatment may also differ depending on age of onset. There are limited data that document these differences.

Objectives: To compare demographic and clinical characteristics including baseline disease severity and changes in severity over time between patients with childhood-onset and adult-onset SLE in the United States.

Methods: We identified patients aged 0–64 years and diagnosed with SLE during 2015–2019 using the IBM MarketScan claims databases. SLE severity was determined using a published algorithm, which combines elements of organ involvement and the use of SLE-related medications to assign patients to mild, moderate, and severe disease states. Baseline disease severity was determined using a 90-day follow-up period before the initial SLE diagnosis. The index date was the day after this initial 90-day period. Baseline comorbidities were assessed during the 12 months prior to the index date. Disease severity was evaluated at 0 to <6 months, 6 to <12 months, and ≥12 to <24 months post-index. Patients were categorised according to the highest severity level identified during each period. Changes in severity vs. baseline were also measured during each evaluation period. For example, worsening severity was defined as a transition from a lower to higher disease severity state (e.g., moderate to severe). Analyses were conducted separately for cohorts with Commercial Health Insurance (CHI) and Medicaid. Within each cohort, patients with childhood-onset (≤17 years) were descriptively compared to those with adult-onset (>17 years) SLE.

Results: Most enrollees were female (CHI: 90%, Medicaid: 92%). Mean age at index date was 14.0 vs. 43.4 years for childhood- and adult-onset groups, respectively. Baseline infections were more prevalent among children vs. adults in both CHI (41.4% vs. 30.1%) and Medicaid (45.3% vs. 39.3%) cohorts (Table 1). A higher proportion of children vs. adults had severe disease at baseline in the CHI (38.3% vs. 10.7%) and Medicaid (48.0% vs. 14.2%) cohorts. Overall, the largest decreases in SLE severity compared to baseline were observed during ≥6 months of follow-up. Children were more likely to experience a decrease in severity than adults. During ≥12 to <24 months, 19.9% of children in the Medicaid cohort had an increase in severity compared to baseline vs. only 12.3% of children in the CHI cohort.

Conclusion: Children with SLE present with greater severity of symptoms compared to adults and are more likely to experience an improvement following the initial treatment period.

REFERENCES:

Background: Primary Sjögren’s syndrome (pSS) has great impact on all aspects of patients’ lives, not only physically, but also mentally, socially and financially. Sicca symptoms are mainly treated with local treatment, but no systemic immunosuppressive treatment is registered yet for pSS, which may have significant consequences on whether patients find their symptom state acceptable (PASS). In a previous study, a cut-off for acceptable symptom state based on the EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI, score <5) was developed for inclusion of patients with an unacceptable symptom state in clinical trials.2

Objectives: To explore the presence of PASS in a standard of care cohort of pSS patients and to compare patient characteristics and disease activity including ESSPRI between patients with and without PASS.

Methods: Consecutive outpatients with pSS from the REGistry of Sjögren Syndrome Longitudinal (RESULT) cohort, who fulfilled the ACR/EULAR classification criteria and had available PASS data at baseline were included. Patient-reported outcomes were reported through questionnaires, which included the PASS (“Considering all the different ways your disease is affecting you, if you were to stay in this state for the next few months, do you consider your current state satisfactory?”, yes/no) and ESSPRI (“How severe has your dryness, fatigue and pain been during the last two weeks?”, scale 0-10).

Results: Of 277 included pSS patients, 248 (90%) were female, median age was 54 years (IQR 43-64) and disease duration 5 years (2-11). 198 (71%) patients scored their symptom state as acceptable according to PASS. Patients with PASS were significantly older and had a longer disease duration compared to patients without PASS. Furthermore, patients with PASS had more often a low disease activity according to ESSDAI, and less often had more often a low disease activity according to ESSDAI, and less often moderate disease activity (Table 1). The difference in ESSDAI activity was mainly observed in the articular and constitutional domains. ESSPRI was significantly lower in patients with PASS (median 5 vs. 7). No differences were seen in functional or laboratory parameters (Table 1). Of all included patients, only 86 (31%) patients had an acceptable symptom state according to the pre-defined cut-off point for ESSPRI (score <5). Sensitivity and specificity of this ESSPRI cut-off point for reaching PASS was 40% and 92%, respectively.

Conclusion: The majority (71%) of pSS patients reported being in an acceptable symptom state according to the PASS question in our standard of care cohort in daily clinical practice, despite high ESSPRI scores (60% with score ≥5). Further analyses of influences of treatment in these patients will be conducted.
release, with maximal inhibition observed at 2 hours post-dose (IL-6: mean ±99%). High inhibition levels were sustained through 24 hours in a dose-dependent manner (IL-6: mean –76–97%). The pattern of cytokine release inhibition was consistent across doses and ethnic groups.

**DETERMINANTS OF HEALTH-RELATED QUALITY OF LIFE (HR-QoL) ACROSS THE SPECTRUM OF SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES: RESULTS FROM THE LEAP COHORT**

S. Dyball, 1 J. Reynolds, 2,3 A. Herrick, 4,5 H. Chinyo, 4,5 S. Haque, 4, S. Naz, 4 E. Bruce, 1 I. N. Bruce, 3,4 B. Parker, 8,9 The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 1University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, College of Medical and Dental Sciences, Birmingham, United Kingdom; 2Sandwell and West Birmingham NHS Foundation Trust, Rheumatology Department, Birmingham, United Kingdom; 3Salford Royal NHS Foundation Trust, Department of Rheumatology, Manchester, United Kingdom; 4NIHR Biomedical Research Centre Manchester, The University of Manchester, Manchester, United Kingdom; 5Manchester University NHS FT, Department of Rheumatology, Manchester, United Kingdom; 6Pennine Acute Hospitals NHS Trust, Department of Rheumatology, Manchester, United Kingdom; 7Manchester University NHS FT, The Kellgren Centre of Rheumatology, Manchester, United Kingdom

**Background:** Poor health-related quality of life (HR-QoL) is recognised in patients with established connective tissue diseases (CTDs), however it is not clear how it affects patients with undifferentiated CTD (UCTD) which has traditionally been associated with a mild or more benign profile.

**Objectives:** To investigate HR-QoL in patients affected with a variety of CTDs (including UCTD) using the SF-36 questionnaire; and secondly, to review demographic and clinical factors predictive of a poor HR-QoL.

**Methods:** The Lupus Extended Autoimmune Phenotype (LEAP) cohort is a multicentre prospective study of patients with a CTD. Rheumatologist diagnosis was used to classify patients into four groups: systemic lupus erythematosus (SLE), primary Sjögren’s syndrome (pSS), UCTD, and (combined because of low numbers) those with an idiopathic inflammatory myopathy (IIM), systemic sclerosis (SSc) or overlap syndrome. The SF-36 quality of life questionnaire was completed at enrolment and includes eight domains: physical function (PF), role physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE) and mental health (MH) which range from 0 to 100, with higher scores reflecting better HR-QoL. Physical (PCS) and mental component score (MCS) were calculated for each group, with a score below 50 representing a worse HR-QoL compared to the general UK population. Predictors for poor HR-QoL was chosen a priori, then tested using linear regression adjusted for age, gender and ethnicity. All statistical analysis was performed using STATA v14, with results expressed as beta coefficients with 95% confidence intervals (95% CI).

**Results:** Data were collected from 309 patients (280 [90.6%] women, with a mean [SD] age of 48.9 [12.9] years) from three UK rheumatology centres. The majority of patients were Caucasian (n=235, 76.1%). By rheumatologist diagnosis, 115 (37.2%) had SLE, 56 (18.1%) pSS, 72 (23.3%) UCTD and 66 (21.4%) SSc, IIM or an overlap syndrome. Patients with UCTD, pSS and SSc/IIM spectrum disorders had a shorter median disease duration (3.8, 3.7 and 6.1 years respectively) compared with patients with those with SLE (11.0 years), p<0.001. Previous steroid and immunosuppressant use was highest in patients with SLE and SSc/IIM spectrum disorders (p<0.001). The most affected domains include VT, GH and BP (Figure 1), and the PCS is more impaired compared with the MCS, with similar scores across disease groups. Agnostic of disease group, factors associated with a lower PCS include increasing age (beta -0.15 [95%CI -0.26, -0.06], p<0.008), prednisolone use (-3.1 [-6.05, -0.19], p=0.037), c-reactive protein (-0.09 [-0.62, -0.10], p=0.007), fatigue (-2.00 [-3.79, -0.22], p=0.028), and sicca syndrome (-4.70 [-7.66, -1.74], p<0.002), and these remained significant in a multivariable model.

**Conclusion:** Patients with UCTD exhibit similar impairment in physical components of HR-QoL compared with other established CTDs, despite perceived differences in disease severity. This study highlights sicca syndrome, fatigue, and steroid burden as key targets for improving HR-QoL in patients across the spectrum of CTDs.

COVID-19 INFECTION AND RECOVERY AMONGST PATIENTS WITH MODERATE-TO-SEVERE LUPUS DURING THE PANDEMIC: RESULTS FROM THE BILAG-BILOGICS REGISTER (BILAG-BR)

S. Dyba1, M. Rodziewicz2, E. Sutton3, B. Parker2,3, I. N. Bruce1,2, on behalf of BILAG-BR. The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 1NIHR Manchester Biomedical Research Unit, Centre for Musculoskeletal Research, Manchester, United Kingdom; 2Manchester University Hospital, The Kellgren Centre for Rheumatology, Manchester, United Kingdom

Background: Patients with systemic lupus erythematosus (SLE) are thought to be at greater risk of severe COVID-19 illness and associated complications due to a combination of inherent aberrant immune responses, immunosuppressive medications and co-morbidities.

Objectives: To review COVID-19 infections, hospitalisation and recovery in a real-world cohort of patients with moderate to severe SLE and high immunosuppressive use.

Methods: The British Isles Lupus Assessment Group Biologics Registry (BILAG-BR) is a national prospective registry of lupus patients from the UK (2010-21) requiring significant immunosuppressive therapies. Patients from the BILAG-BR were invited to complete a paper or online questionnaire which consisted of 17 questions to assess prior COVID-19 infection and their recovery during the COVID-19 pandemic. Questionnaires were completed between 9th Oct 2021 and 7th Jan 2022. Responses were linked with data collected in the BILAG-BR. Mortality data were collected from study centres and the Office of National Statistics from Dec 2019-Jan 2022.

Results: Data were collected from the first 202/1288 patients to respond. Patients were predominantly female (186, 92.1%), had a median age of 51 (IQR 38-61) years and were from 37 UK centres. Previous therapy included rituximab (165, 81.7%), belimumab (33, 16.3%) and cyclophosphamide (54, 26.7%). In the past 12 months, over two thirds of patients (138, 68.3%) had received oral prednisolone (current median dose 5mg [IQR 5-8mg] daily), and almost a third had received parental steroids (60, 29.7%). Self-reported COVID-19 diagnosis occurred in 48 (23.8%) patients, of whom 29 reported a positive test. Eleven (55%) patients reported testing positive for COVID-19 after being vaccinated. Median reported recovery was 80% (IQR 60-100%), with subjective full recovery reported in 30% of patients (6/20) who had received a positive test. Of the 20 patients who tested positive for COVID-19, 5 were receiving belimumab, 1 tocilizumab, and in the prior 12 months, 2 had received cyclophosphamide and 4 rituximab. Of all respondents, three individuals were hospitalised with COVID-19, and one required an ICU admission. Of those hospitalised, two patients were unvaccinated prior to COVID-19 infection, and the other patient had received rituximab and cyclophosphamide prior to vaccination. Four/1387 patients registered in the BILAG-BR were confirmed to have died from COVID-19 since the beginning of the pandemic.

Conclusion: In this cohort of moderate-to-severe SLE patients there was a low incidence of COVID-19 infection. Despite this, full recovery from PCR or lateral flow test proven COVID-19 infection was seen in only a third of patients. This raises concerns over the potential risk of long COVID in patients with SLE and warrants further investigation.

POS0758

REDUCED CENTRAL NERVOUS SYSTEM DRIVE IN PRIMARY SJÖGREN’S SYNDROME IS ASSOCIATED WITH OBJECTIVE DECLINE IN MOTOR PERFORMANCE AND SELF-REPORTED FATIGUE

R. Prak1, S. Arends2, G. M. Verstappen2, G. S. Van Zuinder2, H. Bootsma3, I. Zigendew4, 1University Medical Center Groningen, University of Groningen, Biomedical Sciences of Cells and Systems, Groningen, Netherlands; 2University Medical Center Groningen, University of Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Fatigue is a major complaint in primary Sjögren’s syndrome (pSS). The importance of fatigue in pSS is demonstrated by its inclusion as one of the three domains of the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) as well as being the primary outcome measure of a large clinical trial.1 To date, there is no effective treatment for fatigue and more fundamental studies are needed to identify potential targets for therapy. In a conceptual framework, fatigue is defined as a self-reported symptom derived from two attributes: performance fatigability and perceived fatigability (Figure 1).

Figure 1. Conceptual framework (adapted from Enoka)2

Objectives: To acquire a better understanding of fatigue in pSS, we investigated objective measures of performance decline and evaluated the relation of self-reported fatigue with performance fatigability and factors modulating perceptions of fatigability.

Methods: 39 pSS patients and 27 healthy controls were included. To assess performance fatigability, force decline was measured during a sustained (124s) maximal voluntary contraction (MVC) with the index finger abductor muscle, and voluntary muscle activation was indexed using peripheral nerve stimulation superimposed on maximal voluntary contractions. Self-reported fatigue was quantified using the Fatigue Severity Scale (FSS) and Modified Fatigue Impact Scale (MFIS). Pain, depression, and anxiety were assessed using questionnaires and serological inflammatory markers were measured in serum as factors related to perceived fatigability.

Results: Self-reported fatigue was significantly higher in pSS than controls (FSS: 4.8 vs. 2.3, p<0.001; 67% of patients and no controls reported significant fatigue (FSS>4). Mean voluntary muscle activation was reduced in pSS compared to controls (81.5% vs. 87.8%, p=0.030). Force decline during the sustained MVC did not differ between groups (60.6% vs. 63.1%, p=0.246). MFIS physical was positively associated with symptoms (ESSPRI pain: r=0.51, HADS depression: r=-0.45 and HADS anxiety: r=0.29) and negatively associated with serological inflammatory markers (MxA: r=-0.49 and CXCL10: r=-0.37). Multivariable linear regression showed that force decline, pain and depression were associated with the MFIS physical domain in pSS (total explained variance of 47%). The inclusion of serological inflammatory markers did not help to explain more variance in this model.

Conclusion: This study demonstrates that performance fatigability in pSS was compromised by a reduced capacity of the central nervous system to drive the muscle. Furthermore, self-reported fatigue is a multifactorial symptom associated with both performance fatigability and perceived fatigueability in patients with pSS.

DOES LDLAS DEFINITION MATCH THE RHEUMATOLOGIST OPINION? THE FIRST VISIT EVALUATION OF A LONGITUDINAL SPANISH MULTICENTER STUDY TO ASSESS REASONS OF DISAGREEMENT.

I. Altábab González1,2, I. Rua-Figueroa3, N. Jiménez3, F. Rubínó3, C. Mouriró Rodríguez1,2, I. Hernández1, R. Menor-Almagro1, E. Uriarte Isacelaya5, E. Tomero Muriel6, T. C. Salman Monte1, I. Carrión Barberà7, M. Galindo8, E. Rodríguez Almaraz8, L. Inês9, J. M. Pego-Reigosa1,2.

