Average cost of hospitalization was higher in ILD with MCTD ($104,631 vs $71,264.6, p<0.0001), Myositis ($105,623 vs $71,232.9, p<0.0001) and Scleroderma ($88,736.2 vs $71,135.5, p<0.0001). Average LOS was significantly longer in RA (7.17 vs 6.66 days, p value 0.0006), MCTD (7.71 vs 6.67 days, p value 0.0008), Myositis (8.33 vs 6.66 days, p value <0.0001) and Scleroderma (7.07 vs 6.67 days, p value 0.0176). Though not significant, average LOS was longer in SLE (6.70 vs 6.67 days, p value 0.4999).

Conclusion: Our study shows that the prevalence of RA in ILD cases has significantly reduced through the years. This can be attributed to the better understanding of the disease and its risk factors as well as the availability and use of newer biologic agents to obtain better control. However, the prevalence of SLE, Scleroderma, and MCTD in ILD cases has increased over the years. This points to the need for better therapies as well as highlights the fact that over the years recognition and diagnosis of these diseases have increased over the years. Racial predilection also comes to light, suggesting the need for special attention to certain races to diagnose the autoimmune disease earlier. Average LOS and cost of hospitalization were also higher in ILD cases with autoimmune disease, reflecting the higher socioeconomic burden.

Disclosure of Interests: None declared DOI: 10.1136/annrheumdis-2022-eular.1172
For the aim of this study, we excluded from the analysis NMHC (ICD-10: C44) and diagnoses based on autopsy only or Death Certificate Only.

Results: 2504 patients were followed-up for a total of 18,006 person-years (median follow-up: 6.8 years). After 5 and 10 years of follow-up, the cumulative cancer incidence was 2.6% and 8.5%, respectively. The most common cancers were breast (n=34), lung (n=24), colorectal-anus (n=20), and non-Hodgkin lymphomas (NHL) (n=20). Overall, no excess cancer risk was noted (SIR=0.87, 95% CI: 0.75-1.00), whereas the number of observed NHL cases was more than two-fold significantly higher than expected (SIR=2.52, 95% CI: 1.54-3.89). The subgroup analysis showed a higher risk of NHL among SS patients (SIR=3.84, 95% CI: 1.92-6.87) and SLE patients (SIR=2.69, 95% CI: 0.99-5.84). Conversely, the study population showed a decreased risk for cancers of breast (SIR=0.61, 95% CI: 0.42-0.85) and corpus uteri (SIR=0.21, 95% CI: 0.03-0.77).

Conclusion: The incidence of NHL was higher among patients with SS and SLE than in the general population. Surveillance for haematological malignancies in these patients is recommended. The lower risk of cancer for breast and corpus uteri in CTD indirectly supports cancer screening programs and highlights the role of the continuous clinical follow-up for these chronic conditions.

POS1415
A MACHINE LEARNING ANALYSIS OF FACTORS PREDICTING ORGAN DAMAGE PROGRESSION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS USING THE SPANISH SOCIETY OF RHEUMATOLOGY LUPUS REGISTRY (RELESSER)

Methods: The Spanish Society of Rheumatology Lupus Registry (RELESSER) with patient records from 45 Rheumatology Units across Spain was used. RELESSER data were collected from 2011 to 2021 and captured demographic and comprehensive clinical information. In this analysis, a sample of 2,676 patients was used. The Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) was used to measure organ damage progression between 2015 (start of the prospective data collection in RELESSER) and 2020. To predict the risk of an increase in the SDI, 102 variables were identified as potential predictors. A ML model (gradient boosting trees) was developed and validated by a simple logistic regression (LG) model. The area under the receiver operating characteristic curve (AUCROC) was used to quantify the improvement over random chance (an AUCROC of 0.5). Shapley Additive Explanation (SHAP) values were used in the ML model to identify predictors and their contribution to damage progression.

Results: Of all patients, 13% experienced organ damage progression, with 2-year patient follow-up. The ML algorithm was better at identifying these patients (AUCROC 0.68) than the LG model (AUCROC 0.63) (Figure 1). ML model performance can be contextualized using a random sample of 100 SLE patients of whom 13 suffered organ damage progression, the model would successfully identify 12. However, 66 additional patients would be incorrectly identified (True Positive 90%; False Positive 79%). The top 5 predictors of damage progression, across all patients, were patient age >49 years,
Background: Population-based studies on Systemic Lupus Erythematosus (SLE) patients with a verified diagnosis is considered the gold standard to find true outcomes in SLE, but few population-based SLE cohorts have follow-up over 15 years [1]. Norway is among the few countries worldwide where social and structural factors facilitate the gathering of complete population-based cohorts in rare disease like SLE due to its healthcare organization.

Objectives: To examine long-term outcome of SLE in a population-based setting and determine if immediate cause of death differs between SLE patients and the general population.

Methods: The study included all SLE patients who were resident in the South-east region of Norway during 1999 - 2017 and met the 1997 American College of Rheumatology classification criteria for SLE. All SLE diagnosis was confirmed by chart review. SLE patients and 15 controls for each case (matched by age, gender and ethnicity) were linked to the Norwegian Cause of Death Registry. We examined survival by means of Kaplan-Meyer estimates and used log rank test to test for differences. To estimate risk of death, we performed calculations of standard mortality rate (SMR) by dividing the number of deaths on the number of years observed. The excepted number of deaths were included in SMR. The 95 % confidence interval (CI) of SMR was calculated with Mid-P exact test. We defined immediate cause of death as the final event directly leading to death. An International Classification of Diseases 10th revision code of I00-99 or R96 classified as death from cardiovascular disease (CVD) (except pulmonary embolism and cerebral bleeding) and of infections A00-B99, J10-18, N39, M86 or U07.

Results: We identified 1298 SLE patients in the region, of whom 673 was incident cases; all captures within one year from diagnosis. Of the incident cases, 76 (11%) died during 8434 years of follow-up (Table 1). The five-, ten-, 15- and 20-year survival for incident SLE patients (controls) was respectively 98 (98), 94 (96), 87 (94) and 82 (88) % and differed significantly first after ten years of disease duration compared to controls. Figure 1 shows 20-year survival for incident SLE patients and matched controls; stratified by gender. SMR for all SLE cases was 2.3 (95 % CI 1.5 - 4.0); female SLE 2.5 (95 % CI 1.6 – 3.9) and male SLE 1.9 (95 % CI 1.3 – 2.2). The most common immediate cause of death in SLE patients was CVD; whereas myocardial infarction (21 %) was most frequent. SLE patients died more often of CVD than controls (29 % vs. 21 %, p = 0.01) and had a tendency to more infections (23 % vs. 18 %, p = 0.07), whereof pneumonia (58 %) was most frequent.

POS1417 INTEROSSEOUS TENDON INFLAMMATION IN THE HANDS: A NOVEL FEATURE OF DEVELOPING RHEUMATOID ARTHRITIS? RESULTS FROM A LARGE MRI STUDY IN CLINICALLY SUSPECT ARTHRALGIA

B. Van Dijk1, H. W. Van Steenbergen1, M. Reijnierse2, S. Khidri1, L. J. Wisse3, M. C. Deruiter3, A. Van der Helm-van Mil3, 4Leiden University Medical Centre (LUMC), Rheumatology, Leiden, Netherlands; 5Leiden University Medical Centre (LUMC), Radiology, Leiden, Netherlands; 6Leiden University Medical Centre (LUMC), Anatomy & Embryology, Leiden, Netherlands

Background: Inflammation around the tendons of the hand intersosseus muscles (intersosseous tendon inflammation; ITI) on MRI was recently reported in rheumatoid arthritis (RA) patients and in ACPA-positive individuals with musculoskeletal symptoms. We therefore hypothesized that ITI is an early RA-feature that precedes clinical arthritis.

Objectives: To examine this we assessed the frequency of ITI in clinically suspected arthralgia (CSA) patients and compared this to the frequency in the general population. Additionally we investigated the relation between ITI and other locally inflamed tissues (synovitis/tenosynovitis/ostitis) in MCP-joins of CSA patients as well as the association with future arthritis development.

Methods: 867 consecutive patients presenting with CSA and 193 symptom-free controls from the general population underwent contrast-enhanced hand-MRI. MRIs were evaluated for ITI and for synovitis/tenosynovitis/ostitis, using the rheumatoid arthritis MRI scoring system (RAMRIS). CSA patients were followed for clinical arthritis development (median follow-up 25 months). Logistic and Cox-regression were used. ACPA-stratification was performed. To gain a better understanding of the anatomical relationships, 3D MRI-reconstruction of the intersosseous and lumbral muscles and tendons was performed in a patient with ITI.

Results: At presentation, 10% of CSA patients had ITI, compared to 1% of symptom-free controls (p<0.001). ITI was more frequent in ACPA-positive than ACPA-negative CSA (27% versus 7%; p<0.001). 72% of patients with ITI also had synovitis and/or tenosynovitis at the MCPs (37% synovitis; 7% tenosynovitis; 27% both synovitis and tenosynovitis). Also in multivariable analyses, adjusted for simultaneous presence of synovitis/tenosynovitis/ostitis, ITI was more likely if synovitis (OR 2.2, 95%CI 1.2-4.2) or tenosynovitis (9.7, 5.5-17.0) was present at MCPs. The 3D MRI-reconstruction indicated that ITI is continuous with MCP flexor tenosynovitis (Figure 1). CSA patients with ITI developed arthritis.
more frequent than those without (HR 4.5 (2.8-7.2)); this relation was stronger in
ACPA-negative (3.9 (1.9-7.9)) than ACPA-positive CSA (1.8 (0.9-3.4)).

**Figure** Example MR-image (A) and 3D MRE-reconstruction (B) at the level of the
MCP-joints in a CSA-patient with ITI continuous with flexor tenosynovitis at the 2nd MCP-joint

**Conclusion:** ITI is present in CSA and precedes clinical arthritis, suggesting that
this periarticular inflammation is an early RA-feature.

**Acknowledgements:** We thank G. Kracht for his assistance with preparing the
example MR-image.

**POST1418**

SEPARATING THE EFFECTS OF CHILDHOOD AND ADULT BODY SIZE ON INFLAMMATORY ARTHRITIS: A MENDELIAN RANDOMISATION STUDY

S. S. Zhao1, J. Bowes2, A. Barton2, G. Davey Smith3, T. G. Richardson3.

1The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 2The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom; 3University of Bristol, Population Health Sciences, Bristol, United Kingdom

**Background:** Obesity is strongly associated with inflammation and inflamma-
tory arthritis, but most studies to date have only examined adulthood body mass
index (BMI). Whether childhood obesity has a direct and long-term influence on
risk of inflammatory arthritis is unclear. This question is important as childhood
obesity becomes a growing and global public health crisis [1], but traditional
epidemiologic approaches may be limited by reverse causation (obesity can be
a larger body size during childhood may not be fully reversible even when a
healthy size is achieved in adulthood. How the immune system is altered by early
life adiposity to increase risk of PsA and SLE is unclear. Differential effect esti-
mates of body size on each inflammatory arthritis (PsA vs AS, RA vs SLE) may
help shed light on their unique pathophysiology in future studies.

**Objectives:** To examine whether childhood body size affects risk of inflammatory arthritides – rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA), gout and systemic lupus erythematosus (SLE) – after accounting for the
effect of adult body size using two-sample univariable and multivariable MR.

**Methods:** Genetic instruments for childhood (age 10 years) and adult body
size were derived using data from 453,169 individuals from the UK biobank
study (313 and 580 variants respectively; $r^2<0.001, p<5\times10^{-6}$), which have
been previously validated using BMI data from three independent populations
[2]. Participants recalled their body size at age 10 as “thinner,” “about average”
or “plumper”. Adult body size was determined using BMI at a mean age of 57
years and, to facilitate comparison, split into three groups to match the pro-
portions for childhood body size. Genome-wide association data comprised
of 22,350 RA, 9,069 AS, 3,609 PsA, 13,179 gout and 5,201 SLE cases. We
conducted univariable MR to estimate the total effects of childhood and adult
body size on outcomes and multivariable MR to examine the independent
effect of childhood body size after accounting for adult body size. F statistics
were calculated for each exposure with a value >10 considered suggestive of
adequate instrument strength.

**Results:** The F statistic for childhood and adult body size instruments were 30
and 23 respectively. Genetically predicted childhood body size had a total effect
on risk of PsA (OR 2.18 per change in body size category; 95%CI 1.43, 3.31),
gout (OR 2.18; 1.43, 3.31) and SLE (OR 2.44; 1.14, 5.22), but not RA (OR 0.95;
0.70, 1.29) or AS (OR 0.98; 0.61, 1.52). After accounting for adult body size, the
direct effect of childhood body size was little changed for PsA (OR 1.92; 1.14,
3.25) and SLE (OR 2.69; 1.24, 5.87), but was attenuated for gout (OR 1.40;
0.94, 2.09).

**Conclusion:** Results of this study suggest that the risk conferred from having
a larger body size during childhood may not be fully reversible even when a
healthy size is achieved in adulthood. How the immune system is altered by early
life adiposity to increase risk of PsA and SLE is unclear. Differential effect esti-
mates of body size on each inflammatory arthritis (PsA vs AS, RA vs SLE) may
help shed light on their unique pathophysiology in future studies.

**POST1419**

CANCER INCIDENCE IN PATIENTS WITH AUTOIMMUNE DISEASES TREATED WITH CYCLOPHOSPHAMIDE

Á. Andreu-Suárez1, M. Serrano Warleta1, C. De la Puente Bujidos1, 1University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain

**Background:** Cyclophosphamide (CYC) is one of the first-line drugs for serious manifestations of autoimmune diseases [1]. It has been associated with the appearance of a secondary cancer [2]. Several studies showing a higher incidence of cancer in small-vessel vasculitis in relation to CYC treatment have been carried out [3], but there is not much evidence about this complication in other autoimmune diseases.

**Objectives:** -Estimating the incidence of cancer in patients treated with CYC for serious manifestations of autoimmune diseases.
-Comparing the incidence of cancer in autoimmune diseases treated with immu-
nosuppressants (IS) against the incidence of cancer in the general population.

**Methods:** This is a single-center retrospective cohort study. We included patients over 18 years old assessed in outpatient clinics of the Rheumatology service at the Ramón y Cajal Hospital from 1990 to 2018. They had been diagnosed with: diffuse or limited cutaneous systemic sclerosis (dcSSc/LCSSc), systemic lupus erythematosus (SLE), vasculitis or others. We divided the patients into two groups; those exposed to CYC throughout the follow-up and those not exposed to it (being treated with other IS). Patients who had an active cancer at the time of starting the immunosuppressive therapy were excluded.

A descriptive analysis was carried out. The incidence of cancer was compared to the incidence of cancer in the general population according to the 2020 Spanish
Network of Cancer Registries data. A multivariate analysis was subsequently performed.

**Results:** Regarding the baseline characteristics of the patients included, there were no significant statistical differences in the sex, median age, and personal history of cancer. There was a bigger percentage of smokers in the non-exposed group. The incidence of cancer was similarly by both groups (7.5% vs. 4.1%; p = 0.211). The cumulative incidence of cancer in our sample was 555.5/1000 patients (95% CI 32.1-94.6). The standardized incidence ratio was 2.19 (95% CI 3.30-11.92) and it was stratified by sex and age. The bivariate analysis is shown in Table 1.

Table 1. Comparison between patients with or without appearance of cancer during the follow-up.

Method of administration of CYC

| Intravenous     | 7 (58.33%)          | 78 (38.24%) | 1 |
| Oral            | 0 (0%)              | 6 (2.94%)   | 1 |
| Both            | 0 (0%)              | 2 (0.98%)   | 1 |
| Total administered dose of CYC (grams) | 728.2 (±33.6) | 65.9 (±33.6) | 0.626 |

Regarding the multivariate analysis, the variables that demonstrated a statistically significant association with the appearance of cancer were age at the time of the study (OR 1.18 [1.02-1.36]; p = 0.024) and personal history of neoplasia (OR 7.86 [1.30-47.47]; p = 0.010).

**Conclusion:** The incidence of cancer in patients with autoimmune diseases treated with CYC is not higher with respect to patients with similar diseases treated with other IS. The increased incidence of cancer is associated with the personal history of cancer and older age. Studies with a larger sample size and prospective studies are necessary to verify these results and determine more clearly the associated risk factors.

**DOUBLY ROBUST ESTIMATOR FOR AVERAGE TREATMENT EFFECT AS SENSITIVITY ANALYSIS FOR COMPARATIVE EFFECTIVENESS RESEARCH: AN EXAMPLE COMPARING DRUG MAINTENANCE BETWEEN BARICITINIB AND ALTERNATIVE BILOGIC DMARDS.**

R. Aymon1, B. Gilbert1, D. Mongin1, E. Nham1, C. Laedermann2, R. Müller2, K. Lauper1, D. Courvoisier1, A. Finch1.

1Geneva University Hospitals, Division of Rheumatology, Genève, Switzerland; 2Eli Lilly (Suisse) SA, Medical Department, Vernier, Switzerland; 3Rheumazentrum Ostschweiz, Rheumazentrum Ostschweiz, St. Gallen, Switzerland; 4University of Manchester, Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, Manchester; United Kingdom

**Background:** Drug maintenance is a common outcome measure of real world effectiveness studies, because it combines a measure of drug effectiveness and its tolerance/safety. Major hurdles of observational studies are potential selection biases and confounding. Cox proportional hazard ratio models address this issue by adjusting for potential confounders, but misspecification of the model may lead to biased estimates. Augmented Inverse Probability Treatment Weighting (AIPTW) has the attractive property of being doubly robust, meaning that only one of the two underlying models has to be correctly specified to obtain consistent estimates. It can be used as a sensitivity analysis for Cox models, when analyzing time-to-event data.

**Objectives:** To evaluate AIPTW estimator and test the robustness of the results obtained by a Cox model.

**Methods:** Previous analyses in the Swiss rheumatoid arthritis (RA) registry (SCORM) had demonstrated that time to all-cause-discontinuation was significantly longer in RA patients on bDMARDs (BARI, N = 273) compared to TNF-inhibitors (TNFi, N = 473); but not compared to other mode of actions biologics (OMA, N = 378) [1], in an adjusted Cox regression including age, gender, BMI, concomitant csDMARD, prednisone, CDAI score, disease duration, smoking status, line of therapy and seropositivity. Here we repeat the same analysis using AIPTW, including the same potential confounders. We combine a propensity score using a logistic regression model and an inverse probability weighted Cox regression. Two implementations of the AIPTW estimator are considered. First we use the RiskRegression package in R, to obtain risk ratios. Then we implement the AIPTW manually to obtain the average treatment effect as the difference in median survival time.

**Results:** Time to treatment discontinuation measured with Cox model was significantly longer for RA patients on BARI compared to patients on TNFi according to the adjusted Cox model (HR = 1.79), and a similar non-significant trend existed when compared to OMA (HR = 1.29). When considering 90-day treatment discontinuation measured with the AIPTW, the results were qualitatively very similar; the risk ratio between BARI and TNFi groups is statistically significant (RR = 2.51), while that of BARI against OMA is larger than one (RR = 1.47), but not statistically significant. Confidence intervals are larger with the AIPTW estimation.

Disclosure of Interests: [2] R. Coleman, J.J. Body, M. Aapro, et al., Bone health in cancer patients: ESMO guidelines recommending different T score-based risk model, further studies are needed with prior literature. Since our study period overlaps with publication of newer WHO defined osteoporosis (T ≤-2.5) is ineffective in fracture prevention in keeping with a model such as FRAX based intervention thresholds in mainly those with effective in reducing the pace of decline in BMD. However, standard risk stratification is not directed at the pace of decline in BMD over seven years. It confirms that bone sparing therapy is effective in reducing the pace of decline in BMD with the decline being -5%. (LNOF mean BMD of 0.939 g/cm2 at baseline compared to LNOF mean BMD of 0.788 g/cm2 at repeat DEXA, p=0.82).

Women who were not offered any treatment (n=667, 66%), showed a significant decline in bone density with the decline being -5%. (LNOF mean BMD of 0.939 g/cm2 at baseline compared to LNOF mean BMD of 0.888 g/cm2 at repeat DEXA, p<0.0001).

The rate of fractures remained the same between the treatment (19 fractures, 5.67%) and non-treatment group (38 fractures, 5.70%).

Conclusion: Our study provides long term data for AIBL and confirms a significant decline in BMD over seven years. It confirms that bone sparing therapy is effective in reducing the pace of decline in BMD. However, standard risk stratification model such as FRAX based intervention thresholds in mainly those with WHO defined osteoporosis (T ≤-2.5) is ineffective in fracture prevention in keeping with prior literature. Since our study period overlaps with publication of newer guidelines recommending different T score-based risk model, further studies are required to confirm their utility.

Methods: We retrospectively evaluated consecutive patients admitted to our department from January 2006 to October 2021 whose C7-HRP antigen were measured. We collected their age, sex, primary problem and its lesion, and test results within 3 months before C7-HRP measurement. We also investigated the use of immunosuppressants, and maximum and cumulative dose of administered prednisolone within 6 months before C7-HRP measurement. Maximum and cumulative dose of prednisolone contained methylprednisolone pulse, which was converted into prednisolone equivalent. We investigated the characteristics of CMV-positive and negative patients, and those of CMV-positive patients with or without anti-CMV drug treatment.

Results: Of a total of 472 patients, 85 were positive and 387 were negative for C7-HRP. The average age was 71.2 vs. 64.4 (p=0.0021). Their male-to-female ratio was 20/65 vs. 120/267 (p=0.0290). The following diseases were significantly common among CMV-positive patients: microscopic polyangiitis (21.2% vs. 3.9%, p<0.0001), adult-onset Still's disease (7.1% vs. 1.3%, p=0.0002), and systemic sclerosis (4.7% vs. 2.1%, p=0.0273). Significantly common comorbidities of CMV-positive patients were interstitial lung disease (35.3% vs. 16.0%, p=0.0001), nephritis (23.5% vs. 11.6%, p=0.005), peripheral nervous system disorders (11.8% vs. 5.7%, p=0.0070), alveolar hemorrhage (5.9% vs. 0.8%, p=0.0001), and peripheral circulatory disorders (4.7% vs. 1.6%, p=0.0111).

Conclusion: Intense immunosuppression, especially with higher dose of glucocorticoids, were the major reason to be considered for CMV reactivation. These medications may often require anti-CMV therapy.

Background: Few studies have reported the burden of osteoarthritis (OA) in different parts of India. However, no study has reported the detailed estimates of incidence, prevalence, and years lived with disability (YLDs) and its trends for OA (and its various sites) across the states of India over a long period of time.
Objectives: We aim to describe the state-wise prevalence, incidence, and YLDs for osteoarthritis (OA) in India from 1990 to 2019 according to age and sex.

Methods: Data from the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) 2019 were used. The burden of OA—incorporating knee OA, hip OA, hand OA, and other OA—was estimated for India and its states from 1990 to 2019 through a systematic analysis of prevalence, incidence, and YLDs modelled data using the methods reported in the GBD 2019 Study. All estimates are presented as counts and age-standardised rates per 100,000 population, with uncertainty intervals (UIs).

Results: Around 23.46 million individuals in India had OA in 1990; this increased to 62.35 million in 2019. The age-standardised prevalence of OA increased from 4,485 (95% uncertainty interval (UI): 4,240–5,747) in 1990 to 5,313 (95% UI: 4,799–5,889) in 2019, per 100,000. OA was the 20th most common cause of YLDs in India in 2019, accounting for 14% (95% UI: 7.2–21%) of all YLDs; increasing from 0.8% (95% UI: 0.7–1.0) in 1990 to 1.5% (95% CI 1.3, 1.7) in 2019.

Conclusion: The burden and impact of OA in India are substantial and is increasing; however, it varied among states. Females were affected more commonly than males. Knee OA was the most prevalent site. With improvement in life expectancy and population ageing, greater increases are expected. Adopting suitable control and preventive community measures to reduce modifiable risk factors (such as obesity, injuries, occupational stress) are needed now to reduce the current and future burden of OA in India.

POS1426 INCIDENCE, CLINICAL FEATURES AND OUTCOMES OF PATIENTS WITH POLYMALGIA RHEUMATICA IN SLOVENIA

S. Markez1, A. Hocevar2, M. Tomscic3, J. Kramari1, Z. Rotar1,2
1University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; 2University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Background: Polymyalgia rheumatica (PMR) is common in patients over the age of 50 years. Clinical symptoms promptly respond to glucocorticoid therapy, but there are wide variations of dosage tapering, treatment duration and rate of relapses. In Slovenia epidemiology of PMR is unknown.

Objectives: We aimed to determine the incidence rate of PMR, the clinical characteristics, the relapse frequency and length of glucocorticoid therapy.

Methods: A detailed single centre retrospective review of medical records of all patients diagnosed with PMR between 1 January 2014 and 31 December 2016 was performed at the Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia—the only secondary level rheumatology institution in serving the Central Slovenian and Gorjenska regions, which represent ~40% (7x105) of the Slovenian adult population. The outcomes were assessed up to October 2021.

Results: During the 3-year period 494 patients (460 from Ljubljana and Gorenjska regions) were diagnosed with PMR (64% females, median (IQR) age 75 (69, 80) years), resulting in an annual sex- and age-standardised incidence rate (IR) per 105 adults ≥ 50 years of 46.0 (95% CI 42.0, 50.4), with a female/male ratio of 1.5 (95% CI 1.3, 1.7). The IR peaked between 70–85 years (Figure 1). There was no seasonal variation in IR. The median (IQR) times from symptom onset, and from referral to rheumatology consultation were 6 (4, 11) weeks, and 1 (1, 1) day, respectively. 86% were referred by their GPs, 7% by other internists, and 6% by infectious disease specialists, and the rest by other specialists.

At presentation, 96% had morning stiffness (71% lasting >45 minutes), 99% shoulder pain, 94% pelvic girdle pain, 49% weight loss, 13% peripheral arthritis, and 12% body temperature >37°C. Data on US of shoulders and hips was complete, partial, or missing for 38%, 24%, 39%, respectively. Elevated erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) was present in 98% of patients. The median (IQR) ESR was 55 (42, 71) and CRP 49 (26, 79) ml/l, and 58% had anaemia. RF and ACRA were positive in 4% and 3%, respectively. 8/12 had ACRA values less than 2× the reference value. During follow-up ACRA was repeated in 8/12 patients and negativized in 6/8 patients. Among other pre-existing conditions, 51% (10%) had history of malignancy diagnosed a median 7 (3–11) years prior to diagnosis of PMR. EULAR/ACR classification criteria for PMR were fulfilled in 66% and 71% based on clinical and extended ultrasound criteria (missing items were imputed with 0), respectively. 14% (3%) patients had clinically overt concurrent giant cell arteritis (GCA). All patients were treated with methylprednisolone, administered orally in 92.4%, 93% started at 16mg qd. By the end of follow-up, 295 (60%) patients successfully discontinued methylprednisolone after a median of 117 (104, 143) weeks. Steroid sparing lefunomide and methotrexate were used by 66 (13%) and 27 (6%) patients, respectively. During a median follow-up of 150 (98, 244) weeks, 146 (30%) had at least one relapse. Median time to first relapse was 111 (50, 141) weeks. 54% relapsed after glucocorticoid discontinuation after a median time of 4 (2, 18) weeks, 9% presented with GCA, 12% relapsed due to treatment non-adherence. During the follow-up 6% were diagnosed with malignancies.

POS1427 CLINICAL COURSE IN PATIENTS WITH INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES (IPAF): REAL-LIFE DATA FROM A MULTICENTER ILD REGISTRY

Background: Several patients with Interstitial Lung Disease show autoimmune characteristics but do not meet the classification criteria for a connective tissue disease. In order to define this condition, the classification of patients with interstitial pneumonia with autoimmune features (IPAF) has been adopted (Fischer’s criteria).

Objectives: To describe the sociodemographic, clinical, functional characteristics and therapeutic management of IPAF in clinical practice and to evaluate the incidence rate of functional respiratory impairment.

Methods: A longitudinal observational study was performed (NEREA registry). Patients diagnosed with IPAF according to Fischer’s criteria were included from ILD diagnosis (Feb 2007 to Dec 2019) and followed until loss of follow-up or Jan 1 2021. The study was carried out by a multidisciplinary team ( pneumologi sts and rheumatologists) in seven Hospitals of Madrid. The relative functional respiratory impairment, defined as a ≥ 5% decline in percent predicted forced vital capacity (FVC%) compared to the previous visit was set as main outcome. Respiratory function was measured at baseline and every 6-12 months. Covariates included: a) sociodemographic, b) clinical, c) radiological pattern (non-specific interstitial pneumonia [NSIP]; usual interstitial pneumonia [UIP]; others); d) FVC% DLOC%; e) laboratory tests; f) therapy used. Survival techniques were used to estimate the incidence rate (IR) of relative functional respiratory impairment, expressed per 100 patient-month with their respective confidence interval [95 % CI].

Results: 79 IPAF were included, with a follow up of 462.8 patients-month and a maximum follow-up of 12.3 years. 79% were women with a mean age of 65±11 years. Along with obesity (40%), the most frequent comorbidities at baseline were hypertension, hypercholesterolemia, followed by ischemic heart disease. Baseline FVC% and DLOC% were 86.5±22.7 and 64.2±19.3, respectively. Distribution of IPAF classification criteria was: a) clinical domain: arthritis (46.2%), Raynaud’s phenomenon (35.6%) and mechanic hands (9.3%); b) serological domain: 80.8% positive ANA at >1/320 titer; 29% RF (> 40 IU/ml); 25% positive anti-Ro; c) morphological domain: 46.8% of NSIP and 36.7% of UIP. During the study period, 77.2% of patients (n=61) received treatment: glucocorticosteroids (n=52), mycophenolate (n=25), azathioprine (n=21), rituximab (n=15) and antibiotics (n=11). During the follow-up, 50 patients presented 111 relative functional respiratory impairment events over time. The estimated IR was 23.9 [19.9-28.1] per 100 patient-semester; and 50% of the patients developed functional respiratory impairment at 16 months from diagnosis. IR was similar between patient gender, baseline overall comorbidity, baseline pulmonary functional tests, and age strata, with slight difference in patients >80 years of age. Patients with baseline associated emphysema (IR: 17.8 [10-31]) or without baseline associated fibrosis (IR: 21.1 [15-28]) had lower IR compared to the opposite. As expected, IR was higher in UIP (32.9 [24-42]) compared to NSIP or any other pattern. With respect to serologic markers, patients with ANA titers ≥1/320 had a higher IR (26.7 [21-33]) in comparison with those lower or non-titers of ANA (IR: 15.7 [9.9-25.1]).

Conclusion: In a multicenter registry of Madrid, we have performed a descriptive longitudinal study. IPAF were mostly women in their sixties. The most frequent clinical criteria were arthritis and Raynaud’s phenomenon. An NSIP radiological pattern predominated. At onset, patients have a slightly diminished lung function. The incidence rate of functional deterioration was estimated 23.9% patient-se mester and 50% of the patients developed pulmonary functional deterioration at 16 months from ILD diagnosis. This Incidence rate was higher in patients with an UIP pattern, baseline fibrosis or ANA at medium-high titers.

Results: Among the 98,995 participants, 1,392 women self-reported GCA/PMR. The specific questionnaire was sent to 1,143 (82.1%) of the eligible women (249 women could not be contacted because of death or withdrawn consent) and response was obtained for 830 women (59.6%). Among them, 202 women provided sufficient medical data to ascertain a diagnosis and study accuracy of developed algorithms. 56 women were classified as ACG and 121 as PMR. Self-reported diagnoses alone had an accuracy of 87.6% with medical chart review. If women additionally self-reported a diagnosis confirmation by a physician and the use of glucocorticoids for ≥ 3 months, the accuracy was improved to 89.8%. For patients who did not respond to validation questionnaire, adding the use of glucocorticoids for ≥ 3 months in the reimbursement database also improved the diagnosis accuracy to 92.8%. These two designed algorithms also had the benefit of reducing the number of false positive cases by 10 and 16 respectively. Finally, 589 GCA and/or PMR cases were confirmed by our two devised algorithms: 401 cases with algorithm using the specific GCA/PMR questionnaire and 188 with medication reimbursement database. The mean age at diagnosis was 70.3 (± 8.0) years [73.4 (± 6.2) years for cases detected using the specific GCA/PMR questionnaire and 68.9 (± 8.3) years for cases detected with medication reimbursement database]. Demographic and clinical data were similar between our population of validated cases by medical chart review and the cases detected by our algorithms in the cohort.

Conclusion: The accuracy of self-reported diagnosis of GCA/PMR was high in the E3N-cohort. Using additional data such as medication reimbursement and/or other self-reported data from a specific questionnaire, particularly the prolonged use of glucocorticoids led to a better accuracy with a very small number of false positive cases and seemed to be sufficient to correctly ascertain GCA and/or PMR diagnoses. With the validation of nearly 600 GCA and/or PMR cases in our cohort, we will be able to conduct epidemiological studies to identify risk factors of these diseases.
Conclusion: According to our data, markers of macrophage activation and the activation of acute phase response could be taken as risk factors of a poor outcome in patients with AIP, regardless of clinical diagnosis and process-related features. Nonetheless, due to our study design and sample, these results warrant replication in other cohorts.

POS1433 ROLE OF FAT AND MUSCLE TISSUE ON QUALITY OF LIFE OUTCOMES IN OSTEOARTHRITIS: RESULTS FROM THE KHAOLA COHORT

A. C. Rat1,2, J. Sellamb3, B. Mazières3, W. Nguyen Sime2, P. Fardellone8, F. Guilliermin3,2, Cae-Normandy University, UNICAEN, Caen, UMR-S 1075 COMETE, FFRS, Caen, France; Caen, France; University Hospital Center Caen, Rheumatology Department, Caen, France; University De Lorraine, APEMAC, Nancy, Nancy, France; Sorbonne Université, Inserm UMR_S_938, FHU PaeCeMM, Paris, France; Sorbonne Université, AP-HP Hôpital Saint-Antoine, Department of Rheumatology, Paris, France; University Hospital Center Toulouse, Rheumatology Department, Toulouse, France; University Of Lorraine, CHRU-Nancy, Inserm, CIC 1433 Epidémiologie clinique, Nancy, France; Cru D’amiens-Picardy Site Nord, Rheumatology Department, Amiens, France

Background: The study of associations between body composition and osteoarthritis is still incomplete. While fat-related components are associated with pain in cross-sectional studies, longitudinal studies are rare and the impact on other quality of life (QOL) dimensions is not known.

Objectives: The main objective of the study was to analyze the impact of body composition on the evolution of the perceived health of patients followed for hip and knee osteoarthritis (OA).

Methods: Longitudinal data from the Knee and Hip Osteoarthritis Long-term Assessment (KHAOLA) cohort, a multicenter cohort of 878 patients with symptomatic knee and/or hip OA, were used. Body composition measures were obtained from DXA scans at year 3. Only 3 of the 6 investigating centers with Lunar Prodigy Advance DXA equipment recruited patients for this study. The main outcome criteria were the changes in Patient-Reported Outcomes Measures (PROMs) (physical functioning, pain, mental health and vitality of the SF-36 0=worst, 100=best) between 3 and 7 years of follow up. Body composition variables were as follows: fat mass index (FMI (kg/m²)), percentage of fat mass and trunk to leg fat mass ratio (TFM/LFM), skeletal muscle Mass Index (SMI (kg/m²)) and lean mass if SMI <700 kg/m² for men and <55 kg/m² for women. To account for the correlation of repeated measurements of the same individual, a generalized estimating equation (GEE) models were used to assess the associations between body composition measurements and the 4 SF-36 scores. The GEE models were adjusted for potential confounders (age, sex, education level, occupation, smoking, comorbidity, hand OA, number of painful joints, joint of inclusion and Kelgren grade (KL)) showing a significant association at the 0.2 threshold in the bivariate analysis.

Results: 290 patients with knee and 114 patients with hip OA have been included in the analysis: women 254 (68.7%), mean age 60.3 (SD 8.4) years old, IMC 29.5 (5.7), KL grade2 135 (46.6%) for knee OA, 79 (69.3%) for hip OA. The results of the multivariate analysis of associations between anthropometric measures and quality of life dimensions are presented in Table 1.
Table 1. Obstetric outcomes of Mexican women with autoimmune rheumatic diseases.

| L. G. Espinosa Banuelos 1, C. M. Skinner Taylor 1, L. Pérez Barbosa 1, A. Cárdenas 1, F. Hernández 2, A. Y. Lujano Negrete 1, S. M. Delgado Ayala 1, Eleuterio González 1, Rheumatology Department, Monterrey, Mexico; 2Hospital Universitario Dr. José Eleuterio González, Rheumatology Department, Monterrey, Mexico; 3Hospital Universitario Dr. José Eleuterio González, Obstetrics and Maternal Fetal Medicine Unit, Monterrey, Mexico; 4Hospital Universitario Dr. José Eleuterio González, Obstetrics and Gynaecology, Monterrey, Mexico

Background: Autoimmune rheumatic diseases (ARDs) are more prevalent in women during childbearing age. These women have an increased risk of adverse pregnancy outcomes and maternal morbidity than general obstetric population (GOP).

Objectives: The objective of this study was to evaluate the obstetric outcomes in Mexican women with ARDs.

Methods: A retrospective and descriptive study was conducted in a pregnancy and rheumatic disease clinic of a university hospital in Northeast Mexico from Jan 2017 to Dec 2020. All data were collected from the medical records of childbearing age women with ARDs enrolled in our clinic at the time of their pregnancy and childbirth. Patients with non-inflammatory rheumatic diseases were excluded. The obstetric, maternal, and fetal outcomes were compared with the rate of adverse perinatal outcomes of the GOP (n=31,254) database from the same institution. Sociodemographic and clinical characteristics of the population are described. We used the Mann–Whitney U, Chi-square, or Kruskal–Wallis tests to analyze the differences between groups. A p<0.05 was considered statistically significant. The statistical analysis was performed with SPSS v.24 statistical software (IBM, NY).

Results: A total of 62 pregnancies in women with ARDs were included. RA (n=24, 38%) was the most frequent diagnosis followed by SLE (n=14, 22.5%) and APS (n=9, 14.5%). The median maternal age at conception was higher in pregnancies with ARDs than GOP (p<0.001). Table 1 shows the pregnancy and product outcomes between groups. Maternal age ≥35 years was also more frequent in the ARDs group (p<0.001). The birth weight was lower in ARDs group than GOP (p=0.007). The odds of preterm delivery were increased in ARDs group (p=0.038).

Table 1. Pregnancy outcome, maternal, fetal, and neonatal adverse events

Conclusion: Pregnant women with ARDs had a higher median maternal age at conception, lower birth weight, increased preterm delivery, and more emergency cesarean sections than pregnant women without ARDs. Close monitoring and multidisciplinary care are necessary to prevent and timely treat complications in this population.

Table 1. Estimates of Effect of bDMARD or tsDMARD use on Lymphoma relative to use of csDMARDs

Marginal Structural Models; adjusted for:

- Age, gender, race, ethnicity, year of cohort entry
- Baseline rheumatology visits (yes/no)
- RDCI

Conclusion: In this large study using the nationwide VA data, we did not observe an association between the use of b/tsDMARDs and an increased risk of lymphoma.

REFERENCES:

[1] Zhao SS, Robertson S, Reich T, et al. Prevalence and impact of comorbidities involving the cardiovascular system. Development of a predictive chart for cardiovascular comorbidities. The major limitation of this study was a lack of information on individual smoking status. The findings might aid in the development of a predictive chart score or algorithm for risk of major adverse cardiovascular events (MACE) in patients with incident AS requiring pharmacologic therapy based on identified risk factors is a clinical necessity for a better holistic management. The related epidemiologic studies are still lacking currently.

Objectives: To investigate factors associated with major adverse cardiovascular events (MACE) in patients with incident ankylosing spondylitis (AS) requiring medical therapy.

Methods: We conducted a population-based case-control study using the Taiwanese National Health Insurance Research Database, and 42,585 newly-diagnosed AS patients requiring medical therapy without previous MACE (the composite outcome of myocardial infarction, ischemic stroke, or patients who underwent coronary artery bypass graft or percutaneous coronary intervention) from 2004 to 2012 was identified. Totally 1,151 patients (2.7%) developed MACE during the follow-up period. We matched MACE cases with non-MACE controls at a 1:4 ratio for age, gender and AS follow-up duration and included 4,604 matched controls for final analyses. Using conditional logistic regression analyses, we examined the associations of MACE with low income (≤ 21000 new Taiwan dollars per month), urbanisation, extra-articular manifestations (uveitis, psoriasis and inflammatory bowel disease), comorbidities and use of medications within a year before MACE development. We also examined the influence of NSAIDs of three categories (traditional NSAIDs, selective cyclooxygenase-2 inhibitors [COX-2] and preferential COX-2) with their annual cumulative defined daily dose (cDDD) on MACE risk with a Bonferroni correction of the cut-off of probability value for statistical significance. The risk was shown as adjusted odds ratio (aOR) with 95% confidence intervals (CIs).

Results: MACE development was associated with selective COX-2 use: statistically with aOR > 1.32 (aOR, 1.61; 95% CI, 1.02-2.54, p = 0.011), corticosteroid use with a dose-response relationship (prednisolone equivalent dose < 5 mg/day: aOR, 1.25; 95% CI, 1.02-1.54, p = 0.028; ≥ 5 mg/day: aOR, 4.75; 95% CI, 3.51-6.43, p < 0.001), residence in rural region (aOR, 1.32; 95% CI, 1.03-1.69, p = 0.028), hypertension (aOR, 3.12; 95% CI, 2.53-8.00, p < 0.001), diabetes mellitus (aOR, 1.69; 95% CI, 1.37-2.07, p < 0.001), hyperlipidaemia (aOR, 5.00; 95% CI, 4.14-6.03, p < 0.001), chronic kidney disease (aOR, 1.98; 95% CI, 1.35-2.90, p < 0.001), heart failure (aOR, 4.04; 95% CI, 2.74-5.94, p < 0.001) and valvular heart disease (aOR, 2.06; 95% CI, 1.33-3.30, p = 0.001). We took into consideration of the cut-off of probability value for statistical significance. The risk was shown as adjusted odds ratio (aOR) with 95% confidence intervals (CIs). The authors would like to thank the Biostatistics Task Force of Taichung Veterans General Hospital, Taichung, Taiwan, ROC for statistical support.

POS1436

CLINICAL CHARACTERISTICS AND RISK FACTORS OF INVASIVE FUNGAL INFECTION DURING IMMUNOSUPPRESSIVE INDUCTION THERAPY IN PATIENTS WITH CONNECTIVE TISSUE DISEASE

H. Fukui¹, H. Hanaoka¹, Y. Kaneko¹, ¹Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Invasive fungal infection (IFI) is a life-threatening complication among immunosuppressed patients. Whereas intensive immunosuppressive therapy during remission induction phase in patients with connective tissue disease is a major risk of IFI, little is known about the clinical characteristics and risk factors of IFI.

Objectives: This study aims to reveal prevalence, clinical characteristics, and associated risk factors of IFI during immunosuppressive induction therapy in patients with connective tissue disease.

Methods: We reviewed consecutive patients with connective tissue diseases who underwent immunosuppressive remission induction therapy in Keio University Hospital Rheumatology Department from January 2012 to August 2020. Patients with 0.5mg/kg or more equivalent dose of daily prednisone use were included for IFI, diagnosed according to the definition of invasive fungal diseases from the Infectious Diseases Society of America (IDSA) 2008. Infections caused by Pneumocystis jiroveci were not included.

Results: Among 2701 hospitalized cases, 627 patients had undergone induction or re-induction therapy. Total of 24(3.8%) patients were diagnosed as IFI,
of whom there were 8 proven cases and 16 probable cases; 14 aspergillosis, 5 candidiasis, 2 cryptococcosis, 1 phaeohyphomycosis, and 2 cases with unknown pathogen. Median duration from the start of immunosuppressive therapy to the onset of IFI was 95 days (interquartile range, 36,249 days; range, 13-1397 days) and the mean dose of daily prednisolone was 0.53±0.29 mg/kg at the onset of IFI. Total of 11 patients died; 6 patients (25.0%) due to IFI and 5 patients (20.8%) due to the exacerbation of underlying disease. Univariable analysis comparing the IFI and non-IFI groups, age (65.8±3.7 vs. 56.1±0.7; P=0.01), initial prednisolone dose (0.87±0.01 vs. 0.95±0.04 mg/kg; P=0.037), the history of methylprednisolone (mPSL) pulse therapy (54.2% vs. 20.0%; P=0.001), tumor necrosis factor (TNF) inhibitor use (8.3% vs. 1.1%; P=0.039), 2 or more immunosuppressant or biologic use (33.3% vs. 12.0%; P=0.010), HbA1c 6.5% or higher (58.3% vs. 28.9%; P=0.003), lowest serum IgG during the clinical course (599.4±821.2 vs 787.7±12.4 mg/dl; P=0.003), and cytomegalovirus reaction defined by pp65 antigen 6 or higher (33.3% vs. 11.2%; P=0.004) were significantly different, respectively. Sex, body mass index, presence of interstitial lung disease, and the use of cyclophosphamide, rituximab, or interleukin-6 inhibitors were not significantly different. Multivariable analysis revealed older age for each (for 10-year increase: OR 1.40, 95% CI 1.03-1.91; P=0.023), the history of methylprednisolone pulse therapy (OR 2.60, 95% CI 1.06-6.77; P=0.049), TNF inhibitor use (OR 11.2, 95% CI 1.70-74.0; P=0.012), and serum IgG less than 550 mg/dl (OR 2.59, 95% CI 1.19-5.65; P=0.03) as the independent risk factors of IFI.

Conclusion: Patients with connective tissue disease with older age, lower serum IgG, mPSL pulse therapy, or TNF inhibitor use are at higher risk of IFI. Further studies are needed to determine the benefit of prophylactic anti-fungal treatment in such patients.

ASSOCIATION BETWEEN BEVERAGE CONSUMPTION AND RISK OF Rheumatoid Arthritis: A PROSPECTIVE STUDY FROM THE FRENCH E3N COHORT

S. Ascione1,2, C. Salliot2, F. Artaud2, Y. Nguyen4, C. Macdonald2, F. Barde3, X. Mariette5,6, M. C. Boutron-Ruault2, R. Seror5,6.

Background: The role of nutrition in the pathogenesis of RA has been suggested in many studies but remains controversial.

Objectives: To assess the relationship between consumption of the most frequently drunk specific beverages (coffee, tea, alcohol, and soft drinks) and the risk of RA.

Methods: The E3N Study (Étude Épidémiologique auprès des femmes de la Mutuelle Générale de l’Éducation Nationale) is a French prospective cohort including 98,995 women since 1990. RA cases have been previously identified with specific questionnaires and medication reimbursement database (1). Food and beverage consumption was assessed using a validated food-frequency questionnaire. Hazard ratios (HR) and their 95% confidence intervals (CI) for incident RA were estimated by Cox proportional hazards models, adjusted for age and the main potential confounders, including smoking. Tests for linear trends were performed. As smoking is a major risk factor for RA, stratified analyses were conducted according to the smoking status (ever or never-smoker) even in the absence of statistically significant interaction between the smoking status and beverage consumptions. Sensitivity analyses were performed in the subgroup of seropositive cases (positive RF and/or ACPA).

Results: During a total follow-up of 21 years (mean 20.78 (SD 2.26) years), 62,630 women contributed 1,300,874 person-years, and 481 developed RA (incidence 37/100 000 person-years). Incident RA cases were diagnosed a mean 11.7 (SD 5.9) years after baseline. Of the 179 (37.2%) RA cases with known antibody status, 153 (31.8%) were seropositive. Consumptions of total alcohol, tea and sugar-sweetened soft drinks were not associated with RA risk. Coffee consumption was associated with RA risk with a dose-effect relationship (≥4 cups/day versus ≤ 1 cup/day, HR 1.24, 95% CI [0.94; 1.64], p trend=0.04), in never-smokers. According to the type of coffee consumed, only high caffeinated coffee consumption was associated with an increased risk of RA among never-smokers (≥ 3.5 cups/day versus ≤ 1 cup/day, HR=1.62 95% CI [1.12;2.34], p trend = 0.006, p newtrend = 0.07). Decaffeinated coffee consumption was not associated with RA risk. Risk of RA was higher with artificially-sweetened soft-drinks consumption (consumers versus non-consumers, HR 1.66 [1.12; 2.45], in never-smokers). No association was observed with other soft drinks. Moderate liquor consumption (spirits or aperitifs) intake was associated with a reduced risk of RA among ever-smokers (consumption of 1 - 3 glasses/week versus non-smokers HR 0.63, 95% CI [0.43; 0.91]) and moderate wine consumption was associated with a decreased risk of seropositive RA (consumption of 4 - 10 glasses/week versus ≤ 1 glass/week HR 0.57, 95% CI [0.35 to 0.94], whereas no association was observed with other alcohols.

Conclusion: Consumptions of tea, total alcohol, and sugar-sweetened soft drinks were not associated with RA risk, whereas consumptions of coffee (especially caffeinated coffee), and artificially-sweetened soft drinks were associated with higher RA risk, among never-smokers. By contrast, moderate liquor consumption was associated with a decreased risk of RA in ever-smokers, and moderate wine consumption was associated with a decreased risk of seropositive RA. If further confirmed, these results could lead to novel mechanistic hypotheses and to simple prevention measures.

**BACKGROUND**: TNF inhibitors (TNFi) are highly effective in inflammatory arthritis (IA) treatment. However, concerns are raised about the possible association between TNFi and hematologic malignancies (HMs).

**OBJECTIVES**: To assess the incidence of HMs among IA patients receiving TNFi compared with the general Turkish population.

**METHODS**: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a single center biological disease modifying anti-rheumatic drug (bDMARD) registry since 2005. Patients with IA including rheumatoid arthritis (RA), spondyloarthritis (SpA), and psoriatic arthritis (PsA) who had at least 1 visit after the TNFi usage were screened from 2005 to November 2021. HM diagnosis was determined from the patient files according to the hematologists' decision and/or bone marrow/lymph node biopsy. Demographic data, disease characteristics, and death status were recorded. Standardized incidence rates (SIR) were calculated after adjustment for age and gender and compared with age- and gender-specific SIR values abstracted from the 2017 Turkish National Cancer Registry (TCNR).

**RESULTS**: Of the 6139 patients registered in the HUR-BIO database, 5355 (3116 female [58.2%]) used any TNFi at least once. Median follow-up duration was 2.6 years for all patients receiving TNFi. 13 patients (8 [61.5%] female) had HM on follow-up. In these patients, median age at the IA onset was 38 (range 26 to 67) and the number of patients with SpA, RA, and PsA was 7, 4, and 2, respectively. The median duration of IA was 17.7 years (range 1 to 33). The median age at the HM onset was 55.5 (range 38 to 76) and the type of HM as follow: 8 lymphoma, 2 multiple myeloma, 1 large granular lymphocytic leukemia, 1 plasma cell dyscrasia, and 1 myelodysplatic syndrome. The median duration of the TNFi usage onset to HM onset was 36 (range 4-112) months. The TNFi was as follows: etanercept (n=8), adalimumab (n=6), infliximab (n=4), golimumab (n=1), and certolizumab (n=1). 5 patients used more than one TNFI. Patients using TNFi had an increased incidence for HMs (SIR 4.23, 95% CI 2.35-7.05). These results were also valid for both gender. 10 patients with HMs were under the age of 65. In this group, there was a higher incidence of HMs in both men (SIR 5.19, 95% CI 1.88-11.43) and women (SIR 4.76, 95% CI 1.74-10.55). 5 patients deceased on follow-up.

**CONCLUSION**: The risk of HMs in inflammatory arthritis patients receiving TNFi being four times higher in comparison with the general Turkish population. There is a plethora of information that discusses the association between HMs and rheumatic disease. To determine whether the increased risk is from rheumatic disease or from TNFi usage, it would be ideal to compare patients receiving TNFi with bDMARD naive IA patients.

**Figure 1. Cumulative number of hematologic malignancies in function of time from start of first anti-TNF therapy**

Disclosure of Interests: None declared

the correlation between the two was verified using Spearman’s rank correlation coefficient (first cohort). Next (second cohort), serum IgG4 of 3240 samples of Nagasaki Island Study (NaIS), which had started in 2014 collaborating among Nagasaki University and Goto City, Nagasaki Prefecture, intended for research of varying conditions and diseases including IgG4-RD, were then measured by MBA. These subjects were stratified into the two groups as IgG4-high and IgG4-within normal limit making use of the aforementioned cutoff values, and compared with background information such as age, gender, drinking, smoking, uric acid, serum creatinine, comorbidities and HLA typing, including DRB1*04:06, *04:05, *04:10 as disease-susceptibility gene, DRB1*07:01 and DBQ1*03:01 as protective gene.1

Results: IgG4 by MBA correlated well with IgG4 by NIA (r=0.94, p-value<0.001) which was determined from Kanazawa samples (N=947). 1,463.6 mg/mL of IgG4 of MBA corresponded to 135 mg/dl, the normal cut-off value for IgG4 by NIA. In the analysis of NaIS samples (N=3240), the overall high IgG4 positivity rate was 6.3%. Multivariable analysis including age, gender, smoking and drinking, led by univariate analysis, showed that gender and smoking were significantly associated with high serum IgG4 positivity (male: odds ratio = 1.8, 95%CI =1.2-2.7, p = 0.009, smoking: odds ratio = 1.7, 95%CI =1.1-2.5, p = 0.012). There was no association between high serum IgG4 level and HLA genotyping.

Conclusion: We concluded that MBA is a good method to measure serum IgG4 even by the very small sample volume. In our study, the prevalence of serum IgG4 positivity was high tendency than previous report1. Our data showed that male and smoking are independent factors associated with high serum IgG4 positivity. There were no association between serum IgG4 level and HLA genotyping in healthy subjects. Further comprehensive investigation is necessary to clarify high risk subjects who will develop RA.

THE PREVALENCE OF RHEUMATOID ARTHRITIS IN WESTERN AUSTRALIA EXTRAPOLATED FROM HOSPITALISATION AND BIOLOGICAL THERAPY USAGE DATA

K. Almutairi1,2, C. Inderjeeth1, D. Preen3, H. Keen1,5, J. Nossent1,3.

The University of Western Australia, School of Medicine, Perth, Australia; 2King Fahd Specialist Hospital, Clinical Hospital, Buraydah, Saudi Arabia; 3Sir Charles Gairdner and Osborne Park Health Care Group, Rheumatology, Perth, Australia; 4The University of Western Australia, School of Population and Global Health, Perth, Australia; 5Fiona Stanley Hospital, Rheumatology, Murdoch, Australia.

Background: Rheumatoid arthritis (RA) is a heterogeneous chronic autoimmune disease that affects the synovial joint lining and may result in permanent joint destruction, premature death, and socio-economic burden. Although RA is one of Australia’s national health priority areas and gathering information about the RA burden of disease was one of the national action plans, no published epidemiological study adequately describes RA prevalence and risk factors for frequent hospitalisations in Western Australia (WA) to date. An accurate prevalence estimate of this disease offers a framework for predicting present and growing healthcare service requirements in the future.

Objectives: We estimated RA period prevalence and identified risk factors of frequent RA hospitalisations, using linked administrative health and state-specific Australian Pharmaceutical Benefits Scheme (PBS) datasets in WA from 1995–2014.

Methods: RA prevalence was calculated per 1000 person years. RA patients were identified in the WA linked health dataset using ICD codes 714.0–714.9 and M05.0–M05.9. Dispensing data on biological therapy for RA were obtained from PBS records and converted to daily doses/1000 person/day. Multivariate logistic regression was used to analyse risk factors for frequent RA hospitalisations (>2/year), controlling for sex, age, and geographic locations.

Results: A total of 17,125 RA patients were admitted to WA hospitals between 1995–2014. The total number of RA hospital separations was 50,353, averaging 3.4 per 1000 separations per year. The RA period prevalence was 3.4 per 1000 separations (0.34%), while the RA period prevalence based on biological therapy usage was 0.36%. The corrected RA prevalence based on biological therapy usage was 0.36% and 0.72% for the 2005–2009 and 2010–2014 periods, respectively (Table 1). Female gender, age 60–69 years, and living in rural areas were all factors for frequent RA hospitalisations.

Conclusion: Based on hospital and biological therapy data, the minimal prevalence of RA in Western Australia is 0.34–0.36%, which falls within the literature range. Older female RA patients in rural areas were more likely to be hospitalised, suggesting unmet needs in primary care access.

IDENTIFYING THE NEW EMERGENCE OF RACIAL DISPARITIES IN GOUT OVER THE PAST 3 DECADES – US NATIONAL SURVEY AND PROSPECTIVE COHORT DATA

N. McCormick1,2,3, L. Lu1, C. Yoko2,3,4, A. Joshi2,3, Y. Zhang3,4, H. Choi2,3,4.

1Arthritis Research Canada, Vancouver, Canada; 2The Mongan Institute, Medicine, Boston, United States of America; 3Harvard Medical School, Medicine, Boston, United States of America; 4Massachusetts General Hospital, Rheumatology, Allergy and Immunology, Boston, United States of America; 5MGH Clinical and Translational Epidemiology Unit, Medicine, Boston, United States of America.

Background: Several studies published after 2010 reported a higher frequency of gout and hyperuricemia among US Blacks than Whites.2 However, Blacks (in the US and Africa) were previously thought to suffer gout less often than Whites.3 We hypothesized that the racial disparity in Blacks emerged over the past several decades, with flipped prevalence between the two races.

Objectives: To assess trends in racial differences in gout prevalence in the US using both national survey and cohort study data over the past 3 decades.

Methods: Using data from the NHANES (National Health and Nutrition Examination Survey) III (1988-1994) and latest decade (2007-2016), and data from 5 examination periods in the ARIC (Atherosclerosis Risk in Communities) Study between 1988 through 2013, we compared age- and sex-adjusted prevalences and odds ratios (OR) to determine the trend of racial differences in gout prevalence between Blacks and Whites. A time–race interaction term was used to assess differences in the rate of change between the two races.

Results: Among Whites, the sex- and age-standardised prevalence of gout in the NHANES rose from 2.8% (95% CI: 2.4 to 3.2) in 1988-94 to 3.7% (3.2 to 4.1) in 2007/16. Prevalence of gout among Blacks was lower than Whites in 1988-94 (2.6% [2.2 to 3.0]) but rose more sharply over the subsequent decades (p for race-time interaction=0.003), and in 2007/16 came to exceed that of Whites (5.0% [4.4 to 5.6]). Corresponding age-sex-adjusted ORs for gout in Blacks vs. Whites were 0.93 (0.73 to 1.17) in 1988-94, increasing to 1.46 (1.22 to 1.74) in 2007/16 (Table 1). This disproportionate rise in gout prevalence among Blacks tended to be more prominent among women (OR 1.81 [1.29 to 2.53]) than men (OR 1.26 [1.02 to 1.55]; p for race-time interactions of 0.002 and 0.01, respectively). Similar trends were observed in the ARIC cohort, where the OR for gout among Blacks vs. Whites rose progressively from 0.82 (0.65 to 1.02) in 1987-89 to 1.49 (1.10-2.09) in 2011-13.
Conclusion: Gout prevalence tended to be lower in Blacks than Whites until late 80’s, then rose and surpassed that of Whites over the past several decades. These trends closely parallel the worsening obesity epidemic during this period, particularly in Blacks, partly due to enhanced Western lifestyle. Gout risk genetic profile change would not contribute to this emergence of racial differences, particularly among the same individuals in ARIC, although it remains to be clarified whether Blacks carry genetic profiles that enhance the effect of lifestyle risk factors for gout.

FLT1 AND EPHB2 ARE NOVEL GENETIC MARKERS ASSOCIATED WITH PANCREATITIS IN PATIENTS TAKING AZATHIOPRINE FOR IMMUNE-MEDIATED CONDITIONS: INTEGRATING GENOME- AND TRANSCRIPTOME-WIDE ASSOCIATION STUDIES

S. Shah1, T. Reese1, J. Zanussi2, A. Dickson1, L. Danieli2, R. Tao2, T. Miller-Fleming3, P. Straub4, A. Hung5, P. Nepal5, W. Q. Wei6, E. Phillips1, N. Cox1, C. M. Steinfeld7, Q. Feng2, C. P. Chung1. 1University of California, San Diego and VA San Diego Healthcare System, Gastroenterology, San Diego, United States of America; 2Vanderbilt University Medical Center, Division of Rheumatology, Nashville, United States of America; 3Vanderbilt University Medical Center, Biostatistics, Nashville, United States of America; 4Vanderbilt University Medical Center, Genetics, Nashville, United States of America; 5Vanderbilt University Medical Center, Biomedical Informatics, Nashville, United States of America; 6Vanderbilt University Medical Center, Nephrology, Nashville, United States of America; 7Vanderbilt University Medical Center, Infectious Diseases, Nashville, United States of America; 8Vanderbilt University Medical Center, Pharmacology, Nashville, United States of America

Background: Azathiprine (AZA) is a thiopurine immunosuppressant medication used to treat a variety of immune-mediated diseases. Unfortunately, its use is limited by adverse effects. Pancreatitis, a potentially severe, life-threatening side effect is independent of dose and necessitates AZA discontinuation given the high risk of recurrent pancreatitis with continued use or re-challenge. The mechanisms driving pancreatitis are unclear. While classic thiopurine-induced acute pancreatitis (TAPI) has been associated with HLA haplotypes, most patients taking AZA and presenting with pancreatitis do not fulfill the stringent criteria for TAPI.

Objectives: To identify genetic risk factors for pancreatitis in patients taking azathiprine for immune-mediated conditions.

Methods: Using a biobank linked to electronic health records (EHR) from a tertiary care hospital, we identified new users of AZA. Patients were excluded if the primary indication for AZA was organ transplant or if there was a history of pancreatitis prior to AZA use. The analysis was restricted to patients with EHR-reported race as White due to insufficient case counts for the non-White group. We then identified patients with amylase or lipase values that exceeded twice the upper limit of normal (>2x ULN) or with ICD-9/ICD-10 codes for acute pancreatitis. Each record was manually reviewed to confirm the timing of AZA use in relation to laboratory derangements or ICD coding, as well as to further classify patients into three increasingly strict, but not exclusive categories: 1) pancreatic injury (amylase or lipase >2x ULN); 2) acute pancreatitis; or 3) TAPI. We completed genotyping with Illumina Infinium Expanded Multi-Ethnic Genotyping Array plus custom content data, employed Michigan Imputation servers for genetic imputation, and used PrediXcan (GTEx v8) to impute gene expression. We then conducted genome-wide association and transcriptome-wide association studies (GWAS, TWAS). Acknowledging the relatively small overall cohort, and possible imbalance of cases vs controls, we used the Firth logistic regression method, which is a penalized likelihood-based method.

Results: We studied 2127 AZA users (35.4% male; mean 44.5±17.2 years). The median AZA dose was 100mg/day (IQR: 50-125mg/day). Rheumatologic conditions (56.9%) and inflammatory bowel disease (40.4%) comprised the most common primary indications for AZA. Pancreatic injury, pancreatitis, and TAPI were diagnosed in 42 (2.0%), 16 (0.8%), and 9 (0.4%) patients, respectively. GWAS identified several significantly associated genes, many with overlapping TWAS findings in the pancreas and liver (Figure 1). From these, the two protein-encoding genes Fms Related Receptor Tyrosine Kinase-1 (FLT1) and Ephrin type-B receptor-2 (EPHB2) overlapped in two or more pancreatitis phenotypes in the TWAS and GWAS, respectively. EPHB2 was associated with a 8.6-fold (P=1.84 x 10^-6) and a 31.4-fold (P=2.87 x 10^-8) higher likelihood of pancreatic injury and TAPI, respectively.

Conclusion: FLT1—a gene that encodes a receptor tyrosine kinase and is a member of the vascular endothelial growth factor receptor (VEGFR) family—and EPHB2—a gene that encodes a member of the Eph receptor family, which is the largest subgroup of the receptor tyrosine kinase family—are novel genetic markers associated with pancreatitis in patients taking AZA. VEGF can potentiate inflammation and the pancreas microenvironment is known to promote VEGF expression, which has been linked to pancreatic cancer development; anti-VEGF treatments have been investigated both for mitigating inflammation and also anti-pancreatic cancer treatment. Future studies validating our findings in AZA-induced pancreatitis are warranted.

1 Statistically significant differences between the axPsA and No PsA groups of patients were determined by using Mann–Whitney U test for continuous data and Chi-square test for categorical data.
(CRP) and Myostatin (MSTN) were assessed by ELISA. Differences between robust and frail patients were tested using Mann-Whitney and Kruskal-Wallis test for continuous variables and Chi-square test for discrete variables. For each variable, normality was tested using Shapiro-Wilk normality and Kolmogorov-Smirnov tests. Non-normal variables were natural logarithm transformed to achieve normality. The association between each biomarker and frailty was assessed using multivariate logistic models. Additionally, a sensitivity analysis was performed including a second biomarker in the model in order to detect those biomarkers that influenced the association. All analyses were done using R.

**Results:** Inflammatory markers CRP and GDF-15 were increased in frail patients, OR (95% CI) 1.59 (1.22-2.05; p<0.001) and OR 1.93 (1.01-3.68; p=0.006), respectively, in comparison to robust. There were no significant changes in the inflammatory parameters TNF-α, sgp130, sIL-6R between groups. The anabolic marker IGF-1 did not change significantly between groups, while the anti-anabolic mediator MSTN was reduced in frail patients, OR 0.40 (0.19-0.86; p=0.02). Finally, CK levels were decreased in frail patients when compared to robust subjects, OR 0.37 (0.18-0.76; p=0.007). In sensitivity analysis, this association remained statistically significant with ORs ranging from 0.33 to 0.40 regardless of a second biomarker.

**Conclusion:** We identified chronic inflammation in a cohort of frail patients given the significant increase in CRP and GDF-15, although we did not find association with other inflammation parameters such as TNF-α, sgp130 or sIL-6R, highlighting the difficulty of characterizing the status of systemic inflammation. The decrease in CK levels in frailty suggest that this marker could be an indicator of cumulative muscle mass loss due to chronic inflammation. Since CRP can be sensitive and altered by a multitude of pathological conditions in frail patients, we propose CK as a more specific marker of inflammation-induced muscle impairment.

**Socio-demographic, clinical, and treatment differences of rheumatic diseases in three Mexican regions.**

**Background:** Rheumatic diseases prevalence and characteristics in Mexico may vary depending on the country’s region. To acknowledge these differences is needed to develop focused strategies for early diagnosis and treatment. Objectives: Identify the socio-demographic, clinical and treatment characteristics of the rheumatic diseases in the different regions in Mexico using data from the Mexican Adverse Events Registry (BIOBADAMEX).

**Methods:** In this analysis we included all patients registered from 2016 to 2021. We described the prevalence in the northern region of Mexico (NR, central CR) and southern region (SR). We compared socio-demographic, clinical and treatment characteristics between these three regions. We used descriptive statistics, Chi square and Kruskal Wallis tests to analyze differences between the groups.

**Results:** A total of 780 patients were included in this study. 248 patients (32%) were from the NR, 471 (60%) were from the CR and 61 (8%) from the SR. At baseline, patients had a median (IQR) age of 50 (40-58) years and median disease duration of 7 (3-15) years. NR patients had longer disease duration (9.7 years, p<0.001) and SR patients had higher BMI (29, p<0.001). Overall, 351 (45%) had comorbidities. In CR and SR more than the half of the patient had comorbidities, while in NR only 29% (p<0.001).

The most common diagnosis was rheumatoid arthritis with 512 (66%) patients, followed by ankylosing spondyritis in 115 (15%), psoriatic arthritis in 44 (6%), systemic lupus erythematosus in 30 (4%) and idiopathic juvenile arthritis in 27 (3%), these proportions were maintained when analyzed by regions. We found SR had higher DAS 28 and higher BASDAI (Table 1).}

**DICKKOPF HOMOLOG 3 (DKK3) AS A PROGNOSTIC MARKER IN LUPUS NEPHRITIS: A PROSPECTIVE MONOCENTRIC EXPERIENCE**

S. Sciacia1, M. Radin1, A. Barinoti1, I. Cecchi1, D. Rossi1, R. Fenoglio1, D. Roccatoleti1, 1University of Torino, Department of Clinical and Biological Sciences of the University of Turin, Torino, Italy

**Background:** Lupus nephritis (LN) is a major cause of mortality/morbidity in patients affected by systemic lupus erythematosus (SLE). Reliable prognostic markers, especially related to the degree of interstitial fibrosis, are still lacking and renal biopsy still represents the gold standard. Recent data suggests a role of Dickkopf homolog 3 (DKK3) as a marker of tissue fibrosis in different diseases, however its role in autoimmune diseases still needs to be elucidated.

**Objectives:** To investigate DKK3 serum levels in SLE patients with and without LN, assessing its changes in relation to kidney function, flares and interstitial renal fibrosis, as well as its association with the IFN signature.

**Methods:** 132 SLE patients, 57 of whom diagnosed with LN, were included in this study, as well as 50 healthy donors. DKK3 and Myxovirus resistance protein 1 (MxA) were measured in serum samples, using enzyme-linked immunosorbent assays. Biopsies were evaluated for glomerular involvement, interstitial renal fibrosis and tubular atrophy according to 2003 International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification and the revised 2018 version. Patients were followed up for at least 36 months.

**Results:** DKK3 serum levels were significantly higher in patients with biopsy-proven LN when compared to those without (median[min-max]: 215ng/ml [81-341] vs 21.1ng/ml [1-690], p<0.01). When focusing on patients with LN, DKK3 levels resulted to be associated with the presence of chronic kidney disease (OR: 4.31 [CI 95% 1.06-16.1]) per DKK3 doubling, p<0.01), higher chronicity index at biopsy (OR: 1.75 [CI 95% 1.59-21.3] per DKK3 doubling, p<0.01) and flares rate (OR: 1.45 [CI 95% 1.15-7.71] per DKK3 doubling, p<0.044), DKK3 levels correlated with the IFN signature as expressed by MxA (correlation coefficient: 0.71, p<0.037).

**Conclusion:** While kidney biopsy remains the gold standard for diagnostic and prognostic assessment in LN, DKK3 could represent a useful additional prognostic tool to monitor SLE patients and eventually to guide therapeutic choices.

**VALIDATION OF THE GERMAN LUPUSPRO QUESTIONNAIRE TO MEASURE LUPUS-SPECIFIC HEALTH-RELATED QUALITY OF LIFE IN LUPUS ERYTHEMATOSUS PATIENTS**

V. Mevisser1, T. Filla1, C. Duesing1, M. Schneider1, J. Meenakshi2, G. Chehab1, 1Policlinic for Rheumatology & Histology Research Unit for Rheumatology, Medical Faculty, Heinrich Heine University Duesseldorf, University Clinic, Duesseldorf, Germany; 2Medical Center, Rush University, Chicago, United States of America

**Background:** To date, there is no validated lupus-specific questionnaire for health-related quality of life (HRQoL) in German language. Regular assessment of health-related quality of life is recommended for monitoring and outcome in current management guidelines [1][2]. Given that about 20% of the EU population are native German speakers, it is therefore essential to validate a Lupus-specific questionnaire in German.

**Objectives:** The aim of this study is to present the validity (content, construct, and criterion) and reliability (internal consistency and test-retest) of the German translation of the LupusPro questionnaire, which captures both generic and lupus-specific HRQoL domains.

**Methods:** The German LupusPro was professionally translated and then administered to consecutive patients with systemic lupus erythematosus treated at our tertiary centre. At each visit, clinical and laboratory data were collected, including disease activity and damage (SLEDAI-2K resp. SLICC/SDI). Additional questionnaires were used for validity testing, including questionnaires for HRQoL (SF-36v2), fatigue (FACIT), depression (CES-D), sleep (PSQI) and health impairments (IMET).

We calculated Cronbach’s alpha to test reliability. An alpha >0.70 is considered acceptable. Test-retest reliability was tested by evaluating the consistency between the LupusPro at two time points (T0 and T1 after 2-3 days). Criterion and construct validity was assessed by comparing the results of the LupusPro with the generic HRQoL questionnaire, established clinical endpoints (disease activity, disease damage), and the domains of the additional questionnaires. The confirmatory factor analysis was performed with the Lavaan package (Ver. 0.6-9) in R using the relative fit indices, the Tucker-Lewis index (TLI) and the comparative fit index (CFI).

**Results:** 148 patients with confirmed SLE took part in the study of which 111 participated in the test-retest analysis. About 84% were female with a mean age of 45.5 (SD 12.0) and mean disease duration of 17.7 (SD 9.7) yrs. The mean SLEDAI-2K was 3.1 (SD 3.2) and SLICC/SDI 1.4 (SD 2.1).

The LupusPro domain’s internal consistency by Cronbach’s alpha exceeded >0.7 except for the domains lupus symptoms (α=0.64), lupus medication (α=0.59), procreative ability (α=0.58), and coping strategies (α=0.43). The overall test-retest correlation was excellent (ICC=0.94). The correlation of the corresponding LupusPro and SF-36v2 domains were moderate to strong (ρ=0.54–0.78), whereas correlation with disease activity and damage (SLEDAI-2K and SLICC/SDI) was weak (ρ=0.23 resp. -0.08). Correlation of the selected LupusPro domains with the above mentioned other dedicated outcome measure instrument emphasized construct and criterion validity.

The results of the confirmatory factor analysis showed good construct validity of the LupusPro. The observed model fit for the hypothesized item-scale relationships was very good (CFI = 0.96, TLI = 0.98). Items generally had loadings of >0.6 with their respective factor. Exceptions were especially the domain coping strategies where all items loaded <0.4.

**Conclusion:** The GermanLupusPro is a valid instrument for measuring health-related quality of life. It shows comparable psychometric properties as the original versions. Minor difference in individual domains may be explained by sociocultural factors.

**PSYCHOMETRIC PROPERTIES OF THE CENTRAL SENSITIZATION INVENTORY IN PATIENT WITH FIBROMYALGIA**

F. Salaffi1, S. Farah1, C. Mariani1, P. Sarzi-Puttini1, M. Di Carlo1, 1Università Politecnica delle Marche, Dipartimento Di Scienze Cliniche e Molecolari, Ospedale “Carlo Urbano”, Jesi, Italy; “ASST Fatebenefratelli-Sacco, Rheumatology Unit, Internal Medicine Department, Milano, Italy

**Background:** Patients with fibromyalgia (FM) complain many symptoms besides musculoskeletal pain: e.g. fatigue, sleep difficulties, a swollen feeling in tissues, paresthesia, cognitive dysfunction, dizziness, and symptoms of overlapping conditions such as irritable bowel syndrome, headaches and restless legs syndrome. These conditions can be grouped under the umbrella term of central sensitization (CS) syndromes.

**Objectives:** The goal of the present study was to explore additional evidence of convergent and discriminant validity of the Central Sensitization Inventory (CSI) in a large sample of subjects with fibromyalgia (FM).

**Methods:** Patients were consecutively enrolled for a cross-sectional assessment of the specific measures of the revised Fibromyalgia Impact Questionnaire [FIQ1], the modified Fibromyalgia Assessment Status [modFAS], and the Polysymptomatic Distress Scale [PDS] and of CSI. To test the convergent validity, the Spearman’s rho was used to measure the degree of correlation between the variables CSI and the FM-specific measures. To assess discriminant validity, CSI scores were grouped according to FIQ1 severity states, and differences between these groups studied with the Kruskal-Wallis test. Interpretive cut-offs were established with the univariate reconciliation approach.

**Results:** The study included 562 FM patients, 199 (35.4%) were classified as having central sensitization syndrome (CSI ≥40). CSI was largely correlated with modFAS (r = 0.580; p < 0.0001), FIQ1 (r = 0.542; p < 0.0001), and PDS (r = 0.518; p < 0.0001). The differences between the CSI scores in accordance with the FIQ1 was significant (p < 0.000001). CSI cut-offs proposed for FM: 21 between remission and mild severity, 30 between mild and moderate severity, 37 between moderate and severe disease, and 51 between severe and very severe disease.

**Conclusion:** The current study successfully showed additional evidence of the convergent and discriminant validity of the CSI in FM patients.

EFFECT OF PHYSICAL ACTIVITY ON CHRONIC FATIGUE IN RHEUMATOID ARTHRITIS PATIENTS

A. Aleksandrova, V. Nikitin, N. Aleksandrova, Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy», Department of Functional Research Methods, Volgograd, Russian Federation; «Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation; National Medical Research Center of Rehabilitation and Balneology, Sanatorium-Resort Complex «Vulan» - Scientific and Clinical Branch, Moscow, Russian Federation

Objectives: To evaluate the dynamics of fatigue indices in RA patients depending on the intensity of physical activity (aerobic exercise) in the short term.

Methods: The study included 111 women with RA (mean age 54.4±11.03 years old, mean disease duration 11.9±9.3 years, DAS28-ESR score 2.84 [2.32;3.05]; mean VAS fatigue score 71.6±8.93). All patients underwent a 3-week post-hospital rehabilitation program (PHRP), and aerobic exercise was the main component of this program (dosed walking, daily, up to 1 hour) and outdoor walks up to 3-3.5 hours per day [1]. The level of fatigue was estimated using the British Rheumatoid Arthritis Fatigue Scale - Numerical Rating Scale (BRAF-NRS V2). The 50-meter walking test was used to assess the functional state of patients in dynamics, the 6-minute walking distance test (6MWD) - to assess patients' tolerance to physical activity. The intensity and duration of exercise were compared with serum levels of free fatty acids (FFA), triglycerides (TG), and angiopoietin-like protein type 4 (ANGPTL4), an inhibitor of lipoprotein lipase, which plays an important role in the regulation of lipid metabolism and energy balance.

Results: After completion of PHRP, RA patients showed a significant decrease in fatigue attributes of the NRS severity scale (6.83 ± 1.21 vs. 6.51 ± 1.18 points, p=0.003), NRS-effect (6.24 ± 1.07 vs. 5.95 ± 1.08 points, p=0.037); a decrease in time taken to complete the 50 m. walk test was noted (79.3 ± 8.64 vs. 78.91 ± 8.15, p=0.01) [2]. Increased concentration of ANGPTL4 (p=0.02), FFA (p<0.01) and decreased TG level (p<0.05) were also determined in serum of RA patients. There was a significant correlation between ANGPTL4 and FFA (r=0.54, p<0.02), but not with TG (r=-0.18, p>0.05). The increase in serum ANGPTL4 during exercise may be mediated by increased serum FFA content and increased lipid oxidation processes. Previously, it was shown that muscle tissue, along with liver and adipose tissue, significantly affect to the increase in circulating ANGPTL4 during exercise [3, 4].

Based on the results of the first phase of the study, patients (n=102) were retrospectively divided into two groups: Group I (n=53) included patients with <5-6 thousand steps/day (sedentary lifestyle); Group II (n=49) included patients with ≥7-8 thousand steps/day (mobile lifestyle). Group II of RA patients significantly improved their physical parameters - reduction of walking time (p<0.001) and number of steps in the 50-meter test (p=0.013) at the end of PHRP. There was a reduction in fatigue severity on all scales: VAS (p<0.001), NRS severity (p=0.001), NRS effect (p<0.001), and NRS-overcoming (p=0.001). In group I, there was an increase in VAS fatigue (p=0.008) and NRS effect (p=0.01). No intergroup differences were found among lipid metabolism indices before and after PHRP (p=0.05).

Conclusion: Aerobic exercise (walking) is an effective method of increasing physical activity and reducing fatigue in patients with RA during the post-hospital rehabilitation phase. Increased physical activity during walking ≥7-8 thousand steps/day has a positive effect on physical indices and fatigue components in the short term. Lipid metabolism markers can be used in determining the degree of activity, optimization of the duration and intensity of exercise in RA patients.

NEUROPLASTICITY STIMULATION-BASED REHABILITATION IMPROVES PAIN AND HAND FUNCTIONALITY IN PATIENTS DIAGNOSED WITH CARPAL TUNNEL SYNDROME: A PILOT STUDY

E. Muňoz-Gómez1, S. Molá-Casanova1, N. Sempere-Rubío1, M. Aguilar-Rodríguez1, M. Ingles1, P. Serra-Añó1, Research Unit in Clinical Biomechanics (UBIC), Physiotherapy, Universitat de València, Valencia, Spain

Background: Carpal tunnel syndrome (CTS) is the most commonly diagnosed entrapment neuropathy, characterized by sensory and motor disorders. Physiotherapy interventions based on neuroplasticity stimulation, such as mirror therapy (MT) and cross-education (CE) have been demonstrated effective in pain and impaired function. In those therapies, mirror neurons that are activated when observing an action are considered the possible underlying neural mechanism, creating organized new pathways between two cerebral hemispheres and enabling brain plasticity. However, MT and CE effects have not been widely studied on unilateral CTS.

Objectives: To analyze the effectiveness of MT and CE rehabilitation protocols in a sample of patients with CTS on pain intensity and functionality.

Methods: A randomized-controlled trial was conducted. Subjects diagnosed with unilateral CTS were enrolled in this study. MT group (MTG) (N=36) patients with OA (78% females, age of 43 to 68 years, generalized OA, OA of the knee or hip joints) where included in the randomized placebo-controlled study. Coronavirus infection COVID-19 were diagnosed from 12 to 26 weeks before the study. The main symptoms of post-COVID syndrome were dry cough, smell loss, breathlessness, weakness, fatigue, sleep disorders, cognitive symptoms, memory problems, anxiety, depression, headache, dizziness, joint and muscle pain. All patients were randomized into 3 groups. 13 study group patients received 10 Reoxy therapy procedures, 9 placebo group patients – 10 placebo procedures of Reoxy therapy, 14 control group patients – only standard rehabilitation. The patients of all groups underwent 2-week standard rehabilitation program: 10 procedures of electrotherapeutic massage for muscles and periaricular tissues, 10 sessions of general magnetic therapy, 10 group sessions of physical exercises with elements of breathing exercises. All patients received NSAIDs and SYSADOA at standard dosages. Intra-articular corticosteroids was not used. The study group patients were breathing hypoxic (FiO2 13–15%) and hyperoxic (FiO2 up to 40%) gas mixture through the mask in the interval mode with biofeedback using device «ReOxy» (Al Medig S.A., Luxembourg). 10-min hypoxic test (FiO2 12–13%) was performed before the first and fourth procedures. The duration of 1–4 procedures was 30 min, 5–10 procedures – 40 min. The placebo procedures were performed using the mask with the atmospheric air hole. Joint pain and general health on 100-mm VAS, Lequesne and WOMAC indexes, Spielberger-Khanin anxiety test, Beck depression inventory and breathlessness on Modified Borg scale were evaluated at baseline and at 2 weeks.

Results: After 2 weeks in the study group pain on VAS decreased by 49.6% (p<0.05), Lequesne index – by 39.3% (p<0.05), WOMAC – by 1.4 times (p<0.01), anxiety level on Spielberger-Khanin test – by 40.9% (p<0.05), depression level on Beck depression inventory – by 64.1% (p<0.01), general health on VAS improved by 69.3% (p<0.01), the level of breathlessness on Modified Borg scale in the study group initially was 2.5±0.9 score (moderate – slight breathlessness). After rehabilitation in the study group the level of breathlessness decreased to 0.3±0.4 score (extremely slight – no breathlessness). In the study group there were statistically significant differences from the placebo group (p<0.05) and the control group (p<0.05) in all parameters.

Conclusion: 2-week complex rehabilitation program, including interval hypoxo-hyperoxic training (Reoxy therapy), reduces pain, breathlessness, depression and anxiety, improves functional status and general health in patients with OA and post-COVID syndrome.

REFERENCES:

performed a rehabilitation protocol consisting of six-weeks of MT training, five
days/week. The healthy hand was trained in front of a mirror placed in the mid-
dle of the body, while the affected hand was hidden and quiet on the opposite
side. CE group (CEG) (N=10) intervention was designed to perform the same
training protocol, but without a mirror. Thus, the difference between interven-
tions was the use of the mirror. Training consisted of mobility, strength and
functional exercises. Minimum, maximum and average perceived pain were
assessed through Visual analog scale (VAS), and upper limb function through
Quick-DASH, before and after the intervention. Regarding statistical analyses,
a two-factor mixed multivariate analysis of variance (MANOVA) was carried
out with a between-subjects factor “treatment group” (MTG and CEG) and a
within-subject factor “time measurements” (pre and post-intervention) for all
variables. (Clinical trial id: NCT05115396).

**Results:** Nineteen participants (4 men and 15 women) between 30 and 60
years were included in the study. There were no statistically significant differ-
ences between groups at the beginning of the study. After treatment, there
was a significant decrease in maximum pain (p<0.05), minimum pain (p<0.05)
and average pain (p<0.05) of the affected hand in both groups, being larger
the experienced changes of the MTG compared to that of the CEG (Table 1).
Regarding hand functionality, both groups significantly improved compared with
baseline (p<0.01). This study suggests that activation of mirror neurons either
by MT or CE, is effective on hand pain and functionality in people with unilateral
CTS.

**TEACHING NAILFOLD CAPILLAROSCOPY USING THE “FAST TRACK ALGORITHM” VIA AN ONLINE PLATFORM: THE ASIAN EXPERIENCE**

S. A. N. 1, 2, W. H. Tan 1, E. Saffari 3, A. Loo 2, 3, Singapore General Hospital, Department of Rheumatology and Immunology, Singapore; Singapore; 1Duke-National University of Singapore; Duke-National University of Singapore, Singapore, Singapore

**Background:** Nailfold capillaroscopy (NFC) is being increasingly used in the
early identification of systemic sclerosis (SSc) related disorders. Recent studies
have shown that an optimised simple capillaroscopic definition of normal and
abnormal capillary morphology is reliable and a multi-centre consensus “fast
track algorithm” was developed by the European League against Rheumatism
(EULAR) Study Group on Microcirculation in Rheumatic Diseases (SG MC/
RD) to allow trainees to identify scleroderma patterns from non-scleroderma
patterns.

**Objectives:** To validate the “fast track algorithm” taught via an online teach-
ing platform to identify scleroderma patterns from non-scleroderma patterns on
NFC.

**Methods:** Trainees participated in the NFC teaching workshops conducted via
an online platform by the same SSc expert (AL) over 3 separate sessions. In
the first part of the workshop (training), all trainees attended a talk on NFC by
the SSc expert (AL) whereby they were taught the fast track algorithm to identify
and classify NFC image patterns using a training set of images. The “fast track
algorithm” (Figure 1) consists of three easy rules: 1) Rule number 1: the presence
of ≥ 7 capillaries (capillary density) AND the absence of giant capillaries (capillary
dimension) allows the rater to call the capillaroscopic image a “non-scleroderma
pattern (category 1)”; 2) Rule number 2: the presence of giant capillaries or the
presence of an extremely lowered capillary density (≤ 3 capillaries) in combination
with abnormal shapes (= “late” scleroderma pattern) allows the rater to call the
capillaroscopic image a “scleroderma pattern (category 2)”; 3) Rule number 3: If
the image does not meet rule number 1 or rule number 2 then the image is auto-
matically classified as a “non-scleroderma pattern (category 1)” In the second part
of the workshop (evaluation), each trainee independently rated 45 NFC images
(30 seconds for each NFC image) in the same session, and submitted their
answers in real time using an electronic form. The reading of the expert (AL) was
considered the gold standard. AL is a SSc expert who had previously attended the
EULAR workshop on NFC and has had more than 10 years of experience in NFC.
Within 2-4 weeks of the initial rating exercise, trainees re-evaluated the same
set of images for the intra-reader exercise under supervised conditions via
the online platform. We computed the inter- and intra-rater agreement using

**EFFICIENCY OF PASSIVE MECHANOTHERAPY IN COMPLEX REHABILITATION OF PATIENTS WITH OSTEARTHRITIS**

E. Grivas 1, I. Pogonchenkova 1, 2, 3, Moscow Centre for Research & Practice in Medical Rehabilitation, Restorative and Sports Medicine, Department of Medical Rehabilitation, Moscow, Russian Federation; 2Moscow Centre for Research & Practice in Medical Rehabilitation, Restorative and Sports Medicine, Director, Moscow, Russian Federation

**Background:** Different types of physical exercises relieve pain, improve func-
tional status and quality of life in patients with osteoarthritis (OA) in addition to
drug treatment [1–4].

**Objectives:** To evaluate the efficacy of robotic mechanotherapy (continuous
passive motion) in the complex rehabilitation of patients with OA.

**Methods:** 58 patients with OA of the knee, hip, wrist and hand joints (76%
females, age of 49 to 65 years, disease duration of 3 to 11 years) were included
in the study and randomized into 2 groups. 28 study group patients
underwent robotic passive mechanotherapy (continuous passive motion) for
the knee and hip joints using “ARTROMOT K1” machine (Ormed gmbh,
Germany), for the wrist and hand joints using “Kinetic Maestra hand
and wrist CPM” machine (Kinetc, UK) (10 sessions for 20–25 min) in addition to
the standard rehabilitation program (2 weeks). 30 control group patients
received only the standard rehabilitation program, which included 10
groups of physical exercises for the joints for 45 min under the supervi-
sion of a trainer, 10 procedures of electrostatic massage for muscles and
periarticular tissues, 10 sessions of occupational therapy for 45 min (joint
protection strategies, use of assistive devices and adaptive equipment). All
patients received NSAIDs and SYSDAOD at standard dosages. Intra-articu-
lar corticosteroids were not used. Tender joint count, joint pain on 100-mm
VAS, Lequesne and WOMAC indexes, the amplitude of flexion in the knee
joint measured by goniometer, the march test (passage time of 20 meters
per sec), hand grip strength measured by a dynamometer were evaluated at
baseline and at 2 weeks.

**Results:** After 2 weeks in the study group pain on VAS decreased by 40.9%
(p<0.05), tender joint count – by 38.7% (p<0.05), Lequesne index – by 1.53 times
(p<0.01), WOMAC – by 1.21 times (p<0.01). In the study group the amplitude of
flexion in the knee joint increased by 34.2% (p<0.05), the march test decreased
by 3.5±1.2 sec (28.8%) (p<0.05), the grip strength of the more affected hand
enhanced by 22.3% (p<0.05), of the less affected hand – by 18.5% (p<0.05). In
the study group there were statistically significant differences from the control
group in all parameters (p<0.05), excluding the grip strength of the less affected
hand (p<0.05).

**Conclusion:** 2-week complex rehabilitation program, including robotic mechan-
otherapy (continuous passive motion), relieves pain, improves functional ability,
motor activity (march test, range of motion in the knee joint, hand grip strength)
in patients with OA.

**DOI:** 10.1136/annrheumdis-2022-eular.3930
Results: Ninety-eight trainees from Singapore, Malaysia, Indonesia, Hong Kong, Philippines, Taiwan, Myanmar and Brunei included rheumatologists, rheumatology trainees, pediatric rheumatologists, interns and nurses. Fifty-four participants were novices with no prior NFC experience, 38 participants were “moderately experienced” (< 5 years of NFC experience) and 1 participant was “experienced” with more than 5 years of NFC experience. The mean (SD) inter-rater kappa of the 98 trainees was 0.71 (0.13). For the 61 trainees who participated in the re-evaluation session, mean (SD) inter-rater and intra-rater kappa were 0.74 (0.16) and 0.71 (0.15), respectively.

Background: Previous work has highlighted considerable heterogeneity in the organization of postgraduate rheumatology training programs. EULAR strives to harmonise rheumatology training across Europe with defined standards of key aspects of training including knowledge, skills and professional behaviors.

Objectives: To analyse existing documents on postgraduate training in rheumatology and other related specialties available within Europe and the rest of the world.

Methods: As most documents were unpublished, key documents on specialty training in Rheumatology and 28 related specialties were retrieved by hand-search. We started with the collection of documents developed by UEMS (Europe), ACGME (USA), CanMEDS (Canada) and RACP (Australia). Then we searched for specialty training documents developed by other international boards and we also sent emails to the boards or associations if no document could be found in their websites. Finally, we retrieved national documents from European Countries with a structured rheumatology training process, translated them into English using DeepL/Google translate and, in case of doubt, liaised with native speakers familiar with the documents. The content of all the above documents (including information about the structure of each document) was extracted into a standardized data extraction sheet.