1Complejo Hospitalario Universitario de Vigo, Rheumatology, Vigo, Spain; 2MIIDIS (Investigation in Rheumatology and Immune-Mediated Diseases) Group, Rheumatology, Vigo, Spain; 3Hospital Universitario de Gran Canaria Dr. Negrín, Rheumatology,
Background: Treat to Target strategies are necessary in Systemic Lupus Erythematosus (SLE). They are difficult to establish due to the heterogeneity of the disease. The current definitions of Lupus Low Disease Activity State (LLDAS) according to the Asia Pacific Lupus Collaboration (APLC) and remission according to Definition of Remission in SLE (DORIS) 2021 are difficult to achieve and maintain over time.

Objectives: To evaluate the concordance between the LLDAS and the clinical status according to the rheumatologist opinion and reasons of disagreement. To explore modifications in LLDAS definition that best fit with the expert’s opinion.

Methods: Prospective multicenter study of SLE patients (ACR 1997 Classification Criteria or clinical diagnosis by the physician) from seven Spanish Rheumatology Departments. Statistical analysis: descriptive cross-sectional (at the time of recruitment) analysis of the demographic and clinical characteristics, treatments; remission and LLDAS and the subjective evaluations of SLE activity by the rheumatologist. Analysis of the level of agreement between expert opinion and the definition of LLDAS and its modification were evaluated using Cohen’s kappa.

Results: DEMOGRAPHIC, DISEASE CHARACTERISTICS AND TREATMENTS. Five hundred and eight were included (92% women; mean age (±SD): 50.4 years (±13.7)). Mean SLEDAI-2K (±SD) was 2.84 (±3.31). A total of 406 (79.9%) patients presented SLEDAI-2K>4. A total of 317 (74.1%) patients were on antimalarial treatment. Two hundred and twenty-two (43.7%) patients were on some type of immunosuppressive or biological therapy. More than half of patients were not taking glucocorticoids (n=310, 61%). A total of 38 patients (7.5%) were taking doses of prednisone higher than 75mg/day.

REMISSION/LLDAS 267 (54.4%) patients were in remission and 304 (62.7%) patients were in LLDAS. According to the expert opinion of the rheumatologist, remission was the most frequent state considered (n=206, 41.6%); followed by low activity (n=153, 30.9%); serologically active (n=71, 14.3%); moderate activity (n=55, 11.1%) and high activity (n=10, 2%).

AGREEMENT Overall agreement between expert opinion and the definition of LLDAS was 71.4 % with a Cohen’s kappa of 0.3. The majority of the cases (96.1%) that fulfilled the definition of LLDAS, were classified by the expert as remission, serologically active or low activity. Only 12 (3.9%) patients were classified by the expert as moderate or high activity. Of the patients that did not fulfill the definition of LLDAS, 126 out of 179 (70.4%) patients were classified by the expert as remission/low disease activity (Figure 1). The main reasons for discordance in the group that did not fulfill the definition of LLDAS were the presence of new clinical features compared to previous visit and a SLEDAI 2-K >4, in 74 (58.7%) and 59 (46.8%) patients, respectively. The LLDAS adjustment that meant a significant increase in the agreement was the exclusion of the comparative features with the previous visit, with an increase in the agreement to 82.6% (95% CI: 81.61-83.96). The modification of prednisone to ≤5mg/day, did not represent a significant change in agreement from the original definition.

Figure 1. Comparison of LLDAS and expert opinion

Conclusion: At a given point in time, almost two thirds of SLE patients were in remission or in LLDAS. There is a good correlation between LLDAS and the physician’s opinion, particularly for those patients who fulfill LLDAS definition. However, the agreement is not so good for patients who don’t, these being excessively classified by the physician as remission or low activity. The main LLDAS items causing this disagreement were a SLEDAI-2K >4 and the appearance of different clinical manifestations from the previous evaluation. On the contrary, physician assessment by the PGA adequately fits the LLDAS definition. The modification of the LLDAS definition excluding the comparison with previous assessment increases the agreement with the expert opinion to 82.6%.

M. Edamoto1, J. Kikuchi1, H. Hanaoka1, S. Saito1, K. Hiramoto1, Y. Kaneko1.
1Koel University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Neuropsychiatric systemic lupus erythematosus (NPSLE) is one of severe organ manifestations and directly associated with neuropsychiatric damages, such as cerebral vascular accident, cognitive impairment, or seizures. However, factors associated with damage accrual of neuropsychiatric and non-neuropsychiatric domains in NPSLE patients remain unknown.

Objectives: The aim of this study was to identify factors associated with damage accrual in patients with NPSLE.

Methods: We reviewed all patients with SLE who had attended our hospital between January 2010 to December 2020 retrospectively and identified those with NPSLE. We analyzed clinical characteristics and laboratory data including cerebrospinal fluid (CSF) in association with the Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) damage index (SDI) progression after the onset of NPSLE.

Results: 461 patients with SLE were reviewed. Among them, 37 (8.0%) were diagnosed with NPSLE. Thirty-six patients were included in the analysis after excluding one patient with insufficient information. Seventeen (47.2%) patients were diagnosed with NPSLE at the same time with SLE diagnosis and 19 patients were diagnosed as relapse of NPSLE. In NPSLE onset, the mean age was 33.7 years, 39% were female, and the mean SLEDAI-2K was 21.8. Eighteen (50.0%) patients had active lupus nephritis simultaneously at the onset of NPSLE. The most frequent NPSLE types according to the 1999 ACR classification were lupus headache in 10 patients, followed by cerebrovascular disease in 7, seizure disorders in 6, acute confusional state, psychosis and mononeuropathy in 3, and aseptic meningitis in 2. All patients were treated with glucocorticoids, and the mean initial dose of prednisolone was 52.3 mg/day with steroid pulse therapy in 19 patients.

Thirty (83.3%) patients were treated with concomitant immunosuppressive treatments. During the observation period with the mean of 10.0 years, 17 (47.2%) patients developed at least one point of SDI. Among them, 9 patients (25.0%) had neuropsychiatric damage progression including cerebrovascular accident in 6, seizures requiring drug treatment for more than 6 months in 2, and cognitive impairment in 1. Non-neuropsychiatric damage was also increased such musculoskeletal in 5, ocular in 3, cardiovascular in 2, renal, gastrointestinal, premature gonadal failure, diabetes, and malignancy in each one. Neither neuropsychiatric nor overall damage progression were associated with SLEDAI-2K, anti-cardiolipin antibodies positivity, abnormal electroencephalogram, abnormal single photon-emission computed tomography at NPSLE onset or kinds of immunosuppressive treatments in patients who underwent CSF examination. The high level of CSF IL-6 was associated with neuropsychiatric damage progression (p=0.032). Also, high levels of CSF protein (p=0.030), cell counts (p=0.007), and IL-6 (p=0.032) were associated with overall SDI progression.

Conclusion: CSF IL-6 concentrations are associated with neuropsychiatric damage progression, and high CSF protein, cell counts and IL-6 at onset in patients with NPSLE can predict overall damage accrual.

1Aalborg University Hospital, Department of Rheumatology, Odense, Denmark; 2Aalborg University Hospital, Department of Rheumatology, Odense, Denmark; 3Department of Biomedicine, Aarhus University, Department of Rheumatology, Aarhus, Denmark; 4Odense University Hospital, Department of Rheumatology, Odense, Denmark; 5Aalborg University Hospital, Department of Rheumatology.
**Background:** Nephritis (LN) in systemic lupus erythematosus (SLE) is still a major determinant of poor prognosis[1]. The vast majority of LN occurs in proxim-ity to the SLE diagnosis[2]. Identification of individuals at high risk, especially early onset SLE, is therefore warranted. Inclusion of risk factors prior to the SLE diagnosis may thus be of importance to enable sufficient risk factor profiling. SLE-patients seem to cluster according to clinical and serological phenotypes suggesting distinct disease trajectories[3-5].

**Objectives:** To determine if incident proteinuria associated with the debut age of non-renal SLE characteristics.

**Methods:** Data of SLE patients from six Danish centers were obtained from the Danbio-database from 2017 – 2020. The occurrence and timing of proteinuria was compared with first time onset of any non-renal manifestations as defined by the 1997 American College of Rheumatology Classification Criteria. Cox-regression models were used to identify risk factors for incident proteinuria. Time from first occurring non-renal manifestation to incident proteinuria or censoring defined time at risk. Covariates were eliminated if p >0.01 in a ‘backwards’ manner. After the model reduction process p-values <0.05 were considered statistically significant.

**Results:** 586 SLE patients, mainly white (94%) women (88%), mean age at inclusion of 34.6 years (standard deviation, SD = 6.0 years) and observed for a mean of 14.9 years (SD =0.5 years), were recruited. The cumulative prevalence of proteinuria was 40%. Male gender hazard ratio, HR = 1.35 (95% CI: 1.15-1.58). p=0.005 were associated with incident proteinuria. In contrast, patients with discoid rash had lower risk of incident proteinuria HR 0.42 (range 0.21-0.83), p=0.01. Male patients with lymphopenia had the highest risk of proteinuria with a one-, 5- and 10-year risk of proteinuria ranging from 9-27%, 34-75% and 51-89 %, depending on the age at presentation (debut at 20, 30, 40 or 50 years). The corresponding risk-profiles for women with lymphopenia were 3-9%, 8-34% and 12-58%, respectively, as illustrated in Figure 1.

**Conclusion:** The occurrences of lymphopenia and discoid rash were oppositely associated with risk of incident proteinuria and the risk effects varied according to gender and patient age at onset of these manifestations. Thus, the risk of proteinuria may not be constant but could vary according to presentation of non-renal manifestations that may call for a differentiated clinical follow-up. Based on these findings, we suggest that the debut age of known prognostic factors, even prior to the SLE diagnosis should be considered when designing prognostic statistical models.

Laura Johnsen: None declared, Ada Colic: None declared, Søren Jacobsen: None declared DOI: 10.1136/annrheumdis-2022-eular.3223
Methods: We retrospectively reviewed the medical records of patients with systemic lupus erythematosus who were diagnosed with LN class I, II, V or I+IV by kidney biopsy between 1997 and 2021 at a tertiary referral center. Clinical and laboratory data were compared between patients with and without poor renal outcomes. Poor renal outcome was defined as an estimated glomerular filtration rate (eGFR) of < 60 mL/min/1.73 m2 or death due to renal cause. Univariate and multivariate analyses were performed with the Cox proportional hazard model to identify the factors associated with poor renal outcomes.

Results: We included 71 patients with non-proliferative LN (4: class I; 17: class II; 48: class V; 17: 2: class I+V). Median follow-up duration was 103 months (interquartile range 27–185) and the overall rate of poor renal outcomes at last follow-up was 29% (21/71), including end-stage renal disease (n=2) and renal death (n=1). Univariate analysis indicated that older age (HR 1.05; 95% CI: 1.00–1.09), low eGFR (HR 0.97; 95% CI: 0.95–0.99) and failure to reach complete remission at 6 months (HR 0.332; 95% CI: 0.12–0.92) were significantly associated with poor renal outcomes. Multivariate analysis revealed that low eGFR at 6 months (HR 0.97; 95% CI: 0.95–0.99) was significantly associated with poor renal outcomes.

Conclusion: Poor renal outcomes occurred in approximately 30% of patients with non-proliferative LN (class I, II or V) after long-term follow-up. Our findings suggest that more active management may be needed for non-proliferative LN, particularly in patients with low eGFR at 6 months.

Figure 1. Machine learning-based models to predict cognitive function.
Results: Thirty-eight SS patients were found without sicca manifestations (21.9%). The most common presenting clinical manifestation of non-dryness SS patients were arthralgias (47.4%), followed by parotid gland enlargement (23.6%), Raynaud’s phenomenon (10.5%), generalized lymphadenopathy (10.5%), fatigue (10.5%), palpable purpura (5.3%) and pulmonary symptomatology of dry cough or exertional dyspnea (5.3%). Despite the lack of ocular dryness, non-dryness group had positive ocular tests but statistically lower compared to those with sicca symptoms (55.6% vs 93.9%, p<0.001), and displayed lymphopenia less frequently (0 vs 17.3%, p=0.049). No statistical differences were found in terms of salivary gland enlargement (SGE), focus score (FS), cryoglobulinemia and autoantibody profile between the 2 groups.

Conclusion: SS patients without subjective dryness are characterized by similar underlying immunopathologic processes as typical SS sicca patients.

and assist in the interpretation of conflicting results on aPL testing.

**Background:**
Rheumatology, Moscow, Russian Federation

**Methods:**
The study included 190 patients who signed informed consent, aged 37.0 [29.0-44.0] years and disease duration 7.0 [2.0-15.0] years. Male/ female ratio was 44 (23)/146 (77). 123 (64.7%) of 190 patients had reliable SLE and 55 (29%) had PAPS. The control group was left with 100 relatively female ratio was 44 (23)/146 (77). 123 (64.7%) of 190 patients had reliable SLE and 55 (29%) had PAPS. The control group was left with 100 relatively healthy, age-matched individuals. Classical aPL (IgG/IgM-aCL, IgG/IgM- 
cl2-GP1, LA) were measured at two time points separated by at least 12 weeks in all patients included in this study. IgG/IgG anti-PS/PT was determined by enzyme immunoassay (ELISA) using a Teco sunrise absorbance microplate spectrophotometer (Austria) with an Aeskulisa Serin-Prothrombin-GM antibody reagent kit. IgG/IgM anti-PS/PT were measured in U/ml. Values >18 U/ml were considered positive. The range of measurements was: 1 to 300 U/ml.

**Results:**
In 144 (76%) of 190 patients were revealed IgG anti-PS/PT, 55 (29%) - IgM anti-PS/PT, a combination of IgG anti-PS/PT and IgM anti-PS/PT was found in 53 (28%). IgG anti-PS/PT and IgM anti-PS/PT were detected in 39 of the 70 (56%) remaining patients who were negative for criterion aPL. The median IgG anti-PS/PT was 101.2 U/ml [31.0-180.5] in patients with and was significantly higher than 23.7 [14.1-49.8] U/ml in patients without APS and controls. IgM anti-PS/PT levels in patients with and without APS were comparable. Thrombosis was significantly more common in patients with IgG anti-PS/PT: 95 (81.2%) of 117 patients with thrombosis compared with patients negative for IgG anti-PS/PT (22 (18.8%) of 60 patients) (P=0.03). Arterial, but not venous thrombosis, was associated with IgG anti-PS/PT positivity. IgG anti-PS/PT was detected in 53 (83.8%) of 60 patients with arterial thromboses, and in 7 (11.7%) of 64 patients of IgG anti-PS/PT negative. The incidence of thrombo- cytopenia in the SLE+APS patient group was associated with the presence of IgG anti-PS/PT, which was detected in 18 of 19 patients, versus 6 of 12 in SLE without aPL (P=0.007). In the other patient groups, the frequency of thrombo- cytopenia and IgG anti-PS/PT positivity was not statistically significant. The frequency of anti-PS/PT detection was independent of LA positivity. IgG and/or IgM anti-PS/PT were detected in 26 (87%) of 30 patients positive for LA and in 21 (78%) of 27 patients LA negative. (P=0.05). The sensitivity of anti-PS/PT IgG for APS was 85%, specificity - 64%, the sensitivity of anti-PS/PT IgM was lower - 35%, but higher specificity - 88%.

**Conclusion:**
The frequency of anti-PS/PT detection in the examined patients was high: 76% had IgG anti-PS/PT, 29% - IgM anti-PS/PT and 28% - a combination of them. The levels of IgG anti-PS/PT were significantly higher in patients with APS compared to patients without APS and controls. IgM anti-PS/PT values in patients with and without APS were comparable but higher compared to controls. Thrombosis was associated with IgG anti-PS/PT positivity. Arterial thrombosis was significantly more frequent in patients with IgG anti-PS/PT (P=0.006). The sensitivity of IgG anti-PS/PT for APS was 85%, and specificity was 64%; IgM anti-PS/PT had a lower sensitivity of 35%, but a higher specificity of 88%.

GLANDULAR INVOLVEMENT IN PRIMARY SJÖGREN SYNDROME PATIENTS WITH INTERSTITIAL LUNG DISEASE (ILD) ONSET: A SINGLE CENTER CROSS-SECTIONAL STUDY

G. La Rocca1, F. Ferro2, G. Fulvio3, S. Fonzetti4, G. Governato3, V. Donati3, M. Mosca1, C. Baldini2, 1University of Pisa, Clinical and Experimental Medicine, Pisa, Italy, Rheumatology, Pisa, Italy; Azienda Ospedaliero- Universitaria Pisana, Rheumatology Unit, Pisa, Italy; Azienda Ospedaliero-Univeristaria Pisana, Unit of Pathological Anatomy 2, Pisa, Italy

**Background:**
Primary Sjögren Syndrome (pSS) is an autoimmune exocrinop- athy classically presenting with sicca symptoms. Nonetheless, disease onset was often extraglandular simultaneously. Intersitial lung disease (ILD), is increasingly reported and probably underestimated. However, studies investigat- ing pSS patients presenting with ILD (pSS-ILD) are limited.

**Objectives:**
Aim of this study was to better characterize the phenotype of pSS patients presenting with ILD in comparison to pSS patients with classical sic- ca-onset. We especially investigated whether the two groups differed in glandular involvement comparing functional, imaging and histologic findings, as well as patient reported outcome (PHQ).

**Methods:**
Consecutive newly diagnosed pSS patients, all fulfilling the ACR/ EULAR 2016 criteria, were included in this cross-sectional study from September 2016 to October 2021. Clinical, serological and histological initial features where compared in pSS-ILD patients and in pSS patients without ILD involvement, diagnosed during the same time period. Presence of ILD at pSS diagnosis was defined based on clinical findings, imaging assessment and pulmonary function tests. In addition to functional tests, a minor salivary gland biopsy was performed in all cases, recording number of foci and GC-like structures and focus score (FS). Salivary glands ultrasonography (SGUS) was graded using the OMERACT semiquantitative scoring system (0-3) based on parenchyma inhomogeneity, Pro including ESPIRI, OHIP and OSSDI were collected. Extraglandular clinical features and biological abnormalities included in the ESSDAI were recorded. Data was presented as means±SD, or percent frequency as appropriate. Inter- group comparisons were made using the t-test/Mann–Whitney test for continu- ous variables and Fisher’s exact test for categorical variables.

**Results:**
We included 178 newly diagnosed pSS patients (F:M=158:20). ILD was the first pSS manifestation in 11 (6%) cases, 8 F and 3M, with a median time from ILD onset to pSS diagnosis of 2 ± 2 years. At HRCT, the following patterns were observed: NSIP (4/11), UIP (4/11), NSIP+OP (2/11) and LIP (1/11). Dyspnea on exertion or chronic cough were reported by 7/11 (63.6%) patients. In comparison to sicca-onset patients, pSS-ILD patients presented an older age at diagnosis (55.13 vs 70.7, p=0.001) and a higher ESSDAI (3.9±4.7 vs 12.3±3.4, p=0.001) driven by the pulmonary domain. Regarding glandular involvement, pSS-ILD presented milder sicca-ophthalmopathy (VAS 5.8±3.1 vs 2.8±3.5, p=0.002) and significative lower scores in OSDI (35.6±24.9 vs 15.3±22.9, p=0.04), despite no significant differences observed between the two groups in ocular tests and unstimulated salivary flow rate. With respect to histology, no significant differences were found in number of foci and GC-like structures, and FS. Notably, there was a trend towards a different dis- tribution of the SGUS OMERACT score in the two groups. Particularly, none of pSS-ILD patients presented OMERACT score 3 in parotid and submandibular glands, in contrast to 26/167 (15.5%) and 18/167 (10.8%) of classic sicca-onset pSS patients respectively. Finally, no significant differences were observed between the two groups with respect to non-pulmonary extraglandular manifes- tations, serologic features and other biological parameters.

**Conclusion:**
ILD-onset pSS patients represent an atypical phenotypic subset, with less pronounced sicca symptoms and topographical changes in salivary glands, and with sicca symptoms probably overshadowed by the respiratory disease.

DOI: 10.1136/annrheumdis-2022-earl.3936
Objectives: To examine the rate of transition from at-risk to classified (ACR 1997 criteria) SLE, and identify demographic and clinical predictors. To prospectively evaluate the sensitivity and accuracy of the newer classification criteria (SLICC 2012, EULAR/ACR 2019) and the SLE Risk Predictive Index (SLERP-I)[1] in patients at-risk who progress or not to classified SLE.

Methods: This is a single-centre analysis of individuals at-risk for SLE as part of an ongoing multicentric inception cohort study aiming to identify clinical, environmental and molecular diagnostic factors for SLE onset. Enrolled individuals: a) were aged 18–55 years; b) had clinical and/or serological features suggestive of connective tissue disease, SLE, other connective tissue disease. Methods for non-classification features, and ascertain the disease status (at-risk/undifferentiated connective tissue disease).

Results: A total 124 subjects were included, all Whites, 94.4% women, with an average (standard deviation) age 36 (11) years. At first assessment, individuals fulfilled 2.25 (0.72) ACR 1997 criteria with ANA being the most prevalent feature (75.8%) followed by low complement (43.5%), arthritis (37.9%), photosensitivity (28.2%), malar rash (23.4%), and non-scarring alopecia (18.5%). After a median follow-up of 16 months, 27 participants (21.8%) fulfilled the ACR 1997 criteria, of whom 8 (3.5%) developed moderate or severe SLE. Multivariable-adjusted logistic regression identified anti-Ro/SSA (odds ratio [OR] 6.93; 95% confidence interval [95% CI] 1.75–27.5, p=0.006), combined low C3 and low C4 (OR 4.82; 95% CI 1.42–16.3, p=0.012) and photosensitivity (OR 3.25; 95% CI 1.17–8.99, p=0.023) as independent predictors for transition to classified SLE. The sensitivity of SLICC 2012, EULAR/ACR 2019 and SLERP-I (>7) at baseline for detecting individuals who progressed to SLE (ACR 1997) was 40.7%, 25.9% and 40.7%, respectively, with corresponding specificities of 83.5%, 88.7% and 79.4%. 

Conclusion: Among individuals at-risk for SLE, about 20% may evolve into classified SLE, other connective tissue disease.

Conclusion: SLE patients have an increased risk of fractures, 5- and 10-year recurrent fractures, and 5-year mortality post-fracture compared to controls from the general population. After adjustment for conventional risk factors, these associations remained unchanged in the most recent period (2002-2014). This study highlights the need for improved primary prevention of a first fracture event in SLE patients.

**POS0772 HEPATIC STEATOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: PREVALENCE AND ASSOCIATION WITH DISEASE FEATURES**

A. Barrera-Varaás1, A. A. Baeza-Zapata1, A. Fortanell-Meza1, D. San Agustín-Morales1, J. Merayo-Chalico,1 C. Mocetezuma-Velázquez1,1 Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Immunology and Rheumatology, Mexico City, Mexico; 2 Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Gastroenterology, Mexico City, Mexico

Background: The spectrum of hepatic involvement in patients with systemic lupus erythematosus (SLE) is broad and multifactorial. Steatosis is a common finding in liver biopsies performed on these patients; however, there is no further evidence of its prevalence in this population. Early detection of steatosis is important to consider ideal management options, and transient elastography (Fibroscan) offers a non-invasive, fast, and easy tool that provides reliable diagnoses.

Objectives: To determine the prevalence of hepatic steatosis in patients with SLE by using the controlled attenuation parameter (CAP). We also aimed to describe factors associated with steatosis in lupus, such as metabolic syndrome criteria, treatment, and disease activity.

Methods: Between July and December 2021, we measured the degree of hepatic steatosis in patients who fulfilled the 2019 EULAR/ACR SLE classification criteria from a rheumatology outpatient clinic in a tertiary referral center in Mexico City, using the CAP obtained with Fibroscan. The cut-off value for considering hepatic steatosis was 275 dB/m. Fibroscan results, metabolic syndrome criteria, treatment, and SLE-associated variables were recorded. Variables were analyzed using Chi-squared, Fisher’s exact, and Mann-Whitney U tests. We used logistic regression to compare variables associated with lupus activity and steatosis. A p value <0.05 was considered statistically significant.

Results: A total of 102 patients (83% female, mean age 39±14 years) with SLE were included. We identified 23 patients (22.5%) with hepatic steatosis. Patients with steatosis had a higher mean waist-to-hip ratio (WHR, 0.92 vs 0.85 cm, p<0.001), and prevalence of overweight/obesity (82% vs 49%, p=0.004) compared with patients without steatosis. Univariate analyses showed that steatosis was significantly associated with higher body mass index (BMI; OR 1.24 [95%CI 1.11-1.39], p<0.001), WHR (OR 1.13 [95%CI 1.03-1.23], p<0.001), serum glucose (OR 1.04, [95%CI 1.00-1.07], p=0.04), and paradoxically, higher C3 complement levels (OR 1.03 [95%CI 1.01-1.05], p=0.002). Additionally, hydroxychloroquine was found to be a protective factor (OR 0.34 [95%CI 0.12-0.98], p=0.047). There were no differences between patients with and without steatosis in terms of disease duration and types of activity. Also, no differences were found in the activity (SLEDAI-2K) and chronic damage (SLICC-DI) indices between groups. In the multivariate analysis, the only variables that remained significantly associated with steatosis were BMI (OR=1.23 [95%CI 1.05-1.43], p=0.007), and WHR (OR 1.15 [95%CI 1.03-1.28], p=0.01).

Table 1. UHFUS diagnostic accuracy in pSS (A) and for predicting a MLSG FS≥1 in the cases and in anti-Ro/SSA negative patients. OCP, optimal cut-off value.
Although it did not reach statistical significance, current use of hydroxychloroquine tended to be a protective factor for steatosis (OR=0.18 [95% CI 0.03-1.0]; p=0.06).

Conclusion: The prevalence of hepatic steatosis in patients with SLE is similar to that of the general population. Metabolic risk factors were associated with a higher prevalence of steatosis in patients with lupus, contrary to other SLE disease features such as activity, treatment, and chronic damage. Interestingly, hydroxychloroquine use tended to be a protective factor for steatosis in these patients.

Figure 1. Cluster analysis of autoantibodies (Cluster 1: dsDNA, histone and nucleosome; cluster 2: Sm, nRNP, Ro52, Ro60 and Ribosomal P; cluster 3: cardiolipin, IgG1 and La and lupus anticogulant; cluster 4: Scl-70, Jo-1, PCNA, AMA-M2, PM-SCL, and CENP-B)
Background: Antibodies to Smith (Sm) have been described as one of the most specific autoantibodies for systemic lupus erythematosus (SLE). Other than its association with lupus nephritis, there is, however, limited understanding of its clinical significance.

Objectives: To describe clinical associations and serum protein profiles of anti-Sm positivity in SLE.

Methods: Patients fulfilling SLE classification criteria who were followed longitudinally in a prospective multicentre cohort were studied according to their baseline anti-Sm antibody status. Comparison between Sm+ and Sm- patients was made using descriptive statistics. Clinical associations of Sm positivity with patient disease characteristics were studied using logistic regression. In a subset, 211 serum analytes were measured using Quantibody, Luminex and ELISA assays. Associations between serum proteins and Sm positivity were studied using Least Absolute Shrinkage and Selection Operator (LASSO) penalised regression, adjusting for demographics (age, sex, ethnicity) and medication use.

Results: 383 patients were studied with median (IQR) follow-up of 4.9 (2.9-25) years; 65 (17%) had positive anti-Sm antibodies. Sm+ patients were significantly more likely to be of non-European ancestry (OR 2.73, 95% CI 1.55-4.82, p<0.001), and to be positive for anti-dsDNA antibodies (OR 2.8, 95% CI 2.3-3.4, p<0.001), anti-RNP antibodies (OR 15.7, 95% CI 13.9-17.8, p<0.001), direct anti-globulin test (OR 2.36, 95% CI 2.1-2.7, p<0.001), and anti-Ro antibody (OR 2.07-2.7, p<0.001). Conversely, fewer Sm+ patients attained LLDAS for ≥50% observed difference in damage accrual between Sm+ and Sm- patients. In serum protein analysis including pairwise interaction between predictors, 28 Sm+ associated parameters were identified. Associations between serum proteins and Sm positivity were studied using Least Absolute Shrinkage and Selection Operator (LASSO) penalised regression, adjusting for demographics (age, sex, ethnicity) and medication use.

POS0775 COMBINED MODEL OF RENAL HISTOPATHOLOGY AND CLINICAL PARAMETERS BETTER PREDICT ONE YEAR RENAL OUTCOMES IN LUPUS NEPHRITIS:

ANALYSIS OF 334 KIDNEY BIOPSIES

Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Clinical Immunology, Puducherry, India; Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Pathology, Puducherry, India; AIIMS Bilaspur Himachal Pradesh, Director, Kothipura, India

Background: Diagnosis of Lupus Nephritis (LN) is currently based on laboratory tests and renal histopathology. Role of histopathological features in determining long term outcomes is unclear.

Objectives: 1. To assess if clinical and biochemical parameters at baseline can identify renal histopathological class. 2. To assess the clinico-histopathological predictors of renal response.

Methods: This is a single centre retrospective study comprising 334 LN renal biopsies. Clinical and biochemical parameters at the time of biopsy were noted and their association with histopathological class, activity and chronicity scores (AS/CS) (ISN/RPS classification) were evaluated. Complete, or partial no response (CR, PR, NR) for renal outcome (EULAR/EDTA) at 1 year were assessed for 293 patients. Binary logistic regression was done to look for the predictors of NR.

Class III/IV LN was seen in 240(71.8%). Hypertension was seen in 52(12.1%) of class III/V and <25% each with class II, V and combined class(p<0.001). Class III/IV had lower eGFR (876(62.75-118.8) (p<0.001) than the other classes. Nephrotic range proteinuria was seen in 32% of class V and 21% in class III/V (p<0.004). Among class III/IV, AS had weak correlation with baseline UPCR (r=0.31) and eGFR (r=-0.172) (p<0.01). CS had weak negative correlation with eGFR (r=-0.212, p<0.01). NR at 1 year was higher in males (OR=4.665;95%CI 15.9-10.8, p<0.01), those with abnormal serum creatinine (OR=3.935;CI16.7-702, p<0.01), higher renal SLEDAI (p<0.05), higher AS, CS (p<0.001), interstitial inflammation and tubular atrophy(p<0.005) (Table 1). On binary logistic regression a combined clinico-histopathological model comprising of serum creatinine, UPCC, male sex and CS performed best in predicting NR (Figure 1).

Figure 1. ROC curve and AUC for the three different models: Model 1: Baseline serum creatinine, urine PCR, male sex; AUC= 0.694(0.609-0.779), p<0.001.Model 2: Baseline serum creatinine, urine PCR, male sex, chronicity score; AUC = 0.740(0.660-0.820), p<0.001.Model 3: Baseline serum creatinine, urine PCR, male sex, chronicity score, crescents, interstitial inflammation; AUC= 0.744(0.664-0.824), p<0.001.
Conclusion: Clinical and biochemical parameters can predict the renal histological class to a fair extent but has limited value in predicting the activity and chronicity parameters. Since a combination of clinical and histopathology parameters are better in predicting renal outcomes, performing renal biopsies should be encouraged in LN.

Conclusion: COVID-19 vaccines produced satisfactory but impaired serological response in SLE patients compared to controls which was dependent on the immunosuppressive medications use and type of vaccines received. There was no new short-term safety signal noted. Booster dose is recommended.