Results: 133 documents were retrieved. UEMS, ACGME, CanMEDS documents were available for all the mapped specialties, while RACP documents were retrieved for only 18 specialties. No American or Canadian specialty board developed additional documents on training, while in Europe non-UEMS boards of 11 specialties did (Table 1). With regard to Rheumatology, 2 separate documents for adult and pediatric rheumatology training were available from UEMS and ACGME while one document

Table 1. Documents retrieved and extracted for each specialty. Rheumatology national training documents are not listed.

*2 UEMS and 2 ACGME document on adult and pediatric rheumatology.
on adult rheumatology training was retrieved for CanMEDS and RACP. Upon assessment of the content of these 133 documents, we observed that their organization could be competence-based (48%), role-based (47%), or problem-based (5%). When focusing on Rheumatology, content was fairly similar across national curricula, but several differences emerged in national curricula. These were mainly related to national regulations (e.g. rheumatology training as part of internal medicine training) and a different definition of mandatory/optimal competencies. The number of listed competences in the rheumatology documents ranged from 18 to 196.

**Conclusion:** We collected and analysed documents on specialty training in Rheumatology and other related specialties from a broad set of international sources. Most documents followed a competence-based or role-based framework; similarities and differences in the content of Rheumatology documents were detected. This mapping exercise informed the EULAR Task Force on the development of standards for the training of European rheumatologists.

There were no significant differences in the RC scores among patient educational materials from the ACR or LFA.

**Conclusion:** Patient educational materials on Lupus, available at the ACR & LFA websites, are not easy to read or comprehend, using standardized RC metrics. Additionally, they are not aligned with recommended reading levels suggested by leading organizations (CDC, NIH or AMA). Patient’s understanding is critical in a complex disease like lupus to optimize health outcomes. Revision of patient lupus educational resources at these websites, to target 6-7th grade RC metrics, is recommended & could be overseen by the development of a new taskforce.

Creating a translated content very easily. A very easy to understand way in different languages, with experts being able to answer questions in their local language. Available in English, Spanish, French, Italian, Portuguese, German, and other languages. The proportion of patients with high adherence at baseline was 11%, at 6-months was 17% and at 12-month was 19%. At the end of the follow-up, 49% of the participants moved from being non-adherent to a moderate or high adherence level. When we compared the MMAS scores at baseline and follow-up, they showed a significant improvement (P<0.05) Figures 1-2. The majority of participants (65%) were in remission at baseline, according to DAS28. Therefore, we found no differences between the level of adherence and DAS28.

Conclusion: Our educational program improved medication adherence among patients with RA. Educational interventions are helpful to sustain remission in patients with RA. Further studies focused only on patients with moderate and high disease activity are necessary to assess the impact on clinical outcomes.

POS1461 GIANT CELL ARTERITIS-RELATED STROKE IN A MAN WITH ELDERLY-ONSET RHEUMATOID ARTHRITIS

M. Hmq1, 2, M. Dey3, 4, R. Moots1, 5, 6Antwerp University Hospital, Rheumatology, Liverpool, United Kingdom; 7Sultanah Fatimah Specialist Hospital, Muac, Medical, Muac, Malaysia; University of Liverpool, Institute of Life Course and Medical Sciences, Liverpool, United Kingdom; 8Countess of Chester Hospital NHS Foundation Trust, Rheumatology, Chester, United Kingdom; 9Edge Hill University, Faculty of Health & Social Care, Liverpool, United Kingdom

Background: Giant cell arteritis (GCA) is a connective tissue disease involving the large and medium-sized arteries. The most common location of inflammation is the temporal arteries, which can lead to occlusion and blindness. GCA is a rare condition, with an estimated prevalence of 3-10 cases per 100,000 population.

Objectives: The aim of this study was to describe the clinical characteristics of GCA-related stroke in a 73-year-old man with elderly-onset rheumatoid arthritis.

Methods: We performed a literature review of case reports and case series related to GCA-related stroke. We also conducted a PubMed search using the terms “giant cell arteritis” and “stroke”.

Results: A 73-year-old man with seronegative elderly-onset rheumatoid arthritis (ERA) presented to the emergency department (ED) with a one-week history of new-onset headache, vomiting, and dizziness. He had a past medical history of hypertension and hypercholesterolemia. On examination, he was noted to have left temporal artery tenderness and absent temporal artery pulse. Computed tomography angiography showed occlusion of the left internal carotid artery. The patient was started on prednisone and intravenous magnesium sulfate. Over the next few days, the patient’s symptoms improved, and he was discharged from the hospital on prednisone and aspirin.

Conclusions: GCA-related stroke is a rare complication of ERA. Early recognition and prompt treatment are crucial to prevent permanent neurologic sequelae. This case highlights the importance of considering GCA in the differential diagnosis of stroke in elderly-onset arthritis patients.
A diagnosis of GCA-related cerebellar stroke with vertebral vasculitis was made and, with glucocorticoids, the patient made a good clinical recovery. His inflammatory joint pains also improved in parallel.

Conclusion: Stroke or transient ischemic stroke are rare complications, reported in 2.8-16% of patients with active GCA. Most studies report strokes as occurring between the onset of GCA symptoms and 4 weeks after commencement of glucocorticoids. In contrast, the vertebrobasilar territory is involved in 60-88% of cases of GCA-related stroke. One study reported fatal outcomes in 11 out of 40 patients (28%) with GCA-related stroke, 7 within 2-13 days of stroke. To conclude, this case demonstrates that high-dose glucocorticoids with slower tapering were able to control GCA-related stroke due to vertebral vasculitis in patient with EORA on background methotrexate and sulfasalazine.

*Others: Primary biliary cholangitis 1 case and Pemphigus vulgaris 1 case. SLE= Systemic lupus erythematosus; RA= Rheumatoid arthritis; AH= Autoimmune Hepatitis; GA= Gouty Arthritis; SSc= Systemic sclerosis; DMPPM= Dermatopolymyositis; GS= Goodpasture Syndrome; CAP= Community-acquired Pneumonia; OI= opportunistic infections; MODS= Multiple organ dysfunction syndrome.

Figure 1. Flowchart of case selection

Results: A total of 47 cases were included, 27 (57.5%) were female and 20 (42.5%) were male. The mean age was 39 years old with a range from 13 to 68 years old. The most common disease was systemic lupus erythematosus (40.5%) and rheumatoid arthritis (23.8%), followed by autoimmune hepatitis and gouty arthritis with 3 cases (6.4%) each one. The most common cause of death determined by the autopsy findings was infections (66%) of which more than half were due to opportunistic pathogens, with tuberculosis being the predominant cause with 12 cases. The second cause was organic compromise due to disease activity (23.4%), and lastly other causes (10.6%) such as pulmonary embolism or myocardial infarction, which conditions more likely to present in patients with a rheumatic and autoimmune disease. A detailed description of the case series is displayed in Table 1. Almost all patients were receiving immunosuppressive therapy. The most used agents were prednisone (85%), methotrexate (19%), and azathioprine (15%). The other immunosuppressive medications were cyclophosphamide and tumor necrosis factor inhibitors in 2 cases each one.
TUBERCULOSIS AS A FATAL OUTCOME IN PATIENTS WITH RHEUMATIC DISEASES: AN AUTOPSY-BASED STUDY

M. J. Mantilla Ribeño1, J. C. Santacruz Deval1, J. Londono1, A. M. Santos1, S. A. Serrato2, J. C. Mantilla1on behalf of Spondyloarthopathies Research Group, Universidad de La Sabana, Chia, Colombia. 1Universidad de la Sabana, Rheumatology; Spondyloarthopathies Research Group, Chia, Colombia; 2Universidad Industrial de Santander, Hospital Universitario de Santander, Pathology, Bucaramanga, Colombia

Background: Tuberculosis (TB) is still a worldwide health problem and patients with rheumatic disease (RD) have an increased risk of this infection and fatal outcomes.

Objectives: We aim to report an autopsy case series in patients with an RD whose deaths were caused by TB in a high-level hospital of the Colombian north-east and stress the importance of autopsy as a teaching and research tool.

Methods: A retrospective, descriptive study of the database from the Pathology Department at UIS in Bucaramanga, Colombia. A total of 3390 autopsies were performed between January 2009 and December 2019 in patients whose death occurred at Hospital Universitario de Santander. A total of 1713 autopsy reports were analyzed, of which 10 corresponded to patients with RD whose deaths occurred at Hospital Universitario de Santander. A total of 1713 autopsy reports were analyzed, of which 10 corresponded to patients with RD whose deaths were caused by Mycobacterium tuberculosis.

Results: A total of 12 patients with a premortem diagnosis of RD were included who additionally had autopsy findings consistent with a mortal infection by a Mycobacterium tuberculosis. Nine cases (75%) were male and 3 were female (25%). The mean age was 49 years old with a range from 32 to 69 years old. The most common RD was rheumatoid arthritis (33.3%) followed by systemic lupus erythematosus, dermatopolymyositis and gouty arthritis with 2 cases (16.6%) each one. In 9 cases the autopsy findings were extrapulmonary TB, of which more than half were disseminated and only 3 cases were exclusively pulmonary TB. All patients were receiving immunosuppressive therapy. The most commonly used therapies were prednisone (100%), methotrexate (25%), and anti-TNF agents (16.6%). A detailed description of the reported cases is displayed in Table 1 and Figure 1.

Disclosure of Interests: None declared

Infliximab was added to the treatment at a dose of 3 mg per kg of body weight. A good clinical response was achieved (DAS28 2.67; CDAI 4.0; SDAI 9.4; prednisone canceled). After 4 months, there were complaints of acute decrease in vision in the right eye. Referred to an ophthalmologist. Visual Acuity: best corrected visual acuity (BCVA) on right eye is 0.4 (Snellen Chart). BCVA on left eye is 0.9 (Snellen Chart), intraocular pressure: right eye - 18 mmHg (non-contact), left eye - 19 mmHg (non-contact). Right eye: palpation is painful; cornea and anterior chamber humor are transparent; mild cataract in lens; inflammation cells in vitreous body (3+). Fundus (right eye): disc of optic nerve is normal; edema along upper-temporal vessels in macular region, exudates with pigmentation; periphery is normal. Left eye: findings are not clinical significant. Optical coherence tomography of retina (OCT): macular depression is normal; in paramacular region is epiretinal membrane. Laboratory: Diaskintest is negative; Toxoplasma IgG = 170 ME/ml (positive is > 800 ME/ml). Diagnosis: Toxoplasma chorioretinitis, infiltration phase of right eye. Topical therapy: dexamethasone 0.1% - 1 x 6 times / day - 20 days, nepafenac 0.1% - 1 x 3 TID - 20 days. Oral: rovamycine 3 mil. ME - 2 TID - 20 days. Infliximab and methotrexate were canceled for the entire period of therapy. OCT: decrease evidence of edema; in paramacular region is epiretinal membrane. Laboratory: Diaskintest is negative; Toxoplasma IgG = 170 ME/ml (positive is > 800 ME/ml). Diagnosis: Toxoplasma chorioretinitis, infiltration phase of right eye. Topical therapy: dexamethasone 0.1% - 1 x 6 times / day - 20 days, nepafenac 0.1% - 1 x 3 TID - 20 days. Oral: rovamycine 3 mil. ME - 2 TID - 20 days. Infliximab and methotrexate were canceled for the entire period of therapy with bDMARD infliximab. To avoid risk of activating toxoplasmosis patients with rheumatoid arthritis should be screened for this infection before start bDMARD therapy.

Background: Sialosis is a non inflammatory nor neoplastic expansion of the salivary glands. It is a common mimicker for obstructive, inflammatory and malignant salivary gland disorders. It had been described in acromegaly, vitamin A, and Thiamin deficiency and in amylophagia and bulimia. Imaging should be normal in Sialosis. Here we describe a case of Sialosis due to Vitamin deficiency who was treated for a few months with anti-tuberculoses and anti inflammatory drugs.

Objectives: To raise awareness about this cause of parotid swelling and encourage practice of exclusion prior to treatment.

Methods: A 30 year old lady with no significant past medical history presented to us with 2 years of slowly progressive, non tender bilateral facial swellings, with no excess or reduced salivation and no pain upon eating, she had negative history of preceding upper respiratory tract infection. The condition was associated with feeling a lump in her right axilla, and cervical region, there was no fever or systemic manifestations. She consulted a surgeon during that period, an excisional biopsy of the lump revealed the presence of fatty lumps, she was then prescribed antibiotics and none of the symptoms were vague and because TB is quite common in Iraq. She denied any improvement with these medications. She then was prescribed treatment with hydroxyChloroquin and prednisolone by another physician assuming she had sjogren's syndrome. When we saw the patient she was extremely distressed and depressed, had bilateral diffused parotid swellings, along with submandibular swelling, no mass could be felt during the exam, her mandibles and neck appeared large, she had normal tear film production and negative eye test, with no articular or muscular abnormalities.

Results: Her Labs were negative, and ultrasound for the parotids revealed enlarged glands with normal texture. MRI showed enlarged both parotids and submandibular glands with no other abnormality. mild salivary gland biopsy showed normal tissue with no inflammatory cell infiltrates. She had normal thyroid, parathyroid and growth hormone levels, normal metabolic panel and denied history of Alcohol consumption of Bulimia, but rarely consumed meat. A trial of Vitamin A, Thiamin and pilocarpine was started, the patient improved regression in the size of the swellings after 2 weeks of therapy but then developed mucosal dryness, afterwards, Vitamin A was stopped, she developed bone pain with normal bone markers and for that reason, pilocarpine was stopped, despite stopping these medicines, the size continued to regress on thiamin supplement alone, and she was prescribed antiulotyloty and antidepressants by a Neurologist.

Background: Sialosis is a non inflammatory nor neoplastic expansion of the salivary glands. It is a common mimicker for obstructive, inflammatory and malignant salivary gland disorders. It had been described in acromegaly, vitamin A, and Thiamin deficiency and in amylophagia and bulimia. Imaging should be normal in Sialosis. Conclusion: Sialosis can be a manifestation of variable metabolic and endocrine conditions and it should be kept in mind when facing a patient with parotid swelling being a potentially treatable cause.

Athropathy (is a rare autosomal recessive disorder caused by inactivating mutations in the matrix metalloproteinase 2 (MMP2) gene. It is manifested by osteolysis of the carpal and tarsal bones, progressive joint contractures, and radiological findings, it can be misdiagnosed as juvenile idiopathic arthritis and mucopolysaccharidoses respectively. Most affected children are apparently normal at birth with symptoms’ onset usually between six months and six years of age (5); the range is from birth to 11 years (2). To date, 51 individuals have been identified with biallelic pathogenic variants in MMP2 (3,6). Here we report a case of child MONA and galactosemia which is not known before.

Objectives: To share this interesting extremely rare presentation and new association.

Methods: An eight year old Iraqi boy with Galactosemia at the 4th month of life was referred to a rheumatological center. Genetic study revealed Homozygous MMP2 mutation. The immunological, hematological and ultrasound were normal. The disease and to determine the scope of further examination and adequate treatment.

Conclusion: Diagnosis of MONA Combined with galactosemia was made.

SEPTAL PANNICULITIS AS A MANIFESTATION OF COVID-19 INFECTION

O. Egorova1, G. Tarasova1, A. Datsina1, 1V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; 2Pirogov Russian National Research Medical University, Pirogov Russian National Research Medical University, Moscow, Russian Federation

Objectives: to study the clinical and laboratory features of septal panniculitis in the form of erythema nodosum (EN) in a cohort of patients with COVID-19 referred to a rheumatological center.

Methods: In 2020-2021 we examined 21 patients (18 women and 3 men, average age 43.2±14 years) with EN and polyarthralgia/arthritis. Depending on the time of EN and articular syndrome associated with COVID-19 development, patients were divided into three groups: 1) up to 4 weeks – acute COVID (symptoms potentially associated with infection); 2) from 4 to 12 weeks – ongoing symptomatic COVID and 3) more than 12 weeks – post-COVID syndrome (persistent symptoms not associated with an alternative diagnosis). All patients underwent a comprehensive clinical, laboratory and instrumental examination, including ultrasound of the joints and chest computed tomography (CT), as well as pathomorphological examination of skin and subcutaneous adipose tissue from the node area (in 9 cases).

Results: Based on the history data, COVID-19 in the study cohort had mild (in 3 patients), moderate (12) and severe (6) severity. Two patients (21 and 23 years old) with a mild severity of the disease on the 2nd-3rd day of the development of the respiratory symptom for the first time noted red painful (45 mm on a visual analogue scale) nodes on the legs and polyarthralgia. In 9 patients (52.3%), similar skin changes were detected 24.5 ± 7.6 days after stopping active COVID-19, i.e. during the period of ongoing symptomatic COVID. In 8 patients (38%), including 6 with moderate severity of the disease, nodules appeared after 85.6 ± 12.3 days, which corresponded to post-COVID syndrome. At the time of examination, 100 and 71.4% of patients complained of skin rashes and joint pain, respectively. Shortness of breath, weakness, cough, sweating and myalgia disturbed 67% of patients. An increase in body temperature to subfebrile was observed in 43% of cases, mainly with ongoing symptomatic COVID. In the overwhelming majority of cases (86%), UE was located on the anterior and lateral surfaces of the legs, less often on the posterior and medial surfaces. It is noteworthy that the lesion of more than 50% of the surface of the lower and upper extremities was associated with the number of nodules (p <0.02). CRP level (p <0.03) and post-COVID syndrome (p <0.02). Sixteen patients (76.1%) had signs of arthralgia, mainly ankle (81%) and knee (56%) joints. In a laboratory study, the median ESR was 39 [14; 62] mm/h, the level of CRP was 17 [2; 79] mg/l. The results of the polymerase chain reaction for SARS-CoV-2 were negative in 90.4 % of patients. In 90.4 % of cases, IgG antibodies were detected and in 52.3% - IgM to the SARS- CoV-2 virus. At CT of the chest, ≤25% of lung lesions were detected in 90.4 % of patients, in 90.4% of patients ≥25% of lesion was detected in 25% of patients, from 25 to 50% - in 33% and from 50% to 75% - in 9.5 % of cases. Pathomorphological examination of the nodes showed signs of septal panniculitis.

Conclusion: When EN associated with SARS-CoV-2 appears it is important to timely suspect a post-infectious manifestation, based on the clinical picture of the disease and to determine the scope of further examination and adequate treatment.

Disclosure of Interests: None declared

Background: Progressive multifocal leukoencephalopathy (PML) is a potentially fatal degenerative condition caused by reactivation of the human polyomavirus 2 (JC virus) in immunodeficient individuals. It is well recognised in individuals who have received Rituximab, but patients treated with other immunosuppressants are at risk also (1). Moreover, patients with SLE may be at increased risk, even when they are not taking immunosuppressants (1, 2).

Objectives: Describe the case of a patient with a history of lupus nephritis and cerebral lupus, on long-term Mycophenolate mofetil (MMF) and Prednisolone, diagnosed with PML complicated by immune reconstitution inflammatory syndrome (IRIS).

Methods: Case report.

Results: This patient first presented in 2010 at the age of 18 with ankle swelling and proteinuria. She had high ANA and anti-dsDNA titres, and treatment biopsy showed class IV lupus nephritis. She went on to remission on high dose Prednisolone and MMF and elected to stop her MMF. Four months later, she developed behaviour changes and worsening proteinuria. MRI showed a mild high signal lesion in the right cerebral hemisphere, and she was diagnosed with cerebral lupus. She recovered after treatment with IV methylprednisolone and MMF. Over the subsequent eight years, she had recurrent seizures which responded well to anticonvulsant therapy. Her dexterity in her left hand. MRI showed evidence of IRIS in the right hemisphere with cerebral oedema causing midline shift. She was treated with IV Dexamethasone then Prednisolone 30 mg daily, with a gradual taper over a year. She has made a good recovery with minimal neurological deficit; she was stopped but she continued a low dose Prednisolone with the addition of Hydroxychloroquine. She was re-admitted two weeks after discharge in December 2020 with a right-sided headache, left facial weakness and loss of dexterity in her left hand. MRI revealed pathogenic homozygous splice site mutation in intron 11 of LRBA gene. Both the parents are heterozygous carriers. A largest systematic review 3 of 212 cases of LRBA deficiency showed autoimmunity(70%), hypoparathyroidism(19%), and protein deficiency(18%).

Conclusion: This describes a case of PML in the context of longstanding lupus nephritis, treated with prednisolone and MMF. Her longstanding lymphopenia with low CD4 counts were attributed to the combined consequences of active lupus and her cumulative immunosuppressive burden. CD4 lymphopenia is associated with PML in the HIV population, and may provide information about which patients on immunosuppressive treatments are at risk of developing PML (3). However, not enough is known to routinely screen patients and the counts of other lymphocyte subsets are likely to be important too. The case highlights that PML can be associated with different immunosuppressants, other than B-cell depletion. The prompt diagnosis, facilitated by brain biopsy, and appropriate management led to a good medium-term outcome for this patient, showing that PML is eminently survivable.

**POS1470-HPR**  KNOWING WHAT TO DO WITH THE DATA – A QUALITATIVE STUDY ON CHALLENGES OF USING SMARTPHONE-BASED EPROS IN RHEUMATOID ARTHRITIS

Y. Seidler1, T. S. Jergensen2, P. Studenic3, H. Radner4, T. Nygaard5, N. Welbrecht6, N. Popper7, E. L. Kristensen8, T. C. Wilhelm9,10, J. Rickmann11, E. Moso12, V. Ritsch1, T. Stam1. 1Medical University of Vienna, Section for Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Vienna, Austria; 2Copenhagen University Hospital, Frederiksberg and Bispebjerg, Parker Institute, Department of Rheumatology, Copenhagen, Denmark; 3Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria; 4Karolinska Institutet, Division of Rheumatology, Department of Medicine (Solna), Stockholm, Sweden; 5Daman, P/S, Copenhagen, Denmark; 6dwh, GmbH, Vienna, Austria; 7Vienna University of Technology, Institute for Information Systems Engineering, Vienna, Austria; 8Copenhagen University Hospital, Frederiksberg and Bispebjerg, Parker Institute, Department of Rheumatology, Copenhagen, Denmark; 9EULAR Young PARE, Zurich, Switzerland; 10Austrian Rheumatism League, None, Maria Alm, Austria; 11The Parker Institute’s Patient Association, Department of Rheumatology, Copenhagen, Denmark; 12Medical University of Vienna, Section for Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Wien, Austria

**Background:** Using patient-reported outcomes (PROs) has a long tradition in rheumatology, and PRO measurement is included in many composite indices evaluating disease progression and treatment response [1]. However, little is known about patients’ and health professionals’ (HPs) perceptions of using digitally collected PROs, the so-called ePROs, with a personal smartphone application.

**Objectives:** To identify main challenges in utilising ePROs for management and treatment of rheumatoid arthritis from patients’ and HPs’ perspectives.

**Methods:** We interviewed 25 people with rheumatoid arthritis (RA) and 17 HPs (nurses, rheumatologists, and physiotherapists) from Austria and Denmark. We used the RheumaBuddy app as a practical example to illustrate the digital data collection and the feedback that patients would get from entering their self-reported outcomes. Interviews were recorded and transcribed. We applied a qualitative thematic analysis to identify major themes using a procedure of rigorous coding. Analysis was done by two researchers, and conflicts were solved by consensus. Ethical approval was obtained in both countries.

**Results:** Three main themes emerged: 1) Being simple yet comprehensive; 2) Resources to interpret, use, and act upon the collected data; and 3) Being reminded of the disease. Within the first theme, many valued the intuitiveness and simplicity of ePROs, especially when used as a monitoring tool in between clinical visits. HPs were concerned about not to overwhelm the patients with too many questions. On the other hand, the short ePROs asked in the app were not comprehensive enough to capture psychosocial and lifestyle aspects of the disease which were considered important both by patients and HPs. Within the second theme, patients and HPs expressed that ePROs could be the basis for shared decision making. Nevertheless, some patients had clearer ideas on making use of the feedback they could get from their self-reported data than the others. Participants from Denmark focused on official guidelines, whereas those from Austria were more concerned that the “doctor will make good use of it.” HPs in both countries believed that the “doctor will make good use of it.” HPs in both countries.

**Conclusion:** The potential adoption of ePROs in practice depends on both patients and HPs’ motivations and ideas to use the feedback they would get from the collected data. This might be influenced by the level of digital health maturity of a country, as well as available resources. In addition, ePROs need to be intuitive and simple, but at the same time comprehensive and reliable enough so that they can be used for shared decision making. Challenges remain for the ePROs to be used as supporting and empowering tools, and not as reminders of the disease and pain.

**POS1471-HPR** PAIN CATASTROPHIZING AND ITS ASSOCIATION WITH PATIENTS WITH RHEUMATOID ARTHRITIS IN A NON-INFLAMMATORY CONDITION.

T. Abe1. 1Hyogo College of Medicine, Division of Diabetes, Endocrinology and Clinical Immunology, Nishinomiya, Japan

**Background:** Pain in rheumatoid arthritis (RA) is considered to be linked with non-inflammatory factors, including physical disabilities, psychiatric disorders, and pain catastrophizing (PC).

**Objectives:** We investigated the role of PC in the possible link between physical disabilities and psychiatric disorders in RA patients in a non-inflammatory condition.

**Methods:** In this cross-sectional study, a total of 81 RA patients in a non-inflammatory condition were included; all patients had serum C-reactive protein levels <0.5 mg/dL, without any inflammatory joints. We examined the demographic and clinical data and administered the pain visual analog scale (VAS), the pain catastrophizing scale (PCS), the Health Assessment Questionnaire Disability Index (HAQ-DI), and the patient version of the Brief Scale for Psychiatric Problems in Orthopedic Patients (pBPS-POP). A series of multivariate-adjusted multiple regression analyses were performed to examine the associations between PC and pain intensity, physical disabilities, and psychiatric disorders.

**Results:** We found associations between all the above-mentioned variables in separate models associated with HAQ-DI, pBPS-POP, and PCS scores. However, in the model associated with pain VAS, the PCS score (β=-0.34, p=0.0073) emerged as the only variable showing statistically significant association.

**Conclusion:** PC is associated with pain in RA patients in a non-inflammatory condition, and this association may be mediated through pathways involving physical disabilities and psychiatric disorders.

**CONSTRUCT VALIDITY OF THE PROMIS PHYSICAL FUNCTION 10-ITEM SHORT FORM IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES AND SEVERE LIMITATIONS IN PHYSICAL FUNCTIONING**

**B. Straathof,** M. Van Wissen, T. P. M. Vliet Vlieland, C. Van den Ende, M. Teuwen, A. Van den Broeder, W. Van den Hout, M. Van Schaardenburg, A. Van Tubergen, M. J. G. Gademan, S. Van Weely, Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; Sint Maartenskliniek, Research, Nijmegen, Netherlands; Radboud University Medical Center, Rheumatic Diseases, Nijmegen, Netherlands; Leiden University Medical Center (LUMC), Biomedical Data Sciences, Leiden, Netherlands; Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands; Maastricht University Medical Center, Maastricht, Netherlands; Maastricht University, Care and Public Health Research Institute (CAPHRi), Maastricht, Netherlands; Leiden University Medical Center (LUMC), Clinical epidemiology, Leiden, Netherlands.

**Background:** Physical functioning in patients with inflammatory arthritis (IA) can be severely affected and is often measured using the disease-specific questionnaires Health Assessment Questionnaire Disability Index (HAQ-DI) or Bath Ankylosing Spondylitis Functional Index (BASI). The PROMIS PF-10, an instrument that can assess physical functioning and is standardized, has been increasingly used. This is a generic instrument to assess physical functioning and compare health status across conditions. Several short forms of the PROMIS PF-10 have been developed.

**Objectives:** To investigate the relationship between PA level and exercise self-efficacy, body awareness, and fatigue severity in rheumatoid arthritis: A cross-sectional and pilot study.

**Methods:** A total of 80 RA patients (women/men=61/19, age=56.83±11.56 years) who were diagnosed according to the ACR 2010 criteria were included in this study. All patients were assessed regarding physical characteristics (age, body-mass index), exercise status (yes/no), and occupational status (working/not working/retired). Physical activity level was assessed using the Physical Activity Questionnaire, exercise self-efficacy using the Exercise Self-Efficacy Scale, body awareness by Body Awareness Questionnaire, and fatigue using the Fatigue Severity Scale.

**Results:** Patients' characteristics are presented in Table 1. It was observed that patients with low PA levels. Significant correlation was found between PA and exercise self-efficacy (r=0.410, p<0.001), body awareness (r=0.374, p=0.001), and fatigue (r=-0.482, p<0.001).

**Conclusion:** The relationship between PA level and exercise self-efficacy, body awareness, and fatigue severity in RA patients is significant. Future research is needed to further understand this relationship.

FATIGUE IS AN IMPORTANT COMORBIDITY FOR RA PATIENTS. HOW CAN WE MEASURE IT EASILY IN CLINICAL PRACTICE?

B. Frade-Sosa1, R. Morlà1, N. Sapena1, R. Sanmartí1, J. A. Gómez-Puerta1.
1Hospital Clinic de Barcelona, Rheumatology, Barcelona, Spain

Background: Fatigue is highly prevalent (40-70%) in Rheumatoid Arthritis (RA). Patients describe fatigue as an important symptom, in discrepancy with rheumatologist’s perception. Different validated questionnaires are available to measure fatigue, without any standardised preference in their use. In randomized controlled trials, FACIT-F is a unidimensional tool for fatigue widely used. MDHAQ is a multidimensional tool exploring different dimensions of RA, providing a VAS 0-10 for fatigue. The use of this simple scale to measure fatigue in daily routine for RA patients. The use of this simple scale integrated in the MDHAQ allows capturing important clinical information for the disease.

Background: The minimally important difference (MID) required to interpret the magnitude of changes in lupus patient-reported outcome (LupusPRO), which is a widely used outcome measure to assess quality of life in SLE patients, remains unclear.

Objectives: We report preliminary results of an ongoing prospective observational study that assesses the MID as the interpretability of emotional health (EH) domain in Japanese version of LupusPRO.

Methods: We recruited subjects at three university hospitals in Japan participating in an ongoing multidisciplinary cohort study (the Lupus registry of Nationwide institutions (LUNA)). Of a total of 210 SLE patients enrolled during the 1-month recruitment period, patients with low disease activity, defined as SLE Disease Activity Index 2000 (SLEDAI-2K) ≤ 4, and who were seen at least twice of three months'...

Results: The mean age of the 24 eligible patients was 48 (SD 14.6), and 88% were male. The glucocorticoid dose, SLEDIA-2K, and Systemic Lupus International Collaborating Clinics (American College of Rheumatology Damage Index were 3.4 (2.1) mg, 1.0 (1.1) and 1.1 (1.9), respectively. The mean EH score was 67.5 (30.3). Five patients (21%) had the maximum EH score at baseline, 73.4 (25.0) after three months, 72 (18.0) for the change in EH. The correlation coefficient and the AUC for the change in hand status and the EH were 0.23 and 0.60. The mean changes were 4.1 (18.4) of the groups with ‘unchanged’ health status and 12.3 (17.1) of the groups with ‘improved’ health status. The MID for improvement was estimated at 12.3 using the anchor-based method, and the cutoff point corresponded to 9.3 (95% CI 6.7 to 25.3) of the EH change score by the receiver operating curve method.

Conclusion: In this study, the MID (3 months) for the EH domain in the Japanese version of LupusPRO was estimated to be between 9 and 12, which was similar to the results of the previous cross-sectional study [2]. The challenge in estimating the MID in our setting was the low correlation with external anchors, even though the study population was limited to patients with low disease activity, because disease activity at baseline can generally influence ‘improved’ health status.

IS ECO-INTENSITY A PREDICTIVE FACTOR IN DETERMINING THE PHYSICAL PERFORMANCE OF WOMEN WITH KNEE OSTEOARTHRITIS?

M. Karapanay,* V. A. Ayyildiz1, A. M. Unal1, T. Firat1, 2Suleyman Demirel University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Isparta, Turkey; 3Suleyman Demirel University, Department of Radiology, Faculty of Medicine, ISPARTA, Turkey; 4Private Medem Hospital, Orthopedics and Traumatology Department, Isparta, Turkey; 5Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey

Background: Researchers are increasingly using echo-intensity (EI) as an index of muscle quality or fatty and fibrous tissue infiltration. EI is moderately associated with muscle strength and/or power and a better predictor of muscle performance than measures of muscle mass. In this regard, ultrasound-derived EI may be a promising skeletal muscle assessment tool for monitoring the progression of physical performance. However, there has been no study that investigated the relationship between muscle EI and physical performance in women with knee osteoarthritis (OA).

Objectives: The aim of our study is to investigate the relationship between the physical performance and muscle echo-intensity in women with knee OA.

Methods: Ninety-six women with radiological and clinical knee OA participated in this cross-sectional observational study. Quadriceps femoris (Rectus Femoris-RF, Vastus Intermedius-VIM, Vastus Medialis-VM, Vastus Lateralis-VL) and hamstring (Biceps Femoris-BF, semitendinosus-STT and semimembranosus-SMM) muscles were evaluated using B-Mode ultrasonography. Ultrasound images were analysed offline using an image analysis software (Image J) program and EI of muscles was determined for each subject.

Results: The mean age of participants in the study was 57.3±9.42 years. A positive correlation was found between EI of quadriceps femoris and hamstring muscles and the total KOOS scores. EI of RF, VIM, VL and BF presented a significant negative correlation with FTSS, 20WT and SCT (Table 1).

Therapy and Rehabilitation, Izmir, Turkey; Dokuz Eylül Üniversitesi Hastanesi, Rheumatology and Immunology, Izmir, Turkey

Background: Functional exercise capacity might be affected in ankylosing spondylitis (AS) patients due to factors such as pulmonary function impairment, reduced physical activity, peripheral arthritis, fatigue, muscle weakness and systemic inflammation. In addition to laboratory-based exercise tests, field tests are also used to measure functional exercise capacity. The six-minute walk test (6MWT) which is the most frequently used field test, is valid, reliable, and cost-effective. However, the main disadvantage of the 6MWT is that it allows the patient to set the walking speed. The incremental shuttle walk test (ISWT) is a valid field exercise test of functional capacity. The test requires patients to walk at increasing speeds up and down a 10 m course. The walking speed, which increases every minute, is controlled by audio signals. Performance on the test relates strongly to VO2max, the traditional indicator of cardiorespiratory capacity [1]. Although there are studies evaluating functional exercise capacity in AS patients, no study using ISWT has been found.

Objectives: The aim of this study was to investigate the ISWT results and factors associated with this test in patients with AS.

Methods: Fifty AS patients aged between 25-58 years (27 males,23 females) participated in the study. Age, height, weight, body mass index (BMI) were recorded. Disease-specific indices such as Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI), Bath AS Metrology Index (BASM1) were used. Sit-up test and push-up test were used to measure muscular endurance. Incremental Shuttle Walk Test (ISWT) was used to assess functional exercise capacity. The test was performed in a 10 m course defined by two cones placed 0.5 m from each endpoint. The test was terminated if the patient was unable to maintain the required speed and failed to complete a shuttle in the time allowed for the second time. The total number of shuttles was recorded and distance calculated. Heart rate (HR), blood pressure, perceived dyspnea and leg fatigue (modified Borg Scale) were assessed before and after the test. Age-predicted maximal heart rate (HRmax) was calculated as 220 minus age. Spearman’s correlation coefficients were used to examine the relationship between the ISWT distance and the variables.

Results: The mean incremental shuttle walk distance (ISWD) of the patients was 485.40±198.63 cm (men 290±170 cm). Subjects reached 50% of the predicted ISWD according to the reference equation for healthy people [2]. The mean maximal heart rate rates were lower than predicted value anticipated for the patient’s age. At the end of the test, subjects reached 73.7±18.62 % of HRmax. ISWD showed significant correlations (p<0.05) with gender (r = 0.488, height (r = 0.474), BASFI (r = -0.313), BASMI (r = -0.397), sit-up test (r = 0.620), push-up test (r = 0.476). However, no relationship was found between ISWD and age, weight, BMI, BASDAl, dyspnea, fatigue. Dyspnea and fatigue were not limiting factors for the test. The most common reason for stopping the test was the inability of the patients to maintain the set pace. ISWD has been reported to be associated with age [2], but in our study, unlike the literature, no relationship was found between ISWD and age in AS patients.

Conclusion: According to the results of our study, we found that the incremental shuttle walk test distance in AS patients decreased compared to the reference values reported for healthy individuals. ISWT is associated with factors such as gender, height, mobility, spinal mobility and muscular endurance. ISWT may be appropriate for measuring exercise capacity of AS patients, however, more research is needed.

Disclosure of Interests: None declared.

Background: Although the hand involvement is one of the first manifestations in the disease course of Systemic Sclerosis (SSc), hand functions are generally inquired by using patient-reported tools. Sollerman Hand Function Test (SHFT) is developed to evaluate performance-based hand functions.

Objectives: The aim of this study was to investigate the reliability of the SHFT and the associations with disease- and hand-related parameters in patients with SSc.

Methods: Thirty-six patients (30 females) were included in the study. SHFT includes 20 different hand functions which are scored between 0 (unable to perform) and 4 (performed within 20 seconds with normal quality) (1). In the present study, item 12 ‘put on Tubigrip stocking on the other hand’ was not evaluated, thus, the SHFT was scored over a total score of 76. Inter-rater reliability was investigated by comparing the scores of two different investigators, and test-retest reliability was investigated by assessing the scores obtained at 2-hour intervals. Modified Hand Mobility in Scleroderma Test (mHAMIS), modified Rodnan Skin Score (mRSS), grip and pinch measures were evaluated as hand-related physical characteristics. Duruoz Hand Index, Disability of Arm, Shoulder and Hand Questionnaire (DASH), Health Assessment Questionnaire (HAQ), and Sclerodermatosis Health Assessment Questionnaire (SHAQ) were used as patient-reported outcomes.

Results: SHFT demonstrated excellent inter-rater reliability (75 (72/76) vs. 75 (72/76), ICC: 0.987) and moderate test-retest reliability (75 (72/76) vs. 75 (72/76), ICC: 0.645). SHFT scores correlated significantly with grip and pinch strengths. Duruoz Hand Index scores, HAQ scores, SHAQ-Patient Global Assessment scores, and SHAQ-Digital Ulcer scores (<0.05). No significant correlations were observed between other parameters and SHFT (p>0.05). The hardest task was determined as ‘do up buttons’ which cannot be completed within 20 seconds by the half of the patients. All the patients completed ‘put key into Yale lock, turn 90°,’ ‘lift iron over edge 5 cm in height,’ and ‘lift telephone receiver, put to ear’ tasks within 20 seconds with normal quality.

Conclusion: The results of the present study suggest that SHFT is a reliable tool to evaluate hand functions in patients with SSc.

*p-value for disease activity score 28 (DAS28), Routine Assessment of Patient Index Data 3 (RAPID3).

Conclusion: With a positive predictive value of 0.92 for low disease activity, a RAPID3 score of 2.0 or lower is a good threshold to propose a postponement of the consultation and substantially reduce the clinic burden. Such a proposal is safe if the patient can overrule it.

1. N. G. Tore, D. Oskay, H. Satz, S. Hazinekari, Gazi University, Physiotherapy and Rehabilitation, Ankara, Turkey; A. Abbasrahman Yurtaslan, Training and Research Hospital, Rheumatology, Ankara, Turkey; Gazi University, Rheumatology, Ankara, Turkey.

Background: The Quality Indicators for Physiotherapy Management of Hip and Knee Osteoarthritis (QUIPA) is the only patient-reported outcome measure to assess the quality indicators of physiotherapy management of hip/knee osteoarthritis (OA). It consists of 3 subscales and a total of 18 questions.

Objectives: The purpose of this research was to translate and cross-culturally adapt the QUIPA into the Turkish language and test its validity and reliability in Turkish-speaking patients with hip/knee OA.

Methods: Ninety-two patients with hip/knee OA were enrolled in the research. The QUIPA was cross-culturally adapted according to guidelines defined by Bea-ton et al. Participants completed QUIPA tool twice, with an interval of 7 days. Construct validity was tested via Exploratory Factor Analysis. Test-retest reliability and internal consistency were determined interpreting Intraclass Correlation Coefficient (ICC) and Cronbach’s alpha coefficient, respectively.

Results: The Exploratory Factor Analysis demonstrated that QUIPA has 3 factors. For the first, second and third subscales and total score of QUIPA, ICC was found to be 0.895, 0.947, 0.665, and 0.925, respectively. Cronbach’s alpha coefficient was determined to be 0.682, 0.797, 0.593, and 0.812, respectively, for the first, second and third subscales and total score of QUIPA. These results indicate that Turkish version of QUIPA has excellent test-retest reliability and good internal consistency.

Conclusion: Turkish version of the QUIPA determined to be a valid and reliable tool to assess the quality indicators of physiotherapy management of hip/knee OA in Turkish-speaking patients. It is suggested to be used in clinical settings in Turkey.

POS1482-HPR ASYNCHRONOUS TELECONSULTATION BY WHATSAPP CHATBOT IN CONTROLLED AXIAL SPONDYLOARTHRITIS (SPA) PATIENTS UNDER BIOLOGICAL THERAPY: 10 MONTHS EXPERIENCE AT A SINGLE CENTRE

M. L. García-Vivar1, N. Riveras, E. Galíndez-Agirregoi3a, E. Cuenda1, A. R. Inbarthe Pellejero3a, J. M. Blanco Madrigal1, L. Vega1, C. García1, M. Enjuanes1, M. J. Allande4, O. B. Fernandez Berrizbeitia5, E. Exposito1, M. E. Ruiz Luca5, A. Torre-Salabern1

Background: The use of telehealth in the control of rheumatic diseases had been scarce, but COVID pandemic forced rheumatologists to try alternatives to classic face-to-face consultation. In times of lockdown phone calls and video calls were easy to perform, but later on an asynchronous model of teleconsultation would probably fit better.

The purpose of this study is to prove that asynchronous whatsapp teleconsultation is an effective alternative to classic healthcare consultation models out of pandemic. So, we selected axial spondyloarthritis (SPA) patients with stable controlled disease under biological therapy and we offered teleconsultation with a whatsapp platform chatbot, that’s been created for this purpose as a way to send PROMS to perform, but later on an asynchronous model of teleconsultation would probably fit better. The purpose of this study is to prove that asynchronous whatsapp teleconsultation is an effective alternative to classic healthcare consultation models out of pandemic. So, we selected axial spondyloarthritis (SPA) patients with stable controlled disease under biological therapy and we offered teleconsultation with a whatsapp platform chatbot, that’s been created for this purpose as a way to send PROMS.

Objectives: To prove that teleconsultation through whatsapp platform was not inferior to face-to-face consultation in terms of maintaining axial SPA patients disease under control.

Methods: Prospective study with retrospective control of patients diagnosed of Axial SPA, fulfilling ASAS criteria and with stable disease under biological therapy for the previous year, recruited from 01 Jan to 30 Nov 2021. We offered them two teleconsultation visits using their personal mobile device, once every four months and a face-to-face visit at the end of the study (one year since inclusion). If there is a deviation in the lab test or PROMs or if the patient asks for contact (via whatsapp) he is called up by the person in charge (nurse/docter) that solves the question and arranges an additional presential visit when needed. We consider disease controlled if BASDAI<4, ASDAS<2.1 or if in rheumatologist’s opinion there is no need to change treatment. We collect patient and disease information (age, gender, employment, use of mobile devices, duration and characteristics of the disease, previous and actual treatment), activity (BASDAI, PCR, ASDAS), physical function (BASFI), Quality of life (AsCol) and productivity (WAPA), and we also check number of face-to-face and phone consultations and patients’ preferences.

Results: 62 patients (52 men and 10 women) were recruited, mean aged 47.7 years (range 26-72), 36% were under 45 years at the time of inclusion. They were mostly Ankylosing Spondylitis (AS) (90%; only 6 non radiographic SPA), positive HLA B27 (90%) and with longstanding disease (mean 24 years), and only 6 patients less than five years. 16% had peripheral involvement (arthritis/tenitis/dactylitis), and 40% presented extraarticular manifestations, mainly uveitis (20%). 70% were under their first biological (TNF inhibitor, mostly adalimumab), 24% were refractory to the first, 3 patients to 2 previous biologicals and just 1 patient was refractoy to 5. 50% of patients were treated with tapered dose of TNF inhibitors. We have now a mean followup of 10 months, in which we have had 109 scheduled teleconsultations with aditional need of 36 phone calls and 10 aditional presential visits for the whole group. To date, 3 patients with reduced dose increased to standard dose of biological drug and none change of biological was required.

Conclusion: Asynchronous teleconsultation seems promising, specially for followup in patients with stable rheumatic disease, less interfering with daily activities, less time consuming for the patient and less resource consuming for healthcare systems, with no impairment of disease control and quality of healthcare. This study will also show patient’s preference, and we’ll try to describe a profile of patient more prone to teleconsultation.

POS1483-HPR DYSFUNCTIONAL COPING CORRELATES WITH DEPRESSION AND ANXIETY AND PREDICTS WORSE OUTCOME IN PATIENTS WITH A HIGH DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

J. R. Hoepere, I. IIlassidii, M. Richtere, S. E. Meyere, K. Kahi, T. Witte1, K. Hoepere1, D. Meyer-Olson1,2.

1Medizinische Hochschule Hannover, Klinik für Rheumatologie und Immunologie, Hannover, Germany; 2mdt Fachklinik Bad Pyrmont, Rheumatologie/Innere Medizin, Bad Pyrmont, Germany; 3University Medicine Göttingen, Institut für medizinische Statistik, Göttingen, Germany

Background: Disease flares of rheumatoid arthritis (RA) are important stressors for patients (pts) who may use coping for disease management. Some coping styles are thought to be beneficial and may help to improve disease outcome whereas others are thought to be harmful.

Objectives: We investigate the frequency and intensity of different coping styles in pts with an acute flare of seropositive RA and its impact on disease outcomes and quality of life.

Methods: Coping was analysed with the Brief-COPE (1) using a 4 point Likert scale in 222 pts participating in the ERFASS study (2). Coping styles were analysed by confirmatory and exploratory factor analysis (CFA, EFA). Disease activity was measured via DAS28 (CRP), depression and/or anxiety using Hospital Anxiety and Depression Scale (HADS) and Patient Health Questionnaire 9 (PHQ-9). Repeated measures ANOVA was used to identify the effect of different coping strategies on disease activity and Spearman-Rho to identify correlations.

Results: Factor analysis revealed five dominant coping styles (problem oriented, emotion oriented, dysfunctional, religion, alcohol/drugs) which were consistent during 6 and 12 months follow up. When analysing the relative intensity of each coping strategy over time there was no significant change during the course of disease (Table 1). The other coping styles did not significantly predict the outcome of disease activity and Spearman-Rho to identify correlations.

Results: Factor analysis revealed five dominant coping styles (problem oriented, emotion oriented, dysfunctional, religion, alcohol/drugs) which were consistent during 6 and 12 months follow up. When analysing the relative intensity of each coping strategy over time there was no significant change during the course of disease (Table 1). The other coping styles did not significantly predict the outcome of disease activity and Spearman-Rho to identify correlations.

Disclosure of Interests: None declared
Conclusion: Different ways of coping may be used simultaneously during an acute flare of seropositive RA. In pts with high disease activity dysfunctional coping is the only coping strategy predicting a worse disease outcome after 12 months and dysfunctional coping correlates with depression and anxiety.

LUMBOPELVIC STABILITY, TRUNK POSITION SENSE, AND SPINE POSTURE IN PATIENTS WITH AXIAL SPONDYLOARTHITIS

Y. Akbulut1, T. Duger2, A. Kucuk2, 1Necmettin Erbakan University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, KONYA, Turkey; 2Hacettepe University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 3Necmettin Erbakan University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Konya, Turkey

Background: Axial Spondyloarthritis (axSpA) are chronic systemic inflammatory rheumatological diseases characterized by axial skeletal involvement and enthesis. The trunk is the central key point of the body, playing an essential role for postural control, the coordination of the extremities, and functional activities. The systemic, inflammatory nature of axSpA, chronic pain, inflammatory cytokines, changes in the bone and ligaments of the spine may affect lumbopelvic stability, trunk position sense, and spine posture.

Objectives: We aimed to investigate lumbopelvic stability, trunk position sense, and spine posture in patients with axSpA.

Methods: Twenty axSpA patients (mean age: 33.65± 5.72; 75% female) and 20 age- and gender-matched healthy controls were included in the study. In axSpA patients, mean time since symptom onset was 9.75±4.82 years and mean time since diagnosis was 6±3.97 years. Lumbopelvic stabilization was evaluated by a pressure biofeedback unit (Stabilizer Pressure Biofeedback Unit, Chattanooga Group Inc., Hixson, TN, USA). Trunk position sense, as indicated by trunk reposi- tion errors (TRE), was assessed with a digital inclinometer. Thoracic and lumbar curvature tests were performed with a digital inclinometer.

Results: Comparisons of lumbar pelvic stability, trunk position sense and posture were shown in Table 1. Lumbopelvic stabilization values were significantly lower in the axSpA group when compared to the control group (p<0.001). TRE, in which higher scores indicate poorer trunk position sense, was higher in the axSpA group compared to the control group (p<0.001). The degree of thoracic curvature was higher (p = 0.001) in the axSpA group compared to controls whereas the degree of lumbar lordosis was not significantly different between the groups (p = 0.444).

TRE trunk reposition error, AxSpA Axial Spondyloarthritides, SD standard deviation.

Conclusion: According to our results, patients with axSpA had poor lumbopelvic stability, trunk position sense, and spine posture. The multiplicity and complexity of the symptoms of patients with axSpA require multifaceted symptom management interventions for this purpose, consideration of the training of lumbopelvic stability, trunk position sense, and spine posture might be beneficial in optimal treatment planning.

DIGITALLY ENHANCED TREAT-TO-TARGET AND SHARED DECISION-MAKING APPROACH WITH A DIGITAL HEALTH APPLICATION: INTERIM RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

J. Knittlz1,2, M. Grahame3, S. Boett3,4,5, J. Lang1,2,4,5, M. Detert4,1, M. Bader3,4, J. Knittlz1,2,4, D. Simon1,2, G. Kröckel1,2, G. Schett1,2, J. Detert,3 Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Universitätssklinikum Erlangen, Department of Internal Medicine Rheumatology and Immunology, Erlangen, Germany; FAU Erlangen-Nuremberg and Universitätssklinikum, Deutsches Zentrum fuer Immuntherapie (DZI), Erlangen, Germany; ABATON GmbH, ABATON, Berlin, Germany; Rheumatologisch-Immunologische Arztpraxis Templin, Rheuma - Templin, Templin, Germany

Background: Digital health applications (DHA) became indispensable patient companions accelerated by the current COVID pandemic [1]. In 2020, for the first time worldwide, a regulatory framework to reimburse DHA was established in Germany. To get listed as a DHA, preliminary evidence needs to be generated – next to fulfilling highest standards in quality and safety. The DHA ABATON RA consists of two parts; 1) digital shared-decision-making (SDM) including choosing an appropriate electronic patient reported outcome (ePRO) instrument and the respective ePRO target for the next visit, 2) remote patient monitoring and ePRO tracking by the patient. Hereby, ABATON RA supports a digitally guided Treat-To-Target (T2T) approach.

Objectives: The objective of this study is to evaluate a potentially beneficial effect for the patient by using ABATON RA.

Methods: Three-armed, partially blinded multicenter trial (RCT) including RA patients who regularly use a smartphone. Patients attend 3 visits, 3 months apart (T0, T3, T6), with one follow-up visit (T9). Intervention group (IG): Patients use ABATON RA. Via SDM patients and rheumatologists choose a specific ePRO and respective treatment target for the next visit in three months, e.g. RAID ≤4. Control group (CG): Standard of care treatment (no DHA). Placebo group (PG): Usage of a placebo version of ABATON RA providing only Regensburger Insomnie Skala (RIS) and Epworth Sleepiness Scale (ESS) as ePROs. No SDM is conducted and ePRO results are not presented to MCP.

Results: This interim analysis evaluated the first 38 patients that completed T3. IG: 13 patients (Av. age 55.9, 61.5% females); PG: 12 (Av. age 50.7, 66.7% females); CG: 13 (Av. age 56.1, 76.9% females). We observe a significant improvement in the mean over time in a pairwise comparison within the intervention group for the following: Pt-GA mean difference of 2.98 (p = 0.025, partial η² = 0.12)
Background: Osteoarthritis is the most prevalent joint pathology, knee Osteoarthritis is one of the most frequent locations and has the greatest impact on the health of patients. It can be associated up to 11% with depression and 23% with neuropathic pain. It has also been reported that it can coincide with fibromyalgia (FM) between 6% and 22.83%. This difference may be attributed to some factors, e.g., sample size and/or socioeconomic status. Therefore, the clinical interpretation of symptoms in knee osteoarthritis may be underestimated by the presence of FM. Pincus T. et al. used the FAST4 to identify the coexistence of FM in patients with various rheumatic pathologies. The FAST4 consists of using the MDHAQ (symptom checklist, painful joint count, fatigue and pain). A FAST4 score ≥ 3 allows the association of FM to be considered. The authors demonstrated good concordance with the 2011 FM criteria according to the ACR (with a sensitivity of 70.4% and a specificity of 97.1%).

Objectives: To detect the presence of associated FM in patients with early and established knee osteoarthritis employing the MDHAQ/FAST4.

Methods: Patients >18 years, of both sexes, from our community with early and established knee osteoarthritis (Luyten, FP 2018 and Altman, R 1986 Classification Criteria respectively). All answered the MDHAQ/FAST3-F questionnaire, in addition to the Patient Health Questionnaire (PHQ9) and the Neuropathic Pain 4 Questions (DN4). Depression was considered respectively with a score ≥3 of the PHQ9 and neuropathic pain with 4 points of the DN4.

Results: 100 patients (96 with a diagnosis of early knee osteoarthritis and 4 with established knee osteoarthritis [Luyten - ACR]) with a median age of 58 (RIC 16) and female sex were included 72%. We observed associated FM (FAST4-F) in 31% of patients (27 with early knee osteoarthritis and 4 with established knee osteoarthritis). Median VAS pain, patient and physician global assessment of the disease was higher in patients with associated FM (p<0.001). Disease activity by RAPID 3 was low 4%, moderate in 38% and high in 58% of patients. The cohort had a median pain score of 60 (RIC 60) with absence of neuropathic pain (DN4) in 90% of patients. Depression (PHQ9) was observed in 29% of cases.OA evolution time in months in patients with FM 48 (RIC 12) vs. 36 (RIC 24) without FM (p<0.0001). Binary logistic regression was performed. In the bivariate analysis, it was observed that the presence of early OA by Luyten's criteria (p<0.002), the presence of depression by PHQ9 (p<0.001), patients of white ethnicity (p=0.03), sobrepeso (p=0.002), low RAPID 3 disease activity (p=0.001), kigelrun and lawrence grades II and III (p=0.001), were significant in the bivariate model, although none were statistically significant in the multivariate model.

Conclusion: The evaluation of knee osteoarthritis can be complicated in those patients who coexist with FM. In our study 31% met criteria for this entity according to MDHAQ/FAST4. We consider this questionnaire to be single and practical for detecting associated FM. The results obtained gave clues to the use of PROMs (Patient Reported Outcomes Measures) that can recognize clues of associated diseases such as FM and/or depression. And thus be able to establish a timely and appropriate treatment when these pathologies are overlapping, in order to change the patient’s prognosis and improve their quality of life.

POS1485-HPR | DETERMINANTS OF PATIENT AND PHYSICIAN GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN LARGE VESSEL VASCULITIS.

A. Kernder1, M. Rohde1, H. Acar1, O. Sander1, J. Richter1, R. Fischer-Betz1, M. Schneider1, G. Chehab2, 1Heinrich-Heine-University Düsseldorf, Medical Faculty, Department Rheumatology & Hiler-Research Unit Rheumatology, Düsseldorf, Germany

Background: Factors influencing disease activity assessment by patients and physicians are unknown but are highly relevant in the context of PROs development.

Objectives: To compare the patients’ and physicians’ global assessment of disease activity in large vessel vasculitis and investigate factors influencing the assessment of disease activity.

Methods: Between 2010 and 2020, patients with large vessel vasculitis and their routine caring physicians assessed a global disease activity score (numerical rating scale 0 – 10) in our outpatient clinic. We compared these global scores of disease activity. In a multiple linear regression analysis we examined the influence of potential demographical and clinical factors on the disease activity assessment.

Results: 385 Patients with 866 assessments were available for analysis. At time-point of assessment they had a mean age of 76 (± 9) years and a mean disease duration of 5 years (± 5). The median global score of patient-reported disease activity was 7 points, the median physicians’ disease activity assessment was 2 points. In 25.2% (n=214) there was a deviation of more than 2 points between the patients’ and physicians’ assessment of disease activity. Only 5 times the physicians, but 232 times the patients rated their disease activity higher than 5 points. In this group the patient-reported disease activity was associated with the patients age (β 0.025), the patients BMI (β 0.071) and the extent of pain (β 0.19), p<0.05. The disease duration, CRP level and the psychological well-being of the patient showed no association.

Conclusion: In our cohort, physicians and patients showed greater divergence in disease activity assessment with higher disease activity. Age, BMI and the extent of pain were associated with higher disease activity ratings by the patients. This results are relevant for the development and interpretation of PROs for activity assessment in large vessel vasculitides.

POS1490-HPR | ASSESSMENT OF TREATMENT ADHERENCE IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED WITH SUBCUTANEOUS ANTI-TNF WHO WERE EXPOSED TO A COMPREHENSIVE CARE MODEL.

W. Rivera1, G. Sánchez2, F. Rodríguez2, L. Villarreal3, D. Bultagro-García2, C. Castro2, P. Santos-Moreno1, 1Biomab IPS, Pharmaceutical Chemist, Bogotá, Colombia; 2Fundación Universitaria de Ciencias de la Salud - FUCS, Epidemiology, Bogotá, Colombia; 3Biomab IPS, Administration, Bogotá, Colombia; 4Biomab IPS, Medical services, Bogotá, Colombia; 5SIIES Consultants, Epidemiology, Bogotá, Colombia; 6Biomab IPS, Rheumatology, Bogotá, Colombia

Background: Rheumatoid arthritis (RA) is an autoimmune, chronic, and inflammatory disease, which can be treated with effective medications, but requires a high level of adherence to treatment. Offering a comprehensive care model by a multidisciplinary team could help increase levels of these patients and improves disease outcomes.

Objectives: Compare the level of adherence to treatment before and after the implementation of a comprehensive care model in a cohort of patients with RA, treated with subcutaneous anti-TNF, in a reference center in Bogotá-Colombia.

Methods: An analytical study was conducted before and after the implementation of a comprehensive care model on a cohort of patients over 18 years of age, diagnosed with RA, who have been prescribed management with a subcutaneous anti-TNF by their doctor during the last 12 months. Convenience sequential sampling was performed to reach a defined sample size of 130 patients to estimate a baseline versus final adherence difference of 20%, at an alpha value of 5% and beta value of 20%. The comprehensive care model (CCM) consisted of the approach by a multidisciplinary team, offering a comprehensive care not fragmented, based on evidence (guidelines and protocols) and proposing a treatment by objectives (T2T). Adherence was measured using the CQR-19 scale, with a cut-off point of 80.7 to consider an adherent patient.

Results: The cohort consisted of 131 patients who followed semiannually for 24 months, and who were incorporated into the CCM. 83.9% were women (n=110), in an age range between 30 and 84 years (Average: 62; DS: 9.9 years). 37.4% of patients were treated with etanercept (n=49), 29% with golimumab (n=38) and 33.6% with adalimumab (n=44). The median baseline of CQR-19 was 87.7 points (RI:64.2-91.2); while at month 24 it reached 91.2 points (RI: 87.7-94.7). The difference between the distributions was statistically significant (p=0.00). According to the cut-off point for CQR-19, the baseline percentage of adherent patients was 87.8% (n=115) and increased to a percentage of 96.2% at 24 months of follow-up (n=126). The difference between these two percentages of adherence was 8.39% (95% CI: 19.9-14.9%) (p=0.012). The results of a generalized linear model binomial family, for the outcome of difference in proportions (PD) of basal and final adherence, are presented in Table 1. The estimator is adjusted for activity level (DAS28), disability level (HAQ) and anti-TNF. Golimumab appears to have an effect that increases adherence by 4.5% compared to adalimumab and etanercept, adjusting for the other predictors.

Table 1. Model of the effect of MAI on adherence to treatment.

Conclusion: The CCM, after a follow-up of 24 months in patients with RA in treatment with subcutaneous anti-TNF increases the percentage of adherence by 9.4%, adjusting for treatment, activity level and degree of disability. Golimumab appears to have an effect that increases adherence by 4.5% compared to adalimumab and etanercept, adjusting for the other predictors.

POS1490-HPR | INVESTIGATION OF THE RELATIONSHIP BETWEEN EXERCISE CAPACITY AND PSYCHOSOCIAL VARIABLES IN WOMEN WITH FIBROMYALGIA: A PRELIMINARY STUDY.

B. Beyrek1, M. Kførumluoluo1, K. Nas1, Í. Nazz1, Ízmir Karat Celubi University Institute of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; 2Izmir Karat Celubi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; 3Sakarya University School of Medicine, Department of Physical Medicine and Rehabilitation, Division of Rheumatology and Immunology, Sakarya, Turkey

Background: Various studies have showed that patients with fibromyalgia have lower exercise capacity than healthy individuals (1, 2). This reduced exercise capacity affects these patients’ independence in performing daily activities (3). Although it was shown that exercise capacity related physical status, it is not quite clear that relationship between exercise capacity and patients’ psychosocial variables in patients with fibromyalgia.

Objectives: To identify whether there is any direct link between the exercise capacity of women with fibromyalgia and their psychosocial status.

Methods: Nineteen women with fibromyalgia meeting the criteria of the American College of Rheumatology were included in the preliminary cross-sectional study (age=46.26±6.25 years, BMI=27.64±3.86 kg/m²). Exercise capacity was assessed by 6-min walking test. For psychosocial variables, alexithymia, fatigue, self-efficacy, and social support were measured by Toronto Alexithymia Scale, Multidimensional Fatigue Index, General Self-Efficacy Scale, and MOS Social Support Survey respectively. Spearman correlation was used to investigate the relationship.

Results: The average distance walked was 468.15±57.30 m. It was found that a significant correlation between 6-min walking test and alexithymia (r=.517, p<.001), self-efficacy (r=.475, p=.040), and social support scores (r=.677, p<.001). However, no link was observed between 6-min walking test and social support scores (r=.170, p=.486).

Conclusion: As a result of our study, the exercise capacity of fibromyalgia patients was reduced as in other studies, there was a strong positive correlation between exercise capacity and self-efficacy in patients with fibromyalgia. Furthermore, exercise capacity was strongly associated with a cut-off point of 300 on the alexithymia. In the light of all this, it may be said that exercise capacity is related to patients’ psychosocial status in women with fibromyalgia. We think that the structure of exercise programs aimed at improving the exercise capacity of patients should include strategies that also improve psychosocial factors.
The usefulness of the patient activity score-pass-II to assess disease activity during the COVID-19 lockdown in patients with rheumatoid arthritis

F. Rodríguez1, D. Buitrago-García2, G. Sánchez2, P. Santos-Moreno3
1Biomab IPS, Administrative, Bogotá, Colombia; 2Fundación Universitaria de Ciencias de la Salud - FUCS, Epidemiology, Bogotá, Colombia; 3Biomab IPS, Rheumatology, Bogotá, Colombia

Background: Many measurement tools are designed to assess disease activity for Rheumatoid Arthritis (RA) patients. One of the most used tools is the Disease Activity Score - DAS28 which assesses the number of painful joints, erythrocyte sedimentation, and a patient’s global assessment. The assessment is performed by a clinician and requires laboratory exams. Unfortunately, from March to August 2019, Colombia had one of the strictest responses to the COVID-19 pandemic according to the COVID-19 stringency index(1). One of the main restrictions was the preventive isolation of elderly populations, especially those with comorbidities. These restrictions challenged the rheumatology practice because face-to-face consultations were not possible. Due to the above, measurements like the PAS-II score should be used to assess disease activity during the pandemic.

Objectives: To describe disease activity according to the Patient Activity Score - PAS-II score patients with RA and compare its results to the most recent DAS28 assessment before the COVID-19 pandemic.

Methods: We conducted a descriptive study; patients were followed during the COVID-19 lockdown in a video consultation. The PAS-II score was applied to assess disease activity as an alternative to the DAS28 assessment. The patients were part of an educational program, clinical charts were reviewed to collect the study variables. We collected demographic data and DAS28 before the pandemic started. We present a descriptive analysis of DAS28 severity and the results obtained by the PASS-II score.

Results: The educational program enrolled 250 participants; 196 patients had complete data. 93% of participants were women, mean age was 64 years IQR (54-67). 43% of participants were married or had a civil union, 26% were single, 20% divorced, and 11% were widowed. Regarding educational level, 25% had finished elementary school and 39% high school; the remaining 36% had higher education. When we compared the last DAS28 assessed by a rheumatologist between January and March 2019, 67% of patients were in remission, while in July 2019, the PASS-II score reported that 7% of patients were in remission and 75% had low or minimal activity. Figure 1- Table 1.

Table 1.

<table>
<thead>
<tr>
<th>DISEASE ACTIVITY</th>
<th>DAS28</th>
<th>PASS-II</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remission</td>
<td>67%</td>
<td>6%</td>
</tr>
<tr>
<td>Low (Minimal)</td>
<td>14%</td>
<td>75%</td>
</tr>
<tr>
<td>Moderate</td>
<td>15%</td>
<td>18.5%</td>
</tr>
<tr>
<td>High/Severe</td>
<td>4%</td>
<td>0.5%</td>
</tr>
</tbody>
</table>

Conclusion: The PASS score is a helpful tool to assess disease activity in patients with RA, especially in situations where the patient cannot see a rheumatologist in a face-to-face consultation; however, patients in severe disease activity should not delay the consultation with a clinician. As other studies have demonstrated, patient-reported outcome measures should be adopted in clinical practice as an alternative to the DAS28 score. As other studies have demonstrated, patient-reported outcome measures should be adopted in clinical practice as an alternative to the DAS28 score.

Psychometric properties of the fibromyalgia impact questionnaire – Revised in fibromyalgia and chronic widespread pain: a rasch analysis

P. H. Duhn1,2, K. Amris1,2, H. Bliddal1,3, E. E. Wahrens1,4, Bispebjerg-Fredensborg Hospital, The Parker Institute, Frederiksberg, Denmark; 2Bispebjerg-Fredensborg Hospital, Department of Rheumatology, Frederiksberg, Denmark; 3University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; 4University of Southern Denmark, Occupational Science, User Perspectives and Community-based Research, Department of Public Health, Odense, Denmark

Background: The Fibromyalgia Impact Questionnaire - Revised (FIQr) is one of the most commonly used self-rating instruments developed to quantify the severity of disease burden and impact of disease on functional ability and social participation in patients with fibromyalgia (FM) [1]. The FIQR consists of 21 individual items categorized within three different domains: ‘function’, ‘overall impact’ and ‘symptoms’ [2]. The FIQR that has been translated into several languages, has mainly been validated based on classical test theory (CCT) - except for the Italian version [3].

The psychometric properties of the Italian version of the FIQR was evaluated by Salati et al. based on item response theory using Rasch analysis [3]. The benefit of using Rasch measurement models, is that it allows for a detailed analyses of an instrument’s rating scale properties and aspects of validity, including fit of individual scale items to a unidimensional model [4]. Although the FIQR demonstrated adequate psychometric properties in the original studies based on CCT, the Rasch analysis in the Italian study revealed problems with the rating scale properties [2,3]. The FIQR is a frequently used questionnaire when assessing patients with FM in Denmark, but the Danish version of the FIQR has not yet been validated.

Objectives: The aim of this study was to evaluate the psychometric properties of the Danish version of the Fibromyalgia Impact Questionnaire Revisited (FIQR), when used to quantify the severity of disease burden in a Danish population of patients with Chronic widespread pain (CWP) including Fibromyalgia (FM).

Methods: A total of 924 participants diagnosed with CWP and/or FM completed an electronic version of the FIQR via touchscreens in the clinic at referral for specialist care. Data was collected from January 1st, 2018 to September 3rd, 2020.

Rasch measurement methods were applied.

Results: Rating scale analysis suggested multiple threshold disordering in the 0 to 10-category rating scale. A principal component analysis suggested assessment of a multidimensional construct. Thus, the Rasch analysis of the full FIQR was discontinued. Instead Rasch analyses were performed on the two subscales: ‘function’ and ‘symptoms’. By collapsing the rating scale to a 0 to 4-category scale, the remaining threshold disordering of both subscale was solved. Only the symptom subscale indicated a multidimensionality. There was underfitting misfit of item 21 and overfitting misfit of item 12. No significant Differential Item Functioning was found defined by sex, ethnicity, or education.

Conclusion: The FIQR should be considered as an instrument consisting of three separate subscales representing ‘function’, ‘overall impact’ and ‘symptoms’. We recommend calculating and reporting on both a 0 to 10- and a 0 to 4-category scale. Also, if using the total FIQR score as an outcome measure, this should be done with caution, until revision of the rating scale.

Disclosure of Interests: None declared

Background: Mental disorders constitute a serious and underestimated problem in Latin America and they could have worse features in comparison with Europe or North America (1), that was the case even before the COVID-19 epidemic ensued in 2020.

Objectives: The objective of this study was to determine the factors associated with the occurrence of mental health disorders (MHD) in patients with autoimmune rheumatic disease (ARD) from Peru, a high COVID-19 incidence country.

Methods: Patients with ARD from a single center (Hospital Guillermo Almenara -EsSalud, Lima-Peru) were included during the first and second waves of the COVID-19 pandemic (March to November 2020). Interviews, medical records reviews, and an electronic survey were performed. MHD explored were depression, anxiety (assessed with the Generalized Anxiety Disorder-7: GAD-7) and post-traumatic stress disorder: PTSD (evaluated with the Event Scale-Revised: IES-R). Variables examined were sociodemographic (age, gender, educational level, marital status, living alone, job status, religiosity), previous diagnosis and treatment for mental disorders, living with a COVID-19 patient, COVID-19 diagnosis (current or past), fear of COVID-19 (assessed with the COVID-19 Scale: FCV-19S) and the ARD type. Multivariable logistic regression models using backward elimination were performed to determine the variables associated with depression, anxiety and PTSD (See Table 1).

Table 1. Variables associated with depression, anxiety and PTSD on ARD patients: Multivariable analysis.

Results: Nine hundred and thirteen ARD patients were evaluated. The most frequent diagnosis was rheumatoid arthritis in 446(48.8%) patients followed by systemic lupus erythematosus in 279 (30.6%). Depression, anxiety, and PTSD were observed in 128 (14.0%), 112 (12.30%) and 485 (53.1%) patients, respectively.

In the multivariable analyses, previous treatment for mental disorders and fear of COVID-19 were associated with depression: OR=2.35 (95% CI 1.37-4.03; p=0.002) and OR=1.07 (95% CI 1.05-1.10; p=0.001) respectively; also with anxiety: OR= 2.42 (95% CI 1.37-4.26; p=0.002) and OR=1.09 (95% CI 1.06-1.12; p=0.009), and with PTSD: OR=2.42 (95% CI 1.39-4.21;p=0.002) and OR=1.41 (95% CI=1.11-1.71; p=0.001). A diagnosis of COVID-19 was associated with PTSD: OR=1.75 (95% CI 1.06-2.89; p=0.028), while being single was associated with a decreased probability of PTSD occurrence: OR=0.57 (95% CI=0.35-0.96; p=0.03). Finally, having a high educational level was associated with less anxiety: OR=0.43 (95% CI 0.82-2.1; p=0.009), for university (postgraduate studies and OR=0.52 (CI 95% 0.28-0.95; p=0.032) for secondary studies.

Conclusion: Fear of COVID-19 and previous treatment for mental disorder were associated with all MHD explored on our ARD patients during the COVID-19 pandemic.

HPR Interventions (educational, physical, social and psychological)

Hard times: adapting a fatigue management programme in a pandemic

J. Dobson1, D. Dockrell2, K. Berg3, H. Harris1,1 University of Edinburgh, CGEM, Institute of Genetics and Cancer, Rheumatic Diseases, Edinburgh, United Kingdom; 2University of Edinburgh, CGEM, Institute of Genetics and Cancer, Rheumatic Diseases, Edinburgh, United Kingdom; 3NHS Lothian, Rheumatic Diseases, Edinburgh, United Kingdom

Background: Fatigue is a symptom of many Rheumatology Conditions (1). Hewlett et al have shown that a Fatigue Management Programme (FMP) is effective in reducing fatigue in Rheumatoid Arthritis patients (2). In 2019, a 7-week group-based FMP was developed using a cognitive behavioural approach for Rheumatology patients in NHS Lothian (Scotland). In 2020, due to COVID-19, the in person FMP was adapted for virtual delivery. Referral criteria included Visual Analogue Scale-Fatigue (VAS-F) of ≥6/10 and an inflammatory rheumatic disease diagnosis. The FMP participants recorded Patient Reported Outcome Measures (PROMs) prior to and on completion of the FMP. In August 2021 demand for the FMP far outweighed the capacity of the delivery team and therefore the original 7-week FMP was further adapted to a 4-week programme. This was achieved by focusing on four core elements (i) sleep, (ii) thoughts, emotions and behaviours, (iii) energy conservation, (iv) setbacks.

Objectives: The primary objective was to evaluate whether the 4-week programme produced comparable PROMs results to the 7-week programme. In doing so, the aim was to maintain efficacy of the programme and provide increased capacity by offering more groups in the same timeframe.

Methods: Fatigue Severity Scale (FSS) and Visual Analogue Scale for Fatigue (VAS-F) were used for comparison between pre and post FMP PROMs results, these being the main indicators of improvement in fatigue management. Fisher’s exact test was used to determine any difference between the PROMs results reported at the end of both programmes. Participants who reported that their PROMs result were the same, worse or who did not respond, were all placed into the category “Other”. The FMP team recorded the average waiting time for those attending each group. The length of the waiting list at any one time was calculated by removing those who were not interested, had been referred elsewhere, or who did not respond to the invitation, from the total number of referrals received by the FMP team.

Results: There was no significant difference in FSS and VAS-F results reported by the participants in both groups at the end of the FMPs as determined by Fisher’s exact test (Table 1). Waiting list times reduced from 24 weeks in August 2021 to 6 weeks in December 2021 as a result of the adaptation of the FMP from a 7-week programme to a 4-week programme (Figure 1).

Figure 1. - Review of average waiting times experienced by each group. In August 2021, the decision was made to trial a 4-week FMP to counter large increases in average waiting times.

Conclusion: A 4-week FMP is as effective at improving the management of fatigue in Rheumatology patients as a 7-week FMP and reduces patient waiting times. More research is required to bolster the evidence base to support this novel approach.

Feasibility of a physiotherapist led, behaviour change intervention to improve physical activity in people with rheumatoid arthritis

L. Larkin1, S. Mckenna1, T. Pyne1, S. Gallagher2,3, L. Glynn3,4, A. Fraser4,5, B. A. Esbensen6,7, N. Kennedy1,3,1 University of Limerick, School of Allied Health, Limerick, Ireland; 2University of Limerick, Department of Psychology, Limerick, Ireland; 3Health Research Institute, University of Limerick, Limerick, Ireland; 4University of Limerick, School of Medicine, Limerick, Ireland; 5University Hospital Limerick, Department of Rheumatology, Limerick, Ireland; 6Copenhagen Centre for Arthritis Research, Rigshospitalet, Copenhagen, Denmark; 7University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Background: Physical activity (PA) is an important component in the management of people with rheumatoid arthritis (RA) (1). Interventions incorporating Behaviour Change (BC) theory are needed to target physically inactive people with RA. The study Physiotherapist-led Intervention to Promote Physical Activity in Rheumatoid Arthritis (PIPPRA) was designed using the Behaviour Change Wheel (BCW) and a pilot study of feasibility undertaken (ClinicalTrials.gov Identifier: NCT03644180).

Objectives: To obtain reliable estimates regarding recruitment rates; participant retention; protocol adherence and possible adverse events, and to producing estimates of the potential effect sizes of the BC intervention on changes in outcomes of physical activity; fatigue; disability and quality of life.

Methods: Participants were recruited at University Hospital (UH) rheumatology clinics and randomly assigned to control group (physical activity information leaflet) or intervention group (four BC physiotherapy sessions in eight weeks). Inclusion criteria were diagnosis of RA (ACR/EULAR 2010 classification criteria), aged
Background: People newly diagnosed with inflammatory arthritis (IA) request regular consultations and support from health professionals (HPRs) in rheumatology to manage physiological, emotional, and social challenges. Evidence suggests that providing a tailored tailormade multi-component self-management program may benefit disease management (1). However, there is a lack of evidence in interventions with multiple components targeting people newly diagnosed with IA.

Objectives: To develop a complex evidence- and theory-based intervention in co-creation with patients and HPRs for better self-management in newly diagnosed people with IA in a rheumatology outpatient clinic.

Methods: This study followed the Medical Research Council (MRC) Framework (2,3) for developing a complex intervention. The development phase comprised 1) identifying the evidence base, 2) identifying theory, 3) modelling process and outcomes, resulting in 4) a final description of all components and outcomes of the intervention.

1) Identifying the evidence base

We conducted two literature reviews, on which, we described a preliminary intervention.

2) Identifying theory

Given the fact that the theory of Self-management is built upon Social Cognitive Theory (4) this was chosen as the underlying theory along with Acceptance and Commitment Theory (5) to support our communication strategy.

3) Modelling process and outcomes

The preliminary intervention was discussed and further developed in seven workshops to ensure that the intervention was in accordance with patients’ needs and feasible in clinical practice. Three patients and 38 HPRs (nine therapists, 10 rheumatologists, one psychologist, one social worker, and 17 registered nurses) attended. During the workshops we identified the competencies needed in the HPRs delivering the intervention. In addition, relevant outcomes to measure self-management in a subsequent feasibility study were discussed. Discussions were digitally recorded and analysed using Thematic Analysis (6).

4) Description of all components and outcomes of the intervention

Our intervention, ready for testing in a feasibility study, was a 9-month nurse-led intervention, and consisted of four individual and two group sessions. A physiotherapist and an occupational therapist should attend the group sessions along with the nurse (Figure 1). All sessions should target inflammatory arthritis-specific self-management.

Results: 320 participants were identified through chart review with direct contact then with people meeting the inclusion criteria at rheumatology clinics. Of the clinic attendees n=183 (57%) were eligible to participate and n=58 (55%) consented to participate. The recruitment rate was 6.4 per month and 25 (43%) of those consented to participate. The recruitment rate was 6.4 per month and refusal rate was 59%. Due to impact of COVID-19 on the study n=25 (43%) were able to complete the study (n=11 (44%) in intervention and n=14 (56%) in control). Of the 25, n= 23 (92%) were female, mean age was 60 years (sd 11.5). Intervention group participants completed 100% of BC sessions 1 & 2, 88% session 3 and 81% session 4. No serious adverse events were reported. Secondary outcomes measures data is Table 1.

Conclusion: The PIPPRA study designed using the BCW to improve promote physical activity was feasible and safe. This pilot study provides a framework for future, more complex multi-component self-management interventions in inflammatory arthritis.

Y. Acar1, N. Ilcin2, I. Sarı3.

Background: Yoga is an ancient discipline that emerged thousands of years ago in India to unite the mind, body and spirit. Yoga is widely used by patients with various rheumatic diseases. Although it is recommended for ankylosing spondylitis (AS) patients, there is no randomized controlled study on this subject in the literature. Due to Covid-19, which has changed the world and the people's lifestyle, tele-yoga practice can be considered as an alternative to traditional physical therapy and rehabilitation. In this study, the effects of tele-yoga on disease activity, functional status, spinal mobility, sleep quality, depression, anxiety, stress and quality of life in ankylosing spondylitis patients were investigated.

Methods: Thirty-six volunteer AS patients (21 male, 15 female) who applied to Dokuz Eylül University, Department of Internal Medicine, Division of Rheumatology and Immunology were included in the study. Participants were randomly assigned to a tele-yoga (n=18, mean age 43.22 ±8.54 years) or waiting-list control group (n=18, mean age 44.9 ±8.01 years) by block randomization method. Participants in the tele-yoga group participated in 1-hour tele-yoga sessions with a maximum of 5 people in each group using Zoom (online video-conference method) 3 days a week for 8 weeks. Assessments were performed before and after 8 weeks of yoga training. The waiting list control group did not receive any intervention, participants were advised to maintain their usual activities and continue their routine medical treatments. Assessments were performed at baseline and after an 8-week waiting period. After assessments, patients who wished to participate in the tele-yoga program were invited to a follow-up visit. The following inventory was used for assessment: Bath AS Disease Activity Index (BASDAI) for disease activity, Bath AS Functional Index (BASFI) for functionality, Bath AS Mobility Index (BASMI) for spinal mobility, ASAS Health Index, Pittsburgh Sleep Quality Index (PSQI), Short Form-36 (SF-36), Hospital Anxiety and Depression Scale (HADS), Perceived Stress Scale (PSS).

Results: The groups were similar at baseline in terms of age, height, weight, body mass index, gender and physical activity level (p>0.05). While all parameters improved significantly in the tele-yoga group (p<0.05), no change was observed in the control group after 8 weeks (p>0.05). When the changes in the tele-yoga group and the control group were compared, the improvements in the BASDAI, BASFI, BASMI, ASAS Health Index, SF-36 Physical Function, SF-36 Role Physical, SF-36 Bodily Pain, PSQI and PSS were found to be statistically significant in the tele-yoga group (p<0.05).

Conclusion: According to our preliminary results, tele-yoga is beneficial in reducing disease activity and stress, improving functional level, spinal mobility, sleep quality and quality of life. Due to its therapeutic effects, tele-yoga can be considered as an alternative approach for AS patients.

BABS ON A MISSION: AN EXPERIMENTAL STUDY ON THE EFFECTS OF MESSAGE FRAMING ON BEHAVIORAL AND INTENTIONS OF OSTEARTHRITIS PATIENTS

J. Oomen1, C. Van den Ende2, H. Das3, Sint Maartenskliniek, Department of Research and Innovation, Ubebergen, Netherlands; Sint Maartenskliniek, Department of Research and Innovation, Ubebergen, Netherlands; Radboud University, Department of Language and Communication, Nijmegen, Netherlands

Background: It is important that patients receive appropriate and reliable information that effectively targets beliefs in order for them to adhere to health behaviors. Framing (focusing on either gains or losses; [1]) is one of the most commonly used techniques in health communication to influence beliefs. In addition, the use of a testimonial in educational material might strengthen effects as intentions to adhere to health behaviors seem to rely strongly on testimonies of other patients. However, little is known about the potential of framing and patient testimonies to impact beliefs and change in health behaviors in osteoarthritis (OA).

Objectives: To study the effects of 1) message framing and 2) patient testimonies on beliefs about and intentions to be physically active and use pain medication.

Methods: We conducted an experiment consisting of a 2 × 2 (gain-frame vs loss-frame) × 2 (testimonial versus informative message) factorial design. Members of a research panel (n=639) with a self-reported diagnosis of knee OA were invited to participate. Participants were randomized into one of four video messages applying framing and the use of either a testimonial or facts. The messages (mean (SD) words 1073 (129)) were audiotapecd by the same female speaker, subtitled, and complemented with images (duration of ~10 minutes). The four different combinations were: informative-loss (“If you are not physically active, this can lead to more pain[…]”), informative-gain (“If you are physically active, this will lead to less pain[…]”), testimonial-loss (“When I wasn’t physically active, I experienced more pain[…]”), testimonial-gain (“When I was physically active, I experienced less pain[…]”). After this video, participants filled out a questionnaire on socio-demographic and disease characteristics, and rated 3 statements concerning beliefs on a 7-point Likert scale (completely disagree – completely agree), and one 7-point Likert scale item on intentions (I do not do this now and am not planning doing this – I am doing this already for more than 6 months) each for both physical activity and pain medication based on the Theory of Planned behavior questionnaire [2]. ANOVA was used to assess the main and interaction effects of framing and the use of a testimonial on mean beliefs and intentions.

Results: A total of 154 respondents completed the questionnaire (Table 1). Framing nor the use of a testimonial impacted beliefs and intentions on physical activity. Loss framing resulted in more positive beliefs about pain medication (mean (SD) 5.5 (1.6)) than gain framing (mean (SD) 4.9 (1.9), p=0.04, 95% CI [0.0, 0.1]). Within the loss frame, the patient testimonial scored significantly more positive on pain medication beliefs (mean (SD) 5.0 (1.7)) than the informative message (mean (SD) 6.0 (1.1), p=0.02, 95% CI [0.1, 1.6]) (Figure 1).

</table>

Conclusion: This study showed that the disadvantages of nonadherence to pain medication resulted in more positive beliefs about pain medication than stating the advantages of adherence. The use of a patient testimonial within this loss frame strengthened the effect. Our findings indicate that health care providers should be aware of the potential effects of emphasizing either gains or losses in educational messages to their patients.

Background: Long term health conditions (LTHC) such as rheumatic conditions have significant impact on the biopsychosocial development of young people (YP) including vocational development. Educational transitions are prominent during adolescence and young adulthood yet not all transitional care programmes in the area address this area [1].

Objectives: To identify and synthesise the benefits and experiences of addressing the vocational development of YP with LTHC in health care settings.

Methods: A mixed methods synthesis approach [2] was employed. We systematically searched 10 bibliographic databases. Restrictions were applied on publication date (1996-2020) and publication language (English). Articles reporting quantitative and/or qualitative primary research on addressing vocational/needs/ issues of YP with LTHC in health care settings were included. YP was defined as 10-24 years [3]. Two reviewers independently screened records using predetermined inclusion/exclusion criteria [4]. Quality appraisal was undertaken following the Newcastle Ottawa Scale [4].

Results: 43 articles were included. The quality of qualitative evidence was generally good; but the quality of quantitative evidence was generally poor. The thematic synthesis of stakeholders’ perspectives (n=23 qualitative studies) resulted in seven recommendations for interventions: provide skills training; provide psychological support; offer to liaise with key stakeholders in educational/workplace settings; provide specialist career advice; provide information, signposting and facilitate access to supporting services; provide/facilitate access to social support; provide flexible care and optimal disease management to support education/employment transitions. The narrative synthesis summarised results of 17 interventions (n=20 quantitative studies). The cross-study synthesis mapped interventions against recommendations arising from stakeholders’ perspectives: Four interventions met five recommendations; two interventions met four recommendations; three interventions met three recommendations; six interventions met two recommendations. Transitional care interventions were the type of intervention that most comprehensively met the recommendations. The way in which interventions addressed vocational issues was not always clear, with some interventions addressing them explicitly/directly (reporting vocational outcomes only). Interventions where vocational issues were the core, defining component (reporting vocational outcomes) and others implicitly/indirectly (reporting vocational outcomes addressing them explicitly/directly (reporting vocational interventions addressing them explicitly/directly (reporting vocational outcomes) was not always clear, with some interventions addressing them explicitly/directly (reporting vocational outcomes only).

Conclusion: Stakeholder evidence suggests vocational development is an important area to address in the care of YP with LTHC such as rheumatic diseases. The resulting set of recommendations provides guidance for future research in this area and transitional care developments in rheumatology. Further work in this area should address these aspects to enable better quality evidence and ensure consistency.

**THE VALUE OF REMOTE CONSULTATIONS WITH A PHYSIOTHERAPIST, SPECIALISED IN AXIAL SPONDYLOARTHROPATHY DURING THE COVID 19 PANDEMIC: EVALUATION OF A MEMBER-SUPPORT PROJECT WITH THE NATIONAL AXIAL SPONDYLOARTHROPATHY SOCIETY.**

E. Clarke1, J. Hamilton2, S. Dickinson3.  
1 ASretch, Committee Member; Bath, United Kingdom; 2 National Axial Spondyloarthritis Society, Policy and Health Services, London, United Kingdom; 3 National Axial Spondyloarthritis Society, Member Support Services, London, United Kingdom

**Background:** COVID-19 caused significant disruption to Axial Spondyloarthritis (AxSpA) services during the initial 2020 lockdown. In response, The National Axial Spondyloarthritis Society (NASS) piloted provision of remote consultations with a physiotherapist specialised in the management of AxSpA to their members in urgent need. This project was funded by the UK National Lottery Fund.

**Objectives:** To provide a total of 130 hrs of remote consultation to members of NASS, unable to access specialist care and in need of self-management advice for their condition.

**Methods:** Remote consultations were offered to NASS members from Sept 2020 to Feb 2021. The preferred format being 1hr assessment and 2 x 30min at 1 and 3 weeks from assessment. Participants consented to video consultations via Zoom and the inclusion of anonymised outcomes and comments in the project evaluation. Patient Reported Outcomes (BASDAI and BASFI) were collected immediately prior to assessment, at final consultation and in April 2021, between 8-16 weeks from final consult. Content was individually tailored, centring on self-management (pacing, sleep management), education (AxSpA pathology, medication) and individualised exercise plans. Exercise plans were formulated through “Rehab My Patient” software, including links to YouTube video references and daily exercise log sheets.

**Results:** 67 members received online consultations, 63 receiving the full 3 sessions. Missed appointment rate = 2.5%. Participants represented a wide geographical area across England and a spread in time since diagnosis.

Patient Reported Outcomes Measures (PROMs) on assessment:  
- Mean BASDAI score (n=55) on assessment = 5.8  
- Mean BASFI score (n=56) = 5.5

24 participants returned PROMs at final consultation, 10 at longer follow-up (8-16 weeks). Results for complete data set (n=10):

<table>
<thead>
<tr>
<th>PROMS</th>
<th>Assessment</th>
<th>Final consultation</th>
<th>Follow-up</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean BASDAI</td>
<td>5.0</td>
<td>4.3</td>
<td>4.0</td>
</tr>
<tr>
<td>Mean BASFI</td>
<td>5.1</td>
<td>4.0</td>
<td>4.1</td>
</tr>
</tbody>
</table>

**Satisfaction:** 60 members completed an online feedback survey provided by NASS:

- 9 Feedback to questions were asked, with a satisfaction scale of 1-5 (ascending positivity).
- 96.6% of all scores were 3 or above.

**Example responses:**
- How would you rate the overall experience: 92% = 5, 100% = 3-5
- To what extent do you feel more confident to manage your condition: 40% = 5, 100% = 3-5
- How useful was it to be in direct contact with a Physiotherapist: 93% = 5, 100% = 3-5

46 members chose to leave additional, overwhelmingly positive comments, with 2 obvious themes arising:

1) The value of the experience and knowledge of the therapist: “was great to have the guidance and support of a professional who knows what they are talking about when it comes to AxSpA”

2) The value of education in condition management: “set me back on track, very helpful for my mental strength in dealing with this enduring disease”, “I learned so much about my AS and ways to keep mobile”

**Conclusion:** A set of 1-3 sessions per person achieved desirable patient reported outcomes with modest and enduring improvements seen in disease activity and function. This pilot project enabled those living with AxSpA across England access to a Physiotherapist highly experienced in treatment of their condition. The majority of participants reported having no previous experience of seeing a therapist with specialised knowledge of their condition. The knowledge and experience of the clinician was a key theme in the positive nature of feedback linking to another key theme of improved confidence to manage their condition. These results highlight the value to patients of specialised knowledge amongst health professionals. Remote consultations may provide access to specialist knowledge “out of area” and may be an efficient method of delivering self-management advice.

**POS1504-HPR**  
**THE EFFECT OF REMOTE AND FACE-TO-FACE STABILIZATION EXERCISES ON FUNCTIONAL CAPACITY OF ASYMPTOMATIC INDIVIDUALS**

Y. Ozel Ashiyev1, O. Ulger2.  
1 Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey

**Background:** In recent years, it has been emphasized that preventive rehabilitation approaches for problems such as low back and neck pain, which are very high in health expenditures, are more cost-effective than treating them. Due to the Covid-19 pandemic, risk factors for individuals’ spinal health have increased and access to health care has become difficult. Therefore, interest in tele-rehabilitation, which is an important part of telehealth, has increased recently.