Figure 1. Distribution of neutralizing antibody levels after COVID-19 vaccines comparing (A) SLE patients and matched controls, (B) SLE patients and matched controls in two vaccine subgroups, and (C) two vaccine types in SLE patients. Data for each group are presented as box plots: central values within boxes correspond to median: the range between the lower (Q1) and upper (Q3) bounds of the boxes is the IQR. Whiskers represent scores outside IQR and ends in maximum (higher “calculated value” = Q3 + 1.5 x IQR) and minimum (lower “calculated value” = Q1 – 1.5 x IQR). Spots are outliers above the maximum or under the minimum value. Data regarding were analyzed using Mann-Whitney-U test. Dotted line denotes the cut-off level for positivity (30%).

POSO777

STUDY OF PERIPHERAL BLOOD B CELL IMMUNOPHENOTYPING IN PATIENTS WITH LUPUS NEPHRITIS: PARAMETERS OF DISEASE ACTIVITY, REMISSION AND FLARE

C. Di Mario1,2, V. Varriano2,3, L. Petricca, A. Paglioni4, M. R. Gigante5, S. Costanzo5, L. Buï6, F. Federico6, M. A. D’agostino4, S. Alivernini1,4,7, B. Tolusso1, E. Greseme1,2,7 1Immunology Research Core Facility – Gemelli Science and Technology Park (GSTeP), Fondazione Polcino Universitario A. Gemelli, IRCCS, Rome, Italy; 2Division of Clinical Immunology, Fondazione Polcino Universitario A. Gemelli, IRCCS, Rome, Italy; 3Division of Rheumatology, Fondazione Polcino Universitario A. Gemelli, IRCCS, Rome, Italy; 4Division of Pathology, Fondazione Polcino Universitario A. Gemelli, IRCCS, Rome, Italy; 5Division of Nephrology, Fondazione Polcino Universitario A. Gemelli, IRCCS, Rome, Italy; 6Division of Rheumatology, Università Cattolica del Sacro Cuore, Rome, Italy; 7Division of Rheumatology, Università Cattolica del Sacro Cuore, Rome, Italy

Background: B cells play a central role in systemic lupus erythematosus (SLE) pathogenesis connecting innate with adaptive immunity.
Objectives: To investigate the peripheral blood B cell phenotype in a cohort of SLE patients with renal involvement (LN-SLE) in relation to disease activity and renal histological lesions compared to healthy controls.

Methods: One hundred LN-SLE patients with active renal involvement, 40 at disease onset (Early) and 60 in whom LN occurred after the disease onset (Long) were enrolled. Thirty-seven healthy controls were included. Clinical, laboratory and demographic data were collected at baseline and at 6 and 12 month of follow-up. Disease activity was recorded using SLEDAI-2K. Ultrasound-guided renal biopsy has been performed for the definition of the nephritic class according to the ASN/ESR. The memory B cells immunophenotyping (IgD CD27 classification) was analyzed in peripheral blood through flow cytometry. To clarify the role of key molecules in the B cells activation, IL-6 and BAFF serum levels were assessed by Enzyme-linked immunosorbent assay (ELISA).

Results: According to the onset of renal symptoms, there were no differences in the distribution of the renal classes and in activity and chronicity indices in the two groups. A direct correlation was observed between chronicity index score and creatinine in the whole cohort (R=0.342; p<0.01) and in LN-SLE Early (R=0.526; p=0.01) and Long (R=0.337; p=0.02). The disease activity index was found to be significantly higher in anti-dsDNA positive than in negative ones (6.6±4.8 vs 2.8±3.5; p<0.01), and in patients with at least one antiphospholipid antibody-APL positivity (6.8±4.8 vs 5.1±4.6; p<0.05). Considering predictive biomarkers of the remission within 12 months, the presence of histological lesions (glomerulocapsular and fibrocellular crescents) and the positivity for at least one of the APL antibodies were associated to the failure in achieving clinical remission, while baseline 24-hr proteinuria ≤2750mg was related to remission achievement [OR:2.6 (95%CI:1.1-5.8)]. Studying the role of key molecules in the B cells activation, IL-6 and BAFF serum levels were assayed by Enzyme-linked immunosorbent assay (ELISA).

Conclusion: This study suggests that the active injury and chronic damage histological features of LN do not depend on the SLE duration per se, but could be associated to the clinical failure in achieving clinical remission within 12 months. Furthermore, data on memory B cells immunophenotyping reveals a distinct B cells subset of SLE patients when compared to healthy controls, confirming an alteration of B cells subsets in SLE patients and strengthen the hypothesis of the pathogenetic role played by B lymphocytes in the course of LN.

Conclusion: US-guided CNB of the parotid gland could represent a potential novel tool for the diagnosis of pSS patients. When parotid swelling is present, it may be more convenient than lip biopsy. In addition, CNB can be ultrasound-guided in specific glandular areas showing different sonographic appearances, consistent with different histopathology, leading the way for the role as diagnostic tool for pSS, and not only as improved lymphoma detection tool.

Haifa, Israel
Chinese patients with the antiphospholipid syndrome (APS) β anticoagulant (LAC), moderate/high titers of IgG anticardiolipin and anti-2glycric manifestations occurred before diagnosis of the rheumatic diseases. Lupus (4.7%) had both. In patients with secondary APS, 23% thrombotic or obstet-2thromboembolic manifestations, 85(19.9%) had obstetric morbidities and 2ied by Cox regression.

analysis and risk factors for recurrence of thrombosis and mortality were stud-2underlying rheumatic diseases) and secondary types. The treatment and out-
come (recurrence and mortality) of the patients was studied by Kaplan-Meier analysis and risk factors for recurrence of thrombosis and mortality were stud-
ied by Cox regression.

Results: 428 APS patients were studied - 282 fulfilled the 2006 criteria for APS (probable APS, which was further categorized into primary (without underlying rheumatic diseases) and secondary) manifestations occurred before diagnosis of the rheumatic diseases. Lupus anticoagulant (LAC), moderate/high titer of IgG anticardiolipin and anti-2glyc coprotein-1 antibodies was present in 326(76.1%), 242(56.5%) and 29(6.7%) patients, respectively. 137(32%) patients were double positive while 19(4.4%) patient was triple positive for these aPL antibodies. Among the thromboem-

bolic manifestations, arterial thrombosis (n=201) was more common than venous thrombosis (n=186). The following treatment regimens were used: warfarin (63.6%), aspirin plus subcutaneous heparin (6.8%), aspirin plus warfarin (3%), aspirin alone (17.8%) and direct oral anticoagulant (DOAC) (2.8%). Bleeding complications developed in 77(18%) patients. After a mean follow-up of 8.0±14.1 years, recurrence of thromboembolic or obstetric complications occurred in 83(19.4%) and 14(3.3%) patients, respectively (1 patient had recurrence of both thrombosis and obstetric complications). Cox regression did not reveal any factors significantly associated with recurrence of thrombo-

sis. A total of 67(15.7%) patients succumbed (median time to death 7.3 years).
The causes of death were vascular in 29.9% (intracranial haemorrhage [35%], myocardial infarction [30%), limb ischemia [10%], ischemic stroke [10%], bowel ischemia [5%] and non-vascular in 70.1% of patients (infection [59.6%], malig-
noma [20.9%], SLE disease activity [6.5%], pulmonary arterial hypertension [2.1%], organ failure [6.4%] and others). The cumulative risk of mortality over time was 6.4% at 5 years and 11.9% at 10 years. The age and sex adjusted standardized mortality ratio (SMR) of our APS patients relative to the general population was 18.2(14.2-23.0). In patients with thrombotic APS, mortality was asso-
ciated with older age (≥60 years) (HR 2.57[1.34-4.95]) and the presence of LAC (HR 2.01[1.07-3.75]), adjusted for age, sex and vascular risk factors that included hypertension, diabetes mellitus, dyslipidaemia, smoking and atrial fibrillation.

Conclusion: APS in southern Chinese is relatively uncommon and most cases were associated with SLE. In contrast to the Caucasians, venous thrombosis related to APS is less frequent. Over 8 years, recurrence of thrombotic events in APS patients was uncommon. The mortality of APS in our Chinese patients was increased, with older age and the presence of LAC being independent risk factors.

MONOGENIC SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN NORTHERN ISRAEL

I. Spivak1, T. Hershkovitz12, R. Zaid2, K. Weiss2, Y. Butbul Aviel3.
1Rambam Medical Center, Pediatric B, Haifa, Israel; 2Rambam Medical Center Genetic Institute, Haifa, Israel; 3Rambam Medical Center, Pediatric Rheumatology Unit, Haifa, Israel

Background: Systemic Lupus erythematosus (SLE) is a heterogenic clini-

cal syndrome with a multifactorial etiology including diverse environmental, immunological and genetic causes and modifiers. Increasingly, utilizing next generation sequencing tools, monogenic forms of SLE have been identified in northern Israel.

Objectives: The aim of our study was to identify monogenic causes of SLE in the unique pediatric population of Northern Israel.

Methods: A retrospective and prospective study was carried out between 2010-2021 in a single tertiary pediatric medical center. Genetic testing includ-
ing Whole exome sequencing (WES) was performed for select patients includ-
ing familial history of SLE, consanguinity and/or clinical findings suggestive of monogenic disorder.

Results: 75 children were diagnosed with SLE. 13/75 had one or more relatives with SLE, including a pedigree with 4 affected members. Mean age at presenta-
tion was 10.1±4.7. A monogenic disorder was identified in total of 7/75 of pedi-
grees. Four patients were diagnosed with Proladise deficiency, one patient with ADAR1 mutation related to Aicardi–Goutières syndrome and one pepe with APC5 mutations. Candidate variants in genes related to immune system were identified in one proband and her father requiring further study. Additional WES results are pending

Conclusion: We detected monogenic causes of SLE in a select cohort of patient in Northern Israel. Identification of a genetic basis for disease has direct clinical implication for patients and families and can also enhance our understanding of the pathogenesis and disease mechanisms involved in the more common sporadic forms of SLE.

The latter was more common in LN patients. Overall, 83 patients (25.0%) in our cohort had evidence of serologic activity, of whom 51 (9.3%) of total had a clinical SLEDAI of 0.

Table 1. Distribution of patients based on total and clinical SLEDAI-2K score at most recent visit

Figure 1. Components of SLEDAI-2K at most recent visit (total cohort of patients and patients with LN)

Conclusion: Although a significant proportion of our patients were on HCQ and additional IS, about 40% of them were not in optimal control. Yet, residual disease activity, based on SLEDAI-2K, was moderate, compared to relatively high mean baseline SLEDAI-2K of lupus trials. These data provide a pragmatic view of lupus patients, who could be potential candidates for novel treatments or inclusion in clinical trials.

POS0782 ULTRASONOGRAPHIC EVALUATION OF MAJOR SALIVARY GLANDS IN PRIMARY SJÖGREN’S SYNDROME: COMPARISON OF THREE SCORING SYSTEMS AND ASSOCIATION WITH BIOPSY RESULTS.

C. Galisteo1, S. García-Cirera1, S. Retamozo1, M. Moreno1, E. Casado1, M. Rusholf Gonzalez2, J. Calvet1, J. Gratacols-Masmith3, 1Parc Taulí Hospital Universitari, Institut d’Investigació i Innovació Parc Taulí, Rheumatology, Sabadell, Spain

Background: Salivary glands ultrasound is an imaging technique useful for primary Sjögren’s syndrome (pSS) diagnosis. Nowadays, the use of ultrasound in diagnostic criteria is not clear. Different scoring systems have been published in recent years.

Objectives: This study aims to compare the reliability between three salivary glands ultrasound (SGUS) scores in a series of patients with pSS. Furthermore, we assessed the association of the three SGUS scores with minor salivary gland biopsy.

Methods: A cross-sectional study including 98 subjects fulfilling the ACR-EULAR 2017 classification criteria for pSS. All patients underwent an ultrasound of the salivary glands and a minor salivary gland biopsy requested as per clinical practice. An experienced Rheumatologist in SGUS evaluated systematically the previously acquired images. This Rheumatologist classified the images using three different scoring systems obtained from the grades of bilateral parotid and submandibular glands: Del Vita (0-3), Salaffi (0-4) and Omeract (0-3). These three scores were performed in different days and blinded for the previous scores results. SGUS grade ≥ 2 was considered positive. Positive biopsy was deemed when focus score ≥1. We evaluated the agreement between the three scores and the individual scores with respect to the biopsy.

Results: This study included 98 patients with pSS. The distribution of the different grades according to the score system and the percentage of a positive SGUS are shown in Table 1. The reliability for a positive score for the three evaluated systems was almost perfect, with a Light’s kappa of 0.95 [0.9-1] for the De Vita-Salaffi, 0.87 [0.77-0.97] for De Vita- Omeract and 0.83 [0.71-0.94] for Salaffi-Omeract. We observed a same degree of concordance when the individual parotid and submandibular scores were evaluated. There was only a fair agreement for positivity of SGUS and a positive biopsy in all scoring systems, specifically De Vita (kappa = 0.27 [0.09-0.45]), Salaffi (kappa = 0.26 [0.06-0.45]) and Omeract (kappa = 0.22 [0.03-0.42]). This associations with a positive biopsy did not change in magnitude when individually evaluated parotid and submandibular glands.

Table 1. Distribution of the ultrasound grades and the percentage of positive biopsy in the different scoring systems evaluated.

</tbody>
</table>

Conclusion: The three SGUS scores are reliable for the evaluation of the main salivary glands in pSS. There was only weak agreement for SGUS and biopsy, so these two techniques provides complementary information and currently, SGUS cannot replace the biopsy for diagnosis purposes.

POS0783 ASSOCIATION BETWEEN ENVIRONMENTAL FACTORS AND SALIVARY GLAND ULTRASOUND FINDINGS IN PATIENTS WITH SUSPECTED PRIMARY SJÖGREN SYNDROME

L. Barrio Nogal1, M. Novella-Navarro2, L. Sala-icardo1, A. Prada-Ojeda1, C. Bohórquez3, A. Pérez Gómez4, 1Hospital Universitario de Torrecárdenas, Servicio de Reumatología, Madrid, Spain; 2Hospital Universitario la Paz, Servicio de Reumatología, Madrid, Spain; 3Hospital Universitario Príncipe de Asturias, Servicio de Reumatología, Madrid, Spain

Background: The influence of environmental factors in primary Sjögren’s syndrome (pSS) and their relationship with serological, histological and ultrasound findings remains still poorly understood. A possible protective effect of female sex hormones and smoking has been related to a lower focal lymphocytic sialadenitis on the minor salivary gland biopsy (MSGB), but the relationship between histological findings and other chemical, toxic or dietary factors remains scarce or controversial, and even more so the relationship between these factors with salivary gland ultrasound (SGUS) findings, an emerging tool in the diagnostic and management of pSS.

Objectives: To analyze the relationship between sociodemographic, clinical and environmental factors with pathologic SGUS findings in patients with suspected pSS.

Methods: 72 patients with clinical and/or analytical suspicion of pSS were consecutively recruited. SGUS was performed pathologic (grade ≥2 according to Correc et al system) vs non-pathologic. Final diagnosis of pSS was made according to AECG, ACR/EULAR criteria and MSGB. Sociodemographic, clinical, analytical, activity indexes (ESSPRI and ESSDAI), environmental factors, toxic and dietary habits were collected. Chi-square and Fisher tests were used to compare qualitative variables and T-student and U-Mann Whitney tests, for quantitative variables (statistical significance p<0.05). Defining pathologic vs non-pathologic US as the outcome variable, binomial logistic regression was performed for bivariate analysis, with calculation of Odds Ratio (OR) and 95% confidence interval (CI).