**Objectives:** This study aims to compare the effects of remote and face-to-face spinal stabilization exercise training on functional capacity tests in asymptomatic individuals.

**Methods:** Individuals who did not have chronic low back and knee pain and between the ages of 18-55 were included in the study. While the face-to-face group traditionally exercised under the supervision of a physiotherapist, the telerehabilitation group exercised with videoconferencing and asynchronous video recordings. Both groups performed progressive spinal stabilization exercises for 3 days a week for 8 weeks (2). Before and after the training functional capacity tests (repetitive reaching, lifting object overhead, and sustained overhead work) were performed (3).

**Results:** Twenty (11 female, 9 male) individuals with a mean age of 30,252±9.06 and a mean body mass index of 24.36±4.09 were included in the study. There was no difference between the baseline values of functional capacity test scores of both groups (p>0.05). There were significant improvements in the repetitive reaching and sustained overhead work tests after the exercise program in both groups (p<0.05), while there was no difference in the lifting object overhead test (p>0.05). There was no difference between the changes in functional capacity test scores between the groups after the training (p>0.05).

**Conclusion:** According to our preliminary results, face-to-face and remote spinal stabilization exercise programs caused similarly positive changes in functional capacity test scores (repetitive reaching, sustained overhead tests) of asymptomatic individuals. These exercises are known to improve deep muscle activation. This development may have led to improvements in tests, which mostly evaluate speed, coordination and endurance. Weight lifting capacities have not changed. This may be because stabilization exercises focus more on deep muscle activation and not on developing superficial muscle strength like upper extremity strength(2). Success of exercise training with telerehabilitation may have contributed to the younger population and possibly better adaptation to technology. It is planned that these preliminary results will be extended and make greater contributions to the current literature.

Background: A Fatigue Management Education in Work (FAME-W) programme was developed for individuals with inflammatory arthritis to manage fatigue in work (McCormack et al., 2018).

Objectives: This study tested the feasibility and acceptability of an online format of FAME-W for a future definitive interventional trial.

Methods: This was a mixed methods study. Participants were randomly allocated to intervention (IG) or control group (CG). The IG received a four-week online FAME-W handbook. Participants were required to complete questionnaires on work presenteeism, fatigue, mood, Health Related Quality of Life (HRQOL) and pain at baseline (T0), and two weeks following intervention (T1). They also attended a focus group and individual interviews. Data were analysed using descriptive statistics.

Results: Seven of ten individuals recruited participated in the study (intervention = 3, control = 4). The majority of participants in both groups had Rheumatoid Arthritis and were working full-time in non-manual jobs. The mean age of intervention participants was 53 ± 10.4 and 56.5 ± 3.7 for the controls. Most of the intervention group were males and the majority of controls were female. Disease activity at baseline was similar for both groups: 3.3 ± 2.5 intervention; 3.0 ± 1.8 control. At follow-up, disease activity did not change for intervention group (3.3 ± 0.57) and reduced slightly for CG (2.7 ± 2.4). Slight improvements were noted for both groups in presenteeism and fatigue between T0 and T1 (Table 1). There was no change in anxiety levels of the intervention group, with improvements noted for controls. Greater improvements were noted for the intervention group for depression and HRQOL. Pain measures showed increased pain for controls at T1 in comparison to the intervention group.

Those allocated to FAME-W attended all four sessions. FAME-W participants reported that the programme content was comprehensive and relevant. They stated that the occupational therapist facilitator was able to “see things from a different perspective for managing symptoms.” Participants also reported a better understanding of fatigue: “It helped me understand myself, if you understand it, you can manage it better.” The online delivery format was favored over attending a centre-based programme. Control participants reported the handbook content as “informative and reassuring.” All participants fully completed all study questionnaires and attended focus groups and interviews.

Conclusion: This feasibility study showed that an online programme to improve work ability was feasible and acceptable to individuals with Rheumatic Diseases. Study measures were completed in full and adherence rate was 100% for the intervention. The findings support a definitive intervention trial of FAME-W.

POS1506-HPR  SYMPTOMATIC LITERATURE REVIEW TO INFORM THE EULAR TASK FORCE FOR RECOMMENDATIONS/ POINTS TO CONSIDER FOR THE NON-PHARMACOLOGICAL MANAGEMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS AND SYSTEMIC SCLEROSIS

I. Parodis1,2, A. Gomez1, A. Tao1, J. Weng Chow1, D. Pezzella1, C. Girardin1, T. Stamm1, C. Boström1 on behalf of EULAR Task Force for Recommendations/ Points to Consider for the Non-Pharmacological Management of Systemic Lupus Erythematosus and Systemic Sclerosis. 1Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden; 2Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden; 3University Hospital of Geneva and University of Geneva, Division of Rheumatology, Department of Medicine, Geneva, Switzerland; 4Medical University of Vienna, Section for Outcomes Research, Center for Medical Statistics, Informatics and Intelligent Systems, Vienna, Austria; 5Ludwig Boltzmann Institute, Cluster Arthritis and Rehabilitation, Vienna, Austria; 6Karolinska Institutet, Division of Physiotherapy, Department of Neurobiology, Care sciences and Society, Stockholm, Sweden

Background: The heterogeneity and complexity of the chronic autoimmune diseases systemic lupus erythematosus (SLE) and systemic sclerosis (SSc requires comprehensive person-centred management, including non-pharmacological approaches. Recommendations for non-pharmacological management are currently lacking.

Objectives: To perform a systematic literature review to inform the EULAR task force for recommendations/points to consider for the non-pharmacological management of adult patients with SLE and SSc. Among research questions formulated by the task force, we aimed at identifying (i) non-pharmacological interventions that have been evaluated and (ii) their target health domains or organ systems.

Methods: We searched the Medline, Embase, Web of Science Core Collection and CINAHL for articles published between January 2000 and June 2021. From the initial search (n=15,803), 2 researchers independently performed the article selection. Conflicts were discussed until consensus with 2 additional researchers. Subsequent data extraction from the selected articles was performed by 4 researchers, with an overarching guidance by 2 additional researchers. Risk of bias assessment was performed according to Joanna Briggs Institute Critical Appraisal Checklists.

Results: A total of 111 articles for SLE and 75 for SSc were selected for analysis. Non-pharmacological interventions identified for SLE included physical exercise (n=34), psychological support (n=21), dietary therapy and nutrition (n=15), patient education and self-management (n=14), photoprotection (n=5), medication adherence interventions (n=5), complementary and alternative medicine (CAM) e.g., Chinese medicine (n=5), multidisciplinary care (n=4), and phototherapy/laser modalities (n=4); Interventions identified for SSc included physical exercise e.g., hand, oral and general exercise (n=21), phototherapy/laser modalities or shockwave therapy (n=15), patient education and self-management (n=10), CAM (n=8), hand-bathing e.g., in paraffin (n=5), manual therapy e.g., osteopathic manipulative treatment (n=5), dietary therapy and nutrition (n=5), oral hygiene (n=2), hyperbaric oxygen or ozone therapy (n=2) and multidisciplinary care (n=2). Target health domains and organ systems identified within SLE included (in descending order) (i) disease activity, (ii) health-related quality of life (HRQoL), (iii) depression/anxiety, (iv) fatigue, (v) organ damage, (vi) inflammatory markers, (vii) psychological stress, (viii) pain, (ix) body composition/anthropometry, and (x) aerobic capacity. Intervention targets in SSc included (i) functional impairment e.g., hand mobility, (ii) skin scarring including microstalias, (iii) HRQoL, (iv) pain, (v) circulation e.g., Raynaud's phenomena and telangiectasias, (vi) skin ulcers, (vii) oral hygiene, (viii) fatigue, (ix) digestion, and (x) depression/anxiety.

Conclusion: Physical exercise was a frequently researched non-pharmacological intervention within both SLE and SSc. While psychological support and dietary therapy/nutrition were frequently investigated in SLE, phototherapy modalities were common in SSc. Patient education and self-management was advocated in both SLE and SSc literature. HRQoL was a frequent target domain in both diseases; while disease activity and psychosocial domains emerged as important targets in SLE, functional impairment and skin-related aspects constituted predominant targets in SSc. Efficacy of interventions varied considerably across studies. Current evidence is limited by the overall small study populations, and the lack of large RCTs.

POS1507-HPR INVESTIGATION OF THE EFFECTS OF PELVIC FLOOR TRAINING ON PAIN, SEXUAL DYSFUNCTION, AND QUALITY OF LIFE IN FEMALE PATIENTS WITH SJOGREN

K.T. Aydin1, S.Y. Cetin2, A. Ayan3, 1Turkey, Physiotherapy and Rehabilitation, Antalya, Turkey; 2Akdeniz University, Physiotherapy and Rehabilitation, Antalya, Turkey; 3Antalya Health Sciences University, Rheumatology, Antalya, Turkey

Background: Sjögren’s syndrome is a chronic systemic inflammatory disorder (classified as an autoimmune disorder) characterized by lymphocyte infiltrates in exocrine organs. This syndrome is classified as primary sjögren’s or secondary sjögren’s. Dryness of the eyes, oral cavity, larynx, pharynx and vagina is common in primary sjögren’s syndrome. Although vaginal dryness is a symptom seen more frequently in the healthy population, it often occurs at a young age in cases with primary sjögren’s. The presence of urogenital complaints in women with pSS adversely affected the health-related quality of life of pelvic floor function. However, it has been shown that the sexual functions of women with pSS are also negatively affected. Sexual dysfunction and increased pain were seen with increasing pelvic floor dysfunctions. Many studies showing that pelvic floor training has been accepted in the literature as the first step in the treatment of pelvic floor dysfunctions to increase pelvic floor strength and effectiveness. In addition, the positive effects of pelvic floor exercises on sexual functions have been supported by studies.

Objectives: The aim of this study was to investigate the effects of pelvic floor training on pain, sexual dysfunction and quality of life in female patients with pSS and determine whether pelvic floor training was superior to education program.

Methods: 46 pSS patients (46 female) with an average age of 47.78±9.18 were included in the study. Patients were divided into two groups by block randomization method. Group 1 received 30 minutes of pelvic floor training program every day as a home exercise for 8 weeks. Group 2 received education about pelvic floor muscles and daily living activities. Health Assessment Questionnaire (HAQ) was used to evaluate the quality of life. Visual Analog Scale (VAS) and Pelvic Pain Impact Questionnaire (PPIQ) was used to evaluate the sexual dysfunction, Pelvic Floor Disability Index-20 (PFDI-20) was used to evaluate the degree of certain discomfort caused by pelvic symptoms in women, Female Sexual Function Scale (FSFI) was used to evaluate the sexual dysfunction, Pelvic Floor Impact Questionnaire (PFIQ-7) was used to evaluate the effect of bladder, bowel, and pelvic symptoms on the individual’s activities of daily living, social relationships, and emotions. All evaluations were performed at baseline and at the end of the 8th week.

Results: When the groups were compared before training, there was no significant difference (p>0.05). In post-training comparisons, there was a significant difference in FSFI, VAS, PPIQ, PFIQ-7, PFDI-20 in pelvic floor training group (p<0.02-0.00) and FSFI-lubrication, PFIQ-7 and PFDI-20 (p<0.00-0.03) in education group. In addition, after post-training, pelvic floor training group was found to be superior in terms of FSFI total (Z:-3.40, p:0.01), FSFI-organism (Z:-3.13, p:0.02), FSFI-satisfaction (Z:-2.27p:0.02), FSFI-pain (Z:-2.42, p:0.01), PFDI-20 (Z:-3.42, p:0.00), POPDI-6 (Z:-3.00, p:0.00), CRADI-8 (Z:-2.18, p:0.02), UDI-6 (Z:-3.64, p:0.00) compared with education group.

Conclusion: As a result of our study, pelvic floor training has a positive effect on sexual dysfunction and discomfort caused by pelvic symptoms in patients with pSS. Pelvic floor training should be included in rehabilitation programs as a home exercise to improve sexual function and pelvic dysfunction symptoms for patients with pSS.

POS1508-HPR USE OF PHYSICAL THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS OR AXIAL SPONDYLOARTHRITIS: THE PATIENT’S PERSPECTIVE

M. Van Wissen1, B. Straathof, T. P. M. Vliet Villieland1, M. Teuwen1, C. Van den Ende1,2, W. Peter1, M. G. J. Gademan1,3, S. Van Weely1,1 Leiden University Medical Center (LUMC), Clinical epidemiology, Leiden, Netherlands; Sint Maartenskliniek, Research, Nijmegen, Netherlands; Radboud University Medical Center, Rheumatic Diseases, Nijmegen, Netherlands; Leiden University Medical Center (LUMC), Clinical epidemiology, Leiden, Netherlands

Background: In national and international management guidelines physical therapy (PT) is a recommended treatment for people with inflammatory arthritis (IA). Based on multiple systematic reviews, concluding that supervised exercise therapy and exercise promotion is an effective and safe PT treatment option in patients with IA, recommendation mentions particular endorse active PT treatment. In order to monitor and enhance the quality of PT in clinical practice, knowledge about its active content is needed.

Objectives: To assess the use, frequency, duration and content of PT in patients with IA.

Methods: In this cross-sectional, national study a link to an electronic questionnaire addressing people with rheumatic and musculoskeletal diseases was published between December 2020-July 2021 by the Dutch Arthritis Foundation via their website, newsletter and various social media. It comprised questions on demographic and health characteristics, the EuroQol 5-Dimensions 5-Levels (EQ5D5L) and 29 questions on the usage of PT currently and/or in the past 12 months and, if applicable, the duration, frequency and content of the PT treatment. The content of PT was categorized into exercises (active aerobic, muscle strengthening, range of motion and/or functional exercises), manual treatment, physical modalities and counseling/education. Only data from patients self-identifying as diagnosed with rheumatoid arthritis (RA) and/or axial spondyloarthritis (axSpA) were used for the current study.

Results: A total of 267 people with RA (mean (SD) age 54 (12) years, 96% female) and 104 people with axSpA (age 47 (13) years, 88% female) (10 patients with both diagnoses) completed the questionnaire. More than 90% were treated by a rheumatologist; the mean (SD) EQ5D5L of people with RA was 0.62 (0.2) and of axSpA 0.59 (0.2). 172 RA respondents (64%) reported the use of PT related to their RA (162 individual PT, 1 group PT, 9 both individual and group PT). In axSpA, the rate was 87% (84%; 77 individual PT, 2 group PT, 8 both individual and group PT). Of those reporting individual PT treatment, the duration was long-term (> 3 months) in 134 (89%) and 70 (89%) of the respondents with RA and axSpA respectively, with a duration of more than 2 years in 67 (44%) and 38 (48%). In all users of individual PT, the mean frequency was once per week or less in 116 (77%) of the RA and 63 (80%) of the axSpA patients. Proportions were based on number of respondents to questions on individual PT. Concerning the content of individual PT, and taking into account both short-term and long-term use, for active exercises, the proportion of patients reporting aerobic, muscle strengthening, range of motion or functional exercises ranged from 40-66% in RA and 24-73% in axSpA patients. Regarding manual treatment, the proportions were 61% and 58%, in RA and 73% and 72% in axSpA for massage and passive mobilizations, respectively. With respect to physical modalities (passive), the modality most frequently mentioned were kinesio-taping and dry needling (40 and 25% and 43 and 32% in RA and axSpA). For counseling/education, exercises to perform at home (70 and 78%) and physical activity (PA) promotion (48 and 49%) were most often reported in both RA and axSpA.

Conclusion: Long-term use of PT is common in patients with RA and axSpA. Apart from active treatment modalities (exercises) and promoting recommended PA, passive treatment options appear to be relatively often used. The results must be interpreted with caution, as the respondents may not constitute a representative sample of the IA population, yet warrant further research.
Background: Fatigue is one of the most prevalent and disabling symptoms of systemic sclerosis (SSc). No fatigue specific programs exist for people with SSc. The purpose of this pilot study was to evaluate changes in self-efficacy and use of energy conservation strategies after participation in Fatigue and Activity Management Education for Individuals with Systemic Sclerosis (FAME-iSS).

Methods: Adult participants were recruited from the Scleroderma Foundation chapters and social media to participate in a 6-week, virtual group program focused on SSc-related fatigue. Inclusion criteria: ≥18 years of age, access to device with videoconferencing capabilities, and at least moderate fatigue determined by degree, severity, and distress (scales: 1-10). The program, led by occupational therapists included sessions on factors related to fatigue, management of energy, pain, stress, physical activity and nutrition. At baseline, participants completed a demographic questionnaire, the Self-Efficacy for Performing Energy Conservation Strategies Assessment (SEPESCA) to measure confidence using energy conservation strategies. At post-intervention and 3-month follow-up, participants also completed the Energy Conservation Strategies Survey (ECSS) to identify use and effectiveness of 14 energy conservation strategies (e.g. changing body positions, planning and prioritizing activities, communicating needs) and a qualitative interview to contextualize their responses. Descriptive statistics (means, standard deviations) were used to analyze quantitative data.

Results: The sample for the pilot study included 18 participants (89% women; age 52 ± 11.6 years) with established SSc (disease duration= 13.7 ± 14.5 years). 83% participants completed 100% of FAME-iSS sessions. Directly following the program all 14 energy conservation strategies were used by at least seven (39%) participants. The most frequently used strategy was “planned day to balance rest and activity” which was used by 17 participants post-intervention. (see Table 1). At the three-month follow-up the there was a decline in use for 50% of the strategies and an increase in use for the other 50%.

Conclusion: This pilot study showed that FAME-iSS resulted in increased self-efficacy in use of energy conservation strategies in participants with established SSc. New behaviors were adopted that participants felt reduced their fatigue. The virtual format allowed for sharing of strategies and availability to more people.

Disclosure of Interests: None declared
Background: Physical activity is an important component in the management of people with rheumatoid arthritis (RA) [1]. A Physiotherapist-led Intervention to Promote Physical Activity in people with RA (PIPPRA) was undertaken using the Behaviour Change Wheel, with the aim of examining the feasibility of promoting physical activity in RA. This qualitative study involved participants and health care professionals that participated and were involved in a behaviour change pilot RCT intervention.

Objectives: To determine, qualitatively, the acceptability of PIPPRA to participants with RA and health care professionals, in order to capture their reality.

Methods: A qualitative study design of face-to-face semi-structured interviews was undertaken. The interview schedule explored the following areas: experiences of behaviour change intervention - “I found it very knowledgeable to help you get going” [2]; Improvement in self-management - “... motivate me to go back to doing a little bit more exercise”; Negative impact of COVID-19 on physical activity in RA. This qualitative study involved participants and health care professionals who participated and were involved in a behaviour change intervention.

Results: Fourteen participants [13 female/1 male; mean age of 59 (SD 6.3); mean RA diagnosis of 8.6 (SD 6.8) years; moderate to severe disability (HAQ-DI: 1.4 (SD 1.2)); 8 and healthcare staff [4 female/4 male; mean age of 41 (SD 5.6)] participated. Main themes were generated from participants: 1) Positive experience of behaviour change intervention - “I found it very knowledgeable to help you get going”; 2) Improvement in self-management - “… motivate me to go back to doing a little bit more exercise”; 3) Negative impact of COVID-19 on physical activity - “I don’t think doing it online again would be really good at all”. Two main themes from health care professionals - 1) Positive learning experience of behaviour change delivery - “Really made me realise the importance of discussing physical activity with patients”; 2) Positive approach to recruitment - “Very professional team showing the importance of having a study member on site”.

Conclusion: The findings demonstrated that participants had a positive experience of being involved in a behaviour change intervention in order to improve their physical activity and find it acceptable as an intervention. However, if given the choice they would prefer the intervention delivery face to face rather than telehealth. Healthcare professionals also had a positive experience and in particular found it beneficial to their own development, in particular the importance of recommending RA to patients.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2022-eular.87
Results: 110 respondents of working age took part, including 105 women (95.45%) and 5 men (4.55%). A mean age of the study participants was 32.8 ± 7.97 years, women were a mean age 32.6 ± 7.80, and men - 36.4 ± 11.44. The mean duration of the time experience of SLE a mean experience of 6.4 ± 4.08 years women 6.4 ± 5.77. High activity disease was observed in 37 people (35.2%), and mild and moderate activity - in 73 (64.8%). 59 women (56%) and 2 men (40%) responded positively to the question about the availability of paid work. The activity of the majority of working patients was associated with mental labor - 58 people (53%). Among the unemployed group of respondents, which made up 44%. The number of survey participants, 76% of respondents associate the lack of paid work with the presence of SLE. Absenteeism was zero in 38 patients (62.3%), which indicates that more than half of the patients did not miss work during all the analyzed days. 6 out of 38 (15.8%) had a high activity disease. A mean value of presenteeism in the group of actual workers during the study period was 50.45 ± 28.60% of working time. A mean value of absenteeism was 41.78 ± 36.73%. Work productivity loss in 61 patients with a job was 52.73 ± 30.55%, activity impairment, which was determined in all patients included in the study, was reduced by 51.68 ± 28.44%. In the course of our study, it was revealed that 44.5% of the surveyed patients with SLE of working age do not have a paid job. The absolute majority associate this fact with the influence of the disease on their ability to work. It is also important to say that 23 (37.7%) people out of 61 employees missed work due to their illness. Damage to the musculoskeletal system during the progression of SLE affects the ability to work, labor productivity and daily activity of the adult population is confirmed by the above indicators (presenteeism 50.45 ± 28.60%, absenteeism 41.78 ± 36.73%, work productivity loss 52.73 ± 30.55%, activity impairment 51.68 ± 28.44%).

Conclusion: Activity disease, functional insufficiency and damage developing as a result of the progression of SLE and ongoing therapy have a direct relationship with a decrease in labor productivity, disability and disability, which is confirmed by the values of presenteeism, absenteeism, work productivity loss and activity impairment.

POS1515-HPR UNDERSTANDING AND CHARACTERISING PATIENTs’ PATHWAYS TO TREATMENT FOR VERTEBRAL FRACTURES: A QUALITATIVE STUDY

S. E. Bennett1, R. Gooderman-Hill1, E. Clark1, Z. Paskins2, N. Walsh5, S. Drew1.
1University of Bristol, Bristol Medical School, Bristol, United Kingdom; 2Academic Rheumatology Centre, Midlands Partnership NHS Foundation Trust, Stoke-on-Trent, United Kingdom; 3University of the West of England - UWE Bristol, Centre for Health and Clinical Research, Bristol, United Kingdom

Background: Osteoporosis involves thinning of the bones, making them more prone to break. The most common osteoporotic fracture is a vertebral fracture (VF). People with Osteoporosis are at high risk of further fractures. To reduce this risk, guidelines recommend prescription of bone protection therapies to people who have experienced a fracture. However, many patients do not receive diagnosis. Understanding patient pathways to treatment for OVFs will provide information to improve practice and aid in effective identification and management.

Objectives: To understand and characterise patient pathways to treatment for OVFs.

Methods: Twenty-three semi-structured qualitative interviews were conducted with patients aged ≥50 years with diagnosis of OVf. Patients were recruited through two hospitals in England and were purposively sampled to capture variation in pathways to diagnosis, sex, age, comorbidities and other relevant characteristics. Interviews were audio-recorded, transcribed and analysed thematically, with themes transposed onto key stages of the patient pathway.

Results: Several factors were found to be associated with treatment: Patient appraisal and self-management: Characteristics and attitudes towards back pain impacted treatment-seeking behaviour. Patients who appraised their pain as ‘different’, ‘severe’ or ‘different’, or associated with an injury such as a fall, were more likely to seek help. Limited availability of information about OVFs and risk factors meant most patients did not associate symptoms with a potential OVF. Factors contributing to delayed consultation included the normalisation of back pain and prioritisation of comorbid conditions. Several misattributed their symptoms as a ‘pulled muscle’ or other minor injury. Many adopted strategies to manage pain, including use of painkillers, lying flat or resting. For some, a lack of improvement in symptoms over time, combined with worsening pain, created a ‘tippping point’ in seeking care. There was a moral dimension for some patients who did not want to ‘bother’ healthcare professionals.

CONCLUSION: Healthcare professionals, and patients, are influenced by Differentiation was a barrier to treatment and healthcare professionals interpreted OVF pain as broken ribs, muscular pain, kidney pain or sciatica. GPs tended to instigate watchful waiting, in which patients were asked to re-consult if pain did not improve. Feeling disbelieved caused some patients to become disillusioned and reluctant to re-consult and a small number of patients presented at Accident and Emergency. Those already having a limit for musculoskeletal conditions with access to specialist care, were more likely to receive timely diagnosis.

Communication of diagnosis: Patients discussed multiple methods of communication, including written communication and clinical conversations. Several expressed confusion around the use of unfamiliar medical terminology, the implications of OVFs, how many OVFs they had experienced and how they had been identified.

Treatment initiation: Bone protection therapies were not consistently prescribed after diagnosis. Patients who were familiar with these therapies were unsure whether treatment should be initiated in primary or secondary care. Patients described how they felt a need to be proactive by arranging appointments and asking for treatment.

Conclusion: The study provides novel findings about patient pathways to treatment and will be used to identify targeted solutions to improve management of OVFs. This work addresses stages of the Model of Pathways to Treatment[1] and provides detailed understanding of patients' experiences of these stages. Further work with healthcare professionals in primary care is underway to identify additional system-level factors that may impact patients' journeys to treatment.

POS1515-HPR - CONJUGAL RELATIONSHIPS IN MARRIED PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISMS

O. Hamdi1, S. Jemmi1, S. Boussaid1, S. Rahmouni1, S. Rekki1, H. Sahli1, M. Elleuch1,2.
1La Rabta hospital, Rheumatology, Tunisia, Tunisia

Background: The consequences of chronic inflammatory rheumatisms (CIR) on the sexuality and the relationships between the subject and his/her partner are still underestimated and insufficiently studied.

Objectives: The aim of this study was to investigate the impact of CIR on conjugal relationships.

Methods: We conducted a cross-sectional study involving patients with rheumatoid arthritis (RA) (2010 ACR/EULAR criteria) and spondyloarthritics (SpA) (2009 ASAS criteria). All the patients included in the study were married. We collected demographic data, and participants were asked to complete a questionnaire on their conjugal relationships.

Results: We enrolled 75 patients (40 RA and 35 SpA) with a sex ratio of 0.4 and a mean age of 55.35 ± 9.81 years [22-85]. The mean chronic CIR duration was 18 years. The mean age of marriage was 27 ± 6.41 years [19-33]. The mean number of off-springs was 4. Forty-nine percent of patients and 22.3% of the partners had a profession, respectively. Forty one percent of the partners had a chronic disease: diabetes (n=12), hypertension (n=10), dyslipidemia (n=7), CIR (n=7), coronary disease (n=5), and other conditions (n=5). A psychiatric illness was noted in 22.6% of cases: depression (n=9), anxiety (n=6), and bipolar disorder (n=2). Sixty-four percent of patients consider their spouses sympathetic to their illness. Eighty-nine percent of participants have noticed a change in their life as a couple before and after the CIR onset. According to 64% of participants, the CIR had a negative impact on their married lives. The spouses' emotional reactions to the disease were as follows: indifference (30.6%), denial (29.3%), anger (26.6%), and fear (13.3%). Patients reported being accompanied by their spouses to their medical appointments in 36% of cases, and 40% of them were asked questions by their spouses about their disease and treatment. The CIR has resulted in the termination of the marriage in 2.6% of cases.
Inclusion: Patients suffering from chronic diseases such as CIR are more frequently exposed to difficulties in their conjugal relationships. The disease has thus important consequences on the subject's quality of life, emotional and interpersonal state. A better compliance with the chronic disease and its treatment may improve the couples' relationships.

CHRONIC INFLAMMATORY RHEUMATISMS: DOES PERIODIC FASTING REDUCE THE DISEASE ACTIVITY?

O. Hamdi1, S. Jemmali2, W. Kammoun3, S. Bousaid4, S. Rahmouni5, S. Reki1, H. Sahli1, M. Elleuch1. 1La Rabta hospital, Rheumatology, Tunisia, Tunisia; 2Pasteur Institute, Immunology, Tunisia, Tunisia

Background: Many experimental studies have emphasized the role of periodic fasting in the adaptive responses that reduce inflammation.

Objectives: Our purpose was to assess the impact of periodic fasting on the activity of chronic inflammatory rheumatisms (CIR).

Methods: We conducted a cross-sectional study involving patients with rheumatoid arthritis (RA) (2010 ACR/EULAR criteria) and spondyloarthritis (SpA) (2009 ASAS criteria). CIR activity was assessed during the period of Ramadan (periodic fasting) and three months following Ramadan using clinical parameters including the Patient's Global Assessment of disease activity (PGA), 10-cm Visual Analog Scale (VAS) pain score, morning stiffness, nocturnal awakenings, and joint count for RA (tender joint count (TJC) and swollen joint count (SJC)); biological parameters including C-reactive protein (CRP); disease activity scores including the SDAI, CDAI and DAS28 CRP.

Results: Eight participants with rheumatoid arthritis: seven females; mean [standard deviation, SD] age 52.4 [9.5] years; mean [SD] disease duration 16.1 [16.4] years; eight clinicians; mean [SD] age 46.75 [5.3] years; mean [SD] years of clinical experience 19.5 [2.21] years. Four main themes were identified (Table 1): ‘Feet are a priority’ as the impact of RA on the feet was substantial and had a negative impact on quality of life. The second theme was ‘Need for a clinically feasible foot PROM’ as clinicians and patients recognised the lack of a clinically feasible tool that can determine RA foot disease. The third emerging theme was ‘RADAI-F5 facilitators’ as the tool can promote communication, guide management, help screen foot symptoms, monitor foot disease status and treatments longitudinally, and promote patient education. The final theme was ‘RADAI-F5 barriers’ as there were associated practical difficulties, including lack of appointment time, administrative burdens associated with PROM use, lack of trust in the RADAI-F5’s validity and IT barriers since there is no universal electronic system for reporting RADAI-F5 results.

Table 1. Themes with respective quotes that emerged as part of the individual interviews to understand the clinical utility of the RADAI-F5

<table>
<thead>
<tr>
<th>Theme</th>
<th>Quotations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Theme 1: Feet are important</td>
<td>“Foot disease is common and it’s troublesome for patients.” (C16)</td>
</tr>
<tr>
<td>Theme 2: Existing methods for measuring foot disease activity are inadequate</td>
<td>“The feet are under-represented in the clinical tools for assessing disease activity, and clinicians don’t look at feet enough.” (C11)</td>
</tr>
<tr>
<td>Theme 3: RADAI-F5 facilitators</td>
<td>“I think (The RADAI-F5) improves the clinician-patient relationship.” (C15)</td>
</tr>
<tr>
<td>Theme 4: RADAI-F5 barriers</td>
<td>“I mean, this (RADAI-F5) will obviously go along with other tools. You know, the blood tests and things as well.” (P01)</td>
</tr>
</tbody>
</table>

Conclusion: The RADAI-F5 has significant potential as a therapeutic tool to aid in managing foot disease in RA. However, several implementation barriers need to be overcome before widespread use in rheumatology clinics can occur.

PATIENT AND CLINICIAN PERSPECTIVES ON IMPLEMENTING THE RADAI-F5 TOOL TO HELP INFORM THE ASSESSMENT AND MANAGEMENT OF FOOT DISEASE IN RA: A QUALITATIVE STUDY

A. Hoque1, D. Dickson1, M. Steultjens1, G. Hendry1. 1Braga, Portugal

Background: While patient-reported outcome measures (PROMs) are widely recommended in clinical care, their application is limited [1]. The RADAI-F5 is a validated PROM to determine RA foot disease activity [2]. Patients’ and clinicians’ perceptions of the RADAI-F5’s clinical utility have yet to be captured.

Objectives: This study aims to explore patient and clinician opinions and perceptions of the clinical utility of the RADAI-F5 in managing rheumatoid foot disease.

Methods: A 60-minute semi-structured interview using video conference calls with adult RA patients and rheumatologists, physiotherapists, and podiatrists was conducted as part of the interpretive phenomenological analysis research. The interviews included open-ended questions about the effect of foot disease, current clinical utilization of PROMs, and barriers and facilitators to the clinical application of the RADAI-F5.

Results: Twenty-five patients (female 72.4%, male 27.6%; mean age 51.0 ± 13.2 years; education ≤ 9 years 39.7%, ≥ 9 years 60.3%). Of these, 33 had a diagnosis of RA and 25 of PsA (mean years of disease duration = 8.2 ± 7.3 years; mean disease activity by DAS28-PCR or DAS28-PCR 3 variables = 2.3 ± 0.95). Between March 2021 and June 2021, a brief questionnaire was applied with sociodemographic and clinical variables, such as the use of classic or biological DMARDs and their administration’s route. The Specific Beliefs About Medication Scale (BMQ) was anonymously applied, adapted from the Beliefs About Medicines Questionnaire, comprising 2 sections: section 1 – Specific Needs, patients beliefs about the need for medication;
section 2 – Specific Concerns, beliefs related to the dangers of addiction and long-term toxicity or side effects. Higher scores (scale from 5 to 25 points), in sections 1 and 2, reflect the belief of greater need and greater concern regarding medication, respectively. The average scores in section 1 and in section 2 of the BMQ were 9 and 15.7 points, respectively. Statistics: descriptive, Student t-Test, Pearson Correlation and ANOVA, p<0.05.

Results: Patients with PsA and younger age had a higher mean score in section 2 of the BMQ (p<0.049 and p<0.01, respectively). The variables male gender, education ≥ 9 years and shorter duration of the disease also showed a tendency to be associated with the higher score in section 2 of the BMQ, with p-values close to statistical significance (p=0.091, p<0.074 and p=0.094, respectively). In the multivariate analysis with the above variables, only the diagnosis of PsA showed a statistically significant association with the score in section 2 of the BMQ (B=-4.269; p<0.001; CI 95%=[-2.060-6.477]). There was also a statistically significant correlation (p<0.007) between the scores in section 1 and section 2 of the BMQ.

Conclusion: Patients with PsA and younger age are more concerned about the possible adverse effects of medication than patients with RA. RA patients who take subcutaneous drugs are more afraid of the drug’s toxic potential, and those with lower disease activity have a greater need to comply with the prescribed therapy, which can be explained by the previous effectiveness of the drug in disease control. It was also found that the greater the belief in the need for medication, the greater the concern with its possible long-term harmful effects.

RHEUMATOLOGY PATIENTS TREATED WITH A BDMARD PERSPECTIVE TOWARDS THERAPEUTIC DRUG MONITORING

M. Leeuw1, S. Atiq1, F. De Vries2, L. Boekel1, F. Hooijberg1, M. Nurmohamed1,2, G. J. Wolbink1,2, C. Krieknaert1.

1Reade, Locatie Dr. Jan Van Bremenstraat, Rheumatology, Amsterdam, Netherlands; 2OL VG, Location East, Pharmacology, Amsterdam, Netherlands; 3Amsterdam UMC, Locatie VUmc, Rheumatology, Amsterdam, Netherlands; 4Sanquin Blood Supply, Immunopathology, Amsterdam, Netherlands; *OL VG, Location East, Rheumatology, Amsterdam, Netherlands

Background: Therapeutic Drug Monitoring (TDM) is a tool to determine the optimal dose of a drug for individual patients using measurement of blood concentrations and, optionally, anti-drug antibodies (ADA). In the field of rheumatology interest in applying TDM is increasing. A recent study by Syversen et al., the NOR-DRUM B trail, supports TDM as a treatment strategy. This study showed that treatment with proactive TDM was more effective than treatment without TDM. Applying TDM creates a more personalized treatment for individual patients, therefore it is relevant to understand the patients perception towards TDM.

Objectives: To study the perspective of rheumatology patients treated with a bDMARD in a personalized fashion using TDM.

Methods: Adult rheumatology patients from the Amsterdam Rheumatology and Immunology Center who participate in the COVID-19 prospective cohort study (Netherlands Trial Register, trial ID NL8513) received a digital questionnaire which comprised, in addition to demographic items, of three TDM topics: familiarity, attitude and risk assessment.

Results: Participants were selected based on the following criteria: treatment with a bDMARD and a fully completed questionnaire (n=888). Table 1 shows characteristics of study population.

* Some patients reported more than one diagnosis** Three patients reported more than one bDMARD

Sixty-six percent (n=582) of the participants had never heard of the concept personalized dosing, using TDM. After explaining the concept 60% (n=535) of the participants answered they have a positive attitude towards the concept. Participants with a positive attitude received a follow-up question. They were asked which of the following related aspects: individual dosing, costs, safety and other, they thought was most relevant regarding the concept. Multiple answers were possible. Ninety-four percent (n=502) reported as the main reason for having a positive attitude, that the treatment can be personally adjusted. The second and third reasons, respectively, were safety 43% (n=230) and costs 27% (n=142) of the treatment.
Five percent (n=43) of the participants had a negative attitude towards the concept. Main reasons were; previous experience with unsuccessful dose reduction and unwillingness to change current treatment due to the fact that several previous treatments were ineffective. Participants were also asked what amount of risk they are willing to take when presented with five different situations; worsening rheumatological symptoms: e.g. pain and swelling, increased fatigability, necessary treatment with prednisone, switching to another bDMARD or more frequent visits to rheumatologist. Majority of the patients reported for each of the five situations, respectively: 37% (n=330), 40% (n=359), 51% (n=453), 48% (n=426) and 29% (n=262) that they would only be willing to take a negligible risk, < 0.1%. 

Conclusion: Majority of participants was not familiar with the concept of personalized dosing using TDM. However, the majority had a positive attitude towards the concept. The main reason for a positive attitude is that the treatment can be personally adjusted. On the other hand, patients who are currently being treated with a bDMARD were only willing to take a negligible risk when it comes to their own treatment.

REFERENCES:
Background: Patients with chronic disease need to learn and adapt to symptoms, treatment, and the impact of disease. Knowledge about the specific disease is one way to empower the patients to cope. We previously reported that disease duration and sex, rather than disease characteristics associate with an increased need of educational support in AAV associated vasculitis (AAV) [1]. Data on how specific educational needs vary between different inflammatory rheumatic diseases are lacking.

Objectives: The aim of the study was to compare educational needs among two chronic systemic inflammatory diseases, AAV and Systemic lupus erythematosus (SLE) using the Educational Needs Assessment Tool (ENAT).

Methods: This pilot study included cross-sectional data from two separate cohorts, AAV and SLE, from the Rheumatology clinic at Karolinska University Hospital in Sweden during 2009-2022. Inclusion criteria were minimum age of 18 years and literate in Swedish. Exclusion criterion was cognitive impairment interfering with literate capabilities. Educational needs were captured by patients’ answers to the questionnaire ENAT. The ENAT consists of 39 questions, presented as total ENAT and seven domains (managing pain, movement, feelings, disease process, treatment, self-management and, support systems) each containing 4-7 items (from ‘not at all important’ = 0, to ‘extremely important’ = 3). The participants’ responses were presented as ‘mean % of the domain score’ from 0 interpreted as no educational need to 100 as highest educational need. Participants with SLE and AAV respectively were individually matched for disease duration, sex, and education. For comparisons paired samples t-test were used.

Results: Twenty-two matched pairs (86% female), mean (SD) disease duration 5.7 (8) years, were included. The mean age were 43 (14.0) years for AAV 61 and (14.7) years for SLE (p=0.001), Educational length was reported as mean 14 (3.6) years among SLE patients and 13 (2.9) years among AAV patients (p=0.111). In all patients, the mean total ENAT was 60.4% (range 23-100%) and did not differ between the two cohorts (p=0.2) (Table 1). In the pooled group the highest educational need was found in the domains ‘Disease process’ (mean 78.3%) and ‘Self-management’ (mean 75.9%). Lowest educational need was found in the domains ‘Movement’ (mean 46.7%) and ‘Managing pain’ (mean 51.6%).

</tr>
</tbody>
</table>

Patients with AAV report a higher educational need in total ENAT as well as in all individual domains, compared to SLE (Table 1), but only significantly in the domain ‘Treatments’ where the educational need among AAV was mean 74.2% (30.4) and for SLE mean 46.4% (SD 36.0) (p = 0.02).

Conclusion: In this pilot study with SLE and AAV, we found educational needs regarding ‘Treatments’ to be substantially increased among the participants with AAV compared to SLE, despite that the participants were matched for disease duration and sex, two variables previously found to be indicators of increased educational needs. AAV patients with higher educational needs were older, this result needs to be further explored in a larger sample.

*Statement excludes results from 4 patients who did not complete the second page of the survey.
Conclusion: The results demonstrate the high level of patient satisfaction attained from the Specialist Pharmacist clinic. A small number of patients remain sceptical about medication safety, despite discussion. Inclusion of a pharmacist is especially useful to manage the increasing number of patients starting these medications, maintaining excellent patient experience, reducing the workload for other Rheumatology staff, and ensuring a robust MDT.

Figure 1. Participants’ responses to each treatment

Introduction

A cross-sectional, online survey-based study was conducted in Sweden. People with diagnosed knee or hip OA were recruited through social media outlets and patients’ associations. The survey was divided into two sections: (i) participants’ demographic and clinical characteristics (e.g. gender, age, income, work, height, weight, level of physical activity, previous surgeries, pain, level of disability) and (ii) a set of items with 22 treatments (e.g., weight advice, physical activity, supplements, etc.) where participants were asked to report whether each treatment was ‘recommended’, ‘optional’, ‘not recommended’, or ‘I don’t know’ for the management of knee or hip OA. In the analyses, we grouped the 22 proposed treatments into ‘recommended’, ‘optional’, ‘not recommended’, and ‘I don’t know’ for the management of knee or hip OA. In the analyses, we grouped the 22 proposed treatments into ‘recommended’, ‘optional’, and ‘not recommended’ according to existing international guidelines. Based on the responses, participants were categorised as ‘aware’ if they correctly identified all the treatments, ‘partially aware’ if they correctly identified at least one treatment, and ‘not aware’ if they did not correctly identify any of the treatments.

Methods: A cross-sectional, online survey-based study was conducted in Sweden. People with diagnosed knee or hip OA were recruited through social media outlets and patients’ associations. The survey was divided into two sections: (i) participants’ demographic and clinical characteristics (e.g. gender, age, income, work, height, weight, level of physical activity, previous surgeries, pain, level of disability) and (ii) a set of items with 22 treatments (e.g., weight advice, physical activity, supplements, etc.) where participants were asked to report whether each treatment was ‘recommended’, ‘optional’, ‘not recommended’, or ‘I don’t know’ for the management of knee or hip OA. In the analyses, we grouped the 22 proposed treatments into ‘recommended’, ‘optional’, and ‘not recommended’ according to existing international guidelines. Based on the responses, participants were categorised as ‘aware’ if they correctly identified all the treatments, ‘partially aware’ if they correctly identified at least one treatment, and ‘not aware’ if they did not correctly identify any of the treatments. Participants comprised 123 people with OA of the knee, hip or both (N=65, 22%; N=27, 22% and N=33, 26% respectively). Their mean (SD) age was 60.3 (8.8) and 108 (88%) were women. Forty-eight (39%) were ‘aware’ of the recommended treatments, 63 (50%) ‘partially aware’ and 14 (11%) were ‘not aware’ of the treatments. Two (2%) were ‘aware’, 103 (82%) ‘partially aware’ and 20 (16%) were ‘not aware’. For the treatments that were not-recommended, none was ‘aware’, while 69 (55%) and 56 (45%) were considered ‘partially aware’ and ‘not aware’, respectively. Figure 1 summarises the responses of the participants to each treatment item.

Results: Participants comprised 123 people with OA of the knee, hip or both (N=65, 22%; N=27, 22% and N=33, 26% respectively). Their mean (SD) age was 60.3 (8.8) and 108 (88%) were women. Forty-eight (39%) were ‘aware’ of the recommended treatments, 63 (50%) ‘partially aware’ and 14 (11%) were ‘not aware’ of the treatments. Two (2%) were ‘aware’, 103 (82%) ‘partially aware’ and 20 (16%) were ‘not aware’. For the treatments that were not-recommended, none was ‘aware’, while 69 (55%) and 56 (45%) were considered ‘partially aware’ and ‘not aware’, respectively. Figure 1 summarises the responses of the participants to each treatment item.

Conclusions: Survey participants seem to be more aware of the recommended treatments than the optional and non-recommended ones. A more holistic approach in the education of people with OA should be pursued, providing them with a complete overview of the possible OA treatments. This would help patients identify the most appropriate treatment option for their OA and facilitate a shared decision-making with their health professionals.

problems at various moments along their patient journey; this population can benefit from more continuous information about their medication and healthcare provider support to manage drug-related problems. To most effectively employ telehealth applications for individuals with a rheumatic disease, it is important that offered technologies match with patients’ needs and preferences.

**Objectives:** Identify factors influencing the preference of patients with rheumatic diseases regarding telehealth applications.

**Methods:** A qualitative descriptive study was performed in the Netherlands between May and June 2021. Using a semi-structured interview guide, patients with a rheumatic disease were interviewed face-to-face. First, patients were presented four telehealth applications (frequently asked questions page, digital human, and chatting with video calling with healthcare providers). Second, patients were asked to use each application to answer one medication-related question predefined by the research team. During the process of finding an answer to the question, patients were asked to think aloud and were questioned on which factors influenced their experience and preference for each application. Third, patients were given additional hypothetical questions after which they were asked to explain their preferred application for answering the question, to elicit additional factors influencing preference. Interviews were audio recorded, transcribed verbatim and analysed thematically.

**Results:** Fifteen patients (aged 19–73 years, 53% female) participated. Three domains influenced patients’ preference for telehealth applications. First, preference for telehealth applications was influenced by factors related to individual patients such as medication-related information needs, literacy, and skills with digital applications. Second, preference was influenced by factors related to the specific applications such as speed of answer, level of interaction, extent of privacy, the perceived usefulness of an application, and usability of the application. Third, preference was influenced by factors related to the context in which telehealth applications are offered, such as the support from healthcare providers in using telehealth applications, reliability of information source, and potential of telehealth to save time for healthcare providers.

**Conclusion:** Patients’ preference for telehealth applications is influenced by patient-related, application-related and context-related factors. To effectively support patients with rheumatic diseases, telehealth applications should match with patients’ preferences. Furthermore, it is important to offer a variety of telehealth applications as preferences differ among patients and circumstances.

**HEALTH PROMOTION IN INDIVIDUALS WITH KNEE PAIN – DIFFERENT WAYS TO ENABLE AND MAINTAIN A BALANCE IN EVERYDAY LIFE BASED ON THE ABILITIES**

C. Sylwander1,2, M. Andersson1,2, E. Haglund3,4, E. Sunesson1, I. Larsson1,2,3

**Background:** Most individuals with knee pain develop radiographic knee osteoarthritis (KOA) with axSpA aged between 40 to 65 were included. Frailty status was determined using KOA checklist. Patients were groups as pre-frail, frail and robust individuals. Frailty was accepted as pre-frail, +4 pre-frail, frail. Nutritional status, disease activity, functional level and quality of life were assessed using Mini Nutritional Assessment (MNA), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankiloan Spondylitis Functional Index (BASFI), Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL) respectively. Analysis of variance and multivariate linear regression analyses were used to assess group differences and factors associated with frailty status.

**Methods:** In this monocentric cross-sectional study 50 patients (26 women) with axSpA aged between 40 to 65 were included. Frailty status was determined using KOA checklist. Patients were groups as pre-frail, frail and robust individuals. Frailty was accepted as pre-frail, +4 pre-frail, frail. Nutritional status, disease activity, functional level and quality of life were assessed using Mini Nutritional Assessment (MNA), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankiloan Spondylitis Functional Index (BASFI), Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL) respectively. Analysis of variance and multivariate linear regression analyses were used to assess group differences and factors associated with frailty status.

**Results:** The mean age of the patients was 51.7±8.77, the mean disease duration was 7.8±4.1 years, the mean body mass index was 29.98±4.72kg/m². Twenty-one patients were classified as frail, 16 was pre-frail and 13 was robust. Compared to robust patients, pre-frail and frail individuals had significantly higher BASFI, BASDAI and ASQoL scores. There was a significant high correlation between the KOA checklist score and worse BASFI (r=0.62, p<0.001), BASDAI (0.62, p<0.001), ASQoL scores (0.73, p<0.001). Poor nutritional status was moderately correlated with frailty index score (r=0.53, p<0.001). In multivariable linear regression analysis, nutritional status and level of quality of life were independently associated with frailty index score (p<0.001).

**FACTORS ASSOCIATED WITH FRAILTY STATUS IN PATIENTS WITH AXIAL SpondyloArthritis**

Ö. Öztürk1, Ö. Feyezioglu2, 1Acibadem Mehmet Ali Aydinlar University, Physiotherapy and Rehabilitation, Istanbul, Turkey

**Background:** Frailty is characterized by increased fatigue and vulnerability which leads to adverse health outcomes. Recent studies have reported the increased prevalence of frailty in various rheumatological diseases regardless of age. However, information about the prevalence of frailty in patients with axial spondyloarthritis (axSpA) is limited.

**Objectives:** This study aims to determine prevalence of frailty and its associated factors in patients with axial spondyloarthritis (axSpA).

**Methods:** In this monocentric cross-sectional study 50 patients (26 women) with axSpA aged between 40 to 65 were included. Frailty status was determined using KOA checklist. Patients were groups as pre-frail, frail and robust individuals. Frailty was accepted as pre-frail, +4 pre-frail, frail. Nutritional status, disease activity, functional level and quality of life were assessed using Mini Nutritional Assessment (MNA), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankiloan Spondylitis Functional Index (BASFI), Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL) respectively. Analysis of variance and multivariate linear regression analyses were used to assess group differences and factors associated with frailty status.

**Results:** The mean age of the patients was 51.7±8.77; the mean disease duration was 7.8±4.1 years, the mean body mass index was 29.98±4.72kg/m². Twenty-one patients were classified as frail, 16 was pre-frail and 13 was robust. Compared to robust patients, pre-frail and frail individuals had significantly higher BASFI, BASDAI and ASQoL scores. There was a significant high correlation between the KOA checklist score and worse BASFI (r=0.62, p<0.001), BASDAI (0.62, p<0.001), ASQoL scores (0.73, p<0.001). Poor nutritional status was moderately correlated with frailty index score (r=0.53, p<0.001). In multivariable linear regression analysis, nutritional status and level of quality of life were independently associated with frailty index score (p<0.001).

**Disclosure of Interests:** None declared

BMI: body mass index, BASDAI: Bath Ankylosing Spondylitis Disease Activity Index, BASFI: Bath Anklozai Spondylitis Quality of Life Questionnaire, P1: P value between robust and pre-frail individuals, P2: P value between robust and frail individuals, P3: P value between robust and frail individuals.

Conclusion: Frailty or pre-frailty is common in patients with axSpA and the main factors associated with frailty status were poor nutritional status and level of quality of life. Since it is a reversible condition, identifying the frailty status and its associated factors may help to prevent further decline in functional level and to design appropriate treatment interventions. Further studies are needed to determine frailty prevalence and its predictors in patients with axSpA.

POS1539-HPR | RHEUMATIC MUSCULOSKELETAL DISEASES (RMDS) DURING THE FIRST WAVE OF THE COVID19 PANDEMIC: PATIENTS’ POINT OF VIEW ON THE ROLE OF TELEMEDICINE

K. El Acyoud, K. Melis, M. Balzani, S. Guiducci, S. Bellando Randone, S. Barbosa, L. Rasero, M. Maturco-Cerinic University of Florence, Department of Clinical and Experimential Medicine, Florence, Italy; 'Careggi Hospital, Department of Geriatric Medicine, Division of Rheumatology, Florence, Italy; 'University of Florence, Department of Health Science, Florence, Italy; 'IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR), Milan, Italy

Background: The COVID19 pandemic has caused health problems in people’s daily lives with a significant psychological impact. In fact, patients with RMDs have experienced diseases flare and also psychological problems. The lockdown and the “social quality changes” have impacted the life and the well-being of RMDs patients, influencing directly the implementation of telemedicine during daily practice.

Objectives: A descriptive observational study was designed to analyse the short-term effect of the first wave on RMDs patients on social quality changes and the usefulness of telemedicine.

Methods: The survey was carried out by administering a questionnaire consisting of 30 questions, developed ad hoc using Likert scales, items such as family and work environment, access to healthcare facilities, healthcare provided to patient, patient activity and the mental health status of individuals (anxiety / depressive symptoms) were investigated. Preliminary data on the first wave were collected between September and November 2021 through patient associations and social networks.

Results: 40 RMDs patients (Rheumatoid Arthritis 57.5%, Psoriatic Arthritis 35%, Fibromyalgia and others 7.5%) prevalently women (97.5%) were included in the survey. During the pandemic, 72% of respondents reported cancellation or delays in scheduled appointments and 50% did not have alternative contacts (telephone consultations, e-mail prescriptions, telematics training) with the hospital. 40.5% of patients reported difficulty in finding DMARDs and material for the treatment of ulcers, 28.2% reported difficulties in accessing the health facilities. In particular, 34.2% reported the total closure of the hospital facilities. Moreover, our data show a worsening of health status due to an increased anxiety concerning the management of their RMDs, an increased stress within the
family, a reduced access to care facilities due to their closure or travel restrictions. In 57% of patients, a worsening of health status was reported, while in 90% stress and a feeling of abandonment was developed since the beginning of the pandemic. In this context, telemedicine was considered useful by 97.5% of patients, although patients felt that an improvement was necessary with an integration with the regular follow up.

Conclusion: Patients with RMDs reported that the significant delays or cancellation of the outpatient visits provoked an increase of stress, worry and anxiety for their health. The majority was very concerned about the overall management of their RMDs. The worsening of symptoms in more than half of the patients was the most worrisome observation. Almost all patients agreed that Telemedicine might help the clinical evaluation of their RMDs, also providing a significant support to their psychological condition because of the direct contact with the caring physician and health professionals.

POST1531-HPR

PATIENT-REPORTED ADVERSE DRUG REACTIONS ATTRIBUTED TO THE USE OF ETANERCEPT: DISTINCTION BASED ON NATURE, FREQUENCY AND BURDEN

L. Van Boxem1, H. Gosset1, S. Tas2, B. Van den Bemt3, H. Vonkeman4, F. Hoentjen1, M. Nurmohamed5, M. Van Doorn6, N. Jessurun1. 1Netherlands Pharmacovigilance Centre Lareb, Dutch Biologic Monitor, s-Hertogenbosch, Netherlands; 2Amsterdam UMC, locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 3Sint Maartenskliniek, Pharmacy, Research and Innovation, Utrecht, Netherlands; 4Medisch spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands; 5University of Alberta Hospital, Division of Gastroenterology, Edmonton, Netherlands; 6Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; 7Erasmus MC, Dermatology, Rotterdam, Netherlands

Background: Research regarding adverse drug reactions (ADRs) associated with the use of etanercept in patients with inflammatory rheumatic diseases (IRDs) usually focuses on the nature and frequency of ADRs without considering the burden of the ADRs. However, not every ADR causes the same burden for patients. Information is lacking about the degree of experienced burden per ADR by patients with IRDs.

Objectives: First, to describe ADRs of etanercept based on nature, frequency and burden, and second, to propose a new model for identification of relevant ADRs for health care professionals.

Methods: Data of the Dutch Biologic Monitor (DBM) was used to categorize patient-reported ADRs into high and low burden. In this prospective cohort event monitoring system patients were asked to fill out bimonthly questionnaires on experienced ADRs that they attributed to the use of a biological DMAP. The questionnaire included a quantification of the burden of the reported ADRs using a five-point Likert scale ranging from 1 (no burden) to 5 (very high burden). The nature of the reported ADRs were grouped into preferred terms (PTs) according to the Medical Dictionary for Regulatory Activities (MedDRA). Inclusion criteria for this study were patients with IRDs using etanercept and who reported an ADR with at least one burden score. For every patient, the mean burden scores per ADR were analyzed. The burden was classified in two categories: 'high' when the mean burden score was equal to or more than 2.5, and 'low' when it was less than 2.5. Text analytics of the reported ADRs (MedDRA PTs) and a comparison word cloud were used to visualize ADRs that were more often reported with high burden or more often reported with low burden. For this, the relative ADR frequencies of the low burden classes were subtracted from the relative frequencies of the high burden class, resulting in a percentual difference between the high and low burden class for every ADR. Therefore, the highest percentual difference corresponds to the ADRs that are experienced as most burdensome.

Results: A total of 187 patients (70% female) met the inclusion criteria and reported 905 ADRs, of which 373 (41%) were reported with high burden (see Table 1). The word cloud (Figure 1) visualizes which ADRs were more often reported with high or low burden. These ADRs correspond to the greatest difference in relative class frequency. Patients experienced the burden of headache, pneumonia and pruritis mainly as high, and the burden of injection site pruritus and injection site erythema as low.

</tr>
</tbody>
</table>

Figure 1. Comparison word cloud visualizing adverse drug reactions (ADRs) that patients reported more often with high burden (orange) and with no to low burden (blue). An ADR increases in size if the relative difference in frequency between classes increases.

Conclusion: The outcomes of the word cloud reveal that headache is more often experienced as burdensome which is an unexpected outcome. Visualizing the nature, the frequency and the burden of ADRs in one picture, provides simple guidance to the degree of relevance for the reported ADRs in clinical practice.

Comparison of hand functions and functional status in patients with limited cutaneous systemic sclerosis and diffuse cutaneous systemic sclerosis

E. A. Akatay1, D. Bayraktar2, E. Otman Akad2, O. Ustün1, I. Kurut3, Aysin3, D. C. Saraç2, B. Atalay2, I. Ramazanoglu1, I. Tekin2, T. Kurum2, S. Gucenmez2, M. Ozmen2, S. Akar3. 111017, 041217

Background: Systemic Sclerosis (SSc) is an autoimmune connective tissue disorder which is characterised by the fibrotic changes in the skin effecting especially fingers and hands. Regarding skin manifestations, SSc is classified into two different subtypes as limited cutaneous SSc (lcSSc) and diffuse cutaneous SSc (dcSSc).

Objectives: The aim of the present study was to compare hand functions and functional status in patients with lcSSc and dcSSc.

Methods: Twenty-three patients with lcSSc and thirteen patients with dcSSc were included in the study. Modified Hand Mobility in Scleroderma Test (mHAMIS), modified Rodnan skin score (mRSS), grip and pinch strengths were measured to evaluate hand-related physical characteristics. Duruoz Hand Index, Disability of Arm, Shoulder and Hand Questionnaire (DASH), Health Assessment Questionnaire (HAQ), and Scleroderma Health Assessment Questionnaire (SHAQ) were used as the outcomes.

Results: While differences were detected in mRSS scores between disease subtypes (p<0.05), hand functions and functional status were comparable between groups (p>0.05).

</tbody>
</table>

*Age was missing for 1 male and 1 female patient. Patients could report multiple indications. 5 male and 14 female participants also reported other indications. Reporting comedication at the moment of inclusion. Eleven patients (male=3, female=8) did not start with etanercept or adalimumab at the moment they were included. In these cases, comedication is counted from the moment they reported the start of adalimumab or etanercept treatment.

Conclusion: Although women reported the majority of the ADRs, there was a trend that men experienced certain ADRs as more burdensome in comparison to women, albeit this did not reach statistical significance.

REFERENCES:  
Background: Joint position sense is a marker of proprioception and is defined as being aware of the body position and individual body parts in the space. Position sense in the wrist joint is especially important for the manual dexterity. A possible damage due to arthritis may lead to a decrease in joint position sense. However, the status of joint position sense was not investigated in children with juvenile idiopathic arthritis (JIA).

Objectives: To compare the wrist position sense and a motor performance test related to manual dexterity among children with JIA with wrist arthritis history (JIAWrist+), children with JIA without wrist arthritis history (JIAWrist−), and healthy controls.

Methods: A total of sixty children (26 children for each group) were included in the study. Wrist joint position sense was evaluated by measuring joint re-position error. The wrist was passively placed in a pre-determined position (30° for flexion, 30° for extension, 10° for radial deviation, and 15° for ulnar deviation). Then passively was returned to baseline position. The patient was asked to reposition their wrist into the target degree actively. The absolute error in degrees between each position and reposition was calculated. Manual dexterity was evaluated by using Purdue Pegboard Test. The test was repeated three times and the average number of the correctly placed pines was used in the analysis.

Results: Joint position sense (in all directions except radial deviation) and manual dexterity (except assembly) was found negatively affected in JIAWrist+ patients compared to healthy controls. No differences (except radial deviation) were observed between JIAWrist− patients and healthy controls.

Conclusion: Joint position sense and related manual dexterity is diminished in JIA patients with wrist involvement. The results of this study suggested that children with wrist arthritis should be followed with special attention focusing on manual abilities. Hand therapy programs might help improving joint position sense acuity.

*Kruskal-Wallis Analysis, **Mann-Whitney U Test, ***Chi-Square Test, p<0.05. JIAWrist+ children with JIA with wrist arthritis history; JIAWrist−: children with JIA without wrist arthritis history; NA: not applicable, p1: JIAWrist+ vs. JIAWrist−; p2: JIAWrist+ vs. healthy controls; p3: JIAWrist− vs. healthy controls.
**Background:** Distal stabilization is an essential component for high quality proximal movement. In this regard, scapular stabilization is important for upper extremity and hand functions. Moreover, scapular stabilization might have a role as a support point for hand functions in patients with joint problems. However, the relationships between scapular stabilization and hand functions were not investigated in children with juvenile idiopathic arthritis (JIA).

**Objectives:** To investigate the relationship between scapular stabilization and hand function in children with JIA with wrist arthritis history (JIAWrist+), and children with JIA without wrist arthritis history (JIAWrist-).

**Methods:** A total of forty children (20 children for each group) were included in the study. Scapular stabilization was measured by using scapular muscle endurance test. General functional status, subjective hand functions, and objective hand functions were assessed by using Childhood Health Assessment Questionnaire (CHAQ), Duruoz Hand Index, and Purdue Pegboard Test, respectively. **Results:** JIAWrist+ patients reported poorer hand functions compared to JIAWrist- patients. No significant differences were detected for other parameters. Scapular muscle endurance was moderately related to CHAQ Disability Index score, Purdue Pegboard Test Assembly (single hand score and assembly score) in JIAWrist+ patients, while there was only a significant relationship between scapular muscle endurance and Purdue Pegboard Test both hand score in JIAWrist- patients.

**Results:** Enthesitis related arthritis was the most common JIA subtype in the study (38.2%) followed by oligoarthritis (26.5%), polyarthritis (20.6%), and systemic arthritis (14.7%). Significant negative correlations were detected between SSET and PI-head score (rho=-0.467, p<0.005), SSET and PI-ribcage score (rho=-0.381, p=0.026); FET and PI-head score (rho=-0.469, p=0.005); LET and PI-head score (rho=-0.441, p=0.009).

**Conclusion:** These results indicated that postural displacements of head and ribcage are linked with decreased trunk and scapular muscle endurance in children with JIA. Exercise and physical activity programs targeting muscle endurance may result in improvements in posture in these children.

Behçet’s disease is a vasculitis, causing multisystem inflammation and resulting in oral and genital ulcers and eye and skin lesions (1). A proportion of patients also have neurological involvement, termed Neuro-behçet’s disease (2). We think about that Neuro-behçet's disease can impact balance functions in patients due to neurological involvement. However, there is no study investigating the balance functions in patients with Neuro-behçet.

**Objectives:** To investigate the balance functions in individual with Neuro-behçet’s disease.

**Methods:** In this study 8 Neuro-behçet patients with a mean age of 38.37±16.96 who were followed in the PAU Rheumatology outpatient clinic and diagnosed by a rheumatologist according to the criteria of the International Behçet Study Group and 8 healthy control with a mean age of 42.62±13.94 with similar demographic characteristics were included. Exclusion criteria for the study were age <18 years old, having any disease which mimics BD (including systemic lupus erythematosus, vasculitis of central nervous system). Demographic data of the participants were recorded. Then, balance functions were evaluated with a balance board (Sensamove MaxiBoard, NL) in Neuro-behçet and control groups. This assessment included static balance, proprioception, and reaction. Results were analyzed with Mann Whitney U Test.

**Results:** Participants were similar in terms of age and gender (p>0.05). Neuro-behçet group showed a significant decrease in static balance in all directions except the right side compared to the control group (p>0.05). A significant decrease was observed in the right and left reaction times in Neuro-behçet group compared to control group (p>0.05). There was no significant difference between the two groups in proprioception assessment (p>0.05).

**Conclusion:** This result shows that patients with Neuro-behçet may experience disturbances in static balance and reaction time. Balance and reaction exercises should be included in rehabilitation. Further research is needed on the effect of balance functions and the effectiveness of balance exercises in Neuro-behçet’s disease.

the aim to have signs and symptoms recognized for referrals to diagnostic tests and specialized services. As such, tasks beyond referrals are not expected by service users in primary health care in their encounters with GPs. Upon entering specialized health care services, service users describe diagnostics and prescription of medication for pain as key tasks of the rheumatologists, highlighting the role of the rheumatologists in ruling out severe pathology. Service users attribute the tasks of providing information about the condition, exercises, and assistive devices to occupational therapists (OTs). A lack of familiarity with the OT-profession prior to consultations is also expressed. This shows how patients attribute different tasks to GPs, rheumatologists, and OTs based on experiences in consultations.

**Profession secondary to competence about HOA and interpersonal skills:** service users say they do not have preferences related to who executes what professional tasks in addressing their needs. On the contrary, service users highlight competence about HOA as a key factor independent of whether the health professional is a GP, rheumatologist, or OT, saying professional orientation is secondary to professional knowledge about HOA. At the same time, service users underline interpersonal skills of health professionals as another key element, further downplaying the specific professional background of health professionals and levels of the health care system in meeting service user needs.

**Transfer of tasks to service users:** service users experience that they are presented with few treatment options beyond self-management in encounters with health professionals, leaving service users to cater for their own needs through the self-administration of exercises, medicines, and assistive devices.

**Conclusion:** In the division of labor, service users highlight the importance of professional knowledge and skills within the field and interpersonal skills independent of professional background and levels of the health care system. They also underline few treatment opportunities beyond self-management resulting in task-shifting to service users.

Background: Quality of life (QoL) due to World Health Organization (WHO) is an individual’s perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns. QoL can be decreased during chronic illnesses, including juvenile idiopathic arthritis (JIA). This severe chronic disease of childhood afflicts both joints and body’s system inducing various comorbid conditions, among which eye damage (uveitis) is the most common. Considering the fact of involved joints it was set up that physical functioning (PF) shows the lowest values in some studies, which is associated with joint damage, activity, and duration of the disease.

Objectives: To establish the overall level of QoL and physical functioning in patients with JIA, considering the subtype of the disease, duration and the therapy complex.

Methods: The study involved 118 patients with JIA, among which 47 had polyarticular subtype, 43 had oligoarticular one, 28 were with uveitis-associated (JIA-u) subtype. The investigation included 77 girls and 41 boys in age from 2 till 18 years old. The therapy by methotrexate was provided in 112 patients, among them 30 had MTX with immunobiological therapy (29 adalimumab, 1 tocilizumab), 6 – sulfasalazine. The disease duration due to disease subtype in polyarthritis was (49,2±6,7), oligoarthritis – (35,4±4,2), JIA-u – (76,8±10,2) months. Disease activity was assessed using the JADAS27 questionnaire, functional state (FS) according to CHAQ and QoL according to PedsQLTM 4.0 Generic Core Scales.

Results: It was found that high JIA activity was observed in 31 (26.2%) patients, equally often in all subgroups of children. FS did not show a significant decrease either in the whole group or in each of the arthritis subgroups. The overall indicator of QoL in children with JIA was reduced in the whole group (71.2±1.4 and 72.9±1.4 per week and month). There was no significant difference between the QoL indicators of boys and girls. The polyarticular subtype showed the lowest results in QoL and PF, especially in children in the first year of the disease. They also turned out to be worse in children with JIA-u with the disease from one to three years (QoL – 63,2±3,6; PF – 66,6±3,9). The highest level of the physical component of QoL was observed in children with oligoarthritis older than 14 years (84,9±4,7) and in children under 8 years of age in the JIA-u group (96,8±8,1). There was no significant effect on the physical indicators of QoL of the start treatment timing. Finally, the strong correlation was determined between QoL and PF (r=0,842; p<0,05).

Conclusion: A decrease in QoL and its physical component is typical for children with different types of JIA (oligoarticular, polyarticular, and JIA-y). It has been established that children with polyarticular subtype of arthritis have the greatest decrease in QoL and physical functioning.

POS1543-HPR JOINING TELEMEDICINE SERVICES IN RHEUMATOLOGY: THE ROLE PLAYED BY PERSONALIZED EXPERIENCE FROM PATIENTS’ PERSPECTIVE

E. Listorti1, L. Ferrara1, A. Adinolfi2, M. C. Gerardì2, N. Ughi2, V. Tozzi3, O. M. Episì4. 1CERGAS SSA Bocconi, Bocconi University, Government, Health & Not for Profit, Milan, Italy; 2ASST Grande Ospedale Metropolitano Niguarda, Rheumatology Unit, Milan, Italy

Background: With the beginning of the Covid-19 pandemic, many hospital departments worldwide, including rheumatology ones, were forced to implement telemedicine strategies. Telemedicine revealed to be an umbrella term, with various practical implementations and different degrees of preparedness. Some practitioners were already familiar with telemedicine, as in the case of the Rheumatology Unit of ASST Niguarda Hospital in Milan (Italy), where telemedicine projects have been implemented for more than a decade with structured design and organized processes. Moreover, patients in Niguarda have experimented telemedicine with personalized mixes of channels, including e-mails and phone calls, Patient Reported Outcomes questionnaires, and home delivery of drugs. This represents a paradigmatic case study that enables us to deepen essential questions on the success of telemedicine.

Objectives: Given that the last decision on joining telemedicine rests with patients, we decided to adopt their perspective. We deepened three main aspects: i) the benefits perceived, ii) the willingness to enrol in future projects, iii) the preference on the service-mix, i.e., on-distance contacts rather than in-person visits. Most importantly, we investigated differences in the three areas among all patients based on the type of personalized experience had.

Methods: We conducted a survey from November 2021 to January 2022, enrolling randomly outpatient who attended the rheumatology unit for any reason. The survey originated from well-known surveys, such as the Tele-Health Usability Questionnaire and the intention to use telehealth services. However, we decided to overcome the usual separation that makes surveys addressed either to users or no users of telemedicine. Our survey comprised an introductory set of questions related to personal, social, clinical and ICT skills information, followed by the central part on telemedicine, which explored the three areas mentioned: benefits, adherence, preferences on service-mix. For this part, questions were the same for all patients apart from the tense used, being conditional tense for no-users and past tense for users. All the answers were analysed with descriptive statistics and regression models.

Results: A complete response was given by 400 patients: 71% were female, 59% were 40-64 years old, 53% of them declared to work, and the diseases most represented were Rheumatoid Arthritis (36%) and Osteoporosis/arthrosis (21%). The descriptive statistics revealed interesting differences between users and no-users, e.g., the desire to participate in future projects was stated by 95% of users, 81% of no-users. These results were confirmed by multivariate logistic regression models that controlled for the influencing patients’ characteristics (such as being old or a frequent hospital attender).

It emerged that no-users imagined wide-ranging benefits. As for the willingness to participate to future telehealth projects, even if personal characteristics showed an impact (e.g., being a worker increased the probability to adhere), other things being equal, having had a more intense experience of telemedicine increased the odds of accepting by 3.1 times (95% C.I. 1.04-9.25), compared to no users. Furthermore, the more telemedicine was experienced, the higher the willingness to substitute in-person with online contacts.

Conclusion: Our study contributes to enlighten the crucial role played by the telemedicine experience in determining patients’ preferences. On one side, users appeared more aware of the realistic benefits to be expected from telemedicine. On the other side, it seemed that the more telemedicine was experienced, the higher the willingness to adhere to future projects and to increase on-distance contacts.

Background: Telemedicine is a useful tool in the control of patients with rheumatological conditions, even more so in the pandemic period. The evolution of patients with rheumatoid arthritis (RA) treated exclusively under this modality has been scarcely described.

Objectives: Evolution of clinical activity in RA patients controlled exclusively by the synchronous telemedicine (ST) modality in the COVID-19 pandemic period.

Methods: An observational study was carried out. Two groups of patients were analyzed separately, first group who had been treated using ST before the declaration of a health emergency in Colombia in March 2020 and second who were admitted to ST after this date. ST consists of a real-time video call with a trained general physician help on the referral site to perform physical examination. Assessments of disease activity was measured by DAS28 using C-reactive protein.

Results: Data was obtained from 150 and 65 patients in the first and second group. For the first group, more than a half of the patients had 2 controls with DAS28 assessment after March 2020, only 33% obtained 3 assessments, and very few with 4 or more. We found that the number of patients with high activity decreased significantly from 10% to 3%, remission increased from 44% to 50% and low activity from 14% to 19%, without major changes in the moderate activity group that remained close to a third. Same tendencies happened in group 2, with a difference in reduction of the moderate activity group from 44% to 38% (Figure 1).

Conclusion: When in person attention with rheumatologist is not possible, telemedicine is a useful and efficient way to control patients with RA, mainly finding a reduction in high activity and an increase in remission patients in remission.

had >2yrs follow-up. We have a community rheumatology service arm where all patients with stable inflammatory arthritis on non-biologic treatments are seen in secondary care. The stable patients from community clinics have not been included in this analysis. The data was reviewed using clinical letters, date of first appointment & last appointment. We looked at gender, age, diagnosis, number of follow ups in the first and last year, disease activity scores of the respective diagnosis and treatment given.

**Results:** Sixty percent of follow-up patients are long term with complicated illness or treatment. Of these 52 patients (65%) were female with median age 64 years (range 23-94 years). Median duration of follow up for this group of patients was 6 years (range 2-11 years). Inflammatory arthritis was the most common diagnosis in 75% of patients (11 patients were Psoriatic arthritis, 30- Rheumatoid arthritis, 7- undifferentiated inflammatory arthropathies and 7- Ankylosing spondylitis), 17.5% connective tissue disease, 11.2% vasculitis and others (Still's disease) 3.7%. Some patients had more than one diagnosis. The number of follow up in the first year ranged from 1-13 (median 4). In final year of analysis, patients were seen median of 3 times (range 1-8). Amongst them, 25% of patients were seen 4 or more times. The commonly prescribed drugs were methotrexate (41.2%), sulfasalazine(17.5%), hydroxychloroquine(15%), leflunomide (7.5%),biologics (8.7%), mycophenolate mofetil and azathioprine (6.5%). The activity scores such as DAS28, BVAS, PsARC and BASDAI were documented in 46 patients (57.5%).

**Conclusion:** This study shows that 66.6% of follow-up patients in rheumatology clinics are complicated long term conditions on immunomodulatory treatment. Despite T2T approach, use of combination DMARDs and early use of biologics, majority are inflammatory arthritis. It also shows that even after median follow-up of 6-9 years, these patients require an average review 3 or more times per year. The reasons for this may be poor disease control and lack of follow up. Patient outcomes may be good in disease compliants, comorbidities and medication side effects. Further analysis is ongoing to look into these aspects for better disease control and long term outcome.

**POS1547-HPR** CREATION OF A MULTI-DISCIPLINARY TEAM (MDT) RHEUMATOLOGY CLINIC AT UNIVERSITY COLLEGE LONDON HOSPITAL (UCLH) TO TACKLE THE BACKLOG OF PATIENTS WAITING FOR TREATMENT AS A RESULT OF THE COVID-19 PANDEMIC.

D. Ludwig1, F. Higgs2, N. Allotey1, S. Begum1, J. Burton3, 1University College London, Rheumatology, London, United Kingdom; 2University College London, Therapies & Rehabilitation Department, London, United Kingdom; 3University College London Hospitals, Innovation Directorate, London, United Kingdom

**Background:** Covid-19 has consumed hospital resources since January 2020. In the UK, routine care has been disrupted with an estimated 30 million fewer outpatient attendances (2020/21) and over 6 million patients waiting for consultant led care (1). The British Society for Rheumatology ‘Rheumatology Workforce: a crisis in numbers’ (2021) highlights the challenges facing National Health Service rheumatology departments in managing rising caseloads (2). In 2021, UCLH wait time for follow up rheumatology appointments was 9 months. We were inundated with patients requiring urgent treatment. Innovative ways of running outpatients were required which led to the formation of an MDT clinic.

**Objectives:** Create a Rheumatology MDT clinic to:

- Reduce follow up time
- Increase clinic capacity
- Reduce number of hospital attendances

**Methods:** The consultant lead identified an existing clinical nurse specialist (CNS) interested in supporting the MDT. With a UCLH Outpatient Transformation fund of £15,000 we recruited an advanced physiotherapy practitioner (APP) and an administrative assistant for a 6 month trial period. Managerial support was provided by the board. We met weekly to agree aims and allocate responsibilities. We did the following:

- Reviewed clinic lists for 6 months to identify duplicate appointments.
- Identified patients with CNS and consultant follow up scheduled in a short time frame and cancelled unnecessary appointments.
- Reassessed the medical list weekly to identify patients suitable for APP management. This allowed overbooking of urgent cases.
- Embedded hand ultrasound appointments in the clinic template.
- Created CNS ‘Zoom’ virtual drop-ins for routine enquiries to reduce the administrative burden of patient emails/phone calls occurring outside the clinic.
- Organised patient participation sessions to help shape the service and collate feedback questionnaires.

**Results:** We reduced wait time for follow up appointments from 9 months to 2 months. Pre-MDT the average wait from consultant referral to physiotherapist appointment was 55 days. The MDT allows for same day assessment (reducing 2-3 patient journeys a clinic) and where suitable, facilitates discharge or onwards referral to the appropriate service i.e. pain management, hand therapy, APP-led hypermobility programme. A dedicated MDT CNS has shortened treatment times, reduced email traffic between CNS and consultant and allows for same day, joint decision making resulting in fewer appointments. Patients welcomed the Zoom sessions as an efficient, reliable method of raising concerns/queries. Our administrator helps to facilitate communication between patients and clinicians and streamline MDT processes. Embedding point of care ultrasound reduces hospital visits and enhances treatment decision making thereby reducing follow up attendances.

**Conclusion:** Our MDT model has reduced waiting lists, decreased treatment delays and cut the number of hospital visits. Performing ultrasound helped prevent patients being sent for scans at private providers. This cost saving likely covers the APP, ensuring the project is close to cost neutral. Shared decision making added value to outpatient attendances, reflected in patients positive feedback. The MDT enhances the role of APP and CNS, utilising their unique skill set. Administrative support is crucial, enhances team working and places added value on this often underappreciated role. We encourage other Rheumatology departments to adopt an MDT approach to tackle the backlog of patients awaiting treatment, add value to clinic encounters and maximise the skill set of clinicians involved in patient care.

**POS1548-HPR** USEFULNESS OF AN ELECTRONIC CONSULTATION SYSTEM BETWEEN PRIMARY CARE HEALTH CENTERS AND RHEUMATOLOGY DEPARTMENT OF A TERTIARY HOSPITAL

N. De la Torre Rubio1, J. Campos Esteban2, M. Pavia Pascual3, P. Navarro Palomo4, M. Machattu5, O. Rusinovich6, M. Fernandez Castro7, H. Godoy8, C. Merino Argumánez9, B. García-Magallón9, C. Barbardillo Mateos10, J. Sanz10, L. F. De Villa10, J. L. Andreu Sánchez10, Puerta de Hierro Majadahonda University Hospital; Rheumatology, Majadahonda, Spain

**Background:** The EPISEr study is the first Spanish epidemiological study that has confirmed the great burden of rheumatic diseases in the general population: they consume a large quantity of health resources (doctor visits, medical products) and imply a high social impact in terms of work absenteeism. Rheumatic diseases represent almost 30% of Primary Care medical consultations in Spain12. Electronic consultation could be an alternative response to the increase of this demand, both to make an early diagnosis and derivation and to improve communication with Primary Care physicians23. Objectives: To analyse the impact of an electronic consultation system of the Rheumatology Department of a tertiary hospital.

**Methods:** Retrospective descriptive study of the data collected in the request and information system (Sistema de Peticiones Electrónicas, SiPPE) that supports electronic consultation between primary care physicians of the health area and the Rheumatology Department of a tertiary hospital, between July 2020 and May 2021. The following variables were collected: age, sex, reason for consultation, response time in days and destination (primary care/outpatient follow-up). Descriptive statistics were used to present the results.

**Results:** The last 500 consecutive electronic consultations registered in the system, corresponding to 498 patients were collected. Mean age was 59.5±17.7 years, 74.2% women. Mean response time was 2 days, median response time 1 day and range 0-45. The reasons for consultation (see Graph 1) were: osteoporosis assessment 55 (11%), treatment adjustment 50 (10%), appointment request 49 (9.8%), loss to follow-up 43 (8.6%), local-regional pathology assessment 39 (7.8%), infiltration request 28 (5, 6%), suspected rheumatoid arthritis 19 (3.8%), spondyloarthritis 18 (3.6%), suspected polymyalgia rheumatica or giant cell arteritis 16 (3.2%), COVID vaccine consultation 14 (2.8%), Raynaud's phenomenon 13 (2.6%), monoarthritis assessment 12 (2.4%), assessment of poliarthritis 11 (2.2%), adverse effects of treatment 11 (2.2%), spondyloarthritides 11 (2.2%), suspected psoriatic arthritis 8 (1, 6%), generalized pain 7 (1.4%), suspected Sjögren’s syndrome 5 (1%), suspected systemic lupus erythematosus 1 (0.2%), suspected other systemic autoimmune diseases 9 (1.8%), others 81 (16.2%). Fifty-seven and four (4.2%) of the patients required an appointment at the Rheumatology outpatient clinic and in 42.6% of the patients (213) the electronic consultation was successful, so it was not necessary to refer the patient to the hospital.

POS1549-HPR IMPROVING EFFICACY AND SAFETY OF BLOOD MONITORING IN RHEUMATOLOGY PATIENTS ON DISEASE MODIFYING ANTI-RHEUMATIC DRUGS (DMARDs) USING A NEW AUTOMATED ALGORITHM

M. Mirza1, A. Escudero Sios1, D. Lang1, K. Paddron1, B. Shinee1, A. Soni1, R. Luqmani1. 1University of Oxford, Rheumatology, Oxford, United Kingdom

Background: Most patients in Rheumatology require early management with DMARDs to control their disease. In our department, around two hundred patients start a DMARD therapy every month and monitoring their blood test results whilst on DMARDs play an essential role to detect toxicity and the need for further action. This process has been done manually, which has been prone to error. Over the past six months, a minimum of three patients have had abnormalities which were missed, consequently identifying the need to improve the quality of the blood monitoring.

Objectives: The aim of the project was to develop, test and implement an automated system to review multiple blood test results and highlight any changes, trends or abnormalities in patients starting DMARD therapy efficiently.

Methods: We designed a system to automatically review blood tests from patients newly started on DMARD therapy, following the recommended British Society for Rheumatology (BSR) schedule for blood monitoring. Results are processed in our local laboratory, subsequently uploaded to our unique database and analysed automatically using an algorithm against BSR guided threshold values for each blood test. According to the value, each blood result is identified as normal, mildly abnormal, missing, trending, or abnormal. A trained clinician or pharmacist will review the data and endorse the results after taking any appropriate action. Based on the results, if any actions are needed, patients are contacted either by phone or via a letter automatically generated by this software, recommending them to have a repeat test or temporarily stop the medication as required.

Results: The system was tested on two cohorts, comprised of 100 and 227 blood tests. It was faster and more efficient than the manual alternative. Following this test, each record was compared manually, based on the data stored on a spreadsheet.

This new system led to the identification of more abnormalities versus the manual inspection (29% vs 10%, Chi square P<0.001). Additionally, it took less than a minute compared to the manual method, which took three hours to complete. Follow up manual inspection confirmed that the new system had correctly identified every abnormality, based on test results.

To date, we have analysed 3968 blood results using this technique. 1564 (44%) results have been normal and endorsed within seconds, 374 (10%) were mildly abnormal, 17 (0.5%) results have been abnormal requiring action and 311 (9%) were abnormal requiring no action. 265 (7%) results showed a trend within the blood results. Trending results were defined as being out of range and worsening on two consecutive occasions but not reaching the limits for stopping a drug. 1032 (29%) results contained missing results, a consequence of the different timings of results uploaded by various laboratory sections.

Conclusion: We have developed an efficient and safe blood monitoring system for Rheumatology patients starting on a DMARD, proven to be more accurate compared to previous manual alternatives and able to process up to 10,000 results at a time.

POS1550-HPR DRIVE-THROUGH PHLEBOTOMY – DOES IT WORK FOR DMARDS MONITORING?

J. Begum1, M. Nisar1. 1Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom

Background: Centralised phlebotomy services have been an integral part of providing blood monitoring facility for people with chronic diseases prescribed vital therapies. However the patient experience is not always optimal due to the issues of congestion, parking, long waiting times and have been accentuated during COVID-19 pandemic with the need for minimising physical contact. Expert panels have advocated for the creation of innovative approaches to provide safe patient care while maintaining precautions against COVID-19 spread. Several groups have published the concept and experience of using a drive-through clinic for anticoagulation monitoring and management. There is limited data on how this model of care can impact other clinical services such as rheumatology where patient groups are more vulnerable.

Objectives: In response to the growing pressure on phlebotomy service at our institution enhanced by COVID-19 pandemic, our rheumatology service implemented a drive-through phlebotomy clinic to provide the option for patients and families to stay in their vehicles whilst having venepuncture. The objectives were to evaluate the feasibility and patient experience of the service.

Methods: At our large university teaching hospital, we set up a drive-through phlebotomy service provided by a senior health care assistant supervised by the lead nurse. It was located near the hospital entrance where vehicles could park for a few minutes without disrupting traffic flow. Patients were identified from the departmental database and were offered the facility via telephone. Eligibility was assessed using a standardised proforma focusing on logistics such as ability to drive and access to a mobile phone. Appointments were scheduled in advance with patients choosing this care option. On the day, patients were screened for COVID-19–related symptoms before their appointment and were encouraged to stay in their vehicles wearing a mask before being approached by the HCA. At the end of clinic, all samples were submitted to the central laboratory. All the data was prospectively collated with patients consent and anonymised for analysis. In addition to demographics, diagnosis and drug record, duration of visit and patient feedback was collected.

Results: 112 patients were offered the service during a 12-week pilot. Mean age of the participants was 49.5 yrs (19-91) with 73 (65%) women. 74 (65%) were of Caucasian and 28 (25%) of Asian origin. 94 (84%) had inflammatory arthritides and all were prescribed DMARDs and/or bone active agents. 69 (61%) had been prescribed anti-clotting agents. The median time for blood to be collected from the arm was 2 minutes compared to the manual method, which took three hours to complete. Mean duration of appointment was 12.5 mins (5-60). 68 (60%) provided feedback with 61 (90%) rating 5/5 and 60 (89%) rating it better than standard phlebotomy. All would like to have the option for future and 67 (98%) were highly likely or likely to recommend the service to family and relatives. Most common reason to decline was an already arranged appointment with standard phlebotomy (n=14, 12.5%). Six (5%) could not be bled due to difficult venepuncture. Mean duration of appointment was 12.5 mins (5-60). 68 (60%) provided feedback with 61 (90%) rating 5/5 and 60 (89%) rating it better than standard phlebotomy. All would like to have the option for future and 67 (98%) were highly likely or likely to recommend the service to family and relatives.

Conclusion: To our knowledge, this is the first study to demonstrate the utility of drive-through phlebotomy for people with rheumatic diseases prescribed DMARDs. Excellent feedback of the participants confirms the need and desire for such innovation in health care. Prior publications have shown the benefits of such clinics in anticoagulation services. Arguably, it’s more prudent to have this facility close to where there is no alternative such as point-of-care or home INF monitoring. In post COVID-19 services reconfiguration with telemedicine and innovative models of care, this allowed flexibility for our department to develop...
and establish an alternative process. The availability of drive-through appointments and the close physical proximity to the clinic made it an appealing option for a vulnerable group of patients evidenced by their outstanding experience and feedback. Overall, an HCA-delivered, nurse-supervised drive-through pathway is highly effective, safe and provides an innovative solution to strained phlebotomy services.

**MEDICAL EXPERT KNOWLEDGE MEETS AI: HOW EXPERT KNOWLEDGE CAN IMPROVE SYMPTOM ASSESSMENT APPS - A NEW APPROACH IN RARE DISEASES**

A. Pankow1, 2, M. Neißeiner1, L. Fouquet1, E. Türk1, S. Gilbert1, T. Tüber2, A. Das1, C. Terkamp1, J. Kaufeld1, G. R. Burmester1, A. D. Wagner2

On behalf of Rheumatology 4.0. Charité - Universitätsmedizin Berlin, Medizinische Klinik mit Schwerpunkt Rheumatologie und klinische Immunologie Charité, Berlin, Germany; Medizinische Hochschule Hannover, Ambulanz für seltene entzündliche Systemerkrankungen mit Nierenbeteiligung, Hannover, Germany; Health GmbH, Ada, Berlin, Germany; University Hospital Carl Gustav Carus, Technische Universität Dresden, Else Kröner Fresenius Center for Digital Health, Dresden, Germany; Medizinische Hochschule Hannover, Pädiatrische Nieren-, Leber- und Wechselfehlerkrankungen, Hannover, Germany

**Background:** By definition, rare diseases occur in fewer than 5 in 10,000 people. However, in Germany alone, there are approximately 4 million people affected (1). Due to their rarity, rare diseases are often overlooked by general practitioners with limited knowledge about them. There are often only a handful of specialized experts for each condition. Yet, those experts are frequently not evenly distributed across the healthcare system, and often patients lack access. Therefore, the time to diagnosis is often long and poses many challenges. Artificial intelligence (AI) approaches, such as those used in symptom assessment apps can potentially help to detect disease and thus, shorten the time to diagnosis (2).

The general approach underlying the AI of symptom assessment apps is to gather medical knowledge from data (e.g. electronic health record or literature searches). However, for rare diseases, there is only limited research available. In this study we used a new approach: to abstract medical expert knowledge by conducting guided interviews and transforming them into clinical vignettes.

**Objectives:** There are two objectives. First, we aimed to integrate expert knowledge on the lysosomal storage diseases (LSDs) Fabry, Gaucher and Pompe into the Ada symptom assessment application and use this expert knowledge to optimize Ada’s LSD condition models. LSDs are of particular importance as they represent important differential diagnoses for rheumatic diseases.

Second, we will conduct questionnaires with patients and LSD experts, comparing the optimized to the previous condition models’ performance. We will investigate whether the novel approach of guided interviews, in combination with literature research, results in a better performance than literature research alone.

**Methods:** Our novel approach is to curate expert medical knowledge from guided interviews with medical experts. The interviews aim to gather knowledge on the symptom constellations with which patients typically present to their physicians. This knowledge is subsequently used to create prototype clinical cases and transform them into structured case vignettes. The rare disease structured case vignettes can be readily transcribed into Ada’s knowledge base.

**Results:** We conducted guided interviews with clinical experts from the Medizinische Hochschule Hannover (MHH) to create clinical vignettes for the LSDs Fabry, Gaucher and Pompe disease. We conducted interviews with four medical experts and created a total of 11 clinical vignettes: five vignettes for Fabry disease, four for Gaucher disease and two for Pompe disease. Figure 1 demonstrates the vignette creation process. Then, in combination with systematic literature searches, the vignettes were used to update Ada’s existing condition models for Fabry and Gaucher disease and to add Pompe disease.

**Figure 1.** The novel medical model creation approach uses guided expert interviews to create prototypic clinical vignettes, which can be readily transcribed in a medical modeling language to create individual disease models

**Conclusion:** Participants will complete two assessments: an Ada version with the old knowledge base and an Ada version with the updated models. The study plans to enroll 15 LSD patients - five per condition - and nine LSD experts. For the conditions Fabry and Gaucher disease, we will ask the participants to rate both Ada versions. For Pompe disease, we will ask participants to rate the latest Ada version with the updated knowledge base. This novel approach has various clinical implications, including potentially shortening the ‘time to diagnosis’ for rare diseases, thus giving patients faster access to the treatments they need.