Results: 70.8% presented pathological SGUS, this percentage was significantly higher in patients with a definitive diagnosis of pSS (56.6% vs 26.6%; p=0.02), 97.2% were women with a mean age 57.3±11.8 years. Patients with pathological SGUS had in lower frequency a varied diet (64.2 vs 89.5; p=0.03), higher exposure to environmental toxic (71.1 vs 61.1; p=0.05), lower percentage of smokers (26.4 vs 52.6; p=0.03) and a lower mean age at menopause than patients with non-pathologic SGUS (47.3±3.9 vs 50.2±4.2; p=0.03). Significant differences were found in antiRo52 positivity and hypergammaglobulinemia. Bivariate analysis showed that menopause at younger age confers higher probability...
of presenting pathologic SGUS (OR=1.2 CI95% 1.02-1.41) and smoking was protective against pathologic SGUS (OR=0.32 CI95% 0.11-0.95). Hypergammaglobulinemia (OR=8.80 CI95% 2.37-34.02) and antiRo2 (OR=3.89 CI95% 1.14-13.20) imply an increased risk of pathological findings on SGUS.

Conclusion: Pathologic SGUS was more frequent in patients with definitive diagnosis of pSS, antiRo2 antibodies and hypergammaglobulinemia. Late menopause and smoking were protective factors against pathologic SGUS, and a tendency for a varied diet and absence of exposure to environmental chemicals. SGUS could be the initial diagnostic test in patients with suspected pSS and positive antiRo who have less exposure to estrogens, tobacco and Mediterranean diet and greater exposure to chemicals. For this reason, SGUS could be useful in identifying modifiable environmental risk factors to decrease the incidence and severity of this disease, for which effective therapy is still lacking.

LOW COMPLEMENT LEVELS ARE ASSOCIATED WITH HIGHER MORTALITY IN HOSPITALIZED PATIENTS WITH POSITIVE ANTIPHOSPHOLIPID ANTIBODIES

E. Itelman1, M. Perelman1, D. Kent1, N. Biber1, G. Segal1, L. Negru1, A. Dagan2,  
1Sheba Medical Center, Internal Medicine Ward “T”; 2Ramat Gan, Israel; 3Wolfson Medical Center, Rheumatology Unit, Holon, Israel

Background: Antiphospholipid Syndrome is an autoimmune disease characterized by increased risk for vascular thrombosis (arterial and/or venous) thrombosis and/or pregnancy morbidity in the presence of antiphospholipid antibodies. The mechanisms by which aPLs induce thrombosis are unclear; several are suggested, among them complement activation. (1-2) The complement system is a system of enzymes and regulatory proteins of the innate immune system that play a crucial role in the inflammatory response to various pathogenic stimuli. The complement and coagulation pathways are interconnected, and expanding evidence indicates that complement may be activated in patients with antiphospholipid syndrome (3-5).

Objectives: Our study was intended to better characterize the complicated relations between antiphospholipid antibodies and complement activation among hospitalized patients with antiphospholipid syndrome and its impact on short- and long-term prognosis

Methods: A retrospective cohort studies. Clinical and prognostic data of hospitalized patients with antiphospholipid syndrome and a measurement of complement levels (C3 or C4) were obtained. Rates of long-term mortality, one-year mortality, deep vein thrombosis (DVT), and pulmonary emboli (PE) were compared between patients with low complement levels and patients with normal complement levels. Low complement was defined as C3 < 90 mg/dl or C4 < 10 mg/dl. A multivariate analysis was performed to control for Anticardiolipin levels,β₂-macroglobulin levels and RVVT ratio.

Results: Complete data was available for 6,599 patients, of which 712 (11%) had low complement levels. The median age of the cohort was 47.7, and most of the patients were females (56%). Patients with low complement levels had significantly higher mortality rates 30% vs. 18%, p < 0.001 for long-term mortality (Figure 1) and 15% vs. 5%, p < 0.001 for 1 year mortality when compared to patients with normal complement levels. DVT and PE rates were similar (4% vs 3.8%, P = 0.78 and 4% vs 2.4%, P = 0.13 respectively). Results of the multivariate analysis (Table 1) were consistent and showed that patients with low complement levels had 111% higher mortality rates (CI 1.52-2.90, P < 0.001).

Table 1. Multivariate Analysis for long term mortality

EXPRESSION OF MYXOVIRUS RESISTANCE PROTEIN A IN LUPUS NEPHRITIS

L. Liu1, K. De Leeuw1, G. Diercks2, C. Stegeman3, B. Doornbos-van der Meer1, H. Van Goor2, M. Heuvel3, J. Westra1. 1University Medical Centre Groningen, Department of Internal Medicine, Division of Nephrology, Groningen, Netherlands; 2University Medical Centre Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands; 3University Medical Centre Groningen, Department of Internal Medicine, Division of Nephrology, Groningen, Netherlands

Background: Lupus nephritis (LN) is regarded as one of the most severe organ manifestations of systemic lupus erythematosus (SLE) [1]. It has been shown that type I interferons (IFN) are important cytokines in the pathogenesis of SLE and LN and could possibly serve as a histological marker for kidney lesions in LN [2]. However, the direct measurement of type I IFN protein in tissues has remained elusive. Myxovirus resistance protein A (MxA) which is upregulated by IFN-1, can easily be measured, and could be used as a potential biomarker. In addition, dendritic cells are main producers of IFN-1.

Objectives: To investigate the expression of MxA and CD303 which is a plasma-cytoid dendritic cells (pDCs) specific marker [3] by immunohistochemical analysis of renal specimens obtained from LN patients and from patients with other types of nephritis.

Methods: LN was diagnosed based on the International Society of Nephrology/Renal Pathology Society (ISN/IPS) classification. In total, 41 renal tissue samples were collected from lupus nephritis including all classes (I-V according to ISN/IPS classification), and compared to 70 biopsies from other forms of nephritis. MxA was detected by immunohistochemistry staining. Scoring of MxA staining was done semi-quantitative for four groups of patients with a range from 0 to 3+. Scoring was based on the intensity of the staining, in which '0' meant no expression; '1': weak expression; '2': moderate expression; and '3+': strong expression. The expression of CD303 was measured by counting the number of CD303 positive cells in the glomerulens or in the tubular interstitium.

Results: The MxA average scores of the total LN group were higher than control specimens especially in distal tubules (Figure 1). The MxA expression in LN...
classes I, II, and V biopsies was mainly increased compared to tissues of patients with minimal change disease, mesangio proliferative nephritis, and membranous nephropathy (Figure 2a, 2b, 2d). However, MxA staining was comparable in LN classes III/IV compared to control groups (Figure 2c). The staining of CD303 showed that pDCs are more present in tubular interstitium than in glomeruli. Furthermore, CD303-positive cells were highest in LN class IV, but overall numbers of pDCs were higher in controls groups compared to LN groups (Figure 3).

Conclusion: Our data indicate that MxA expression is higher in LN vs. other types of nephritis. These results suggest that MxA could be a potential additional histological marker to establish the diagnosis of lupus nephritis on the kidney biopsy. In contrast to the increased expression of MxA in LN, we found decreased numbers of pDCs. Therefore, it is important to investigate which other cells are the main producers of IFN-1 in further studies.

Background: Cognitive dysfunction (CD) and mood disorders (MD) are among the most frequent neuropsychiatric (NP) events in Systemic Lupus Erythematosus (SLE), but their pathogenesis has not been clarified yet. Until now, an unquestionable correlation between the presence of specific autoantibodies, brain alterations and the presence of CDs and MDs in SLE is lacking.

Objectives: The primary aim of the study was to explore the effects of anti-NR2 (anti-DWEYS) and anti-ribosomal-P (anti-P) antibodies on CDs and MDs and their relation with functional brain connectivity in patients affected by SLE.

Methods: A cross-sectional study was conducted, between April 2019 and February 2020, including adult patients who fulfilled the ACR/EULAR 2019 SLE criteria. Demographics, ongoing medications, SLEDAI and SLICC/Damage Index were recorded. Serum level quantification for anti-P (normal values <18 U/ml) and anti-NR2 (normal values <0.5 OD) antibodies were performed using an ELISA. A battery of neuropsychological testing was interpreted by a neuropsychologist, exploring cognitive domains, depression and quality of life. A resting-state functional connectivity (rs-fc) MRI analysis was performed within 2 weeks since the neuropsychological status assessments. Two region

IDENTIFYING INDIVIDUALS AT RISK FOR SJÖGREEN’S SYNDROME – THE PRE-SJÖGREEN SYNDROME TARGETED IMMUNOLOGICAL EVALUATION (PRESTIGE) STUDY

S. Zenz1, E. Erlacher1, E. Winisch1, B. Dreo2, P. Javorova3, A. Lackner1, M. D’orazio1, Thiel1, D. Corneç1, M. Stradner1.

1Medical University of Graz, Department of Rheumatology and Immunology, Graz, Austria; 2University of Brest, Department of Rheumatology, Brest, France.

Background: Primary Sjögren’s Syndrome (pSS) is a chronic autoimmune disease. Symptoms range from sicca to systemic, potentially life-threatening organ damage. Little is known about the onset of the disease. Anti-Ro antibodies are described to develop years before the first symptoms. In addition, first degree relatives of pSS patients have an 11- to 19-fold increased risk of developing pSS themselves.

Objectives: To identify and follow-up individuals at risk for pSS in order to study symptoms and immune pathology before and at development of pSS.

Methods: In this ongoing long-term study individuals at risk for developing pSS but not fulfilling the ACR-EULAR classification criteria of pSS were included, defined as: 1) Anti-SsA-positive individuals (Anti-SsA) without any sicca symptoms or diagnosis of an underlying systemic autoimmune disease; 2) First degree relatives of patients (relatives) with an established diagnosis of pSS and typical autoantibodies (ANA ≥ 1:160 and/or anti-SsA and/or rheumatoid factor); 3) Individuals with at least one feature of the ACR-EULAR classification criteria for pSS, but not fulfilling the criteria (incomplete). At baseline and at annual visits, demographic data, blood, saliva and urine samples were collected and stored. Salivary and lacrimal flow, salivary gland ultrasonography (SGUS), and patient-related outcome measures were analysed. A lip salivary gland biopsy was performed at baseline and upon development of symptoms suggestive of pSS. The primary endpoint was the development of definite pSS according to the ACR-EULAR classification criteria.

Results: After the first year of recruitment, 50 individuals (Anti-SsA: n=27, relatives n=23, incomplete n=2) were screened at baseline, of whom 28 were identified as individuals at risk for pSS and were included in the study. Twenty-two individuals were excluded from the study, most of whom were “relatives” with negative autoantibodies. Of these 28 individuals at risk, 89% were female (n=25), they had a median age of 53 years (IQR: 19) and 57% (n=16) had positive antinuclear antibodies. 86 percent were positive for anti-SsA and 14% were positive for anti-SSB. Decreased complement C3 and C4 were found in 18% and 41%, respectively. Serum IgG concentration was elevated in 79% of individuals. A reduction of lacrimal flow was found in 29% and stimulated whole salivary flow was reduced in 29%. The median of the ESSPRI was 1.6 (3.0). Eighteen per cent of the investigated individuals had a pathological ultrasonography [Hoevear score median 4.5 (9.0)] and in 9% a focus score ≥1 (median 0.15 (0.57)) was found in the lip salivary gland biopsies. Four patients (14%) met the primary endpoint and were diagnosed with pSS within the first year.

Conclusion: The design of the PRESTIGE study allows us to follow individuals at risk for pSS and will help to unveil symptoms and immune pathology as pSS develops. We suggest to establish a larger international pre-pSS cohort to increase statistical power.

Disclosure of Interests: None declared

of interest to region of interest (ROI-to-ROI) analyses with the graph theory was performed.

**Results:** Thirty-three SLE patients (9% male) were enrolled, mean age 43.5 (±14) years, and median disease duration of 10.4 years (IQR 2.9-25.4) (Table 1). Anti-P were positive (range 0-255 U/ml) in 6 patients (18.2%) and anti-DWEYS (range 0-1.8 OD) in 14 (42.4%). Nineteen out of 33 patients (57.6%) showed at least a cognitive test alteration, but no significant association with antibodies was found. Depression was found in 14 (42.4%) patients using the Center for Epidemiologic Studies Depression Scale (CES-D) as screening instrument. In multiple regression backward models, after correction for age, disease duration, SLEDAI and SDI, the CES-D showed an independent association with anti-P titre (β= 0.32 per U/ml; p=0.049) and prednisone daily dose (β=0.38 per mg/day; p=0.023). The rs-fc MRI analysis revealed a statistically significant association between the titre of anti-P and many altered properties of the brain ROIs (Figure 1), but no effects of PDN daily dose on specific cerebral networks.

**Figure 1.**
Conclusion: For the first time we suggest the potential usefulness of IL-2RA as a marker of disease activity in SjS. Notably, IL2RA has been used as a marker to identify CD4+Foxp3+ regulatory T cells. So far, it is known that T follicular helper (Tfh) cell differentiation is inhibited by IL-2 while regulatory T cell differentiation and survival depend on it. Nonetheless, Wing et al. (1) described a CD25- subpopulation within human PD1+CXCR5+Foxp3+ Th cells preferentially located in germinal centers which is reduced by the presence of IL-2, possibly explaining the association with disease activity. IL-12p40 is known to have a pathogenic role in SjS (2) and we suggest that it may represent a complementary tool in the evaluation of patients’ symptoms. The presence of high levels of IL-15 in SjS is not novel and associated with T cell migration and proliferation in germinal centers. Finally, the observation of very high BAFF/BLYS levels in the male with cryoglobulin will require further analysis.

CLINICAL FEATURES OF SJÖGREN’S SYNDROME WITH AND WITHOUT NEUROLOGICAL INVOLVEMENT (NEURO-SJÖGREN)

T. Seeliger1, E. Kramer2, F. F. Konen1, S. Beider2, A. Jablonka2, T. Witte3, T. Skripuletz1, D. Ernst1, 1Medizinische Hochschule Hannover, Neurology, Hannover, Germany; 2Medizinische Hochschule Hannover, Rheumatology and Immunology, Hannover, Germany

Background: Sjögren’s Syndrome is well known for its characteristic sicca symptoms due to autoinflammatory destruction of the salivary and lacrimal glands, but extraglandular involvement is also common in this entity. Nevertheless, previously published smaller studies suggested distinct clinical features for Sjögren’s syndrome with and without neurological involvement, such as a more balanced gender distribution and lower IgG levels in patients with Sjögren’s syndrome and neurological involvement1-2.

Objectives: We therefore aimed to systematically assess clinical features of patients with Sjögren’s syndrome with and without neurological involvement, find relevant in-between group differences and hereby aid early detection of both patient groups in the clinical routine to facilitate further studies, potentially with new therapeutic approaches.

Methods: We retrospectively assessed patients with Sjögren’s syndrome treated at the neurological and rheumatological/immunological department of our university hospital between 05/2014 and 09/2021 for available laboratory and clinical data. The displayed data represent preliminary results of this ongoing study.

Results: 405 patients, who fulfilled the current ACR/EULAR classification criteria for Sjögren’s syndrome were currently included in the study (median age 59 years [IQR 50-70 years], median ESSDAI 10 [IQR 3-16]). 228 patients (56%) showed neurological involvement. They were significantly more often male (32% vs. 14%; p<0.001) and showed lower IgG serum levels (median 11 g/l [IQR 9-13 g/l] vs 12 g/l [IQR 10-16 g/l], p<0.01) in comparison to patients with Sjögren’s syndrome but without neurological involvement.

Conclusion: Preliminary analysis of this ongoing study supports the hypothesis, that patients with Sjögren’s syndrome and neurological impairment might express a distinct clinical phenotype in comparison to patients with Sjögren’s syndrome but without neurological involvement.