**A SYNTHESIS OF GUIDANCE AVAILABLE FOR ASSESSING METHODOLOGICAL QUALITY AND GRADING OF EVIDENCE FROM QUALITATIVE RESEARCH TO INFORM CLINICAL RECOMMENDATIONS: A SYSTEMATIC REVIEW**

M. Sekhon1, 2, A. De Thurian3, G. E. Fragoulis4, T. Stamm1, T. P. M. Vliet Vlieland5, B. A. Ebsenber6, H. Lemp5, L. Beare1-4, M. Kouloumbas7, P. Polohnikova4, T. W. Swinnen4, C. Blunt1, R. J. O. **Background:** Qualitative research is crucial to understand key stakeholders experiences and perspectives of care and health services. However, there is a lack of explicit frameworks and guidelines about how best to use qualitative evidence to formulate clinical recommendations. Part of the problem includes uncertainties about the contributions of qualitative research to the evidence, and the empirical and theoretical basis for appraising and synthesizing qualitative evidence in a standardized manner. In addition, most existing grading systems of qualitative research originate from quantitative research, and there is no clear guidance about how to incorporate qualitative research into the evidence hierarchy.

**Objectives:** To conduct a systematic literature review (SLR) to answer two research questions (RQ):

**RQ1)** What guidance (e.g., tools, checklists, frameworks) exists to assess the methodological quality of qualitative research employed to inform clinical recommendations?

**RQ2)** What methods exist specifically to grade levels of evidence for qualitative research?

**Methods:** The protocol for this review was registered on www.researchregistry. (reviewregistry1240). Electronic databases (PubMed/Medline, EMBASE, Web of Science, COCHRANE, Emcare, PsyINFO, ERIC, Academic Search
Premier, Sociological Abstracts, ProQuest Dissertations and Thesis Global) were searched for published and unpublished studies. Searches were completed from inception to 23rd October 2020. No restrictions were applied to clinical population. Eligible studies for both questions included primary articles and guideline documents available in English, describing the: i) development; ii) application of validated tools (e.g., checklists); iii) guidance on how to assess methodological quality of qualitative research and iv) guidance on how to grade levels of qualitative evidence. Opinion pieces and conference abstracts were excluded. Manual searches of the reference lists of full text articles were conducted. Two reviewers independently screened the titles, abstracts, and full text. A narrative synthesis was conducted to identify key aspects between the included studies.

Results: 9071 records were retrieved (Figure 1). After de-duplication and title/abstract screening, 51 full-articles articles were assessed for eligibility yielding 15 included articles. For RQ1, six articles were included that described six tools (1) The society for Critical Care Medicine Family – Centered Care Guidelines; 2) Nursing Management of the Second Stage of Labour evidence based clinical practice guidelines; 3) Jonna Briggs Institute Critical Appraisal of Qualitative Studies; 4) Critical Skill’s Appraisal Programme (CASP) and 6) the Modified CASP checklist. All tools ranged from 10 to 30 items, and evaluated research design, recruitment, ethical rigour, data collection and data analysis. Seven articles described one approach (GRADE CER-Qual) to assess methodological quality of qualitative research. This approach advised on the importance for assessing methodological limitations. For RQ2, two articles were included, one described a qualitative hierarchy of evidence, and another described a research pyramid that included a section on qualitative research.

Conclusion: This review highlights lack of consensus and limited availability of tools, checklists, and approaches to 1) appraise the methodological quality of qualitative research used to inform clinical recommendations and 2) grade levels of evidence for qualitative research. Current research agendas will need to determine the most relevant and appropriate method for the quality appraisal of qualitative research. This way, qualitative research could be more consistently determine the most relevant and appropriate method for the quality appraisal of qualitative research. This approach advised on the importance for assessing methodological limitations. For RQ2, two articles were included, one described a qualitative hierarchy of evidence, and another described a research pyramid that included a section on qualitative research.

A VIRTUOUS IMPLEMENTATION OF TELEMEDICINE SERVICES IN RHEUMATOLOGY: DESCRIPTION OF CHANGE MANAGEMENT PRACTICES ADOPTED BY THE NIGUARDA HOSPITAL

L. Ferrara1, E. Listorti1, A. Adinolfi2, M. C. Gerardi3, N. Ughi2, O. M. Epis2, V. Tocci2,3, Cergas SDA Bocconi, Bocconi University, Government, Health & Not For Profit Division, Milan, Italy; 2ASST Grande Ospedale Metropolitano Niguarda, Rheumatology Unit, Milan, Italy

Background: Over the past few decades there have been an increasing debate around the use of telemedicine. Despite this, there is still a slow rate of adoption of telemedicine services. According to a recent scoping review this may be due to a piecemeal approach to the change process, and a lack of understanding of how to plan, manage and reinforce change when implementing telemedicine service1. A virtuous example of implementation of telemedicine services can be found within the rheumatology unit of Niguarda Hospital in Milan (Italy), where the whole staff has been involved in experimenting with new multichannel interactions to communicate with patients for more than a decade. Developed in 2011 with the introduction of the IAR Plus app for the collection of Patient Reported Outcomes (PROs), the project was first targeted to patients with Rheumatoid arthritis, Psoriatic arthritis and Spondyloarthritis. In 2019 the project was consolidated and added the home delivery of biological drugs for the stable patients. During spring 2020, this experience was further extended and extended to all patients treated with biological drugs to facilitate patient interaction during Covid-19 and was characterized by three elements: remote monitoring, triage through phone calls and home delivery of medication. What contextual factors and mechanisms adopted to plan, manage, and reinforce change where more successful?

Objectives: This study aimed to highlight what were the distinctive and successful elements of this implementation experience, what we could learn from it, and which managerial implications we could derive for future implementations.

Methods: We adopted a realist evaluation approach2 to identify the underlying generative mechanisms that explain ‘how’ the outcomes were caused and the influence of context. Thus, we deepened how the change management process has been managed by conducting semi-structured interviews with the unit director, and the staff members involved in the phases of the project (i.e., clinicians, nurses, and administrative staff). The interviews were recorded and analyzed through an ad-hoc framework3 for the analysis of change management practices. This framework identifies 10 change steps divided into 13 strategic practices and 6 operational practices that are important during the preparatory phase of the change process, for managing the change, and to sustain and reinforce long-term change.

Results: Our study identified the most relevant actions put in place by the rheumatology unit during the three major steps of preparing for change (e.g., developed telemedicine App, assigned coordinating role, identified champions), managing change (e.g., developed and articulated a clear vision, provided training, developed ownership), and reinforcing change (e.g., continued to engage partners). The analysis highlighted four main lessons learned: first the characteristics of the context and a strong managerial structure were a prerequisite for success. The generative mechanisms that explain how these successful outcomes were caused are: leadership role able to define a clear vision and a clear specialization of tasks and roles; the involvement of all team members; regular meetings and interactions. Second, patients should be involved as central actors in the definition of the care pathway. The final decision on the kind of services to be used was made by the patient. Third, the relevant stakeholders should be involved since the co-design of the app. Finally, change should be incremental. The Rheumatic unit introduced one change at a time, and this brought to constant improvements.

Conclusion: The framework adopted can be used either to retrospectively analyze the experiences developed but may also act as a tool to guide future telemedicine service implementation and research. As well as the lessons learned can guide the implementation of future telemedicine experiences

**HEALTH PROFESSIONALS’ PERSPECTIVES ON THE USE OF JANUS KINASE INHIBITORS TO TREAT PATIENTS WITH INFLAMMATORY ARTHRITIS**

S. De Souza1, A. Bassett1, R. Williams1, E. Nikphorou1,2,3. ‘King’s College London, Centre for Rheumatic Diseases, London, United Kingdom; 4King’s College Hospital, Rheumatology, London, United Kingdom

**Background:** Janus kinase inhibitors (JAKi) are relatively new to the field of rheumatology and provide health professionals in rheumatology (HPRs) with more therapeutic options for treating inflammatory arthritis (IA), specifically rheumatoid arthritis (RA) and psoriatic arthritis (PsA) [1]. Aside from a different target, JAKi differ from often currently prescribed biologics by being administered orally. To date, there is a lack of evidence on what HPRs think about their real-world use and how the COVID-19 pandemic affects JAKi prescription.

**Objectives:** To explore UK-based HPRs’ perspectives towards JAKi use in IA patients, and in the context also of the COVID-19 pandemic.

**Methods:** A 15-item anonymous online survey, with both closed and open-ended questions, was designed and piloted on 5 HPRs with amendments made based on their feedback. The survey was advertised on Twitter and shared by email in September 2021. Data were exported from the online survey platform and analysed descriptively with the assistance of statistical software.

**Results:** Fifty-one HPRs responded to the survey; 37 Consultants, 7 Registrars, 5 Clinical Nurse Specialists, 1 Clinical Fellow and 1 ‘other rheumatology role’ (not stated). Responses were received from 11/12 UK regions. Most represented was Greater London (18%) and North-West England (16%), 69% of respondents worked in secondary care, with the remaining 31% in tertiary care. The majority (40%) spent 1-25% of their job role doing research, followed by 27% who were not research active. 60% of HPRs indicated that 15%-5% of their RA and/or PsA patients take a JAKi (no HPRs had more than 15% of their RA/PsA patients on JAKi). 96% of HPRs indicated that they prescribe JAKi in their clinical practice, patients take a JAKi (no HPRs had more than 15% of their RA/PsA patients on JAKi). 96% of HPRs indicated that they prescribe JAKi in their clinical practice, patients take a JAKi (no HPRs had more than 15% of their RA/PsA patients on JAKi). 96% of HPRs indicated that they prescribe JAKi in their clinical practice, patients take a JAKi (no HPRs had more than 15% of their RA/PsA patients on JAKi). 96% of HPRs indicated that they prescribe JAKi in their clinical practice, patients take a JAKi (no HPRs had more than 15% of their RA/PsA patients on JAKi).

**Conclusion:** A large proportion of HPRs indicate confidence in prescribing JAKi to their patients with IA, adhering to local guidelines. JAKi are largely prescribed as monotherapy, with the most frequent reason for discontinuation being inefficacy. The COVID-19 pandemic seems to have positively impacted JAKi prescription, however, safety concerns over JAKi use remain for some HPRs.

**EVALUATION OF CONVERSATIONS IN MOTION: A PROGRAM DESIGNED TO IMPROVE PATIENT-PROVIDER COMMUNICATION IN THE CARE OF RHEUMATOID ARTHRITIS**

E. Nikphorou1, S. Péloquin2, M. Augustyniak2, A. Negescu3, D. Walker4, F. Haq5, P. Lazure2, S. Murray2, ‘King’s College, Centre for Rheumatic Diseases, London, United Kingdom; 4AXDEV Group Inc., Performance Improvement Division, Brossard, Canada; 2Addenbrooke’s Hospital, Cambridge University Hospitals NHS Trust, Cambridge, United Kingdom; 3Northumbria Healthcare NHS Foundation Trust, Rheumatology Department, Northumbria, United Kingdom; 4Eli Lilly and Company, Global Medical Education, Toronto, Canada

**Background:** Previous studies have found a need for improvement in communications between healthcare professionals (HCPs) and patients with rheumatoid arthritis (RA), especially in relation to shared-decision making (SDM), managing patient expectations, and goal-setting. Conversations in Motion (CIM) is an educational program, consisting of four modules, that teaches HCPs how to use validated communication techniques to improve the quality and efficiency of their consultations with RA patients.

**Objectives:** This pilot study assessed the impact of CIM deployed in the United Kingdom (UK) on HCPs’ knowledge, skills, confidence, beliefs, and performance using validated communication techniques in interactions with RA patients.

**Methods:** A longitudinal mixed-methods study, consisting of three surveys (pre-before the program, 2-3 weeks post, and 5-6 months follow-up) and semi-structured interviews (4-6 weeks post) was used to evaluate CIM based on the outcome model by Moore et al.2,7 Surveys assessed outcomes via multiple choice or 11-point rating scale questions (0-none, 10-extreme). Participants included UK rheumatology physicians, nurses, and allied HCPs, all of whom had a minimum yearly caseload of 10 RA patients and participated in CIM between September and October 2020. Survey data was descriptively analysed in SPSS by comparing pre with post and pre with follow-up (matched samples). Interviews were thematically analysed using NVivo.

**Results:** Almost half (15/34) of registrants completed all four CIM modules. Of those, 53% (n=8) completed pre and post surveys; 33% (n=5) pre and follow-up surveys; and 27% (n=4) completed interviews. Post surveys showed greater knowledge for strategies to build trust and empathy with RA patients and practice efficiency than at pre (Figure 1). A decrease in helplessness was noted for dealing with a patient who is nonadherent (pre=3.9/10; post=1.6/10). Interviewees described CIM as “thought provoking” and reported improvement in their ability and confidence to use patient’s own stories and words as a strategy to build trust and empathy (n=4). Post and follow-up surveys showed changes in skills and confidence were more pronounced for practice efficiency and discussing nonadherence (Table 1). At follow-up, most participants reported practicing at least one
technique to build trust and empathy with patients (80%, 4/5), save time (100%, 5/5), engage in SDM, or discuss nonadherence (60%, 3/5).

</tbody>
</table>

The final questionnaire contained 90 items divided into 3 sections (Figure 1).

Figure 1. Changes in knowledge post-CIM

Table description: All items were rated on an 11-point scale (0-none, 10-extreme). The matched sample of participants who completed the pre and 2-3 weeks post-CIM survey was not the same as the one who completed the pre and 5-6 months follow-up survey. Change (Δ) was measured as the percent difference between means.

Conclusion: This pilot evaluation suggests that CIM has a measurable impact on HCPS' learning and use of techniques that can enhance communication and collaboration with RA patients. Future studies should validate CIM impact in a larger sample size and/or by evaluating patients' perspective on observed changes in their communication and collaboration with HCPs.

POS1556-HPR RECOMMENDATIONS FOR NURSES ON THE MANAGEMENT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A DELPHI CONSENSUS

L. Cano García1, C. Dominguez2, A. I. Rodriguez Vargas3, E. Trujillo Martín4, J. M. Martin Martín5, 1Regional University Hospital of Malaga, Rheumatology Service, Malaga, Spain; 2Virgen Macarena University Hospital, Rheumatology Service, Seville, Spain; 3Canarias University Hospital, Tenerife, Rheumatology Service, Tenerife, Spain; 4Nuestra Señora de la Candelaria University Hospital, Rheumatology Service, Tenerife, Spain; 5Regional University Hospital of Malaga, Rheumatology Service, Malaga, Spain.

Background: Nurses play a key role in the management of Systemic Lupus Erythematosus (SLE) due to their close contact with the patient. Well-structured resources and specialized training are necessary to ensure comprehensive and quality care. However, no complete clinical practice guidelines for nurses have been developed for the management of SLE in Spain or Europe [1].

Objectives: In this context, the OpenReuma scientific society decided to promote the RECOMIENDAes project, the aim of which is to create consensus-based recommendations for the management of SLE patients by nurses in Spain. Methods: Following a bibliographic review, the Delphi method [2] was followed to reach the consensus and a structured survey was sent to nurses with expertise in SLE. Two successive rounds were conducted. Consensus was established when at least 70% of the panelists agreed or disagreed on a topic.

The final questionnaire contained 90 items divided into 3 sections (Figure 1).

Figure 1. Structure of the RECOMIENDAes project questionnaire.

Results: In Spain, few nurses could be considered experts in SLE, hence the number of panelists was small: 25 nurses from different specialties (Rheumatology: 80%, Autoimmune Disease Units: 4%, Internal Medicine: 4%, and Day Hospital Services: 12%) with sufficient experience to ensure validated recommendations that could translate into practice. All the participants worked in public hospitals and had more than 2 years of experience treating SLE patients.

A high consensus was reached on the role and responsibilities that nurses should have in relation to SLE patient management. The main results are summarized in Table 1.

Table 1. Summary of the main recommendations reached in the RECOMIENDAes Project.

</tr>
<tr>
<td>Promote family planning measures</td>
<td>100%</td>
</tr>
<tr>
<td>Monitor patient needs during the youth-adult transition</td>
<td>96%</td>
</tr>
</tbody>
</table>

Conclusion: Despite the high consensus achieved, to bring these recommendations to fruition it is necessary to: 1) Reinforce the role and presence of the specialized nurse in multidisciplinary teams treating SLE patients; 2) Establish a specific training plan for nurses: accredited, subsidized and supported by the Scientific Societies; and 3) Create detailed clinical practice guidelines for the SLE nurse specialist.

PATIENT-CENTRIC INTERPROFESSIONAL EDUCATION AS A MEANS TO INCREASE HEALTH PROFESSIONALS' AWARENESS AND UNDERSTANDING OF SCLERODERMA

H. Bowen1,2, M. Morgan1,2, L. Shapiro1,2,3, *Steffens Scleroderma Foundation, Research, Albany, United States of America; 2Hartwick College, Translational Biomedical Research Management, Oneonta, United States of America; 3Russell Sage College, Nutrition Science Department, Troy, United States of America; *Steffens Scleroderma Foundation, Educational Awareness, Albany, United States of America; 1Albany Medical Center, Rheumatology, Albany, United States of America; 2Steffens Scleroderma Foundation, Chief Medical Officer, Albany, United States of America

Background: Incorporating a complex chronic disease into an interprofessional education (IPE) event is an appropriate method to increase knowledge and awareness of diseases that require multiple disciplines to manage. Scleroderma is one example of a rheumatic condition that requires an interprofessional (IP) team management approach. In practice, the rheumatologist must rely heavily on awareness of diseases that require multiple disciplines to manage.

Objective: To increase awareness and understanding of scleroderma among health care professional students and enable patients to draw on their health histories to act as lead educators. Based on the success to date, we hope to promote replication of this model at other scleroderma centers.

Methods: Over four years, approximately 800 students from Russell Sage College, Albany College of Pharmacy and Health Sciences, and most recently The State University of New York at Albany, have participated in an IPE event which included individuals living with scleroderma and/or caregivers. For the first three years the event was held in person and the most recent was hosted virtually following the same structure as years prior. The event includes introductions of the moderators and words from a patient advocate followed by guidance on active listening and patient interview techniques. Eight to ten students enrolled in health-related programs including nutrition, psychology, occupational therapy, physical therapy, pharmacy, nursing and public health are assigned to small IP teams. Each team joins a round table or breakout room with one patient and/or caregiver. Students ask discipline specific questions which allows the patient and/or caregiver to share their narrative(s), enabling students to cultivate active listening skills and elicit the perspective of the patient. As the disease presentation and symptoms vary, the student IP teams will then interview another patient and/or caregiver. During the event students also hear best practices through a facilitated patient interview. An expert panel reflective of the disciplines represented on the student IP teams who have experience working with those diagnosed with scleroderma and other chronic conditions answer student questions. All attendees are asked to complete an anonymous pre and post event survey.

RESULTS: Including patients with scleroderma as educators is effective in increasing student awareness and knowledge of the disease. The implementation of this model into IPE also allows students to practice IP collaboration specific to the needs of an individual living with scleroderma, as it would occur in the health care setting.

Conclusion: This patient-centric IPE enables patients to share their medical journey as lead educators in increasing future health care professionals’ awareness and knowledge of scleroderma. Replication of this pilot model at other scleroderma centers worldwide could promote the collaboration needed from healthcare professionals to assure the best quality of care for those living with scleroderma.

INFLUENCING FACTORS ON WORK BURNOUT OF PRE-EXAMINATION AND TRIAGE NURSES UNDER THE NORMAL EPIDEMIC PREVENTION AND CONTROL

B. L. Zhang1,2, S. X. Zhang1,2, T. Cheng1,2,2, F. P. Lian1,2, X. S. Li1,2, C. H. Wei1,2,3, *The Second Hospital of Shaxian Medical University, Department of Rheumatology, Taiyuan, China; 2Shaxian Medical University, Academy of Microbiology, Taiyuan, China; 3Shaxian Medical University, Key laboratory of Cellular Physiology, Taiyuan, China

Background: Nurse is a high-risk groups work fatigue feeling, which seriously affects the quality of conventional work efficiency and burden pressures for contradiction between nurses and patients especially during the COVID-19 pandemic. Normalized epidemic prevention and control during the preview triage nurse need to all patients to the hospital and the accompanying personnel carries on the preliminary screening. COVID-19 fixed point hospital preview triage
nurse with an infected person contact, more prone to anxiety, depression, results in the decrease of efficiency, to treat the service object formulation work sense of fatigue performance, etc.

Objectives: To explore the influencing factors of work burnout of pre-test and triage nurses under normal epidemic prevention and control.

Methods: A total of 110 pre-test and triage nurses from 4 Grade-A hospitals in Shanxi Province were enrolled in this study. The general data questionnaire, Nurse Job Burnout Scale, Pittsburgh Sleep Quality Index Scale, Self-Rating Anxiety Scale and Self-Rating Depression Scale were investigated to work burnout of pre-examination and triage nurses. Comparison between groups using two independent sample t-test and single factor variance analysis. Multiple regression was conducted by SPSS22.0. P values<0.05 were considered significant.

Results: As shown in Table 1, different professional title, department, and the sleep quality of preview triage nurses emotional exhaustion dimension comparison(P<0.001), different department nurses to personalized level dimension comparison(P<0.05), professional title, working department, sleep quality and educational level were the influencing factors of job burnout of pre-test and triage nurses.

Conclusion: In the COVID-19 epidemic, managers should pay more attention to support counselees' adherence to individual, unsupervised exercising.

Background: The 2018 EULAR recommendations for physical activity (PA) in people with inflammatory arthritis and osteoarthritis state that PA in generally recommended dose is effective, safe and feasible (1). Based on the recommendations, the Ankylosing Spondylitis Association of Switzerland (SVMB) developed a concept for their exercise group, consisting of guidance on exercising, regular fitness assessments and individual PA counselling by the group-leading physical therapist (PT). The use of behaviour change techniques (BCTs) during PA counselling ought to support counselees’ adherence to individual, unsupervised exercising.

Objectives: To assess the BCTs used by the PTs during their PA counselling sessions with the members of their axSpA exercise groups.

Methods: An observational cross-sectional study was performed with the first cohort of PTs (n=16) who applied the new concept and provided PA counselling, and their group members who agreed to participate. All first counselling sessions with an individual with axSpA were audiotaped, transcribed and analysed using a coding manual for BCTs (2). The manual includes 38 BCTs across the determinants ‘knowledge’ (2 BCTs), ‘awareness’ (8 BCTs), ‘social influence’ (3 BCTs), attitude (4 BCTs), ‘self-efficacy’ (6 BCTs), ‘intention (6 BCTs), 2 rates familiar with BCTs identified the BCTs used by the PTs. They repeatedly discussed and agreed about their classifications of PTs’ phrasings to BCTs in an iterative process to achieve consistency over all counselling sessions. A BCT could be used several times within one counselling session.

Results: A total of 12 PTs (75%) who counselled 41 people with axSpA participated. All 41 PA counselling sessions, lasting between 30-55 minutes were analysed. Overall, 15 out of the 38 BCTs were identified. Across each determinant (with its number of BCTs), the most and least frequently used BCTs were as follows: 1) determinant ‘knowledge’ (1 of 2 BCTs used); ‘provide general information’ (469 times by 12 PTs); 2) ‘awareness’ (3 of 8 BCTs used); reflective listening and ‘self-monitoring of behaviour’ (268x by 12 PTs and 39x by 9 PTs respectively); 3) ‘social influence’ (of 3 BCTs used); ‘attitude’ (1 of 4 BCTs used); persuasive communication (194x by 11 PTs); 4) ‘self-efficacy’ (of 3 BCTs used): verbal persuasion and guided practice (77x by 11 PTs and 3x by 3 PTs respectively); 6) ‘intention’ (of 4 of 6 BCTs used); general intention formation and develop training schedule (250x by 12 PTs and 18x by 5 PTs respectively); 7) ‘action control’ (of 2 BCTs used); use of cues (199x by 12 PTs), ‘facilitation’ (of 2 BCTs), ‘maintenance’ (5 BCTs). Two raters familiar with BCTs identified the BCTs used by the PTs. They repeatedly discussed and agreed about their classifications of PTs’ phrasings to BCTs in an iterative process to achieve consistency over all counselling sessions. A BCT could be used several times within one counselling session.

Conclusion: In the COVID-19 pandemic, managers should pay more attention to the main factors that affect the sense of pre-test and triage nurses, and take targeted intervention measures to alleviate the sense of exhaustion of nurses, so as to ensure the safety of nursing.

PHYSIOTHERAPISTS MAKE LIMITED USE OF BEHAVIOUR CHANGE TECHNIQUES DURING PHYSICAL ACTIVITY COUNSELLING FOR PEOPLE WITH AXIAL SPONDYLOTARTHRITIS

K. Niedermann Schneider1, U. Vogt1, A. K. Rausch Osthoff1, Institute of Physiotherapy, School of Health Sciences, Winterthur, Switzerland; 2Startpunkt PhysioTraining, physiotherapy practice, Zurich, Switzerland
Conclusion: The study identified that PTs used only a limited number of BCTs. BCTs considered less effective such as providing information were widely used, whereas BCTs that are considered effective, such as specific aims or coping with barriers were much less or not at all used. This study provides an insight in real clinical practice and may help to develop counselling training for PTs. There is a need to translate theoretical BCTs into effective measures that are easy to use in clinical practice.

“MY GUT FEELING IS...”: IDENTIFYING HOW HEALTHCARE PROFESSIONALS COMMUNICATE ABOUT PAIN IN PAEDIATRIC RHEUMATOLOGY MULTI-DISCIPLINARY TEAM MEETINGS

R. Lee1, J. Modonagh1,2, T. Rapley1, A. Farre1, M. Connelly1, T. Palermo2, K. Toupin-April3,8, L. Cordiner1,2. 1University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 2Manchester University Hospital NHS Trust, National Institute for Health Research Biomedical Research Centre, Manchester, United Kingdom; 3Manchester University Hospitals Trust, Royal Manchester Children’s Hospital, Manchester, United Kingdom; 4Northumbria University, Department of Social Work, Education and Community Wellbeing, Northumbria, United Kingdom; 5University of Dundee, School of Health Sciences, Dundee, United Kingdom; 6Division of Developmental and Behavioral Health, Children’s Mercy Kansas City, Kansas City, United States of America; 7Seattle Children’s Research Institute, Center for Child Health, Behavior and Development, Seattle, United States of America; 8University of Ottawa, School of Rehabilitation Sciences, Faculty of Health Sciences, Ottawa, Canada; 9University of Ottawa, Department of Pediatrics, Faculty of Medicine, Ottawa, Canada; 10Children’s Hospital of Eastern Ontario, Research Institute, Ottawa, Canada; 11University of Manchester, Manchester Centre for Health Psychology, Division of Psychology and Mental Health, Manchester, Manchester, Canada

Background: Multi-disciplinary teams (MDTs) are common in paediatric rheumatology where UK standards of care state that all children/young people should have access to a paediatric rheumatologist, nurse, physiotherapist, occupational therapist and a psychologist. MDTs in paediatric rheumatology regularly meet for the broader purpose of discussing the assessment of and future management plans for children/young people with a range of complex conditions in which chronic pain may feature. The content of these discussions has not been previously researched. Little is known about healthcare professional to healthcare professional communication and how this may influence the care of children/young people with chronic pain.

Objectives: The objective of the current study was to investigate healthcare professionals communication about children and young people with chronic musculoskeletal pain during MDT meetings in paediatric rheumatology.

Methods: This study was a non-participant ethnographic observation of virtual and face-to-face MDT meetings in three paediatric rheumatology centres in the UK. A structured observation checklist was used to capture and organise field notes which were analysed using an inductive thematic approach amongst research team members. Interpretation of field notes was guided by discussions with healthcare professionals from each of the teams involved.

Results: Forty-two healthcare professionals from across the three teams participated. Ten meetings from each team (n=30) were observed, with meetings ranging from 1-2 hours. Analysis was organised into three themes; 1)Describing the child/young person with pain: Healthcare professionals’ perceptions about personality characteristics (e.g. “He is mature,” “She is sensitive”) were frequently used to introduce a child/young person to the team. A child/young person description was always accompanied by a description of parents and perceptions about their behaviour (e.g. “Dad is very disengaged,” “Mum can shout”). 2)Interpreting the pain of the child/young person: A core component of interpretations was professional familiarity with the child/young person and parents (e.g., “I haven’t got a handle on them yet”). Professionals also discussed how their interpretation was influenced by “gut feelings” or “vibes that something else is going on at home”. 3)Managing the child/young person with pain: Healthcare professionals discussed the need for acceptance of pain and treatment from children/young people (e.g., “She wasn’t buying into that; “He needs to get used to it”). Setting boundaries for children/young people and parents for accessing the team also featured in discussions (e.g., “We need to re-assure them but not always be available”).

Conclusions: This study highlights a range of healthcare professional approaches and processes to communicating about and discussing children/young people with pain at paediatric rheumatology MDT meetings. Findings suggest that healthcare professionals in paediatric rheumatology describe, interpret and manage the child/young person presenting with pain alongside the broader psycho-social (and less frequently the biological) context. These findings will inform the development and methods of a behaviour change intervention to improve pain communication in consultations with children/young people, parents and amongst the paediatric rheumatology team of healthcare professionals in the UK.

POS1561-HPR
HEALTH CARE PROVIDERS’ PERSPECTIVE ON CONTINUATION VERSUS TEMPORARY INTERRUPTION OF IMMUNOMODULATORY AGENTS IN CASE OF AN INFECTION: AN INTERVIEW STUDY

M. Opdam1, J. E. Vriezekolk2, A. Den Broeder1,3, L. M. Verhoef1. 1Sint Maarten’skliniek, Rheumatology, Ubbingen, Netherlands; 2Sint Maarten’skliniek, Research, Ubbingen, Netherlands; 3Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands

Background: Immunomodulatory agents (IA) are often used in the treatment of immune mediated inflammatory diseases (IMIDs). The use of some of these IA is associated with a slightly increased infection risk (1), which raises concerns especially during the current COVID-19 pandemic. It is however unknown whether it best to continue or temporary interrupt IA in case of an infection, and what the views of health care providers are on this subject.

Objectives: To obtain insight in the health care providers’ perspective regarding continuation and temporary interruption in case of an infection and to assess barriers and facilitators for both treatment strategies.

Methods: Health care providers, involved in the pharmacological treatment of different IMID patients, were interviewed by phone or face-to-face using semi-structured interviews. Recruitment was done using purposive sampling based on age, gender, function, specialty and affinity with the topic. Interviews were conducted until data saturation and analyzed by two researchers using inductive thematic analysis.

Results: Thirteen health care providers with three different functions (medical specialist, physician assistant, resident in training) from three different medical specialties (rheumatology, gastroenterology and dermatology) were interviewed. Mean age was 49 years (range 34 to 66) and the majority was female (69%). Ten main themes were constructed, yielding 77 barriers and facilitators across the two treatment strategies (see Table 1 for themes and a selection of barriers/ facilitators). Health care providers mentioned that the choice between continuation and temporary interruption is often about balancing infection severity, IMID severity (e.g. risk of flare) and patient characteristics (comorbidities/vulnerability). They struggled with the lack of evidence on these two treatment strategies, which leads to choices being made based on previous experiences or intuition.

**CAN EDUCATION PROGRAMS REDUCE ANXIETY IN PATIENTS WITH RHEUMATOID ARTHRITIS?**

S. Lezhnien1, N. Shuvalova2, E. Guryanova3, N. Igoshina1, I. Chuvash State University by I. N. Ulianov, Department of Healthcare Management and Economics, Cheboksary, Russian Federation; 1I. Ya. Yakolev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation; 2Chuvash State University by I. N. Ulianov, Department Internal Diseases, Cheboksary, Russian Federation

**Background:** Persistence of pain syndrome is accompanied by emotional changes and contributes to the formation of anxiety disorders in patients with rheumatoid arthritis (RA). Models of training patients with RA are aimed at developing the correct behavioral stereotype and improving the psychological status. To evaluate the effectiveness of these educational programs, it is required to study the impact of these programs on the level of anxiety in patients with RA.

**Objectives:** To assess the impact of education in an educational program in patients with RA on the level of anxiety.

**Methods:** The study was conducted in the Chuvash Republic, the city of Alatyr, from December to January 2020. 90 patients with RA of varying severity were examined. The inclusion criterion was a diagnosis of RA in accordance with the criteria of the European Antirheumatic League (EULAR) / ACR 2010. All patients were randomized into two groups: the main group (n=45), which, on the background of drug therapy (methotrexate at a dose of 7.5 to 15 mg/week and nimesulide 200 mg/week) was trained in the educational program: lectures and practical exercises. In the practical part, most of the time was devoted to the skills of self-control of the disease (taught how to self-assess swollen and painful joints). The training was carried out in two stages. The first stage (lecture-practical course) - twice a week for 1.5 hours, for two weeks, full-time education. The second stage (lecture course) - twice a week for 1.5 hours for two weeks, distance learning. In the control group (n=45), patients received the same treatment but were not trained in the educational program. Patients in these groups were representative by sex and age. All patients before and after completing the training program (after 1 month) were determined the level of situational and personal anxiety according to the Spielberger questionnaire modified by Yu.L. Khanina. The results obtained were interpreted: up to 30 points – a low level of anxiety, 31-45 corresponded to an average level, over 45 - a high level of anxiety. Statistical processing was carried out in the MS Office Excel package with the determination of average values (M), standard deviation (SD), and p-value

**Results:** Before training in the main group, the structure of personal anxiety was represented by a high level of 62.14 ± 4.46 points (83.0% of patients), while reactive anxiety was represented by average values of 39.25 ± 3.29 (62% of patients). 2% of respondents had a low level of personal anxiety, 5.2% of patients had low levels of reactive anxiety. Anxiety scores were about the same in the two groups. After training in the main group, the level of personal anxiety decreased in 41% of respondents (53.22 ± 6.87 points), reactive anxiety decreased by more than 2 times in 27% of patients. The number of patients with low levels of both personal and reactive anxiety increased to 40% and 40.2%, respectively. The differences were statistically significant (p<0.05). In the control group, the level of anxiety did not change statistically significantly.

**Conclusion:** Patients with RA who were trained in an educational program had a two-fold decrease in the level of personal anxiety and more than a two-fold decrease in the level of reactive anxiety, compared with patients who did not receive training. It is possible that the decrease in the level of anxiety in patients with RA occurred both due to a higher level of awareness of patients about this disease, and due to changes in the psycho-emotional state.

Conclusion: People with RMD prioritized information about medications and prognosis in educational materials, providing guidance for the development of educational tools. A sizeable minority felt educational materials were an important component of a smartphone app, but also identified other important features such as participation in research.

ASSESSMENT OF QUALITY AND RELIABILITY OF YOUTUBE VIDEOS FOR PATIENT AND PHYSICIAN EDUCATION ON INFLAMMATORY MYOSITIS

M. Joshi, N. R.2, R. Gupta1, V. Agarwala2, R. Aggarwala2, L. Gupta2, Byramjee Jeejeebhooy Government Medical College and Sassoon General Hospitals, Department of Medicine, Pune, India; 3Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India; 4University of Pittsburgh, Department of Medicine, Rheumatology and Clinical Immunology, Pittsburgh, United States of America

Background: Nowadays 80% of internet users access health information online, with YouTube being the second most popular search website worldwide. This study was undertaken to assess the reliability and quality of videos pertaining to myositis on YouTube and identify lacunae in information material on the platform.

Objectives: This study aims to assess the quality and profile of myositis information videos on YouTube, and to compare and delineate attributes of useful and not useful videos using standard metrics.

Methods: A thorough search was carried out on YouTube using 9 search terms related to myositis. The inclusion criteria were primary English content related to myositis, acceptable audio-video quality, and multi-part videos to be considered as one, while duplicates and advertisements were excluded. The videos were classified as useful, not useful or misleading, and patient experiences (Figure 1).

Results: Of 493 analyzed videos 74% and 2% provided useful and not useful information respectively. 24% were patient experiences, and 324 (71%) were intended specifically for patients while 313 (69%) were for healthcare providers and students. Nearly one-thirds (n=143) reported information related to treatment intended specifically for patients while 313 (69%) were for healthcare providers.

Conclusion: A majority of useful YouTube videos on myositis provide useful information for patients, largely related to treatment of myositis. However, the dynamic nature of YouTube could potentially change this equation in the future and physicians should correct any misinformation identified in face-to-face meetings or teleconsultations. High quality useful videos, often predicted by validated scores and produced by professional medical societies should be promoted as the first line of content consumed.

Disclosure of Interests: None declared

Conclusion: Majority of English YouTube videos on myositis provide useful information for patients, largely related to treatment of myositis. However, the dynamic nature of YouTube could potentially change this equation in the future and physicians should correct any misinformation identified in face-to-face meetings or teleconsultations. High quality useful videos, often predicted by validated scores and produced by professional medical societies should be promoted as the first line of content consumed.

**THE BRIEF-ILLNESS PERCEPTION QUESTIONNAIRE: A METHOD FOR ASSESSING THE COGNITIVE REPRESENTATION OF RHEUMATIC DISEASE**

Z. Zeineb1, S. Jemmali1, S. Rekik1, S. Boussaid1, S. Rahmouni1, K. Zouari1, H. Sahli1, M. Elleuch1, 1Rabta University Hospital, Rheumatology, Tunis, Tunisia

Background: The common-sense model proposes that illness perception (IP), is how patients make sense of their illness and respond emotionally to it, influencing the way they cope with the illness and subsequently illness outcomes. This proposition has gained considerable empirical support, and the relevance of IP in understanding illness-related behaviors or outcomes has also been supported in patients with rheumatic diseases (RD). The Brief Illness Perception Questionnaire (B-IPO) was designed to provide a simple and rapid assessment of IP. This questionnaire has been widely used in diverse ages, illness types, countries, and languages.

Objectives: This study aimed to examine the construct of IP as measured by the B-IPO in patients with RD.

Methods: A cross-sectional study was conducted at a Tunisian rheumatology department on 80 patients with RD. Sociodemographic, disease-related variables were reported. Participants completed a questionnaire on illness beliefs (B-IPO).

Results: Subjects were aged 22-74 years (mean 51 years), 61.6% were female. Diagnoses included Rheumatoid arthritis (RA) (63%), axial spondyloarthritis (AS) (37%). The mean disease duration was 11 years and 7 years for RA and AS respectively. The proportion of physical comorbidities was higher in RA patients (36%) versus AS patients (11%). Disease activity was low in 28.8% of patients. All patients were on medications for their rheumatic disease, and 34.6% were on biological therapy.

In both diseases, the participants perceived their rheumatic illness as a chronic condition (9.4) that could be controlled by treatment (6.6) but not strongly influenced by personal actions (4.3). Overall, Rheumatic disease was seen as having an important impact on their life (7.9) without significant difference between patients with low or high activity disease (p=0.23). The majority believe that they have a moderate understanding of their illness (6.6). The frequency of symptoms was highly evaluated in RA patients than AS patients (73 vs 56) (p=0.01). In RA patients, 76% were extremely affected emotionally by their disease, however, the majority of AS patients were moderately affected emotionally with a significant difference (p=0.02). In addition, RA patients considered their disease mainly a result of psychological factors (66.8%). On the other hand, AS patients (73%) attributed their illness to various risk factors (especially physical overexertion).

Conclusion: High scores of B-IPO shown in our studies, encourage the design of psychotherapeutic trials targeting disease-related cognitions in AS and RA in an attempt to improve patients' reported outcomes and disease outcomes.

**POS1567-PARE**

**ASSESSMENT OF ADHERENCE AMONG GREEK PATIENTS WITH RHEUMATIC DISEASES DURING THE COVID-19 ERA**

K. Koutsogianni1, E. Repa1, K. Spanidou1, I. Papadakis1, I. Chatzkyraklis4, P. Pratsidou-Gertsi5, F. Asimakopoulou1 on behalf of ReuMAzein's Team.

Background: Patient’s (pts) adherence is a EULAR important recommendation for an optimal disease course and outcome. COVID-19 pandemic has globally challenged the issue of adherence. As relevant Greek data are lacking, the Pan-Hellenic Federation “Rheumazein” (i.e., co-living with a Rheumatic Disease) conducted a survey among their members to assess adherence and a possible COVID-related negative impact.

Objectives: The main endpoint of the study aimed to capture the degree of pt adherence to treatment, either with conventional synthetic or/and biologic DMARDs (csDMARDs, bDMARDs). The secondary endpoints were: a. To record pts’-physicians’ interactive communication to assess the level of shared disease making (SDM), b. The emerged barriers to medication access during the pandemic and consequent restrictive measures. c. To record pt perceptions on the usefulness of mobile reminder applications towards an uninterrupted regimen.

Methods: A 29-item quantitative questionnaire was uploaded in the social media of the Federation and its associations, in order to register pts’ responses on the aforementioned sections. The questionnaire was accessible for a 58-day period (21/09/2021-17/11/2021).

Results: Participants’ characteristics: The responses of 303 adults with RD (M:F 63:240), aged (in yrs) 18-44: 35%, 45-54: 26%, >55: 38% respectively, were available for analysis. The RD types were RA 33%, AS 18%, PsA 13%, SLE 18%, Juvenile Arthritis 5% and Other RD 13%, respectively. The education level was low/moderate 39%, high 30%, post-graduate 31%, respectively. Receivers of a monotherapy with either cs- or bDMARDs were 93(31%) and 83(27%), of a combined regimen cs+bDMARDs 114(38%) and of treatment ad 13 (4%). BDMARD receivers were mostly AS pts (93%) while the least, SLE pts (48%). The route of bDMARD administration (sc vs iv) did not significantly differ (57% vs. 43%). Since diagnosis, the mean disease trajectory was 7.6 yrs, the mean time on medication 6.9 yrs, while the mean duration on the current regimen 3 yrs, respectively. Adherence: At least one skipped dose during the last trimester was reported, significantly more often by pts under csDMARDs than by those under bDMARDs, (60% vs. 40%, p<0.001) with a significant difference (p=0.02). In addition, RA patients had a significantly higher adherence than AS patients under bDMARDs (76% vs 40%, p<0.001), but not for csDMARDs (60% vs. 40%, p<0.001) with a significant difference (p=0.01). In RA patients, 76% were extremely affected emotionally by their disease, however, the majority of AS patients were moderately affected emotionally with a significant difference (p=0.02). In addition, RA patients considered their disease mainly a result of psychological factors (66.8%). On the other hand, AS patients (73%) attributed their illness to various risk factors (especially physical overexertion).

Conclusion: A significant percentage of pts skip scheduled DMARD administration, especially those (60%) under csDMARDs. The relationship with the physician was considered relatively satisfactory. Most of the pts did not have any mobile phone reminder application regarding their dose. Finally, the COVID-19 pandemic appeared to have had little effect on pts’ access to both cs- and bDMARDs and consequently, adherence to their treatments.

Arthritis research

POS157/PARE A PATIENT-LED SURVEY INTO THE BENEFITS AND LIMITATIONS OF TELEMEDICINE APPOINTMENTS FOR ASSESSING CHILDREN AND YOUNG PEOPLE WITH RHEUMATIC CONDITIONS: COMPARING EUROPEAN AND CANADIAN COHORTS

R. Bleesey1,2, G. Angewane3,4, J. Wilson5, W. Costello6,7,8,1 Juvenile Arthritis Research, JAR Project, Tonbridge, United Kingdom; 2European Network for Children With Arthritis, ENCA, Geneva, Switzerland; 3KAISZ, KAI SZ, Amsterdam, Netherlands; 4Autoinflammatory Alliance, Autoinfl ammatory Alliance, San Francisco, United States of America; 5Cassie And Friends Society, CAF Society; Vancouver, Canada; 6Irish Children’s Arthritis Network, ICAN, Bansha, Ireland

Background: During the COVID-19 (coronavirus) pandemic, some provision of healthcare shifted to remote, technology-assisted appointments (telemedicine). Whilst parents/carers of children and young people with rheumatic conditions have reported benefits of telemedicine, concerns remain.

Objectives: This patient and parent-led project sought to understand the views of parents/carers about telemedicine, identifying the benefits and limitations of remote technology-assisted appointments, and comparing views between Canadian and European cohorts.

Methods: An online survey was developed, translated into multiple languages and shared via social media and patient organisations, targeted at parents of children and young people with rheumatic, autoimmune and autoinflammatory conditions. Fieldwork took place in April 2021 in Europe and May 2021 in Canada. Consent was provided during enrollment.

Results: A total of 290 responses were received (133 Europe; 157 Canada). Of these, 73% were female, median age 12. Over half of respondents (53%) in Europe reported travelling over an hour to in-person appointments with their paediatric rheumatologist, compared to a significantly higher proportion of respondents in Canada (97%). Consequently, in-person appointments represent a greater time burden amongst Canadian caregivers, though both groups report appointments taking over three hours in total (51% Europe, 69% Canada).

Prior to COVID-19, most had never had a telemedicine appointment (92% Europe, 95% Canada). Since March 2020, the majority (71% Europe, 82% Canada) had at least one telemedicine appointment.

Table 1. Shows the scores (1 worst, 5 best) given by parents about their telemedicine experience. Overall, most aspects scored positively (p<.05). However, parents felt telemedicine was not as good as in-person appointments.

Table 1. Top Goals based on rating as “Very Important” by >70% of subjects, from set of 36. “My goals for living with RA are to…”

Goals Not Important Somewhat Important Important Very Important
Symptom Management improve the quality of my life with RA 0% (0) 0% (0) 6% (3) 94% (44)
manage my RA pain 0% (0) 2% (1) 11% (5) 87% (41)
Life Impact reduce how my RA pain interferes with my life 0% (0) 9% (4) 17% (8) 74% (35)
be independent in my daily functioning 0% (0) 2% (1) 21% (10) 77% (36)
Managing my RA feel like I can manage my RA 0% (0) 4% (1) 15% (4) 81% (22)
have the information I need to make treatment decisions 0% (0) 0% (0) 19% (9) 81% (38)
Impact goals were rated as Important or Very Important by >85% of participants; endorsement for Management and Treatment goals was somewhat more variable, with ≥85% endorsing these as Somewhat to Very Important. Results suggested that domains match key goals. Steering committee ratings supported the feasibility of this approach.

Conclusion: Goals relevant for RA treatment evaluation can be efficiently identified and rated for importance by patients. Patient-important goals can be incorporated into deliberative healthcare valuation using this method to permit “crow-sourced” input from people living with RA and to capture heterogeneous patient perspectives in healthcare valuation.

Acknowledgements: I have no acknowledgements to declare.

</tbody>
</table>

When asked about aspects of telemedicine, a greater proportion of respondents from Canada answered favourably compared to those from Europe with the majority reporting telemedicine appointments had saved them time, enabled them to have an appointment and that it made the appointment safer. However, most felt that their consultant could not properly assess their child (72% Europe, 78% Canada, p<.05).

Overall respondents said they would prefer the next appointment to be in-person (82% Europe, 62% Canada, p<.05), although 31% from Canada were amenable to a combination of in-person and telemedicine-based care.

Conclusion: There are advantages to telemedicine, notably saving time and making appointments accessible. Families from Canada tended to view telemedicine more favourably than those from Europe, although the majority from both cohorts reported concerns about the ability to assess their child. There may be value in providing training to parents to enhance the accuracy of home-based assessments, particularly when the disease is stable. However, parents continue to report the value of in-person appointments.

Innovations in arthritis health care.

**POS1571-PARE**

Online Counselling for Patients with Arthritis

S. Đorđević, M. Lapčević, Association Of Patients With Rheumatic Diseases of the Republic of Serbia (ORS), Association of Patients, Belgrade, Serbia; "Association of Patients With Rheumatic Diseases of the Republic of Serbia" (ORS), Association of Patients, Belgrade, Serbia

**Background:** The Covid-19 pandemic has changed many aspects of our lives. Perhaps the biggest changes have been in medical services. Institutes specializing in RMD in Serbia were part of the covid system and patients only had access in emergency cases, there was no regular examination.

**Objectives:** The paper shows how the "Online Counselling for Arthritis Patients (OCAP)" worked during the pandemic, how many rheumatologists and patients were involved and were patients satisfied with the service provided.

**Methods:** Through the platform "Lekarinfo" ORS, in cooperation with pharmaceutical companies, organized an OCAP. Patients were informed about the possibility of using online consultations with rheumatologists via social networks, viber groups, email, and they were given instructions on how to use it, they were advised to send medical documentation before, so the doctor has time to look at it, which gives more time for conversation. Consultations were held by phone or online, depending on patient’s wishes and abilities. The time set aside with a rheumatologist was 20 minutes and with a psychologist 30 minutes. One psychologist and 23 rheumatologists were available. The ORS distributed cards to rheumatologists with contact data and instructions on how to contact OCAP to inform their patients.

**Results:** ORS conducted a Survey about OCAP. It was completed by 100 respondents, aged 20 to 75 of whom 75% were women. The 44% of respondents were from Belgrade, but it also included respondents from all over the country. RA have 61% of respondents, but patients with other types of arthritis were also included. 4/5 of patients are non-smokers and half of them are on biological therapy. All but one respondents are ORS’s members. The results of Survey are the following: OCAP was used by 27% of respondents and all of them were satisfied except one. Everyone would use it again and would advise others to do so. Online consultation can replace live examination, when the disease is in remission, thanks 62% of respondents. The majority (90%) found it technically easy to use, but also the majority of respondents felt that there is a space for improvement (70%). One third prefers to have online consultations with their rheumatologist, Half of them understand the importance of telemedicine, 61% think that C-19 pandemic has increased the need for it and 64% think that digital solutions are our perspectives and it should be further developed.

**Conclusion:** It is desirable to continue with this kind of telemedicine. Patients and their families should be encouraged and educated about using digital platforms, aim is to explain them the benefits of telemedicine and that consultations do not necessarily have to be with their rheumatologists. Regardless of the pandemic, digitalization is in every aspect of our life, it is inevitable, but also it is a great advantage that should not be missed. Investments in the development of online platforms, that will facilitate patients access to doctors are an investment in self-control of chronic diseases in extraordinary circumstances, but also in normal conditions when because of the overscheduled doctors, lack of time for employed patients or other reasons, it is not possible for frequent examinations. Telemedicine is an investment not only in physical health but also in mental health of patients, having a doctor “just a step from you” has calming and positively affects for patients. And without positive attitude it’s hard to keep a chronic disease under control.

Helping a way of working in ORS branch – NIS during the COVID-19 pandemic in 2021

D. Jankovic, V. Filipovic, Association of Patients With Rheumatic Diseases of the Republic of Serbia - ORS, Nis Branch, Belgrade, Serbia

**Background:** Helper is a person with RMD educated to help other patients. Based on the clearly defined authorizations this person helps in advising and information sharing among the ORS members. Association of patients with rheumatic diseases of the Republic of Serbia (ORS) operates across the country through the reference centers/branches, but in pandemic the functioning of helper in a regular way was significantly impacted.

**Objectives:** In order to continue with the functioning in Association and with Helper during the Covid-19 pandemic, new communication and information sharing methods has been applied. In this work will be shown how the strategy of communication was shifted from physical to digital, methods used for information sharing and communication tools of the modern world has been used for this purposes. Also, functioning of the branch in Niš and its Helper will be shown through statistical comparison of data prior and during the Covid19.

**Methods:** In the definition of Association’s members’ request for the new circumstances, it has been concluded that most of the members are using some of IM platform or e-mail. Based on this fact, out of 247 members of branch in Niš, 168 members have been joined through the most popular IM platform in Serbia – Viber. Through the group the patients has been sharing the information, notifications and other news important for the patients. Group administrators supported discussions, but also identified patients who do not use IM platforms and those members were notified by phone or e-mail. This method of communication was symbiotic with other projects of the Association because we used the same communication channels to increase the awareness of members about the activities of the Association.

**Results:** During 2019, Helper’s work took place under normal conditions. At the Niska Banja Institute, Helper used the office where patients with rheumatic diseases used to come. Four lectures by eminent experts in the field of rheumatology and physiatry were organized, as well as socializing in the form of meetings and field trips. We marked the World Arthritis Day and the World Osteoporosis Day.

During 2021, most activities took place online or outdoors, depending on the intensity of the Covid-19 wave. Helper’s work took place from home in January and February 2021, and from March to the end of 2021, Helper worked in the office. The lectures that were organized were exclusively online. We have marked the World Arthritis Day with a small number of participants. The event was realized with media support.

**Analysis and participation of members in 2019 and 2021 are shown below**:

- In 2021, 208 vs 260 live contacts in 2019; on average 17 vs 22 contacts per month.
- In 2021, 216 contacts through online meetings; on average 18 per month.
- IN 2019 no such exercise.
- In 2021, 2000 vs 239 contacts in Viber group in 2019; on average 167 vs 20 members.
- In 2019, alternative communication methods were not used. In 2021, 1,023 contacts were made with messages, calls and emails, or 85 per month.

**Conclusion:** Based on the fact mentioned above, 2019 was richer and more fulfilling with lectures, socializing and direct communication with members, while in 2021 communication was dominated by digital tools and methods (Viber groups, calls, emails) and consultation with doctors via e-consultations and by phone.

The pandemic disabled direct contact with members of the Association and live lectures, but the Association used digitalization as a complement to new ways of working that connected us more than ever before, enabled instant transmission of information and created a network support at any time it was necessary, the most. With this process in place, we not only fulfilled the goal of the Association, but we went a step further - we became the first contact for patients with RMD.

Patient-Reported Outcome Measures of Pain Alleviation with Cannabinoid Usage in Rheumatoid and Psoriatic Arthritis: A Cross-Sectional Study.

T. Jehu1, N. Bhaskar1, S. Beg2, K. Camargo Macias2, S. Chalise3, N. Bhanusali1,2

1University of Central Florida College of Medicine, Statistics, Orlando, United States of America; 2University of Central Florida College of Medicine, Rheumatology; 3University of Central Florida College of Medicine, Statistics, Orlando, United States of America

**Background:** Patient-Reported Outcome Measures (PROMs) give us direct, immediate evidence of patient experience. Pain is a chronic, debilitating, multifactorial, presenting symptom that remains a difficult target to treat in populations with Inflammatory Arthritis. Increasingly, cannabis products are being utilized and investigated for their potential analgesic and immune-modulatory effects. The legislation and form of cannabis products deployed as therapy varies around the world and across populations. More data on usage and patient reported outcomes is needed to guide better clinical practice and inform sound legislative policy.
Psychosocial support

S. Chapman1,2, A. Jordan3, W. Tillett4,5. *King’s College London, Waterloo Bridge Wing, Franklin Wilkins Building, Institute of Pharmaceutical Sciences, London, United Kingdom; 2University of Bath, Pharmacy & Pharmacology, Combe Down, United Kingdom; 3University of Bath, Psychology, Bath, United Kingdom; 4Royal United Hospital, Rheumatology, Bath, United Kingdom

Background: Patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are often nonadherent to prescribed symptom-modifying drugs. [1] Concerns about the potential negative effects of medication have been implicated in medication nonadherence. Evidence-based interventions to address concerns about medication and support medication-taking are available in the UK context.

Objectives: To inform the development of intervention to support people with RA and PsA to manage medication we conducted a survey of unmet needs relating to perceptions of arthritis and arthritis medication, medication-taking behaviour and experience of side effects.

Methods: We recruited people with arthritis via local and national patient groups for participation in an online survey. The survey included clinical and demographic questions, validated measures of treatment (Beliefs about Medication Questionnaire (BMQ)) and illness perceptions (brief Illness Perception Questionnaire; biPQ), medication adherence (Compliance Questionnaire Rheumatology; CQR), and patient-reported side effects. Participants were asked about consequences of taking and not taking their arthritis medication as free text to contextualize scores.

Results: Questionnaires were received from 98 participants (42 with PsA, 56 with RA, 89.8% female) indicated participants typically viewed arthritis negatively with ratings on the biPQ indicating high emotional impacts, symptoms and affects on everyday life, and doubts about their ability to control their arthritis. Analysis of the BMQ indicated ambivalence about RA/PsA medications; while few people expressed doubts about their personal need for medication, concerns about RA/ PsA medications were common, see Figure 1. Most, 85.7% (n=84), reported a side effect in the last month, with a mean of 10 ‘moderately severe’ or ‘very severe’ side effects (m=10.02, sd = 5.98). Just over a quarter (26.0%, n=25) were classified as low adherers using the CQR with 54.6% reporting they had missed some of their arthritis medication over the last year. Free text responses indicated that some participants had additional concerns about medication (e.g. worries about impact on life expectancy) not addressed in the questionnaire measures.

Conclusion: In this pilot survey, many participants reported concerns about medication, doubts about whether medication controls arthritis symptoms, severe side effects and medication nonadherence. Although our small sample is unlikely to be generalizable to all arthritis patients, these findings suggest potential targets for intervention and indicate that some patients have needs for support with medication that are not currently being addressed.

Work and rehabilitation

T. Garen1, A. Tollisen2, H. Andersen1, B. Gudbrandsaso2, Ø. Præm2, 1Oslo University Hospital, Rheikshospitalet, Department of Rheumatology, Oslo, Norway; 2Lovisenberg Diagonal Hospital, Oslo, Unger-Vetlesens Institute, OSLO, Norway; 3Oslo University Hospital, Rheikshospitalet, Department of Rheumatology, Oslo, Norway

Background: Takayasu arteritis (TAK) is a rare vasculitis of large vessels, mainly in young women, with a point prevalence of 25.6/10⁵ in a Norwegian population. TAK is most prevalently limited to the aortic arch and its branches (Type 1) among North Europeans (1). Early symptoms include fever, myalgia and loss of appetite. Later, irreversible vascular damage and ischemic symptoms with claustration of the extremities may occur. We have previously observed a reduced life expectancy, mainly due to cardiovascular complications, and a median age among those deceased of only 58 years (2). These findings clearly indicate that TAK may have severe impact on the wellbeing of the patients and their physical capacity. Furthermore, being part of the working life is a major component of life but is affected in chronic autoimmune diseases (3,4).

Objectives: (i) To describe general health status and quality of life in patients with different working status. (ii) To estimate the rates of patients having paid work or receiving disability benefits, compared to the general Norwegian population.

Methods: Patients with TAK registered in “The Norwegian Systemic Connective Tissue Disease and Vasculitis Registry” (NOSVAR) were included. All patients fulfilled the American College of Rheumatology classification criteria and/or the modified Ischemic criteria for TAK (3). General health status was measured with 10-cm visual analogue scale (VAS) of pain and fatigue, ranging from 0 (best possible score) to 10 (worst possible score) and with Patients’ global assessment (PfGa) of health measured by a five-point Likert scale with scores ranging from 1 (very good health) to 5 (very bad health). The SF-36 was applied
to measure health related quality of life and included 8 scales with score ranging from 0 (worse) to 100 (best). Disease duration was defined as the time from diagnosis to date of registration. Working full- or part time was defined as paid work. We adjusted for age, gender and residence counties in southeast Norway, using reference data from Norway Statistics. Indirect standardization with 95% confidence interval rates was calculated. Descriptive analyses were conducted.

Results: Patients with paid work were more educated compared with those receiving disability benefits (81% vs 19% p<0.031). Patients receiving disability benefits reported higher levels of pain (3.4 vs 1.4, p=0.024) and disease activity (3.9 vs. 0.8, p=0.025), more frequently claudication in legs (83% vs. 17%, p=0.009) and impaired quality of life measured with SF-36, physical functioning (66 vs 88, p=0.002) and role physical (32 vs 65, p=0.017) compared to patients with paid work/students (Figure 1). Compared with the age and gender matched general population, the disability rate of female patients was 16 % higher, adjusted ratio (CI 95%) 1.2 (1.2-3.3), p=0.038. The paid work rate was 51% lower in women with TAK compared to the general population, adjusted ratio (CI 95%) 0.38 (0.23-0.64), p=0.001.

Conclusion: TAK-patients receiving disability benefits reported lower health status and lower quality of life by physical functioning and role physical in SF 36. Work disability in female TAK patients was 16 % higher and for paid work 51 % lower compared to the general population.

Best practice campaigning

POS1576-PARE | IMPROVING METHOTREXATE PRESCRIBING AND DISPENSING SAFETY THROUGH A SIMPLE ADJUSTMENT TO ELECTRONIC PRESCRIBING.
C. Stovin1, K. Lawan2, C. Byrne2, A. Choy3, N. Purkayastha1. 1Kings College Hospital, Rheumatology, London, United Kingdom; 2Kings College Hospital, Pharmacy, London, United Kingdom

Background: Methotrexate (MTX) is the most commonly prescribed disease-modifying antirheumatic drug (DMARD) in rheumatoid arthritis, as well as being frequently used in other rheumatic conditions. Having been discovered in 1948, 1 its use is established and the toxicity profile is well recognised. In the rheumatology setting, it is prescribed as a once weekly dosing regimen. However, despite experience in the use of MTX, there still remains a concern for patient safety with regards to more frequent ingestion than the weekly dose. This can result in severe complications such as acute kidney injury, myelosuppression, mucositis and even death. According to Medicines and Healthcare products Regulatory Agency (MHRA), there were 11 adverse event reports between 2006 and 2020, and as a result, in 2020 the MHRA outlined guidance to reduce the potentially fatal dosing errors associated with the prescription of MTX 2.

Amongst this guidance, prescribers are instructed to discuss, document and include in the prescription, the specific day of the week MTX is to be taken. Dispensers are also advised to document the day of the week on the MTX drug dispensing label. At King’s College Hospital (KCH) there is an existing mandatory field for day of the week for when prescribing inpatient non-cancer MTX treatment. However, this does not exist currently for outpatient electronic prescribing.

Objectives: To update practice in the KCH Rheumatology department, in line with MHRA guidance on MTX prescription.

Methods: A retrospective audit of 30 MTX new and renewal prescriptions over 1 month was conducted to assess concordance with MHRA guidance. The safety-nets of documentation of day of the week on most recent clinic letter, drug prescription and drug dispensing label were reviewed. Following this the electronic prescription system was updated to make “day of the week” a mandatory field required to complete MTX prescriptions. A sample of 30 patients post intervention was then re-audited.

Results: The percentage of new prescriptions across the 2 groups were roughly equivalent (30% vs 33%). Prior to intervention, 44% of new MTX prescriptions had no form of documentation of the day of the week across all 3 safety-nets, and only 33% had at least 2 of the 3 safety-nets completed. Post-intervention this has increased to 100%. Of those newly prescribed MTX, the inclusion of day of the week on clinic letters rose from 22% to 40%. There were similar improvements seen in safety-nets achieved for repeat prescriptions.

POS1577-PARE | WHAT PATIENTS VALUE AND NEED FROM HEALTHCARE IN THE DIAGNOSIS AND MANAGEMENT OF AXIAL SPONDYLOARTHRITIS

Disclosure of Interests: None declared
Background: The clinician’s understanding of what constitutes good quality care for axial spondyloarthritis (axial SpA) has been explored (1) and used to define quality standards (2,3). However, research into the patient perspective on what constitutes good quality care was lacking. The UK’s National Axial Spondyloarthritis Society (NASS) commissioned Headstrong Thinking, and its research partner, Community Research, to investigate this issue.

Objectives: The objectives of the research included: to explore the lived experience of those with an axial SpA diagnosis, to identify all the stages (domains) and milestones they identify and describe in their journey; to identify tangible person-centred indicators of “quality” in each of those stages, covering clinical care, patient care (non-clinical) and support for their mental health needs; to capture the everyday language used to articulate their values and needs around “quality”; and to understand possible differences between individual/subgroup experiences.

Methods: The project will use both qualitative and quantitative methods sequentially. This paper reports only on the qualitative stage of the project, which comprised twelve individual depth interviews, conducted online, across a broad spectrum of people living with axial SpA in the UK, allowing for variation in age, sex, socio-economic status, presence of children, length of time since diagnosis, physical symptoms and comorbidities.

Findings from the qualitative stage will inform the questionnaire for the quantitative stage (target n=1,500), which will seek to validate and refine initial hypotheses and quantify differences between sub-groups.

Results: This paper presents a rich understanding of the impacts on mental, emotional, cognitive and practical aspects of life with axial SpA. A detailed picture of a wide range of clinical, psychological and practical adverse impacts around delayed diagnosis is described.

Further, the qualitative research found that, from the perspective of people with axial SpA, quality care consists of three elements, defined by patients as: to be seen, heard and believed; to experience a purposeful, consistent pathway of care, underpinned by effective administration and communication (rather than a series of care “snapshots”); and to be helped to know what they can do to help themselves, including making a care plan that evolves as needs change.

Individuals with multiple or complex comorbidities were less likely to report having experienced good quality care, as they defined it, in part due to the challenges of accessing a joined-up patient journey and their greater reliance on an individualised approach to their care.

Conclusion: Patients define quality care in the diagnosis and management of axial SpA differently to clinicians. Professionals involved in the diagnosis and care of people living with axial SpA (including rheumatologists, but also those involved in the wider care of people living with axial SpA, such as physiotherapists and even mental health professionals) would benefit from a greater understanding of the patient perspective.

The individual stories uncovered in this qualitative phase underpin the importance of collecting and analysing quantitative data by demographics, life stage and by discrete phases in the diagnostic /ongoing patient (self) management journey.

P0S1578-PARE TO OBTAIN GREATER AWARENESS OF ARTHRITIS AND THE DANISH ARTHRITIS ASSOCIATION BY MEDIA COVERAGE

J. Lüthcke1, 2. Digtforingen, Communications Department, Gentofte, Denmark

Background: Despite arthritis being among the most common diseases in Denmark, the overall personal consequences followed are generally unknown. You don’t die of arthritis. This is reflected in the population’s general knowledge of The Danish Arthritis Association of a mere 57 %, despite being Denmark’s third largest patient organisation.

Objectives: To obtain greater awareness of arthritis and the Danish Arthritis Association by media coverage.

Methods: We use case stories strategically in our offensive political agenda. By presenting a good case story with a personal, yet wide perspective, we quite often succeed in getting our agenda in the media – as personal and emotional case stories are more likely stories to be chosen by journalists than political solutions from organisations like ours.

On social media (especially Facebook and Instagram) we also use case stories to a great extent – 2 – 3 times a week. Our followers like to read stories about people who struggle with the same issues as themselves – and to reflect their own issues. Whether they are newly diagnosed or have lived with arthritis for a long time, in general, we get good response on these personal case stories. Many likes, and often our followers share their own experience with each other and pass on good advice.

Helping out the media: The media and journalists are always in need of case stories to back up their articles and agendas. We have introduced the principle of always being willing to help the media with case stories. By providing cases with arthritis – even though the issues aren’t exclusively about arthritis, we help solving a problem, as well as we manage to turn the agenda into a story about arthritis as well. Examples are corona, vaccination, deferred surgeries, lack of coherence in the health system.

What does it take to use cases?: As an organisation, you have a responsibility to take care of your cases by informing them of what it means to be in the media. They must be prepared and helped out – also along the way. It is also important to choose cases who are well spoken and not afraid to express themselves.

Debate group: Some of the topics such as coherence in health care, are immediately academic topics, and difficult to understand – and therefore more difficult to get covered in the media. We have successfully initiated a debate group consisting of a small group of young arthritis patients, whom we have taught how to write debate posts. By telling their own personal stories – often with an underlying political angle – these articles have been published in the major national newspapers.

Results: We have succeeded in getting media coverage in both women’s magazines, tabloid newspapers, national newspapers as well as radio and television.

Conclusion: It is a fairly simple concept that easily can be copied by other patient organisations despite size.

Disclosure of Interests: None declared

P0S1579-PARE LET’S TAKE AN HEALTHY WALK IN THE PARK

U. Viora1, P. Guiso2, M. T. Mascarino3, G. Mascarino1, ANMAR Piemonte, Turin, Italy; 1AMA R Piemonte, AAI, Moncalieri, Italy; 2AMA R Piemonte, Presidency, Turin, Italy; 3AMA Piemonte, Young, Turin, Italy

Background: Patients with RMDs are not yet used to live physical activity such as an important part of their therapy; Covid 19 pandemic, with the restrictions imposed on interpersonal approaches and the fear of being infected and spreading the virus, has further slowed down the way towards these kind of empowerment.

During the pandemic, in Italy the number of pets (mainly dogs) had an exponential increase.

Animal Assisted Interventions /Animal Assisted Therapies seems to be really successful.

Objectives: Our project aims:

to offer people with RMDs the opportunity to move playing fitwalking under control of WALKin trainers who can teach them the right way to practice this new discipline or simply walking properly with their dogs or playing rehabilitative exercises (specific for each one) with the help of animals specially trained.

each session, to let us have a number of encoded informations which drive us to verify all progresses in term of improvement of mobility and mood and reduction of drugs consumption.

Results: The participation (face to face and virtual) in the first three meetings (October, November 2021 and January 2022) has been continuously increasing and we have a good core of "fans"; but also every time a lot of new people want to join us.

We are collecting the first inscriptions and we preview to start the activity on March 20 when the first groups will be led by Maurizio Damilano, twice world and Olympic running champion and inventor of fitwalking.

Each group will be lead by an expert (walking trainers, health professionals, teamsters).

Either each group leader or each participant will write a diary at the end of the activity session, to let us have a number of encoded informations which drive us to verify all progresses in term of improvement of mobility and mood and reduction of drugs consumption.

Debate group:

either academic topics, and difficult to understand – and therefore more difficult to get covered in the media. ALLELIC POLYMORPHISM OF INFLAMMATORY CYTOKINES GENES FOR PREDICTION OF CARDIOVASCULAR DISORDERS IN CHILDREN WITH JIA

A. Artsymovych¹, O. Oshlianska¹, Kyiv, pediatrics #1, Kyiv, Ukraine

**Background:** It is known that defects in the synthesis and structure of cytokines or their receptors can lead to modification of many pathological processes in the organism: inflammation, coagulation, impaired cell regeneration, which makes it appropriate to further study the genetic preconditions for the violation of immunoregulatory mechanisms. Great attention is paid to the study of allelic polymorphism of genes in chronic inflammatory diseases as a potential marker of functional activity of proteins encoded by them and related features of the course of various disease.

**Objectives:** To assess the impact of allelic polymorphism of TNFα (G308A) & IL6 (G174C) genes on the development of cardiovascular disorders in children with JIA.

**Methods:** 102 children with JIA were examined. Allelic polymorphism of TNFα (G308A) & IL6 (G174C) genes was determined by PCR using specific oligonucleotide primers, subsequent analysis of polymorphism of restriction fragments was made. Activity of disease was calculated using JADAS27. Functional state of the myocardium was assessed using software-hardware complex “Cardioplus 4”, an ECG of 4th generation. Cluster analysis of obtained data was performed. K-means and EM algorithms were used. The number of children who finally entered this stage of the analysis was 25.

**Results:** According to the disease activity, the number of mutations and the complex indicator of the functional state of the myocardium (CI FS, %), two clusters were identified. In cluster 1 (10 children, group 1) the higher score of CI FS (median 78%) and lower disease activity degree (JADAS 27 median 9.5) was noted, and in cluster 2 (15 children, group 2) high disease activity (JADAS 27 median 14) was observed and a decrease in the CI FS (median 62%). The CI FS according to the ECG of 4th generation differed significantly (p = 0.00001) in clusters. It is noted that in the second group the disease debuted relatively earlier (p<0.01). Among these cluster groups of patients with JIA there were a number of significant differences in general clinical laboratory parameters: the activity of AST in the blood of patients with JIA was 29±3.1 IU/l in the first group vs 24±2.2 IU/l in the second group (p = 0.07 Wald-Wolfowitz), serum creatinine was higher in the first group 68±11.0 μmol/l (against 57±9.3 μmol/l in the second group; t = -2.24, p = 0.044), also in the second group according to the results of the study according to the general analysis of blood there was leukocytosis (11±6.4 x 10^9 vs. 6.6±9.0 x 10^9, p = 0.075 Wald-Wolfowitz). According to the obtained data of the cluster analysis, the total number of mutations in the genes IL6 and TNF-α was significant for the course of disease. In cases with a larger number of mutations, a more aggressive course of the disease, a more pronounced degree of inflammation, a higher frequency of extra-articular lesions, including changes in the CVS, was noted.

**Conclusion:** The overall number of mutations in TNFα (G308A) & IL6 (G174C) genes makes impact on the course of the disease; two and more mutations are associated with a more aggressive course of the disease and can lead to cardiovascular lesions more likely. Determination of allelic polymorphism should be recommended to patients who have changes on ECG performed by a 4th generation ECG.

ATTEMPTS TO LINK EXONIC GENE POLYMORPHISMS TO ANKYLOSING SPONDYLITIS (AS)-ASSOCIATED PROTEIN MODIFIED FUNCTIONALITY: A STRUCTURAL BIOLOGY APPROACH

E. Eliopoulos¹, G. Goulielmos², M. Zervou², Agricultural University of Athens, Department of Biotechnology, Athens, Greece; Medical School of Crete, Department of Internal Medicine, Heraklion, Greece

**Background:** Genome wide association studies (GWAS) have played a primary role in depicting genetic contributions to ankylosing spondylitis (AS) development, while accommodating the exonic polymorphisms on the protein structure level, when available, enhances our understanding of protein function modification. AS is a polygenic disorder and it is the archetype of a group of inflammatory conditions known as spondyloarthropathies because of their tendency to involve the spine[1]. Linking human genetics with therapeutic targets requires understanding of the biological function and structure of the expressed protein by the causal gene variant to be known.

**Objectives:** We sought to investigate recently identified AS-associated functional gene polymorphisms, such as ERAP1, PON1, CARD9 and JARID1A [2-6] by correlation to protein structure and function.

**Methods:** The experimental 3D model structures of the human ERAP1, PON1, CARD9 and JARID1A proteins were used for the localization of the polymorphisms under study. Molecular mechanics/dynamics studies were applied to determine the impact of the polymorphisms on the structural stability of the enzyme and the conformational changes caused were structurally analyzed. The mutants were constructed using molecular modeling with the program MOE (Molecular Operating Environment V.2019.01, Chemical Computing HPC), which was also used to analyze the conformational changes caused by the mutation. All figures depicting 3D models were created using the molecular graphics program PyMOL V.2.2 [6].

**Results:** ERAP1 plays a role in trimming peptides for optimal binding to MHC1 molecules by utilizing a complex catalytic mechanism. High resolution structures of ERAP1 have shown that K528 and Q730 are located distal from the active site of the enzyme (Figure 1a). Recent enzymatic and computational studies have demonstrated that the presence of Lys or Arg at position 528 and of glutamine or glutamic acid in position 730 affects differently the conformational distribution of the protein ensemble by altering the conformational plasticity of the enzyme and, therefore, indirectly affecting dissimilarity its activity [7]. The PON1 rs682 (Gln192Arg) variant affects stability and recognition of the ligand recognition site and plays a functional role in inflammatory disorders (Figure 1b). The caspase recruitment domain (CARD) interaction of CARDS with Bcl10 promotes downstream activation of factors including NF-kB and the mitogen activated protein kinase (MAPK) [p38 [8]]. The CARD9 rs4077515 (Ser12Asn) variant affects the conformational flexibility of the interacting N-terminal [9] (Figure 1c). JARID1A gene codes for lysine demethylase 5A (KDM5A) a histone demethylase that specifically demethylates ‘Lys-4’ of histone H3. The JARID1A rs11062385 (Met865Thr) SNP that is strongly correlated with expression has been associated with a protective role for the disease but is located in a region of the KDM5A protein with an undefined yet function.

**Conclusion:** Based on several examples, we have tried to define a rational link from AS-associated gene polymorphisms to structure and to modified function, including metagenomic analysis of SNPs, protein crystallography, protein molecular modeling, molecular mechanics and dynamics. Locating, shaping and understanding the target protein interaction interface plays a decisive role in most cases and provides clues for further pharmacological or medical actions.

**DOI:** 10.1136/annheumdis-2022-eular.971
Objectives: Survey the phenotypic consequences of a naturally occurring partial loss of TYK2 function, and directly test for an effect of naturally occurring TYK2 partial loss of function on risk of cardiovascular disease, thromboembolism, and lymphoma.

Methods: We performed phenotype-wide association studies (PheWAS) in 2 large biobanks (FinnGen and UK Biobank) and across public case-control genetic studies using Open Targets Genetics.

Results: This study found additional support for a protective effect (odds ratio [OR] ≤0.8, P<1x10^-7) of TYK2 partial loss of function in multiple autoimmune disease categories, including rheumatoid arthritis, psoriasis, psoriatic arthritis, systemic lupus erythematosus, sarcoidosis, type 1 diabetes, inflammatory bowel disease, and hypothyroidism. We did not observe any novel phenotypic associations that could highlight safety concerns for TYK2 inhibition. Additionally, we used well-powered and focused analyses to demonstrate that TYK2 partial loss of function is not associated with nonselective Janus kinase inhibitor safety concerns in any of the genetic studies. Our meta-analysis across the included studies showed no association with increased risk of cardiovascular disease (OR=0.97; P=0.02, 258,279 cases / 549,387 controls), venous thromboembolism (OR=0.97; P=0.52, 11,966 cases / 260,704 controls), and lymphoma (OR=1.06; P=0.47, 2687 cases / 220,721 controls).

Conclusion: TYK2 P1104A, a partial loss-of-function polymorphism, enables assessment of TYK2 involvement in immune-mediated disease and other pathologies. Loss of function in TYK2 reduces risk of immune-mediated disease but does not significantly increase risk of cardiovascular disease, thromboembolism, or lymphoma.

PTPN22 AND TNFAP3, BUT NOT STAT4, ARE RISK FACTORS FOR IGG4-RELATED DISEASE

F. Martin-Narés1, G. Hernandez-Molina1, J. Ramirez Belio2, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Depamento of Immunology and Rheumatology, Mexico City, Mexico; 2Instituto Nacional de Cardiología Ignacio Chávez, Department of Endocrinology, Mexico City, Mexico

Background: The etiology of IgG4-related disease (IgG4-RD) is not yet clear, but environmental and genetic factors are thought to be involved. Little is known about the genes that confer susceptibility to this disease, which is why various loci related to inflammation or autoimmunity have begun to be studied. Such studies are limited to Asian and European cohorts. To date, no study has searched susceptibility genes for the development of IgG4-RD in the Mexican Mestizo population.

Objectives: To determine whether three single nucleotide variants (SNVs) located in classic genes associated with systemic lupus erythematosus and rheumatoid arthritis, namely, TNFAIP3 (rs2330926T/G), STAT4 (rs7574865G/T), and PTPN22 (rs2476601C/T), confer susceptibility for the development of IgG4-RD in the Mexican Mestizo population.

Methods: Patients who met the 2019 ACR/EULAR classification criteria for IgG4-RD were included. For each patient, two healthy controls were matched by sex who had no history of chronic, inflammatory, or autoimmune diseases. Both patients and controls were unrelated and self-reported with Mexican Mestizo ancestry by lineage (at least three generations including their own). Genomic DNA was extracted from peripheral blood cells. SNVs were genotyped using TaqMan SNP probes and the Sanger sequencing assay. The Chi-square test was used to determine odds ratios.

Results: We included 124 controls and 60 patients with IgG4-RD (31 (51.6%) female and 29 (48.4%) male). Patients with IgG4-RD had a mean age of 52.1 ±15 years. Ten (16.6%) had single organ involvement, 10 (16.7%) had two involved organs, and 40 (66.6%) had ≥3 involved organs. Thirty (21.7%) belonged to the Mikulicz/pancreatic, 19 (13.17%) to the head/neck-limited, 18 (30%) to the Mikulicz/systemic, and 5 (8.3%) to the undetermined phenotype, while 43 (71.7%) belonged to the proliferative and 17 (28.3%) to the fibrotic phenotypes.

ASSOCIATION OF RS172378 VARIANT IN C1Q GENE CLUSTER WITH SOME CLINICAL AND IMMUNOLOGICAL ASPECTS OF SYSTEMIC LUPUS ERYTHEMATOSUS IN BULGARIAN PATIENTS

1Varna Medical University, Department of Propedeutics of Internal Diseases, Varna, Bulgaria; 2Varna Medical University, First Department of Internal Diseases, Varna, Bulgaria; 3Varna Medical University, Department of Biochemistry, Molecular Medicine and Nutrigenomics, Varna, Bulgaria; 4Sofia Medical University, Department of Nephrology, Sofia, Bulgaria

Background: Single nucleotide polymorphisms (SNPs) in complement C1q component are found to be linked with systemic lupus erythematosus (SLE), but less is known about their association with the clinical and immunological aspects of the disease.

Objectives: The aim of the study was to examine five SNPs – rs865691, rs682638, rs172378, rs254179, rs292001 in C1q gene cluster for association with some clinical (age at disease onset, organ involvement, BILAG score, SLICC/ACR DI) and immunological (ANA, anti-dsDNA, complement factors C3 and C4) aspects of SLE.

Methods: 53 SLE patients were enrolled in this cross-sectional study and relevant clinical information was collected. SNP genotyping was performed on extracted DNAs from patients using a TaqMan allelic discrimination assay. ANA, anti-dsDNA and complement proteins C3 and C4 were measured by IF, ELISA and radial immunodiffusion resp.

Results: G-allele and GG-genotype of rs172378 were overrepresented among patients with LN compared to the other SLE patients – 64% vs 31% for G-allele and 48% vs 7.7% and were associated with renal involvement – OR=3.96 (95%CI: 1.53 – 10.23), p=0.005 for G-allele and OR=10.86 (95%CI: 1.29 – 91.58), p=0.028 for GG-genotype. G-allele and GG-genotype were also associated with increased levels of anti-dsDNA antibodies – OR=2.95 (95%CI: 1.21 – 7.18), p=0.017 and OR=6.33 (95%CI: 1.41 – 28.39), p=0.016, resp.

G-allele showed weak correlation with earlier age at disease onset (point biserial r=-0.22, p=0.03) and patients, carrying it (GG- and AG-genotypes) were younger at disease onset then those with AA-genotype (p=0.05 and p=0.02 resp.).

Conclusion: rs172378 associates with some clinical and immunological parameters of SLE, traditionally linked to disease severity, therefore it may possibly play a role in disease pathogenesis.

ACERO APPLICATION: AN INTEGRATED GENOTYPE ANALYSIS WEB SERVER FOR CLINICAL GENOMICS IN CROHN’S DISEASE AND IBD-RELATED ARTHRITIS

I. Papageorgiou, M. Zervou, I. Katsimpoula, D. Vlachakis, G. Bertias, G. Goulieomos, E. Eleopoulou. 1Agricultural University of Athens, Department of Biotechnology, Athens, Greece; 2University of Crete, Section of Molecular Pathology and Human Genetics, School of Medicine, Heraklion, Greece; 3University of Crete, Department of Rheumatology and Clinical Immunology, School of Medicine, Heraklion, Greece

Background: Genome Wide Association Studies (GWAS) observe the set of different variants throughout the genome of different individuals and study whether a particular trait is due to one variant. Many autoimmune diseases have been identified to have a linkage with specific loci and metabolic pathways, but the exact cause of disorders is still remaining unknown [1]. Aceso Application is an integrated bioinformatics web-tool designed for researchers and medical experts towards to estimating the clinical genomic profile of a candidate patient with Crohn’s Disease (CD)[2-4].
Differentially Expressed Genes Between Flare of Palindromic Rheumatism and Active Rheumatoid Arthritis

H. H. Chen1, Taichung Veterans General Hospital, Internal Medicine, Taichung, Taiwan, Republic of China

Background: Although the mechanisms of palindromic rheumatism (PR) is still unclear, an association between PR and rheumatoid arthritis (RA) has been well recognized in previous studies, with one to two-thirds of PR patients developing RA during a period of follow-up. RNA sequencing (RNA-Seq) is a next-generation sequencing (NGS) method that measures genome-wide RNA abundance. Using RNA-Seq to identify the DEGs between flare PR and active RA could help elucidate the pathogenic mechanisms of PR flare and find novel genes to predict RA progression.

Objectives: The aim of this study is to identify gene expression signatures between PR flare and active RA using whole blood RNA-seq.

Methods: We collected clinical data, and blood samples from 12 flare PR patients and 12 active RA patients (defined as DAS28-ESR≥3.2) patients from Taichung Veterans General Hospital. We obtained high-quality RNA by using PAXGene tube for whole blood sampling and PAXGene blood RNA Kit to extract RNA. Cuffdiff (Cufflinks option) output was filtered for differentially expressed genes (DEGs) with p-value < 0.05. Gene set enrichment analysis (GSEA) were performed using the GSEA version 4.0 with immunologic gene sets (C7 sets containing 4872 gene sets) from The Molecular Signatures Database (MSigDB). According to GSEA web suggestion, a false discovery rate (FDR) < 0.25 with a p-value < 0.05 was considered statistically significant. We obtained ranked ordered gene list from GSEA.

Results: We compared flare PR and active RA using GSEA. Five of the top 12 enrichment in phenotype with flare PR were related to lipopolysaccharide (LPS), which was found in the outer membrane of Gram-negative bacteria. And we observed that 3 genes had statistically significant t-test result (HK3, p-value < 0.001; HIST1H2AI, p-value < 0.002; BST1, p-value < 0.001) (Figure 1a, 1b and 1c). This result showed that FCGBP, GLRX3 and RTN4R may play an important role in immune response related to flare PR. In active RA patients, 3

Figure 1. Differential gene expressions between flare PR and active RA. (a) FCGBP, (b) GLRX3, (c) RTN4R, (d) HK3, (e) HIST1H2AI, (f) BST1 genes had statistically significant t-test result (HK3, p-value < 0.001; HIST1H2AI, p-value < 0.002; BST1, p-value < 0.001) (Figure 1a, 1b and 1c).

Conclusion: GSEA analyses showed that five of the top 12 enrichment in flare PR was related to LPS and other pathways were related to immune responses of B cell, T cell and macrophage. However, in active RA, the characteristic gene expressions included genes up-regulated in dendritic cells, genes down-regulated in B cell, and genes up-regulated in T cells, suggesting different physiological pathways from flare of PR.

Association of Some Non-HLA Gene Polymorphisms with Susceptibility to Systemic Lupus Erythematosus in Women in Belarusian Population

N. Dostanko1, E. Siniauskaya2, V. Yagur1, R. Goncharova2, H. Yatsku2.
1Belarusian State Medical University, 2-nd Department of Internal Medicine, Minsk, Belarus; 2National Academy of Sciences of Belarus, Institute of Genetics and Cytology, Minsk, Belarus

Background: Despite the recent progress in our understanding of the genetic predisposition to systemic lupus erythematosus (SLE) its clinical and functional significance is not fully clarified yet and needs to be implemented in personalized care [1].

Objectives: To estimate the association between some single nucleotide polymorphisms (SNPs) of 9 non-HLA genes-candidates as STAT4 rs7574865, TPPTN2 rs2542151, TPPTN2 rs2476601, AGER rs1035798, TRAF1/C5 rs3761847, SLCT7A1 rs13128867, RUNX1 rs9973983, IL6 rs1800795, IL6R rs2228145, IL6R rs4845618 and susceptibility to SLE in Belarusian women for the following predictive model development.

Methods: We examined 316 women: among them 59 SLE patients (mean age 39.84, CI95% 36.62-43.06) classified according to the 1997 American College of Rheumatology (ACR) revised classification criteria and 257 age-matched healthy controls (blood donors, mean age 38.12, 95% confidence interval (CI95%) 36.77-39.46). Deoxyribonucleic acid was extracted from peripheral blood samples by phenol-chloroform method. Genotyping was performed by real-time PCR with fluorescent probes. Descriptive analysis, test for Hardy–Weinberg equilibrium, multiple inheritance models (co-dominant, dominant, recessive, over-dominant and log-additive) for single SNPs, Akaike information criteria (AIC) and Bayesian information criteria (BIC) were analyzed using SNPSstats web tool [2]. Pearson χ² (χ²), two-way Fisher exact test (F, p<0.05), odds ratio (OR), likelihood ratio of positive (LR +) and negative (LR -) tests with corresponding CI were also calculated.

Results: Exact test for all genotype frequencies distribution of all studied SNPs didn't reveal significant differences with Hardy-Weinberg equilibrium in all controls and SLE groups. We noted significant increase of minor TT genotype frequency of STAT4 rs7574865 in SLE vs healthy women with recessive inheritance model as the best-fitting one according to its less AIC and BIC values (OR=3.78 (CI95% 1.35-10.62); p=0.016; LR + = 3.45 (CI95% 1.37-8.60); LR - = 0.91 (CI95% 0.84-0.98)). We revealed protection of minor A allele of AGER rs1035798 carriage with log-additive model of inheritance as the best-fitting one according to AIC and BIC values against SLE development in women (OR=0.52 (CI95% 0.33-0.83); p=0.004; LR + = 0.70 (CI95% 0.50-0.93); LR - = 1.47 (CI95% 1.10-1.86)). We also noted significant increase of minor allele G frequency of TRAF1/C5 rs3761847 in SLE vs healthy women with dominant inheritance model (OR=3.61 (CI95% 1.00-12.0)).

AB0010
Background: Tocilizumab (TCZ) is a disease-modifying antirheumatic biologic drug, which targets the IL-6 signalling pathway and is effective in ameliorating disease activity in rheumatoid arthritis (RA). However, approximately 20% of patients do not respond adequately to TCZ and some patients report adverse events. Considering there is growing evidence that DNA methylation is implicated in RA susceptibility and response to some biologics (1, 2), we investigated DNA methylation as a candidate biomarker for response to TCZ in RA.

Objectives: To identify differential DNA methylation signatures in whole blood associated with TCZ response in patients with RA.

Methods: Epigenome-wide DNA methylation patterns were measured using the Infinium Epic 850k BeadChip (Illumina) in whole blood-derived DNA samples from patients with RA. DNA was extracted from blood samples taken pre-treatment and following 3 months on therapy, and response was determined at 6 months using the Clinical Disease Activity Index (CDAI). Patients who had good response (n=10) to TCZ by 6 months were selected. Samples from secondary poor responders (n=10) (patients who had an improvement of CDAI and were in remission versus Arthritis Centre for Epidemiology, Manchester Academic Health Sciences Centre, Manchester, United Kingdom; 3University of Leeds, Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom; 4NIHR Leeds BRC, Leeds Teaching Hospitals Teaching Trust, Leeds, United Kingdom; 5NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester University NHS Foundation Trust, Manchester, United Kingdom; 6The University of Manchester, Versus Arthritis Centre for Epidemiology, Manchester Academic Health Sciences Centre, Manchester, United Kingdom; 7University College Dublin, School of Medicine and Medical Science, Dublin, Ireland.

Background: Sinomenine (SIN) were extracted from Caulis Sinomenii and achieved an remarkable therapeutic effect for Rheumatoid Arthritis (RA). However, the mechanism of SIN acting on RA is not clear yet.

Objectives: To excavate potential targets and mechanisms of SIN for RA through bioinformatics.

Methods: The microarray data were downloaded from the Gene Expression Omnibus (GEO) database. GEO2R was used to identify differentially expressed genes (DEGs) and the unique value was retained. The potential targets of active compounds from various databases were screened. Based on the overlapping genes, Cytoscape 3.7.2 software was used to construct a protein-protein interactions (PPI) network and to visualize the mechanisms of the treatment by Gene Ontology (GO) enrichment analysis Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis by DAVID database. Finally, we used AutoDockTools 1.5.6 for molecular docking.

Results: A total of 5053 DEGs and 1070 intersections were obtained, including 486 up-regulated and 584 down-regulated targets. 298 SIN targets were collected from various databases, 84 potential targets were obtained by intersecting with DEGs. There are 80 nodes and 305 edges were obtained in PPI network. Based on the degree, the top 10 target genes were AKT1, RGFRI, MTROR, JAK2, NOS3, IL2, IL6, MMP9, MAPK8, HSP90AA1. The core targets was most relevant to protein phosphorylation, signal transduction though GO analysis. The results of the KEGG enrichment analysis included PI3K-Akt signaling pathway and Neuroactive ligand-receptor interaction. Following analysis found that AKT1, EGFR, MTROR and JAK2 existed in the PI3K-Akt signaling pathway. Molecular docking was used to confirm that the binding energy of AKT1 was -7.68 kJ mol⁻¹, EGFR was -5.33kJ mol⁻¹, MTROR, JAK2, NOS3, IL2, IL6, MMP9, MAPK8, HSP90AA1. The core targets was most relevant to protein phosphorylation, signal transduction though GO analysis. The results of the KEGG enrichment analysis included PI3K-Akt signaling pathway and Neuroactive ligand-receptor interaction. Following analysis found that AKT1, EGFR, MTROR and JAK2 existed in the PI3K-Akt signaling pathway. Molecular docking was used to confirm that the binding energy of AKT1 was -7.68 kJ mol⁻¹, EGFR was -5.33kJ mol⁻¹, MTROR and JAK2 was -7.74 kJ mol⁻¹, AKT1 and EGFR was further identified as the core targets.