18F-FLUORODEOXYGLUCOSE (FDG) PET-CT IMAGING OF SALIVARY GLANDS IN PRIMARY SJÖGREN’S SYNDROME AND ITS CORRELATION WITH ULTRASONOGRAPHIC SCORES AND SALIVARY FLOW RATE COMPARED TO HEALTHY CONTROLS

K. Abacar1, T. N. Kissas2, K. Oksuzoglu2, T. Ones2, G. Mumcu3, G. Brynet4, N. Inanc1, 1Marmara University School of Medicine, Rheumatology Department, Istanbul, Turkey; 2Marmara University School of Medicine, Nuclear Medicine Department, Istanbul, Turkey; 3Marmara University School of Health Sciences, Health Management, Istanbul, Turkey; 4ReumaKind Lelystad, Rheumatology, Lelystad, Netherlands

Background: The use of salivary gland imaging modalities in patients with primary Sjögren’s syndrome (pSS) has been increasing recently. The contribution of each imaging method in terms of diagnosis or disease activity differs from each other. Although ultrasound and MRI are the most commonly used imaging modalities, the role of PET-CT for diagnosing pSS and determining glandular and extraglandular involvement has largely been neglected.

Objectives: This study aimed to compare the sizes and metabolic activities of the major salivary glands in patients with pSS and healthy controls (HC). Correlation of the 18F-FDG PET-CT uptake characteristics with ultrasound scores and salivary flow rates of the patients and HC was also determined.

Methods: 22 patients with pSS and 10 age-sex-matched HC were included in the study. The sizes and FDG uptakes of the parotid and submandibular glands of pSS patients and HC were assessed by PET-CT. The maximum standardized uptake value (SUVmax) was evaluated for FDG uptakes, and each patient’s liver uptake and salivary gland uptake ratio were calculated. In addition, correlations of gland sizes and FDG uptakes in PET-CT with OMERACT and Hoeveca ultrasound scores, stimulated and unstimulated SFR, ESSPRI dryness scores and disease durations of pSS patients were calculated by Spearman test.

Results: The mean age (SD) of the patients was 58.6 years (10.5) versus 58.6 years (19.1) of HC; the mean (SD) disease duration was 8.96 (8.77) years. ANA was positive in all patients, anti-SSA positivity was present in 82.6%, and 30.4% of patients experienced ≥1 parotid swelling episode. Compared to HCs, the mean size of both submandibular glands (p=0.006 for left and p=0.032 for right) and SUVmax of the left submandibular gland (p=0.044) were significantly smaller in patients with pSS. In pSS patients, both right and left parotid sizes were smaller and SUVmax uptake was greater than in HC; these differences however did not reach statistical significance. When the PET-CT involvement characteristics of the patients were compared with the salivary gland ultrasonography scores, there was a statistically significant negative correlation between the left parotid gland size in PET-CT and the ultrasonographic inhomogeneity of Hoevecar score and OMERACT score. There was a statistically significant negative correlation between right parotid gland size measured on PET-CT with ultrasonographic inhomogeneity, hyperchoic foci, parenchymal echogenicity, Hoevecar total score, and OMERACT score. No statistically significant correlation was found between SUVmax scores detected by PET-CT and ultrasound scores in both parotid glands and submandibular glands. A statistically significant positive correlation was found between the total gland size measured in PET-CT and the unstimulated salivary flow rate (p=0.038, r=0.604). There was a negative correlation between total gland size and ESSPRI dryness scores and symptom duration, which did not reach statistical significance.

Conclusion: PET-CT SUVmax measurements do not provide sufficient information for pSS-related involvement of the major salivary glands. Secondly, size measurement of the parotid glands by PET-CT is associated with OMERACT ultrasound scores, and also the sizes of both submandibular and parotid glands are smaller than HC.

Vasculitis — large vessel vasculitis.

A NATIONWIDE STUDY OF OCULAR MANIFESTATIONS AMONG HOSPITALIZED PATIENTS WITH GIANT CELL ARTERITIS

P. Therkildsen1,2, A. De Thurah1, M. Faurusch3, B. Baslund1, I. Hansen1, M. Nørgaard1,2, B. Dalgaard Nielsen1, E. M. Hauge1,2, Aarhus University Hospital, Department of Rheumatology, Aarhus N, Denmark; Aarhus University, Department of Clinical Medicine, Aarhus C, Denmark; Aarhus University Hospital, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus N, Denmark; Horsens Regional Hospital, Department of Internal Medicine, Horsens, Denmark

Background: Ocular manifestations are common among patients with giant cell arteritis (GCA). Most feared is a permanent visual impairment reported in up to 15-20% of GCA patients. Estimates of ocular manifestations vary significantly between studies, and large, nationwide studies are currently lacking. In GCA, visual impairment has been associated with high and low inflammatory markers. Also, low-dose aspirin treatment has been associated with a reduced risk of visual impairment in patients with GCA, but the evidence remains sparse.

Objectives: To investigate the risk of ocular manifestations among hospitalized patients with GCA. Furthermore, to investigate the association between inflammatory marker levels and low-dose aspirin treatment with the risk of ocular manifestations.

Methods: A Danish, nationwide, register-based cohort study including 14,574 incident GCA patients diagnosed between 1996 and 2018, and 145,740 general population referents, matched on age, sex, and calendar time. Ocular manifestations were defined as retinal vascular occlusions, disorders of optics, visual impairment, diplopia, and amaurosis fugax. We tabulated characteristics of the GCA and reference cohort at the time of diagnosis including ocular manifestations recorded within one year of the GCA diagnosis. Regression analyses for incident ocular manifestations were performed using a pseudo-observational approach with the index date defined as the date of the GCA diagnosis. Cumulative incidence proportions (CIPs) and relative risks (RRs) of incident ocular manifestations with 95% confidence intervals (CIs) were calculated with death as a competing risk.

Results: Within one year of the diagnosis, 1,026/14,574 (7%) of GCA patients were registered with ocular manifestations with 392/1,026 (38%) being prior to and 634/1,026 (62%) after the GCA diagnosis, and 744/1,026 (73%) were registered within one month of the diagnosis. A total of 336/1,026 (33%) were retinal vascular occlusions, 300/1,026 (29%) disorders of the optic nerve, 177/1,026 (17%) visual impairment, 90/1,026 (9%) diplopia, and 123/1,026 (12%) amaurosis fugax. The CIP of ocular manifestations among GCA patients was 4.0% (95% CI: 3.6-4.3), 4.2% (95% CI: 3.9-4.6), and 4.6% (95% CI: 4.2-4.9) after 5, 6, and 12 months following the diagnosis with a 1-year RR of 28.0 (95% CI: 24.0-32.7) compared to the general population. Age above 70 years, male sex, and a positive temporal artery biopsy were associated with an increased 1-year RR of incident ocular manifestations. Neither treatment with low-dose aspirin nor baseline CRP nor ESRI levels was related to the risk of ocular manifestations.

Conclusion: In GCA, most cases of ocular manifestations occur at the time of diagnosis with over one-third of cases occurring prior to the diagnosis, emphasizing the need for early recognition and treatment. Low-dose aspirin treatment was not associated with a reduced risk of ocular manifestations among patients with GCA.

POS792 PULMONARY ARTERY INVOLVEMENT IN BEHÇET’S DISEASE: SINGLE CENTER RESULTS

O. Ozdemir Isik1, S. San1, D. Temiz Karadag1, A. Yazio1, A. Cefle1. 1Kocaeli University, Faculty of Medicine, Rheumatology, Kocaeli, Turkey

Background: Behçet’s disease (BD) is a multisystem inflammatory vasculitis. Skin, mucosa, eye, vascular area, joint, gastrointestinal system and central nervous system involvement is observed.

Objectives: In this study, we aimed to present the data of patients with pulmonary artery involvement (PAI) followed up with the diagnosis of BD.

Methods: The clinical, demographic and laboratory data of 394 patients with the diagnosis of BD, who were followed up in our rheumatology outpatient clinic between 2000 and 2020, were evaluated retrospectively.

Results: Of the patients followed up with the diagnosis of BD, 44% were female and 56% were male. Oral aphthous ulcers were found in 96%, genital ulcers in 65%, papulopustular lesions in 33%, erythema nodosum in 38%, and pathergy positivity in 47% of the patients. PAI was detected in 3% (n:13) of the patients who were followed up with a diagnosis of BD. 69% of the patients who had PAI were male, and their mean diagnosis age was 27.9, disease duration was 10±4.7 years. Pulmonary artery aneurysm was observed in 62%, pulmonary artery thrombosis (PAT) was observed in 46%, and both conditions were observed in 46% of the patients. Oral aphthous ulcer were found in all patients, genital ulcers in 70%, papulopustular lesions in 23%, pathergy positivity in 39%, and erythema nodosum in 23%. One of the patients with PAI had hereditary thrombophilia and also extremity deep vein thrombosis (DVT). Cardiac involvement was in the form of intracardiac thrombus in patients with BD. Patients with and without PAI were compared in terms of clinical findings. A significant difference was observed in terms of DVT in the lower extremity, venous and cardiac involvement. The relationship between PAI and these involvements was also shown in the regression analysis (Table 1).

Significant data in logistic regression analysis were presented, GIS: Gastrointestinal system

Cranial involvement was not detected in any of our patients with PAI. In subgroup analysis, a significant relationship was observed between PAT and intracardiac thrombus (p=0.001 OR:21.05 95%CI:3.4-139) and lower extremity DVT (p=0.001 OR: 8.79 95%CI:2.58-29.96).

Conclusion: PAI is rare but the most important involvement affecting mortality in BD patients. Recently, there has been an increase in the incidence of isolated PAT with the contribution of the developments in imaging methods.1 PAI is associated with lower extremity DVT, cerebral venous thrombosis and intracardiac thrombus.2 In our study, a significant correlation was found between PAI and the presence of venous involvement, lower extremity DVT and intracardiac thrombus.

Yoshifuji8, 1Osaka University Graduate School of Medicine, Department of Obstetrics and Gynecology, Osaka, Japan; 2Osaka University Graduate School of Medicine, Department of Clinical Oncology, Osaka, Japan; 3Osaka University Graduate School of Medicine, Department of Internal Medicine, Osaka, Japan; 4Faculty of Medical Pharmaceutical Sciences, Department of Chronic Kidney Disease and Nephrology, Sapporo, Japan; 5Osaka University Graduate School of Medicine, Department of Obstetrics and Gynecology, Osaka, Japan; 6Kochi Medical School, Department of Obstetrics and Gynecology, Kochi, Japan; 7Sapporo Medical University, Department of Obstetrics and Gynecology, Sapporo, Japan; 8Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Department of Chronic Kidney Disease and Cardiovascular Disease, Okayama, Japan; 9Okayama University Hospital, Division of Hemodialysis and Apheresis, Okayama, Japan; 10Shimane University Faculty of Medicine, Department of Rheumatology, Izumo, Japan; 11Kyoto University, Department of Medicine, Department of Nephrology and Rheumatology, Kyoto, Japan; 12Tokyo Women's Medical University Hospital, Department of Rheumatology, Institute of Rheumatology, Tokyo, Japan

Background: Takayasu arteritis (TAK), a granulomatous large vessel vasculitis, mainly involves the aorta and its proximal branches and commonly occurs in young females. However, studies of pregnancy in women with TAK are sparse and limited, probably due to the rarity of the disease.

Objectives: The purpose of this study was to understand the status quo of medical treatments of the primary disease and outcomes of pregnancy in patients with TAK, and to post-birth consequences in Japan.

Methods: Patients with TAK who conceived after the onset of the disease and were managed at medical facilities participating in the Japan Research Committee of the Ministry of Health, Labour, and Welfare for Intractable Vasculitis (JPVAS) were retrospectively enrolled in this study. The following information was collected from patients who had a live-born baby: age at diagnosis of TAK, disease classification, age at delivery, treatments before and during pregnancy, complications during pregnancy, birth outcomes of the children, and changes in disease activity during pregnancy and after delivery.

Results: Fifty-one cases and 69 pregnancies from 19 ethics committee-approved centers were enrolled during the study period 2019–2021. Of these, 49 cases and 66 pregnancies (95.7%) resulted in delivery and live-born babies. The Numano classification of the 49 cases was as follows: type I, 11; type IIa, 15; type IIb, 12; type III, 1; type IV, 1; type V, 6; with type V being the most common. The age of diagnosis was 22 years (13–37 years, year of diagnosis 1965–2017), the median age of the delivery of 66 pregnancies was 31 years (year of delivery 1969-2021), and the median duration of illness at delivery was nine years. There were 34 planned pregnancies (51.5%, including four pregnancies by artificial insemination/ovulation induction). Preconception therapy included prednisolone (PSL) in 51 pregnancies (77.3%, median dose 7.5 mg (range 4–30 mg/day)), immunosuppressive drugs in 18 pregnancies (27.3%, azathioprine 8, tacrolimus 7, methotrexate 4, cyclosporine A 1, and colchicine 1), biologics in 12 pregnancies (18.1%, infliximab 6, tocilizumab 5, and adalimumab 1), antihypertensive drugs in 5 pregnancies (7.6%). Surgical treatment had been performed before delivery in 6 cases (aortic root replacement 2, subclavian and carotid 1, subclavian 1, carotid 2, subclavian 1, and ascending aorta semicircular artery replacement 1). Medications used during the course of pregnancy included PSL in 48 pregnancies (72.7%, median dose 8 mg (range 4–30 mg/day), increased in 13 pregnancies, decreased in 1 pregnancy), immunosuppressants in 13 pregnancies (19.7%, azathioprine 6, tacrolimus 6, and cyclosporine A 1), biologics in 9 pregnancies (13.6%, infliximab 4, tocilizumab 4, and adalimumab 1), Immunosuppressants and biologics were discontinued in five and four cases during pregnancy, respectively. During pregnancy, birth outcomes of the children, and changes in disease activity during pregnancy and after delivery. One pregnancy resulted in restenosis of subclavian artery for which dilata-
tion procedure was performed prior to the pregnancy. There were 13/66 (19.7%)
preterm infants and 17/59 (28.8%) low birth weight infants; all but one had a birth weight of more than 2,000 g and no had serious postnatal abnormalities. Forty-three (82.7%) of the 52 confirmed infants were breastfed fully or mixed. Comorbidities: Most of the pregnancies in patients with TAK were successfully delivered while they had low disease activity at a dose of less than 10 mg/day of PSL. Relapse occurred during pregnancy and after delivery in some cases. The babies tended to have low birth weight, but 82.7% of them were breastfed without serious complications.

DaiichiSankyo Co., Ltd.

**Background:** Epidemiological information on Giant Cell Arteritis (GCA) comes mainly from the Scandinavian countries of northern Europe, which show a higher incidence than the countries of southern Europe. GCA clinical manifestations can be divided into cranial, extracranial, and general syndrome.

**Objectives:** In a large series of GCA from Spain, we studied a) the incidence of GCA, b) clinical manifestations, and c) comorbidities at the time of disease diagnosis.

**Methods:** ARTESER is a retrospective epidemiological observational study of GCA promoted by the Spanish Society of Rheumatology in which 26 hospitals participate. The inclusion criteria were: all new patients diagnosed with GCA by a) ACR criteria, b) positive diagnostic test (temporal artery biopsy, temporal artery ultrason or other relevant imaging techniques) and/or c) investigator's clinical judgment. The patient recruitment period ranged from June 1, 2013 to March 29, 2019. The overall incidence of GCA per 100,000 people ≥50 years for the whole period and the mean annual incidence were evaluated. The clinical variables were collected by reviewing the patient’s medical history.

**Results:** 1675 patients were included. The average annual incidence rate was 7.42 (95% CI: 6.57-8.27). All the cases were older than 50 years, and the age group with the highest annual incidence was that of 80 to 84 years, where it reached a value of 22.63 (95% CI: 22.04-23.22). The mean annual incidence is higher in women than in men 10.07 (95% CI: 8.74-11.55) vs 4.81 (95% CI 3.84-5.93) (Table 1).

**The principal clinical characteristics of the population is shown in Table 1, the mean age at diagnosis was 76.9±8.1 years, 1178 (70.3%) were women. 1045 patients (62.39%) had ACR criteria and some positive objective test, 355 patients (21.9%) presented only ACR criteria and 213 (12.72%) only had a positive diagnostic test; 62 (3.7%) of the patients underwent diagnosis based on clinical judgment. The more frequent comorbidity was arterial hypertension (n=1079; 64.8%),**
followed by dyslipidemia (n=801, 48%). The predominant cranial manifestation was headache (n= 1337, 79.9%) and 605 patients experienced visual symptoms. The most widely used immunosuppressant was MTX both at diagnosis (n=165; 96.9%) and during follow-up (n=532; 31.8%), followed by TCZ, at diagnosis (22; 13%) and at follow-up (153; 9.1%). AE with GC were described in 393 patients (23.8%), highlighting serious infections (n=67; 10.03%) followed by diabetes mellitus (n=63; 9.43%), steroid myopathy (n=53; 7.9%), vertebral fractures (n=47; 7.04%), non-vertebral fractures (n=36; 5.39%), heart failure (n=36; 5.39%), arterial hypertension (n=34; 5.09%) and neuropsychiatric alterations (n=27; 4.04%). During the follow-up, 334 (19.9%) patients had relapses, 532 (31.8%) were hospitalized on some occasion, and 142 patients (8.48%) died. The main cause of death were infections (n=44; 30.99%), neoplasms (n=23; 16.2%), cardiovascular (n=15; 10.56%), and cerebrovascular (n=10; 7.04%).

Conclusion: The main treatment for GCA was oral GC, which were required for almost two years on average, in a quarter of patients associated with IV pulses. The cumulative steroid dose was high as well as the side effects. MTX was the most widely used immunosuppressant and TCZ was prescribed in 10%. Relapses and admissions at the hospital were relatively frequent.

Results:

After 6 months’ treatment, no difference was observed in ER between two groups (LEF group: 31/35 (88.57%) vs. TOF group: 28/32 (87.50%), p=1.00). During 12 months’ treatment, the relapse rate was also comparable between two groups (LEF group: 6 (17.14%) vs. TOF group 7 (21.88%); p=0.76); ESR and CRP were decreased significantly at 6 (ESR: LEF group: p<0.0001; TOF group: p=0.15; CRP: LEF group: p=0.06; TOF group: p=0.06); 12 months (ESR: LEF group: p<0.0001; TOF group: p=0.06; CRP: LEF group: p=0.06; TOF group: p=0.14) in both groups compared with their corresponding baseline levels. The proportion of patients with imaging improvement after 12 months’ treatment were low in both groups (LEF group: 1 (2.86%) vs. TOF group: 3 (9.38%) p=0.17). After treatment, the doses of GCs were significantly reduced in both groups from the third month onwards compared with their corresponding baseline dose (p<0.05). Among patients with initial GCs dose ≥30mg/day, patients in TOF group gained a much lower daily GCs dose than that of LEF group at 9 months and 12 months (p<0.05). Furthermore, the frequency of side effects was higher in LEF group than that of TOF group (12/33, 34.29%, vs. 3/33, 9.38%; p=0.02).

Conclusion: LEF and TOF have comparable treatment effects for patients with TAK. However, TOF is superior to LEF in GCs tapering and safety profile.

POS0798 NUMAN0 TYPE IBII, INFLAMMATORY PROGRESSION OF DISEASE AND DILATION OF ASCENDING AORTA AND AORTIC ROOT ARE IMPORTANT RISK FACTORS CAUSING AORTIC VALVE INVOLVEMENT IN TA PATIENTS.

X. Shi1, 1Beijing Anzhen Hospital, Rheumatology, Beijing, China

Background: Takayasu arteritis (TA) can involve cardiac valves. In Chinese patients with TA, valvarular abnormalities were found in 48.9% (201/411) patients[1,2]. Another research showed that cardiac valvarular involvements were found in 34.9% (373/1069) TA patients in China[3], and in a recent study, they also found that 64.08% (66/103) of TA patients had valvular damage[4]. In addition, the most common valve involved in TA is the aortic valve, and the most common valvular lesion caused by TA is valvular insufficiency. The incidence of aortic regurgitation in patients with TA has been reported as 33.2% (455/1372) in Japan[5], 21.7% (13/60) in Italy[6], 18.1% (29/160) in Korea[7], and 20.4% (44/214)[1] to 39.8% (41/103)[4] in China. AR can further induce congestive heart failure or arrhythmia, both of which are considered one of the main causes of death in TA patients[8].

Objectives: Aortic valve involve is not uncommon in patients with Takayasu arteritis (TA). The aim of our study was to evaluate the clinical characteristics of aortic valve involvement in TA patients, and to explore the risk factors of aortic valve involvement in TA.

Methods: In this retrospective study, 174 patients with TA were divided into groups with or without aortic valve involvement. We compared the clinical manifestations, laboratory parameters, and imaging results between the two groups.

Results: In our study, a total of 94 TA patients (54.02%) had aortic valvarular lesion. The proportion of elevated ESR and elevated high-sensitivity CRP, and ITAS-A score in the aortic valve involvement group were significantly higher than in the non-aortic valve involvement group. 2 patients were found to have the infiltration of inflammatory cells in surgical specimens of the aortic valve. The Numano type Iib and elevated hs-CRP level were found to be statistically correlated with aortic valvular lesion in TA patients. 6 (853 [1685-27875], p=0.007; 4.896 [1646-14561], p=0.004). Dilation of the ascending aorta and aortic root were significantly associated with aortic valvular involvement in TA patients (4.509 [1517-13403], p=0.007; 9.340 [2188-39875], p=0.003).

Conclusion: The Numano type Iib, elevated hs-CRP level, dilation of the ascending aorta and aortic root are risk factors for aortic valve involvement in TA patients.

POS0799 BIOMARKER CHANGES IN TAKAYASU ARTERITIS AFTER TOFACITINIB TREATMENT AND THE MOLECULAR SIGNATURE ASSOCIATED WITH DISEASE CHARACTERISTICS

X. Dai1, L. Wang1, S. Wu1, J. Wang1, Y. Sun1, Z. Ji1, L. MA1, X. Dai1, H. Chen1, L. MA1, X. Kong1, L. Jiang1, Zhongshan Hospital, Fudan University, Department of Rheumatology, Shanghai, China

Background: Takayasu’s arteritis (TAK) is a chronic, non-specific, granulomatous macrovasculitis and its pathogenesis is still unclear. The increasing evidence indicated that multiple pathological process involved in the development of TAK. According to previous reports, multiple biomarkers represent different pathological process (1-3). However, which biomarker can closely reflect disease activity or vascular changes and whether these abnormal processes can be prevented by current therapies remained unknown.

Objectives: To analyze changes of serum cytokine, chemokine, and growth factor profiles in patients with Takayasu arteritis (TAK) after tofacitinib treatment and explore potential molecular signatures related with various disease characteristics.

Methods: Seventeen patients from a TAK cohort treated with tofacitinib and 12 healthy controls were recruited in this study. Potential biomarkers with TAK including cytokines, MMPs, chemokines and growth factors were detected in these patients (0, 6, 12 months) and healthy controls. Molecular changes, disease activity, disease remission, and vascular imaging changes were analyzed in these patients after treatment. Furthermore, molecular signatures associated with these clinical features/outcomes were explored via radar plot and correlation analysis.

Results: At baseline, all the patients were in active status. Meanwhile, patients’ cytokines (PTX3, IL-6, IFN-γ), chemokines (IL-16, CCL22, CCL2), growth factor (VEGF) and MMP9 were significantly higher than those of healthy controls (all p<0.05), while FGF-2 was significantly lower in patients with TAK (p=0.02). After treatment, 94.12% of patients achieved complete remission at 6 and 12 months; patients’ ESR and CRP levels were significantly reduced at 6 months (p<0.05), and vascular improvement was observed in 6 (35.29%) patients at 12 months. With regards to these molecules, IL-10 was increased at 6 months compared with its baseline level (p=0.007). No changes were observed in other cytokines, chemokines, or growth factors. Besides, the radar plot demonstrated that PTX3 was closely related with disease activity. In addition, patients with vascular imaging improvement had relatively higher baseline levels of TNFα, ESR, and CRP (p=0.04, p=0.05 and p=0.07, respectively), lower CCL22, FGF, and PDGF-AB levels (p=0.056, p=0.06 and p=0.08 respectively) compared with patients without it.

Conclusion: Multiple molecules representative different pathological mechanism participated in the pathogenesis of TAK. PTX3 was a prominent marker for disease activity, and CCL22 may have a predictive value for vascular imaging changes.

Background: The most frequent form of vasculitis in elderly people is giant cell arteritis (GCA) with an annual incidence rate less than 10 per 100,000 persons over the age of 50. Like most vasculitides, GCA is characterized by chronicity and relapses, leading to significant overall morbidity and high mortality in a subset of patients with aortic or central nervous involvement. After being diagnosed with vasculitis or who have changed their treatment due to a recent relapse (inception cohort). The GeVas-Registry allows a long-term follow-up of a substantial cohort of vasculitis patients in a prospective and multicenter manner. The Joint Vasculitis Registry in German-speaking countries (GeVas) – a prospective, multicenter registry for the follow-up of long-term outcomes in vasculitis. BMC Rheumatol. 2021 Jul 31;5(1):40. doi: 10.1186/s41927-021-00206-2.

Methods: GeVas is a prospective, web-based, multicenter, clinician-driven registry for the documentation of organ manifestations, damage, long-term outcomes, and therapy regimens in various types of vasculitis. Recruitment started in June 2019. By January 2022, 17 centers in Germany were initiated and have begun enrolling patients. Meanwhile, more than 350 patients have been documented in 2019. By January 2022, 17 centers in Germany were initiated and have begun enrolling patients. Meanwhile, more than 350 patients have been documented so far. The participating centers recruited 131 GCA patients into the registry. 21.7% of patients (n=28) were enrolled in the registry by mid-October 2021. The most frequent form of vasculitis in elderly people is giant cell arteritis (GCA) with an annual incidence rate less than 10 per 100,000 persons over the age of 50. Like most vasculitides, GCA is characterized by chronicity and relapses, leading to significant overall morbidity and high mortality in a subset of patients with aortic or central nervous involvement. POS0801 VISUAL INVOLVEMENT AND PERMANENT VISUAL LOSS IN GIANT CELL ARTERITIS: PREDICTIVE FACTORS

In the same line, the set of variables associated with PVL were headache, and jaw claudication. By contrast, polymyalgia rheumatica (PmR), and large-vessel involvement were protective factors (Figure 1). The AUC for this model was 0.77 (95%CI 0.71-0.83; p<0.0001).

Conclusion: Headache, and jaw claudication seem to be associated with visual involvement in GCA, while large vessel involvement seems to be a protective factor. PmR also appears to be a protective factor for the development of PVL.

Relevant adverse events were observed in 12 per 100 patients-year. A corticosteroid-sparing effect was observed from month 1 of TCZ onset in 100% of patients reached a sustained remission, that was progressively increasing. (Figgia rheumatica, constitutional syndrome and headache were the most frequent symptoms at TCZ onset). Maintained remission was considered according to EULAR definitions (5).

**Methods**: Multicenter observational study of 196 patients with GCA and involvement of the aorta and/or its major branches treated with TCZ. GCA was diagnosed by: a) ACR criteria, and/or b) temporal artery biopsy, or c) imaging techniques. The presence of aortitis was performed by imaging techniques, mainly PET, and A-MRI.

**Results**: The main features of the 196 patients are showed in Table 1. Polymyalgia rheumatica, constitutional syndrome and headache were the most frequent clinical manifestations at TCZ onset. At 6 months after starting TCZ, 20% of the patients reached a sustained remission, that was progressively increasing (Figure 1). A corticosteroid-sparing effect was observed from month 1 of TCZ onset (Figure 1). Relevant adverse events were observed in 12 per 100 patients-year, documenting serious infections in 4.8 per 100 patients-year (Table 1).

Background: Tocilizumab (TCZ) has shown to be effective for large vessel vasculitis including giant cell arteritis (GCA) and Takayasu arteritis (TAK) (1-3). However, LVG-GCA and TAK show different demographic and clinical features that may influence on TCZ therapeutic response.

Objectives: To compare the effectiveness of TCZ in patients with LVG-GCA and patients with TAK.

Methods: Observational multicenter study of patients with LVG-GCA and TAK who received TCZ. Outcome variables were: a) proportion of patients who achieved complete clinical improvement along with normalization of laboratory markers (CRP ≤ 0.5mg/dL and/or ESR ≤ 20mm/1st hour) at 12 months b) complete improvement in imaging techniques. A comparative study between patients with LVG-GCA and TAK was performed.

Results: We evaluated 70 LVG-GCA and 57 TAK patients who received TCZ. Main clinical and demographic characteristic are described in Table 1. Patients with TAK were younger, had longer disease duration, had received more commonly previous biologic therapy and were receiving higher doses of prednisone at baseline. TCZ intravenous administration was more common in TAK patients (80.7% vs 48.6%; p<0.01). Follow-up time after TCZ onset was similar in both groups. At 12 months, about 75% of patients achieved complete clinical improvement and ESR/CRP normalization in both groups. A follow-up imaging technique was performed in 37 LVG-GCA patients after a mean time of 12.9±6.0 months and 38 TAK patients after 9.5±5.0 months. Complete improvement in imaging techniques was only observed in 18.9% and 21.1% of patients with LVG-GCA and TAK, respectively (Figure 1).

Figure 1.

Conclusion: The effectiveness of TCZ was similar in TAK to LVG-GCA and TAK, despite a more refractory disease in TAK patients. A discordance between clinical and imaging activity improvement was observed in both LVG-GCA and TAK, as reported in previous studies (5).

GLUCOCORTICOID-RELATED ADVERSE EVENTS IN GIANT CELL ARTERITIS: APPLICATION OF THE GLUCOCORTICOID TOXICITY INDEX IN A MONOCENTRIC COHORT OF 140 PATIENTS

F. Regola1,2, J. Mora1, G. Bosio3, L. Andreoli1,2, F. Franceschini1,2, P. Toniati2.

1University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy; 2ASST-Spedali Civili di Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 3ASST-Spedali Civili di Brescia, Nuclear Medicine Unit, Brescia, Italy

Background: Oral glucocorticoids (GC) are the mainstay of treatment for giant cell arteritis (GCA) but chronic exposure to GC is associated with serious comorbidities.

Objectives: The objective of this study was to determine the GC exposure and risk of GC-related adverse events (AEs) in GCA, validating the Glucocorticoid Toxicity Index (GTI) in a cohort of real-world patients.

Methods: 140 consecutive patients with GCA were enrolled in this retrospective monocentric study. All patients were older than 50 years of age, met the 1990 ACR criteria for GCA and/or had the evidence of a large vessel vasculitis at FDG-PET/CT scan. Patients' clinical data were collected from clinical charts, calculating GC cumulative dose and GTI at baseline and in the following 5 years.

Results: 140 patients were enrolled in the study: median (iQR) age at diagnosis 74 (67-79), Female: 97 (69%), Male: 43 (31%). According to vascular involvement patients were classified in cranial-GCA (C-GCA, n:91), large vessel-GCA (LV-GCA, n:29), and cranial and large vessel-GCA (UV-GCA, n:28). Furthermore, 50 (36%) patients were treated with only GC, 44 (31%) with GC+mouthwash (MTX), 46 (33%) with GC+tocilizumab (TCZ) in (20 cases TCZ was started in the first 3 months after diagnosis: early-TCZ, in 26 cases after 3 months for relapses or AEs: late-TCZ).