Conclusion: Present study shows that AKT1 and EGFR may be the key targets of SIN acting on the PI3K-Akt signaling pathway, thereby inhibiting the progression of disease and improving RA.

Keywords: Sinomenine; Rheumatoid Arthritis; bioinformatics;
Background: A strong female predisposition is characteristic of Systemic Lupus Erythematosus (SLE), with female-to-male ratio ranging from 7:1 to 15:1. The molecular basis of this gender bias remains incompletely understood. In a previ- ous whole-blood RNA profiling study, we identified genes with differential expres- sion in SLE males versus females but not in their healthy counterparts. Among these genes, the cohesin complex protein SMC1A (Structural Maintenance of Chromosomes 1A) displayed the highest statistical significance [1].

Objectives: To (a) determine the immune cell type that displays the strongest gender-biased SMC1A expression in SLE versus healthy individuals, and (b) elucidate the role of SMC1A in regulating immune/inflammatory responses in the context of SLE.

Methods: Multiple immune cell types (CD19+ B cells, CD4+ T cells, CD14+ monocytes, neutrophils) were purified from peripheral blood specimens of SLE and healthy individuals, followed by Taqman PCR and Western blot to measure SMC1A mRNA and protein levels, respectively. The genome-binding properties of SMC1A were assayed by chromatin immunoprecipitation (ChIP)-sequencing in monocytes cultured under lupus-inducing conditions (lupus-like monocytes) [2]. To recapitulate the female/male difference in SMC1A expression, ex vivo cul- tured lupus-like monocytes were transfected with si-SMC1A (to downregulate SMC1A) versus si-control reagent, followed by genome-wide transcriptome anal- ysis by RNA-sequencing.

Results: Among the various tested immune cell types, CD14+ monocytes best recapitulated the initial whole blood RNA-seq findings, demonstrating significantly decreased SMC1A mRNA and protein expression in male versus female SLE patients but not in their healthy counterparts. In blood monocytes cultured under lupus-inducing conditions and tested by ChIP-sequencing, SMC1A binding was increased on enhancers and promoters of genes associated with inflammation (including type I/II interferon and other inflammatory cytokines) and cell migra- tion. In accordance, lupus-like monocytes with lowered SMC1A expression (i.e., female-like) displayed significantly reduced expression of inflammatory genes like IL6, GBP5, ADA and IL1A, as compared to monocytes with unaffected SMC1A (i.e., female-like). Furthermore, IL6 mRNA synthesis was significantly enhanced in female versus male monocytes cultured under lupus-inducing conditions. Conclusion: SMC1A may transcriptionally regulate genes associated with the inflammatory response of monocytes. Our findings of gender-biased SMC1A levels in SLE monocytes raise the hypothesis that differential SMC1A expres- sion and function might contribute to the disease gender bias and/or sexual dimorphism.

Disclosure of Interests: None declared

Primary cilia were manually counted. Approximately 500 cells for each replicate were recorded for the presence of a primary cilium. The length of primary cilia was measured using Image J (Version 1.53o). Synovial fibroblasts were treated with Trichostatin A (2µM), an inhibitor of HDACs (HADCi), for 24h.

**Results:** Pathway enrichment analysis of genes changed after HOXD13 silencing of synovial fibroblasts showed that HOXD13 regulated genes are involved in primary cilium related pathways. We confirmed lower mRNA expression of the ciliary proteins, PKD2, KIF3A and IFT88 after HOXD13 silencing (n=4; PKD2: 0.65 ± 0.4, p<0.05; KIF3a: 0.6 fold ± 0.3, p<0.05; IFT88: 0.7 fold ± 0.3, p<0.05), and IFT88 expression (ARL13B 0.18 fold ± 0.4, p<0.05). An increase in the number and length of primary cilium, as well as acetylation of alpha-tubulin, a characteristic feature of primary cilium, was seen after HOXD13 silencing (n=4). Accordingly, expression of HDAC4, -5 (n=4; HDAC4: 0.25 fold ± 0.1, p<0.05; HDAC5: 0.4 fold ± 0.1, p<0.05; HDAC7: 0.3 fold ± 0.2, p<0.05). SIRT1 expression was higher (n=4; 1.7 fold ± 0.4, p<0.05), but SIRT2 expression was lower (n=4; 0.1 fold ± 0.03, p<0.05) in HOXD13 silenced synovial fibroblasts. Trichostatin A treatment increased the acetylation level of alpha tubulin (n=4) as well as the expression of ARL13B, KIF3a, and IFT88 in synovial fibroblasts (n=4; ARL13B: 2.3 fold ± 0.9, p<0.05; IFT88: 1.5 fold ± 0.3, p<0.05; KIF3A: 3.7 fold ± 1.8, p<0.05). The length and number of primary cilium was not changed by Trichostatin A treatment.

**Conclusion:** Our data show that HOXD13 plays a role in regulating the assembly of primary cilium in synovial fibroblasts. This effect seems partially mediated by the expression of HDACs and partly by the expression of ciliary proteins. The primary cilium is a sensory organelle mediating reactions to mechanical and chemical signals from the environment. Thus, our results suggest specific regulation of synovial fibroblasts in response to stimulation via the primary cilium.

**AB0016 GENETIC VARIANTS OF PREDISEPOSITION TO RHEUMATOID ARTHRITIS IN BELARUSIAN POPULATION**

E. Siniauskaya, Y. Yatsku, N. Dostanko, V. Vagar, R. Goncharov. Institute of Genetics and Cytotology of NAS of Belarus, Laboratory of Molecular Basis of Genomic Stability, Minsk, Belarus; 2SMU, Belarusian State Medical University, 2-nd Department of Internal Medicine, Minsk, Belarus

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by autoimmune inflammatory response focused in the synovium. RA is a complex disorder with significant genetic component and it is also known to have possible environmental triggers. Microbiota and bacterial infections play a significant role in RA etiology. The onset of RA may be accompanied by the previous or ongoing chlamydia infection in some cases.

**Objectives:** To observe genetic variants of susceptibility to RA in Belarusian population

**Methods:** 650 individuals were divided into 2 cohorts: 305 patients with RA (59.69 ± 12.20), and 345 controls (mean age 37.42 ± 10.62). Patients with RA were further stratified into two subsets — with cataractogenic Chlamydia trachomatis/Chlamyphila pneumoniae infection (43, “RAChi”) and those without (262, “Rach-”). 11 SNPs of 10 genes (IL6 (rs1035798), IL6R (rs2228145 and ns4845618), STAT4 (rs7574865), TRAF1/C5 (rs3761847), RUNX3 (rs9979383), PTPN2 (rs11249215), PTPN22 (rs2542151), STAT4 (rs1035798), SLC7A11 (rs13128867)) were genotyped using Real-time PCR or PCR-RFLP.

**Results:** It was found that homozogous TT genotype at the rs7574865 locus of the IL6 gene and CT/TT genotypes at the rs2476601 locus of the RUNX2 gene are associated with RA in general (OR 2.71 [1.31 – 5.61], p = 0.005 and OR 2.47 [1.75–3.48], p<0.000, respectively). CC genotype at the rs9979383 locus of the RUNX1 gene and AG+GG genotypes at the rs11249215 locus of the RUNX3 gene revealed protective effect (OR 0.63 [0.40–0.98], p=0.036 and OR 0.58 [0.36–0.92], p=0.02, respectively). The lack of association with RA was shown for polymorphic loci of the IL6 (rs1800795), IL6R (rs2228145 and ns4845618), SLC7A11 (rs13128867), AGER (rs1035798), PTPN2 (rs2542151) and TRAF1/C5 (rs3761847) genes. For RA subsets stratified according to presence/absence of the C. trachomatis/C. pneumoniae infection it was shown that CC genotype at the rs1800795 locus of the IL6 gene and AA genotype at the rs11249215 locus of the RUNX3 gene were associated specifically with the risk of developing Chlamydia infection-associated RA (OR 5.22 [1.85–14.71], p=0.0024 and 2.63 [1.09–6.35], p=0.037). In addition, TG+GG genotypes at the rs2542151 locus of the PTPN2 gene is also associated specifically with RAChi+ clinical phenotype. Our data may indicate that genetic variants of STAT4 and PTPN22 contribute to genetic basis of the pathogenesis of RA through renewal of T-cell initiated immune response.

**AB0017 T HELPER REGULATORY T CELLS RATIOS IMBALANCE IN DIFFERENT STAGING RHEUMATOID ARTHRITIS**

R. Su1, C. Wang1. 1The Second Hospital of Shanxi Medical University, Taiyuan, Department of Rheumatology, Taiyuan, China

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that results in the destruction of the bone and cartilage of the joints[1]. The imbalance between Th17 and Treg cells has been demonstrated to play a role in RA pathogenesis[2]. With the advances in the RA field, curing and even preventing RA has become a new direction of efforts. To explore the immune characteristics in multi-staging RA is helpful for the development of accurate strategies.

**Objectives:** To observe the immune characteristics in different staging rheumatoid arthritis patients

**Methods:** A total of 127 patients with RA were recruited for this study, in cluding 30 early RA (newly diagnosed and treatment-naïve, duration of disease ≤3months), 30 middle RA (newly diagnosed and treatment-naïve, duration of disease >3months and≤1 year), 30 advanced RA (newly diagnosed and treatment-naïve, duration of disease >1 year) and 37 active treated RA (remissioned after target treatment and this time due to disease recurrence in hospital). All patients were hospitalized in the second hospital of Shanxi medical university and diagnosed with RA fulfilled the ACR 1987 or 2010 criteria. The percentage and absolute numbers of lymphocyte phenotypes and CD4+ T subsets in peripheral blood were examined by flow cytometry.

**Results:** There were no significant difference in the percentage and value of T,B,NK,CD4+T,CD8+T and CD4+ T subsets. But the Th1/Th2 cell ratios in active treated RA group were increased than that in early RA, middle RA and advanced RA group. The Th17/Treg cell ratios in middle RA and advanced RA group were higher when compared with those of active treated RA group. In addition; the Th1/ Treg cell ratios were decreased in middle and advanced RA group as compared with those in active treated RA.

**Conclusion:** Th1/Th2, Th17/Treg and Th1/Treg imbalance varied with disease staging. The different disease stage in RA, the immune function is different. Providing targeted immunotherapy according to disease staging is helpful to improve remission rates and even prevent disease.

SERUM ANTIBODIES AGAINST ORAL AND INTESTINAL BACTERIA IN INDIVIDUALS AT RISK FOR RHEUMATOID ARTHRITIS, CHRONIC RA PATIENTS, AND NEW ONSET PATIENTS WITH DIFFERENT RHEUMATIC DISEASES

L. Amend 1, B. Gilbert 1, A. Finckh 1, T. Ströwig 1, Helmholtz Centre for Infection Research, Microbial Immune Regulation, Braunschweig, Germany; 2Geneva University Hospitals, Division of Rheumatology, Geneva, Switzerland

Background: Evidence about the influence of microbes in autoimmune diseases such as rheumatoid arthritis (RA) has grown in recent years. However, the precise role of specific bacteria remains largely unknown. Previous investigations identified several oral pathogens to be specifically targeted by serum antibodies in RA patients. In addition, P. intermedia and P. melaninogenica were identified as potential pathobionts in RA patients. We analyzed IgG reactivity against several oral pathogens from stool samples of healthy donors and RA patients, as well as the following oral pathobionts: Porphyromonas gingivalis, Prevotella intermedia, and Prevotella melaninogenica. We observed 120 IgG samples from a Swiss cohort of first-degree relatives, individuals in various pre-clinical RA stages (SCREEN-RA), and 45 samples of patients with established RA (SCQM cohort). These participants were categorized as asymptomatic seronegative individuals (FDR), individuals with systemic autoimmunity associated with RA (ACPA and/or RF autoantibodies) (preRA 1), individuals with clinically suspect arthritids or undifferentiated arthritis with/without autoantibodies (preRA 2) and chronic RA patients (cRA). Additionally, we included 92 serum samples from new-onset patients diagnosed with RA, psoriatic arthritis (PsA) or spondyloarthropathy (SpA), or other non-rheumatic diseases (NRD) recruited via the german RheumaVOR cohort (Table 1).

Methods: We used custom-made ELISA assays measuring pathogen-specific IgG levels in patient’s serum. Samples were tested against P. copri strains isolated from stool samples of healthy donors and RA patients, as well as the following oral pathobionts: Porphyromonas gingivalis, Prevotella intermedia and Prevotella melaninogenica. We analyzed 120 samples from a Swiss cohort of first-degree relatives, individuals in various pre-clinical RA stages (SCREEN-RA), and 45 samples of patients with established RA (SCQM cohort). These participants were categorized as asymptomatic seronegative individuals (FDR), individuals with systemic autoimmunity associated with RA (ACPA and/or RF autoantibodies) (preRA 1), individuals with clinically suspect arthritids or undifferentiated arthritis with/without autoantibodies (preRA 2) and chronic RA patients (cRA). Additionally, we included 92 serum samples from new-onset patients diagnosed with RA, psoriatic arthritis (PsA) or spondyloarthropathy (SpA), or other non-rheumatic diseases (NRD) recruited via the german RheumaVOR cohort (Table 1).

Figure 1. Serum IgG responses against different microbes from individuals recruited via SCREEN-RA, SCQM or RheumaVOR cohort

Results: Overall, there were no significant differences in the IgG reactivity profiles between the patient groups against the distinct P. copri strains or oral pathobionts (Figure 1). However, performing this assay with P. copri strains from distinct subtypes identified clear differences and revealed important variability in the IgG reactivity.

RITUXIMAB TREATMENT DOES NOT ALTER EXPRESSION OF CO-STIMULATION MARKER CD19 ON B CELLS IN SYSTEMIC SCLEROSIS PATIENTS

B. Dreier 1, B. Prietl 2,3, S. Kofer 2,3, V. Pfeiffer 2,3, H. Souri 2,3, F. Moazed-Fürst 1, S. Kiehauer 1, M. D'Orazio 1, S. Zenz 1, J. Thiel 1, M. Stradner 1, H. P. Brezinsek 1, 1Medical University of Graz, Division of Rheumatology and Immunology, Graz, Austria; 2Cimed GmbH, CBimed GmbH – Center for Biomarker Research in Medicine, Graz, Austria; 3Medical University of Graz, Division of Endocrinology and Diabetology, Graz, Austria

Background: CD19 is a membrane glycoprotein interacting with different surface molecules on the B-cell membrane (BCR) and is crucial for antigen-independent development as well as immunoglobulin-induced activation of B cells. [1] Alterations in this signalling pathway can incline autoimmune production and systemic autoimmunity in humans. Rituximab (RTX), a CD20 antagonist appears to be an effective candidate in the treatment of different autoimmune diseases that are partly driven by autoreactive B cells, such as systemic sclerosis (SSc). [2] It has been speculated that RTX might work not only by depleting B cells but also to down regulate activation markers, such as CD19.

Objectives: In-depth analysis of CD19 abundance and activation on B cells in SSc patients with and without RTX treatment

Methods: Peripheral blood samples from 41 patients suffering from SSc (median ± standard deviation SD, age: 54.3 ± 10.6 years, female ratio: 0.8) and 45 age- and sex-matched healthy controls (HC) (age: 51.0 ± 13.9 years, female ratio: 0.8) were drawn and PBMCs were isolated on-site. We performed flow cytometry analysis on a standardized BD LSRFortessa platform to identify B cell (CD19+CD20+) subpopulations. The geometric mean fluorescence intensity (gMFI) for CD19 was compared between both the B cell populations. The frequency of CD19 antibodies bound per cell.

Results: 3 out of 41 SSc patients were in high disease activity at the time of blood drawal. 23 SSc patients were under RTX therapy of whom 5 patients still displayed measurable B cell frequencies. Naïve B cells made up the most abundant B cell population in SSc patients. Thus, the frequency of IgM+IgD+CD27- cells was 67.9% ± 13.2 (mean ± SD), followed by class-switched memory B cells (IgM−IgD−CD27+, 10.5 ± 4.9), non-switched memory B cells (IgM−IgD+CD27−, 4.0 ± 3.6) and plasmablasts (0.3 ± 4.4). Pairwise Wilcoxon Tests (Bonferroni-corrected for multiple testing) showed significant differences (p < 0.001) between frequencies of naïve B cells and all other cell types. In contrast, naïve B cells displayed the second lowest CD19 gMFI levels (7600.1 ± 1912.0) in the dataset. Non-switched memory B cells in SSc patients showed the highest CD19 gMFI (10620.0 ± 15689.8), followed by class-switched (9383.8 ± 3048.8). As expected, Plasmablasts displayed the lowest CD19 gMFI levels (4799.0 ± 4815.7). The decrease in CD19 gMFI was again highly significant. This trajectory in decreasing CD19 gMFI was found in both HCs and SSc patients. We saw a significant reduction in percentages of non-switch B cells and class-switched B cells in SSc patients compared to HCs (4.0 ± 3.6 vs 6.5 ± 4.2, p = 0.029, 10.5 ± 4.9 vs 13.2 ± 7.2 p = 0.04) but an increase in CD19 gMFI in non-switched B cells (HC: 9204.5 ± 2166.8, p = 0.05). Interestingly, SSc patients under RTX treatment had significantly lower class-switched memory B cell frequencies compared to HCs (6.4 ± 4.2 vs 13.2 ± 7.2, p = 0.015). However, RTX did not affect CD19 gMFI or bound CD19 in SSc.

Conclusion: RTX treatment in SSc is not associated with downregulation of the co-stimulation marker CD19. Thus, the main effect of this drug is the reduction of B cells, especially class-switched memory B cells that might have a high capacity to activate other cells involved in the pathogenesis of SSc.

COMPARATIVE DESCRIPTION OF CYTOKINES AND MATRIX METALLOPROTEINASES IN A GROUP OF PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEARTROPATHY UNDER A STRICT FOLLOW-UP COMPARED WITH COVID-19 PATIENTS

S. Naveeratna1, L. D. Gutiérrez-Castañeda2,3, P. K. Bautista-Nino4, J. A. Rubio-Rubio5, G. S. Rodríguez-Vargas3, P. Santos-Moreno3, D. Echeverri6, L. Saenz2, L. Torres Tobar7, A. Aparicio1, A. Rojas-Villarraga8, F. Sierra-Matamoros9, Foundation University of Health Sciences, Basic Science Institute, Bogotá, Colombia; 2Foundation University of Health Sciences, General Dermatology Group, Bogotá, Colombia; 3Foundation University of Health Sciences, Research Institute, Bogotá, Colombia; 4Cardiovascular Foundation of Colombia, Research Center, Floridablanca, Colombia; 5Biobanc IPS, Scientific Direction, Bogotá, Colombia; 6Fundacion Cardio Infantil Instituto De Cardiología, Hemodynamics and cardiovascular function laborator, Bogotá, Colombia; 7Foundation University of Health Sciences, Epidemiology, Bogotá, Colombia

Background: COVID-19, rheumatoid arthritis (RA) and osteoarthrosis (OA) are diseases characterized by the secretion of cytokines related to the stimulation of the inflammatory response.

Objectives: To identify the differences in the cytokine and matrix metalloproteinases (MMP) profile within one acute infectious disease and two chronic inflammatory rheumatic diseases.

Methods: Analytical cross-sectional study. RA patients under a strict follow-up program (T2T evaluated every two months), OA patients without strict clinical follow-up, evaluated once or twice a year, and Severe (mortality) COVID-19 patients were included. Eleven proteins (cytokines, MMPs, and its tissue inhibitors) were quantified through Luminox multiplex assay in serum samples. Univariate and bivariate analyses were performed. Approval of Ethics Committee and informed consent were obtained.

Results: A total of 108 patients with RA and OA were compared with 20 severe COVID-19 patients. There were no significant differences through the method of Kruskall–Wallis, between RA and OA patients. IL-1B and MMP-2 were significantly lower in COVID-19 patients. Levels of IL-10, IL-1RA, IL-6, MMP-1, MMP-9, and TIMP-1 were significantly higher in COVID-19 patients. There were no differences in TIMP-2, TIMP-1 and INF-G. (Table 1)

FEATURES OF IMMUNOLOGICAL MANIFESTATIONS OF COMMON VARIABLE IMMUNODEFICIENCY COMBINED WITH RHEUMATOID ARTHRITIS

S. Kudryashov1, L. Karzakova1, I. Sidorov2, N. Zhuravleva1, The Chuvash State University named after I.N. Ulyanov, Department of Internal Medicine, Chuvash Republic, Cheboksary, Russian Federation; 2City Clinical Hospital No. 1 of Public Health Ministry of Chuvashia, The Chuvash State University named after I.N. Ulyanov, polyclinic No. 1, Department of Internal Medicine, Chuvash Republic, Cheboksary, Russian Federation

Background: The prevalence rate of common variable immunodeficiency (CVID), the most common symptomatic form of primary immunodeficiency disease (PIDs), is growing every year. In the Republican Register of PID in the Chuvash Republic (Russia) there are 32 patients with CVID, 5 (16.1%) of whom have CVID combined with an autoimmune disease - rheumatoid arthritis (RA). The immunological studies occupy a large place in the diagnosis of PID and autoimmune diseases.

Objectives: The aim of the study was to search for immunological criteria for the differentiation of RA from CVID combined with RA.

Methods: The object of the study were 2 groups of patients. Group 1 consisted of 20 RA patients; group 2 consisted of 5 patients with CVID in combination with RA. Patients with CVID, who had the results of an immunological study conducted before the appointment of immunoglobulin replacement therapy, were selected for this study. The control group consisted of 20 practically healthy people.

Results: The significant changes were revealed in the concentration of serum immunoglobulins in the studied groups of patients, in particular, a sharp decrease in IgG levels in group 2 (1.9±0.3 g/l vs. 15.2±2.3 in group 1, p<0.001), IgA (0.1±0.2 g/l vs. 3.1±0.7 g/l in group 1, p<0.001), IgM (0.2±0.3 g/l vs. 1.7±0.2 g/l in group 1, p<0.001). Immunoglobulin levels in both groups of patients were lower (p<0.001) compared to the control group. In both groups, the number of regulatory cells – Treg (CD4+CD25+FoxP3) was reduced: in group 1 - 2.5±0.03%; in group 2 - 2.3±0.02%, while in the control group it was 4.2±0.5%, p<0.001. The result of our study confirms that the development of RA and CVID is associated with the decrease in the number of Treg cells responsible for ensuring peripheral tolerance and preventing the development of autoimmune diseases.

Conclusion: CVID and RA have a common immunopathological sign - a decrease in the content of Treg cells in the blood. In the differential diagnosis between RA and CVID, combined with RA, it is necessary to rely on the results of the determination of immunoglobulins in the blood serum.

SELECTIVE ESTROGEN RECEPTOR MODULATORS AND TISSUE-SELECTIVE ESTROGEN COMPLEX DO NOT SHARE ESTROGENIC EFFECTS ON IGG SIALYLATION IN AUTOIMMUNE CONDITIONS

P. Gupta1,2, K. L. Gustafsson2, H. Carlsen1, P. Henning2, C. Engdahl1,2, 1Department of Rheumatology & Inflammation Research, Institute of Medicine, Sahlgrenska Osteoporosis Centre, Centre for Bone and Arthritis Research, University of Gothenburg, Gothenburg, Sweden; 2Department of Internal Medicine & Clinical Nutrition, Institute of Medicine, Sahlgrenska Osteoporosis Centre, Centre for Bone and Arthritis Research, University of Gothenburg, Gothenburg, Sweden

Background: Women entering menopause, with a decrease in estrogen levels, display an increased incidence of rheumatoid arthritis (RA). Estrogen (E2) treatment has beneficial effects on IgG pathogenicity by altering the sialylation grade which affect the binding ability to FcR [1]. E2 replacement may therefore be beneficial in pre-RA patients having autoantibodies. Exposure to estrogen is associated with negative side effects, therefore selective estrogen receptor modulators (SERMs) have been developed with estrogenic protective effect on bone but minimal impact on the reproductive system [2]. The SERM, Bazedoxifene (BZA), as well as tissue-selective estrogen complex (TSEC), a combination of conjugated estrogen and BZA, have been approved for treatment of postmenopausal bone loss [3-5].
Objectives: The purpose of this study was to investigate the impact of BZA and TSEC on IgG sialylation grade which affects the pathogenicity as well as to determine the effects on total serum protein sialylation.

Methods: pbMCs were subjected to ovariectomy to stop the endogenous E2 production and mimicked the postmenopausal status. Mice were then treated with E2, BZA, TSEC, or vehicle, followed by ovariabulin (OVA) immunization to induce the IgG levels. Blood was collected before treatment started and at termination. In serum total IgG, OVA specific IgG and the degree of IgG-sialylation were quantified with ELISA. Sialylation of total serum proteins was determined with aCD3 and subjected to transcriptional analysis by RNAseq (Illumina).

Results: Neither BZA nor TSEC significantly altered the total IgG levels or sialylation grade of IgG. Indeed, E2 significantly altered IgG sialylation. We showed that BZA increased sialyltransferase protein in plasma cells in a similar manner as E2. Further, neither E2, BZA or TSEC had any significant impact on sialic acids in whole serum protein and not in the mRNA expression of glycosyltransferase in the liver, BM, or gonadal fat.

Conclusion: In this study, we were not able to detect any alteration by TSEC or BZA treatment on IgG-sialylation grade and thereby pathogenicity of the IgG. Neither E2 nor BAZ or TSEC show any significant alteration on general sialylation, but our results suggest that further studies are required to understand E2, SERM, and TSEC full effect on protein sialylation in autoimmune conditions.

Keywords: sialylation, protein glycosylation, SERMs

AB0023 JAK-INHIBITORS DISRUPT CD4+CD4+ CELL INTERACTION SUPPRESSING RHO-GTPASE DEPENDENT LEUKOCYTE RECRUITMENT TO JOINTS OF RA PATIENTS

E. Malmhiäl-Bah, K. M. Andersson, R. Ericsson, V. Chandrasekar, S. Töyräl Silfverswärd, M. I. Bokarewa.

Background: While examining arthritis development due hyperactivated Rho-GTPases in a mouse model, we found that macrophages with hyperactive Rho-GTPases regulate the migration of thymic T regulatory cells to peripheral lymphoid organs, which contributed to arthritis development interestingly, T cells reciprocally upregulate Rho-GTPases leading to suppression of homing and formation of a mechanosensory complex of centered around j1 integrin facilitating migration.

Objectives: In response to the finding in mice we sought to explore this relationship in patients diagnosed with RA, aiming to expand understanding how different treatment mechanisms may act to prevent arthritis development. We observed in mice.

Methods: To confirm if similar interaction mechanisms between macrophages and T cells are present in RA patients, we used paired transcriptome (RNAseq) of CD4+ and CD4+ cells from 80 RA patients active on conventional DMARDs prior to treatment with TNF-inhibitors (exploratory cohort) and from 56 RA patients with inactive disease on various DMARD treatment (confirmatory cohort); In both cohorts, patients were stratified by mean expression of CD24 in CD4+ cells to mimic hyper activation of Rho-GTPases. Transcriptomics of CD4+ and CD4+ cells were analyzed and translated into clinical correlates.

Results: Examining the exploratory cohort, we found a reciprocal upregulation of Rho-GTPases across the cell types. The CDC42+ group had upregulation of RHOA and RAC1 in CD4+ cells and CDC42, RAC1 and RHOA in CD4+. Interestingly, expression of IL6, IL1RA, IL18 and NLRP3 signified pro-inflammatory phenotype of those cells. Furthermore, CDC42+CD4+ and CD4+ cells shared the upregulation of AP-1 TFs, and the circadian rhythm controlling molecules PER1, AHR and KLF6 assisting cell migration. Next, CDC42+ cells were enriched with a synovial macrophage marker CD163, and ITGB1 to facilitate focal adhesion and migration into joints. Moreover, high expression of CXCL-chemokines and CD163 on CD4+CD24+ cells indicated the ability to recruit T cells, and high CCRx4 on CDC42+CD4+ cells suggested their synovial destination. Unfortunately, CDC42+CD4+ and CD4+ cells were not recognized by strong production of the key pro-arthritis cytokines TNF-α and IFN-γ. Consequently, the CDC42+ profile of CD4+ and CD4+ cells was not predictive for clinical response to TNF-inhibition in the exploratory cohort.

Conclusion: Examination of the confirmatory cohort revealed the majority of CDC42+CD4+ cells belong to the patients treated with conventional DMARDs, while CDC42+ group were treated with JAK-inhibitors (20 vs 4, OR=11.87, 95% CI [3.387, 49.72], p<0.0001). We also found a correlation between CDC42 expression in CD4+ cells and DAS28 in patients treated with JAK-inhibitors (r=0.5, p=0.0072) pointing at tight relation between the treatment effect and Rho-GTPase dependent processes. This significantly affected the Rho-GTPase dependent interaction between CD4+ and CD4+ cells.

Transcriptional profile of CDC42+CD4+ cells of the confirmatory cohort showed many similarities with the exploratory cohort including upregulation of the canonical Rho-GTPases, ITGB1 and the inflammasome activation that were enhanced by upregulation of the vast number of ITGA and chemokines. Transcriptional regulation through AHR and KLF6 persisted, while AP-1 and PER1 was down-regulated. In contrast to CD4+ cells of the exploratory cohort, CD4+ cells of the patients with CDC42+CD14+ cells were low in CDC42, RAC1 and HOXA expression. Also, CD4+ cells were deficient in AHR, KLF6 and PER1.

Conclusion: Taken together, these data show that Rho-GTPases regulate interaction between CD4+ and CD4+ cells and their migration to RA joints. Treatment with JAK-inhibitors suppresses the Rho-GTPase dependent recruitment to joints by changing communication between CD4+ and CD4+ cells. This finding opens new perspective to use Rho-GTPase signature to identify patients suitable for treatment with JAK-inhibitors and in predicting the treatment response.

AB0024 PLURIPOTENCY MARKER PBX1 PREDICTS TREATMENT EFFECT IN RHEUMATOID ARTHRITIS

Background: Accelerated immunosenescence with contraction of T cell repertoire, demise of thymic function and expansion of CD28− T cells with poor T cell reconstitution is the hallmark of rheumatoid arthritis (RA)

Objectives: In this study we assessed if PBX1 transcription factor that maintains the pluripotency of hematopoietic stem cells could be used to predict treatment response in RA patients.

Methods: CD4+ T cells of 87 RA female patients (age, median 61y (23-76); disease duration, median 9y (0-45)) were isolated from the peripheral blood, activated with aCD3 and subjected to transcriptional analysis by RNAseq (Illumina). External RNAseq of CD4+ T cells of 80 RA patients (f 56, m 24) was used for validation. The genes differentially expressed (DEG, nominal p<0.05) between PBX1+ and PBX1− groups were identified by R-studio using Benjamini-Hochberg correction (0.05DESeq2 package). DEGs were clustered by covariance to identify PBX1 associated genes and biological processes. Clinical variates and treatment regimens in PBX1+ and PBX1− groups were compared.

Results: The patients of PBX1+ and PBX1− groups were of similar age and disease duration but differed in anti-rheumatic treatment. PBX1+ group was often treated with conventional DMARDs and monotherapy, while PBX1− group was mostly treated with biologics and/or JAK-inhibitors in combination with cDMARDs (2, p=0.0099). This treatment led to sufficient disease control in PBX1− group (r=0.0099).

Pathway analysis of the DEGs identified strong enrichment for regulation of transcription (cor.p=10−6), RNA metabolic processes (cor.p=10−6) and differentiation (cor.p=10−6) in PBX1+ cells, which corresponds to the known biological properties of PBX1. PBX1+CD4+ cells in both datasets had imprinted features of pluripotency and expressed higher levels of KIT and CAT, low proliferation...
markers Ki67 and BIRC5, and had virtually no cytokine production. In the main cohort, PBX1hiCD4+ cells were recognized by naïve T cell marks CD62L (SELL) and CD45 (PTPRC), and also PECA1, CR2, and CD28, indicating recent thymic egress. In the validation cohort, PBX1hiCD4+ cells were enriched with stem cell markers CD34, MEG3, and DNMT3B. Lineage specific TFs (TBEI, GATA3, FOXP3, RORC) and cytokines (IFNG, TNF, IL10, IL17F, etc.) were accumulated in PBX1hiCD4+ cells indicating terminally differentiated effector CD4 T cells.

Conclusion: This study shows that enrichment with PBX1hiCD4+ cells is associated with naïve pluripotent phenotype of CD4 lymphocytes. Patients with high PBX1 expression are less heavily treated and respond better to treatment. This suggests boosting of PBX1-expression to be a way of treating RA.

PERIPHERAL BLOOD CD4+ AND CD8+ RECENT THYMIC EMIGRANTS IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS DISPLAY AN ACTIVATED PHENOTYPE

F. V. Kraus1, V. Eckstein2, L. V. Klotz3, H. Winter3, H. M. Lorenz3, M. Souto-Carneiro1. 1University Hospital Heidelberg, Division of Rheumatology, Dept. of Medicine V, Heidelberg, Germany; 2University Hospital Heidelberg, dFFCU, Dept. of Medicine V, Heidelberg, Germany; 3German Center for Lung Research (DZL), Translational Lung Research Center (TLRC), Heidelberg, Germany

Background: T cells play a major pathogenic role in Rheumatoid Arthritis (RA). Their pro-inflammatory potential, interaction with B-cells (CD4) and cytotoxic capacities (CD8) have a high impact on disease progression, at the site of inflammation as well as in the periphery. T cells in RA have an altered glucose metabolism, which further amplifies their pro-inflammatory and auto-immune profile.1,2 This phenotype is even displayed by RA naïve CD8 T cells, and several studies propose that defects in RA T cell development occur already during thymic development. Thus, acquisition of an activated (auto)inflammatory phenotype may occur at very early stages of RA T cell development.

Objectives: We studied Recent Thymic Emigrants (RTEs) in peripheral blood to establish, whether the activated pro-inflammatory signature present in naïve RA T cells can already be found at such an early stage of T cell development.

Methods: We analysed previously described RTE surface markers on CD8 and CD4 T-cells of human adult thymus samples, as well as on cord-blood samples and additionally confirmed the identified cells as RTEs based on their TREC (T cell Receptor Excision Circle) content. Next, we phenotypically characterised RTEs in the peripheral blood of 10 RA patients, 6 PsA (Psoriatic Arthritis) patients and 5 healthy donors (HC) by 24-parameter Flow Cytometry. Cell clustering was analysed using the UMAP algorithm.

Ethic approval NR: S-969/2020

Results: As expected, RTEs only made up a small proportion of the total CD4 and CD8 T cells, on average 1.3 % and 2.5 % respectively. Contrary to previous reports 3 we could see no significant differences between patients and controls. A first global analysis of CD45RA and CCR7 on CD4 and CD8 via UMAP revealed that RA and PsA RTEs cluster together with naïve and effector cells (Figure 1).

We further analysed several functional surface markers for homing (CD11a, CD49a), effector functions (CD69, CD27, CD107a), regulatory functions (CD25) and exhaustion (CD95, PD-1, CTLA-4).

In CD4 RTEs we observed more cells expressing homing, effector and exhaustion markers in RA and PsA when compared to HC. CD11a and CD49a were expressed on 3 times more CD4 RTEs in RA and PsA and CD95 and PD1 expressing CD4 RTEs were 2 times more frequent in the arthritic groups compared to HC, while PD1 expressing CD4 RTEs in patients were 10 times more frequent. The CD25+ CD4 RTE population was 3 times larger in RA and PsA than in HC.

In CD8 RTEs the frequency of CD11a expression was similar, whereas the CD49a+ population was 3 times larger in RA compared to PsA and HC. CD69 expressing CD8 RTEs were increased in RA and PsA compared to HC, while the degranulation marker CD107a was expressed on similar amounts of HC and PsA RTEs and 2 fold increased compared to RA. CTLA-4 and PD1 expressing CD8 RTEs were 5 - and 2 times more frequent in the RA group than in HC.

Conclusion: Overall, the RTE populations of RA and PsA patients displayed a more active and exhausted phenotype than the control group. However, this seemed to be more prominent for CD4 RTEs than CD8 RTEs. According their CD45RA/CCR7 profiles, both CD4 and CD8 RTEs fall into the less active naïve compartment, corresponding to the early developmental stage, but also into the effector compartment. The RTEs from RA and PsA patients also express markers that are usually associated with pro-inflammatory activity and even exhaustion. This implies that indeed even RTEs are already biased towards a more active phenotype in RA and PsA, compared to RTEs from healthy individuals, suggesting alterations in T cell development in the RA and PsA thymus.

AB0026

AB0025
Background: Sjögren’s disease (SjD) is a chronic, heterogeneous autoimmune disorder characterized by inflammatory destruction of the exocrine glands and Ro autoantibodies. Previous studies, most in whole blood, reported transcriptional and cell type differences between SjD subphenotypes.

Objectives: Evaluate the role of cell type-specific dysregulation in subpopulations of SjD patients having focal lymphocytic sialadenitis and/or anti-Ro/SSA and/or ANA positivity using single-cell RNA-seq (scRNA-seq).

Methods: Peripheral blood mononuclear cells (PBMCs) stored at -120°C from 30 SjD patients and 10 healthy controls (HCs) were selected from our OMRF Sjögren’s Research Cohort based on ACR/EULAR 2016 criteria. PBMCs were captured, libraries processed using 10X Genomics Chromium v3.1 and sequenced to a depth of ~45,000 reads/cell. 10X Genomics Cell Ranger (v 6.1.2) cell multiplexing pipeline was used to align reads to the GRCh38 human genome and separate combined data to per-sample output files. Seurat R package was used for quality control (QC), integration, clustering, and cell type assignment. Differential expression (DE) analysis was done using Seurat for genes with 10% or more of the cells showing expression. DE transcripts (defined as \(\text{P}<0.05\)) were evaluated using Ingenuity Pathway Analysis (IPA).

Results: After removing cells with low feature counts, high mitochondrial gene counts, and/or other QC criteria, a total of 331,981 cells were captured. Cells were mapped to 26 clusters using Seurat, then cell types were predicted using marker genes developed from an in-house reference panel of publicly available scRNA-seq datasets. Hierarchical clustering of 28 observed cell clusters yielded 19 clusters of specific cell types; 4 clusters remained unidentified. Percentages of each cell type were compared across various subsets of SjD (Ro+; Ro−; Ro−/ANA+; Ro−/ANA−) and HCs. CD14 monocyes were decreased in Ro−/ANA− vs. Ro+ or Ro+/ANA+ cases (\(p<0.05\)) and trended downward when compared to HCs (\(p=0.057\)). CD8 central memory T cells (TCM) were decreased in Ro+ vs. Ro− or Ro−/ANA− cases (\(p=0.02\)) and trended downward when vs. HCs (\(p=0.076\)). Conventional dendritic cells (DCs) were increased in Ro+ vs. Ro−/ANA− SjD cases (\(p=0.036\)) and trended upward in Ro+ vs. Ro− cases (\(p=0.08\)) but were not significantly different from HCs. Natural killer (NK) cells were increased in both Ro−/ANA− and Ro+ vs. Ro−/ANA− (\(p<0.05\)).

DE analysis between immune cell subsets revealed potential subphenotype-specific differences in pathophysiology. Interferon signaling was upregulated in CD14 monocyes, naive B, and CD4 central memory (TCM) cells from the Ro+ subset. Ro+ subset also showed upregulation of genes involved in T cell receptor signaling in CD4 cytotoxic T (CTL), CD4 TCM, and CD4 effector memory (TEM) cells, but downregulation of this pathway in CD8 TCM cells. Ro+ subset also exhibited increased B cell receptor signaling pathway in naive and memory B cells. Ro− subset showed downregulation of autophagy in naive B, CD4 CTL, CD4 TCM, and CD4 TEM cells. Several cell types in Ro+ and Ro− (ANA−) subsets showed decreased DE of genes involved in nitric oxide production and NRF2 oxidative stress pathways. Ro− (ANA−) vs. HCs showed increased IL6 and TREM1 signaling pathways in CD14 and CD16 monocyes. While Ro− subsets showed upregulation of B and T cell pathways (shown previously in lupus), Ro− (ANA−) showed dysregulation of osteoarthritis and neuroinflammatory pathways. Interleukin-2, among the DE long intergenic non-coding (linc)RNAs found herein, we observed that LINC01871, which we previously reported as DE in all subsets of SjD, was overexpressed in CD4 CTL and NK cells in both Ro+ and Ro− (ANA−) vs. HCs.

Conclusion: This interim analysis shows similarities and differences in the dysregulation of genes and pathways for specific cell subsets from our Ro+ and Ro− (ANA−) subsets of SjD, potentially allowing for more tailored diagnostics and interventions for the disease in the future.

CD39 and CD73 rendering the antiinflammatory agent adenosine 4. CD39, the rate-limiting enzyme in this cascade, is highly expressed by a subset of human FoxP3+Tregs (Treg39+) 1-3. Methotrexate (MTX), the first line of treatment in Rheumatoid Arthritis (RA) 4, inhibits AICAR transformylase which results in an enhanced release of extracellular adenine nucleotides 4 to be metabolized by Treg only in PM/DM patients (p<0.05). In parallel, there were higher frequencies of CD45RO+CCR7- effector/memory cells (p<0.01) and of Ki67+ proliferating cells (p<0.06) among CD3+CD4+FoxP3-Tcon in pSS patients compared to HC, which was not observed in PM/DM patients.

Conclusion: The loss of the CD25+ Treg subset in PM/DM and pSS patients is similar to previous findings in SLLE patients 1 and represents a hallmark of IL-2 deficiency. This suggests that shortage of IL-2 is pathophysiologically relevant also in PM/DM and pSS providing a rationale for low-dose IL-2 therapy in these diseases. In addition, activation and expansion of effector/memory Tcon appears to be more pronounced in pSS compared to PM/DM. The different distribution of Treg and of Tcon subsets between pSS and PM/DM patients might reflect differences in the availability of IL-2 and in the regulation of Tcon responses in these diseases.

AB0029 CIRCULATING CD39+ TREG CELLS IN EARLY RHEUMATOID ARTHRITIS FACILITATE THE ANTINFLAMMATORY ACTION OF METHOTREXATE AND SERVE AS EARLY BIOMARKERS OF CLINICAL RESPONSE

A. Villalba1, L. Nuño1, M. Benito-Migue1, I. Monjo1, M. Novella-Navarro1, D. Peiteado1, A. García-Carazo2, A. Balsa1, M. E. Miranda-Carus3.

1Hospital Universitario La Paz -IdiPAZ, Rheumatology, Madrid, Spain; 2Universidad de Nebrija, Physiology, Centro de Ciencias de la Salud San Rafael. Fundación San Juan de Dios., Madrid, Spain

Background: FoxP3+ regulatory CD4+ T cells (Tregs) are key to the homeostasis of the immune system 1,5. Stressed cells at inflammatory foci release adenine nucleotides to the extracellular space 5 that can act as enhancers of inflammation 5 but are rapidly hydrolyzed by the sequential action of ectonucleotidases CD39 and CD73 rendering the antiinflammatory agent adenosine 5. CD39, the rate-limiting enzyme in this cascade, is highly expressed by a subset of human FoxP3+Tregs (Treg39+) 6, Methotrexate (MTX), the first line of treatment in Rheumatoid Arthritis (RA) 7, inhibits AICAR transformylase which results in an enhanced release of extracellular adenine nucleotides 5 to be metabolized by Treg39+ cells; hence MTX may cooperate with Treg39+ cells in the control of inflammation.

Objectives: To examine the relation of CD39 expression on Tregs cells of early RA (ERA) patients with the ex vivo and in vivo effect of MTX.

Methods: Peripheral blood was obtained from 63 DMDAR- and steroid-naive ERA patients with a disease duration <24 weeks and 63 age and gender-matched healthy controls (HC) 33 ERA patients donated blood again 12 months after initiating MTX (ERA-R). The frequency of Treg and Treg cell subsets was assessed by flow cytometry. CD4+CD25+CD127- (total T reg), CD4+CD27+CD127+CD39+ Treg (Treg39+) and CD4+CD25+CD39- responder T (Treg39-) cells were isolated by sorting. The suppressor potency of Tregs was determined in cocultures of isolated Tregs with Tresp. Proliferation was determined by CFSE dilution; cytokine secretion was measured by ELISA of culture supernatants. Disease activity was assessed using the DAS28-ESR score. Low disease activity (LDA) was defined as a DAS28 ≤ 3.2.

Results: The proportion of Tregs that expressed CD39 (Treg39+) was significantly increased in ERA. Total ERA Tregs were more potent suppressors than HC Tregs, and the difference was reduced by adenosine A2AR antagonists. In vitro, MTX further heightened the total Treg cell potency, with greater amplification in ERA vs HC and this was also reversed by A2AR antagonists. The potency of isolated Treg39+ and its enhancement by MTX were comparable for ERA and HC; the potency of isolated Treg39- was inferior to that of Treg39+ cells in both groups of subjects and was not modified by A2AR antagonists; this further suggests that the differences observed in assays using total Tregs are due to the increased ERA Treg39+ frequency. Patients who achieved LDA had significantly higher basal frequencies of Treg39+ cells and multiple logistic regression (OR 1.93, 95% CI 1.33-4.51) showed that this was independent of basal disease activity, RF or ACPA titres. The Receiver Operating Characteristic (ROC) analysis area under the curve (AUC) was 0.97 (0.94-0.99) for Treg39+ cells. The relative risk (RR) of achieving LDA for patients with a cTreg39+ frequency above the p=0.05 value observed in HC was 13.4 (2.9-75.6) (Fisher’s exact test). The proportion of Treg39+ significantly decreased in all patients whether they had or not achieved LDA, and the frequency and function of ERA-R Treg cells were not different from HC. In fact, 12 months after initiating treatment with MTX, the circulating Treg39+ cell frequency was no longer elevated in ERA; however, its association with the clinical response remained: the cTreg39+ cell frequency observed at 12 months was still significantly higher in those patients who had achieved LDA. This suggests that Treg cell expression of CD39 is upregulated during the initial stages of ERA as a negative feedback mechanism of inflammation.

Conclusion: MTX cooperates with Treg39+ cells to control inflammation and the pretreatment Treg39+ frequency in ERA is associated with the clinical response to MTX at 12 months.

AB0030 THE BIOLOGICAL FUNCTION AND MECHANISM EXPLORATION OF TACI IN SJOGREN’S SYNDROME

H. Zhang1, H. Zhang1, D. Gao3, L. Ji2, Z. Zhang1. 1Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China

Background: primary Sjogren’s syndrome (pSS) is a chronic autoimmune disease that affects the lacrimal, salivary and other exocrine glands. More and more studies have shown that B cells play a central role in the pathogenesis of SSS. Objectives: We intended to explore the expression of the transmembrane activator, calcium modulator and cyclophilin ligand interaction (TACI) on the B cells, its role in pSS, and possible signal transduction pathways. Methods: We included 34 naive pSS patients who visited the rheumatology department of Peking University First Hospital, and 37 gender- and age-distribution matched healthy controls (HCs). (1) To compare the B cell subsets, expression of TACI and relevant receptors in pSS patients, peripheral blood mononuclear cells were separated to analyze the ratio of B subsets, TACI, and BAFF-R by flow cytometry; ELISA was applied to detect the serum BAFF and soluble TACI (sTACI) concentration. (2) For as functional research of TACI, CD19+ B cells separated by magnetic sorting were treated under in vitro culture circumstances with raw TACI, TACI knocked down by siRNA, and sTACI analog (teiltacibibrin) intervention with varying doses. The apoptosis, proliferation, differentiation and regulatory capacity on T cells were analyzed by flow cytometry, inflammatory cytokines and immunoglobulin levels in the culture supernatants were detected by CBA. (3) As for TACI-associated signaling pathway exploration, based on our previous miRNA data and relevant report of high quality, miRNA associated with
TACI with significantly biased expression was confirmed by RT-qPCR. Screening the target gene of the candidate miRNA, and miRNA overexpression and inhibition experiments were conducted to validate the targeted relationship in B cells. And TACI-associated signaling pathway was explored via overexpressing and inhibiting the target gene.

**Results:** (1) Compared to HC, peripheral blood B subsets of pSS patients exhibited a significant bias, manifesting as increased proportion of CD19+CD24hiCD38hi Breg and decreased ratio of CD19+CD24+CD38- memory B cells. The expression of TACI in all B subsets was down-regulated, while that of BAFF-R was up-regulated. Both the serum concentration of BAFF and sTACI in pSS patients increased significantly. (2) As for functional research of TACI, in the setting of raw TACI, B cells in the pSS group showed higher apoptosis rate than HC under culture in vitro, where the ligand of TACI (APRIL or BAFF) addition turned the rate comparable; more active proliferation, and impaired capacity of inducing Treg cells to secrete IL-10. When TACI was knocked down by 50%, B cells performed less late apoptosis, significantly increased proliferation, impaired differentiation, significant dysfunction of Breg itself and impaired induction of Treg cells to secrete IL-10. While telitacicept intervention increased early apoptosis rate of B cells, significantly inhibited proliferation in 500ng/mL group and impaired ability of Breg and Treg cells to secrete IL-10. Besides, increased TACI on B cells treated with telitacicept, decreased IgG and increased IgA in the culture supernatants were observed. (3) As for TACI-associated signaling pathway exploration, hsa-miR-30b-5p showed satisfactory correlation between both transmembrane and sTACI. Besides, the expression of hsa-miR-30b-5p was significantly down-regulated, and inhibition its expression in vitro could lead to differentiation retard, impaired secretion of IL-10 by Breg cells. SMA1 was screened based on database and validated as its target gene by overexpressing and inhibiting hsa-miR-30b-5p in B cell. After targeted up- or down-regulating the transcription of SMA1 further, the transcription of ID2 downstream the TGF-β/Hippo signaling pathway changed accordingly.

**Conclusion:** The expression of TACI on peripheral blood B cells was deficient in pSS patients. TACI deficiency was closely associated with the downregulation of hsa-miR-30b-5p, activating TGF-β/Hippo pathway mediated by its target gene SMA1 and taking part in the pathogenesis of pSS.

**AB0032** CHARACTERIZATION OF PERIPHERAL BLOOD B-CELL SUBSET IN UNTREATED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND SYSTEMIC SCLEROSIS

F. Gerasimova1, D. Tabakova2, A. Aleksankin2, R. Shyakhetmova2, T. Popkova1, A. Avdeeva3, V.A. Nasonova Research Institute of Rheumatology, Department of systemic rheumatic disease, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Laboratory of Systemic Sclerosis, Moscow, Russian Federation

**Background:** Breakdown of self-tolerance is an important common mechanism in autoimmunity. Despite considerable clinical heterogeneity, many autoimmune diseases exhibit common immunological mechanisms leading to a breakdown of self-tolerance. Identification of unique and similar patterns across different autoimmune disease may help to understand their pathophysiology behind.

**Objectives:** Establishing workflows for the multi-parameter deep immune phenotyping of T- and B-cells by unsupervised machine learning (ML) methods for feature extraction, cluster analysis and anomaly detection.

**Methods:** We use machine learning to identify common patterns and dissimilarities between type 1 diabetes (T1D, n=69), rheumatoid arthritis (RA, n=63), systemic lupus erythematosus (SLE, n=38) and healthy controls (n=69) samples based on multi-plex immune phenotyping. PBMCs were isolated from patients with T1D, RA, SLE, and controls. A flow cytometry-based approach was applied, and a traditional analysis was compared to a ML method implemented in R [1] and based on self-organizing maps (Figure 1). Our pipeline includes unsupervised pre-gating, normalization, FlowSOM clustering [2], and a statistical model (GLMM), to check for significant differential abundances of cell populations among the autoimmune conditions.

**Results:** After applying our automated workflow to one T cell panel we could identify 14 cell clusters present in all the samples. The GLMM test revealed a cluster with a significant difference (p=0.035) and a trending one (p=0.059) on the abundance across the different diseases. In particular, CD4^{+}^{+} T cells expressing high IL-7 receptor (CD127) levels and median amounts of CD15s but low CD25, CD161 and FoxP3 are increased in T1D whereas CD4^{+}^{+}^{+}^{+}CD15s^{+}FoxP3^{+}CD161^{+}^{+}CD45RA cells are increased in SLE.

**Conclusion:** This unbiased, unsupervised ML workflow was able to identify canonical and novel clusters of T cells that are similar in RA, SLE and T1D. Additionally, a novel memory T cell population expressing CD15s was shown. This unsupervised analysis approach for large datasets enables the discovery of new immune cell populations complementing traditional workflows.

**DOI:** 10.1136/annrheumdis-2022-eular.3072
Background: B-cells play a critical role in the regulation of systemic autoimmune diseases pathogenesis, that extends beyond antibodies production. Objectives: To examine B-cell subsets in peripheral blood of patients (pts) with untreated systemic lupus erythematosus (SLE) and systemic sclerosis (SSc), to analyze of their associations with disease-specific autoantibodies. Methods: Thirty six untreated SLE pts (31F/5M) and 32 untreated SSc pts (25F/7M) were enrolled. SLE pts had median age of 37(range)(32-41) years, disease duration of 3.5(1-11)years, SLEDAI 2K of 7(4-8), BILAG of 14.5(10.2-23). SSc pts had median age of 42(38-50) years, disease duration of 3.5(1-10) years, Disease Activity ESSG of 2.5 (1-3.2). The control group consisted of 29 volunteers (23F/6M, median age 38(35-48) years. CD19+B cells, memory B cells (CD19+CD27+), switched memory B cells (CD19+CD27+IgD+), non-switched memory B cells (CD19+CD27+IgD-), naive (CD19+CD27+IgD+), double-negative (CD19+CD27-IgD), transitional (CD19+CD38++CD10+IgD+CD27-) B cells, and plasmablasts (CD19+CD38+++CD10+IgD+CD27-20+) were analyzed using multicolor flow cytometry. Results: Differences in the median percentage and of absolute B-cell subsets levels in untreated pts with RA and SLE were not found. The absolute counts of memory B cells (CD19+CD27+), switched memory B cells (CD19+CD27+IgD+), transitional B cells (CD19+CD38++CD10+IgD+CD27+), and plasmablasts (CD19+CD38+++CD10+IgD+CD27-20+) were higher in SLE and SSc pts compared to healthy donors, p<0.01 for all cases. The absolute counts of double-negative B cells (CD19+CD27-IgD-) were lower in SLE pts than in donors, p=0.03 (Table 1). At significant correlation was found in SLE pts between anti-dsDNA levels and absolute counts of the following B-cell subtypes: CD19+B cells (r=0.72), memory B cells (CD19+CD27+IgD-20) (r=0.76), switched memory B cells (CD19+CD27+IgD+) (r=0.75) and naive B cells (CD19+CD27-IgD+) (r=0.73); the a-Sm levels and absolute counts of CD19+B cells (r=0.76), switched memory B cells (CD19+CD27+IgD-), non-switched memory B cells (CD19+CD27+IgD-) (r=0.51); the antibodies to cardiolipin (aCL) IgG levels and absolute counts of CD19+B cells (r=0.75) and naive B cells (CD19+CD27-IgD+) (r=0.73); the a-Sm levels and B cells (CD19+CD27+), switched memory B cells (CD19+CD27+IgD-), non-switched memory B cells (CD19+CD27+IgD-) (r=0.76), and with naive B cells (CD19+CD27-IgD+) (r=0.59), p<0.01 for all cases. There was a correlation against anti-topoisomerase-1 antibodies (a-Topo-1) and the absolute counts of double-negative B cells (CD19+CD27-IgD-) (R=0.82, p=0.01) in SSc pts.

Table 1. Levels of the blood B-cell subsets in SLE pts, SSc pts and in control.

Note: * Differences in B-cell subset of the control group with SLE and SSc groups.

Conclusion: Immunophenotyping showed similar levels of B-cell subset in untreated SLE and SSc pts, an increase in the absolute counts of memory B cells (CD19+CD27+), switched memory B cells (CD19+CD27+IgD+), transitional B cells (CD19+CD38++CD10+IgD+CD27+) and plasmablasts (CD19+CD38+++CD10+IgD+CD27-) in untreated SLE and SSc pts compared with healthy subjects. Positive correlation between the counts of B-cell subsets and values of disease-specific autoantibodies (anti-dsDNA, a-Sm, scIgG, a-Topo-1) suggests that B-lymphocytes may be involved in SLE and SSc pathogenesis. Pavlov First St. Petersburg State Medical University of the Ministry of Healthcare of Russian Federation, Department of Molecular Medicine, Saint-Petersburg, Russian Federation

Background: Systemic lupus erythematosus (SLE) and primary Sjögren’s syndrome (pSS) are chronic autoimmune diseases with complex pathogenesis. T-lymphocytes are known to be prime effectors of autoimmune diseases, while B-lymphocytes play a key role as sources of antibodies and antigen presenting cells. Considering the implications of T- and B-cells in the pathophysiology of SLE ans pSS, the assessment of their distribution in the blood could be helpful in the complex process of determining a precise diagnosis.

Objectives: The study aimed to compare composition of peripheral blood T- and B-cell subsets and investigate their diagnostic utility in patients with SLE and pSS.

Methods: The study was performed with 37 patients suffering from SLE, 57 patients with pSS, and 49 apparently healthy volunteers (HVs). The diagnosis of SLE was performed according to the 2019 EULAR – ACR classification criteria, the diagnosis of pSS- according to the 2016 EULAR – ACR criteria. 11 patients in pSS group met the criteria for both pSS and SLE, the relative distribution and percentage of T- and B-cell subsets were evaluated by flow cytometry. T helper (Th) and cytotoxic T-cell subsets (Tcye) were identified by using CD3, CD4, and CD8 antibodies. Regulatory T cells (Tregs) were characterized by the expression of CD3, CD4, and high IL-2R alpha chain (CD25high) levels. All peripheral blood B-cells were identified by using CD19 antibody, detection of subpopulations of B cells based on expression of IgD, IgM, CD27. The absolute and relative values of B-lymphocyte subpopulations were evaluated using three main classifications: based on IgD / CD38 expression classification (Bm1-Bm5), co-expression of IgD / CD27 and CD38 / CD27. The statistical analysis of data was performed with STATISTICA Version 12.0.0.1c. Method of discriminant analysis was performed to evaluate diagnostic utility of relative values of T- and B-cell subsets.

Results: In the discriminant model the top significance was documented while assessing the percentage of naive B-cells (Bm1, IgDdimCD38low), germinal center B-cells (Bm 3+8Bm4, IgDdimCD38hi), naive B-cells (IgDdimCD27low), unswitched memory B-cells (IgDdimCD27dim), naive mature B-cells (CD27dimCD38low), transient B-cells (CD27lowCD38hi), all T-cells (CD3hi), Tregs (CD3hiCD4hiCD25hi), Tcyt (CD3hiCD4) and Th (CD3hiCD4hi). Model percent correct was 78%, p<0.05. The discriminant function was either 11 for distinguishing HVs versus il patients SLE and pSS, while B-lymphocytes play a key role as sources of antibodies and antigen presenting disease are accounted). During ROC analysis, performed for the differential diagnosis of healthy and sick patients, this discriminant model had a sensitivity of 86.5% and a specificity of 72.8%, the area under the curve (AUC) 0.94, p < 0.001. Among the group of il patients, the differential diagnosis between SLE and pSS has a sensitivity of 68.6% and specificity of 64.8%, AUC 0.87, p<0.001. Graphic representation of the discriminant analysis is performed on Figure 1. The group of patients, meeting the criteria for both pSS and SLE, is between the main groups.

INVESTIGATING THE ROLE OF ACCELERATED IMMUNESENESCENCE IN THE PATHOGENESIS OF RHEUMATOID ARTHRITIS

1Amsterdam Medical Center, Experimental Immunology, Amsterdam, Netherlands
2Karolinska Institute, Solna, Sweden
3Faculty of Medical Sciences, University of Newcastle, Newcastle, United Kingdom
4Department of Rheumatology, Leiden University, Leiden, Netherlands

Background: Advancing age is recognised as a major risk factor for autoimmune inflammatory conditions, such as Rheumatoid Arthritis (RA). Despite strong associations with older age we understand little of the role ageing processes play in disease pathogenesis in RA. The immune system undergoes a dramatic remodeling with age, termed immune senescence, which contributes towards increased risk of autoimmunity1. Previous research in patients with established RA has shown certain features of immune senescence, such as thymic atrophy and telomere shortening in T cells, at a younger age2,3.

Objectives: In this study we aimed to determine if immune senescence is seen in the very earliest stages of RA and therefore might be a contributor to RA pathogenesis rather than a result of the disease.

Methods: We have assessed aspects of the aged immune phenotype by immune-phenotyping and flow cytometry4 in adults with arthralgia (n=25), undifferentiated arthritis (UA; n=41), confirmed RA of less than 3 months (n=25) and more than 3 months duration (n=78) and compared these to age and sex matched healthy controls (n=38). Nanostring methodology was used to determine gene expression changes associated with the development of RA.

Results: We observed increased features of T and B cell immune senescence in DMARD-naive recently diagnosed RA patients driven by reduced naive T cells (p<0.01) and B cells (p<0.01), increased senescent (CD28-ve, CD57+ve, KLRG1+ve) T cells (p<0.01), an increased Th17/Treg ratio (p<0.01) and increased frequency of age-associated B cells (p<0.01). With the exception of naive T cell frequency, which was reduced in UA patients (p<0.05), these changes were not seen in the very early stages of RA, namely patients with arthralgia and UA. These data suggest that immune senescence only occurs once disease is established. Furthermore, using nanostring we have identified several biological ageing processes (DNA damage, autophagy) associated with this state of immune senescence in RA.

Conclusion: Accelerated immune ageing is an early feature of RA and biological ageing processes represent novel targets to modulate disease progression.

FREQUENCY OF LYMPH NODE Stromal CELLS HLA-DR+ IS REDUCED IN INGUINAL LYMPH NODES FROM HUMAN DONORS WITH RHEUMATOID ARTHRITIS COMPARED TO CONTROLS

C. Grasso1,2 Amsterdam Medical Centre, Experimental Immunology, Amsterdam, Netherlands

Background: Rheumatoid arthritis (RA) is an autoimmune disorder where the immune system gradually damages a wide variety of body systems, including the skin, eyes, lungs, heart, and blood vessels1. Animal studies have shown that lymph node stromal cells (LNSCs) are key players in peripheral tolerance through their capacity to present self-antigen to T cells thereby controlling auto-reactivity and regulating autoimmunity and humoral response2. Although self-antigen presentation by human LNSCs needs to be formally proven in human, this study speculates that malfunctioning LNSCs might be associated with loss of tolerance in autoimmune diseases like RA.

Objectives: The objective of this study is to assesses and compare the frequency of main LNSC subsets in human lymph node needle biopsies of healthy controls, autoantibody positive individuals at risk of developing RA (RA-risk) and RA patients. We especially focussed on markers for antigen presentation expressed by LNSCs.

Methods: RA at risk, RA and healthy (n=1 participants underwent an ultrasound-guided inguinal LN needle core biopsy as previously described3. We included RA-risk participants (n = 6) with elevated IgM-RF and/or ACPA levels, but without any evidence of arthritis upon examination; RA patients (n =13) with established disease based on fulfilment of the American College of Rheumatology and European League Against Rheumatism (ACR/EULAR) 2010 criteria as assessed by the rheumatologist. For comparison we included healthy participant (n = 17) The healthy control was without any joint complaints and without elevated IgM-RF and/or ACPA level and without active viral infection or any history of autoimmunity or malignancy. To increase the number of healthy participants in the control group, we included lymph node biopsies from individuals receiving a kidney transplant (n=16). After collection, tissue samples were enzymatically digested to obtain a single cell suspension, followed by flow cytometry analysis with the following cell surface markers CD40, CD80, CD86, PD-L1, HLA-DR, CD45, PDPN, CD31, CD235a, Vialia dye.

Results: Antigen presentation related co-stimulatory molecules (CD40, CD80, CD86, PD-L1) and HLA-DR were detected at low levels. Blood endothelial cells having the highest expression of HLA-DR followed by LECs, FRCs, DNs. We observed a reduced frequency of HLA-DR+ lymph node stromal cell (CD45-, CD235a-) in RA and RA at risk compared to controls. After we found that FRCs, DNs, and BECs were reduced in RA and RA at risk compared to healthy control population.

Conclusion: Our findings show that the frequency of HLA-DR positive LNSCs is lower in RA-risk individuals and RA patients compared to controls. As HLA-DR is crucial to present self-antigens and promote self-tolerance, it will be of interest to investigate whether the antigen presenting capacity of LNSCs is diminished already before onset of disease and how we could restore this.

Innate immunity in rheumatic diseases

**AB0036** BUTYRIC ACID SUPPRESSES MIGRATION OF MONOCYTE-DERIVED DENDRITIC CELLS BY INHIBITING MDIA1-MEDITATED ACTIN POLYMERIZATION

T. Nagamoto1, T. Okano2, Y. Fujikawa3, Y. Ueda4, H. Yamada5, S. Sendo6, J. Saegusa1, 1Kobe University, Rheumatology, Kobe, Japan; 2University of California, Medicine, San Diego, United States of America

**Background:** Butyric acid is known to improve chronic inflammation such as inflammatory bowel disease and arthritis [1, 2]. Dendritic cells activate in inflammatory condition, migrate to regional lymph nodes, and activate naive T cells.

**Objectives:** In this study, we investigated the effect of butyric acid on the migration ability of monocyte-derived dendritic cells (moDC).

**Methods:** Human CD14+ Monocytes were purified by positive selection from PBMC using CD14 magnetic beads. Cells were cultured in the presence of GM-CSF (50 ng/ml) and IL-4 (20 ng/ml) for 5 days. After culturing for 5 days, cells were matured with LPS (1 μg/ml) for 24 hours. Butyric acid was administered at different dose or period. Surface antigen on moDC was analyzed by flow cytometry (BD FACS VERSE). Migration assay was performed on Boyden chamber CytoSelect 24-Well Cell Migration Assay (SUM). Actin was stained with Alexa Fluor 488 Phalloidin before and after migration assay. After administration with butyric acid assigned to each period and concentration, moDC were lysed for western blot analysis for evaluating signaling. Chemiluminescent signals were detected and calculated by Amersham Imager.

**Results:** We demonstrated that butyric acid decreased the CCR7 expression of moDC, which has a key role in DC homing to the lymph nodes and intestinal Peyer’s patches. We also showed that butyric acid decreased the migration ability of moDC.

Furthermore, moDCs cultured with butyric acid showed a round shape and poor formation of dendrites and pseudopodia. Then we studied the effect of butyric acid on cytoskeleton, which plays an important role in migration and pseudopodia formation of DCs. Polymerized Actin (F-Actin) staining revealed that butyrate suppressed actin polymerization of moDC in a dose dependent manner. CDC42 works important role of lamellipodia and membrane protrusions. RhoA is upstream of mDia1, and mDia1 was reported to accelerate actin nucleation and elongation. We revealed that butyrate decreased the protein expression of mDia1, RhoA, and CDC42, while beta actin was not downregulated, by Western blot analysis. Our results suggested that butyric acid suppresses migration of moDCs by inhibiting mDia1-mediated actin polymerization.

**Conclusion:** Butyric acid suppresses migration of moDCs by inhibiting mDia1-mediated actin polymerization.

**AB0037** APE1 REGULATES THE MIGRATION OF FIBROBLAST-LIKE SYNIOCYTOCES FROM PATIENTS WITH RHEUMATOID ARTHRITIS

H. R. Lee, J. Kim, S. J. Yoo, J. A. Park, H. K. Joo, Y. R. Lee, S. Kim, B. H. Jeon, S. W. Kang, Chungnam National University School of Medicine, Research Institute for Medical Sciences, Daejeon, Korea, Rep. of (South Korea); 2Chungnam National University Hospital, Department of Internal Medicine, Daejeon, Korea, Rep. of (South Korea); 3Chungnam National University, Department of Physiology, College of Medicine, Daejeon, Korea, Rep. of (South Korea)

**Background:** The level of apurinic/apyrimidinic endonuclease 1 (APE1) is elevated in synovial fluids from patients with rheumatoid arthritis (RA). However, the role of APE1 in RA pathogenesis remains unclear.

**Objectives:** To explore whether APE1 affects cell migration through reactive oxygen species (ROS) level, fibroblast-like syncytios (FLS) from RA patients were stimulated with human recombinant APE1.

**Methods:** Synovial tissues were obtained from RA patients who were undergoing synovectomy or joint replacement. The isolated cells were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum and maintained in a 5% CO2 incubator at 37 °C. FLS were used for experiments after three to six passages. Cells were stimulated with or without recombinant interleukin 17 (IL-17; 10 ng/ml), tumor necrosis factor alpha (TNF-α; 10 ng/ml), and long-lasting recombinant human APE1 (MR201; 1, 10, 100 ng/ml) for 24 h. ROS levels were analyzed using MitoSOX dye. Cell migratory ability was examined using wound migration assay.

**Results:** RA FLS treated with APE1 showed slightly decreased level of mitocondrial specific ROS. To induce pro-inflammatory conditions, RA FLS were incubated with IL-17 and TNF-α. These cytokines are highly detected in RA synovium and directly stimulate FLS activation. Stimulation with IL-17 and TNF-α upregulated ROS by 30% compared to control. Cytokines-induced increase of ROS was inhibited by 22% in APE1 treatment. When FLS cultures were approximatively 90% confluent, FLS monolayers were wounded with pipette tips and treated with IL-17/TNF-α and APE1 for 24 h. Cell migration was increased after treatment with IL-17/TNF-α. Cytokines-induced cell migration was markedly attenuated by APE1 treatment.

**Conclusion:** Recombinant APE1 markedly inhibited mitochondrial specific ROS production and IL-17/TNF-α-induced cell migration in RA FLS.

**AB0038** DUAL TARGETING PEPTIDE RLS-0071 REDUCES AND INHIBITS MYELOPEROXIDASE (MPO) IN HEALTHY HUMAN VOLUNTEER

P. Kumar, K. Cunnion, N. Krishna, U. Thienel, P. Hair, J. Goss, C. Gabriel on behalf of ReAlta Life Sciences, Research, Norfolk, United States of America; 2Children’s Hospital of The King’s Daughters, Rheumatology, Norfolk, United States of America

**Background:** RLS-0071-101 was a first in human clinical trial to evaluate safety of the peptide RLS-0071 in healthy volunteers in a single ascending dose and multiple ascending dose format. RLS-0071, previously referred to as Peptide Inhibitor of Complement C1 (PIC1) is a dual-targeting peptide being developed for clinical use to moderate humoral and cellular inflammation via inhibition of complement activation and inflammatory effectors including, myeloperoxidase (MPO) and Neutrophil extracellular trap formation (NETosis). Humans that are otherwise asymptomatic are considered at risk for cardiovascular complications if they have a plasma MPO level of > 420 pmoL. A post hoc analysis of plasma samples from subjects participating in RLS-0071-101 identified an individual with mildly elevated baseline MPO level (142 pmoL).

**Objectives:** Evaluate if RLS-0071 dosing would change MPO level or activity in a subject with elevated baseline MPO.

**Methods:** Frozen plasma samples prepared from blood collected by venipunture into K2EDTA tubes (BD) was utilized to determine MPO quantity and activity levels. MPO quantity in the plasma was analyzed using a human MPO ELISA kit (BMS2038IN, Invitrogen) and MPO activity within the plasma was analyzed using a fluorescence-based myeloperoxidase assay kit (K745-100, BioVision).

**Results:** Upon screening 54 subjects from RLS-0071-101 we identified one individual with a mildly elevated MPO level at baseline, a 21-year-old white female with BMI of 21.7. The subject received 9 intravenous infusions of RLS-0071 each at a dose of 10 mg/kg. Her vital signs and body temperature remained normal.
throughout the study and the only blood laboratory abnormality were a mildly low plasma protein concentration of Day 2 and Day 4 which was noted both among recipients of the peptide and placebo subjects. Analysis of MPO blood concentrations demonstrated a mildly elevated baseline plasma MPO concentration that decreased after multiple doses of RLS-0071 with partial recovery to baseline 24 hours after cessation of dosing. MPO activity analyzed using a fluo-
rescence-based myeloperoxidase assay kit demonstrated an elevated baseline plasma MPO activity level that decreased after multiple doses of RLS-0071 with partial recovery after 24 hours.

Conclusion: These results suggest promise for RLS-0071 to reversibly moder-
ate plasma MPO activity and potentially affect MPO-mediated diseases including acute coronary syndrome (ACS), atheromatous plaque vulnerability and auto immune conditions.4,5,6,7

AB0039 MONOCYTE EXTRACELLULAR TRAPS: A NEW POTENTIAL DIAGNOSTIC BIOMARKER IN RHEUMATOID ARTHRITIS?

I. Zborovskaya1, S. Bedina1, E. Mozgovaya1, A. Trofimenko1, M. Mamus1, S. Spitsina1.

1 Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy, Clinical biochemistry lab, Valogorod, Russian Federation

Background: Studies demonstrating the important role of neutrophil extracellu-
lar traps (NETs) in the pathogenesis of autoimmune diseases, including rheumatoid arthritis (RA), have been published extensively in recent years. The researchers are also discussing the possibility of considering NET as a source of potential diagnostic biomarker in RA. As compared with NETs, the monocyte extracellular traps (METs) formation by mononuclear phagocytes, although they have also been implicated in the development of autoimmune reactions, has been studied insufficiently. No studies have been reported on the MET formation in active RA patients.

Objectives: Assessment of METs generation by peripheral blood monocytes from RA patients in association with the disease exacerbation.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles after the local ethical board approval. Circulating monocytes were isolated with one-step density gradient centrifugation using double layers of the in-lab-made ficoll-amidotrizole gradient. Composition of isolated cellu-
lar fractions, their viability, and non-specific activation were evaluated by light microscopy using common Romanowsky-Giemsa staining, trypan blue exclu-
sion test as well as NBT test. METs were induced by LPS. Monocyte fractions contained low extents of activated and dead cells. Spontaneous and induced formation of extracellular traps was assessed using fluorescence microscopy [1]. Results were presented as values (95%CI).

Results: 30 healthy volunteers (9 males and 21 females, mean age 37.2 years) were enrolled as a reference group. 37 patients (6 males and 31

females, mean age 42.7 years) with verified RA according to the ACR/EULAR 2010 criteria were included in the study. RA disease activity was assessed using DAS28 score did not exceeded 2.6 in every patient at the inclusion timepoint. In 16 (15.4%) patients, the activity of DAS 28 exceeded 3.2 at subsequent visits (after 3, 8 and 12 months). Spontaneous and induced MET formation by isolated monocytes in RA patients (DAS ≥8≥2.6) was 8.7 (8.3-
9.1%) and 26.2 (24.7-27.9%), respectively. Spontaneous and induced MET formation by isolated monocytes in RA patients (DAS ≥8≥3.2) was 18.1 (17.8-
18.4%) and 38.2 (36.0-38.4%), respectively. Spontaneous and induced MET formation by isolated neutrophils in active RA patients (DAS 28>3.2) was significantly higher than in inactive RA patients and in comparison to the reference group. Induced MET formation was also significantly higher than spontaneous one (p<0.05). Monocytes did not demonstrate any difference between ACPA-positive and ACPA-negative RA patients in their MET produc-
tion. The growth rate of spontaneous MET formation was 114.7%, for induced MET formation – 44.2%. The growth rate of spontaneous MET formation is 2.6 times higher than the induced MET formation.

Conclusion: METs formation by isolated monocytes can be considered as a new potential diagnostic biomarker associated with RA flare. Further study of the mechanisms of MET formation and their composition may improve our understanding of the role of monocytes and METs in the patho-
genesis of RA.

AB0040 STUDYING THE MACROPHAGE ACTIVATION AND THE INTIMA-MEDIA THICKNESS OF THE CAROTID ARTERIES IN UNRETTED PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS (PRELIMINARY DATA)

E. Gerasimova1, T. Popkova1, T. Kirichenko2, A. Markin2, I. Kirillova3, A. Orekhov3,1.

1V.A. Nasonova Research Institute of Rheumatology, Department of systemic rheumatic disease, Moscow, Russian Federation; 2Research Institute of Human Morphology, Laboratory of Cellular and Molecular Pathology of the Cardiovascular System, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Laboratory of systemic rheumatic diseases, Moscow, Russian Federation

Background: Autoimmune Rheumatic Diseases (ARDs) occur with a high risk of atherosclerosis development. The macrophages are at the same time a part of the inflammatory response, and also tightly linked to the foam cell formation, thus taking part in both crucial for atherosclerosis processes.

Objectives: To evaluate the macrophage activation, and the intima-me-
dia thickness (IMT), subclinical atherosclerosis of the carotid arteries in untreated pts with rheumatoid arthritis (RA) and systemic lupus erythema-
tosus (SLE).

Methods: Thirty six untreated RA pts (30F/6M) and 36 untreated SLE pts (31F/5M) were enrolled.

RA pts had median age of 39 years (range) (33-45), disease duration of 2.5 years (1-5), moderate clinical disease activity DAS of 28 5.3 (3.5;5.8), SDAI of 17 (15;19), HAQ of 1 (0.75;1). SLE pts had median age of 37 years (range) (32-41), disease duration of 3.5 years (1-11), SLEDAI 2K of 7 (4-8), BILAG of 14.5 (10.2-23).

Isolation of monocytes was carried out according to the standard procedure for obtaining a leukocyte fraction in a Ficoll gradient and subsequent selec-
tion of CD14 + cells using magnetic separation. The growth rate of spontaneous MET formation was 2.6 times higher than the induced MET formation.

Conclusion: METs formation by isolated monocytes can be considered as a new potential diagnostic biomarker associated with RA flare. Further study of the mechanisms of MET formation and their composition may improve our understanding of the role of monocytes and METs in the patho-
genesis of RA.

Scientific Abstracts

In RA pts, there was a significant correlation between carotid m-IMT and age (R=0.76), level of total cholesterol (R=0.51), LDL cholesterol (R=0.27), systolic blood pressure (R=0.71), diastolic blood pressure (R=0.76), aMCV levels (R=0.73), p<0.05 in all cases. No correlation between carotid m-IMT/M-IMT and the disease’s duration, stage or activity was found in RA pts. In SLE pts, carotid m-IMT was associated with the mean SLICC/ACR Damage Index score (R=0.50, p<0.01), with antibodies to cardiolipin (aCL) IgG levels (R=0.42, p=0.02), and with antibodies to beta2-glycoprotein 1 (anti-beta2GP1) IgG levels (R=0.49, p<0.01). No correlation between carotid m-IMT/M-IMT and the traditional CVR factors and disease’s activity was found in SLE pts. No association was found between the carotid m-IMT/M-IMT and macrophage activation.

Conclusion: No differences in macrophage activation were found in RA and SLE pts. Macrophage activation was independent of CVR and ARD-related factors. Subclinical atherosclerotic lesions of the carotid arteries were observed in a every fifth untreated RA and SLE pts. Carotid m-IMT correlated with traditional CVR factors and disease’s activity was found in SLE pts. No association was found between the carotid m-IMT/M-IMT and macrophage activation.

THE PHENOTYPE OF PERIPHERAL BLOOD DENDRITIC CELLS OF PATIENTS WITH ADULT-ONSET STILL’S DISEASE COMPARED TO HEALTHY DONORS AND PATIENTS WITH PSORIATIC ARTHRITIS

S. Schnitte1, T. Funk1, J. Henes2, S. Saur2. 1UKT, Department of Medical Oncology, Hematology, Immunology, Rheumatology and Pulmonology., Tübingen, Germany; 2UKT Rheumatology and Auto-inflammatory Diseases and Department of Internal Medicine II (Hematology, Oncology, Immunology and Rheumatology), Centre for Interdisciplinary Clinical Immunology, Tübingen, Germany

Background: Adult-onset still’s disease (AOSD) is a rare autoinflammatory disease. A triad of high fever, arthritis and skin rash is described, but multiple forms of manifestation, as the lack of detectable biomarkers, aggravate making the diagnosis (1).

Psoriatic arthritis (PsA), another autoimmune disease with jointal manifestation, affects approximately 30% of all patients with psoriasis (2).

Dendritic cells (DCs) are potent antigen presenting cells linking adaptive and innate immunity. In various autoimmune diseases alterations of DCs were detected (4).

Objectives: The etiology and effect of peripheral blood DCs on the arthritis in both diseases is not cleared yet (1,3). This project tried to examine alterations of DCs in AOSD patients compared to those with PsA and a healthy control group (HC).

Methods: 13 patients with AOSD were analysed and compared. Leukocytes were separated with density gradient centrifugation and sorted with flow cytometry. The contingent of DC subsets in the peripheral blood (pDCs, CD1c+DCs, CD141+DCs) was compared between AOSD patients and the other two groups (n=12).

Monocytes of the peripheral blood were incubated with IL-4 and GM-CSF to differentiate to DCs. The addition of lipopolysaccharides helped gaining immature (n=11) and mature (n=9) DCs. Their phenotype was characterized by CD1a, CD206, Osteoactivin (OA), CCR7, CD14, DC sign, CCR7, CD14, CD40, HLA-DR, CD80, CD83, CD86. The expression levels of the surface proteins were again compared.

Results: The DC subset rates did not differ significantly between AOSD patients and both other groups.

OA expression on immature DCs is statistically different between HC compared to patients with AOSD (p=0.0128). The expression levels of AOSD patients and those with PsA do not differ significantly.
The interaction of CD80 and CD86 with CD28 is necessary to produce IL-6. The pro-inflammatory effect is limited by CD80/CD86 itself (6). CD80, in contrast to CD86, is expressed differentially in patients with AOSD and PsA. As CD80 and CD86 function as cofactors, an alteration of both might have been expected.

OPTIMAL CONDITIONS FOR THE DETECTION OF INFILAMMASOME ACTIVATION IN CD14+ CD16- MONOCYTES FROM HUMAN BLOOD BY FLOW CYTOMETRY
N. Wittmann1, N. Mishra2, A. K. Behrendt1, L. Bossaller2, A. Meyer-Bahlburg1.
1University Medicine, University of Greifswald, Pediatric Rheumatology, Department Pediatric and Adolescent Medicine, Greifswald, Germany;
2University Medicine, University of Greifswald, Section of Rheumatology, Department Medicine A, Greifswald, Germany

Background: The inflammasome activation is linked to the aggregation of the adaptor protein ASC into a multimeric structure, known as the ASC speck. The aggregation of cytosolic ASC into ASC specks is therefore used as a readout parameter for inflammasome activity. The direct detection of ASC speck formation on a single cell basis through flow cytometry, can analyze inflammasome activity in a clinical setting. Objectives: Investigating the optimal conditions for a reliable identification of inflammasome activated ASC speck positive cells ex vivo using flow cytometry.

Methods: Freshly donated blood from five different healthy donors was used for all experiments. The choice of anticoagulant, storage time and storage temperature were examined. PBMCs were isolated from blood collecting tubes with ethylenediaminetetraacetic acid (EDTA) or lithium heparin (LH). PBMCs were also isolated from LH blood stored at 4 °C, room temperature (RT), 37 °C and after different storage times. After isolation, PBMCs were also isolated from LH blood stored at 4 °C, room temperature, for all experiments. The choice of anticoagulant, storage time and storage temperature until unspecific ASC speck signals occur was investigated. A significant increase in ASC speck positive CD14+CD16- monocytes was detected after 4 h storage at RT compared to directly processed samples and the number of ASC speck positive monocytes further accumulated over time. The incubation with nigericin in PBS leads to a significant increase in ASC speck positive CD14+CD16- monocytes and THP-1 cells compared to incubation in RPMI media.

Conclusion: The flow cytometric detection of ASC specks is adapted for practical clinical usability. To reduce background signals, LH- instead of EDTA blood collecting tubes are recommended. The LH blood should be processed within 2 h after blood collection and be stored at RT. To avoid nonspecific activation and formation of ASC specks, the PBMCs should be isolated directly after venipuncture and fixed immediately. It is also possible to freeze the PBMCs until further usage. However, this will cause some loss of ASC speck positive cells. With these settings, clinical samples can now be examined.

AB0043
THE IMPACT OF ANTI-RO52 ANTIBODIES ON THE EXPRESSION OF ANTIVIRAL RESPONSE-RELATED GENES – PRELIMINARY STUDY
A. Opinc1, J. Sarnik1, Z. Lukasik1, J. Makowska1.
1Medical University of Lodz, Department of Rheumatology, Lodz, Poland

Background: Ro52, also known as TRIM21, is an essential agent of the innate host defence, especially of the antiviral responses. It was found to be induced by type I and II interferons. Due to its activity of E3 ligase, TRIM21 is involved in the ubiquitination of several IFN regulating factors (IRFα)9. Ro52 enables antibody-dependent intracellular neutralization as a high-affinity Fc immunoglobulin receptor. The auto-ubiquitination of the TRIM21-related complex induces signaling pathways with the production of pro-inflammatory cytokines1. Anti-Ro52 autoantibodies are found in various autoimmune conditions. The hypothesis of our project assumes that viral infections in genetically susceptible individuals trigger overexpression of Ro52, followed by the production of autoantibodies, which suppress its function as the negative regulator of type I interferon responses, leading to enhanced production of proinflammatory agents that uphold autoimmune process.

Objective: To compare the expression of antiviral response-related genes in patients with anti-Ro52 autoantibodies and healthy volunteers in order to assess the significance of anti-Ro52 in the antiviral defence.

Methods: Anti-Ro52+ patients, hospitalized at the Department of Rheumatology, Medical University of Lodz or treated in the united outpatient clinic were recruited. 19 patients with anti-Ro52 antibodies were included in the study group (mean age: 54.2 years; F:M ratio 14:5). Among them, 5 patients were diagnosed with primary Sjogren syndrome, 4 with idiopathic inflammatory myopathies, 4 with systemic lupus erythematosus, 1 with rheumatoid arthritis, 3 with overlapping syndromes and 1 was undergoing diagnosis of connective tissue disease at the time of the recruitment. Data on the diagnosis, clinical symptoms and laboratory results were collected from the patients and the available medical records. 10 healthy individuals without autoimmune disorders were recruited to the control group. Whole blood samples were collected from both anti-Ro52+ patients and healthy controls, PBMCs were isolated using Biocoll reagent. RNA was isolated from each sample with RNeasy and cDNA synthesis was performed with RevertAid™ H Minus First Strand cDNA Synthesis Kit. The mRNA expression levels of TRIM, IRF3, IRF5, IRF7, NFκB, RIG-1, MDAS genes were examined by quantitative real-time PCR with TaqMan™ Universal PCR Master Mix according to the manufacturer’s instructions. The expression levels of genes relative to that of GAPDH were calculated by delta Ct (ΔCt). The ΔCt value is the Ct value of the target gene subtracted its Ct value of GAPDH. ΔCt – Ct (Gene) – Ct (GAPDH). Therefore, the smaller the ΔCt values, the higher the expression levels of the target mRNA. The Mann–Whitney rank sum test was used to compare the control group and anti-Ro52+ patients.

Results: The ΔCt values for TRIM, IRF3, IRF5, IRF7, NFκB, RIG-1, MDAS were found to be lower in the anti-Ro52+ group as compared to the control group, indicating higher mRNA expression of these genes in anti-Ro52+ patients. Statistical significance was reached for all of the examined genes but IRF3. Detailed results are presented in Table 1.
Table 1. The ΔCt values for antiviral response-related genes in anti-Ro52+ patients and healthy controls. P – statistical significance

Conclusion: Presented results confirm the enhancement of the antiviral defence in anti-Ro52+ patients. As overexpression is observed independently in various connective tissue diseases, impaired response to viral infections via Ro52 pathways could indicate a common trigger factor of autoimmunity.

AB0044 REDUCED PERIPHERAL BLOOD MYELOID CELLS IN PATIENTS WITH VEXAS SYNDROME

V. Jachiet1, 2, L. Ricard3, P. Hirsch4, F. Malard5, L. P. Zhao6, L. Adès7, P. Fenaux8, O. Fairn9, M. Moorthy10, B. Gaugler11, A. Mekinian12, 3. Sorbonne Université, AP-HP, Hôpital Saint Antoine, INSERM UMR938, Paris, France; 2 Sorbonne Université, AP-HP, Hôpital Saint Antoine, Service de Médecine Interne et Inflammation-Immunopathologie-Biothérapie Department (DMU 3), Paris, France; 3 Sorbonne Université, AP-HP, Hôpital Saint Antoine, Service d’Hématologie Clinique et de Thérapie cellulaire, Paris, France; 4 Sorbonne Université, AP-HP, Hôpital Saint Antoine, Service de Médecine Interne et Inflammation-Immunopathologie-Biothérapie Department (DMU 3), Service d’Hématologie Biologique, Paris, France; 5 Université de Paris, AP-HP, Hôpital Saint Louis, Département d’hématologie, Paris, France

Background: Systemic inflammatory or dysimmune diseases (SIDDs) are encountered in up to a quarter of patients with myelodysplastic syndromes (MDS). Recently identified VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome, associated with somatic mutations in UBA1, encompasses a range of severe inflammatory conditions along with hematologic abnormalities, including myelodysplasia. Only limited data are available on the pathophysiology of MDS-associated SIDDs, and especially about the role of different myeloid cell subsets.

Objectives: The aim of this study was to describe the phenotype of myeloid immune cells (dendritic cells and monocytes) in MDS patients with associated SIDDs, and to compare their distribution with MDS patients without SIDDs and controls.

Methods: Phenotype analysis by flow cytometry from PBMCs of 14 MDS patients with SIDDs, 23 MDS patients without SIDDs and 7 controls. Eight of the 14 MDS/SIDDs patients (57%) had a somatic UBA1 mutation.

Results: In this study analyzing peripheral blood myeloid immune cells in MDS patients with and without SIDDs, we observed a quantitative reduction of different DC and monocyte subsets in MDS/SIDDs patients, especially in patients with active SIDDs and above all in patients with newly described VEXAS syndrome.

Conclusion: Further functional studies are warranted to better understand the mechanisms and the consequences of the phenotypic modulations of immune myeloid cells in the pathophysiology of MDS-associated SIDDs, especially in VEXAS syndrome.

AB0045 EFFECTS OF AEROBIC EXERCISE AND PREBIOTIC FIBRE SUPPLEMENTATION ON THE VASTUS LATERALIS AND SOLEUS MUSCLES IN A RAT MODEL OF DIET-INDUCED OBESITY

H. de Brito Fontana1, 3, J. Lourdes Rios2, R. A. Seerattan2, V. Joumaa3, D. A. Hart4, K. Reimer3, W. Herzog5 on behalf of Human Performance Laboratory. 1 Universidade Federal de Santa Catarina, Campus Florianópolis, School of Biological Sciences, Florianópolis, Brazil; 2 University of Calgary, Human Performance Laboratory, Calgary, Canada; 3 University of Calgary, Human Performance Laboratory, Calgary, Canada

Background: A high-fat/high-sucrose (HFS) diet leads to osteoarthritis-like damage in the knee and shoulder (Collins et al., 2018), and to a low-level systemic inflammation that is accompanied by a decrease in insulin sensitivity. Recently, we demonstrated in a rat model, that when prebiotic fibre supplementation, aerobic exercise, or their combination, are started at the onset of the HFS diet exposure, the development of the osteoarthritis-like lesions in the knee joints and the metabolic dysfunction is prevented (Rios et al., 2019).

A central role in the altered metabolic state of rats fed a HFS diet is thought to be played by skeletal muscle (Collins et al., 2018). Besides the detrimental effect on metabolic and inflammatory regulation, muscular dysfunction might be a contributor to the decline in running endurance and coordination observed with prolonged exposure to a low quality diet (Clayton et al., 2022).

Objectives: To evaluate the changes in insulin sensitivity and vastus lateralis and soleus muscle composition in a HFS diet rat model and determine whether the expected muscle alterations can be prevented with a prebiotic fibre supplementation, aerobic exercise, or their combination.

Methods: Twelve-week-old male Sprague Dawley rats fed a high-fat/high-sucrose diet (HFS, Diet #102412, Dyets) were randomized into a sedentary (HFS, n=12), moderate aerobic exercise (HFS+E, n=12), prebiotic fibre supplementation (HFS+F, n=12), or moderate aerobic exercise combined with prebiotic fibre supplementation (HFS+F+E, n=12) group for 12 weeks. Eight chow-fed (Diet #5001) age- and sex-matched animals were used as controls.

Whole body insulin sensitivity (composite insulin sensitivity index – C ISI) was determined at the end of the intervention period and, after sacrifice, the VL and soleus muscle composition was evaluated through a triglyceride colorimetric assay and histological analysis of collagen with picrosirius red staining. Non-parametric Kruskal-Wallis testing with pairwise comparisons was used to compare groups.

Results: HFS group rats had less than half (40%, p = 0.001) of the whole-body insulin sensitivity of control rats while rats in the HFS+F+E and HFS+F groups were similar to control. Rats that were fed the HFS diet showed increased VL (p = 0.033) but not soleus muscle composition was evaluated through a triglyceride colorimetric assay and histological analysis of collagen with picrosirius red staining. Non-parametric Kruskal-Wallis testing with pairwise comparisons was used to compare groups.

Conclusion: While a positive effect of prebiotic fibre and exercise in managing metabolic disturbance was present with a clear recovery of insulin sensitivity to control levels in the groups that were fed the HFS diet, the protective effect of exercise and prebiotic fibre that has been previously described for knee joints in this model was not observed for the VL and soleus muscles. The HFS diet led to alterations in muscle composition that seem to be muscle-specific

Osteo arthritis, aetiology, pathology and animal models
and cannot be prevented by combining prebiotic fibre or exercise with the HFS diet.

AB0046 RESISTANCE TO OXIDATIVE DEGRADATION OF A FORMULATION COMBINING HYALURONIC ACID AND Niacinamide

F. Hadj-ab 1, Albomed GmbH, Research and Development, Schwarzenbruck, Germany

Background: Hyaluronic acid plays a major role in the homeostasis of cartilage. In cases of osteoarthritis, hyaluronic acid is subjected to significant oxidative stress linked to the inflammation cascade leading to drastic diminution of its quantity at the level of the joint. This decrease in hyaluronic acid reduces dramatically the lubricating properties of the synovial fluid. Several preparation methods have been developed to further stabilize the hyaluronic acid used as viscosupplement such as crosslinking or adding adjuvants.

Objectives: A new formulation intended for intra-articular administration has been developed consisting of a combination of hyaluronic acid and vitamin B3 commonly called Niacinamide. The addition of niacinamide has a protective effect against hyaluronic acid under heat stress and under oxidative stress.

Methods: In order to assess the resistance to free radials, 4 products were compared (HA 2.2%+vitamin B3 vs HA at 2.2% vs 2 cross-linked HA). 1 gram of sample were placed on Peltier Plate of a Rheometer – TA instrument and submitted to a temperature of 37°C. 50µL of H2O2 was introduced on the sample. The rheological properties of the mixture were followed-up at a shear stress of 1Hz until full degradation of the sample (i.e. until reaching a viscosity close 0). The degradation was calculated at each time point and plotted on a graph to compare the enzymatic degradation kinetics.

To assess the thermal resistance, 2 products were compared (HA 2.2%+ vitamin B3 vs HA at 2.2%). The samples consisting of 2 grams of gel packaged in glass syringe were placed in a dry oven at 50°C. The viscosity was measured at 3 different timepoints.

Results: This study demonstrates a significant better resistance to free-radical degradation for the HA+Niacinamide vs comparative products. The viscosity follow-up under heat stress demonstrated that the adjuection of Niacinamide does have a positive effect in preserving the HA viscosity consistently throughout time.

Conclusion: Vitamin B3 commonly called Niacinamide exhibits a dual positive effect when associated with Hyaluronic Acid. The study demonstrates a better resistance to oxidative degradation for the HA+Niacinamide most probably due to the antioxidant effect of Niacinamide. This study confirmed the adjuection of the Niacinamide into the HA-based gel formulation does increase the stability of HA against thermal degradation.

AB0047 CARTILAGE DEGRADATION STATUS OF KNEE OSTEARTHRITIC PATIENTS CAN BE PREDICTED BY CHONDROCYTE GENE EXPRESSION ANALYSIS

L. Tíyi 1 , L. Triger 1 , A. Ribes 1 , P. Camps 1 , R. Torres-Claramunt 2, J. O. Monllau 1,2 , J. Monfort 3 on behalf of HOLOA 

1MIM (Hospital del Mar Medical Research Institute), Barcelona, Infarnamation and Cartilage Cellular Research Group, Barcelona, Spain; 2Hospital del Mar, Servei de Cirugia Ortopédica i Traumatologia, Barcelona, Spain; 3Hospital del Mar, Servei de Reumatologia, Barcelona, Spain

Background: Osteoarthritis (OA) is the most common degenerative joint disease, but its pathogenesis is still poorly understood. OA is characterized by articular cartilage loss due to an imbalance in anabolic and catabolic gene expression of the chondrocyte, together with aberrant expression of transcription factors and inflammatory mediators.

Objectives: We aim to evaluate de genes implicated in the chondrocyte failure regarding the four issues assessed to evaluate cartilage integrity using Mankin score (MsK): surface integrity, cellularity, cell cloning and staining.

Methods: Knee OA (KOA) patients aged 60-75 undergoing a total knee replacement, were recruited. At surgery, tibial plateau and femur condyles were deposited in DMEM medium and sent to the laboratory within 4 hours of the extraction. Punches from areas located at low, medium and high load (1) were excised from each sample (approximately 11 areas per patient). For RNA analysis, punches were kept in RNA later at -20°C until analyzed. RNA extraction, cDNA synthesis and cDNA amplification of the selected genes were performed previous to gene expression quantification by OpenArray Assay with custom plates. ΔCt was analyzed by ExpressionSuite V1.3 using 6 housekeeping genes. For histology study, punches were fixed in formalin and embedded in paraffin. Sections of 4 µm were stained with hematoxilin eosin and Safranin O-Fast Green. Slices were scored using the modifed MsK (2) by 3 independent observers. R (v3.3.2) analysis was used to explored the results with principal components analysis (PCA) and linear regression (LRL).

Results: Surgical samples were obtained from a total of 27 patients and 219 different areas were analyzed. ΔCt of the 51 genes analyzed by PCA showed that 9 components were enough to represent >80% of variance of the model. The genes associated with each component are summarized in Table 1. LR shows that second and first component were significantly associated to all or most of the fields included in the MsK, respectively. In contrast, component 4, 5 and 9 were not associated with any field. Lower expression of genes represented in component 1 (mainly related with extracellular matrix content) are associated with higher MsK values. On the other hand, component 2 summarizes data of genes mainly related with factors regulating cell metabolism. In this case, higher expression of TNFαP6, NGF, IGFBP1, CRLF1, TNFα and lower expression of ACAN, COL11A2, COL2A1, COL10A1, SOX9 and TGFβ1, among others, are associated with increased MsK values.

Table 1. Genes that most contribute (by order) to component 1 & 2 (due to space limitation). Data of LR analysis for each component and MsK value. Significant association marked in bold.

Conclusion: There is a correlation between the expression level of the studied genes and the MsK values, although the role played by each gene might be
Background: Osteoarthritis (OA) is one of the most common joint disorders and is characterized by the degeneration and loss of articular cartilage with chronic arthritis of the joint edge and subchondral bone. OA is causally influenced by several factors, including age, gender, familial susceptibility, as well as local biomechanics, cartilage cell apoptosis, and the action of degenerative enzymes. Despite intensive research, there are still few effective therapeutic approaches.

Objectives: In the rat OA model, shikonin was shown to inhibit inflammatory processes, MAPKs, and IL-6/STAT3 downstream regulation in human healthy chondrocytes and primary OA chondrocytes. For the study of inflammatory processes, we performed a proteome profile screening assay. As MAPK signaling pathways play a key role in cartilage destruction in OA, we analyzed the effects of shikonin and its derivatives using protein expression analysis of the phosphorylation pattern and the corresponding downstream gene regulation using RT-qPCR.

Results: Both HC and pCH-OA showed a dose-dependent inhibition of cell viability after treatment with shikonin derivatives, whereby the strongest effects were found for shikonin with IC50 values of 1.2 µM and 1.3 µM, respectively. Shikonin counteracts inflammatory response caused by IL-1β by massively reducing the expression of pro-inflammatory mediators.

Conclusions: Our results demonstrate for the first time that shikonin and its derivatives acetylshikonin and cyclopropylshikonin on inflammation, MMP expression, and regulation of MAPK signaling in human OA chondrocytes.

Methods: Viability was analyzed using the CellTiter 96 AQeous Luminescence Assay on human healthy chondrocytes (HC) and primary OA chondrocytes (pCH-OA). For the study of inflammatory processes, we performed a proteome profile screening assay. As MAPK signaling pathways play a key role in cartilage destruction in OA, we analyzed the effects of shikonin and its derivatives using protein expression analysis of the phosphorylation pattern and the corresponding downstream gene regulation using RT-qPCR.

Results: Both HC and pCH-OA showed a dose-dependent inhibition of cell viability after treatment with shikonin derivatives, whereby the strongest effects were found for shikonin with IC50 values of 1.2 µM and 1.3 µM, respectively. Shikonin counteracts inflammatory response caused by IL-1β by massively reducing the expression of pro-inflammatory mediators.

Conclusions: Our results demonstrate for the first time that shikonin and its derivatives acetylshikonin and cyclopropylshikonin on inflammation, MMP expression, and regulation of MAPK signaling in human OA chondrocytes.
OA patients had higher NAD levels than at baseline, but significantly lower than non-OA>50y controls (Figure 1).

Figure 1. Monocyte NAD⁺ content at baseline and 1 hour after nicotinamide supplementation. *p<0.05 **p<0.01 ***p<0.001.

**Conclusion:** A specific plasmatic and synovial adipokine signature characterizes OA and patients with more severe disease. In monocytes there is a age-related reduction of INAMPT and anti-inflammatory cytokine expression, whereas eNAMPT is higher in elderly compared with younger subjects. In non-OA>50y subjects there might be an increase of INAMPT activity which leads to NAD⁺ production, while in OA patients this mechanism seems to be impaired and can be only partially enhanced by nicotinamide supplementation, leading to reduced intracellular redox efficiency. These results suggest that NAMPT activity might be a key component of the mechanisms underlying inflammation in OA patients.

**CHANGES IN THE MOLECULAR ARCHITECTONICS OF PLASMA MEMBRANES (PM) OF NEUTROPHILIC LEUKOCYTES (NL) FROM SYNOVIAL FLUID (SF) IN GONARTHROSIS (GA)**

V. Shishkin1, Y. Malenkov1, V.V. Shishkin1, G.V. Kudryavtseva1. Saint Petersburg state University, Diagnostic of functional systems, Saint Petersburg, Russian Federation

**Objectives:** Changes in the spectrum of phospholipids (PL) in NL membranes correlate with the activity of their metabolic and phagocytic processes. The aim of the work was to study PL homeostasis of NL from SF in GA.

**Methods:** SF of knee joints of 12 patients with GA with active synovitis and 7 conditional donors postmortem (D) were researched. PL analysis: phosphatidylcholine (PC), sphingomyelin (SM), phosphatidylethanolamin (PEA), phosphatidylinositol (PI), phosphatidylserine (PS), lysophosphatidylcholine (LPC) were performed by conventional lipid-gas and fluid chromatography methods. Active forms of oxygen (AFO2) have been registered by applying EPR. Electrokinetic mobility (EM) of NL determined by the automatic microscope.

**Results:** With GA, against the background of the sharp increase (2.7 times) of free radical processes, there are quantitative changes in the FL plasma membranes NL, expressed in the decreases in the percentages of PS, CM, PEA, PI and the increases in PS and LPS.

* - p<0.05 ** - p<0.01 *** - p<0.001

A decrease in the level of PC and SM in GA indicates an increase in the sensitivity of NL membranes to reactive oxygen species and a decrease in their structural stability, an increase in microviscosity and fluidity. A decrease in the PEA level in GA is also associated with the sharp increase in the active forms of oxygen radicals, which leads to “loosening” of the membranes and the formation of hydrophobic pores. PI is an effector of many membrane enzyme-substrate complexes, and with GA, the percentage of PI is halved. An increase in the level of PS and LPC in GA indicates the presence of structural rearrangements and loosening of the hydrophobic region of the lipid layer of the NL membranes. The PEA / PS ratio in the control group was 2.87, and with GA - 0.89. This indicates a change in the saturation of the lipid bilayer of the NL membrane, an increase in microviscosity and fluidity. Quantitative shifts in the FL composition in NL membranes during GA lead to their pronounced depolarization and the 4.4-fold decrease in EM.

**DOIs:** 10.1136/annrheumdis-2022-eular.3165
Conclusion: FL form the NL apoptotic response, determine their plastic and energy potential. In GA, FL homeostasis of NL is disturbed and membrane-destructive processes development. Modification of the lipid bilayer of plasma membranes NL causes their depolarization, a decrease in plasma membrane viscosity, electrical conductivity and EM. The noted changes in the molecular-architectonics of NL membranes in GA inhibit their membrane-protective properties, antioxidant potential, and stimulate the apoptotic response.

LNCRNA NUTM2A-AS1 ALLEVIATED OSTEOPOROSIS BY REGULATING MIR-183-5P/TGFA PATHWAY

N. Geng1, D. Yun1, D. Liu1, P. Liu1. 1The First Affiliated Hospital of Xi’an Medical College, Department of Rheumatology and Immunology, Xi’an, China

Background: Osteoporosis(OA) is a common comorbidity in the elderly, characterized by articular cartilage degeneration, hyperostosis and synovitis. Long non-coding RNAs (LncRNAs) have been shown to be involved in several human diseases, including OA. However, the effect of NUTM2A-AS1 on chondrocytes remains unknown.

Objectives: The purpose of this study was to evaluate the role of LncRNA NUTM2A-AS1 in OA pathological changes in vitro.

Methods: Chondrocyte cells were treated for 24 hours to mimic OA pathological conditions. The experimental center used chondrocytes with interleukin-1 beta (IL-1β) intervention to simulate the pathological state of OA. The expression levels of LncRNA NUTM2A-AS1, miR-183-5p and TGFA mRNA were detected by quantitative real-time PCR (qRT-PCR), along with CCK-8 to determine cell viability. Inflammatory response was assessed by determining the release of pro-inflammatory factors such as TNF-α and IL-6 using ELISA kits. Cell apoptosis was examined by flow cytometry assay. The binding relationship between miR-183-5p and LncRNA NUTM2A-AS1 or TGFA was confirmed by dual-luciferase reporter assay.

Results: IL-1β-induced chondrocytes to express LncRNA NUTM2A-AS1 and TGFA, and the miR-183-5p expression was decreased in IL-1β-treated cells. Low expression of LncRNA NUTM2A-AS1 or TGFA mitigated IL-1β-induced chondrocyte viability reduction and apoptosis promotion. miR-183-5p overexpression alleviated IL-1β-mediated chondrocyte apoptosis and inflammatory injury via decreasing TGFA expression. In addition, our work revealed that miR-183-5p is a target of LncRNA NUTM2A-AS1. Rescue experiments showed that TGFA overexpression could reverse the effects of low expression of LncRNA NUTM2A-AS1 on the pathological changes in IL-1β-induced chondrocytes.

Conclusion: Low expression of LncRNA NUTM2A-AS1 significantly mitigated the chondrocytes damage induced by IL-1β through regulating miR-183-5p/TGFA axis, which might be an important target to regulate the promotion of OA.

NEW THERAPEUTICAL TOOLS FOR HETEROTOPIC OSSIFICATION TREATMENT AND PREVENTION

A. Alonso-Pérez1, M. Guillán-Fresco1, E. Franco-Trepát1, A. Lois-Iglesias1, A. Jorge-Mora1, R. Gómez1. 1Health Research Institute of Santiago de Compostela (IDIS), Musculoskeletal Pathology Group, Santiago de Compostela, Spain

Background: Heterotopic ossification (HO) consists in abnormal bone growth in soft tissues, in a non-porroosteoblastic environment. This pathology origin can be congenital (progressive osseus heteroplasia, progressive osseous heteroplasia), or acquired (burns, big traumas, electrocutions, articular replacement surgeries, ...). Currently, the available therapies (radiotherapy and removal surgery) are aggressive, associated to multiple adverse effects, and not suitable for every populations. Therefore, new therapeutic tools are needed to HO.

Objectives: The aim of this work is to study osteoblastogenesis inhibition through adipogenesis promotion using a new therapy (Tri-therapy) composed by a PPARγ agonist, a NSAID, and a corticoid.

Methods: Mice mesenchymal stem cells (C3H10T1/2) were differentiated towards adipogenesis and osteoblastogenesis for 7 days, in the presence of the Tri-therapy compounds alone and combined. Simultaneously, human preosteoblast cells (SaOs2) were differentiated to osteoblast for 14 days, being treated with the Tri-therapy. Human HO cells (acquired HO and congenital HO independently), obtained from HO explants, were exposed to an adipogenic environment in the presence of the Tri-therapy for 7 days.

Osteoblastogenesis (ALPL, SPP1, GPMB2, RUNX2) and adipogenic (FABP4, PLIN2, ADIPOQ, PPARγ) marker genes mRNA expression measured by RT-PCR was used to evaluate differentiation processes. All the results were expressed as the media SEM of, at least, 3 independent replicates.

Results: In C3H10T1/2 differentiations Tri-therapy synergically induced FABP4, PLIN2, ADIPOQ expression in both cell fates, demonstrating therefore its ability to promote adipogenesis. In SaOs2, the proposed therapy diminished osteoblastogenesis marker genes expression (SPP1, GPMB2, RUNX2), being this effect greater than PPARγ agonists’ themselves. In HO cells, Tri-therapy augmented adipogenesis markers expression, showing a partial effect in osteoblastogenic marker genes expression.

Conclusion: Pro-adipogenic switch in differentiation marker genes expression induced by the Tri-therapy suggested the clinical use of this drugs combination to treat and prevent HO and abnormal bone growth.

BONE AND MINERAL DISORDERS IN RENAL HEMODIALYSIS PATIENTS

R. Ben Tekay1, H. Hachi1, M. Brahem1, O. Joma’a1, Z. Atifi1, Y. Mohamed1. 1University Hospital Tahar Sfar, Rheumatology Department, Mahdia, Tunisia; 2University Hospital Tahar Sfar, nephrology department, Mahdia, Tunisia

Objectives: To analyze the prevalence of osteoporosis in group of patients with chronic renal failure and to evaluate the relation between bone mineral density (BMD) and specific markers of bone turnover in hemodialysis (HD) population.

Methods: This is a cross sectional study conducted in hematology department of Taher University hospital in mahdia, Tunisia. The study involved 61 patients with chronic hemodialysis. They were invited to participate and were included after signing informed consent until the calculated sample size was reached. Patients were asked to undergo a hip and lumbar (L2-L4) densitometry by DEXA to measure bone mineral density (BMD). Serum levels of iPTH and alkaline phosphatase (ALP) were measured before the dialysis session.

Results: The studied group of 61 patients was 26 females (42.6%) and 35 males (57.4%), their mean age was 53.9 [17-83] years, with mean dialysis duration 6.1 years. The mean onset age of hemodialysis therapy was 44.7 +/- 15.4 years. It was diabetic nephropathy in 25 cases (41%) vascular nephropathy in 15 cases and tubulointerstitial nephropathy in 21 cases (34.4%). 23 patients (37.7%) had osteoporosis according to the WHO criteria (T-score < -2.5), 26 patients (42.6%) had osteopenia and 12 patients had normal BMD. The mean serum level of iPTH with normal BMD and lower BMD 167.84 vs 535.71 respectively, the mean serum level of ALP with normal BMD and lower BMD 144.59 vs 271.99 respectively (p<0.001). The mean duration of dialysis therapy with normal BMD and lower BMD 4.57 years vs 6.55 years (p<0.001).

Conclusion: Our study showed that osteoporosis is common in dialysis patients. The main determinants of BMD is PTH activity and the duration of dialysis therapy. The importance of prevention and treatment of metabolic bone disease has become better appreciated.

Rheumatoid arthritis - aetiology, pathogenesis and animal models

**AB0056**

**COMPARATIVE ANALYSIS OF THE DISTRIBUTION OF LYMPHOCYTES, MACROPHAGES AND MAST CELLS IN THE MARGINAL SYNOVIVUM AND JOINT CAPSULE IN GENERAL AFTER ANTENATAL ANTIGENIC STIMULATION**

A. Fedotchenko,[1],[2] Zaporizhzhia, Ukraine; [2]Ziegewaldkliniken Bethanien Chemnitz, Rheumatology, Chemnitz, Germany

**Background:** The joint capsule is one of the main pathogenic sites of arthritis development [1]. In addition, the initial signs of the inflammatory joint diseases are usually detected in the marginal synovial tissue zone [2]. The joint capsule morphology was studied using hip joints of Wistar rats during the postnatal period in norm and after antigenic stimulation. The last one was modeled through the transuterine intrafetal intercapsular subcutaneous injection of antigen (0.05 ml of human normal immunoglobulin) for the rat fetuses on the 18th day of its antenatal life under general anesthesia and sterile conditions via laparotomy for the pregnant female (Vosolshyn’s method [1981]). The control group of rats was injected with 0.05 ml of physiological saline in the same manner. The earlier recovery of certain parameters (total cells quantity, vessels, collagen fibers and ground substance) to normality in the marginal synovium compared to the rest (larger) part of the joint capsule in antigen-suppressed rats was previously revealed.

**Objectives:** A comparative analysis of the distribution of lymphocytes, macrophages and mast cells in the marginal synovium in relation to the rest (larger) part of the joint capsule after antenatal antigenic stimulation was conducted.

**Methods:** Collection of the biomaterial was carried out on the first, seventh, 14th, 30th, 45th, 60th and 90th day of postnatal life under general anesthesia (intact, antigen-suppressed and control rats; six rats in each group, 126 rats in total). The joints were fixed, decalcified and dehydrated. Paraffin-embedded tissue sections were stained with hematoxylin and eosin. Cells of the synovial subintima of the marginal synovium and rest (larger) part of the joint capsule were counted using the light microscopy (x100) and morphometric lattice. The obtained data were processed using the statistical methods. The parameters of intact and control rats did not differ significantly from each other.

**Results:** In the joint capsule of antigen-suppressed rats compared to intact and control rats, an increased number of lymphocytes till the 90th day (in the marginal synovium – till the 45th day), macrophages till the seventh day (in the marginal synovium – also till the seventh day) and mast cells till the 90th day (in the marginal synovium – till the 45th day) was found. The integrity of the synovium-cartilage barrier is under the antigenic stimulation, contribute to earlier recovery of parameters in the synovium – till the 14th day was found. The integrity of the synovium-cartilage barrier is of fundamental importance, failing which it would lead to excessive synovial tissue penetration into the articular cartilage, recognition of it by immunocompetent cells and initiation of immune-mediated cartilage destruction. The previous premature appearance (on the seventh day) of strong expression of receptors for peanut agglu- tinin (PNA) in the marginal cartilage of antigen-suppressed rats I detected could lead to the assumption about the premature appearance of “chondroprotective substances” such as fibroenectin, laminin etc. and their intensive glycosylation. This fact might be considered a compensatory mechanism to create the defensive wall for adhesion and deactivation of the immunocompetent cells, therefore reducing their influence on cells and tissues getting to accelerated cartilage degradation.

**Conclusion:** The compensatory defence mechanisms, occurring in the marginal cartilage after the antigenic stimulation, contribute to earlier recovery of parameters in the marginal synovium compared to the joint capsule in general. In so doing, the marginal transitional zone forms the important innate, nonspecific, immunobiological, anatomical and physiological barrier between the joint capsule and articular cartilage.

[4] De Rycke L, Peene I, Hoffman IE, Kruithof E, Union A, Meheus L, et al. Rheumatoid arthropathies, ACPA- and anti-CCP-positive RA patients. Expression of VGLL3 in the synovial tissues and FLS was analyzed by immunohistochemistry and PCR. RNA sequencing was performed in RA-FLS upon VGLL3 overexpres-

**Conclusion:** VGLL3 was upregulated in the RA synovium and RA-FLS compared to OA. Overexpression of VGLL3 promoted the expression of ISGs in RA-FLS. The expression of STAT1 and MX1 was associated with the expression of VGLL3 in RA and OA patients. VGLL3 promoted the IRF3 activation, IFN-β expression, and IFN-β1 autocrine signaling in RA-FLS. VGLL3 also modulated the expression of the Hippo pathway molecules WWP1 and AMOTL2, which mediated the regulation of IRF3 activation and IFN-β1 production by VGLL3 in RA-FLS. The expression of VGLL3 in the synovium of patients with RA was positively associated with the expression of STAT1 and MX1.

Background: Autoimmune diseases represent a large and heterogeneous group of disorders that afflict specific target organs. However, multiple factors point to common links between the differing presentations of autoimmune disorders. With increased interest in further understanding the neuro-immune axis, autoimmune diseases represent an important opportunity to explore whether systemic inflammation from these autoimmune pathways has a central effect and, if so, whether there is a common or discrete central effect caused by different autoimmune diseases.

Objectives: The present study aimed to analyse hippocampal volume in patients with rheumatoid arthritis (RA) and ulcerative colitis (UC) as compared to healthy control groups. The hippocampus was chosen as a region of interest given the regulatory role it exhibits in the hypothalamic–pituitary–adrenal (HPA) axis.

Methods: Data from 1,040 individuals in the UKBiobank imaging sub-study were included in the present study. This was divided into two separate patient populations with separate control groups. Data from 267 individuals (mean age ± SD = 65.52 ± 70.2, 70.8% females) were included in the RA patient group with 267 age and sex matched controls (mean age ± SD = 65.51 ± 7.08%, females). Data from 253 individuals (mean age ± SD = 64.09 ± 703, 51.6% females) were included in the UC patient group with 253 age and sex matched controls (mean age ± SD = 63.4 ± 702, 51.6% females). The UKBiobank is a prospective observational study with a proposed cohort of 500,000 participants. The imaging substudy is planned to scan 100,000 of those participants with a standardised scanning protocol including MRI of the brain. Multi-modal images were acquired on a 3T scanner. From the T1w data, volumetric imaging derived phenotypes (IPDs) are provided using the FMRIB Integrated Registration and Segmentation Tool (FIRST); http://fsl.fmrib.ox.ac.uk/fsl/fslwiki/FIRST. This study utilised the right and left hippocampal volume outputs from that tool.

Results: We observed a smaller hippocampal volume in UC patients when compared to healthy controls (difference right: 99.78 mm³, SD ± 38.97, p = 0.01; left: 74.30 mm³, SD ± 39.41, p = 0.06). The Cohen's effect size was d = -0.24 [95% CI -0.43, -0.05] for right hippocampal volume and d = -0.12 [95% CI -0.27, 0.06] for left hippocampal volume.

Conclusion: This study provides evidence of moderate reduction in hippocampal volume in UC patients as compared to age and sex matched healthy controls. This same effect was not seen in a similarly matched rheumatoid arthritis patient population. Further analysis of additional subcortical regions could provide further context for whether there are alternative regions affected in both RA and UC.

**PHARMACOKINETICS OF METHOTREXATE POLYGALMATAMUTES IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF RA PATIENTS IS SIMILAR AFTER ORAL OR SUBCUTANEOUS ORAL ADMINISTRATION**

R. Hebing1, M. Lin2, E. Struys3, S. Mahmoud1, I. Muller2, W. Lems1, B. van den Bermt4, G. Jansen2, R. De Jonge2, M. Nurmohamed2,3, Reade, Rheumatology, Amsterdam, Netherlands; 2Amsterdam UMC, locatie VUMC, Clinical Chemistry, Amsterdam, Netherlands; 3Amsterdam UMC, locatie VUMC, Rheumatology, Amsterdam, Netherlands; 4Sint Maartenskliniek, Rheumatology, Utrecht, Netherlands; 5Radboud University Medical Center, Pharmacy, Nijmegen, Netherlands

**Background:** Pharmacokinetics of methotrexate (MTX) after oral and subcutaneous administration to RA patients differs: MTX levels in plasma and MTX-polylgumatamutes (MTX-PG) accumulation in erythrocytes are higher during equidosed subcutaneous compared to oral MTX treatment. (1,2) No data are available whether administration route of MTX differentially impacts the intracellular concentrations of MTX-PGs in peripheral blood mononuclear cells (PBMCs) during MTX therapy.

**Objectives:** To investigate the pharmacokinetics of MTX-PGs in PBMCs of newly diagnosed RA patients receiving oral or subcutaneous MTX in the early phase (1, 2, 3, and 6 months) of MTX treatment.

**Methods:** In a clinical prospective cohort study (MeMo study (NTR7149)), RA patients were administered oral (n=24) or subcutaneous (n=22) MTX up to 25 mg MTX/week, as described before. (1) At 1, 2, 3, and 6 months after the start of therapy, PBMCs were isolated via Ficoll density gradient centrifugation. Individual MTX-PG forms as described before. (1) At 1, 2, 3 and 6 months after the start of therapy, PBMCs were isolated via Ficoll density gradient centrifugation. Individual MTX-PG forms (MTX-PG1-6) were isolated via Ficoll density gradient centrifugation. Individual MTX-PG forms as described before. (1)

**Results:** Anti-TNF therapy increased ACE levels in the full cohort, as well as in the RA and AS subsets. ACE2 activity increased in the full cohort, whereas RBC MTX-PG accumulation increased between 1 to 3 months to reach a plateau (Figure 1).

**Conclusion:** This study demonstrated that MTX-PG accumulation in PBMCs early on in the MTX treatment of RA patients was not significantly different between oral or subcutaneous MTX administration routes.

**ANGIOTENSIN CONVERTING ENZYME ACTIVITY IN ANTI-TNF-TREATED RHEUMATOID ARTHRITIS AND ANKYLOPSY Spondylitis PATIENTS**

B. Soós1, M. Fagyás3, A. Horváth1, E. Végh1, A. Puszta1, M. Czokolová3, A. Csongrádi1, A. Hamar4, Z. Pető4, N. Bodnár2,4, G. Kerekes2, K. Hodosi1, E. Szekeanecz1, S. Szamosi1, S. Szántoi1, G. Szűcs1, Z. Papp1, Z. Szekanecz1, University of Debrecen, Rheumatology, Debrecen, Hungary; 2University of Debrecen, Cardiology, Debrecen, Hungary; 3University of Debrecen, Internal Medicine, Debrecen, Hungary; 4University of Debrecen, Oncology, Debrecen, Hungary; 5University of Debrecen, Rheumatology, Debrecen, Hungary

**Background:** Angiotensin-converting enzyme (ACE) and ACE2 have been implicated in the regulation of vascular physiology. Elevated sYnval and decreased or normal ACE or ACE2 levels have been found in rheumatoid arthritis (RA). Very little is known about the effects of tumour necrosis factor α (TNF-α) inhibition on ACE or ACE2 homeostasis.

**Objectives:** In this study, we assessed the effects of one-year anti-TNF therapy on ACE and ACE2 production in RA and ankylosing spondylitis (AS) in association with other biomarkers.

**Methods:** Forty patients including 24 RA patients treated with either etanercept (ETN) or certolizumab pegol (CZP) and 16 AS patients treated with ETN were included in a 12-month follow-up study. Serum ACE levels were determined by commercial ELISA, while serum ACE2 activity was assessed using a specific quenched fluorescent substrate. Ultrasonography was performed to determine flow-mediated vasodilation (FMD), common carotid intima-media thickness (cIMT), and arterial pulse-wave velocity (PWV) in all patients. In addition, CRP, rheumatoid factor (RF) and ACPA were also measured. All assessments were performed at baseline and 6 and 12 months after treatment initiation.

**Results:** Anti-TNF therapy increased ACE levels in the full cohort, as well as in the RA and AS subsets. ACE2 activity increased in the full cohort, whereas RBC MTX-PG accumulation increased between 1 to 3 months to reach a plateau (Figure 1).

**Conclusion:** Anti-TNF treatment may increase ACE and ACE2 in the sera of RA and AS patients. ACE and ACE2 may be associated with disease duration, markers of inflammation and vascular pathophysiology. The effects of TNF inhibition on ACE and ACE2 may reflect, in part, these effects of the biologics on the cardiovascular system.

AMPA CANNOT BE DETECTED IN FAECES OF SEROPOSITIVE RA PATIENTS: NO EVIDENCE FOR LOCAL AMPA PRODUCTION IN THE LOWER GASTRO-INTESTINAL TRACT

V. Derksen1, T. Huizinga1, R. Toes1, D. van der Woude1. 1Leiden University Medical Center, Rheumatology, Leiden, Netherlands

Background: Rheumatoid arthritis (RA) patients harbor antibodies against several post-translational modifications (AMPAs), for example anti-citrullinated protein antibodies (ACPA) and anti-acetylated protein antibodies (AAPA). The exact mechanism underlying the development of these autoantibodies is currently unclear, but the mucosal immune system has been hypothesized to play a role. ACPA IgA have been detected in sputum and saliva of seropositive RA patients (1-2), suggesting local production of autoantibodies in the gut and oral mucosa. This raises the question whether ACPA can also be produced at other mucosal sites. The intestines are an interesting candidate, as microbiome dysbiosis has been described in RA patients and intestinal content may represent a source of post-translationally modified antigens. However, it is currently unknown whether AMPAs are also produced locally in the intestine.

Objectives: To determine whether AMPA are produced locally in the intestine, we set out to detect ACPA and AAPA in faeces samples of seropositive RA patients. These findings were compared to the ACPA/AAPA levels found in paired serum and saliva samples of the same patients.

Methods: Paired faeces, saliva and serum samples of 16 established seropositive RA patients and 16 healthy volunteers were collected. All patients fulfilled the ACR/EULAR 2010 criteria. Saliva was collected using the passive drooling method. Faeces were self-collected by participants at home and immediately frozen. Faeces samples were homogenized in PBS containing protease inhibitors and supernatants were used in ELISA. Saliva was diluted 1:4. Total IgA and anti-E. Coli IgA were measured using commercial and in-house ELISA, respectively. ACPA/AAPA IgA (serum, saliva) and ACPA/AAPA Ig (faeces) were detected using in-house ELISAs, coated with citrullinated and acetylated CCP2 or the unmodified arginine and lysine variants as control. Saliva samples were considered AMPA positive when the value was above the cut-off (mean + 2 standard deviation of healthy donors) and the delta OD between the modified and unmodified peptide was larger than 0.1.

Results: 9/16 ACPA IgG-positive RA patients were also ACPA IgA positive in serum. In the faecal supernatants total IgA was clearly detectable by ELISA: the supernatants contained on average 85 μg/ml total IgA, only slightly less compared to the mean 117 μg/ml total IgA found in the pre-diluted saliva. However, in none of the faecal supernatants ACPA Ig could be detected. Differences in optical density (OD) between the CCP2 and unmodified arginine peptide were close to 0 (Figure 1A). On the contrary, 8 RA patients were positive for ACPA IgA in saliva (Figure 1B). Similar results were found for AAPA (Figure 1C-D). To control whether the lack of an AMPA signal is explained by technical difficulties associated with measuring IgA in an antigen-specific manner in faeces, we determined anti-E. Coli IgA in the same faeces samples. Anti-E. Coli IgA was clearly detectable in 11/32 faeces samples, indicating intact antigen-specific IgA was present in the faecal samples (Figure 1E).

Figure 1.

Conclusion: No ACPA or AAPA Ig antibodies could be detected in faeces of RA patients, even though these patients were positive for ACPA/AAPA IgA in both serum and saliva. The fact that it was possible to detect other antibodies in faeces, indicates that the absence of an AMPA signal is not due to inherent methodological issues. These findings indicate that the lower gastrointestinal tract does not contain measurable levels of AMPA IgA and suggest that it is not a main site of AMPA production in RA patients.

AB0064

PHARMACOLOGICAL INHIBITION OF IL-6/JAK/STAT AXIS INCREASES MUSCLE MASS IN AN EXPERIMENTAL MODEL OF SARCOPENIA ASSOCIATED TO RHEUMATOID ARTHRITIS

I. Bermejo1, S. Pérez-Baos1, J. P. Medina1, P. Gratia1, I. Prieto-Potín1, R. Largo1, G. Herrera-Beaumont2 *on behalf of Bone and Joint Research Unit. 1Instituto de Investigacion Sanitaria EID, Rheumatology, Madrid, Spain; 2Fundación Jiménez Díaz, Rheumatology, Madrid, Spain

Background: Sarcopenia is a frequent comorbidity of rheumatoid arthritis (RA) due to an imbalance in muscle remodelling with dominance of catabolism over anabolism. IL-6/JAK/STAT axis is of particular importance in this regulation because of its dual activity. According to local and acute factors, it promotes muscle healing and hypertrophy, whereas in chronic inflammation, this signalling substantially increases muscle catabolism activating pro-atrophic pathways involving atrogin expression and ubiquitin proteasome system (UPS). JAK/STAT blockade suppresses muscle wasting induced by IL-6 through STAT3 activation. Interestingly, different clinical trials have shown that JAK inhibitors produce an asymptomatic increase in serum creatine kinase (CK) and creatinine levels in RA patients, suggesting an impact on muscle.

Objectives: To evaluate the effect of JAK inhibition and its effect in muscle remodelling in an experimental model that accurately mimics human rheumatoid sarcopenia.

Methods: An experimental model of antigen-induced arthritis (AIA) was carried out in 14 rabbits by immunization against ovalbumin followed by 4 intra-articular injections of this protein. One week after the first i.a injection, 7 of these rabbits received tofacitinib (TOFA, orally 10mg/kg/day) for 2 wk. Animals were euthanized one day after the last i.a injection, when tibialis anterior (TA), extensor digitorum longus (EDL) and gastrocnemius (GN) were isolated from both hind limbs. Histological changes and ATPase staining were analysed in TA, while the number of myonuclei was determined in EDL fibres by quantifying immunofluorescence signals. C-reactive protein (CRP) and myostatin (MSTN) serum concentration were determined by ELISA. The gene expression of proinflammatory cytokines (IL-6, IL-1, TNF-α, MCP-1), atrogenes (Atrogin-1, MuRF-1) and MSTN was measured by quantitative PCR, while proliferative muscle maker (PAX-7), differentiation muscle markers (MyoD, Myogenin), pSTAT3, pSTAT1, MSTN and CK protein expression was analysed by western blot in GN. Creatine presence in CK was analysed by colorimetric assay.

Results: A significant increase in body weight was observed in the AIA+TOFA group vs. AIA at the end of the study. A significant increase in TA cross-sectional area and diameter in the AIA+TOFA, in comparison to AIA, was found, while the decrease in the area of type II fibres observed in the AIA animals was not noticed in AIA+TOFA. Moreover, the number of myonuclei in the EDL that was increased in AIA group when compared to healthy animals, was significantly decreased in AIA+TOFA. However, systemic inflammation measured by CRP was not modified by TOFA treatment at the end of the study, in comparison to AIA, and so did serum MSTN concentration. TOFA evoked a significant reduction in the gene expression of IL-6, MCP-1, atrogin-1 and MuRF-1 in GN in comparison to untreated AIA rabbits. Notably, AIA+TOFA showed higher protein levels of CK and lower creatine compared to AIA in muscle. Simultaneously, no differences in the proliferative marker PAX-7 were found between groups, while AIA rabbits showed an increase in the differentiation markers MyoD and Myogenin in the muscle that was prevented in AIA+TOFA.

Conclusion: These data provide novel insights into the effects of JAK inhibitors in muscle remodelling during rheumatoid cachexia. Despite an elevated systemic inflammatory status, JAK inhibition was able to rapidly increase muscle mass through attenuating IL-6/JAK/STAT activation, decreasing atrogin expression and restoring to baseline the muscle cell differentiation markers in the tissue. The increase in muscle mass was accompanied by an increase in CK presence, supporting the role of CK as a valuable marker of muscle gain following treatment with JAK inhibitors. However, the low levels of MCP-1 and the disorganization of muscle fibres raise the question of whether these treatments are able to trigger a complete regeneration of muscle fibre cell or just hypertrophy of cells already present.

Disclosure of Interests: Ismael Bermejo: None declared, Sandra Pérez-Baos: None declared, Juan Pablo Medina: None declared, Paula Gratia: None declared, Ivan Prieto-Potín: None declared, Raquel Largo: None declared, Gabriel Herre-no-Beaumont Grant/research support from: The Bone and Joint Research Unit has received funding from several pharmaceutical laboratories (Pfizer, Lilly...).
Background: Rheumatoid arthritis (RA) is primarily associated with pain levels and limited function. Depression disturbances and anxiety levels are not usually considered. The focus is on the physical aspects of the disease. At the same time, patients with high disease activity often experience a decrease in body weight and lack of appetite, which is referred to as rheumatoid cachexia. Nesfatin-1 (NF-1), discovered as an anorexigenic protein. The participation of NF-1 in the regulation of eating behavior and reactions to emotional stress together with oxytocin, melatonin, serotonin, and histamine receptors has been proven. Elevated levels of NF-1 are detected in more severe forms of inflammation, and NF-1 protein expression is positively correlated with the duration of the disease. The focus is on the physical aspects of the disease. At the same time, patients with high disease activity often experience a decrease in body weight and lack of appetite, which is referred to as rheumatoid cachexia. Nesfatin-1 (NF-1), discovered as an anorexigenic protein. The participation of NF-1 in the regulation of eating behavior and reactions to emotional stress together with oxytocin, melatonin, serotonin, and histamine receptors has been proven. Elevated levels of NF-1 are detected in more severe forms of inflammation, and NF-1 protein expression is positively correlated with the duration of the disease.

Results: Mood disorders of varying severity were detected in 48% of patients with RA. The highest levels of NF-1 were found in patients with high RA activity according to DAS-28 and disease duration of more than 10 years. The level of anxiety was more correlated with the severity of the disease activity ($r = 0.351; p<0.01$), and the level of depression was more correlated with the duration of the disease ($r = 0.273; p<0.01$). Western blotting showed that QXT could reduce the pro-inflammatory activity of QXT-50 and QXT-100 groups showed statistically significant ($p<0.001$).

Conclusion: Qinxitong can inhibit the proliferation, promote apoptosis, inhibit migration and invasion of rheumatoid arthritis synovial fibroblasts by regulating Erk signaling pathway, providing scientific basis for clinical application of Qinxitong.

Disclosure of Interests: None declared.

is up-regulated in rheumatoid arthritis (RA) and associates with disease activity, autoantibodies and NEToSis.

**Objectives:** As autoantibodies and neutrophil activation are factors thought to drive the pathological processes at early phase of RA development, we aimed to investigate IL-40 in relation to neutrophils and early stages of RA (ERA).

**Methods:** The levels of serum IL-40 were determined in a cohort of treatment naïve patients with ERA at baseline (n=60) and three months after initiation of conventional treatment (n=80). Serum IL-40 was also determined in sex- and age- matched healthy controls (n=60). Levels of IL-40, cytokines and NEToSis markers (proteasine 3, PR3 and neutrophil elastase, NE) were measured by commercially available ELISA kits. The levels of autoantibodies were analysed by routine laboratory techniques. In vitro experiments were performed on peripheral blood neutrophils from patients with ERA (n=15).

**Results:** Levels of IL-40 were elevated in ERA patients at baseline compared to healthy controls (p<0.0001) and normalised after three months of the treatment (p<0.0001). Baseline serum IL-40 was associated with the levels of autoantibodies RF (gM) (p<0.01) and anti-CCP (p<0.01) and markers of NEToSis PR3 and NE (both p<0.0001). Moreover, significant decreases in the serum IL-40 following the therapy correlated with the decrease of NEToSis markers PR3 (p<0.01) and NE (p<0.05). In vitro, neutrophils from patients with ERA significantly enhanced the release of IL-40 with early RA (n=7) from Hospital Universitario Marqués de Valdecilla (Santander, Spain) were included in this study. The relative mRNA expression of IL-40 in relation to neutrophils and early stages of RA (ERA).

**Conclusion:** We demonstrated for the first time that IL-40 is upregulated in ERA and decreases after three months of conventional therapy. Moreover, we showed that neutrophils are an important source of IL-40 in RA and its release is potentiated by pro-inflammatory cytokines such as IL-1 β, IL-8 (p<0.05), TNF (p<0.01) or to LPS (p<0.05). Lastly, recombinant IL-40 induced the secretion of IL-1 (p<0.05) and TNF (p<0.05) by ERA neutrophils.

**Disclosure of Interests:** None declared.
Conclusion: Jak/STAT3 activity of PBMC from RA patients with active disease may be differently modulated by specific inhibitors. Selectivity of Jak-inhibitors seems more relevant in lymphocytes after IL-6 stimulation. These preliminary findings may explain discrepancies in effectiveness of selective Jak-inhibitors and pave the way for different choices in clinical practice.

ANTI-ACETYLATED PROTEIN IG-M ANTIBODIES AS THE STARTING POINT OF AUTOANTIBODY FORMATION IN RHEUMATOID ARTHRITIS?

1. Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Nagasaki University Graduate School of Biomedical Sciences, Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; 3Nagasaki University Graduate School of Biomedical Sciences, Department of General Medicine, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; 4Nagasaki University Graduate School of Biomedical Sciences, Community Medicine, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan

Background: Anti-modified protein antibodies (AMPA) are an important hallmark of rheumatoid arthritis (RA) and the fact that they have consistently been found to develop years before disease onset, has provided important insights into the immunopathology underlying RA. In (auto)antibody development, IgM is the first isotype to be produced. However, it is unclear whether IgM-autoimmunity differs between AMPA targeting different post-translational modifications (citrulline, homocitrulline and acetylated residues), which could provide clues about the starting point of the AMPA response.

Objectives: We therefore investigated IgM-levels of anti-citrullinated protein antibodies (ACPA), anti-carbamylated protein antibodies (anti-CarP) and anti-acetylated protein antibodies (AAPA) in healthy individuals, non-RA and RA patients.

Methods: Autoantibodies were investigated in 2 cohorts:
1) a Japanese cohort of healthy individuals (community based Nagasaki Island study) known to be ACPA-positive (n=65) or ACPA-negative (n=197) were compared to Dutch healthy donors (n=30) and ACPA-positive RA patients (n=29).
2) early arthritis patients from the Leiden Early Arthritis Clinic who had RA (n=648) or another form of arthritis (non-RA, n=555) and healthy controls (n=80). ACPA and AAPA were determined by ELISAs using CCP4, ChcitrP4 and CAcetylP4 peptides with sequences similar to the commercial CCP2 antigen and homocitrulline and acetylated control peptides.

Results: Comparison of IgM-reactivity levels between healthy individuals and ACPA-positive RA patients (Figure 1A) and to a lesser extent in ACPA-positive healthy Japanese individuals, and non-RA arthritis patients (Figure 1D). A similar picture was observed for anti-CarP IgM reactivity, for which again highest levels were found in established RA patients (1B and 1E) and AAPA-positive compared to ACPA-negative healthy Japanese individuals (1B). Intriguingly, AAPA IgM reactivity-levels displayed a different pattern as these were comparable between healthy individuals and ACPA-positive RA patients (1C and 1F). Likewise, AAPA IgM reactivity-levels were also not increased in ACPA-positive healthy Japanese individuals, who instead had lower levels compared to their ACPA-negative counterparts. Furthermore, the AAPA IgM-reactivity levels did not differ between non-RA arthritis patients, healthy controls and RA patients (1F). AAPA IgM-levels on the other hand were clearly elevated in RA patients compared to healthy controls and non-RA arthritis patients (1G).

Conclusion: AAPA are exceptional compared to other AMPA because IgM AAPA-levels are similar among healthy individuals, non-RA arthritis and RA patients. This suggests that AAPA IgM is part of the “normal” immune repertoire and could constitute the starting point for RA-associated AMPA responses, with isotype switching and epitope spreading to other post-translational modifications leading to the typical RA-associated mature AMPA response.

GLUCOCORTICOID MODIFY NOT ONLY THE PROPERTIES OF DENDRITIC CELLS, BUT ALSO PROGENITOR CELLS

V. Kurochkina1, A. Sizikov2, E. Chernykh1, T. Tyrnova2.
1. Research Institute of Clinical and Experimental Rheumatology – branch of the Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Science, Rheumatology, Novosibirsk, Russian Federation; 2. Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Rheumatology, Novosibirsk, Russian Federation; 3. Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Laboratory of cells immunotherapy, Novosibirsk, Russian Federation

Background: Dendritic cells (DCs) are universal antigen-presenting cells that can have both tolerant and immunosuppressive properties. Tolerogenic properties of DCs are mediated by activation T-regulatory cells, production of anti-inflammatory cytokines and activation T cell apoptosis. Currently, DC is an attractive object of study as a new treatment for rheumatoid arthritis. It is known that glucocorticoids make it possible to control properties of DCs to the tolerogenic side.

Objectives: The aim of the study is to investigate the effect of pulse therapy by glucocorticoids on the properties of DCs and peripheral blood monocytes from which DCs were generated.

Methods: Twenty five patients with rheumatoid arthritis were recruited in this study. All patients follow ACR/EULAR criteria (2010). All studies were performed after receiving informed consent. All patients received conventional synthetic DMARDs. DCs were generated from blood monocytes culturing for 5 days with GM-CSF and IFN-α, LPS as maturation stimuli was added on fourth day. The properties of DCs were studied before pulse therapy (methylprednisolone 500mg Ne3) and 4 days after pulse therapy. The relative number of monocytes (classical CD14+CD16−, intermediate CD14+CD16+ and nonclassical CD14+CD16+) before and after pulse therapy was also studied in comparison with healthy donors.

Results: Prior to pulse therapy, the DCs from RA patients were characterized by a high ability to stimulate the proliferation of allogeneic T-lymphocytes about 20000 cpmp. After pulse therapy, the stimulating ability of DCs significantly decreased (9800 vs. 2000 cpmp, p=0.04). Evaluation of the relative content of classical (CD14+CD16−), intermediate (CD14+CD16+) and nonclassical (CD14+CD16+) monocytes of healthy donors (n=18) and RA patients (n=25) revealed a decrease in the relative content of CD14+CD16− cells in patients (Me 78 vs. 90%; p=0.02) and an increase in the proportion of CD14+CD16− (Me 4.0 2.0%; p=0.034) and CD14+CD16+ monocytes (Me 5.0 1.5%; p=0.02). After the end of pulse therapy in RA patients, the relative content of CD14+CD16− cells increased (89 vs. 78%), and the proportion of CD14+CD16− monocytes decreased (1 vs. 5%), and RA patients no longer significantly differed in these indicators from healthy donors. Thus, a decrease in the content of CD14+CD16− cells in the monocytes population after pulse therapy was associated with a decrease in the effectiveness of DCs generated to stimulate the proliferation of allogeneic T cells.

Conclusion: The effect of pulse therapy of glucocorticoids is associated not only with the ability of glucocorticoids to inhibit the maturation of IFN-DC and induce their tolerant phenotype at the stage of differentiation of monocytes into DCs, but also with the effect on the subpopulation of circulating monocytes that are precursors of DC.

NEUROPHIL EXTRACELLULAR TRAPS: COUPLING WITH RHEUMATOID ARTHRITIS FLARES AND ANTI-CITRULLINE AUTOANTIBODIES BESIDE

S. Bedina1, E. Mozgovaya1, A. Tofrmenko1, S. Spitsina1, M. Mamus1.
1. Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy, Clinical biochemistry lab, Volgograd, Russian Federation
Background: Rheumatoid arthritis (RA) is characterized by dysregulation of the adaptive immune system. Detection of subcellular structures with localization of most typical citrulline-containing rheumatoid autoantigens in a single compartment is of special interest considering importance of antitopo II autoantibodies for autoimmune response in RA. Neutrophil extracellular traps (NETs) can be suggested as a most likely candidate for the role of such structures.

Objectives: To study of peripheral blood neutrophils from RA to generate NETs, associated with diseases exacerbation.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles after the local ethical board approval. Circulating neutrophils were isolated with one-step density gradient centrifugation using double layers of ficoll-amidotrizoate gradient. Composition of isolated cellular fractions, their viability, and non-specific activation were evaluated by light microscopy using common Romanowsky-Giemsa staining, trypan blue exclusion test as well as NBT test. Neutrophil fractions contained minute percent ages of impurities and low extents of activated and dead cells. NETs were induced by PMA. Spontaneous and induced formation of extracellular traps was assessed using fluorescence microscopy [1]. Results were presented as values (95% CI).

Results: 37 patients (6 males and 31 females, mean age 42.7 years) with verified RA according to the ACR/EULAR 2010 criteria were included in the study. RA disease activity at the inclusion timepoint should exceed ≥2.6 DAS28 points. 16 (45.4%) patients had subsequent increase of the DAS28 score above 3.2 at following visits (3, 8 and 12 months after the inclusion), 30 healthy volunteers (9 males and 21 females, mean age 37.2 years) were enrolled as a reference group. Mean proportions of spontaneous and induced NET formation by isolated neutrophils of inactive RA patients (DAS 28 ≤ 2.6) were 6.0 (5.7-6.3)% and 26.9 (24.0-28.9)% respectively. Active RA patients (DAS 28 ≥ 3.2) had dramatic increase of the respective values: 16.6 (16.4-16.8)% and 38.0 (37.7-38.3)%.

Both active and inactive RA patients had significant increase of NET-generating neutrophils proportion comparing to the reference group as well as significant difference of both these parameters between active and inactive phase (p<0.05).

The growth rate of spontaneous NET formation in the active RA was 183.8%, the respective value for induced NET formation was 46.7%. The growth rate of spontaneous NET formation is 3.9 times higher than the induced NET formation. Neutrophils from ACPA-positive RA patients were found to have increased spontaneous and induced NETs formation compared to ACPA-negative RA patients (p<0.05).

Conclusion: Thus, our study demonstrated a strong relationship between onset of RA flare and increase of spontaneous and induced NET formation by circulating neutrophils, which were also a clear distinction between ACPA negative and positive RA patients as to higher spontaneous and induced NET formation in the latter subgroup. The comparison using larger group of patients will magnify the differences above significance limit. Continued research in this direction can promote the development of new therapies of RA.

DOES HELICOBACTER PYLORI HAVE AN IMPACT ON RHEUMATOID ARTHRITIS?

H. Wu1-2, C. Wu1. 1The Eighth Affiliated Hospital of Sun Yat-sen University, Department of laboratory medicine, Shenzhen, China; 2The Eighth Affiliated Hospital of Sun Yat-sen University, Department of laboratory medicine, Shenzhen, China

Background: Rheumatoid arthritis (RA) is an autoimmune disease of not completely defined pathogenesis. A growing body of studies shows that microbiota may be a critical environmental trigger in the development of RA. Helicobacter pylori (Hp) is a common human pathogenic bacterium and is associated with multiple autoimmune diseases. However, the role of Hp in RA is far less well understood.

Objectives: The study aims to investigate the impact of Hp on RA.

Methods: We recruited 81 RA patients (disease duration >1 year) in this study, and all patients met the 2010 ACR/EULAR diagnostic criteria. They were divided into two groups depending on their infection status: the Hp-uninfected group (9 male, 33 female) and the Hp-infected group (10 male, 29 female). C-reactive protein (CRP), Rheumatoid factor (RF), and Anti-citrullinated protein antibodies (ACPA) were measured in serum of patients for assessing disease severity.

Results: The results, as shown in Figure 1, indicated that the serological levels of CRP (P=0.004), RF (P=0.0004), and ACPA (P=0.009) were significantly elevated in the Hp-positive group compared to the Hp-negative group.

Conclusion: Hp-positive RA patients present with higher levels serological of CRP, RF, and ACPA, which suggested that Hp infection could influence the disease progression or severity of RA. Thus, further research is required to investigate the pathogenic mechanism of Helicobacter pylori in rheumatic diseases.

Disclosure of Interests: None declared.

Figure 1. The serological levels of CRP (A), RF (B), and ACPA (C) in two groups. *P<0.05, **P<0.01, ***P<0.001.
indicating that the increase in total IgA is not due to translocation of mucosal IgA into the bloodstream. However, chronic mucosal inflammation might be one of the mechanisms involved in the raise in IgA(2) levels in RA, given the association between smoking and total IgA levels. Despite its pro-inflammatory properties, no strong associations between IgA2 and markers of inflammation were found, which suggests that IgA2 does not play a essential role in the ongoing pro-inflammatory processes in RA patients.

AB0078 NESFATIN-1 EXPRESSION ASSOCIATED WITH A MARKER FOR BONE MATRIX FORMATION P1NP IN RHEUMATOID ARTHRITIS
L. Seewordova1, J. Polyakova1, E. Papichev1, Y. Akhverdyan1, B. Zavadovsky1
1Federal State Budgetary Institution «Zborovsky Research Institute of Clinical and Experimental Rheumatology», lab. methods of treatment and prevention of joint diseases, Volgograd, Russian Federation

Background: Currently, the role of tissue cytokines in the pathogenesis of various diseases is being actively studied [1,2]. Nesfatin-1 (NF-1) is an endogenous peptide with melanotropin activity. Recently, there have been works on the involvement of NF-1 in osteogenesis. In the experiment, intravenous administration of NF-1 to ovariectomized rats (OVX) leads to an increase in bone mineral density (BMD). There are works showing inhibition of osteoclastogenesis in mice [3,4]. We assume that the level of NF-1 affects the processes of bone matrix formation. The aim of the study was to determine the relationship between the level of NF-1, bone mineral density, composite body composition and markers of bone metabolism in patients with rheumatoid arthritis (RA).

Objectives: The study randomized 110 patients with RA according to the ACR/EULAR criteria, 2010 and 30 people in the control group.

Methods: All of them underwent osteodensitometry LUNAR DPX-Pro with the determination of composite body composition (BCT) and bone mineral density (BMD). NF-1 levels and bone turnover markers were determined using a commercial ELISA test.

Results: The average concentration of NF-1 in patients with RA was 50.49±34.05 ng/ml, which is significantly higher than in healthy individuals. The average level of NF-1 in the blood serum of healthy individuals was 31.61±13.7 ng/ml (M±SD). The level of reference indicators of NF-1 in healthy individuals, defined as M±2SD, ranged from 25.27 to 37.95 ng/ml.

According to the level of NF-1, all patients with RA were divided into 2 subgroups. The 1st group included patients (n=44) with normal serum NF-1 concentration (less than 37.95 ng/ml), the 2nd group (n=66) included patients with elevated NF-1 levels (more than ng/ml).

During the analysis of the results of the study, we revealed a statistically significant correlation between NF-1 and the N-terminal propeptide of type I procollagen (P1NP) (r = 0.218, p = 0.022). The level of CRP and the erythrocyte sedimentation rate positively correlated with the indicators of NF-1.

We found no relationship between NF-1 levels and BMD; composite body composition; as well as the level of C-terminal type I collagen telopeptide (i-CTx).

Conclusion: Thus, the relationship between nesfatin-1 and a marker of bone matrix formation (P1NP) was revealed. This may indicate a possible effect of nesfatin-1 on the differentiation and function of osteoblasts.

AB0079 THERAPEUTIC EFFECT OF ANTIGEN B, A PROTEIN FROM ECHINOCOCCUS GRANULOSUS, IN EXPERIMENTAL ARTHRITIS
M. L. Gasparini Vieira2, M. Farinon1, R. T. Pedro1, V. Schuck Clarimundo1, A. Zaha3, H. Bunsellmeyer Ferreira4, K. Mariane Monteiro5, P. Gnielwas de Oliveira6, R. Xavier7 on behalf of Laboratorio de Doencas Autoimunes. 1Federal University of Rio Grande do Sul, Laboratory of Doencas Autoimunes, Porto Alegre, Brazil; 2Federal University of Rio Grande do Sul, Departamento de Biologia Molecular e Biотecnologia, Porto Alegre; 3Hospital de Clínicas de Porto Alegre, Serviço de Reumatologia, Porto Alegre, Brazil

Background: Antigen B (AgB) is a lipoprotein secreted in the hydatic cyst by Echinococcus granulosis larval stage and seems to be responsible for regulating the immune balance of host via Th2 response to promote survival of the parasite. A Th2 response can suppress the pro-inflammatory Th1 response generated in several immunopathologies, such as rheumatoid arthritis.

Objectives: To evaluate the anti-inflammatory and immunomodulatory effects of AgB in mice models of Zymozan-induced arthritis (ZIA), Antigen-induced arthritis (AIA) and Collagen-induced arthritis (CIA).

Methods: In all models, mice were divided into three groups: vehicle (saline), AgB 2 μg and AgB 10 μg (intraperitoneal once a day). In ZIA, arthritis was induced in Balb/c mice with an intra-articular (ia) injection of zymosan in the left knee joint thirty minutes after treatment. Nociception was analyzed over a 6h period and mice were euthanized 6h after arthritis induction to assess leukocyte migration into the joint. In AIA, Balb/c mice were sensitized by subcutaneous (sc) injection of methylated bovine serum albumin (mBSA) on day 0. Booster was administered on days 7 and 14. On day 21, arthritis was induced by ia injection of mBSA in the left knee joint. The treatment was performed 24h and 30min before the ia injection of mBSA. Nociception was analyzed over a 24h period and mice were euthanized 24h after arthritis induction to assess leukocyte migration into the joint. Male DBA/1J mice had CIA by subcutaneous injection of an emulsion containing Freund’s adjuvant and bovine collagen type II on days 0 and 8. The treatment took place between the 18th and 45th day after induction, as well as the evaluation of clinical arthritis score and nociception. Serum concentrations of IL-2, IL-4, IL-6, IL-10, IL-17, IFN-γ and TNF were evaluated in AIA and CIA.

Results: In ZIA, both doses of AgB diminished leukocytes migration to the knee joint compared with vehicle (AgB 2ug: 5.6±2.7; AgB 10ug: 5.6±2.7; vehicle: 4.8±3.1, p<0.05), but did not affect nociception. In AIA, both doses of AgB reduced nociception (AgB 2ug: 7.3±1.6; AgB 10ug: 7.2±1.6; vehicle: 6.0±2.1, p<0.01). Moreover, treatment with 2 μg of AgB inhibited in 70% the neutrophils migration (12.0±9.0, p<0.001) as well as it was reduced in mice treated with 10 μg of AgB as much as 58% (8.9±7.5, p<0.001), compared with control/vehi-

Conclusion: These results suggest an effect of AgB on the initial pathophysiology of arthritis, reducing the influx of inflammatory cells to the knee joints of mice with CIA and arthritis. It also showed anti-inflammatory and anti-atherogenic potential on murine models of rheumatoid arthritis, highlighting the immunomodulatory role of parasitic helminth proteins on immune-mediated diseases.

GDF-11 AND GDF-8 INVOLVEMENT IN MUSCLE IMPAIRMENT OF COLLAGEN-INDUCED ARTHRITIS MODEL

B. Bartolucci1,2, M. Farinon1,2, T. Hein da Rosa1,2, R. T. Pedo1, T. Karnopp1,2, R. Cavalheiro do Espírito Santo1,2, J. Miranda de Souza Silva1,2, R. Xavier1,2, R. C. de Porto Alegre, Autoimmune diseases laboratory, Porto Alegre, Brazil; 1Federal University of Rio Grande do Sul, Medical Sciences program, Porto Alegre, Brazil; 2Federal University of Rio Grande do Sul, Rheumatology Service, Porto Alegre, Brazil

Background: Rheumatoid arthritis is an autoimmune, inflammatory disease which affects primarily synovial joints and can induce skeletal muscle wasting (1). It is known that growth differentiation factors 8, 11 plays an important role in muscle homeostasis (2-3).

Objectives: Evaluate muscle mRNA and protein expression of GDF-8, GDF-11 in early and established stages of collagen-induced arthritis.

Methods: DBA1/J mice, were randomized into 5 groups: baseline animals (BL); control animals evaluated at days 25 and 50 (CO25=8, CO50=8) and collagen-induced arthritis mice evaluated at day 25 and 50 (CIA 25=8, CIA 50=8). Clinical score, paw edema, and body weight were evaluated. Clinical score, hind paw edema, and body weight were assessed. Grip strength, nociception, fatigue time, and walking speed were measured on days 0, 18, 25, 50 of experimentation. Animals were euthanized on days zero (BL group), 25 (CIA 25 and CO 25) and 50 (CIA 50 and CO 50) after disease induction. TA muscle was used to myofiber cross-sectional and GA muscle was used to evaluate gene expression of GDF-8, GDF-11 levels via qRT-PCR. Protein expression of GDF-8, GDF-11 levels in GA muscle was performed by ELISA.

Results: There was an increase in the CIA 25 and established CIA 50 groups was confirmed by high values of clinical score, nociception, paw edema and histological score when compared to the respective controls (p<0.001; p=0.001; p=0.001). There was an increase in the CIA 25 group and a worsening in this decrease at CIA 50 (p=0.0021, p=0.007). Fatigue time was shorter in CIA 25 compared to CO 25 (p=0.006) and maintained in CIA 50 (p=0.006). Walking speed showed a decrease in both time points (p=0.001; p=0.000). After normalization by body weight, only the CIA muscle had weight loss in CIA 50 when compared to CO 50 (-34.5%). Similarly, the CSA TA muscle myofiber showed a reduction of 14.04% only at CIA group compared to the CO 50 (p=0.026). The GA muscle GDF-11 mRNA levels were higher in the CIA 25 group compared to the CO 25 and BL groups (p=0.004; p=0.007 respectively); in CIA 50, there was a trend towards increased muscle GDF-11 mRNA levels (p=0.07). The protein expression of GDF-11 in serum samples did not show any differences between the analyzed groups; however, in GA muscle, GDF-11 protein expression showed differences at the CIA 25 (p=0.0023) and the CIA 50 group (p=0.017) compared with the respective controls and a significant difference in muscle protein expression between the CIA 25 groups and CIA 50 (p=0.0138). There was a decrease in mRNA content of GDF-11 on muscle, in CIA 50 and a decreased between the CIA 25 and CIA 50 in GA muscle (p=0.0377; p=0.0019); GA muscle had an increase of GDF-8 protein levels compared with the CIA 25 and CIA 50 group (p=0.001), while protein levels in serum of GDF-8 were increased in CIA 50 compared with CO 50 (p=0.037). Low muscle strength was associated with higher protein levels of GDF-11 in GA muscle (r=-0.64, p=0.01) and decreased walking speed (r=-0.534, p=0.04). Higher serum levels of GDF-8 were associated with higher muscle strength (r=0.74, p=0.02) and increased walking speed (r=0.64, p=0.01).

Conclusion: At early arthritis, GDF-11 mRNA and protein expressions were increased and are related to the physical impairment, while GDF-8 expression is reduced at established disease and increased in serum over time in CIA model, possibly as GDF-8 had a more systemic role in inflammatory arthritis. Thus, the GDFs may have a role in muscle outcome in the CIA model and can be involved in muscle atrophy and loss of physical function in RA.

BIODISTRIBUTION OF NIPOCALIMAB (ANTIHUMAN FCRN ANTIBODY) IN HUFCRN TRANSGENIC MICE

A. Vermeulen1, J. H. Leu2, S. Sipsey3, S. Lee2, L. Ling1, Clinical Pharmacology and Pharmacometrics, Janssen Research and Development, a Division of Janssen Pharmaceutica NV, Beerse, Belgium; 2Clinical Pharmacology and Pharmacometrics, Janssen Research and Development, Spring House, PA; 3United States of America; 4Biologics Discovery, Janssen Research and Development, Cambridge, MA, United States of America; 5Translational Sciences, Immunology, Janssen Research and Development, Cambridge, MA, United States of America

Background: Nipocalimab (JNJ-80202135, M2B1) is a fully human IgG1 monoclonal antibody (mAb) designed to bind to the human FcRn receptor with high affinity at both neutral and acidic pH, and is currently in investigational clinical trials. The primary role of FcRn is to extend the half-life of IgG due to its ability to bind, salvage, and recycle IgG in the circulation. Nipocalimab specifically targets the FcRn IgG binding site, thereby interfering with the binding of native IgG, reducing IgG recycling and accelerating IgG clearance (1).

Objectives: To determine the biodistribution of nipocalimab compared to an iso-type control IgG in huFcRn transgenic (Tg32) mice. This type of study is well suited to non-invasively determine the blood PK of labeled antibodies, as well as the kinetic biodistribution into various organ systems.

Methods: Four formulations were prepared for dosing: nipocalimab-VT680XL (N027a), nipocalimab-VT680XL plus 2x unlabeled nipocalimab (N027b), iso-type control IgG-VT680XL and control vehicle. The biodistribution assessment experiments were performed in Tg32 mice (n=3/group, strain: B6.Cg-Fcgrttm1Dcr Tg[FCGRT]32Dcr/J). A time series of in vivo fluorescence- mediated tomography (FMT) imaging sessions of body and brain was collected to follow the biodistribution of antibodies (Abs) after single IV administration. In vivo, whole body fluorescence was assessed immediately after administration of each formulation, and at 1, 5, 24, 48, 72, 96 and 144 hrs post administration. Mice were killed at the final in vivo imaging timepoint, followed by resection of tissues and ex vivo imaging. The in vivo tissues were also resected ex vivo at the terminal time point by exsanguination, Ex vivo fluorescence measurements were obtained for gall bladder, muscle, spleen, pancreas, white blood cells, lymph nodes, and intestines, which were flushed prior to imaging to remove fecal material.

Results: Biodistribution of nipocalimab and control IgG1 mAb were similarly observed to exhibit 2-compartment blood pharmacokinetics, dominant liver accumulation with minimal kidney and bladder signal and a prolonged terminal half-life in circulation (70-90h). Nipocalimab showed only subtle differences compared to IgG1 control antibody, attributed to specific binding to target antigen. Early tissue accumulation/binding was seen between 1 and 5 hrs post-injection, which yielded an apparent, modest increase in blood clearance and a slightly lower AUC as compared to control IgG. The bulk of increased tissue binding could be attributed to liver retention, with trends for lower accumulation/binding in other tissues, such as pancreas, lung, and muscle. Addition of 2-fold excess of unlabeled nipocalimab to the labeled nipocalimab yielded some small trends of changes in biodistribution of the labeled material.

Conclusion: Whole body biodistribution and blood pharmacokinetics of nipocalimab were similar to that observed for the isotype control IgG1 antibody. Nipocalimab exhibited a subtle trend towards higher liver distribution within the first 5 hours after dosing and a more rapid distribution phase compared to the control antibody. This is possibly related to its FcRn targeting and its shorter anticipated halflife compared to isotype control IgG or other human IgG mAbs. Overall results for both nipocalimab and control IgG were typical for IgG mAbs.

Background: Rheumatoid arthritis (RA) is a common autoimmune disease with inflammation. Total saponins of Panax japonicus (TSPJs) are effective components extracted from Panax japonicus. They are known to exhibit anti-inflammatory and immunosuppressive properties, but their effect of anti-inflammation in collagen-induced arthritis (CIA) remains unclear.

Objectives: To investigate the anti-inflammatory targets of TSPJ predicted by bioinformatics and the verification in CIA mice.

Methods: The targets of RA are obtained in the GeneCards database, we used Cytoscape 3.7.2 software to construct a protein-protein interactions (PPI) network and obtain the hub genes. There are four effective components of TSPJ: Araloside A, chikusetsusaponin IVA, ginsenoside Rg2, and ginsenoside Ro.

Through molecular docking between the screened hub genes and the four effective components of TSPJ, the possibility of TSPJ treating CIA mice can be predicted. The collagen II (COL) and complete Freund’s adjuvant (CFA) were used to induce the CIA model. After establishing the model, 32 DBA1/J mice were divided into G group (n=8), M group (n=8), and H group (n=8). The L and H groups were gavaged with TSPJ at 30 mg/kg or 150 mg/kg, and the C and M groups were gavaged with normal saline. The thickness of the hind paw, number of swollen joints, and arthritis index were evaluated. After 11 days of treatment, all the mice were sacrificed after anesthesia. Sera were collected to centrifuge tubes and the levels of inflammatory factor were determined by the ELISA kit following the instruction.

Results: A gene list that enriches 263 genes was obtained by searching RA from the GeneCards database. The hub genes of the top 3 obtained from Cytoscape 3.7.2 software were tumor necrosis factor (TNF), interleukin-1β (IL-1β), and interleukin-6 (IL-6). In addition, interleukin-17A (IL-17A), a classical inflammatory marker in the top 10, was selected and included in the predicted target. The results of molecular docking between the predicted target and the components of TSPJ showed that the combined pose has good stability. The numerical value of hind paw thickness, swollen joint counts, and arthritis index in the intervention groups were lower than those in the M group, suggesting TSPJ played a critical role in improving pathological changes. Compared to those of the C group, the serum levels of TNF-α, IL-1β, IL-6, and IL-17A were increased in the M group. Compared to those of the H group, the levels of TNF-α, IL-1β, IL-6, and IL-17A in the L and H groups were decreased. Compared to those of the L group, the levels of TNF-α, IL-1β, IL-6, and IL-17A in the H group were decreased. The results suggested that TSPJ may decrease the levels of TNF-α, IL-1β, IL-6, and IL-17A in CIA mice.

Conclusion: Current study demonstrated a novel inhibitory effect of TSPJ on inflammation in CIA mice, and TSPJ can act on the targets predicted by bioinformatics of CIA mice, suggesting the potential of TSPJ as a therapeutic agent for RA and providing new ideas for the clinical treatment of RA.

BACKGROUND: Increased liver disease risk in rheumatoid arthritis is associated with disease activity, inflammatory markers, insulin resistance and acpAs. influence of methotrexate

I. Arias de la Rosa1, M. Ruiz-Ponce2, L. Cuesta Lopez3, M. D. Gałate4, N. Herman-Sanchez4, A. Lucendo-Villarin5, P. Navarro-Sanchez4, M. C. Abalos-Aguilera4, C. Perez-Sanchez4, R. Ortega Castro4, J. Calvo Gutierrez4, C. Lopez-Pedrera5, A. Escudero Contreras2, E. Collantes Estevez6, N. Barbarroja Puerto7. 1UFRy-University of Granada-Junta de Andalucía Centre for Genomics and Oncological Research, Genomic Medicine, Granada, Spain; 2IMIBIC/Reina Sofia Hospital, Rheumatology Department, Cordoba, Spain; 3University of Cordoba/IMIBIC/Reina Sofia Hospital, Cell Biology, Immunology and Physiology Department, Cordoba, Spain; 4Hospital General de Tomelloso, Gastroenterology Department, Cuidad Real, Spain; 5University of Cordoba/IMIBIC/Reina Sofia Hospital, Medicine and surgical sciences, Cordoba, Spain

Background: Liver alterations, especially nonalcoholic fatty liver disease (NAFLD) are associated with Rheumatoid Arthritis (RA). This abnormality appears as asymptomatic and can progress to a severe liver damage rapidly. Chronic inflammation, treatment with methotrexate (MTX) or even autoimmune factors are factors that might be involved, however the mechanisms related to this comorbidity in RA are not completely established yet.

Objectives: 1) To evaluate the liver disease risk in RA patients through feasible indexes to be used in the daily clinical practice and its relationship with clinical features of the disease; 2) To analyze the impact of antibodies to citrullinated peptides (ACPs) on hepatic function; 3) To examine the influence of MTX treatment on clinical parameters and new indices of hepatic dysfunction in a cross-sectional and longitudinal cohort.

**Methods:** 1) Cross-sectional study in 307 body mass index matched subjects: 55 healthy donors (HDs), 190 RA patients and 62 non-RA patients diagnosed with NALFD through echography. Obese patients were excluded from the study. 2) Longitudinal study with 50 RA patients treated with MTX for 6 months. Clinical and laboratory parameters, subclinical liver disease biomarkers and 4 indexes to evaluate the presence of fibrosis and steatosis (APRI, AST to platelet ratio index”); FIB-4, “fibrosis 4 score”; HSI, “hepatic steatosis index” and TyG, “triglycerides and glucose index”) were measured. Association studies of hepatic dysfunction with clinical parameters were performed; A panel of 15 proteins directly involved in hepatic disease was analyzed in serum (C1QTNF1, IL7R, TIE1, CCL5, REG3A, C3A, LCN2, CCL14, NRP1, ICAM3, CD59, TIMP1, CNDP1, GNL1, IGFB8). 3) In vitro experiments were carried out in hepatocyte cell line (HEPG2) treated with ACPAs.

**Results:** Using NALFD patients as positive controls for the four liver disease indexes, RA patients showed significantly higher levels of HSI and TyG biomarkers. In fact, a high proportion of these patients (42.7%) were estimated to suffer NALFD. The association studies in RA patients showed that liver disease biomarkers (HSI and TyG) were related to the insulin resistance state, inflammation, complement component 3(C3), disease activity, and the levels of ACPAs. Serum levels of CNDP1, CCL5, GNL1, TIMP-1, CD59 and CCL14 were significantly increased in RA patients and correlated with hepatic damage indexes. Treatment with ACPAs on hepatocytes promoted the secretion of C3 in parallel with a significant alteration of genes related to glucose and lipid metabolisms, inflammation, fibrosis and apoptosis. MTX treatment, from the point of cross-sectional analysis, was not associated with an increase of hepatic enzymes, serum proteins nor liver disease indexes. Treatment with MTX for 6 months did not affect those levels either.

**Conclusion:** 1) A high proportion of RA patients present an alteration in markers of NALFD, associated with insulin resistance state, disease activity, inflammation, component C3 and ACPAs levels; 2) the autoantibodies could directly impact hepatocyte biology altering the expression of genes related to glucose and lipid metabolisms, inflammation, fibrosis and apoptosis. 3) Treatment with MTX did not promote any alteration in subclinical liver disease biomarkers after 6 months of treatment. **AB0085 TIGLYLCARNITINE AS KEY FACTORS IN LIVER–JOINT AXIS**

H. Wang1, Y. Zhang1. 1Qilu Hospital, Department of Clinical Laboratory, Jinan, China

**Background:** Gut microbiota could promote RA progression metabolites mediated gut–joint axis [1]. We previously reported that liver metabolism has a close linkage with Rheumatoid arthritis (RA) [2]. However, the inter-relational mechanisms between liver and joint are still unclear.

**Objectives:** This article aimed to explore the shared metabolites signatures of liver, plasma and joint in RA.

**Methods:** We integrated multomics datasets metabolites of liver and plasma from in the healthy group (n=10) and CIA group (n=10), and metabolites of knee-joint fluid (synovial fluid) from 40 participants in osteoarthritis (OA) group (n=20) and RA group (n=20). The Weighted Gene Co-Expression Network Analysis (WGCNA) was used to identify the co-expression modules related to liver, plasma and joint.

**Results:** The blue modules were negatively correlated with CIA (r = 0.74, p < 0.001), included 200 liver metabolites. The black modules were positively correlated with CIA (r = 0.63, p < 0.001), included 78 plasma metabolites. The yellow modules were positively correlated with RA (r = 0.53, p = 0.008), included 55 synovial fluid metabolites. There were only 1 metabolite (Tiglylcarnitine) overlapped in RA-related module of liver, plasma and joint.

**Conclusion:** Tiglylcarnitine may be the key factors to liver–joint axis.

**AB0086 PORPHYROMONAS GULAE INFECTION IS NOT RELATED TO EXOGENOUS CITRULINATION OR DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS**

C. Castellar1, D. M. Castillo2, L. Chila3, W. Bautista-Molano4, J. M. Bello-Guaiteras4,5, C. Romero-Sánchez4,5,1.1Universidad El Bosque, School of Science, Biomedical Master Program, Bogotá D.C., Colombia; 2Universidad El Bosque, Unit of Basic Oral Investigation, School of Dentistry, Bogotá D.C., Colombia; 3Universidad El Bosque, Cellular and Molecular Immunology Group - INMUBO-, Bogotá D.C., Colombia; 4Universidad Militar Nueva Granada, School of Medicine, Clinical Immunology Group, Bogotá D.C., Colombia; 5Hospital Militar Central, Rheumatology and Immunology Department, Bogotá D.C., Colombia.

**Background:** Porphyromonas gulae (P. gulae) is a Gram negative microorganism of the Porphyromonadaceae family. It presents in its structure virulence factors similar to P. gingivalis, including the PAD enzyme. An enzyme responsible for catalyzing citrullination, related to the formation of autoantibodies against citrullinated peptides associated with Rheumatoid Arthritis (RA).

**Objectives:** To evaluate the presence of P. gulae and anti-citrullinated peptide antibodies of P. gulae PAD in patients with RA and their possible association with clinical markers of activity.

**Methods:** Ninety RA patients and 90 controls matched for age and sex were included. Serum levels of rheumatological markers such as erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), anti-citrullinated protein antibodies (Anti-CCP/ACPA) and rheumatoid factor (RF) were measured. Disease activity was assessed using Disease Activity Indices-28 (DAS28) and SCDAI. The periodontal diagnosis was according to CDC and American Academy of Periodontology. The presence of P. gulae was established by qPCR, verifying the specificity and confirmed due to the high homology between P. gingivalis and P. gulae. The presence of antibodies against 2 peptides called VDK and LPO were evaluated in their native structure and citrullinated at one end and inside the PPA molecule of P. gulae. It was determined by ELISA in-house. Prediction of B and T epitopes of PPA from P. gulae was made taking into account the location of arginines within the molecule, restricting it to HLA alleles associated with RA. Associations were established by Kruskal Wallis, Mann Whitney U tests and multiple correspondence discriminant analysis (MCDA) in SPSS V24 and STATA for Windows software, with a significance of 95%, p ≤ 0.05.
**Results:** A frequency of *P. gulae* was observed in the RA group of 15.8% versus controls of 9.5%; *p*<0.0125. A despite finding a diagnosis of periodontitis in 70.3% of the patients, it was not associated with clinical severity or diagnosis of periodontitis. Comparisons were made classifying the patients according to periodontal diagnosis, the presence of *P. gulae* was observed more frequently in the RA group with a diagnosis of periodontitis, compared to the control group (6.7% vs 2.5%, respectively) without statistical significance (p=0.2576). Of the 180 individuals evaluated, 17 had the presence of anti-citrullinated peptide antibodies of *P. gulae* PAAD. Despite a higher frequency in the RA group of antibodies against two citrullinated peptides, the results were not significant (p=0.378 and p=0.346), there was no evidence of a relationship with activity or disease markers in RA. The MCDA test generated two dimensions, one with the clinical activity variables of RA with CC: 0.218, and a second dimension in which the presence of anti-citrullinated peptide antibodies of PAD CC were related to each other CC: 0.748; No positive correlation was found between the clinical variables of RA and the anti-citrullinated peptide antibodies of *P. gulae* PAD.

**Conclusion:** Despite the presence of *P. gulae* and PAD citrullinated peptide antibodies from *P. gulae* in patients with RA, it was not possible to establish the relationship with clinical variables, which could indicate a lower contribution of this microorganism to the biological mechanism and molecular of citrullination common between RA and periodontitis. However, an additive effect of *P. gulae* with *P. gingivalis* in the citrullination process cannot be ruled out.

**AB0087**

**THE EFFECT OF BARICITINIB ON STAT1 PHOSPHORYLATION IN MONOCYTES FROM RHEUMATOID ARTHRITIS PATIENTS**

C. Garuti1, G. Tucci1, I. Pacella1, M. Zagaglioni1, A. Pinzon Grimaldos2, F. Cecarelli1, S. Picone1, F. R. Spinelli1, F. Conti1. 1Sapienza University of Rome, Department of Internal Clinical Sciences, Anesthesiology and Cardiovascular Sciences, Roma, Italy

**Background:** Baricitinib is a Janus kinase (JAK)1/JAK2 inhibitor approved for the treatment of rheumatoid arthritis (RA)1-2. STAT proteins bind JAK kinase dimers coupled with cytokine receptors and regulate gene transcription. The JAK/STAT system is responsible for the intracellular signaling of different cytokines contributing to the activation process of the monocyte lineage, therefore the use of JAK inhibitors can affect cell functionality3-4. **Objectives:** The aim of the present study was to verify the effects of baricitinib on STAT phosphorylation in peripheral mononuclear cells (PBMCs) of RA patients and to evaluate any correlation between STAT phosphorylation and response to therapy.

**Methods:** At baseline (BL) and after 4 weeks (w4) of treatment, we evaluated patients’ disease activity (DAS28cR, CDAI and SDAI), dividing them into responders and non-responders according to the Minimal Clinically Important Difference for DAS28cR (1.2 points) at w4. The phosphorylation of STAT1, STAT5 was analyzed at BL and W4 in gated monocytes, Treg, CD8+ and CD4+ lymphocytes from 4 responder and 4 non-responder patients through flow cytometry, at basal conditions and after IL2, IFN and IL6 stimulation.

**Results:** Baseline clinical and demographic characteristics of patients are reported in Table 1. We showed that monocyte count decreased from BL to w4 mostly in responders. Basal pSTAT1 phosphorylation tended to be higher in monocytes of non-responders patients; after 4 weeks of treatment, the reduction of the cytokine-induced pSTAT1 was significantly greater in monocytes from responders compared to non-responders (Figure 1). The phosphorylation of STAT4 and STAT5 was not affected by treatment in any cell type and at any time point. We further studied the STAT1 phosphorylation pathway isolating the effect of stimulation with IFN and stratifying monocytes according to their surface marker expression of CD14 and CD16 in classical, intermediate and non-classical. We observed the same pattern with a significant greater reduction of pSTAT1 in monocytes from responder patients, compared to non-responders, after the treatment with baricitinib.

**DOUBLE-STRANDED DNA BREAKS ARE A MARKER OF THE INFLAMMATORY ACTIVITY OF RHEUMATOID ARTHRITIS**

A. Audeeva1, Z. Verizhnikova1, V. Rybakova1, V. Kozlova1, T. Popkova1, A. Lila1, E. Nasonova1, 1V.A. Nasonova Research Institute of Rheumatology, laboratory of immunology and molecular biology rheumatic diseases, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, Department of systemic rheumatic diseases, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Medical Academy of Continuing Professional Education, Rheumatology, Moscow, Russian Federation; 4V.A. Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation

**Background:** Double-strand DNA breaks (DNA-DSB) are one of the most biologically significant DNA damage lesions that leads to chromosome breakage and/or rearrangement, mutagenesis and loss or gain of genetic information. The phosphorylation of H2AX histone proteins which are located in the vicinity of the DSBs is known as one of the earliest responses to DNA DSBs in cells. Induction
of DNA DSBs in live mammalian cells triggers the phosphorylation near the C-terminal of H2AX protein, which results in the phosphorylated form of H2AX, termed γH2AX. [1,2].

Objectives: To examine DNA-DSB among patients with systemic autoimmune rheumatic diseases (SARDs) by evaluating phosphorylation γH2AX and 53BP1 at the site of injury.

Methods: The analysis included 25 patients with SARDs (19 with RA (16 women, Me,jOR the disease duration 60 (20-103) months, DSAS28-ESR 5.05 (4.06-6.91); 4 - with systemic lupus erythematosus (4 women, the disease duration 324 (204-372) months, SLEDAI-2K 9.5 (4.5-16.5) and 2 women with Sjögren’s disease. The control group consisted of 14 healthy donors, comparable in gender and age with the examined patients. DNA-DSB breaks were determined as a discrete focus during immunofluorescence staining with anti-γH2AX and anti-53BP1 antibodies of the lymphocyte culture, followed by analysis on the automated platform ALCIDES (Medipan, Berlin/Dahlewitz, Germany).

Results: There were no significant differences in the number of DNA breaks among patients with SARDs and healthy donors (p=0.05). There was a positive correlation between % pos. cells by γH2AX and CDAI (r=0.45 p=0.035), Nuclei with foci by 53BP1 and ESR (r=0.53 p=0.02) and IgM RF (r=0.63 p=0.005). Among patients with high CDAI activity (n=10), there was a greater number of Nuclei with foci by γH2AX - (22.5 (6.0-43.0); a higher average number of foci mean (0.39 (0.19-0.62) and a higher % pos. cells (32.6 (18.7-39.1) comparing with patients with low/moderate inflammatory activity (9.0 (2-12); 0.12 (0.02-0.28); 11.5 (1.8-23.5) accordingly, p<0.05, n=9).

Conclusion: The evaluation of double-stranded DNA breaks can be beneficial as an additional marker for assessing the disease activity among patients with RA.

AB0089 INTEGRIN Α111 DEFICIENCY AFFECTS THE COURSE OF DISEASE IN THE ARTHRITIC HTNFtG MOUSE

1University Hospital Muenster, Institute of Musculoskeletal Medicine, Münster, Germany; 2University of Cologne, Translational Matrix Biology, Köln, Germany; 3University of Bergen, Department of Biomedicine and Centre for Cancer Biomarkers, Bergen, Norway

Background: Rheumatoid arthritis (RA) is an autoimmune disorder conducted by fibroblast-like synoviocytes (FLS), which acquire a tumor-like phenotype with the examined patients. DNA-DSB breaks were determined as a discrete focus during immunofluorescence staining with anti-γH2AX and anti-53BP1 antibodies of the lymphocyte culture, followed by analysis on the automated platform ALCIDES (Medipan, Berlin/Dahlewitz, Germany).

Objectives: We herein sought to assess the value of total serum IgG Fc γ-glycosylation as a diagnostic and prognostic biomarker in patients with early inflammatory arthritis (EIA). Specifically, we aim to assess whether IgG N-glycoform levels may predict the diagnosis of RA or undifferentiated arthritis (UA) and the long-term disease's outcome in patients with EIA arthritis patients naïve to treatment.

Methods: The “Early Arthritis Clinic” of the University Hospital of Heraklion is a prospective cohort of patients with inflammatory arthritis. For the present study, we selected a group of patients naïve to any immunosuppressive treatments with available serum at baseline evaluation (n=118). At baseline, demographic, RA clinical characteristics (DSAS28, HAQ-DI) and laboratory tests (autoantibodies (RF and/or ACPA)), were also recorded. The patients were prospectively followed for two years, with clinical, laboratory and disease-related treatments documented. A diagnosis of RA or UA was based on established classification criteria 3. In order to assess long-term prognosis we formulated a combined “index” of favourable outcome if the patients fulfilled all the following at 24 months of follow-up: remission or low disease activity (based on DAS28 < 3.2) and normal functionality (based on HAQ ≤ 0.25) while on treatment with csDMARDs and never use bDMARDs. We applied a state-of-the-art liquid chromatography - mass spectrometry (LC-MS) based workflow for analysis of subclass-specific IgG Fc γ-glycosylation at the baseline 4.

Results: We studied 118 EIA patients (age, mean (SD), 53 (15.6) years, females (80.5%), symptoms duration (53.8, 8.7) years, ACPA positive (16%), DSAS28 (4.8, 0.14)). During the 2 years of follow-up, 60% of the patients were diagnosed with RA and 40% with UA. Although patients with UA had higher relative abundances of galactosylated and sialylated N-glycoforms (H4N4F1, H5N4F1 and H5N4F1S1) in all IgG subclasses at baseline compared to RA patients, differences were not statistically important. Interestingly, we observed a significant association between high levels of IgG2/3 galactosylation for H5N4F1 (effect 0.63, adjusted p=0.036) and H3N4F1 (effect -0.55122, adjusted p=0.0496) and favorable outcome after two years of treatment.

Conclusion: Our cohort of EIA we found IgG2/3 Fc N-glycoforms to be associated with a favorable prognosis after 2 years of follow-up. Should the present data be confirmed in a larger cohort could be of clinical value. Since currently available prognostic tools have significant limitations, further research should aim to the development of a predictive tool of high specificity and sensitivity based on the combination of clinical, serological data and novel biomarkers.