During the follow up, 57 (41%) patients presented at least one relapse. In the GC group 22 relapses in 18 patients were reported, in MTX group 33 relapses in 25 patients (with 15 relapses before and 18 after MTX start), in early-TCZ group no relapses were reported, in late-TCZ group 21 relapses in 14 patients (with 17 relapses before and 4 after TCZ start) were reported.

Median cumulative GC doses after 1 and 5 years were respectively 7.9 (6.3-9.8) gr and 16.5 (13.8-18.9) gr in GC group, 8.7 (5.9-10.0) gr and 16.5 (13.2-20.7) gr in MTX group, 7.1 (5.5-8.0) gr and 13.3 (12.8-13.7) gr in early-TCZ and 7.7 (6.2-11.1) gr and 19.7 (12.2-23.8) gr in late-TCZ. Eighty-eight percent of patients treated at least one GC-AE, with infections and hypertension being the most common reported AEs (42% e 44%, respectively). Median GTI-CTS (Cumulative Worsening Score) after 1 year was 65 (20-137) in GC, 63 (10-95) in MTX, 51 (33-116) in TCZ-early, 44 (0-91) in TCZ-late. Median GTI-CWS and the GC cumulative dose was found (after 5 years: r: 0.295, p: 0.026).

Conclusion: Chronic GC treatment is associated with a high risk of developing comorbidities. GTI score demonstrated to be an effective tool to assess GC-related AEs and proved to correlate with GC cumulative dose. TCZ confirmed its efficacy in reducing relapse rate, both in early and late-TCZ groups (3), TCZ showed for the first time in a real-life cohort a GC sparing effect, with a 19% reduction in GC cumulative dose and a 33% reduction in GTI-CWS in 5 years (comparing GC group vs early-TCZ group).

OPTIMIZATION OF TOCILIZUMAB THERAPY IN GIANT CELL ARTERITIS: A MULTICENTER REAL-LIFE STUDY OF 471 PATIENTS

behalf of Tocilizumab in Giant Cell Arteritis Spanish Collaborative Group.

Background: Tocilizumab (TCZ) has shown to be useful in the treatment of large-vessel vasculitis, including giant cell arteritis (GCA) (1-4). There is general agreement on the initial and the standard maintenance dose of TCZ. However, information on duration and optimization of TCZ in GCA is really scarce.

Objectives: Our aim was to assess the effectiveness and safety of TCZ therapy optimization in an unselected wide series of GCA in real-world clinical practice.

Methods: Multicenter study on 471 patients with GCA who received TCZ therapy. Once complete remission was reached (n=231) TCZ was optimized in 125 patients. We compared patients in whom TCZ was optimized (TCZopt group) or not (TCZnon-opt group). Complete remission was defined as normalization of clinical and analytical (CRP and ESR) data. Optimization was done by decreasing the dose and/or prolonging the TCZ dosing interval progressively. We performed a comparison in effectiveness and safety parameters between optimized and non-optimized patients.

Results: We evaluated 231 GCA patients treated with TCZ with complete remission. No demographic or laboratory data differences was observed at TCZ onset between both groups (Table 1). The mean prednisone dose was higher in the TCZnon-opt group at TCZ onset. The first TCZ optimization was performed after a median [25-75th] follow-up of 12 [6-17] months.

Table 1. Main general features at TCZ onset of 231 GCA patients with prolonged remission.

Scientific Abstracts
Objectives: To investigate disease manifestations during pregnancy and adverse pregnancy outcomes (APOs) in female patients with BS. Methods: In this single centre study, 110 voluntary women who had long-term follow-ups in Ankara University Multidisciplinary Behçet outpatient clinic and their 323 pregnancies were evaluated. Patients were interviewed about their previous pregnancies. As 238 of 323 (73.6%) pregnancies were before BS diagnosis and additional 13 pregnancies were terminated due to family planning, we evaluated disease manifestations and APOs of 72 pregnancies. APOs were defined as spontaneous abortion, IUGR-SGA, gestational diabetes mellitus (GDM), macrosomia, Rh incompatibility, colchicine toxicity, and cesarean section. GCA was diagnosed based on the 1990 American College of Rheumatology classification criteria. Azathioprine was used in 2 (2.7%) pregnancies, which resulted in termination and spontaneous abortion. Conclusion: In this study, we found that APOs occurred in almost half of BS patients and colchicine use seemed to be safe throughout pregnancy. Some BS manifestations exacerbated and even occurred de novo during pregnancies. Prospective studies are needed to reveal the effects of BS and drugs on pregnancy.

SD=Standard Deviation*Calculations were done in 42 pregnancies of the group without APOs and in 26 pregnancies of the group with APOs**Calculations were done in 40 pregnancies of the group without APOs and in 21 pregnancies of the group with APOs.
Methods:

Objectives: The leading symptoms at relapse are headache and fatigue, while loss of vision is rare (0.78%). Baseline characteristics seem to be poorly informative about the risk of relapse, therefore regular monitoring of GCA patients is necessary.

Conclusion: About one fourth of GCA patients relapsed and the overwhelming majority of relapses occurred before patients were able to stop glucocorticoids. The leading symptoms at relapse are headache and fatigue, while loss of vision is rare (0.78%). Baseline characteristics seem to be poorly informative about the risk of relapse, therefore regular monitoring of GCA patients is necessary.

including visual acuity, pupil exam and full-dilated fundus assessment. Systemic and Ophthalmic symptoms and signs were recorded.

Methods: From January 2012 to September 2021, 350 individuals were diagnosed with GCA by biopsy, ultrasonography or position emission tomography. The mean age was 74 ± 7.7 years. 235 (67%) of patients were females. 101 (29%) presenting with GCA had visual symptoms and/or signs. 42 of them had mono-ocular and 5 had binocular loss of vision. A summary of the key visual symptoms and signs are shown in Table 1. Only 6 patients with visual symptoms did not have any symptoms commonly associated with GCA.

1 Central retinal artery occlusion 2 Anterior ischaemic optic neuropathy

Results: From January 2012 to September 2021, 350 individuals were diagnosed with GCA by biopsy, ultrasonography or position emission tomography. The mean age was 74 ± 7.7 years. 235 (67%) of patients were females. 101 (29%) presenting with GCA had visual symptoms and/or signs. 42 of them had mono-ocular and 5 had binocular loss of vision. A summary of the key visual symptoms and signs are shown in Table 1. Only 6 patients with visual symptoms did not have any extra-ocular symptoms commonly associated with GCA.

Conclusion: We report the frequency of visual involvement in one of the largest cohorts of individuals with GCA. 29% have ocular symptoms. Partial or total field loss occurred in 13% of cases. 2% of patients presented with visual manifestations as the only feature of GCA. Rarely, permanent visual loss may occur without any other manifestation of GCA.

POSE0811 CHARACTERS OF INTESTINAL MICROBIOTA AND ITS RELATIONSHIP WITH LYMPHOCYTE SUBSETS AND CYTOKINES IN PATIENTS WITH VASCULITIS

J. Wang1,2,3, S. X. Zhang1,2,3, S. Song1,2,3, J. Qiao1,2,3, R. Zhao1,2,3, T. Cheng1,2,3, J. Liu1,2,3, C. Wang1,2,3, X. Li1,2,3. 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 3Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, China

Background: Vasculitis include a group of autoimmune inflammatory diseases with clinical heterogeneous characterized by inflammation of vascular wall, inflammation of perivascular tissues, and cell-like necrosis[1]. Disorder of gut microbiota, which plays a crucial role in regulating immune cells such as Th1, Th17 and Treg, is associated with other autoimmune diseases[2]. Importantly, the relative abundance of Muribaculaceae were positively correlated with the absolute count of Th2 and the proportions of Th1 and CD4+T cells and negatively correlated with CRP and ESR, while relative abundance of [Eubacterium], ventricum were positively associated with the absolute number of Treg cells and negatively correlated with the percentages of Th2 and CD8+T cells (Figure 1F).

Figure 1. Differences in α diversity (A), β diversity (B), phylum (C), genus (D), and microbial composition (E) between vasculitis patients and HC and correlation analysis between differential microflora and clinical data in patients with vasculitis (F).

Conclusion: Disturbance of intestinal flora, mainly manifested by decreased diversity and richness, may be involved in the occurrence and development of vasculitis by inducing disorders in lymphocyte subsets and cytokines. Consequently, further studies on the immune mechanisms and influencing factors of intestinal flora may reveal new ideas for the diagnosis and treatment of the disease for vasculitis patients.

POSE0812 CAROTID INTIMA-MEDIA THICKNESS/DIAMETER RATIO AND PEAK SYSTOLIC VELOCITY AS RISK FACTORS FOR NEUROLOGICAL SEVERE ISCHEMIC EVENTS IN TAKAYASU’S ARTERITIS

L. Wang1, Y. Sun1, X. Dai1, X. Kong1, L. MA1, X. Dai1, L. MA1, L. Jiang1,2. 1Zhongshan Hospital Fudan University, Department of Rheumatology, Shanghai, China; 2Zhongshan Hospital Fudan University, Evidence-based Medicine Center, Shanghai, China

Background: Takayasu’s arteritis (TAK) is an idiopathic systemic vasculitis characterized by the involvement of the aorta and its major branches[1]. The supra-aortic arteries are often involved in TAK, with the reported prevalence ranging from 40% to 84%[2-3]. Importantly, patients with supra-aortic involvement carry a higher risk of neurological severe ischemic events (SIE)[4-5]. The common carotid artery (CCA) is the most affected artery and is more closely associated with neurologic symptoms than other supra-aortic arteries[6]. Ultrasonography (US) has been regarded as the most popular, user-friendly, and repeatable tool for the diagnosis and follow-up of CCA injuries.

Objectives: Our aim was to characterize TAK with supra-aortic involvement and determine the associations between clinical features, carotid US parameters, and neurological SIE.

Methods: Patients with supra-aortic involvement including brachiocephalic trunk, bilateral common carotid artery and internal carotid artery, and bilateral subclavian level (P < 0.001, Figure 1C). In vasculitis patients, the relative abundances of 23 bacteria differed from HCs at the genus level was all decreased, including Gemella, Anaeroglobinus, Campylobacter, Fournierrae, et al (P < 0.001, Figure 1D and E). More importantly, the relative abundance of Muribaculaceae were positively correlated with the absolute count of Th2 and the proportions of Th1 and CD4+T cells and negatively correlated with CRP and ESR, while relative abundance of [Eubacterium], ventricum were positively associated with the absolute number of Treg cells and negatively correlated with the percentages of Th2 and CD8+T cells (Figure 1F).

REFERENCES:

Disclosure of Interests: None declared

and vertebral artery and baseline carotid US examination were enrolled. Bilateral carotid diameter, intima-media thickness (IMT), and peak systolic velocity (PSV) were measured by US. Then, IMT/diameter ratio (IDR) was calculated. Risk factors associated with neurological SIE were analyzed by multivariate logistic regression.

**Results:** Totally, 295 patients were included, of whom 93 (31.5%) experienced neurological SIE, with common carotid artery involved (81.7%). Involved supra-aortic artery distribution (p<0.04) and number (p<0.01) differed between neurologic and non-neurologic SIE subjects, showing higher prevalence of common carotid and vertebral artery involvement in cases with neurological SIE and 57.1% neurological SIE patients having more than four involved arteries. The left carotid IMT (p=0.03) and IDR (p<0.01) differed between patients with and without neurological SIE. The left carotid IDR (cut-off value ≥0.55, odds ratio [OR] 4.46; 95% confidence interval [CI] 2.05-9.71; p<0.01) and PSV (≥76 cm/s, OR 3.38; 95% CI 1.82-704; p<0.01) and involved supra-aortic artery number (≥4, OR 3.16; 95% CI 1.54-6.47; p<0.01) were independently associated with neurological SIE.

**Conclusion:** The left carotid IDR and PSV and involved supra-aortic artery number would perform as valuable markers for recognizing neurological SIE in TAK patients with supra-aortic lesions.

[3] Michailidou D, Rosenblum JS, Rimland CA, Marko J, Ahlman MA, Gray J. CRP 13.6 vs 5.3 mg/L, p=0.038, ΔCRP = -87.7%; cDMARDs-treated: ESR 27 vs 3 mm/h, p=0.001, ΔCRP = -87.7%; cDMARDs-treated: ESR 36 vs 27 mm/h, p=0.134, ΔESR = -152%, CRP 13.6 vs 3.5 mg/L, p=0.038, ΔCRP = -66.3% and TCZ-treated: ESR 27 vs 3 mm/h, p=0.017, ΔESR = -86.7%, CRP 11.4 vs 2.7 mg/L, p=0.023, ΔCRP = -80.2%.

**Conclusion:** 18F-FDG PET may be useful in assessing disease activity and monitoring response to therapy. Tocilizumab treatment significantly reduce vessel’s metabolic activity over time, when compared to conventional treatment. A persistent low-grade uptake during remission is common features in LV patients, irrespective to treatment regimens.

**References:**

normalization of CRP level defined as <10mg/dl) 3) lack of worsening of the primary vascular lesion or a new lesion vascular at another site on imaging. Remission was assessed at month 6 and month 12. Secondary endpoints were relapse, overall disease activity assessed with BDCAF (n=2), not wanting to come to the infusion frequently during the pandemic (n=2), pregnancy (n=1), to incorporate less serious causes of IFX discontinuation were infusion reactions in 5, tuberculosis, disseminated zoster, lung adenocarcinoma, fibromyxoid sarcoma, heart failure, SLE, palmpoplantar pustulosis, auricular chondritis, and aortic stent graft infection in 1 patient each.

</table>

### Results:
Among the 371 patients who used IFX between 2004 and June 2021, 127 patients (102 men, 25 women, mean age 40 ± 8.7 years) had used it for vascular involvement. The types of vascular involvement that required IFX were venous thrombosis in 61 patients (48%), pulmonary artery involvement in 37 (29%), non-pulmonary arterial involvement in 16 (13%), and venous ulcer in 13 (10%). Remission rate was 72% (92/127) at month 6 and 61% (71/117) at month 12. 17/99 (17%) patients experienced 22 relapses during a mean follow-up of 28.4±21 months of IFX therapy. Among the 22 relapses, 12 were the progression of the pre-existing vascular lesion and 10 were new vascular lesions. Overall disease activity improved with a decrease in mean BDCAF score from 1.76 ± 1.27 to 0.6 ± 0.8 at the final visit (p<0.001). Remission and relapse rates according to type of vascular involvement and causes of IFX discontinuation are presented in the Table 1. Adverse events leading to IFX discontinuation were infusion reactions in 5, tuberculosis, disseminated zoster, lung adenocarcinoma, fibromyxoid sarcoma, heart failure, SLE, palmpoplantar pustulosis, auricular chondritis, and aortic stent graft infection in 1 patient each.

### Discussion of Interests:
Gulen Hatemi speaks for AbbVie, Intellegens, and UCB Pharma. Grant/research support from: Gulen Hatemi has received grant/research support from Celgene, Bexza Tukel. None declared, Sinem Nihan Esatoglu speaks for Sinem Nihan Esatoglu has received honorariums for presentations from UCB Pharma, Roche, Pfizer, and Merck Sharp Dohme., Yesim Ozguzer speaks for Yesim Ozguzer has received honorariums for presentations from UCB Pharma, Novartis, and Pfizer., Sıtkı Safa Taflan: None declared, Melike Melikoglu: None declared, Serhat Yurdakul: None declared, Izzet Fresko: None declared, Zekayi Kutlubay: None declared, Vedat Hamuryudan speaks for Vedat Hamuryudan has served as a speaker for AbbVie, Celgene, Novartis, and UCB Pharma, Grant/research support from: Vedat Hamuryudan has received grant/research support from Celgene.

### Conclusion:
Infliximab may be beneficial in BS patients with vascular involvement, even in those who are refractory to immunosuppressives and corticosteroids.