Background: Immunesenescence in the adaptive immune system, subsequent to thymic involution, results in compromised immunity and increased susceptibility to autoimmune disease and chronic inflammation. There are reports in the literature that the process yielding thymic atrophy and telomere shortening, is accelerated in patients with rheumatoid arthritis (RA). What is unclear is whether RA includes accelerated biological ageing overall in addition to immune ageing which may help to explain the increased risk of age-related diseases in RA2. Recent studies have identified a set of DNA methylated sites across the genome that are highly correlated with chronological age and mortality, termed epigenetic clocks3,4 or DNAm age (DNAma), and can be used to determine an individual's biological age.

Objectives: The aim of our study is to determine if the biological epigenetic clocks of RA patients are accelerated.

Methods: We evaluated the Horvath5 and Hannum6 epigenetic clocks of control and RA patients using published DNA methylation data, accessions GSE42861 (EIRA, Swedish cohort of 342 RA patients and 328 non-RA controls) and E-MTAB-6988 (77 RA discordant monozygotic twins).

Results: We did not detect significant differences between DNAma of RA and non-RA twins. Similarly, there were no significant differences between the DNAma of RA patients and controls from the Swedish EIRA cohort. However, we detected a significant acceleration in DNAma of male discordant twins, both RA and non-RA, by 5.4 years (p=3.29e-5) and 2.8 years (p=0.04) using the Hannum and Horvath clocks, respectively. Male participants, both control and RA patients, from the EIRA cohort also exhibited an accelerated DNAma, by 1.5 years (p=7.55e-5) using the Hannum clock but using the Horvath clock a significant DNAma acceleration, by 1.4 years (p=0.002) was detected in male RA patients from the EIRA cohort.

Conclusion: Overall, we detected a significant biological age acceleration in male patients with rheumatoid arthritis over 50 years: a systematic review and meta-analysis of cohort studies. Rheumatol 48:1309-1313.

AB0093  MODELING OF ANTIGEN-COLLAGEN-INDUCED ARTHRITIS IN BALB/C MICE

M. Fisher 1, V. Kurilin 1, S. Sennikov 1, 2 1Research Institute of Fundamental and Clinical Immunology, Laboratory of Molecular Immunology, Novosibirsk, Russian Federation

Background: Rheumatoid arthritis (RA) is one of the most common autoimmune diseases. Currently, disease-modifying drugs and biological agents are used to treat RA [1]. The available drugs are not perfect: they have serious side effects and do not always cause a stable improvement or remission [2]. The above sets the task of finding new approaches to treatment that will be effective, more specific and safe. In this connection, it is necessary to develop and apply experimental models as close as possible in pathogenesis to rheumatoid arthritis. One such model, rarely used at present, is the combined antigen-collegen-induced arthritis [3].

Objectives: To show immunological and histological changes similar to RA in the AIA/CIA model and the model of arthritis application in research activities.

Methods: Experimental AIA/CIA was induced according to 2 different protocols in 50 BALB/c mice. Clinical assessment of arthritis was made by measuring the swelling of the paws with a caliper at different times. The assessment of immunological changes included the analysis of the content of antibodies to type II collagen by ELISA, the content of T-regulatory cells by flow cytometry. Also, a histological analysis of the obtained data was carried out.

Results: On the 10th day, a significant increase in paw thickness was recorded in animals induced both according to the first and second protocols. The intensity of swelling subsided by the 23rd day. A significant increase in the content of antibodies to type II collagen was observed in all experimental groups, but in animals from Protocol No. 1, the amount of antibodies to type II collagen was significantly higher. A high level of T-regulatory cells was registered only in mice animals from the first protocol on the 10th day. Histological changes in the form of synovial hyperplasia, pannus, usurasations were observed to varying degrees in all experimental groups, but the most pronounced changes were in animals from the first protocol.

Conclusion: In experimental animals, in all the presented protocols, changes were observed that were closest to RA, when compared with classical models of experimental arthritis induction. Based on the fact that protocol 1 animals showed an increase in the content of T-regulatory cells, the levels of antibodies to type II collagen were consistently high, and the histological changes were the most pronounced, it can be assumed that protocol 1 of the combined AIA/CIA model on the line of Balb/c mice, is the most suitable for testing and developing new methods of RA therapy.

AB0094  DENDRITIC CELLS AS TARGETS OF PATHOGENETIC THERAPY FOR AUTOIMMUNE DISEASES

Y. Kurochkin 1, M. Korolev 1, E. Letyagina 1, A. Akimova 1, N. Banshhikova 1, V. Omechenko 1, Y. Ushabawa 1 1Research Institute of Clinical and Experimental Immunology - branch of the Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Sciences, Rheumatology, Novosibirsk, Russian Federation

Background: Dendritic cells (DCs) are known to contribute to the pathogenesis of autoimmune diseases through presentation of cartilage glycoprotein, production of proinflammatory cytokines and activation of Th1/Th17 responses. DCs are a heterogeneous population and can be divided into groups: myeloid (mDCs) and plasmacytoid (pDCs). DCs can induce both immune response and tolerance.

Objectives: The study is aimed at investigating the subpopulations of peripheral blood DCs (myeloid and plasmacytoid) in patients with rheumatoid arthritis (RA) and axial spondyloarthritis (axSpa) under disease-modifying antirheumatic drugs (DMARDs) treatment as a target of pathogenic therapy.

Methods: There are thirty patients were included in the study. Twenty patients with early RA (ACR/EULAR criteria, 2010, duration of the disease up to 12 months) and ten patients with axSpa (ASAS criteria) were recruited. RA patients received methotrexate, leflunomide, sulfasalazine or their combination. All patients received NSAID in combination with conventional synthetic DMARDs. Analysis of the content of the B-lymphocytes, myeloid and plasmacytoid DCs was carried out by flow cytometry. B-lymphocytes, subtypes of peripheral blood DCs were characterized by the following phenotypes: myeloid DCs (CD3-CD14-CD19-HLA-DR + CD11c + CD123-), plasmacytoid DCs (CD3-CD14-CD19-HLA-DR + CD11c + CD123 +), B-lymphocytes (CD19 +). Analyses were performed before treatment and 6 months later.

Results: RA patients were characterized by high activity of the disease (DAS28=5.46). At the beginning we revealed significant increasing of the population of myeloid DCs (1.6%) and B-lymphocytes (5.4%). No significant differences were observed in the number of plasmacytoid DCs. After 6 months of treatment, most of the patients had a decrease in the activity of the disease (DAS28=3.05v.46, p=0.05, n=12) coupled with a significant decrease mDCs (0.85 vs16%, p=0.03) and B-cells (4.2 v.5.4%, p=0.05). In the remaining patients (n=8), there was no clinically significant improvement (DAS28=2.46) or differences in mDCs (1.45 vs1.6%) and B-cells (5.05vvs5.4%). Six months later, there was a decrease in ASDAS activity among axSpa patients (2.56 vs 2.09). We were revealed no differences in amount in mDCs between RA and axSpa patients (1.4 vs 1.6%). After 6 month of investigation we detected decreasing mDCs (1.4 vs 0.9%, p=0.05). We have also found a decrease in B lymphocytes among axSpa patients (5.1 v 4.1%) that is consistent with some authors data on B lymphocytes in spondyloarthritis pathogenesis.

Conclusion: Reduction in the number of DCs in the context of treatment combined with reduced activity of diseases confirm the role of DCs in the pathogenesis of autoimmune diseases. In addition, probably being a target of pathogenetic therapies they can serve as a marker of a good clinical response to the therapy.

AB0095  CHARACTERISTICS OF TUMOR NECROSIS FACTOR-ALPHA AND INTERLEUKIN-6-INDUCED OSTEOCLASTS IN PERIPHERAL BLOOD AND BONE TISSUE FROM PATIENTS WITH RHEUMATOID ARTHRITIS

K. Yokota 1, M. Sekikawa 2, S. Tanaka 2, a, Y. Azaki 1, Y. Kadono 2, H. Oda 3, T. Mimura 4, 1Saitama Medical University, Rheumatology and Applied Immunology, Saitama, Japan; 2Saitama Medical University, Orthopaedic Surgery; Saitama, Japan; 3Japan Community Health care Organization Saitama Northern Medical Center, Orthopaedic Surgery, Saitama, Japan; 4National Hospital Organization Ibusuki Medical Center, Orthopaedic Surgery, Kagoshima, Japan

Background: We have previously reported that stimulation of mouse bone marrow-derived macrophages with tumor necrosis factor-α (TNF-α) and interleukin-6 (IL-6) induces differentiation of osteoclast-like cells having bone resorption ability 1. Recently, we have shown that the combination of TNF-α and IL-6 can induce osteoclasts from human peripheral blood mononuclear cells (PBMCs) via RANKL-independent pathways, and that there are functional differences between TNF-α and IL-6-induced osteoclasts (T6-OCs) and RANKL-induced, conventional osteoclasts (cOCs). In particular, the number of T6-OCs differentiated from PBMCs in patients with rheumatoid arthritis (RA) positively correlated with the modified total Sharp score (mTSS) 2. On the other hands, no such correlation was observed between the number of cOCs from RA and mTSS. Objectives: Objectives of this study were to compare the differential potential into T6-OCs of PBMCs from RA patients with those from healthy donors, to clarify mRNA and protein expressions of T6-OCs derived from PBMCs from patients with RA, and to identify tartrate resistant acid phosphatase (TRACP) positive multinuclear cells with the same characteristics as T6-OCs histologically in the sub-chondral bone tissues from patients with RA and osteoarthritis (OA). Methods: PBMCs and CD14+ monocytes derived from RA patients and healthy volunteers were stimulated with TNF-α and IL-6 or RANKL. Real-time quantitative PCR and immunofluorescence staining were used to measure expression levels of osteoclast-associated mRNA and protein. Consecutive sections of the proximal tibial bone tissue from patients with RA and OA (n=6 each) were stained by TRACP, and analyzed expression levels of osteoclast-associated molecules by immunohistochemistry.

Results: The number of T6-OCs differentiated from PBMCs in RA patients was significantly increased compared to that in healthy donors, to clarify mRNA and protein expressions of T6-OCs derived from PBMCs from patients with RA, and to identify tartrate resistant acid phosphatase (TRACP) positive multinuclear cells with the same characteristics as T6-OCs histologically in the sub-chondral bone tissues from patients with RA and osteoarthritis (OA). PBMCs and CD14+ monocytes derived from RA patients and healthy volunteers were stimulated with TNF-α and IL-6 or RANKL. Real-time quantitative PCR and immunofluorescence staining were used to measure expression levels of osteoclast-associated mRNA and protein. Consecutive sections of the proximal tibial bone tissue from patients with RA and OA (n=6 each) were stained by TRACP, and analyzed expression levels of osteoclast-associated molecules by immunohistochemistry.

Disclosure of Interests: None declared

RANKL-MMP-3+ osteoclasts were present in the subchondral bone from patients with RA, on the other hands, no such cells observed in OA patients.

**Conclusion:** The PBMCs of RA patients have definitely increased differentiation capacity into T6-OCs, which have potential of degrading chondral tissue. Additionally, cells having same characteristics with T6-OCs are observed in subchondral bone from patients with RA. These results suggest that novel T6-OCs may be involved in the pathogenic mechanisms of inflammatory bone destruction in patients with RA.

**Background:** Arachidonic acid (AA) is a polyunsaturated fatty acid, released in inflammatory disease, such as rheumatoid arthritis (RA). Cyclooxygenase [COX] and lipoxygenase pathways have received greater attention than cytochrome P450 (CYP) pathway of AA, which also plays a significant role in RA. AA is a substrate of CYP enzymes through two different pathways: the ω-hydroxylase, and epoxygenase pathways, respectively. The epoxygenase gives rise to epoxycyclo-oxygenic and epoxygenic acids (EETs) [5]. Moreover, data suggest that sEHi inhibit also PGE2 production, and exert anti-inflammatory effects. sEHi are also metabolized through soluble epoxide hydrolase (sEH) hydrolyzing to dihydroxyeicosatetraenoic acids (DHTEs) [1].

**Objectives:** The aim of this study is to evaluate the role of Cytochrome P450 metabolites of arachidonic acid and their therapeutic targeting in rheumatoid arthritis.

**Methods:** Pubmed and Scopus databases were the main databases used to identify all the studies conformed to the eligibility criteria.

**Results:** CYP enzymes (CYP3A, CYP2C19, CYP2C9, CYP1A2) suppression was observed in the synovial fluid of RA patients with higher IL-6 levels. EETs inhibit bone resorption and osteoclastogenesis, have an important role in blocking inflammation by reducing TNF-α, and are negatively linked with pro-inflammatory cytokines (IL-1, IL-6, IL-8)[2]. The anti-inflammatory effects of EETs are potentially attributed to peroxisome proliferator-activated receptor gamma (PPARγ) activation. EETs are also metabolized through soluble epoxide hydrolase (sEH) that didehydroxyeicosatetraenoic acids (DHTEs), which have a pro-inflammatory activity. On the other hand, 20-HETE deriving from CYP ω-hydroxylation pathway has pro-inflammatory effect [3]. Data have shown that the genetic variations of CYP could affect the individual susceptibility to RA [4].

**Conclusion:** sEHi inhibitors (sEH) can not only block the inflammation caused by EETs metabolite, but can also act on LOX and COX pathway, and can be used in chronic-phase arthritis to reduce both inflammation, and the pain. In a meta-model of RA, sEHi showed decent RA assessment score improvement [5]. Moreover, data suggest that sEHi inhibit also PGE2 production, and exert an additional anti-inflammatory effect in arthritis. Since NSAIDs can lead to gastriac and cardiovascular problems, sEHi are considered a better pharmacological approach in inflammatory rheumatic disease. Despite the failure of some of sEHi to reach clinical trials, we believe that CYP-derived eicosanoids should be further studied as potential target in rheumatic disease. Dual inhibitors sEHi/S-LOX activating protein (FLAP) are also very promising compounds as they can inhibit leukotriene formation, without affecting the levels of anti-inflammatory pro-resolving mediators. In perspective we suggest that multiple ligands targeting different AA pathways or mediators should be further explored as potential targets for designing new compounds to treat RA patients.

Background: Tofacitinib is a potent and selective oral inhibitor prevalently of JAK1 and JAK3and is currently included in the international recommendations for the management of psoriatic arthritis (PsA). Nonetheless, the mechanisms of the immune response to the treatment remain unclear, particularly regarding the effects on overlooked immune cell subpopulations specifically involved in the pathogenesis of PsA, i.e. mucosal-associated invariant T cells (MAIT), innate lymphoid cells (ILCs), both relevant sources of IL-17 and T lymphocytes producing interleukin 9 (Th9). We thus investigated the effect of tofacitinib on these cell population function and compared with glucocorticoids.

Objectives: To investigate the effect of tofacitinib and dexamethasone on MAIT cells, ILCs, and Th9 cells in PsA.

Methods: We investigated synovial fluid and peripheral blood mononuclear cells from patients with PsA that were cultured with phorbol myristate acetate (PMA)/ionomycin in the presence or absence of 100 or 300μM Tofacitinib or 1000μM Dexamethasone for 24 hours and the addition of brefeldin in the last 2 hours. FACS analysis allowed to identify MAIT cells by CD3+CD161Valpha2/2CIITA: ILCs by CD3+CD4+CD127+, from this population ILC1 were arrayed as cKit-; CRTH2-; ILC2 as cKit +/- and CRTH2+, and ILC3 as cKit+ and CRTH2-; Th9: CD3+CD4+IL-9+.

Results: A significant decrease in IL-17 production was observed in CD8+ MAIT cells treated with tofacitinib 300μM compared to untreated conditions, with a magnitude similar to what observed with dexamethasone (mean fluorescence intensity-MFI median 1920 (interquartile range-IQR 1597-2761), 16.8% (3.9-31.4) in untreated cultures; 1481 (1325-3163), 13.4% (4.5-9.3) in tofacitinib-treated cultures; 1511 (1147-2882); 11.5% (2.5-49) in Dexamethasone-treated cultures; see Figure 1). A reduction of IL-17 production was observed also in ILC3 [52.1% (4.2-59.4) in untreated cultures; 25.6% (5.3-40.3) in Tofacitinib-treated cultures; 35.4% (6.3-47.9) in dexamethasone-treated cultures]. A reduction of IL-9 production was observed in peripheral blood T cells [2.19% (13.2-3.2) in untreated cultures; 0.6% (0.0-1.8) in Tofacitinib-treated cultures; 0.97% (0.07-1.13) in Dexamethasone-treated cultures].

Conclusion: In PsA, tofacitinib is superior to dexamethasone in reducing the production of IL-17 by synovial fluid MAIT cells and ILC3 cells and of IL-9 by peripheral blood T cells.

Faculty of Medicine, Mansoura University, Egypt, Department of Clinical Pathology, Mansoura, Egypt

Background: Rheumatoid arthritis (RA) is a chronic, inflammatory joint condition that affects about 5 out of 1000 persons of the general population [1]. Environment, genetics, and autoimmunity may all have a role in the pathogenesis of the disease [2]. Overproduction of pro-inflammatory cytokines like tumor necrosis factor-α (TNF-α) is the end result of these mechanisms [3]. However, little is known about its soluble concentrations in synovial fluid and serum and its association with clinical and ultrasonographic joint parameters.

Objectives: The aim of this study was to assess the presence of TNF-α in serum and synovial fluid of the knee in RA patients with knee effusion and to evaluate its correlation with musculoskeletal ultrasound (MSUS) parameters of the affected knee joint.

Methods: This study included 40 patients (20 RA, 10 systemic lupus erythematosus (SLE) and 10 osteoarthritis (OA)) who had knee effusion (unilateral or bilateral) upon clinical examination. The sample size was selected as convenient sample, all patients who fulfilled the inclusion criteria were offered to participate in the study, unless they qualify for any of the exclusion criteria or refuse to participate. The inclusion criteria included the following: a) age ≥ 18 years old, b) patients with knee effusion detected by clinical examination and confirmed by MSUS, c) patients with RA diagnosed according to 2010 ACR /EULAR classification criteria [4], SLE according to SLICC criteria [5] or knee OA diagnosed according to EULAR criteria [6].

Demographic, clinical, and therapeutic data were recruited from all participants. Visual analogue scale (VAS) was used to determine the pain intensity in the affected knee. MSUS examination of the affected knee was performed, and a sample of synovial fluid was aspirated. TNF-α was measured in the aspirated synovial fluid and serum of each patient.

Results: There was a total of 40 patients (20 RA, and 20 age and sex matched non-RA (10 SLE, and 10 OA)). The mean age of RA patients was 48.4 years, most of them were females (80%) with median duration of knee pain of 2 months. Serum TNF-α was barely significantly higher in RA vs. non-RA cases (3.66 ± 0.76 vs 3.24 ± 0.58 U/ml, p= 0.052), while in synovial fluid, difference was not statistically significant (3.73 ± 0.72 vs 3.48 ± 0.58 U/ml, p= 0.252). Also, there was a statistically significantly higher serum TNF-α in RA vs. OA (3.66 ± 0.76 vs 3.06 ± 0.32, p= 0.022).

Conclusion: Serum TNF-α level do not differ in RA from non-RA patients. No role of synovial TNF-α in knee pathologies in RA patients.

LONGER DISEASE DURATION OF RHEUMATOID ARTHRITIS IS ASSOCIATED WITH TNF RECEPTORS REDISTRIBUTION ON IMMUNOCOMPETENT CELLS AND CHANGES IN CELL SENSITIVITY TO CYTOKINE

A. Alshevskaya1, J. Zhukova1, J. Lopatinikova1, O. Chumasova2, N. Shkaruba2, A. Sizikov2, S. Sennikov2. 1RIFCI, Rheumatology Department, Novosibirsk, Russian Federation; 2RIFCI, Rheumatology Department, Novosibirsk, Russian Federation

Background: Longer duration of rheumatoid arthritis (RA) is associated not only with higher disease severity, but also with lower treatment efficacy including anticytokine therapy. One of key mechanisms implementing this is changing in expression of cytokines and their receptors actively involved in the pathological process, such as tumor necrosis factor (TNF).

Objectives: The aim of the study was to study the redistribution of TNF receptors in patients with different duration of RA and depending on the severity of the disease.

Methods: Subanalysis of RA patients with disease duration less than 10 years (Early RA group, n=34) and more than 10 years (Late RA group, n=30) was performed. Late RA patients had DAS-28 activity comparable with Early RA group (4.98 vs 4.69, p=0.68), but had higher radiological stage, higher levels of inflammatory markers, and more often received biologics and had systemic features. As a control group, data from 43 comparable healthy donors were used. Co-expression profile of TNF receptors type 1 and 2 (TNFR1/2) were assessed in main mononuclear subsets: T cells, B cells, monocytes, Tregs, T helpers, cytotoxic T cells. Dynamics of percentage of cells with different co-expression combination was estimated as well as receptors expression density per cell.

Results: The redistribution of receptors on 12 subpopulations of immune cells was studied. Two types of cell responses were associated with disease duration increase. The first trend was presented by monocytes, regulatory T cells and general pool of cytotoxic T cells and consisted in significant decrease in TNFR2 expression density with simultaneously increase of double-positive TNFR1+T-NFRII+ cells percentage and decrease of TNFR1-TNFRII+ cells percentage with no changes in proportion of cells without receptors, as compared with healthy and with disease progression. The second type of response was presented by B cells, T cells, T helper naive cells and activated T cells and represented a significant increase in TNFR1 expression density and increase of double-positive cells proportion compared to healthy without influence of disease duration and tendency to decrease in proportion of cells without receptors over time.

Conclusion: Two trends in the response of immunocompetent cells to changes in the level of TNF that occur during chronic inflammation in RA were established. These two trends demonstrate the reactive and adaptive mechanisms of immune cells actively involved in pathological process and are of significant interest for the possibilities of modulating cell sensitivity to the proapoptotic and proinflammatory effects of cytokine and for futher development of targeted RA therapy.

INCREASED DNA DAMAGE AND LACK OF DNA REPAIR IN FIBROBLAST-LIKE SYNOVIOCYTES OF INDIVIDUALS AT RISK OF DEVELOPING RHEUMATOID ARTHRITIS

T. de Jong1,2, J. F. Semmelink1,2, R. A. Hoebe3, P. Krawczyk3, L. van Baarsen1,2.
1Amsterdam UMC, Academic Medical Center, Department of Rheumatology & Clinical Immunology, Department of Experimental Immunology, Amsterdam, Netherlands; 2Amsterdam Rheumatology & Immunology Center (ARC), Amsterdam UMC, Academic Medical Center, Amsterdam, Netherlands; 3Amsterdam UMC, Academic Medical Center and Cancer Center Amsterdam, Department of Medical Biology, Amsterdam, Netherlands

Background: Rheumatoid arthritis (RA) is a chronic inflammatory immune-mediated disease leading to synovial tissue inflammation and bone destruction. Inflammation-induced DNA damage in fibroblast-like synoviocytes (FLS) is thought to play an important role in RA pathogenesis. However, since a recent functional genomics study revealed a causal role for FLS in the genetic susceptibility of RA and synovial inflammation is absent in autoantibody positive individuals at risk for RA, we aimed to investigate whether DNA damage in FLS is present before onset of disease.

Objectives: Determine the extent of DNA damage in FLS and their capacity to repair this damage during the earliest phases of systemic autoimmunity.

Methods: We included individuals with arthralgia who were IgM rheumatoid factor (RF) and/or anti-citrullinated protein antibody (ACPA) positive but without any evidence of arthritis (RA-risk individuals, n=6), RA patients (n=6), osteoarthritis (OA) patients (n=6) and controls without inflammatory disease (n=8). Synovial tissue biopsies were collected either during joint surgery or induced arthroscopy using a mechanical synovial biopsy instrument. FLS were cultured from FLS in vitro expanded upon enzymatic synovial tissue digestion. DNA damage in FLS (passage 6) was assessed by immunofluorescence staining for γH2AX. DNA damage repair was assessed by first irradiating the cells with 1 gray to induce DNA damage and assessing γH2AX staining directly and after 3 and 24 hours of culture to allow for DNA repair.

Results: Preliminary immunofluorescence staining for γH2AX shows that DNA damage is present in RA-risk and RA FLS to more extent compared with FLS from non-inflammatory controls. OA FLS exhibit even more DNA damage and their nuclei show signs of impaired chromosomal segregation, forming micronuclei with high γH2AX staining intensity. Overall, DNA damage repair is slower in FLS from RA-risk individuals, RA and OA patients compared with controls as shown by persistent γH2AX staining after inducing DNA damage.

Conclusion: These findings reveal increased DNA damage and concomitant impaired DNA repair in FLS of not only patients with synovial inflammation but also in FLS from RA-risk individuals, suggesting that DNA damage is already present in absence of overt synovial tissue inflammation and before clinical
There is no clear consensus regarding the etiology of the hand deformity.

**Methods:** Iron content in synovial fluid was determined by colorimetry. Lipid peroxidation was assessed by flow cytometry and immunofluorescence. MDA and GSH were used as markers to assess ferroptosis. K/BxN spontaneous arthritis mice and serum-induced arthritis mice were used as in vivo animal models of ferroptosis.

**Results:** Iron overload and hyperlipid peroxidation of mononuclear-macrophages were found in the synovial fluid of RA patients. Liproxstatin-1, the specific inhibitor of ferroptosis, alleviated the progression of arthritis mice model by increasing M2-like macrophage numbers. Mechanistically, iron overload in arthritis lesion induced anti-inflammatory macrophage ferroptosis by promoting glutathione peroxidase 4 (GPX4, a classical anti-ferroptosis molecule) to undergo P62-dependent autophagy degradation.

**Conclusion:** Our results provide compelling evidence that macrophages ferroptosis plays a major role in RA. M2-like macrophages are more sensitive to ferroptosis than M1-like macrophages under iron overload circulation. This finding heavily contributes to the immune imbalance of rheumatoid arthritis.

**GPX4-ASSOCIATED FERROPTOSIS OF MACROPHAGE EXACERBATES IMMUNE IMBALANCE IN RHEUMATOID ARTHRITIS**

Y Liu1, Y. Jiang1, Y. Pan1.1 The Third Affiliated Hospital of Sun Yat-sen University, Rheumatology department, Guangzhou, China

**Background:** Reactive oxygen species accumulation and iron overload are involved in the pathogenesis of rheumatoid arthritis (RA). Ferroptosis, as a non-apoptotic form of programmed cell death, characteristically depends on iron and lipid peroxidation. However, the role of ferroptosis in RA has not been explored.

**Objectives:** To explore the role of ferroptosis in immune imbalance of rheumatoid arthritis.

**Methods:** Iron content in synovial fluid was determined by colorimetry. Lipid peroxidation was assessed by flow cytometry and immunofluorescence. MDA and GSH were used as markers to assess ferroptosis. K/BxN spontaneous arthritis mice and serum-induced arthritis mice were used as in vivo animal models of ferroptosis.

**Results:** Iron overload and hyperlipid peroxidation of mononuclear-macrophages were found in the synovial fluid of RA patients. Liproxstatin-1, the specific inhibitor of ferroptosis, alleviated the progression of arthritis mice model by increasing M2-like macrophage numbers. Mechanistically, iron overload in arthritis lesion induced anti-inflammatory macrophage ferroptosis by promoting glutathione peroxidase 4 (GPX4, a classical anti-ferroptosis molecule) to undergo P62-dependent autophagy degradation.

**Conclusion:** Our results provide compelling evidence that macrophages ferroptosis plays a major role in RA. M2-like macrophages are more sensitive to ferroptosis than M1-like macrophages under iron overload circulation. This finding heavily contributes to the immune imbalance of rheumatoid arthritis.

**SITE SPECIFICITY OF RHEUMATOID ARTHRITIS INFLAMMATION: A SECONDARY ANALYSIS OF BIOPSIES FROM RADIAL AND ULNAR ASPECTS OF MCP JOINTS**

K. Skovsgaard Itenov1, N. Seo2, E. M. Bartels1, H. Bliddal1, M. Andersen1.1 Copenhagen University Hospital, Parker Institute, Frederiksberg, Denmark; 2 Copenhagen University Hospital, Department of Hand Surgery, Gentofte, Denmark

**Background:** Ulnar drift is a common complication of Rheumatoid Arthritis (RA) (1,2). There is no clear consensus regarding the etiology of the hand deformity. Observations from corrective hand surgery and other studies have noted more pronounced inflammation in the radial side of the MCP-joints (3,4). This could partly explain the pathophysiology behind the ulnar deviation.

**Objectives:** To determine if there is more pronounced inflammation, measured by increased CD68 expression (5) and Krenn-synovitis score (6), at the radial side of the MCP joints when compared to the ulnar side, in patients with verified RA.

**Methods:** We included RA patients from a previous study who had biopsies taken from the most affected joints based on clinical examination and ultrasound (7). Twenty-nine PIIPs-, MCP- and wrist-joints were biopsied. Biopsies from the MCP-joints were taken from the dorso-ulnar and dorso-radial concavity. Inflammation was graded by the Krenn-synovitis score (0-9) and the density of CD68-positive cells (%). The difference between radial and ulnar joint inflammation was calculated by paired t-test. P-value <0.05 was considered statistically significant.

**Results:** In 8 patients biopsies were taken from both the ulnar and the radial side of the same MCP-joint. The mean difference in inflammation on the radial and ulnar site of MCP-joints was based on differences in CD68-density: 0.67% (95%-CI -4.77 to 6.10; P = 0.77) (Figure 1) and Krenn-score: 0.83 (95%-CI -1.31 to 2.98; P = 0.36), respectively.

**Conclusion:** There was no difference in concentration of inflammatory cells or overall synovial pathology between the radial and ulnar site of MCP-joints in RA patients. The impression of a more pronounced inflamed synovium on the radial site of MCP joints, as observed during surgery, does not seem to arise from an immunological preference, but rather to be linked to a larger synovial volume.

**AB0104 CHANGES IN SECRETION OF TH17 EFFECTOR CYTOKINES IN SYNOVIAL FLUID CELL CULTURES BY THE ATOPIC DERMATITIS BIOLOGIC DUPILUMAB (ANTI-IL-4 RECEPTOR ALPHA)**

M. P. Hundahl1, S. Lomholt1, T. W. Kragstrup3, 1Aarhus University, Institute of Biomedicine, Aarhus, Denmark

**Background:** Inflammatory arthritis and enthesis has been documented as adverse events in patients with atopic dermatitis treated with dupilumab targeting the interleukin 4 (IL-4) receptor alpha subunit (1,2). The disease mechanisms underlying atopic dermatitis are primarily driven by a substantiated Th2 response. Therefore, blockade of IL-4 and IL-13 signaling rationally inhibits Th2-mediated atopy. However, IL-4 and IL-13 are also well-known suppressors of Th17 cells. Therefore, we hypothesize that dupilumab-induced arthritis could be caused by increased production of Th17 effector cytokines.

**Objectives:** Here, we tested the effect of dupilumab on in vivo activated peripheral blood and synovial fluid mononuclear cells from patients with active inflammatory arthritis.

**Methods:** We used peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) from patients with immune mediated inflammatory arthritis (juvenile idiopathic arthritis, spondyloarthritis, polyarthritis, psoriatic arthritis, and arthritis with intestinal bowel disease (IBD), n=8). PBMCs and SFMCs were either unstimulated or stimulated with CD3/CD28 beads, and then cultured with three different concentrations of dupilumab (0.2 μg/mL, 1.0 μg/mL, or 5.0 μg/mL). Supernatants were analyzed by the two MSD Multi-Spot Assay System in the Proinflammatory Panel 1 (INF-γ, IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12p70, IL-13 and TNF-α) and the Th17 Panel 1 (IL-17A, IL-21, IL-22, IL-23, IL-27, IL-31 and CCL20). All data were transformed to ratios by dividing the value of the samples treated with dupilumab with the value of untreated samples. Data were then analyzed with repeated measures one-way ANOVA or the paired t-test depending on the number of groups. P-values <0.05 were considered statistically significant.

**Results:** In SFMCs not cultured with CD3/CD28 beads, dupilumab decreased the production of IL-17A, IL-22, CCL20 and IL-10 (P-values: 0.0007, 0.0002, 0.0025 and 0.0432 respectively). IL-1α was decreased by dupilumab in both PBMCs and SFMCs not cultured with CD3/CD28 beads (P-value = 0.013 and P-value = 0.001). The concentration of cytokines measured in supernatants from the PBMCs cultured without CD3/CD28 were low in both the Proinflammatory Panel and the Th17 panel. Interestingly, the response to increasing concentrations of dupilumab in PBMCs and SFMCs pre-conditioned with CD3/CD28 showed a biphasic curve. Thus, the low concentration of dupilumab (0.2 μg/mL) resulted in increased production of TNF-α, IL-1α, IL-1β, IL-4, IL-8, IL-10, IL-12p70, IL-13, IL-17A, IL-21, IL-22, IL-23, IL-27, IL-31 and CCL20. All data were transformed to ratios by dividing the value of the samples treated with dupilumab with the value of untreated samples. Data were then analyzed with repeated measures one-way ANOVA or the paired t-test depending on the number of groups. P-values <0.05 were considered statistically significant.

**Conclusion:** This data contradicts the hypothesis and indicates that dupilumab does not increase the production of Th17 related cytokines. However, the increase in proinflammatory cytokines seen with the low concentrations of dupilumab suggest that partial blockade of the IL-4 receptor alpha under some conditions could lead to augmented inflammation.

Holm Nielsen1,1 Nordic Bioscience A/S, Immunoscience, Herlev, Denmark; 2The University of Copenhagen, Faculty of Health and Medical Sciences, Clinical Medicine, Kopenhagen, Denmark; 3Nordic Bioscience A/S, Immunoscience, Herlev, Denmark; 4Gentofte Hospital, Orthopaedic Surgery Unit, Hellerup, Denmark

**Background:** Altered extracellular matrix (ECM) remodeling is a common event in rheumatic diseases. Type II collagen is the most abundant ECM protein in the cartilage and provides tensile elasticity and strength to enable support to the joints. Chondrocalcin, also known as the C-terminal propeptide of type II collagen, is among the most highly synthesized polypeptides in cartilage. It is cleaved off by BMP-1/C-endopeptidase during maturation and plays a role in assembly of type II collagen and in calcification of cartilage matrix. When cleaved off, the chondrocalcin fragments are released into circulation, where they can be quantified in a blood sample.

**Objectives:** This study aimed at developing an immunoassay targeting a neo-epitope of chondrocalcin, named CALC2. Moreover, we explored its biomarker potential to evaluate type II collagen formation in an ex vivo human osteoarthritis (OA) cartilage explant model (HEX) with anabolic treatment, and in serum from healthy controls, patients with rheumatoid arthritis (RA) and patients with ankylosing spondylitis (AS).

**Methods:** A novel direct immunoassay targeting the neo-epitope of type II collagen C-terminal (PIICP) was developed and technically validated. The technical validation included inter- and intra-variation, linearity, spiking recovery, stability, and specificity. Specificity of the monoclonal antibody was tested using an elongated peptide, a truncated peptide, and a non-sense peptide to exclude possible cross-reactivity. CALC2 levels were measured in supernatant from HEX cultured for 35 days in serum free DMEM/F12 medium with IGF-1 (Insulin-like Growth Factor-1) (100 ng/mL), including a control group without (i/o) treatment. The supernatant was harvested 3 times weekly and replaced with new culture medium. IGF-1 levels were confirmed by western blot. Serum samples from 18 healthy donors (mean age 35.8 ± SD 3.8, 100% Caucasian), 19 patients with AS (mean age 35.8 ± SD 3.2, 100% Caucasian) and 18 patients with RA (mean age 35.8 ± SD 3.4, 100% Caucasian) were also measured by CALC2. Linear regression models with pairwise comparisons were performed.

**Results:** A technically robust and specific assay was developed. The inter- and intra-assay variation of CALC2 was determined as 12% and 7% respectively. CALC2 showed a good dilution recovery, spiking recovery, and storage freeze-thaw stability (All, 100%±20%). CALC2 showed specificity towards the targeted sequence and did not show any reactivity towards the truncated peptide, elongation peptide, or non-sense peptide. CALC2 needlepeptide levels were significantly elevated after 14, 21 and 28 days of IGF-1 treatment compared to untreated (p<0.01, p<0.0001 p<0.001, respectively). The western blot confirmed the CALC2 results by the presence of a band of ~35kDa in all explants, corresponding to the weight of chondrocalcin previously established (1). Furthermore, the bands were more pronounced at day 21 in the IGF-1 treated explant compared to the untreated explant. CALC2 also showed significantly lower levels in patients with RA compared to controls (p=0.003; mean 0.32ng/mL ± SD 0.16 vs 0.64ng/mL ± SD 0.31).

**Conclusion:** Higher levels of CALC2 were detected in supernatants from explants after 14, 21 and 28 days of IGF-1 treatment compared to untreated. Lower levels of CALC2 were present in patients with RA compared to healthy controls. Overall, this suggests that CALC2 may have potential as biomarker for type II collagen formation. However, further preclinical and clinical studies are required to validate these findings.

Figure 1. CALC2 measurements in HEX model.

Objectives: To investigate the use of 18FDG μPET/CT as a guide for inflammation in joints otherwise inaccessible for clinical scoring, enabling the use of additional joints for histological analysis.

Methods: CAIA was induced in 8 male DBA/1 mice using the ArthritoMab Antibody cocktail (4mg/mouse on day 0), followed by 100 µg LPS at day 3. Body weight, clinical signs of arthritis such as paw swelling and grip strength loss were recorded 3 times per week in both front and hind paws. Whole body 18FDG μPET/CT was performed at day 11, the estimated time of peak inflammation, and inflammation was scored visually on images scaled to the same standardised uptake value. At day 28, animals were euthanized and peripheral joints were collected for histological analysis.

Results: Cumulative disease incidence based on paw swelling dropped from 100% to 87.5% when looking only at hind paws, and to 75% when taking into account only the region suitable for histological analysis, namely the ankle and midfoot of the hind paws. Symmetrical, bilateral hind paw arthritis was not observed. While hind paw arthritis showed a tendency to be less severe in comparison to front paw arthritis, grip strength was equally affected, indicating possible involvement of other hind limb joints. μPET/CT images detected inflammation in the hind paws (at least unilateral involvement in 62.5% of the mice, bilateral involvement in 0%), knee joints (at least unilateral in 75%, bilateral in 50%), hip joints (at least unilateral in 50%, bilateral in 0%), elbow joints (at least unilateral in 50%, bilateral in 37.5%) and shoulder joints (at least unilateral in 25%, bilateral in 25%). Histology could confirm this inflammation with the presence of inflammatory infiltrates and bone erosions. Grip strength loss in hind limbs without paw swelling correlated only weakly with knee inflammation detected by μPET/CT.

Conclusion: In the CAIA model, inflammatory arthritis can develop in all peripheral joints, in particular with a high incidence in knee joints, which are highly suitable for subsequent histological analysis. Since clinical scoring seems insufficient for detecting these affected joints, implementation of in vivo imaging modalities such as μPET/CT, offers a substantial benefit in disease monitoring and assessment.

AB0106 THE PATTERN OF JOINT INFLAMMATION IN THE CAIA MOUSE MODEL OF ARTHRITIS

M. Van Mechelen1,2, S. Hayer2, K. Van Laere4, R. Lories1,2, B. Neerinckx1,2 1KU Leuven, Laboratory of Tissue Homeostasis and Disease, Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, Leuven, Belgium; 2University Hospitals Leuven, Division of Rheumatology, Leuven, Belgium; 3Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Vienna, Austria; 4KU Leuven, Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, Leuven, Belgium

Background: Animal models of inflammatory arthritis such as the collagen-antibody induced arthritis (CAIA) have a variable disease incidence in hind paw arthritis, complicating experimental design.

Objectives: To evaluate the effect of SARS-CoV-2 infection on disease activity and bDMARDs responses in patients with PsA.

Methods: We performed a retrospective analysis including all the patients with PsA, meeting the CASPAR criteria and under biologic therapy, followed in the Rheumatology department of a tertiary university hospital. Demographic and clinical data, including occurrence of SARS-CoV-2 infection, were collected from our national database (reuma.pt). Disease activity (CDAI, SDAI, BASDAI, ACR and PsARC) responses were evaluated before and after SARS-CoV-2 infection. Statistical analysis was performed with SPSS. Continuous variables were compared through paired samples t-test.

Results: A total of 102 patients with PsA were included. Fifty-two were females (51%). The mean age was 53 ± 11.09 years and the median disease duration was 15 years [min 2, max 47]. Overall, 54 (53%) patients had predominant axial involvement, 26 (26%) peripheral and 36 (37%) enthesopathic. The most used bDMARD was etanercept [n=28, 27.5%] followed by adalimumab [n=22, 21.6%] and secukinumab [n=16, 15.7%]. The prevalence of SARS-CoV-2 infection was 15.7% (n=16). Fifty-three percent of infected patients experienced an increase in disease activity (+16.8±13.2, p=0.001) and 93% experienced an increase in clinical activity (+2.2±1.2, p<0.001). The number of patients unresponsive to bDMARDs (according EULAR, ACR and PsARC) before the infection wasn’t different from post-infection.

Conclusion: Our study suggests that SARS-CoV2 infection has no negative impact on PsA disease activity and bDMARD responses. However, more studies are needed to better understand the long-term effects of SARS-CoV2 infection.

AB0108 INFLAMMATION IN AXSPA AS A DISRUPTOR OF BONE METABOLISM – THE EFFECT OF PATIENTS’ SERA ON AN IN VITRO BONE MODEL

E. Sebova1, P. Skubicas1, M. Husakova1, P. Dankova1, 1Faculty of Science, Charles University, Department of Anthropology and Human Genetics, Prague, Czech Republic; 2Institute of Experimental Medicine CAS, Department of Tissue Engineering, Prague, Czech Republic; 3Institute of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic

Background: In axial spondyloarthritis (axSpA), two opposing processes of bone resorption and neogenesis are closely related, with a common denominator – chronic inflammation. This pathological condition affects osteoblasts, among other cells, residing in sites of inflamed tissue, but it can also activate mononuclear precursors in the blood to form osteoclasts [1,2]. To this day, it is not...
yet clear how the interplay between osteoblasts and osteoclasts affects pathogenesis of axSpA.

Objectives: The aim was to evaluate the effect of sera from patients with different forms of the disease, non-radiographic (nr-axSpA) and radiographic (r-axSpA) including ankylosing spondylitis, in comparison to the effect of sera from healthy individuals (axC) on osteoblasts and osteoclasts co-culture.

Methods: The immunological characterization for each diagnosis was simulated by age- and sex-matched pools of 12 nr-axSpA and 12 r-axSpA patients’ sera, healthy condition by a pool of 12 axC sera. We used THP-1 monocyctic cell line and SaOs-2 osteosarcoma cell line co-culture to model bone physiology. After THP-1 adhesion, SaOs-2-S2 cells were added with 10 % of nr-axSpA, r-axSpA or axC sera, respectively, in the media for 14 days. Activity of osteoblastic alkaline phosphatase (ALP) and osteoclastic enzymes tartrate-resistant acid phosphatase (TRAP), cathespin K (CTSK) and carbonic anhydrase II (CAII) on days (D) 1, 7, and 14 were measured. Simultaneously, we examined metabolic activity (MTS assay), cell proliferation (PicoGreen assay) and mRNA expression of selected genes in co-culture.

Results: In all three studied co-cultures the ALP activity increased with length of the cultivation; nevertheless, the onset of the activity in D1 was more rapid in axC sera compared to nr-axSpA (P<0.05) and r-axSpA (P<0.001). The ALP activity increase from D1 to D14 was 4.9 fold in axC, 5.7 fold in nr-axSpA and 6 fold in r-axSpA. Moreover, rise of ALP gene expression corresponds well with rise of ALP activity. TRAP activity peaked in all sera on D7 and decreased again towards D14, mirroring the same mRNA expression profile. The TRAP activity on D7 was highest in axC sera and lowest in r-axSpA (P<0.01). Gradual drop of CA II activity from D1 to D14 was detected in co-cultures with axC and nr-axSpA sera; in r-axSpA, however, the activity increased 1.4 times from D7 to D14 and was thus significantly higher on D 14 compared to cultures in other two sera (P<0.0001). In all cultures, CTSK activity increased from D7 to D14. Activity was highest in culture with axC sera (nr-axSpA D7 and D14 P<0.0001; r-axSpA D7 P<0.0001, D14 P<0.05). A gradual increase in cell proliferation was observed in axC sera and was thus significantly higher compared to both patients’ sera on D14 (P<0.0001). In contrast, the proliferation in patients’ sera peaked on D7 with the significantly highest D7 proliferation observed in r-axSpA (P<0.05). While the metabolic activity per cell followed U shape trend in all co-cultures, the changes were more distinct in patients’ sera: 2 fold drop in r-axSpA, 1.6 fold in nr-axSpA and 1.3 fold in axC sera on D7 followed by increase of 3.4 fold in r-axSpA, 2.9 fold in nr-axSpA and 1.8 fold in axC on D14.

Conclusion: Data acquired from the in vitro bone model point to an imbalance in the enzymatic activity of osteoclasts and to changes in the metabolic activity and proliferation of both, osteoblasts and osteoclasts. These changes seem to be caused by inflammatory agents in patients’ sera. However, the changes are not the same in both forms of disease, which may explain differences between nr- and r-axSpA symptoms.

INCREASED NEUTROPHIL FREQUENCY IN LYMPH NODES OF PATIENTS WITH PSORIATIC ARTHRITIS

A. M. O'Byrne1,2,3, J. W. Belt1,2, C. van Ansenwoud2,3, J. F. Semmeling1,2, M. Maas4, M. G. H. van de Sande1,2,3, L. van Baaren1,2,3
1Amsterdam University Medical Centre, Clinical Immunology and Rheumatology, Amsterdam, Netherlands; 2Amsterdam Rheumatology Centre, Amsterdam, Netherlands; 3Amsterdam University Medical Centre, Experimental Immunology, Amsterdam, Netherlands; 4Amsterdam University Medical Centre, Radiology, Amsterdam, Netherlands

Background: Increased presence of neutrophils in the skin1, synovium2,3, and entheses4 of patients with Psoriatic Arthritis (PsA) and their downregulation upon successful treatment2,5,6, suggests a role for neutrophils in PsA pathogenesis. As neutrophils have been implicated in Th17 differentiation, gaining insight in the presence and function of neutrophils within lymph nodes, which are the epicentre of T cell activation and differentiation, could be important in unravelling disease pathogenesis.

Objectives: We hypothesize that activated neutrophils migrate from inflamed peripheral tissues to lymph nodes, where they steer inflammation by interaction with tissue resident cells and immune cells, ultimately resulting in activation of IL-17 producing T cells. To investigate this, we studied the presence of neutrophils in lymph node biopsies of patients with inflammatory arthritis, including PsA, and compared their frequencies to controls.

Methods: Ten PsA patients, 34 seropositive individuals at risk of developing rheumatoid arthritis (RA-risk), 26 ACPA- RA patients and 10 healthy controls (HC) underwent ultrasound-guided inguinal lymph node biopsy. These bio-banked biopsies were analysed using qPCR and immunohistochemistry. Flow cytometry on fresh biopsies was used to determine cell frequencies in six active PsA patients (defined as arthritis in ≥1 joint) and two RA-risk individuals.

Results: qPCR analyses showed significantly increased mRNA levels of Cathepsin G (CTSG), which is highly expressed by neutrophils, in PsA patients compared to HC (p = 0.020). Immunohistochemistry showed that the neutrophil marker CD15 is significantly increased in PsA patients compared to HC (p = 0.008). Preliminary flow cytometry analyses indicates a clear population of CD45+CD16+CD66b+ neutrophils in lymph node biopsies of PsA patients while this was not observed in RA-risk individuals.

Conclusion: Overall, we show for the first time an increased presence of neutrophils in lymph nodes of PsA patients when compared to controls. Future studies are needed to investigate their functional role in immunoregulation within lymph node organs.

References:

Acknowledgements: We would like to thank all participating patients and Tom de Groot for his expertise in evaluating neutrophils by flow cytometry.

TRANSCRIPTOMICS-BASED INVESTIGATION OF THE MECHANISM OF ANKYLOSING SPONDYLITIS WITH UVEITIS

H. Hai1, H. Li1, B. Deng1, 2Sichuan Provincial People's Hospital, Department of Rheumatology and Immunology, Cheng Du Shi, China; 3Sichuan Provincial People's Hospital, Department of Health Management, Cheng Du Shi, China; 4Sichuan Provincial People's Hospital, Department of Ophthalmology, Cheng Du Shi, China

Background: Spondyloarthritis is a large group of autoimmune diseases that are associated with HLA-B27. Among them, Ankylosing spondylitis is a typical representative of these diseases. In addition to spine and joint involvement, AS has many extra-articular manifestations, among which uveitis is one of the most common. Several particular manifestations of AS[1]Untreated or inappropriate treatment can lead to serious consequences such as blindness. However, there are few studies on the mechanisms of AS-related uveitis, and the pathogenesis of AS-related uveitis is not fully understood, so there is no way to prevent it.

Objectives: We performed a whole-blood gene expression profiling and then analyzed gene expression differences between AS-associated uveitis patients and normal controls by bioinformatics analysis. Protein–protein interaction network was constructed to predict the relationship among the products of the differentially expression genes (DEGs). Furthermore, module mining and function
annotation were applied to assess the interaction network of DEGs. The aim is to find predictive biomarkers for AS-associated uveitis, to further discuss the pathogenesis of AS-associated uveitis in depth, and to provide a reference for clinical precision treatment.

Methods: This microarray-based discovery study used samples from three patients with AS, classified according to the New York criteria, four patients with AS-associated uveitis, and three gender- and age-matched controls. Total RNA was extracted from whole blood samples and enriched for mRNA after DNA digestion using DNase, and then constructed cDNA libraries were quality-checked with an Agilent 2100 Bioanalyzer and sequenced using an Illumina HiSeq TM 2500 sequencer. The data were normalized and initially screened for differential genes using the DESeq R package in R 4.1.0 Prediction of relationships between products of differentially expressed genes (DEGs) using String database prediction and construction of protein-protein interaction networks in Cytoscape. GO with KEGG analysis of differential genes using ClueGO and CluePedia. Screening for hub genes associated with AS-associated uveitis using cytoHubba.

Results: We initially screened 14607 differential genes, from which 112 significantly differential genes with p-values<0.05 and |log2FC|>2 were selected. Among them, 82 were up-regulated genes and 30 were down-regulated genes. Sixty-six relationships between 49 nodes were shown in the PPI network interaction graphs constructed from the String database results. The results of GO analysis showed that most genes were involved in biological processes related to immune response, such as positive regulation of inflammatory response, integrated stress response signaling and toll-like receptor 4 signaling pathway. The molecular functions were mainly focused on chemokine receptor binding, the results of KEGG analysis showed that the gene products were mainly involved in cytokine-cytokine receptor interaction, IL-17 signaling pathway. The target genes screened included CXCL8 CXCL2 NFKBIZ NFKBIA IL11 IL1A, all of which have adequate immune response effects (Figure 1).

Figure 1. Using the EPC algorithm in cytohubba to screen hub genes, the graph shows the top 10 scoring genes, with different colors representing higher scores.

Conclusion: We have identified a series of genes associated with immunity in this study. These DEGs may provide a basis for insights into the pathogenesis of AS-associated uveitis. Further experimental studies are needed to confirm our hypothesis.

AB0111  EFFECT OF TOFACITINIB AND GLUCOCORTICOIDS ON INTESTINAL PERMEABILITY, EPITHELIAL DAMAGE AND BACTERIAL TRANSLOCATION IN RAT ADJUVANT-INDUCED ARTHRITIS

S. Heucuet1,2, P. Totozon3, M. Tournier2, C. Prat3, D. Wendling1,2, C. Demougeot2, F. Verhoeven1,2, 1Centre hospitalier régional universitaire de Besançon, Rheumatology, Besançon, France; 2University of Franche-Comté, UR 4267 PEPITE, Besançon, France; 3University of Franche-Comté, UR 4266 EPILAB, Besançon, France

Background: Growing evidence indicated that the intestine is not only a target but also an actor of the pathogenesis in chronic inflammatory rheumatic diseases (CIRD). Consistently, increased intestinal permeability (IP) and damage (ID) as well as bacterial translocation (BT) have been described in patients with CIRD. However, the effects of treatments used in patients with CIRD on gut health are unknown.

Objectives: To determine the effect of glucocorticoids (GCs) and tofacitinib on IP, ID and BT in rats with adjuvant-induced arthritis (AIA).

Methods: AIA was induced in 6-week-old male Lewis rats by a tail injection of Mycobacterium butyricum in incomplete Freund's adjuvant. At onset of arthritis, rats were treated daily with prednisolone at low (0.1 mg/kg/day, i.p.) or high dose (10 mg/kg/day, i.p.), or with Tofacitinib (10 mg/kg twice a day, s.c.) or with vehicle. After 21 days, IP, ID and BT were assessed by measurement of plasma levels of zonulin, intestinal Fatty Acid Binding Protein (iFABP) and serum levels of soluble CD14 (sCD14) by ELISA, respectively. Arthritis severity was daily evaluated through the determination of an arthritis score.

Results: Compared to vehicle, Tofacitinib and high-dose of GC both reduced arthritis score (p<0.001) and levels of sCD14 (-44%, p<0.001 and -41% p<0.001 respectively) in AIA. High dose of GC decreased iFABP (-17%, p<0.05) levels but had no effect on zonulin levels. Tofacitinib did change nor iFABP neither zonulin levels. As compared to vehicle, the low-dose of GC had no effect on arthritis severity, sCD14, iFABP and zonulin plasma levels.

Conclusion: Prednisolone at a dose efficient on arthritis did not worsen but on the contrary reduced intestinal bacterial translocation and epithelial damage. These results are consistent with the positive effects of GCs on intestinal dysbiosis observed in case of sepsis or colitis. The lack of efficacy of the sub-therapeutic dosage of prednisolone suggested that effects of GC are, at least partly, related to their anti-inflammatory effects. Consistent with the positive effect of jakinibs in patients with inflammatory bowel disease, Tofacitinib blunted intestinal bacterial translocation in AIA. Given the suspected pathophysiological link between bacterial translocation and arthritis, our results identified a new mechanistic involvement in the positive effects of GC and tofacitinib in arthritis diseases.

AB0112  DECOY RECEPTOR 3 AND ITS SIGNAL PATHWAY CONTRIBUTE TO PATHOGENESIS IN ANKYLOSING SPONDYLITIS

Y. Jiang1, S. B. Wang1, X. Liao1, Y. X. He1, Y. F. Qing1 on behalf of Institute of Research Center of Gout and Hyperuricemia of the Affiliated Hospital, North Sichuan Medical College. 1Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology, Nanchong, China

Background: Ankylosing spondylitis (AS) is a chronic progressive disease with invasion of spine and sacroiliac joint as the main clinical manifestation, which can be combined with systemic inflammation or abnormalities in multiple parts at the same time. There are complex changes of immune function in patients with AS, and its immune and genetic pathogenesis is still unclear. Decoy receptor 3 (DcR3), as a new immune molecule discovered in recent years, plays an important role in regulating T cell activation, proliferation, differentiation and apoptosis. Studies have confirmed that DcR3 is involved in the immune disorder process of rheumatoid arthritis, SLE, AS and other autoimmune diseases, so that the role of DcR3 in AS has attracted attention. However, the expression of DcR3 related pathway genes[1-3] and studies evaluating the DcR3 related pathway genes in AS are scarce.

Objectives: To assess the contribution of DcR3 and its signal pathway to AS and the clinical importance of these genes in AS.

Methods: The mRNA expression levels of DcR3 and its signal pathway(DcR3, T-L1A, Fas, Fasl, Ligh, LighR, LTgRNA expressed in peripheral blood mononuclear cells (PBMCs) from 50 AS patients and 50 healthy subjects. The relationship between DcR3 related molecular pathway expression and laboratory features was analyzed in AS patients.

Results: The expression levels of DcR3, DR3, Fas, Light were much lower in the AS group than in the HC groups (p<0.05 [a,b,c,d]), and the expression levels of LT The relationship between DcR3 related molecular pathway expression

Disclosure of Interests: None declared

Conclusion: Compared with HC group, DCR3 and its signal pathway in PBMCs of AS patients are differentially expressed. It is speculated that DcR3 related molecular pathway gene may be involved in the pathogenesis of AS.

Figure 1. Relative Expression of DcR3 related molecular pathway gene in the PBMCs of Patients. The mRNA levels in PBMCs from AS patients (n=50) and HC (n=50) were measured by RT-qPCR. The expression levels of DCR3, DcR1, Fas, Light were much lower in the AS group than in the HC group in (p<0.05)(a,b,c,d), and the expression levels of LT were much higher in the AS group than in the HC groups in (p>0.05)(e).

AB0013 A MINIMAL-INVASIVE METHOD TO RETRIEVE AND IDENTIFY ENTHESEL TISSUE FROM PSORIATIC ARTHRITIS PATIENTS

M. G. Raimondo1, 2, M. Pachowsky1, 2, C. Xu1, 2, S. Rauber1, 2, K. Tasciliar1, 2, H. Labinsky1, 2, A. Soare1, 2, D. Simon1, 2, A. Kleyer1, 2, G. Schett1, 2, A. Ramming1, 2

1Friedrich-Alexander-University (FAU) Erlangen-Nürnberg, Department of Clinical Immunology, Translational Immunology, Erlangen, Germany; 2Friedrich-Alexander-University Erlangen-Nuremberg and Universitätsklinikum Erlangen, Deutsches Zentrum Immuntherapie, Erlangen, Germany; 3Friedrich Alexander University Erlangen-Nürnberg, Institute of Functional and Clinical Anatomy, Erlangen, Germany

Background: Entheses represent a hallmark feature of spondyloarthritides, including psoriatic arthritis (PsA). So far, most of the data on entheseal tissue in PsA are based on clinical assessment of tenderness as well as MRI or ultrasound examinations. These approaches, however, do not allow molecular analysis of entheseal tissue, which will require acquisition of entheseal tissue. Up today, it is unknown, which entheseal structure in humans would qualify for a feasible biopsy and how correct sampling of entheseal structures could be ascertained within such biopsy material. These technical challenges have led to substantial lack of knowledge on human entheseal tissue.

Objectives: To establish a minimally invasive biopsy technique of human entheses for the analysis of entheseal tissue in patients with PsA.

Methods: Human cadavers were used for establishing the technique to retrieve tissue from the lateral humeral epicondyle enthesis (cadiaveric biopsies). After biopsy, the entire entheses were surgically resected (cadaveric resections). Biopsies and resections were assessed by label-free second-harmonic-generation (SHG) microscopy. The same biopsy technique was then applied in PsA patients with subsequent definition of entheseal tissue by SHG.

Results: Enthoseal biopsies were performed in five cadavers and allowed the retrieval of entheseal tissue, validated by analysis of the resection material. Thus, microscopy of biopsy and resection sections allowed differentiation of entheseal, tendon and muscle tissue by SHG and definition of specific intensity thresholds for entheseal tissue. The same method was then successfully applied to 10 PsA patients. Hence, the fraction of entheseal tissue within the PsA biopsy specimens was high (65%) and comparable to the fraction retrieved in cadaveric biopsies (68%) as assessed by SHG microscopy.

Conclusion: Enthoseal biopsy of the tendon plate of the lateral epicondyle is feasible in PsA patients allowing reliable retrieval of entheseal tissue and its identification by SHG microscopy.

AB0114 IMPROVEMENT OF GUT MICROBIOTA DYSBIOSIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AFTER ONE YEAR OF BIOLOGICAL TREATMENT

V. Rios Rodriguez1, M. Essex2, J. Rademacher1, M. Torgultalp1, F. Proft1, U. Lobser2, L. Marquet1, D. Poddubnyy1, 2, 3, 4, 5, S. Forslund3, 4, 6, EMBL Heidelberg, Structural and Computational Biology Unit, Heidelberg, Germany

Background: Emerging evidence suggests that dysbiosis of the gut microbiota is involved in the initiation and perpetuation of spondyloarthritides (SpA). Biological disease-modifying antirheumatic drugs (bDMARDs) are a successful treatment to improve symptoms and reduce structural damage occurring in SpA; however, non-responders are frequent and few predictive factors for clinical response have been identified. Whether or not a patient responds to treatment could be related to gut microbiota composition.

Objectives: To investigate the gut microbiota changes in patients with radiographic axial SpA (r-axSpA) after receiving one year of treatment with bDMARDs and identify potential microbial biomarkers predictive of treatment response.

Methods: Patients with r-axSpA were recruited between 2015 and 2019 in an extension of the prospective GERman SPondyloarthritides IncoHent GEnetics (GES- PIC) before beginning bDMARD therapy. All patients had high disease activity (BASDAI >=4 and/ or ASDAS >=2.1) despite previous treatment with nonsteroidal anti-inflammatory drugs, and had not received treatment with bDMARDs for at least three months before enrollment in the study. The choice of bDMARD was left to the discretion of the clinical rheumatologists in accordance with standard practice. Disease activity measures (BASDAI, CRP and ASDAS) and fecal samples were assessed at baseline prior to treatment and after one year of treatment. Patients with back pain negative for inflammatory disease served as a control group. Microbiota composition was determined by 16S rRNA gene sequencing, followed by taxonomic profiling with the SILVA138 database. Response to bDMARD therapy was defined as a clinically important improvement of ASDAS (>=1).

Results: A total of 99 patients with r-axSpA and 63 control individuals were included based on the availability of clinical and microbiome samples. Average age (mean±SD) was 36.4±10.4 years and 64 patients were males. The prevalence of HLA-B27 was 89.9% among r-axSpA patients compared to 7.9% among control individuals. Simpson indices showed an increase in alpha diversity between baseline and year 1 in r-axSpA patients which was statistically insignificant (paired Wilcoxon p=0.154) but brought the r-axSpA cohort nearer to controls. Likewise, Bray-Curtis dissimilarities to measure beta diversity showed a qualitative normalization to healthy individuals after treatment when visualized in principal coordinate space.

At the genus level, patients were mainly depleted in Lachnospiraceae such as Blautia, Roseburia, and Fusicolabacter and enriched in Collinsella compared to the control group at baseline. After one year of treatment, most SpA patients exhibited increased abundances of these taxa, most notably Blautia. Patients also exhibited depletions in Bacteroides and...
Faecalibacterium, which was strongly enriched in HLA-B27+ individuals at baseline (adjusted Wilcoxon p<0.001). Collinsella showed a very slight median increase after one year of treatment, with no significant difference between responders and non-responders (adjusted Wilcoxon p=0.33). Shifts in highly abundant Prevotella and Bacteroides were strongly correlated with the change in ASDAS after one year when controlling for intra-individual variance and overall changes in alpha diversity.

Conclusion: The gut microbiota composition of r-axSpA patients who underwent treatment with bDMARDs for one year more closely resembled the controls. The unique enrichment of Collinsella in r-axSpA patients remained stable across time and treatment, suggesting it may be a disease biomarker.

ABO116 NEW INFLAMMATORY MARKERS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

K. Nurbava1,2, T. Reshetnyak1,2, F. Chedidova1,2, M. Cherkascova3, E. Samarkina1, A. Lila1,2,1 V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; 2-Russian Medical Academy of Continuing Professional Education of the Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation

Background: Thromboinflammation is a pathological process that is associated with uncontrolled inflammation, leading to hypercoagulability and thrombotic complications. Systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) are prototypical chronic thromboinflammatory diseases. Neutrophils are important cells in the development of systemic inflammation and thrombosis. Neutrophil reactivity (NEUT-RI), neutrophil granularity (NEUT-GI), immature granulocytes (IG), and neutrophil-to-lymphocyte ratio (NLR) are considered as inflammatory markers.

Objectives: To determine the role of parameters of neutrophil activation (NEUT-RI, NEUT-GI), immature granulocytes (absolute IG#, relative IG% counts), NLR, ESR in assessing inflammation in SLE, primary APS (PAPS), and SLE with APS.

Methods: The study included 80 patients and 40 healthy donors (HD). Patients were classified into three groups: Group 1 included 37 patients with SLE. The median age of patients with SLE was 34 years [28-43]. Group 2 included 20 patients with SLE+ APS (45 years [37-49]). Group 3 included 23 patients with PAPS (38 years [34,5-47,5]). Current disease activity was evaluated with SLEDAI-2K and adjusted GAPSS (aGAPSS).

A complete blood count (WBC-white blood cell, NEUTI-absolute neutrophil count, NEUT-RI, NEUT-GI, IG5, IG count, NLR, thrombocytes, ESR-erythrocyte sedimentation rate) was performed with XN-1000 automated hematolgy analyzer (Sysmex, Japan).

Results: Patient characteristics are shown in Table 1. IG# and IG% levels were significantly increased in patients with SLE and SLE+APS compared to controls and PAPS. ESR levels was significantly higher in patients with SLE, SLE+APS, and PAPS compared to HD. There was no significant difference between NEUT-RI, NEUT-GI, NLR, fibrinogen and CRP levels in patients with SLE, SLE+APS, and PAPS.

Correlation was found between the IgG and aGAPPS values.

The study was performed at V.A. Nasonova Research Institute of Rheumatology, within the framework of the fundamental research FURS-2022-003.

AB0118 IMMUNE CELL IMBALANCES IN PLACENTAS OF SYSTEMIC LUPUS ERYTHEMATOSUS AND SJÖGREN’S SYNDROME PATIENTS

J. L. Fierro1, G. M. Verstappen2, J. R. Prins3, J. W. Westra4, H. Boomsma4, K. de Leeuw1
1On behalf of Rheumatology and Clinical Immunology, 2University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 3University Medical Center Groningen, Obstetrics and Gynecology, Groningen, Netherlands

Background: Systemic lupus erythematosus (SLE) and primary Sjögren’s syndrome (pSS) are associated with adverse pregnancy outcomes (APOs) [1,2]. During pregnancy, maternal immune activation is related to a higher risk of hypertension, preeclampsia, preterm labor, and fetal growth restriction in SLE patients [1,2]. Furthermore, these patients have an increased risk of neonatal lupus due to the transplacental passage of maternal anti-RO/SSA antibodies to the fetus [3]. Nevertheless, there is no compelling evidence about the type of immune cell imbalances in the placenta in patients with SLE and pSS.

Objectives: Identify immunologic imbalances, focusing on interferon (IFN) and immune cell subtypes in placenta tissue of patients with SLE or pSS.

Methods: Retrospective analysis of immune cell composition of paraffin-embedded placental tissue from 6 SLE, 4 pSS, and 12 healthy women was conducted. For each case, one full-thickness sample of normal-appearing parenchyma from the central two-thirds of the placental disc was taken. APOs history and pregnancy outcomes were recorded. Placenta immunohistochemistry stainings were performed for myxovirus resistance protein A (MxA, an interferon induced protein), CD20, CD68, CD3, CD45, and Biotecnology Charles Darwin, Roma, Italy;

F. Ceccarelli1, M. Saccucio2, F. Nataleucci3, G. Olivieri1, E. Bruni2, R. Iacono2, T. Colantoni3, G. Di Carlo3, C. Alessandri1, D. Uccellletti3, F. Russo2, A. Pilloni2, F. Conti1, A. Polimeni1, 1Sapienza Università di Roma, Reumatologia, Dipartimento di Scienze Cliniche, AnestesioLogiche e Cardiovascolari, Roma, Italy; 2Sapienza Università di Roma, Department of Oral and Maxillofacial Science, Roma, Italy; 3Sapienza Università di Roma, Department of Biotechnology and Biotecnology Charles Darwin, Roma, Italy

Background: Several data have demonstrated the occurrence of erosive arthritis in Systemic Lupus Erythematosus (SLE) patients. However, few studies have focused on the pathogenic mechanisms involved in this feature. The implication of oral pathogens has been proved in Rheumatoid Arthritis: in particular, Porphyromonas gingivalis (Pg), by inducing citrullination, could trigger autoimmune response.

Objectives: We evaluated amount of Pg in the tongue of a cohort of SLE patients with arthritis, focusing on the association with the erosive phenotype.

Methods: SLE patients with arthritis were enrolled. We evaluated the presence of ACPA and RF by using commercially enzyme-linked immunosorbant assay kits. SLEDAI-2k was applied to assess disease activity and DAS28 to assess erosive arthritis in SLE.

P71052 ORAL PATHOGENS AND THE NERVOUS SYSTEM: CLINICAL MANIFESTATIONS AND LABORATORY EVIDENCE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

B. Mattoli1, N. Orchardi1, E. Deidda1, L. Cattaneo2, A. Fridda1, C. Doria1, G. Bottaro1,1Sapienza Università di Roma, Reumatologia, Dipartimento di Scienze Cliniche, AnestesioLogiche e Cardiovascolari, Roma, Italy; 2Sapienza Università di Roma, Department of Oral and Maxillofacial Science, Roma, Italy

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease that affects multiple organs, including the central nervous system (CNS). Several studies have demonstrated that oral pathogens, such as Porphyromonas gingivalis (Pg), could play a role in the pathogenesis of neuropsychiatric manifestations in SLE. The aim of this study was to assess the association between oral pathogens and CNS manifestations in SLE patients.

Objectives: We evaluated the presence of ACPA and RF by using commercially enzyme-linked immunosorbant assay kits. SLEDAI-2k was applied to assess disease activity and DAS28 to assess erosive arthritis in SLE.
joint inflammatory status. Erosive damage was evaluated by ultrasound at level of metacarpophalangeal and proximal interphalangeal joints. All subjects underwent a tongue cytologic swab in order to quantify the amount of Pg (real-time PCR). The bacterium expression was obtained from the ratio between the patient’s DNA amount and that obtained from healthy subjects.

Results: The present analysis included 33 SLE patients (M/F 3/30; median age 47 years, IQR 17; median disease duration 216 months, IQR 180). Concerning activity at the time of the enrollment, we found a median DAS28 value of 3.8 (IQR 2.8) and a median SLEDAI-2k of 4 (IQR 5). Twelve patients (36.4%) showed US-detected erosive damage in at least one joint, significantly associated with ACPA positivity (p=0.0001). Furthermore, patients with erosive damage showed significantly higher median DAS28 values in comparison with those without [4 (IQR 3.1) versus 3.2 (IQR 2.1), p=0.03]. Moving on the oral pathogen analysis, we found a mean Pg ratio of 19.7±31.1 (median 6.6, IQR 22.3). When dividing patients according to the presence of erosive damage, we found higher Pg amount in SLE patients with this phenotype in comparison with those without (31.4±44.3 versus 12.9±19.2, p=ns; Figure 1A). Thus, we used Pg mean values as threshold, identifying two groups of patients, namely highPg and lowPg. In a receiver operating characteristic curve analysis (ROC), this threshold resulted in the most sensitive and specific one (sensitivity of 85%; specificity of 50%). As reported in Figure 1B, erosive damage was significantly more frequent in highPg patients in comparison with lowPg (60.0% versus 26.0%, p=0.001). Furthermore, highPg patients showed higher prevalence of skin manifestations, serositis and neurological involvement compared to lowPg patients (p=0.005, p=0.03, p=0.0001, respectively).

Conclusion: The possible contribution of oral microbiota in SLE erosive arthritis was here evaluated for the first time, finding a significant association between erosive damage and higher expression of Pg at tongue level.

AB0119

ROLE OF COSTIMULATORY MOLECULES IN SYSTEMIC LUPUS ERYTHEMATOSUS: FOCUS ON CD137

F. Natalucci1, A. Di Filippo2, F. Ceccarelli3, I. Zizzari4, G. Olivieri1, V. Orefo1, C. Pirone1, F. R. Spinel1i, C. Alessandri1, M. Nunt2, F. Conti1.1 “Sapienza” University of Rome, Policlinico Umberto I, Lupus Clinic, Rheumatology Unit, Department of Clinical, Internal, Anaesthesiological and Cardiovascular Science, Roma, Italy; 2 “Sapienza” University of Rome, Policlinico Umberto I, Laboratory of Tumour Immunology and Cell Therapy, Department of Experimental Medicine, Roma, Italy

Background: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease characterized by a wide autoantibodies production. The traditionally concept of a B-cell driven disease has been changed in the last years due to time evidence demonstrating the crucial role of T cells in SLE pathogenesis. In particular, regulatory (Treg) and memory T cells seem act through co-stimu-latory and co-inhibitory molecules, such as CD137, CD137L and CD80. The over-expression of these molecules on lymphocytes may contribute to immune system dysregulation.

Objectives: The primary objective of the present case-control study was to evaluate the over-expression of CD137, PD-1 and CTLA4 on T cell surface of SLE patients by using flow-cytometry. Secondly, we evaluated the percentage of Treg and memory T cells.

Methods: We enrolled patients SLE patients (2019 ACR/EULAR criteria) and sex/age-matched healthy subjects (HS). Demographic, clinical, and laboratory data were collected in a standardized computerized electronically filled form. Disease activity was assessed by SLEDAI-2k. Each subject underwent peripheral blood sample collection. By using flow-cytometry we evaluated the expression of FOXP3, CD137, PD-1 and CTLA4, CD45, CD25, CCR7 to determine the percentage of Treg and memory T cells.

Results: The present analysis included 21 SLE patients (M/F 1/20; median age 48 years [IQR 17], median disease duration 144 months [IQR 204]). The Treg percentage was significantly lower in SLE compared to HS [median 4.2 (IQR 0.32) versus 2.5 (IQR 2.44); p=0.001, Figure 1A]. Moving on effector Treg (eTreg), SLE patients with high disease activity (SLEDAI > 4) showed a significantly higher prevalence for these cells compared to patients with SLEDAI ≤ 4 [1.16 (IQR 0.51) versus 0.53 (IQR 0.8), p=0.014, Figure 1B]. Moreover, inverse correlation was found between eTreg percentage and SLEDAI-2k (p=0.029, r=-0.47 [CI 0.75 - 0.04]) Figure 1C). The evaluation of CD137 expression was significantly higher in SLE patients compared to HS on CD3+ cells [median 5.32 (IQR 6.11) versus 3.3 (IQR 1.7), p=0.001, Figure 1F]. On CD4+ cells, CD137 expression positively correlated with disease activity (p=0.0082, r=0.58 [CI 0.15-0.82]). Finally, when analysing memory T cells subpopulations, inverse correlation has been found between effector memory T cells (TEM, CD45RA-CCR7+) and SLEDAI-2k when considering CD3+ (p=0.029, r=-0.56 [CI 0.81 – 0.12]) and CD4+ cells (p=0.016, R=-0.54 [CI -0.80 – -0.1]). Of note, CD137 expression on T central memory cells (TCM, CD45RA-CCR7+) positively correlated with SLEDAI-2k [(p=0.019, r=-0.52 [CI 0.09 – 0.79]).

Conclusion: Our results suggest a possible role of CD137-CD137L axis in SLE pathogenesis. The stimulatory role of this molecule is indicated by the positive correlation between SLEDAI-2k values and surface expression of CD137. Moreover, inverse correlation between SLEDAI-2k and eTreg percentage suggests a possible Treg dysregulation in SLE.

Table 1. SLE cohort features

AB0120

to evaluate the changes in XOR activities in plasma, lysed white blood cells (WBC), and lysed red blood cells (RBC) of SLE patients.

Methods: Diagnosis of SLE was verified using the SLICC criteria (2012). Activities of XOR interconvertible forms, xanthine oxidase (XO) and xanthine dehydrogenase (XDH), were measured in plasma, lysed WBC and lysed RBC by the spectrophotometric method [3]. The enzymatic activities were expressed as nmol/min/ml and normalized to 1x10^6 cells/ml in lysed WBC, and to 1x10^6 cells/ml in lysed RBC. The results were expressed as Me (Q1; Q3). Statistical comparison tests were selected in accordance to the common guidelines. Differences were considered significant when p<0.05. Reference ranges were calculated as 95th percentile interval.

Results: 56 adult SLE patients (mean age 35 (31; 42) years; mean disease duration was 8 (5; 11) years) and 35 healthy individuals were enrolled in the study. Reference intervals of plasma XO and XDH activities were 2.29 – 4.31 and 5.92 – 9.97 nmol/min/ml, respectively. Reference intervals of plasma XO and XDH activities in lysed WBC were 11.11 – 31.33 and 18.62 – 39.65 nmol/min/ml, respectively. Reference intervals of XO and XDH activities in lysed RBC were 20.62 – 25.46 and 41.85 – 55.04 nmol/min/ml, respectively. Enzymatic activities of SLE patients were significantly different from healthy controls. Increased XO activity and decreased XDH activity were observed in plasma of SLE patients (p<0.001 for both enzymes). The activities of both XOR forms were decreased in lysed WBC (p<0.001 for both enzymes). Lysed RBC were characterized by a decrease in XO activity (p<0.001).

Conclusion: Significant changes in the balance of XO and XDH activities were revealed in plasma, lysed WBC and RBC of SLE patients. These enzymes can also exhibit NADH oxidase and nitrate reductase activities under conditions of low pH and hypoxia. Such conditions are formed in SLE due to the development of pronounced inflammation and microthrombosis in various tissues. Reactive forms of oxygen and nitrogen, which production is increased as a result of XOR activity, have a damaging effect on cellular structures, initiate the processes of lipid per-oxidation, participate in the stimulation of NF-kB, and contribute to the formation of neutrophil extracellular traps. It can be assumed that the imbalance of XOR enzymatic activities in WBC indicates the previous stages of purine metabolism disturbances, which leads to a change in functional state and death of these blood cells. Free radicals generated by the XO may have a damaging effect on RBC.

AB0122

to the expression of SLAMF7 in primary Sjogren’s syndrome (pSS).

Methods: SLAMF7 expression was studied using flow cytometry on different subpopulations (CD4 T cells, CD8 T cells, NK cells, plasma cells (CD19+ CD38+ CD27high) and naive (CD27-) or mature (CD27+) B cells before (IgD-) or after (IgD+) class switching in pSS patients and healthy donors (HD). SLAMF7 protein expression was measured by the difference in expression (condition with antibody recognizing SLAMF7 - condition without antibody) of the mean fluorescence intensity (delta MFI).

Results: The pSS cohort consisted of 18 patients (17 women). 71% of patients were anti-SSA+, 41% anti-SSB+, 44% had rheumatoid factors (RF). The median IgG level was 13.3 g/l (9.88-21.45). 8/18 patients had evidence of systemic activity (ESSDAI score >0). Twenty-one healthy donors (19 women) were used as controls. No overall difference in SLAMF7 expression was observed between pSS and healthy donors, or among pSS patients between patients with or without systemic complications. SLAMF7 expression was higher in patients with than in patients without autoantibodies or markers of B-cell activation.

1/ RF-positive patients had a higher expression of SLAMF7 than RF-negative patients by IgD- CD27+ B cells (median delta MFI: 397 for RF+ pSS vs 185 for RF- negative pSS [p=0.001] vs 187 [p<0.0001] for HD) and by IgD+ IgD- B cells (median delta MFI: 450 for RF+ pSS vs 307 for RF- negative pSS [p=0.005] vs 329 [p=0.001] for HD).

2/ Anti-SSA-positive patients had a higher expression of SLAMF7 than anti-SSA-negative patients by CD27+ IgD- B cells (median delta MFI: 346 for anti-SSA+ pSS vs 149 for anti-SSA-negative pSS [p=0.019] vs 187 [p=0.007] for HD) and by CD27+ IgD+ B cells (median delta MFI: 403 for anti-SSA+ pSS vs 264 for anti-SSA negative pSS [p=0.021] vs 329 [p=0.012] for HD). The same association with a higher expression of SLAMF7 was observed for anti-SSB.

Conclusion: SLAMF7 expression was correlated with IgG levels in pSS patients on IgD- CD27+ B cells (r=0.51, p=0.04).

IMPACT OF TOBACCO ON PRIMARY SJÖGREN SYNDROME: ANALYSIS OF THE FRENCH COHORT ASSESS

L. Pacoureau1, J. E. Gottenberg2, G. Nocturne1,3, E. Dernis4, M. Couderc5, J. E. Gottenberg2, G. Nocturne1,3, E. Dernis4, M. Couderc5, J. E. Gottenberg2, G. Nocturne1,3, E. Dernis4, M. Couderc5

Background: It has been shown that smoking could be negatively associated with the risk of developing primary Sjögren's Syndrome (pSS), and that amongst smoking pSS patients, seropositivity for anti SSA antibodies and frequency of focal sialadenitis were lower. However, data are scarce concerning the impact of smoking on disease activity, glandular features, patient reported outcomes (PROs) and disease progression.

Methods: A French prospective multicenter, longitudinal cohort involving 395 patients with pSS enrolled in 15 French centers between 2006 and 2009 and followed since then. In these patients, we compared baseline characteristics of smokers and non-smokers. After five years, no difference was observed, according to smoking status, in terms of change in disease activity or PROs.

Results: Smokers pSS patients are more likely to be men and younger than non-smokers. Ever smokers tended to have less dryness, and take less immunosuppressives. After five years, no difference was observed, according to smoking status, as well as no change in dryness (p = 0.968), pain (p = 0.280), fatigue (p = 0.605) or in UWSF (p = 0.192).

EFFECTS OF INHIBITOR K-CARRAGEENAN ON HAECs INFLAMMATORY RESPONSE TO LDLS ISOLATED FROM SLE PATIENTS

S. Parré1, A. Avila2, J. Rivalta3, M. Guardiola3, R. Rodríguez4, A. Castro1

1Hospital Universitari Sant Joan de Reus, Internal medicine. Autoimmune diseases units, Reus, Spain; 2Hospital Universitari Sant Joan de Reus, Pathology department, Reus, Spain; 3Rovira i Virgili University, Unitat de Recerca de Lípides i arteriosclerosis, Tarragona, Spain

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with a high risk of atherosclerosis and cardiovascular events. It was previously reported by our group that low-density lipoprotein (LDL) particles isolated from SLE patients, during an active state of the disease (‘flare’), promoted an exaggerated inflammatory response in human aortic endothelial cells (HAEcs). However, the molecular mechanisms underlying this response still remain elusive.

Objectives: The hypothesis of this study is that these SLE-LDLs would be using receptor LOX-1, associated with inflammatory conditions and altered lipopro- teins, to generate the proatherogenic response in HAEcs.

Methods: LOX-1 pharmacological inhibitor k-carrageenan was used before the stimulation of HAEcs with LDLs isolated from healthy controls (10), non-active (13), or active-SLE patients (13). Gene expression, protein, and cell migration assays were performed to evaluate HAEcs inflammatory response.

Results: LOX-1 inhibition with k-carrageenan significantly reduced the expression of vascular cell adhesion molecule 1 (VCAM-1) and restored the gene expression of endothelial nitric oxide synthase (eNOS) in HAEcs incubated with non-active SLE LDLs.

Conclusion: While VCAM-1 down-regulation was expected, the immediate next step derived from the observed results will be a deeper understanding of how LOX-1 inhibition may reduce the endothelial ability to synthesize NO in the presence

IL-25 PARTICIPATES IN KERATINOCYTE-DRIVEN DERMAL MATRIX TurnerOVER AND IS REDUCED IN SYSTEMIC SCLEROSIS (SSc) EPIDERMIS

B. Russo1,2, J. Borowczyk3, P. Cacialli4, P. Moquet1, M. E. Truchetet1, A. Modarresi6, N. Brembilla2, J. Bertrand3, W. H. Boehncke2, C. Chizzolini3.

1University of Geneva, Department of Medicine, Geneva, Switzerland; 2Hôpitaux Universitaires de Genève, Genève, Switzerland; 3University of Geneva, Department of Pathology and Immunology, Geneva, Switzerland; 4Ronon Hospital APHP, Department of Pathology, Paris, France; 5University Hospital, Department of Rheumatology, Bordeaux, Switzerland; 6Hôpitaux Universitaires de Genève, Plastic, reconstructive & aesthetic unit, Geneva, Switzerland

Background: Evidence shows that dysfunctional SSC keratinocytes contribute to fibrosis by altering dermal homeostasis (1, 2). Whether interleukin-25 (IL-25), an IL-17 family member regulating many epidermal functions (3), takes part in skin fibrosis is unknown.

Objectives: To investigate the role of IL-25 in skin homeostasis.

Methods: The expression of IL-25 was evaluated by immunofluorescence and in situ hybridization in 10 SSC and 7 healthy donors (HD) skin biopsies. Epidermal equivalents (EE) reconstituted by primary HD keratinocytes were used as a model to study transcriptomic changes induced by IL-25 in the epidermis. FRNA expression profile in EE was characterized by RNAseq. The conditioned medium (CM) from primary SSC and HD keratinocytes primed with IL-25 was used to stimulate fibroblasts. IL-6, IL-8, MMP-1, type-I collagen (col-I), and fibronectin production by fibroblasts was assessed by ELISA.

Results: SSc epidermis expressed lower levels of IL-25 compared to HD. In EE, IL-25 regulated several molecular pathways related to wound healing and extracellular matrix (ECM) remodeling. Compared to control CM, the CM from IL-25-primed keratinocytes enhanced the fibroblast production of MMP-1, IL-6, IL-8, but not of Col-I nor fibronectin. However, IL-25 significantly reduced the production of Col-I when applied directly to fibroblasts and partially inhibit a-smooth muscle actin (α-SMA) expression promoted by TGFβ. The activation of keratinocytes by IL-25 was receptor-dependent and evident after a very short incubation time (10min), largely mediated by IL-1, suggesting enhanced and specific release of preformed mediators.

Conclusion: These results show that IL-25 participates to skin homeostasis and its decreased expression in SSc may contribute to skin fibrosis by favoring ECM deposition over degradation.

BRONCHOALVEOLAR LAVAGE (BAL) FLUID AND SERUM FROM PATIENTS WITH SYSTEMIC SCLEROSIS WITH INTERSTITIAL LUNG DISEASE (SSC-ILD) PROMOTE A PRO-INFLAMMATORY GENE SIGNATURE IN HUMAN PRIMARY LUNG FIBROBLASTS

Y. Al-Adwy1, J. Westra2, A. J. Stefl2, H. van Goor3, D. J. Mulder1, 1University Medical Center Groningen, Internal Medicine (Vascular), Groningen, Netherlands; 2University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 3University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands

Background: While circulating cytokines are frequently investigated in SSC patients, they may also play a role in local tissue, such as the lungs. Although most SSC patients show limited systemic inflammation, some studies have demonstrated that BAL fluid obtained from patients with SSC contains elevated levels of pro-inflammatory and pro-fibrotic cytokines. However, the relevance of the local milieu of the bronchial tree on the development of ILD has not been studied. We hypothesized that the bronchial milieu as represented by BAL fluid will have pro-inflammatory and pro-fibrotic effects on lung fibroblasts as the major effector cells in lung fibrosis. We also anticipated a greater pro-inflammatory and pro-fibrotic effect of BAL fluid obtained from patients with ILD (SSc-ILD) compared to patients without ILD (SSc). Finally, we hypothesized that serum obtained from both SSc-ILD and SSC will have a similar and concordant effect on lung fibroblasts, due to the systemic nature of the disease.

Objectives: To show the differential effect of BAL fluid and serum obtained from SSc patients with and without ILD on mRNA expression of pro-inflammatory and pro-fibrotic markers in human primary lung fibroblasts.

Methods: Serum and BAL fluid were collected from 40 patients with SSC-ILD and 3 without ILD who were all treatment-naïve. ILD diagnosis was based on HRCT and lung function tests. Normal human primary lung fibroblasts were cultured and treated with either BAL fluid (5%) or serum (0.5%) from all individual patients. No treatment (CTRL) or treatment with pooled serum from healthy controls were used as control. After 4h, fibroblasts were harvested in TRIzol. The mRNA expression levels of inflammatory markers (interleukin-6, IL-6, interleukin-8, TNFα, interferon gamma-induced protein-10, IP-10), fibroblast markers (Connective Tissue Growth Factor: CTGF, Transforming Growth Factor: TGF-β1, and Alpha-Smooth Muscle Actin: α-SMA) were assessed using RT-qPCR. Nonparametric Mann-Whitney U test was used for comparison between groups. Correlation between BAL and serum treated fibroblast was calculated for the expression of the markers using Pearson correlation coefficient method.

Results: Fibroblasts treated with either SSc or SSc-ILD BAL fluids showed a significantly higher mRNA expression of IL-6 compared to CTRL (Figure 1 a). The same was observed for IP-10, except for SSc serum which was not significant (Figure 1 b). When comparing the effects of BAL fluid between SSc or SSc-ILD patients, the effect of SSc-ILD BAL fluid was strikingly more profound.
than observed with SSc on both IL-6 and IP-10 (Figure 1 a,b). Similar effects were seen when fibroblasts were treated with SSc serum, where serum from SSc-ILD resulted in significantly higher expression of IL-6 and IP-10 compared to SSc (Figure 1 a,b). The effect of serum and BAL on IL-6 gene expression were strongly and significantly correlated (r=0.9; P=0.015) while were weakly correlated regarding IP-10 expression (r=0.4; P=0.03) (not shown). The fibrotic markers TGF-β and α-SMA showed no difference in expression in BAL or serum-treated fibroblasts compared to controls (Figure 1 c,d). Only the fibroblasts treated with SSc-ILD serum showed a significant increase in mRNA expression of the early fibrosis marker CTGF when compared to control or SSc serum (Figure 1 e).

**Conclusion:** We showed a clear pro-inflammatory effect of BAL fluid obtained from patients with SSc on human fibroblasts as demonstrated by mRNA expression of IL-6 and IP-10. This pro-inflammatory effect was 5-10 times more profoundly observed in SSc patients with ILD compared to those without ILD. Similar effects were observed when fibroblasts were treated with serum obtained from the same SSc patients where the BAL fluid and serum of each patient seemed to provoke a concordant pro-inflammatory effect. Although further studies are warranted, our results underline the systemic nature of SSc and provide new insights into the role and interaction between the local bronchial and systemic milieu in ILD development.

**AB0128 IMMUNE RESPONSE GENE 1 (IRG1) IS DYSREGULATED IN SYSTEMIC SCLEROSIS**

S. O'Reilly1, 2Durham, Biosciences, Durham, United Kingdom

**Background:** Systemic sclerosis (SSc) is an autoimmune idiopathic connective tissue disease in which there is inflammation and fibrosis of the skin. The innate immune system is intrinsically linked in the disease. IRG1 is a gene that codes for an enzyme that is essentially to make itaconate a metabolite of the TCA cycle. Iaconate has recently been ascribed function in immunity by negatively regulating inflammation through mechanism that involve upregulation of nrf2 and possibly downregulation of nf-kb to act as a molecular rheostat to balance the positive and negative aspects of inflammation. IRG1 is known to be robustly upregulated in macrophages after LPS stimulation.

**Objectives:** To determine the expression of IRG1 in systemic sclerosis macrophages.

**Methods:** Early diffuse SSc patients (≤ 2 years from first non-Raynaud’s symptom) had blood drawn and monocytes were isolated on CD14 using MACS. Healthy controls blood was also taken and CD14+ monocytes were isolated. All female (6 donors each). After isolation cells were differentiated to macrophages using M-CSF for a set period. After which they were treated with ultrapure LPS for 18 hours. Cells were lysed and mRNA expression for IRG1 and Nqo1 was quantified by qPCR. Data is normalized to housekeeping gene 18S for normalization.

In some experiments macrophages were stimulated with the itaconate derivative 4 Octyl Iaconate (4OI) at 100 µM for 2 hours, then stimulated or not with LPS for a further 24 hours. IL-1β and IL-6 cytokines were measured by ELISA. Bleomycin mouse model of skin fibrosis was employed by repeated intra dermal injections of bleomycin or sodium chloride vehicle. Skin biopsies were taken in the lesioned skin and H&E performed and fibrosis markers by qPCR was analysed.

**Results:** Healthy monocytes in response to LPS stimulation robustly upregulated IRG1 expression but in comparison to SSc monocytes this upregulation was significantly attenuated (n=3). Pretreatment of SSc monocytes with the itaconate derivative 4OI prior to LPS stimulation led to significantly reduced IL-1β and IL-6 production.

The also led to upregulation of the nrf2 target gene Nqo1 6 fold compared to LPS treated alone. No difference in nf-kb was observed. mRNA expression of bleomycin skin found significantly downregulated nrf2 expression in association with elevated fibrosis markers compared to vehicle control treated mice (n=3 per group).

**Conclusion:** Failed upregulation of IRG1 in SSc macrophages may lead to a failure of inflammatory resolution and subsequent fibrosis. The itaconate derivative 4OI could be a possible anti-fibrotic through restoration of homeostasis via upregulation of nrf2 target genes.

**Disclosure of Interests:** Steven O'Reilly Employee of: I am employed by STipe therapeutics

INDUCTION OF COLLAGEN CHAIN FORMATION IN RESPONSE TO FIBROTIC FACTORS IN DERMAL AND PULMONARY FIBROBLASTS

S. F. Madsen1,2, P. Juhl3, J. M. B. Sand4, M. Karsdal5, A. C. Bay-Jensen4, C. Thudium1, University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark; 3Nordic Biosciences, Immunology, Herlev Denmark; 4Nordic Bioscience, Fibrosis, Herlev, Denmark; 5Nordic Bioscience, R&D, Herlev, Denmark

Background: Systemic sclerosis (SSc) patients who develop pulmonary fibrosis, have an increased mortality rate1. Excessively activated fibroblasts deposit extracellular matrix (ECM), which leads to fibrosis resulting in stiffening of the tissue in both skin and lung. Currently there is no cure for fibrosis in SSc, only drugs which can slow the fibrotic process, and there is therefore, a medical need for further understanding of the pathogenesis. Fibrosis is associated with growth factors, including tumor growth factor beta 1 (TGF-β1) and platelet derived growth factor-ab (PDGF-ab).

Objectives: We investigated how TGF-β1 and PDGF-ab stimulation affected the gene and protein expression of specific collagen chains of type I, III and VI collagen in primary healthy human dermal (DF) and pulmonary fibroblasts (PF).

Methods: The fibroblasts were grown in 0.4% fetal calf serum DMEM, ficol (to produce a crowded environment) and ascorbic acid for up to 12 days. They were stimulated with TGF-β1 [0.01 nM], PDGF-ab [3 nM] or a combination of TGF-β1 [0.01 nM] and PDGF-ab [3 nM], while non-stimulated fibroblasts served as control. ECM protein formation was assessed in supernatant from day 0, 4, 8, and 12, by ELISAs which detects the N-terminal of the pro-collagen of type I and III collagen, and the C5 domain of type III collagen. Gene expression was analyzed after 4 days and the relative gene expression was calculated based on multiple reference genes2. Statistical analysis includes one-way and two-way ANOVA.

Results: TGF-β1 increased the gene expression of Col1α1 in DF (p<0.0001) and Col1α2, Col3α1 and Col6α3 in both DF (p<0.01, p<0.001, p<0.05, respectively) and PF (p<0.0001) compared to control. PDGF-ab showed no difference in gene expression of the DF but decreased multiple genes in PF (p<0.01). The combination of TGF-β1 and PDGF-ab increased the gene expression of Col1α1 in DF (p<0.01), Col3α1 in PF (p<0.0001) Col1α2 and Col6α3 in both DF (p<0.05 and p<0.01) and PF (p<0.0001) compared to control. None of the stimulations lead to an increase in the Col6α2. The TGF-β1 induced gene expression corresponded with increased ECM formation of type I and VI collagen from day 4 (p<0.01), and type III collagen from day 8 (p<0.05) in both DF and PF. PDGF-ab stimulation led to an increased ECM formation of type I and VI collagen in both DF and PF (p<0.01), and type III collagen in DF (p<0.01). The combination stimulation with TGF-β1 and PDGF-ab induced a corresponding increase in both gene expression and ECM formation of type I and VI collagen in both DF and PF (p<0.01). While the combination increased the ECM formation of type III collagen in both fibroblasts types, the gene expression of Col3α1 were only increased in PF (p<0.0001).

Conclusion: This study demonstrates that TGF-β1 stimulation alone and in combination with PDGF-ab results in increased gene and protein expression of type I and VI collagen in both DF and PF, and additionally type III collagen in PF. However there was a disconnect between the gene and protein expression profiles after PDGF-ab stimulation, which have to be investigated further. This study may provide new insights to the differences between fibroblast of different origin and their response to fibrotic factors.

AB0132  STIMULATION OF SOLUBLE GUANYLATE CYCLASE (sGC) FOSTERS ANGIOGENESIS AND BLUNTS ENDOTHELIAL-TO-MESENCHYMAL TRANSITION (ENDOMT) OF SYSTEMIC SCLEROSIS (SSC) DERMAL MICROVASCULAR ENDOTHELIAL CELLS

E. Romano,1 I. Rosa,2 B. S. Fioretto,1 D. Giuggioli,2 M. Manetti,3 M. Matucci-Cerinic3,4 1University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy; 2University of Modena and Reggio Emilia, Sclerodermat Unit, Department of Medical and Surgical Sciences for Children and Adults, Modena, Italy; 3IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy

Background: In SSC, early abnormalities in microvessel morphology and angiogenic impairment in parallel advance with the development of tissue fibrosis orchestrated by myofibroblasts. Increasing evidence suggests that the EndoMT process, in which endothelial cells transdifferentiate into profibrotic myofibroblasts, may take centre stage in SSC pathogenesis [1,2]. sGC is an enzyme regulating cell growth/proliferation and vascular tone/remodelling by catalysing the production of cyclic guanosine monophosphate. Previous studies reported that sGC stimulation inhibits TGF-induced fibroblast-to-myofibroblast differentiation and collagen synthesis by blocking non-canonical ERK-dependent TGFβ signaling, and that sGC stimulators (sGCS) may exert antioxidant effects in experimental models of fibrotic disorders.

Objectives: To investigate the possible modulatory effects of sGC stimulation on impaired angiogenesis and EndoMT of SSC dermal microvascular endothelial cells (SSc-MVECs).

Methods: To evaluate the effects of treatment with sGC on endothelial cell viability/proliferation, 5 lines of SSc-MVECs and 5 lines of healthy dermal MVECs (H-MVECs) were challenged with sGCS (here MK-2947) and assayed with both annexin V/PI flow cytometry and WST-1. To analyse the modulation of angiogenesis by sGCS, SSc-MVECs were challenged with MK-2947 and subsequently tested for wound healing and capillary-like tube formation capabilities. To study the effects of MK-2947 on EndoMT, the same cells were assayed for the expression of endothelial and mesenchymal/myofibroblast markers by quantitative real-time PCR, western blotting and immunofluorescence, as well as for their contractile ability by collagen gel contraction assay. Phosphorylation of ERK1/2 was assayed by western blotting.

Results: Treatment with MK-2947 did not affect viability/proliferation of H-MVECs, while it significantly increased the proliferation of SSc-MVECs (p<0.001 vs. basal). Compared to basal condition, the MK-2947 challenge ameliorated both wound healing capability (p<0.001) and angiogenic performance (number of nodes: p<0.01; segments: p<0.001; meshes: p<0.01; and junctions: p<0.001) of SSc-MVECs. Upon stimulation of sGC, SSc-MVECs exhibited increased gene expression of proangiogenic matrix metalloproteinase (MMP)-9 (p<0.05) and decreased expression of both antiangiogenic MMP-12 (p<0.05) and pentraxin-3 (p<0.001) respect to basal SSc-MVECs. A significant increase in both gene and protein expression of the endothelial markers CD31 and VE-cadherin, and a par-allel decrease in the expression of the mesenchymal/myofibroblast markers - SMA, S100A4, and type I collagen were found in MK-2947-treated SSc-MVECs. MK-2947 also downregulated the EndoMT-driving transcription factor SNAIL1 in SSc-MVECs. Stimulation with MK-2947 was able to significantly counteract the intrinsic ability of myofibroblast-like SSc-MVECs to contract collagen gels (p<0.001) and effectively reduce phosphorylated-ERK1/2 protein levels (p<0.01) respect to basal cells.

Conclusion: Stimulation of sGC effectively ameliorates the angiogenic performance and blunts the pathogenic myofibroblast-like profibrotic phenotype of SSc-MVECs.

AB0133  TARGETING INFLAMMATION RESOLUTION IN SYSTEMIC SCLEROSIS: PRECLINICAL DATA OF A NEW DISEASE MODIFYING BIOLOGIC DRUG CANDIDATE RESOLVIX

F. Bonenfosi1, S. Perruche1, 1RIGHT Institut (UMR 1098) /MED’INN’Pharma, EFS B/FC, BESANCON, France; 1RIGHT Institut (UMR 1098) / MED’INN’Pharma, EFS B/FC, BESANCON, France

Background: Systemic sclerosis (SSc) is a complex immune-mediated connective tissue disorder characterized by microvascular damage, inflammatory cell infiltration, and excessive deposition of extracellular matrix proteins (ECMs) resulting in fibrosis in the skin and various internal organs. Limited treatment options are currently available in the clinic and are mostly focusing on symptom control with limited impact on disease progression. New treatment approaches are needed to address the complex dysregulated pathways and disease drivers to develop effective therapies. While the pathophysiology of SSc remains incompletely understood it is well-recognized that progressive chronic inflammation is a part of the disease and its progression. Accumulation of apoptotic cells in tissues and defective clearance of these cells contributing to unresolved tissue repair is emerging as a root cause leading to sustained uncontrolled chronic inflammation and fibrosis. Naturally-ending and resolving chronic inflammation to initiate healing and repair processes could present a novel therapeutic approach for SSc.

Resolvix, a next generation biological drug candidate under development, harnesses a complex mix of naturally occurring pro-resolutive factors emitted by human cells, has demonstrated promising disease modifying effects in models of experimental arthritis and inflammatory bowel disease.

Objectives: The objective of our preclinical study presented here, was to evaluate the potential therapeutic effects of Resolvix in experimental models of SSc.

Methods: Two established inducible preclinical models of SSc (bleomycin (BLM) and HOCl) were used to monitor the impact of Resolvix mouse equivalent versus a control treatment on skin (thickness and collagen deposition), lung (leucocyte infiltration and alveolar macrophage effectorcytosis) and lymphoid organs/blood (Tregs) as well as selected plasma proteins. A single treatment or respective controls were administrated intra-venously at 3 weeks post disease induction and mice were monitored daily and sacrificed for analysis after 3 weeks post treatment.

Results: In our hands both preclinical models clearly show phenotypes associ-ated with sclerosing processes of SSc. In both models we could show a significant reduction of skin thickening and collagen deposition in skin samples after a single treatment with Resolvix when compared to controls. Leucocyte infiltrates particularly evident in the HOCl model were significantly reduced by the Resolvix treatment in skin and lung tissues. Interestingly, alveolar macrophages collected from broncho-alveolar lavage (BAL) fluids of the diseased mice in both model systems demonstrated a significant reduction of effectorcytosis capacity (elimi-nating apoptotic cells) a sign of uncontrolled ongoing chronic inflammation and recently reported in SSc patients2. Resolvix treatment successfully restored the effectorcytosis activity to comparable levels detected in healthy mice. In addition, Foxp3+ regulatory T cells were increased in the blood of BLM-mice treated with Resolvix.

Conclusion: Collectively our preliminary data demonstrate that harnessed pro-resolutive factors making up Resolvix are able to revert skin fibrosing pro-cesses, control inflammatory cell infiltration and restore defective macrophage effectorcytosis as a novel a therapeutic approach in SSc.

Resolvix should be considered as a next generation disease modifying biological drug candidate for further development for the treatment of SSc.

AB0134  IN-VITRO STUDY ON THE EFFECT OF SELECTIVE JAK- INHIBITORS ON PBMCs STAT3 PHOSPHORYLATION FROM SYSTEMIC SCLEROSIS PATIENTS

F. Cacciapaglia1, S. Perniola1, S. del Vescovo1, S. Stano1, R. Bizzoca1, D. Natuzzi1, M. Formaro1, F. Iannone1, 1Rheumatology Unit, Department of Emergency and Organs Transplantation (DETO) - University of Bari, Bari, Italy; 2Clinical Immunology Unit, Fondazione Policlinico Universitario “A. Gemelli” IRCCS, Rome, Italy

Background: Systemic sclerosis (SSc) is a rare autoimmune connective tissue disease characterized by autoimmunity-driven damage and vasculopathy leading
to fibrosis of the skin and internal organs (1). The Janus kinase (Jak) - signal transducer and activator of transcription (STAT) pathway has been evidenced markedly activated in SSC patients (2, 3), and its inhibition has been proved in pre-clinical and clinical trials (4), but no data on Jak selective inhibition are available.

Objectives: To explore the effect of selective inhibition of Jak/STAT pathway in peripheral blood mononuclear cells (PBMC) from SSC patients.

Methods: In vitro Jak inhibition of the subunit 3 of phosphorylated (p) activated STAT was measured by flow cytometry in peripheral blood mononuclear cells (PBMC) from SSC patients naïve to any immunosuppressive and/or corticosteroids (n=5). pSTAT3 expression was also assessed after stimulation with recombinant human 1 mg/ml IL-6 (Peprotech – NJ, USA). The PBMC were overnight incubated with IC50 concentrations of selective Jak-1, Jak-2, Jak-3 and Tyk2-inhibitors (Bioserv Inc. - CA, USA). Percentages of pSTAT3 positive cells were compared in presence of different compounds stimulation.

Results: After overnight incubation, percentage of pSTAT3 positive cells was significantly higher in CD4+ cells compared to CD8+ (16.3%; 95CI 10.2-22 vs 10.7%; 95CI 4.18, p=0.02). pSTAT3+CD4+ cells were halved only by selective Jak1-inhibitor, while pSTAT3+CD4+ cells were reduced by 36% by selective Jak1-inhibitor. Selective Jak2- or Tyk2-inhibitors did not interfere with STAT3 phosphorylation in PBMC from SSC patients. After IL-6 stimulation, we observed a 2- and a 1.5-fold increase in percentage of pSTAT3+CD4+ and pSTAT3+CD14+ cells, respectively. pSTAT3+CD14+ cells were reduced in the PBMC co-culture with IL-6 and Jak-selective inhibitors, in contrast no effects were found in CD8+ cells. Specifically, selective Jak1- and Jak3-inhibitors reduced pSTAT3+CD14+ cells by an average of 37% and 25%, respectively. No effects were observed after co-culture with IL-6 and selective Jak2- or Tyk2-inhibitors.

Conclusion: Jak/STAT pathway of PBMC from SSC patients with active disease may be further inhibited by selective inhibitors. Selectivity of Jak1- and Jak3-inhibitors seems more relevant, especially in CD14+ monocytes after IL-6 stimulation. These preliminary findings highlight some evidence for effectiveness of selective Jak-inhibitors in SSC treatment.

PROTEIN CONFORMATIONAL CHANGES AND FUNCTIONAL ALTERATIONS IN DERMAL FIBROBLASTS FROM PATIENTS WITH SYSTEMIC SCLEROSIS

Background: Despite intensive studies and clinical trials, there is still no available precise diagnostic tool and treatment of the patients affected by systemic sclerosis (SSc). Proteopathies are diseases characterized by the production of aberrant conformers of certain proteins that lead to a disturbance of their cellular functions and disease. It is believed that the structure of a protein is principally responsible for its function. By identifying selectively altered peptides on a proteome-wide scale, there is a possibility to detect protein functional changes.

Objectives: To screen for changes in the protein conformation and to correlate with cell function in SSc dermal fibroblasts compared to fibroblasts from healthy donors (HC) using a novel approach of limited proteolysis followed by functional assays.

Methods: Diffuse cutaneous SSc and HC dermal fibroblasts were used for recently established Limited Proteolysis-coupled Mass-Spectrometry (Lip-MS)1 to examine protein structural alterations in a proteome-wide scale. A change in conformation was defined as having a foldchange greater than 1 or smaller than -1 and a significant p-value of -log10> 1.3 (p<0.05). Further, the responsive signalling targets in these cells, including the NF-κB-dependent pathway and energy metabolism, were evaluated. Fibroblasts were stimulated with inflammatory cytokines, highly relevant in SSc, including TNFα, IL-1β, TGF-β, IL-17A, and a combination of IL-17A and TGF-β. To examine the NF-κB activity, cells were transfected with a pseudo-typed HIV-1-based lentiviral vector. The measurements of luciferase signal were analysed. RT-qPCR was used to assess the expression of NF-κB-dependent genes for non-transduced cells. ATP measurements were analysed and presented as the amount of luminescent signal.

Results: Lip-MS analysis detected 53253 common peptides in SSc (n=6) and HC fibroblasts (n=6), of which 41 peptides showed conformational changes in SSc fibroblasts in comparison with HC fibroblasts. The 41 conformationally altered peptides showed significant enrichment in GO pathways for: biological processes (9), molecular function (7) and cellular components (21). SAE1, CTNND1, CD3G, and PPPI13L were related to the NF-κB-dependent pathway, while ATP5A1, GSTM1, PCK2, ANPEP, GM2A, GNS, CAD, ACOT2 were connected with metabolic processes. There was a tendency of lower levels of mRNA RELA, NFKBIA, MMP1 and TNC expression levels in untreated and stimulated SSc fibroblasts (n=6) compared to HC fibroblasts (n=6). The assessment of the NF-κB activity in untreated SSc fibroblasts (n=9) showed a trend to lower fold change compared to HC fibroblasts (n=9) (0.63 vs 1, SE 0.19, p=0.07). A statistically significant difference between SSc (n=8) and HC (n=8) fibroblasts was found in TGF-β-stimulated fibroblasts (0.84 vs 1, SE 0.16, p=0.046). SSc fibroblasts (n=9) showed a lower ATP level compared to HC fibroblasts (n=9) in untreated condition (0.82 vs 1, SE 0.09, p=0.07), after stimulation with IL-1β (0.85 vs 1, SE 0.08, p=0.07) and TGF-β (0.81 vs 1, SE 0.09, p=0.05). Of note, a statistically significant difference between SSc and HC fibroblasts was found in IL-17A stimulated cells (0.82 vs 1, SE 0.07, p=0.02).

Conclusion: Lip-MS approach allowed for the identification of conformational changes in SSc fibroblast mainly related to signal transduction and metabolic pathways. Confirmatory functional studies showed deregulated NF-κB activity and ATP levels in SSc fibroblasts. Therefore, Lip-MS approach may create a distinctive opportunity to discover new disease biomarkers and functionally transformed pathways. This method may advance therapeutical approaches, where only selectively altered proteins could be specifically targeted, without interfering with non-changed proteins.

AB0356 ELUCIDATING THE PATHOGENIC EFFECTS OF ANTI-TOPOISOMERASE-1 ANTIBODIES IN SYSTEMIC SCLEROSIS

M. Aspäni1, K. V. Petersen1, J. Geertsen Keller2, S. R. Greisen1,3, K. Soenergedraad4, J. Hauge Mikkelsen1, B. Knudsen5, B. Deleuran1 on behalf of Bent Deleuran’s group. 1Aarhus University, Biomedicine, Aarhus, Denmark; 2Aarhus University, Molecular Biology, Aarhus, Denmark; 3Aarhus University Hospital, Rheumatology, Aarhus, Denmark

Background: Prediction of the pattern of organ involvement in patients with diffuse cutaneous systemic sclerosis (dcSSc) is supported by the specificity of autoantibodies. These autoantibodies are generally mutually exclusive and highly specific for dcSSc. The autoantibody reactivity allows patients to be stratified early in the disease course, leading to a tailored approach and management. Anti-topoisomerase I antibodies (ATA) are predictors of the development of interstitial lung disease (ILD) and digital ulcers but appear to be protective against pulmonary artery hypertension (PAH).

Objectives: The aim of this project is to elucidate the functioning of ATA and their role in the pathogenicity of the disease.

Methods: Sera from healthy volunteers (HV) and dcSSc patients with and without ATA were collected from Aarhus University Hospital. Total IgG was purified from the sera using a Protein G column. ATA was further purified from the total IgG fractions from dcSSc patients who were positive for ATA. This could inhibit TOP1 activity at various dilutions. Similarly, purified total IgG fractions from dcSSc patients could also inhibit TOP1 activity. ATA was successfully separated from IgG from dcSSc patients who were positive for ATA. This could inhibit TOP1 activity even at lower concentrations than total IgG. This was the case for both mitochrional and nuclear TOP1 activity.

Results: Serum from patients with dcSSc, but not from HV, could inhibit TOP1 activity at various dilutions. Similarly, purified total IgG fractions from dcSSc patients could also inhibit TOP1 activity. ATA was successfully separated from IgG from dcSSc patients who were positive for ATA. This could inhibit TOP1 activity even at lower concentrations than total IgG. This was the case for both mitochondrial and nuclear TOP1 activity.

Full in line with presence of ATA, PBMCs from dcSSc patients contained a lower TOP1 activity compared to HVs PBMCs.

Conclusion: To our knowledge we are the first group to be able to successfully separate ATA from total IgG from dcSSc patients, our unique in house developed REEAD assay clearly demonstrates the function of ATA and provides the opportunity to better understand.

AB0137 SERA DERIVED EXTRACELLULAR VESICLES FROM SYSTEMIC SCLEROSIS PATIENT AND AUTOANTIBODIES MEDIATE PERIPHAL BLOOD MONOCYTES ACTIVATION

A. Hackel¹, A. Müller², H. Grasshoff², G. Marschner¹, G. Riemekasten¹ on behalf of Rheumatology and Clinical Immunology Lab. University Clinic Schleswig-Holstein, Lübeck, Germany, Clinic of Rheumatology and Clinical Rheumatology, Lübeck, Germany.

Background: In SSc, autoantibodies (abs) directed against G protein-coupled receptors (GPCR) are prominent and for example induce release of inflammatory and profibrotic proteins by monocytes (1-3). Increased levels of autoantibodies against angiotensin II type 1 receptor (AT1R abs) have been found in patients with renal involvement in systemic sclerosis (SSc) (4-5). The elevated amount of anti-GPCR abs is accompanied by increased secretion of extracellular vesicles (EVs) in SSc (6). The importance of EVs in the pathogenesis is also based on packing and horizontal transfer of AT1R to different tissues and immune cells, exemplary shown by activated cardiomycocytes leading to higher responsiveness to Angiotensin II of recipient cells and vessels (7). Taken together, the relevance of studying anti-GPCR abs together with GPCR-EVs in SSc pathogenesis becomes evident (8). Interestingly, CCL18 is found to be upregulated in SSc patients and suggested to be upregulated by AT1R abs (9), indicating CCL18 and CCR8 cross-talk via EVs plays an essential role in the pathogenesis of SSc.

Objectives: Unravel the immune response of peripheral blood monocytes mediated by anti-AT1R abs and EVs to gain new insights into the pathomechanism in SSc.

Methods: Human peripheral blood monocytes of healthy donors were stimulated by the endogenous AT1R ligand angiotensin II as well as by a monoclonal anti-human AT1R ab and, in comparison, by purified IgG from HD (HD IgG) versus those from SSc (SSc IgG). Further, human peripheral blood monocytes of HD were treated with EVs derived from sera of SSc patients versus sera of HD, in the presence or absence of a monoclonal recombinant anti-AT1R ab. Monoclonal AT1R ab has been generated by hybridoma technique, sequenced and recombinantly expressed in HEK cells. The specificity of AT1R ab was tested by using an AT1R blocker (telmisartan, TEL). EVs were isolated from sera by differential centrifugation to exclude large particles and microvesicles and further by one-step polymer precipitation procedure utilising ExoQuick Exosome Precipitation Solution (System Biosciences, Palo Alto, CA) and subsequent purification by size exclusion. Further, primary human peripheral blood monocytes of HD (n=6) were treated with EVs derived from sera of SSc patients (n=8) versus sera of HD (n=6), in the presence or absence of a monoclonal recombinant anti-AT1R ab. The response of the monocytes was measured via CCL18 secretion by ELISA.

Results: The recombinant monoclonal anti-human AT1R antibody induced secretion of CCL18, a profibrotic cytokine, by primary monocytes derived from HD. Similarly, the purified IgG fractions derived from SSc patients also induced an increased CCL18 release by monocytes compared to IgG fractions derived from HD. Further, complete amelioration of the AT1R ab effect on CCL18 secretion was found, when monocytic AT1R expression was blocked with TEL. In addition, antagonistic effects of Angiotensin II to the monoclonal AT1R ab were observed. In line, enhanced CCL18 secretion of human monocytes stimulated with SSc-EVs alone and together with the monoclonal AT1R ab was induced.

Conclusion: The secretion of pro-fibrotic CCL18 by human monocytes in response to a monoclonal AT1R antibody as well as to SSc-IgG indicates that anti-AT1R abs are involved in the SSc pathogenesis. Further, this effect could also be due to SSc-EVs potentially presenting anti-GPCR abs to their receptors on immune cells.

AB0138 XANTHINE OXIDOREDUCTASE BLOOD PROFILE IN SYSTEMIC CONNECTIVE TISSUE DISEASES

E. Mozgovaya¹, S. Bedina¹, A. Trofimenko⁵, M. Mamush¹, S. Sptisa¹, I. Zborovskaya¹. ¹Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy; Clinical biochemistry lab, Volgograd, Russian Federation.

Background: Systemic lupus erythematosus (SLE) and systemic sclerosis (SSc) are systemic connective tissue diseases. Their development is based on a generalized immune inflammatory process. Deep immunological and metabolic disorders in these diseases have along with general characteristic distinctive features. XOR is a multifunctional enzyme. The reactions catalyzed by XOR are a source of reactive forms of oxygen and nitrogen, nitric oxide, which are of great physiological importance, and are also responsible for the development of many pathophysiological reactions. Analysis of changes in the activity of interconverting forms of XOR (xanthine oxidase (XO), EC 1.17.3.2 and xanthine dehydrogenase (XDG), EC 1.17.1.4) in plasma and blood cells is of interest.

Objectives: to characterize differences of XO and XDG activities profiles in blood of SLE and SSc patients.

Methods: The researcher was carried out in agreement with the WMA Declaration of Helsinki principles. 56 SLE patients and 51 SSc patients were enrolled in this study. Diagnosis of SLE was verified using the SLICC criteria (2012). SSc was verified according to ACR/EULAR criteria (2013). The reference group consisted of 35 healthy controls. XO and XDG activities were measured in plasma, lysed WBC, lysed RBC using spectrophotometric method [1]. Results were expressed as Me (Q₂5 – Q₇5). The Mann-Whitney U test was used for statistical analysis, differences were considered significant when p<0.05.

Results: Mean age of SLE patients was 35 (31; 42) years, mean duration of disease was 8 (5; 11) years. Mean age of SSc patients was 43 (38; 48) years, mean SSc duration was 8 (6; 9) years. The enzyme indices included in the study did not depend on the sex and age of healthy individuals. XO activity was increased in plasma of SLE and SSc patients (p<0.001 for both disease). The activity of XO was higher in SLE (p<0.001). XO activity of lysed WBC was decreased in both diseases (p<0.001). XDG activity was decreased in lyced WBC and lyced RBC of patients with SLE and SSc (all p<0.001). Activity of this enzyme was lower in lyced WBC and higher in lyced RBC in SLE compared with SSc (all p<0.001). In contrast to SLE, accompanied by low levels of plasma XDH activity (p<0.001), SSc was characterized by increased activity of this enzyme (p<0.001). Also, increased XO activity was revealed in lyced RBC of SSc patients (p<0.001). The values of this enzymatic activity did not differ between the group of SLE patients and healthy controls (p=0.977).

Conclusion: Changes in the activity of oxidase and dehydrogenase forms of XOR are revealed in plasma, lyced WBC, lyced RBC of SLE and SSc patients, which determine characteristic blood profiles in these diseases. Changes in the balance of XOR enzymatic activities can affect the exchange of purine nucleotides, the pool of reactive oxygen and nitrogen species in body tissues, participating in the processes inherent in these diseases.

DEEP IMMUNE PHENOTYPING OF T LYMPHOCYTE SUBSETS IN SYSTEMIC SCLEROSIS PATHOPHYSIOLOGY AND FOLLOWING RESPONSE TO TARGETED CYTOTOXIC TREATMENT

T. I. Papadimitriou1, A. van Caam1, J. Lemmers1, X. He2, E. Vitters1, M. Koenders1, R. Smeets2, M. Vonk1, P. van der Kraan1, H. Koener2, R. M. Thurlings1. 1Radboud University Medical Center, Rheumatic diseases, Nijmegen, Netherlands; 2Radboud University Medical center, Laboratory of Medical Immunology, Nijmegen, Netherlands

Background: Abnormalities in T lymphocyte populations are associated with the pathogenesis of many autoimmune diseases, such as systemic sclerosis (SSc). Various studies report on the aberrations of different T cell cytotoxic (CTL) and helper (Th) subsets that appear to be linked with inflammatory and/or fibrotic manifestations of patients with SSc. Since T cells seem to play a pivotal role in the pathophysiology of SSc, targeting the pathogenic T cell subsets might be a promising therapeutic option.

Objectives: Here we set out to comprehensively compare T lymphocyte phenotypes between SSc patients and healthy donors. We further test the in-vitro efficacy of a combination of anti-CD3/CD7 immunotoxins (CD3/CD7-IT) that have been developed to eliminate activated CD4- and CD8+ T cells, to study specific sensitivity of T-cell subpopulations to CD3/CD7-IT.

Methods: 30 SSc patients and 15 age and sex matched healthy donors were included. Of these patients, lymphocyte populations were quantified by 17-parameter flow cytometry of peripheral blood mononuclear cells (PBMCs) to identify CD4+ Th helper cells (Th1, Th2, Th17, T peripheral helper), CD8+ naïve, memory, effector CTLs and senescent/exhausted subsets. We next developed a cell killing assay to evaluate the effect of T cell depletion. To address this, patients’ PBMCs were first activated for 24 hours in the presence of phytohemagglutinin, followed by CD3/CD7-IT addition for 48 hours. Subset-specific T cell depletion was assessed by using a combination of CellTiter-Glow luminescent cell viability assay and multi-parameter flow cytometric (FCM) quantification of CD3/CD7-IT-induced cell death.

Results: Frequencies of effector CD8+ CTLs, Th2 and T peripheral helper cells were elevated in SSc patients compared to healthy controls. Furthermore, SSc patients exhibited lower percentages of the anti-fibrotic Th1 subset. A striking expansion of the senescent CD4+CD28- and CD8+CD28-populations was noted in patients, while these subsets were barely detectable in healthy controls. In-vitro addition of anti-T cell immunotoxins effectively depleted 50 % of patients’ CD8+ T cells (including the CD8 effector subset) and 62% of CD4+ T cells (including Th2 and T peripheral helper cells). No difference in cytolytic sensitivity between different T cell subsets was observed.

Conclusion: Our findings demonstrate that deep FCM immunphenotyping reveals pathophysiological differences in peripheral T cell subsets of SSc patients. Strikingly, the developed cytolytic assays show that CD3/CD7-IT is able to target the potential disease-associated T cell subsets in an in vitro setting.

ROLE OF ENDOGLIN IN THE PATHOGENESIS OF SYSTEMIC SCLEROSIS: A PRISMA-DRIVEN SYSTEMATIC REVIEW

S. Grignaschi1,2, B. L. Palermo1,2, G. Spinozzi2, A. Salichiero3, C. Cantarini4, C. Stefaniello4, C. Oliveri4, L. Cavagnal1,2, Fondazione I.R.C.C.S. Policlinico San Matteo, Department of Rheumatology, Pavia, Italy; 2The University of Pavia, Department of Internal Medicine and Medical Therapeutics, Pavia, Italy; 3Fondazione I.R.C.C.S. Policlinico San Matteo, Department of Otorhinolaryngology, Pavia, Italy; 4The University of Pavia, General Biology and Medical Genetics unit, Dept of Molecular Medicine, Pavia, Italy

Background: Systemic sclerosis (SSc) is a rare autoimmune disease characterized from peculiar vascular alteration and fibrosis of the skin and internal tissues. SSc pathogenetic mechanisms are still partially unclear but an involvement of the TGFβ pathway, known for being responsible of both angiogenesis and fibrosis, has been proven. Endoglin (ENG) is a TGFβ receptor type III involved in signal regulation, and mutations in ENG gene cause Hereditary Hemorrhagic Telangiectasia type I, a rare disease that shares with SSc the presence of mucocutaneous telangiectasias and disturbed angiogenesis.

Objectives: The aim of this systematic review is to highlight the role of ENG in the pathogenesis of SSc focusing on a subset of clinical manifestations.

Methods: We performed a systematic review following the PRISMA guidelines, searching the MEDLINE (PubMed), Web of Science and EMBASE databases using as keywords: “Endoglin”, “sENG”, “CD105”, “Systemic sclerosis”, “SSc”, “Scleroderma”, “CREST”. The last search was made on November 2nd 2021. This review includes both conference abstracts (without subsequent publication) and articles that evaluated the relationships between SSc and ENG. We excluded the papers that used CD105 only as a cell marker. We then consulted the references from the papers found in order to search possible articles that escaped our first search.

Results: Of the 656 records identified from the database research, 42 were included in our systematic review (16 abstracts and 26 original papers) (Figure). The majority of these studies (25) measured serum ENG (sENG) looking for correlations with cutaneous, pulmonary and cardiac disease in patients with SSc.

Figure. PRISMA flow diagram.

High levels of sENG demonstrated an independent association with telangiectasia in 2 studies, with the presence of digital ulcers (DU) in 6 studies but was not related to the occurrence of new DU (2 studies) and it was related to scleroderma pattern late in 2 studies. Between limited and diffuse cutaneous SSc, SENG showed no differences in one study and significantly higher values in lcSSc in another, this latter study also found ENG to be higher in cSSc compared to systemic lupus erythematosus and healthy controls (HC). SENG, moreover, demonstrated a positive correlation with anti-centromere antibodies (two studies). Regarding pulmonary involvement, no correlation between sENG and mean pulmonary arterial pressure was recorded, and two studies found sENG elevated in patients with pulmonary arterial hypertension while no correlation was found from two other papers. High sENG concentrations demonstrated a positive correlation with subclinical atherosclerosis and with high sensitivity troponin, but its concentration did not relate to right heart dysfunction (1 study each). Two different groups evaluated sENG concentration in Localized Scleroderma and found no differences with other connective tissue diseases. One study searched for genetic alterations in the expression of ENG gene and found no difference between SSc patients and HC. Four studies evaluated ENG expression on fibroblast surface. SSc fibroblasts from both systemic circulation and lung showed higher production of ENG than HC. Tissue Eng, moreover, is up regulated in SSc patients where it acts as a regulator of TGFβ signaling and of extracellular matrix production.

Conclusion: As suggested by the role of Endoglin in the TGFβ pathway, several authors demonstrated an altered expression of Endoglin in SSc patients. A particular focus of interest is the role of ENG in PAH and DU that occur in SSc. A direct involvement of ENG in PAH is known as mutation in this gene are one of the genetic causes of PAH. However, particularly in pulmonary vascular disease, there are still controversial and insufficient data to draw definitive conclusions. As PAH is a leading cause of mortality in SSc patients, this is an area of clinical interest and the study of the TGFβ pathway could lead to useful clinical findings.
**AB0141** DIFFERENTIAL CYTOKINE PRODUCTION PROFILES IN STIMULATED MONONUCLEAR CELLS OF PATIENTS WITH SYSTEMIC SCLEROSIS AND CONTROLS

I. Szabo1, M. Badil2, C. Sirbe3, O. Gaal3, C. Pamfil3, S. Rednic1,2
1Iuliu Hatagenu University of Medicine and Pharmacy, Cluj-Napoca, Romania; 2Iuliu Hatagenu University of Medicine and Pharmacy, Medical Genetics, Cluj-Napoca, Romania; 3Radboud University Medical Center, Internal Medicine, Nijmegen, Netherlands; 4Radboud University Medical Center, Radboud Institute of Molecular Life Sciences, Nijmegen, Netherlands

**Background:** Altered innate and adaptive immune responses represent the link between microvascular injury and fibrosis in systemic sclerosis (SSc) pathophysiology. Peripheral monocytes and lymphocytes are responsible for the secretion of cytokines with proven pro-inflammatory and pro-fibrotic activities. Chronic immune activation in SSc is supported by distinct serum and peripheral blood mononuclear cell (PBMC) cytokine profiles in relation to disease duration, autoantibody subtype, as well as severity of clinical manifestations.

**Objectives:** This pilot study aimed to: (1) evaluate the PBMC cytokine production in SSc patients versus healthy controls (HC) after in vitro stimulation with lipopolysaccharide (LPS) and heat-killed Candida albicans and (2) distinguish different SSC clinical phenotypes based on their cytokine signature.

**Methods:** Eighteen SSc patients (8 limited cutaneous, 9 diffuse cutaneous, 1 sine scleroderma) and 17 age and gender matched HC were enrolled between February 2020 and October 2021. PBMCs were isolated and further subjected to stimulation with LPS and Candida albicans. Cytokine production was measured after 24 hours using ELISA kits for interleukin (IL)-1β, IL-1 receptor antagonist and IL-6. IL-17 and interferon gamma (IFN-γ) concentrations were determined at 7 days from samples stimulated with Candida albicans—in the presence of 10% human pooled serum. Non-parametric data was analyzed using Mann-Whitney test while T-test was used for parametric data.

**Results:** Significantly elevated IL-1β and IL-6 concentrations were detected in SSc patients compared to HC after stimulation with either LPS or Candida albicans. IL-17 cytokine production was also enhanced in SSc patients compared to HC after stimulation with Candida albicans for 7 days, but no difference was identified with respect to IFN-γ. No significant statistical difference was demonstrated between cytokine levels and extent of cutaneous involvement. Furthermore, no association was observed between autoantibody subtypes and cytokine production. Patients with diffuse cutaneous SSC and those positive for anti-Scl-70 antibodies revealed elevated C-reactive protein (CRP) levels.

**Conclusion:** SSC patients exhibit a pro-inflammatory phenotype irrespective of the extent of cutaneous involvement or autoantibody profile. This appears to be mediated through increased production of innate immune cytokines, which correlated to elevated Th-17 responses on later time-points. Elevated CRP levels might define a subgroup of SSc patients with specific disease characteristics. Validation of these findings and mechanistic assessment is warranted in larger cohorts of patients.

**AB0142** EVIDENCE OF TYPE I INTERFERON ACTIVATION DURING VASCULAR MANIFESTATIONS OF SYSTEMIC SCLEROSIS

S. Di Donato1,2, M. Hughes3,4, G. Abignano5, G. Lettieri6, R. Ross7, E. De Lorenzis3,8, P. O’Connor9, O. Kubassova, F. Del Galdo1,1. Leeds Institute of Rheumatic and Musculoskeletal Medicine, Raynoud’s and Scleroderma Programme, NIHR Biomedical Research Centre, University of Leeds, Leeds, United Kingdom; 2Università Campus Bio-Medico di Roma, Rheumatology, Immunology and Clinical Medicine Unit, Department of Medicine, Rome, Italy; 3Centre for Musculoskeletal Research, The University of Manchester, Northern Care Alliance NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom; 4Leeds Institute of Rheumatic and Musculoskeletal Medicine, Faculty of Medicine and Health and NIHR Biomedical Research Centre, Leeds, United Kingdom; 5Catholic University of the Sacred Heart, Fondazione Policlinico Universitario A. Gemelli IRCCS, Division of Rheumatology, Rome, Italy; 6Image Analysis Group, Chief Executive Officer, London, United Kingdom

**Background:** Vascular involvement in Systemic Sclerosis (SSc) is known to start even before clinical diagnosis, to drive Digital Ulcer disease and later in the disease natural history to cause Pulmonary Artery Hypertension, among other manifestations. Despite the proven immune origin of Scleroderma, vascular involvement is not currently targeted by immune driven interventions. Similarly, little data is available on immune or inflammatory biomarkers and outcome measures of vascular disease in SSc. Digital Artery Volume Index (DAVIX) has been recently proposed as imaging surrogate outcome measure of vascular disease activity in SSc [1].

**Objectives:** Here we aimed to determine the value of DAVIX as overall biomarker of vascular involvement and its correlation with Type I IFN activation in patients with SSc.

**Methods:** Eighty-six patients attending our Scleroderma Program were consecutively enrolled for the evaluation of serum IFN score as previously described [2]. Clinical features including presence or history of Digital Ulcers, Presence of Pulmonary Artery Hypertension (PAH) and DLCO, were recorded. Digital Artery Vascular Index (DAVIX) of the dominant hand’s fingers was calculated using time of flight magnetic resonance images analysed through IAG proprietary algorithm, as previously described [1]. Medians were compared by Mann-Whitney-Wilcoxon test, correlation with clinical parameters was performed using Spearman’s or Pearson test, as appropriate (R).

**Results:** Sixty-two patients fulfilled the 2013 ACR/EULAR classification criteria for SSc (diffuse cutaneous 24.6%, limited cutaneous 75.4%) whereas 23 were classified as Very Early Diagnosis of Scleroderma Criteria (CRC) score between 6 and 8). Twenty-three patients had DU disease (History of DUs in the previous 24 weeks, presence of DUs at baseline assessment, or onset of new DUs during the following 24 weeks). Eighteen patients had reduced DLCO (<70 with FVC/DLCO>1.8 (suspected PAH). DAVIX showed a negative correlation with disease duration (r=-0.33 and p<0.003) and with FVC/DLCO ratio (r=-0.34 and p<0.009). Patients with DU disease presented lower DAVIX than patients without (p<0.018).

DAVIX showed a significant correlation with Serum IFN score (r=-0.24, p<0.032). Accordingly, patients classified as IFN-HI had lower DAVIX than those within the IFN-LO group (p=0.016).

**Conclusion:** DAVIX correlated both with presence of Digital Ulcer disease, DLCO and disease duration. The correlation of DAVIX and Serum IFN score does support the notion of innate immune involvement in vascular disease manifestations of SSc. Prospective testing in the context of Randomised controlled trial will determine the value of DAVIX as surrogate outcome measure of vascular disease severity in SSc.

Background: Imaging mass cytometry (IMC) is a high-plex imaging technique that incorporates flow cytometry principles while preserving the histological and architectural components of the tissue sample. Characterizing the entire cellular composition of temporal artery (TA) in patients with giant cell arteritis (GCA) may provide clues towards novel diagnostic and therapeutic approaches.

Objectives: We aimed at a comprehensive summary of the immune cells and pathways involved GCA by using IMC approach.

Methods: TA samples from biopsy-proven GCA patients (n=2) and controls (CTLs, n=2) were analyzed using IMC with a panel of 15 staining antibodies.

Results: Eleven cell populations were identified in arterial wall from GCA patients including both immune (CD20+ B cells, CD8+ T cells, CD4+ T cells, FOXP3+ Tregs, CD66b+ granulocytes, CD11b+ myeloid cells, CD14+ monocytes, CD68+ macrophages) and non-immune (SMA+ smooth muscle cells, CD31+ endothelial cells, Vimentin+ fibroblasts) cells (Figure 1). The 3 layers (intima, media and adventitia) of the arterial wall was enriched by all the immune cell subsets in GCA except for granulocytes and myeloid cells. CD8+, CD4+ and FOXP3+ regulatory T cells were significantly increased in any layer of the TA. The proportion of B cells was also enhanced in both intima and adventitia and displayed a high level of Ki67 expression.

Figure 1. Unbiased clustering of cellular infiltrate in temporal arteritis using Imaging Mass Cytometry.

Conclusion: Our study provides an exhaustive overview of the distinct cell lineages involved in GCA and supports IMC approach to further characterize the immune networks active in GCA.

PD-1 deficiency in the regulatory T cell may be involved in the pathogenesis in Takayasu’s arteritis

N. Gao, L. Pan

1 Capital Medical University Affiliated Anzhen Hospital, Department of Rheumatology, Beijing, China

Background: Regulatory T cell (Treg cell) has been demonstrated decreased in peripheral blood of TAK patients in recent researches. PD-1 may regulate T cell differentiation and apoptosis as an important checkpoint molecule.

Objectives: This study aims to investigate whether PD-1 is involved in the abnormal of Treg cell in TAK.

Methods: This study enrolled 49 patients with TAK and 23 healthy controls. Treg cell related serum cytokines IL-10, IL-7, IL-2 and IL-15, as well as serum chemokines CCL2, CCL3 and CXCL10 were detected using cytokine cyrometric bead array. The expression of PD-1 in CD4+Foxp3+ T cells and Tregs were analyzed by flow cytometry analysis in 15 patients with TAK and 18 healthy controls.

Results: Mean fluorescence intensity of PD-1 in CD4+PD-1+ cells decreased in TAK patients [72.2 (45.8, 84.7) vs. 363.00(335, 431), P = 0.000]. The frequency of CD4+Foxp3+PD-1+ cells in CD4+T cells decreased in peripheral blood (0.90 ± 1.06% vs. 12.61 ± 1.17%, P = 0.034) of TAK patients. The percentage of CD4+CD25+Foxp3+PD-1+ cells in CD4+CD25+ T cells (0.40 ± 0.20% vs. 0.63 ± 0.09%, P = 0.047) is lower in TAK patients than healthy controls. Higher serum levels of IL-10[4.84 (0.70,409.57) vs. 3.16 (0.69, 15.)], P = 0.004 and IL-7[0.01 (2.68,227.72) vs. 7.4 (2.68,16.77), P = 0.014] level were observed in TAK patients. Compared to healthy controls, serum CCL2[30.64 (0, 686.84) vs. 10.31 (0, 32.92), P = 0.000] and CCL3(3.01(0.69,19.24) vs.1.84 (0.67, 4.8), P = 0.000) increased obviously.

Conclusion: The frequency of CD4+Foxp3+PD-1+CD4+CD25+Foxp3+PD-1+ CD4+PD-1+ T cells decreased. This study suggested that PD-1 may contribute to the imbalance of regulatory T cell in TAK.

Background: IgA vasculitis (IgAV) and IgA nephropathy (IgAN) are inflammatory conditions that share pathogenic and molecular mechanisms [1] and may represent different outcomes of a continuous spectrum of the disease [2]. Interleukin (IL)-33 is a cytokine that exerts its biological functions by binding to its receptor, IL-1 receptor like 1 (IL-1RL1) [3]. Several lines of evidence demonstrate that genetic variants located both in IL1RL1 and IL33 genes are implicated in the increased risk of numerous immune-mediated diseases [4].

Objectives: To determine whether ILAV and IGAN exhibit a similar IL33-IL1RL1 association pattern.

Methods: Three tag genetic variants within IL33 (rs9392986, rs7025417 and rs7044343) and three tag polymorphisms within IL1RL1 (rs2310173, rs13015714 and rs2058660), which cover the major variation of these loci and that were previously associated with several inflammatory diseases were genotyped in 380 Caucasian patients with IgAV, 96 patients with IgAN and 845 sex and ethnically matched healthy controls.

Results: Similar genotype and allele frequencies were observed in the whole cohort of patients with IgAV when compared to those with IgAN when IL33-IL1RL1 genetic variants were analyzed independently (Table 1). In accordance with that, no IL33-IL1RL1 genotype or allele differences were detected between IgAV patients who developed nephritis and patients with IgAN (Table 1). Additionally, no statistically significant differences between the whole cohort of patients with IgAV and healthy controls as well as between patients with IgAN and healthy controls were observed when each IL33-IL1RL1 genetic variant was also analyzed independently (Table 1). Similar results were disclosed when haplotype frequencies were compared between the different comparative groups above mentioned (data not shown).

Conclusion: Our results reveal that IgAV and IgAN share a similar IL33-IL1RL1 association pattern.

IgAV: IgA vasculitis; IgAN: IgA nephropathy.
Background: IgA vasculitis (IgAV) and IgA nephropathy (IgAN) are inflammatory conditions [1, 2], that share pathogenic mechanisms [1], in which B-lymphocytes are described as key cells implicated in these processes. BAFF, APRIL and BAFF-R are cytokines implicated in the development of B-lymphocytes [3, 4] and in autoimmune processes [5, 6]. In this regard, an influence of BAFF, APRIL and BAFF-R polymorphisms was observed on several immune-mediated conditions, being BAFF GCTGT>A a shared insertion-deletion variant for inflammatory conditions [7, 8].

Objectives: To determine whether BAFF, APRIL and BAFF-R could be used as differential biomarkers between IgAV and IgAN.

Methods: BAFF rs374039502 (which colocalizes with BAFF GCTGT>A), two tag variants within APRIL (rs11526708 and rs6608) and two tag variants within BAFF (rs7290134 and rs7787453) were genotyped in 394 Caucasian IgAV patients, 95 patients with IgAN and 832 matched healthy controls.

Results: Similar genotype and allele frequencies were observed in the whole cohort of patients with IgAV when compared to those with IgAN when BAFF, APRIL and BAFF-R variants were analyzed independently (Table 1). In accordance with that, no BAFF, APRIL and BAFF-R genotype or allele differences were detected between IgAV patients who developed nephritis and patients with IgAN (Table 1). Additionally, no statistically significant differences were observed between the whole cohort of patients with IgAV and healthy controls as well as between patients with IgAN and healthy controls when each when BAFF, APRIL and BAFF-R genetic variant was also analyzed independently (Table 1). Similar results were disclosed when haplotype frequencies of APRIL and BAFF-R were compared between the different comparative groups above mentioned (data not shown).

Conclusion: Our results reveal a similar BAFF, APRIL and BAFF-R genetic distribution in IgAV and IgAN, suggesting that these genes could not be used as differential biomarkers between these pathologies.

INFLAMMATORY AND NEUTROPHIL ACTIVATION MARKERS IN PATIENTS WITH BEHÇET’S DISEASE
K. Nurbayeva1,2, T. Litsitsyna, T. Rosthentakap1, R. Goloeva1, A. Lila1,2.
1Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; 2Russian Medical Academy of Continuing Professional Education of the Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation

Background: Behçet’s disease (BD) is a systemic variable vessel vasculitis with different clinical manifestations. BD does not have specific laboratory findings. Neutrophil hyperactivation is a major pathogenic factor in BD-related inflammation and tissue damage. Neutrophil reactivity (NEUT-R), neutrophil granularity (NEUT-GI), immature granulocytes (IG), neutrophil-to-lymphocyte ratio (NLR), mean platelet volume (MPV), and platelet-lymphocyte ratio (PLR) are considered as inflammatory markers. Their role in BD remains unclear.

Objectives: to determine the importance of parameters of neutrophil activation (NEUT-R, NEUT-GI), immature granulocytes (absolute (IG#), relative (IG%)) counts), NLR, MPV, PLR in assessing inflammation in BD.

Methods: 29 patients with a reliable BD according to ICBD 2014 and 40 age-matched healthy donors (HD) without acute infectious diseases or cancer were included in the study (Table 1). Patients with BD were separated into two groups: 22 with active and 7 with inactive BD. Active BD was defined as involvement of at least two of the following features: oral ulcers, genital ulcers, uveitis, intestinal involvement, skin lesions, neurological involvement, arthritis, and vascular involvement. Current disease activity was evaluated with transformed Behçet’s Disease Current Activity Form (BDCAF). A complete blood count (WBC-white blood cell, NEUT#-an absolute neutrophil count, NEUT-R, NEUT-GI, IG%, IG#, NLR, thrombocytes, MPV, PLR, ESR-erythrocyte sedimentation rate) was performed with XN-1000 automated hematologist analyzer (Sysmex, Japan).

Results: A WBC count was significantly higher in BD patients compared to controls (Table 1). Patients with active BD had a higher WBC count than inactive. Patients with BD were found to have significantly higher levels of IG#, IG%, and NEUT-R compared to HD. There was no significant difference between NEUT-GI, NLR, MPV, PLR, and ESR levels in patients with BD and HD.

No significant difference in NEUT-R, NEUT-GI, IG#, IG%, PLR, or MPV between active and inactive BD was found. These hematological parameters did not correlate with the transformed BDCAF score. IG# levels positively correlated with total leukocyte count (r=0.656, p<0.001) and the absolute neutrophil count (r=0.548, p=0.002). There was a tendency to a positive correlation between IG% and NEUT-GI (r=0.354, p=0.050) and a negative correlation between IG# and PLR (r=−0.356, p=0.052).

Conclusion: Patients with BD had significantly higher total WBC counts, immature granulocyte levels, and neutrophil reactivity than controls. Except for the leukocyte count, there was no statistically significant difference in the studied parameters between patients with active and inactive BD.

The study was performed at V.A. Nasonova Research Institute of Rheumatology within the framework of the fundamental research FURS-2022-003.

COULD THE RENIN-ANGIOTENSIN SYSTEM AFFECT THE PROGNOSIS OF GIANT CELL ARTERITIS?
SINGLE-CENTRE RETROSPECTIVE OBSERVATIONAL STUDY
1University of Leeds, School of Medicine, Leeds, United Kingdom; 2Leeds Teaching Hospitals NHS Trust, Biomedical Research Centre, Leeds, United Kingdom; 3University of Leicester, School of Medicine, Leicester, United Kingdom; 4University of Leeds, School of Medicine, Leeds, United Kingdom; 5The University of Manchester, School of Medicine, Manchester, United Kingdom

Background: About half of patients with giant cell arteritis (GCA) relapse while tapering glucocorticoid therapy. A previous observational study reported that blockade of the renin-angiotensin system, with angiotensin II receptor blockers (ARBs), was associated with lower relapse risk.

Objectives: To determine whether angiotensin blockade, with angiotensin converting enzyme inhibitor (ACEI) or ARB, is associated with differential relapse risk in GCA.

Methods: GCA patients from a tertiary centre diagnosed 2012–2020 with two years follow-up were included from UK GCA Consortium. All provided written informed consent. Retrospective review of medical records included demographics, comorbidities, drug history, and relapses. Relapse was defined as return of symptoms, raised inflammatory markers, or active vasculitis on imaging confirmed by the treating clinician. Relapse-free survival was analysed using Kaplan Meier (KM) curves and Cox proportional hazards.

Results: 111 patients were included (Table 1: demographic data), all were initially treated with 40–60mg Prednisolone. 42% received further immunosuppressants due to relapse or disease severity. 50% patients relapsed in two years, presenting with cranial symptoms (72%), PMR-like symptoms (30%) and/or raised inflammatory markers (48%). There was no association between relapse and age, gender, comorbid HTN/IHD or pre-steroid inflammatory markers and relapse. Rate of steroid taper can affect relapse. EULAR recommend 15–20mg of steroid by three months, 9 patients relapsed within that time, and were excluded, there was no difference in steroid dose at three months between the two groups. KM analysis showed ACEi did not significantly affect time to relapse compared to no angiotensin blockade (HR 0.57, 95% CI 0.28–1.18, unadjusted p-value=0.128), and neither did an ARB (HR 0.78, 95% CI 0.31–1.98, unadjusted p-value=0.605).

* a statistically significant test result (p ≤ 0.05); NS-not significant; Fluorescence intensity; SI- scatter intensity; Fl- femorotibial.

Results: A WBC count was significantly higher in BD patients compared to controls (Table 1). Patients with active BD had a higher WBC count than inactive. Patients with BD were found to have significantly higher levels of IG#, IG%, and NEUT-R compared to HD. There was no significant difference between NEUT-GI, NLR, MPV, PLR, and ESR levels in patients with BD and HD.
Conclusion: In the two years following GCA diagnosis 50% relapsed. There was no significant difference in the rate of relapse in patients taking an ACEi or ARB. The main limitation, in this retrospective, observational study was the inability to exclude a reluctance of clinicians to diagnose GCA relapse in the presence of cardiovascular comorbidity. A randomised controlled trial would be needed to determine whether starting an ACEi could reduce relapse risk in patients with new-onset GCA.

Disclosure of Interests: S. Lichołai: None declared, K. Wójcik: None declared, K. Wawrzycka-Adamczyk: None declared, M. Surmiak: None declared, M. Korkosz: None declared, S. Lichołai1, K. Wójcik2, K. Wawrzycka-Adamczyk2, M. Surmiak1, M. Korkosz3, 5

Background: Granulomatosis with polyangiitis (GPA) belong to ANCA-associated vasculitides, a heterogeneous group of disorders whose clinical presentation ranges from isolated lesions affecting a single organ to life-threatening conditions. The etiology of the disease is not fully understood, and there is a lack of reliable and unambiguous diagnostic and prognostic markers.

Research in recent years points to the potential use of circulating free nucleic acids as a potential biomarkers in human pathology. Circulating RNA (cIRNAs) belong to the group of non-coding RNAs, a group of potentially regulatory RNAs generated by linkage between a downstream 3' splice site and an upstream 5' splice site in a process known as backsplicing. CircIRNAs were found in in nearly all tissues and recently have been reported to regulate gene expression by sponging miRNA. However their role in specific human conditions is largely unknown.

Objectives: The aim of our study was to assess the potential role of cIRNA in diagnosis and monitoring of GPA.

Methods: CircIRNAs were selected using bioinformatic analysis of RNA-seq data. Serum samples were obtained from 30 patients with GPA and 30 healthy controls. Levels of circRNA were assessed using qPCR with specific primers.

Omics data from NCBI-GEO and Array Express databases are lacking from IgAV samples of adult patients.

Objectives: Our aim was to perform RNA sequencing and to identify differentially expressed genes and dysregulated molecular pathways in the affected skin of adult IgAV patients with renal involvement, patients with skin-limited IgAV and healthy controls (HC).

Methods: Skin biopsy samples were collected from treatment-naive adult IgAV patients at time of diagnostic procedure: 1) skin-limited disease (n=3), 2) IgAV with renal involvement (n=3), and age-/sex-matched HC (n=3). RNA was isolated and 100 bp paired-end sequenced using the Illumina HiSeq 4000 platform (25.9 to 30.8 million reads were obtained per sample). Reads were mapped with Salmon tool against the human transcriptome (Ensemble Release 104). Differentially expressed genes (log2 fold change ≥ 1, padj < 0.05) were computed using the R package DESeq2. Data were clustered using principal component analysis (PCA), and KEGG pathway over-representation analysis (ORA) was performed with R package clusterProfiler.

Results: We identified 72 differentially expressed genes (34 up- and 38 down-regulated) between skin-limited IgAV and HC, while 669 genes were differentially expressed (421 up- and 265 down-regulated) in the affected skin between adult IgAV patients with renal involvement and healthy controls (HC). PCA distinguished between IgAV (renal and skin-limited) and healthy controls, suggesting specific transcriptome signatures in IgAV. 21 overlapping genes were differentially expressed in both groups of patients in comparison to HC. 196 genes were differentially expressed between IgAV patients with renal involvement compared to skin-limited IgAV.

Genes, differentially expressed in patients with skin-limited disease were enriched in the oxidative phosphorylation (padj = 3.08 x 10−5) and cell adhesion molecules (padj = 6.32 x 10−5) KEGG Pathways. Differentially expressed genes in patients with renal involvement exhibited enriched KEGG Pathways involved in the ribosome (padj = 0 x 10−5), the regulation of lipolysis in adipocytes (padj = 9.066 x 10−5), cell adhesion molecules (padj = 8.0008 x 10−5), renin secretion (padj = 4.288x10−5), complement and coagulation cascades (padj = 3.58547 x 10−5), vascular smooth muscle contraction (padj = 3.76132 x 10−5) and aldosterone synthesis and secretion (padj = 3.76132 x 10−5).

Conclusion: Deregulated genes in skin of adult IgAV patients with renal manifestation could serve as biomarkers for organ-specific involvement. Further studies are needed that would support deciphering the involvement of perturbed molecular pathways and the contribution of individual cell types to skin manifestations of adult IgAV patients.

Acknowledgements: The authors also wish to thank all the patients who volunteered to participate into this study and the funding.

AB0150 CIRCULARRNA AS A POTENTIAL BIOMARKER OF GRANULOMATOSIS WITH POLYANGIITIS

S. Lichocki, K. Wójcik, K. Wawrzycka-Adamczyk, M. Surmiak, M. Korkosz, J. Musiał. Jagiellonian University, Medical College, Department of Molecular Biology and Clinical Genetics, Krakow, Poland; Jagiellonian University Medical College, 2nd Chair of Internal Medicine, Krakow, Poland; Jagiellonian University, Medical College, Department of Rheumatology and Immunology, Krakow, Poland

Background: Granulomatosis with polyangiitis (GPA) belong to ANCA-asociated vasculitides, a heterogeneous group of disorders whose clinical presentation ranges from isolated lesions affecting a single organ to life-threatening conditions. The etiology of the disease is not fully understood, and there is a lack of reliable and unambiguous diagnostic and prognostic markers.

Research in recent years points to the potential use of circulating free nucleic acids as a potential biomarkers in human pathology. Circulating RNAs (cIRNAs) belong to the group of non-coding RNAs, a group of potentially regulatory RNAs generated by linkage between a downstream 3' splice site and an upstream 5' splice site in a process known as backsplicing. CircIRNAs were found in in nearly all tissues and recently have been reported to regulate gene expression by sponging miRNA. However their role in specific human conditions is largely unknown.

Objectives: The aim of our study was to assess the potential role of cIRNA in diagnosis and monitoring of GPA.

Methods: CircIRNAs were selected using bioinformatic analysis of RNA-seq data. Serum samples were obtained from 30 patients with GPA and 30 healthy controls. Levels of circRNA were assessed using qPCR with specific primers.
Background: Microvesicles (MVs) are membrane enclosed extracellular vesicles released upon cellular activation and stress, which maintains features and constituents of their parental cells. Large vessel vasculitides (LVVs) are inflammatory conditions of the wall of large-sized arteries, mainly represented by giant cell arteritis (GCA) and Takayasu arteritis (TA). Arterial stenosis and dilation directly affect prognosis and, according to latest EULAR guidelines can be assessed by positron emission tomography and magnetic resonance angiography. Endothelial cells are believed to play a role in the pathogenesis of LVVs and circulating microvesicles could be a biomarker of vessel wall injury.

Objectives: To verify whether arterial wall derived-MVs detectable in the blood of TA patients and expressing bioactive molecules potentially involved in arterial injury, inflammation and remodeling could correlate with clinical and radiological features of those patients.

Methods: Platelet was obtained from 112 LVV pts (73 TA, 39 GCA). Plasma flow cytometry was performed with anti-CD14, CD16, anti-CD144 (VE-cadherin), anti-CD105 (endothelial marker), anti-CD140a/b (PDGF receptor A/B a vascular stromal marker), anti-HMGBl, anti-PTX3, MitoTracker green and MitoSox, which are expression of mitochondrial moieties and ROS. Vascular imaging was carried out by angio-RM and PET. Circulating microvesicles from LVVs patients were correlated with disease characteristics, namely CRP, NIH activity, PGA, ITAS2010, and remission (hsa_circ_0015167 – RQ 5.97, p<0.05; hsa_circ_0045268 – RQ 4.53, p<0.05). CircRNA that differentiates patients from healthy individuals were quantified by different methods, mainly represented by RT-qPCR. High throughput methods were used for statistics. Pearson’s and Spearman’s correlation tests were used for parametric and non-parametric analysis. The SPSS IBM Software was used for statistics.

Results: Levels of at least 10 serum circRNAs distinguished GPA patients from controls and 6 of them reached statistical significance. There was also an apparent difference in the levels of selected molecules between GPA exacerbation and remission (hsa_circ_0015167 – RQ 5.97, p<0.05; hsa_circ_0045268 – RQ 4.53, p<0.05). CircRNAs that differentiate patients from healthy individuals were associated with genes for P-selectin, VCAM and interleukins, among others. In contrast, molecules derived from cathepsins do not differentiate between the study and control groups.

Conclusion: Our results suggest that circRNA could be potentially used as a biomarker facilitating GPA diagnosis. Moreover, the observed differences depending on the stage of the disease could allow for monitoring the disease and predicting its progression. The association of molecules which levels differ between the test and control groups with genes previously associated with the development of the disease strongly suggests their potential involvement in its pathogenesis, which in turn strengthens the diagnostic specificity of the proposed markers.

AB0152 MITOCHONDRIAL DNA IS ELEVATED IN PLASMA OF PATIENTS WITH GIANT CELL ARTERITIS

S. Giaglis1,2, D. Kyburz1,2, N. Venhoff1, U. Walker1,2, University of Basel, Department of Biomedicine, Laboratory for Experimental Rheumatology, Basel, Switzerland; 2University Hospital Basel, Department of Rheumatology, Basel, Switzerland; 3University Medical Center Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany

Background: Giant cell arteritis (GCA) represents the most prevalent form of systemic vasculitis in elderly, and characterized by a remarkable heterogeneity regarding clinical and histological phenotype, pathogenetic mechanisms and treatment choice (1). The pathophysiology of GCA is driven by an interplay between cells of both innate and adaptive immune systems (2). Neutrophils seem to hold a cardinal role in GCA pathology, given their abundance in vicinity to the foci of tissue injury (3). Most importantly, neutrophils secrete neutrophil extracellular traps (NETs) which are decorated with a series of immunocompetent epitopes, essential for the dissemination of the inflammatory response (3, 4).

Objectives: The diagnostic and prognostic value of cell-free DNA in GCA is still unknown. The aim of the present study was therefore to examine the clinical utility of cell-free DNA quantification as a biomarker in GCA.

Methods: Total DNA was isolated from platelet-free plasma samples of matched healthy controls (HC) and consecutive GCA patients. Plasma and clinical data were collected at baseline and follow-up. Copy numbers were quantified by quantitative PCR for mtDNA (ATP-6 gene) and nuclear (n) DNA (GAPDH gene) (5).

Results: Twenty-one GCA patients (median age 64.0 ± 9.0, 49% female) and 22 sex matched HC were enrolled for analysis.

mtDNA levels were significantly elevated in GCA plasma (2.0x10⁷ copies/ml plasma, 95% CI: 7.0x10⁶ to 3.8x10⁸), compared to HC plasma (7.0x10⁶ copies/ml plasma, 95% CI: 2.8x10⁶ to 1.1x10⁷, p<0.0001), nDNA levels in contrast did not differ between GCA (5x10⁶ copies/ml plasma, 95% CI: 2.5x10⁶ to 9.5x10⁶) and HC (4.1x10⁶ copies/ml plasma, 95% CI: 2.3x10⁶ to 9.3x10⁶, p=0.74).

Receiver operating characteristic curve analysis showed that a cut-off value of 2.8x10⁷ mtDNA copy numbers differentiated between GCA and HC with 90.5% sensitivity, 95.2% specificity and an AUC of 0.95.

Figure 1. (a.) Plasma mtDNA levels in GCA patients are elevated (2 orders of magnitude) compared to healthy controls. Whiskers represent 95% CI. (b.) Receiver operating characteristic curve for mtDNA plasma concentrations discriminate between HC and GCA patients. AUC area under the curve.

**EFFECT OF STANDING FRAMES USED IN REAL LIFE ON BONE REMODELING IN NON-WALKING CHILDREN WITH CEREBRAL PALSY**

B. Vincent1, V. Goeb2, S. Fritot1, M. Romuald3, J. M. Sobhy-Danial4, P. Fardellone5, L. Le Monnier5, 1. Chu Amiens-Picardy, paediatric physical medicine and rehabilitation unit, Amiens, France; 2. Chu Amiens-Picardy Site Nord, rheumatology; Amiens, France; 3. Chu Amiens-Picardy Site Nord, human biology and bone metabolism; Amiens, France

**Background:** Children with severe cerebral palsy are prone to low bone mineral density. Standing frames are recommended as postural management for these children who used a standing frame for an average of 30 min/day. This was a prospective study comparing the two groups using dual X-ray absorptiometry data and densitometric data were not significantly higher, a postural trend favored the use of a standing frame in the children. Bone resorptive markers (alkaline phosphatase, osteocalcin) were higher in the non-standing group, whereas there was no difference among osteoformation factors. No difference in fracture history was found.

**Conclusion:** Used in real life, we showed that static standing practice improved mineralization by reducing osteoresorption in non-ambulant children with cerebral palsy. Further studies are needed to determine how standing practice could impact bone mineralization over time in real life and to explore more bone remodeling factors.

**PHYSICAL FUNCTION ASSESSMENT TOOLS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: JAFAS VERSUS CHAQ**

A. Faza1, M. Kammouri2, S. Miladi1, H. Boussaid1, K. Ouenniche1, L. Souabni1, S. Kassab1, S. Chekili1, K. Ben Abdelghani1, A. Latara1. 1. Hospital Mongi Slim or La Marsa, Department of Rheumatology, Marsa, Tunisia

**Background:** Children with juvenile idiopathic arthritis (JIA) frequently experience impairments in one or more body systems. These may include pain, fatigue, muscle weakness, and poor exercise capacity. Functional disability can be evaluated by means of questionnaires and observed performance tests. Only the Juvenile Arthritis Functional Assessment Scale (JAFAS) and the Childhood Health Assessment questionnaire (CHAQ) were developed specifically for children with juvenile arthritis.

**Objectives:** The aim of this study was to investigate the relationship between JAFAS and CHAQ in the evaluation of physical function.

**Methods:** This is a cross sectional study including patients with JIA. Assessment of disease activity (DAS28), number of tender joints (NTJ) and swollen joints (NSJ) were determined. The JAFAS (range 0-20) includes 10 items of activities of daily living (dressing, cutting food, getting in and out of bed, picking up an object from the floor while standing, moving from standing to the floor and returning to standing, walking 50 feet unaided, and walking up a flight of 5 steps). The score range for each item is 0–2, based on the time in seconds the child takes to complete each task. Higher scores indicate greater activity limitation (1). The original CHAQ including 30 activities in eight different domains, with a total score ranging from 0 (no limitation) to 3 (maximal limitation) was completed by interviewing the patient (2). Spearman correlation test and Cohen’s kappa coefficient (k) were used. Significance level was set at p<0.05.

**Results:** Twenty-nine patients with a median age of 25 years [8-40] and median disease duration of 16 years, were included. Age of onset of the disease was 8 years [2-16] years. The median JAFAS score was 3 [0-12] and the median CHAQ score was 0.05 [0-3]. There was a slight agreement between JAFAS and CHAQ k=0.1 (p = 0.05). A positive correlation was found between NTJ and CHAQ (r=0.54, p=0.03) and JAFAS (r=0.5, p=0.05). A correlation was noticed also between NSJ and CHAQ(r=0.51, p=0.05). Both the JAFAS and CHAQ scores correlated with DAS28 (r=0.55, p=0.01 and r=0.44, p=0.02, respectively). At the level of the individual joints, coxitis was the most frequent complication (13 patients out of 28), six of them had surgery of total hip prosthesis. There was a linear relationship between JIA complicated with coxitis and the level of functional disability measured with JAFAS (p=0.027).

**Conclusion:** Our study shows that, even though JAFAS had a slight agreement with CHAQ, both were correlated with the level of disease activity and the number of swollen and tender joints.

**INTRA-ARTICULAR AGRIN PROVIDES DIRECT PAIN RELIEF IN OSTEOARTHRITHIS AND CARTILAGE DEFECTS**

S. Eldridge, A. Barawi, A. S. Thorup, B. F. Fernandez, S. Bhane, S. Sikandar, Z. Guan, M. Kaneva, H. Lydon, F. Henson, C. De Bari, A. McCaskie, F. Dell’Accio. 1The William Harvey Research Institute, Experimental Medicine and Rheumatology, London, United Kingdom; 2University of Cambridge, Department of Veterinary Medicine, Cambridge, United Kingdom; 3University of Aberdeen, Aberdeen Centre for Arthritis and Musculoskeletal Health, Aberdeen, United Kingdom; 4University of Cambridge, Division of Trauma and Orthopaedic Surgery, Department of Surgery, Cambridge, United Kingdom

**Background:** Osteoarthritis is the leading cause of disability worldwide with a financial burden estimated between 1.5 and 2% of the GDP in all westernised countries. The main driver of progression in osteoarthritis is cartilage loss, which may be associated with bone changes, low degree synovitis and lesions to menisci and ligaments. These pathological features result in pain, which contributes to chronic disability.

Improving cartilage integrity without pain relief does not help patients and results in failure in clinical trials. Therefore, there is a need for therapeutics that induce rapid pain relief and long-term cartilage regeneration.

We previously showed that Agrin results in cartilage regeneration and in this study, following on the serendipitous finding of rapid pain relief after Agrin administration we explore its analgesic effect in animal models of osteochondral defects and osteoarthritis.

**Objectives:** Test the analgesic potential of Agrin in post-surgical pain associated with osteochondral defects in mice and sheep.

Determine whether Agrin can relieve chronic pain induced by osteoarthritis in mice.

Investigate the therapeutic potential of Agrin in models of primary and injury-induced secondary osteoarthritis.

**Methods:** Acute post-surgical pain: Surgery was performed on skeletally mature male mice and female sheep to create critical-sized osteochondral defects; defects were filled with collagen gel containing PBS or Agrin. Animals were sacrificed 6 weeks (mice) and 6 months (sheep) after surgery. Pain was measured in mice using von Frey filaments and incapacitance readings. Sheep were fitted with accelerometers for the duration of the study.

Osteoarthritis pain: Osteoarthritis was surgically induced in skeletally mature male mice by menisco-ligament injury (MLI). Control mice received sham surgery. Nine weeks post-surgery, once chronic pain was established, mice were injected intra-articularly with recombinant Agrin. Pain was measured by von Frey filaments and incapacitance.

Treatment in therapeutic regime: Tamoxifen-inducible transgenic mice over-expressing Agrin under the AggreCanCre promoter were generated. Skeletally mature male mice were subjected to menisco-ligament injury surgery. Four weeks later, tamoxifen was administered to overexpress Agrin in the cartilage. Pain was measured by von Frey filaments and incapacitance.

Ex-vivo: MicroCT, X-ray, Kellgren-Laurence scoring, histology, OARSI scoring and immunohistochemistry.

**Results:** In sheep, Agrin administration induced regeneration in osteochondral defects and, more importantly, reduced the levels of secondary osteoarthritis. This was associated with a rapid and sustained symptomatic relief. In mice, Agrin expression was lost in the dorsal root ganglia corresponding to the limb subjected to MLI but not in the dorsal root ganglia corresponding to the sham operated limbs.

Intra-articular recombinant Agrin in mice with established OA (9 weeks after MLI surgery) resulted in pain relief as early as three hours after administration. Acute administration of recombinant Agrin does not have any analgesic effects in sham operated mice.

Inducible, cartilage-specific Agrin-overexpression mice were protected from developing pain associated with instability-induced osteoarthritis. In mice with acute osteochondral defects, intra-articular Agrin administration resulted in pain relief for at least five days.

In humans, the loss of Agrin in the articular cartilage correlated significantly with the Mankin score of patients undergoing knee replacement surgery.

**Conclusion:** Agrin has analgesic properties in both the acute phases of cartilage damage and in established osteoarthritis. Our findings support the therapeutic use of Agrin for joint surface regeneration and pain relief.

EFFICACY AND SAFETY OF FILGOTINIB IN ACTIVE RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO METHOTREXATE: COMPARATIVE STUDY WITH FILGOTINIB AND TOCILIZUMAB EXAMINED BY CLINICAL INDEX AS WELL AS MUSCULOSKELETAL ULTRASOUND ASSESSMENT (TRANSFORM STUDY): STUDY PROTOCOL

T. Shimizu1,2, S. K. Kaschawski3, S. Morimoto4, Y. Kawazoe3, K. Kuroda5, R. Kasawagi6, Y. Ito7, S. Satori, H. Yamamoto6, A. Kawakami2, Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan; *Nagasaki University Graduate School of Biomedical Sciences, Departments of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; NAGASAKI UNIVERSITY Graduate School of Biomedical Sciences, Departments of Community Medicine and, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan; NAGASAKI University Graduate School of Biomedical Sciences, Innovation Platform & Office for Precision Medicine, Nagasaki, Japan

Background: The administration of Janus kinase (JAK) inhibitors as well as biological disease-modifying anti-rheumatic drugs has dramatically improved even the clinical outcomes in rheumatoid arthritis (RA) patients with inadequate response to methotrexate (MTX). The dysregulation of JAK-signal transducer and activator of transcription (STAT) pathways via overproduction of cytokines, such as interleukin-6 (IL-6), is involved in the pathogenesis of RA (1). Filgotinib, a preferential JAK1 inhibitor, is effective in suppressing disease activity and preventing the progression of joint destruction due to inhibition of the JAK-STAT pathway. IL-6 inhibitors such as tocilizumab also inhibit the JAK-STAT pathways due to inhibition of IL-6 signaling. Thus, it should be desirable to investigate whether the effectiveness of filgotinib monotherapy is non-inferior to those of tocilizumab monotherapy in RA patients with inadequate response to MTX. In addition, it is important to accurately evaluate disease activity at the joint level by using musculoskeletal ultrasound (USUS) and clinical disease activity indices, including subjective parameters (2).

Objectives: This study’s principal objective is to evaluate the effects of filgotinib monotherapy in RA patients with inadequate response to MTX. In addition, we will evaluate changes in patients’ parameters, including clinical disease activity indices, MSUS scores, serum biomarkers, patient-reported outcome (PRO), and modified total Sharp score (mTSS) after the administration of filgotinib or tocilizumab. Herein, we describe the study protocol for this study.

Methods: This study is an interventional, multicenter, randomized, open-label, parallel-group and non-inferiority clinical trial with a 52-week follow-up. In total, 400 RA patients with inadequate response to MTX will be included. Patients will be randomized in a 1:1 ratio to administration of filgotinib or tocilizumab. Herein, we describe the study protocol for this study.

Results: Although the study results cannot be shown because the research entry is in progress, they are expected to show the non-inferiority of filgotinib monotherapy to tocilizumab monotherapy in RA patients with inadequate response to MTX.

Conclusion: The strength of this study is its prospective evaluation of therapeutic efficacy using not only clinical disease activity indices but also MSUS, which accurately and objectively evaluate disease activity at the joint level among patients drawn from multiple centers with a standardized evaluation by MSUS. In addition, we will evaluate the effectiveness of both drugs by integrating multilateral assessments, i.e., clinical disease activity indices, MSUS findings, and serum biomarkers.

PREVENTION OF PROGNOSIS AT ONE YEAR AFTER THE ADMINISTRATION WITH B/TSDMARD FOR PATIENT WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS

I. Yoshih1, S. Sawada2, T. Chijiwa1, Yoshih Hospital, Musculoskeletal Medicine, Shimanto-City, Japan; Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan; Kochi Memorial Hospital, Rheumatology, Kochi, Japan

Background: Patients with difficult-to-treat rheumatoid arthritis (D2T RA) are the most serious problem in recent systemic RA treatment protocols [1].

Objectives: Prognosis after biologic or targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) is beneficial when predicted in patients with D2T RA. Predictors of post b/tsDMARDs in D2T RA patients were investigated using retrospective cohort data.

Methods: RA patients more than 1 year after the start of newly administered b/tsDMARDs were recruited. The patients were divided into two groups according to the EULAR definition of D2T RA [2]. Patients who met the criteria were classified into the D2T RA group and others into the non-D2T RA group. The incidence of the clinical features described in the criteria of D2T RA and the rheumatoid disease comorbidity index (RDCI) [3] were compared between the two groups at the time of drug initiation (baseline). The primary endpoint was “Success or Failure” at 1 year after baseline. Success was defined as b/tsDMARD persisted in remission as the 28 joint disease activity score with erythrocyte sedimentation rate (DAS28) ≤ 2.6, or as b/tsDMARD was discontinued upon achieving clinical remission. The Failure was defined as other decisions such as discontinuation due to failure, adverse events, or characteristic patient problems. In the discontinued cases, the monitoring value at the last observation was carried forward to 1 year. Cox regression analysis was used to assess each variant as a potential risk factor for Failure. Receiver operating characteristic analysis (ROC) was tested on variants with significantly higher risk ratios, and Kaplan-Meier survival analysis was also tested for cut-off indices.

Results: 71 cases of the D2T RA and 259 cases of the non-D2T RA group were analyzed. As shown in Table 1, the clinical characteristics of the D2T RA group were significantly worse than those of the non-D2T RA group. Higher DAS28 had a significantly higher risk ratio for the Failure from month 3 in D2T RA group, whereas from baseline in the non-D2T RA group (Figure 1-A). Other factors in the D2T RA group at and after baseline listed in the Table 1 had no significant risk ratios. PS-VAS and EQ5D score had significant higher risk ratios in the non-D2T RA group using univariate models, however, only DAS28 had significant higher risk ratio using multivariate model. The cut-off index (COI) and the area under the curve (AUC) using ROC for each observational period in the two groups were shown in Figure 1-B. Results of Kaplan-Meier survival analyses were shown in Figure 1-C. Hazard ratios of DAS28 > COI exceeded 2.5 even from months 3 with high sensitivity (p < 0.001) in the D2T RA group.

Conclusion: These results indicated that higher DAS 28 suggested a failure prognosis at 12 months after initiation in D2T RA and non-D2T RA patients. Even in patients with D2T RA, strict disease activity control is most important for prognostic management, with 1-year prognosis predictable in the first 3 months. However, this study is a short-term prognostic predictor, and accumulation of short-term predictions is a long-term predictor.

AB0159

HEALTH RELATED QUALITY OF LIFE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS AT TIKUR ANBESAA SPECIALIZED HOSPITAL: A HOSPITAL-BASED CROSS SECTIONAL STUDY

B. A. Adugna, 1 A. D. Ababa university, Internal medicine, Addis Ababa, Ethiopia

Background: Rheumatoid Arthritis (RA) is a chronic disorder associated with substantial morbidity and mortality. Patients with active RA suffer from significant decline in functional capacity and many become work disabled within five years, from onset of symptoms despite treatment. Measurable outcome of these can be done with the help of HRQoL questionnaires. There is a need to study the HRQoL in RA patients, as there is no available data in Ethiopia.

Objectives: This study was conducted to evaluate HRQoL in patients with Rheumatoid Arthritis and factors associated with it.

Methods: A Cross sectional study was conducted at Rheumatology Clinic in Tikur Anbessa specialized Hospital, Addis Ababa, Ethiopia from June 1 to October 31. Data was collected using a structured interviewer administered questionnaire and data extraction form. Data was entered and it was analyzed using SPSS Version 26. To identify associated factors in Health related quality of life of patients with rheumatoid arthritis, bivariable and multivariable analysis were done. Statistical significance was considered at 5%, and a p-value with 95% confidence interval was used to present the estimates of the strength of the association.

Results: A total of 213 participants were included in this study. The mean age of participants was 44.7±14. Majority 191(89.7%) of participants were female. In this study all the 8 domains of RAND 36 are reduced. The mean value of two scales from physical component and one scale from the mental component are below 50. These are Role limitation due to physical problems, General Health Perception and Role limitation due to emotional problems. Both summary score are affected with the PCS more affected than MCS. The multivariable analysis identified rural residence and modified health assessment questionnaire score as factors associated with PCS. For each shift of a patient from urban to rural residence, the PCS decreases by 9.1. For each one score increase in modified health assessment questionnaire score, the PCS score decreases by 28.25. Whereas factors associated with MCS are rural residence, adherence score, MHAQ score, peptic ulcer disease, and rheumatoid nodules. For each shift of residence from urban to rural, the MCS decreases by 15.2. For each one score increase in adherence score, the mental component score increases by For each one score increase in MHAQ score, the MCS decreases by 14.3. For each shift of peptic ulcer disease from absent to present, the mental component score decreases by 16. Finally, for each shift of rheumatoid nodule from absent to present, the MCS by 20.8.

Conclusion: This study showed that Rheumatoid Arthritis has a significant effect on the Health Related quality of life of patients. Rural residence and functional disability was the most influencing factor on both the physical and mental function. Routine assessment of the Health Related quality of life in those patients is recommended to detect and monitor the impact of the disease and its medications on different aspects the patient's life.

THE RELATIONSHIP OF TRYPTOPHAN CATABOLISM WITH RHEUMATOID ARTHRITIS DISEASE ACTIVITY ABSTRACT

A. Kor1, S. Erten1, E. F. Yurt2, I. Dogan2, H. Apaydin3, M. A. Serdar3, C. Bilcizer4 on behalf of ankara city hospital working group. 1Ankara Yildirim Beyazit University Faculty of Medicine, Rheumatology, ANKARA, Turkey; 2Beyazap Public Hospital,, Medical Biochemistry, ANKARA, Turkey; 3Ankara Şehir Hastanesi, Rheumatology, ANKARA, Turkey; 4Acibadem Hospital Ankara, Medical Biochemistry, ANKARA, Turkey. 5Ankara Yildirim Beyazit University Faculty of Medicine, Medical Biochemistry, ANKARA, Turkey

Background: Tryptophan (Trp) is an essential amino acid. The immunosuppressive effect caused by Kynurenine (Kyn) and its metabolites formed by the catabolism of Trp is thought to be an important physiological mechanism.

Objectives: This study aims to evaluate the relationship of Kyn and its metabolites formation of Trp catabolism with rheumatoid arthritis (RA) disease activation and to investigate the usability of these markers in the diagnosis and treatment of RA.

Methods: 50 RA patients followed in our rheumatology clinic and 41 healthy controls were included in this study. Disease Activity Score 28 (DAS28) was used to evaluate the association of Kyn metabolites and Indolamine 2,3 dioxygenase (IDO) enzyme activity with RA disease activity. The task of this marker is to provide the best way to use in RA.

Results: In this study, lower Trp levels were found in the RA group compared to the control group (11285.47±2316.93-13320.31±37771.27, respectively) compared to the Trp mean (p<0.01). In terms of the Kyn/Trp ratio, a significantly higher Kyn/Trp ratio (4.42±1.737.27±0.71, respectively) was found in the RA compared to the control group (p<0.001). There was no significant difference between the study groups in terms of Kyn averages (p>0.05). A significant correlation was found between Trp levels and morning stiffness (r=-0.321, p<0.05) and the DAS28 score (r=-0.566, p<0.01). A significant positive correlation was found between the Kyn/Trp ratio and C-reactive protein (r=0.317, p<0.05), sedimentation (r=0.319, p<0.05), morning stiffness (r=0.287, p<0.05) and DAS28 score (r=0.322, p<0.01).

THE RELATIONSHIP BETWEEN THE LEVEL OF FETUIN-A AND LABORATORY MARKERS OF CONNECTIVE TISSUE DESTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Akhverdyan1, B. Zavodovsky2, E. Papichev3, J. Polyakova1, L. Seevedorva1, 1Federal State Budgetary Institution “Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky”, Laboratory of methods of treatment and prevention of joint diseases, Volgograd, Russian Federation

Background: It is known that there are biochemical markers of cartilage and bone tissue destruction, which reflect the metabolic processes occurring in tissues. For example, in rheumatoid arthritis (RA), routine markers such as CTX-I, a bone degradation marker (C-terminal telopeptide of type I collagen) and CTX-II, a cartilage degradation marker (C-terminal telopeptide of type II collagen), can be used. Also, to assess the state of cartilage tissue, the determination of type II collagen fragments by Urine Cartilaps is widely used, which allows not only primary diagnosis, but also dynamic monitoring of metabolic processes.

Objectives: The aim of our research was to study the relationship between the level of fetuin-A (FeA) and laboratory markers of bone and cartilage tissue degradation in the blood serum of patients with RA.

Methods: We observed 110 patients with a verified diagnosis of RA, the control group consisted of 30 practically healthy individuals without joint diseases. The group of patients with RA and the control group were comparable in terms of age (p=0.003), gender (p=0.116), BMI (p=0.302). The diagnosis of RA was based on the clinical classification adopted at the EULAR/ACR in 2010. The level of FeA in the blood serum was determined once by enzyme immunoassay using commercial test systems (Human Fetuin-A ELISA Biovendor Cat No. 191-0371).

Results: We have assessed the FeA level in the group of RA patients and healthy donors. The normal level of FeA in healthy individuals, calculated as MA±2SD, ranged from 653.55 µg/ml to 972.19 µg/ml. FeA level was normally distributed (K-S=0.082, p=0.2). We also studied the relationship between indicators of bone metabolism and the concentration of FeA. In patients with normal FeA levels (n=87), the mean CTX-1 level was 35 ng/mL; in patients with reduced FeA levels (n=23), the mean CTX-1 level was 51 ng/ml (t=-2.42 p =0.016). Thus, we have a decrease in the FeA level, CTX-I (an indicator of osteodestruction) tended to increase.

Next, we analyzed the relationship between low and normal levels of FeA and the bone collagen origin marker, using intragroup analysis methods. In the group with low FeA level Cartilaps/urine creatinine was 598.9±223.72 µg/mmol versus 481.7±226.93 µg/mmol in the group with normal FeA level (z=2.311; p=0.021). Our data probably allow us to associate the FeA level with the rate of cartilage tissue destruction.

Conclusion: Considering that the levels of laboratory markers of cartilage and bone collagen degradation Cartilaps and CTX-I were statistically lower in the presence of an elevated serum level of FeA, we can conclude that FeA has chondro- and osteoprotective properties. It can also be assumed that the level of this marker can be used to predict the rate of cartilage destruction in patients with RA, but this issue requires further study.

All values were expressed as mean ± SD. All values were calculated using independent sample t-test for normal distribution.

Figure 1. Correlation relationship between DAS 28 and Tryptophan levels (r = -0.321, p < 0.01)

Conclusion: In this study, we observed that RA has a significant relationship with Tryptophan levels and Kyn/Trp ratio. In addition to the literature, we found that RA activation indicator DAS28 score and Kyn/Trp ratio and Tryptophan level showed a statistically significant correlation. Our study has shown that the Tryptophan catabolic pathway can be an important field of study for more effective and safe treatment of RA.

AB0162 PREDICTION OF TREATMENT DISCONTINUATION DUE TO ADVERSE EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING BIOLOGICAL DMARDS AND TARGETED SYNTHETIC DMARDS

E. Koltova1, M. Lukina2, E. Shmidt2, K. Lytkina4, E. Zhilyaev4 on behalf of Moscow Unified Arthritis Registry. 1The Logino Medical Center, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 3City Clinical Hospital 1 named after N.I. Pirogov, Rheumatology, Moscow, Russian Federation; 4Pirogov Russian National Research Medical University, Moscow, Russian Federation; 5Pirogov Russian National Research Medical University, Moscow, Russian Federation; 6CJSC «European Medical Center», Rheumatology, Moscow, Russian Federation

Background: The main goal of rheumatoid arthritis (RA) patients therapy is to achieve low activity or remission of the disease (T2T strategy). However, it is sometimes necessary to interrupt effective treatment due to the development of adverse events.

Objectives: To reveal predictors of target drug withdrawal due to adverse RA.

Methods: The study includes patients with RA used bDMARDs, total 1217 treatment events. Search for predictors was carried out in two steps. At the first step were selected variables which demonstrated significant correlation with time to treatment discontinuation in Kaplan-Meier analysis. At the second step selected factors were included in the Cox regression model. The final set of independent significant predictors was obtained by backward stepwise variable selection.

Results: Of 661 patients 85.8% were women, the mean age of onset disease 58.7 ± 12.9 years, the mean disease duration 14.6 years. The longest mean time until withdrawal due to adverse events had Abatacept, Tocilizumab, Tocilizumab, the shortest time had Infliximab. There were 146 cases of therapy discontinuation due to adverse events. The side effects that caused the cancelation of treatment were: infections of respiratory system, skin, urinary system, allergic and infusion reactions, drug-induced hepatitis, changes in the hematopoietic system, death and other. Presence of rheumatoid nodules (p < 0.001), higher doses of glucocorticoids (p<0.001), lower doses of methotrexate (p = 0.009) were independent significant predictors of increased risk of bDMARDs withdrawal due to adverse events. Used target drug also showed independent significant correlation with this risk. Relative risk (compared to Etanercept) was for Infliximab - 6.57 (CI: 3.69-11.73), Certolizumab pegol - 2.61 (CI: 1.23-5.56), Abatacept - 1.23 (CI: 0.65-2.30), Adalimumab - 1.37 (CI: 0.75-2.50), Rituimab - 0.56 (CI: 0.26-1.20), Tofacitinib - 0.46 (CI: 0.15-1.40), Tocilizumab - 0.77 (CI: 0.37-1.60).

Conclusion: Growth glucocorticoid doses for every 1 mg increases the risk of discontinuation of therapy by 8.7%. Reducing the methotrexate doses for every 1 mg increases the risk of discontinuation of bDMARDs and tsDMARDS by 3%. There are significant differences between target drugs for the risk of discontinuation due to adverse events. High risk of infliximab discontinuation was associated more with infusion reactions and infection, discontinuation of certolizumab pegol was associated with infection.

REFERENCES: [1] The identified predictors for the treatment withdrawal due to side effects may be discussed to identify measures necessary to prevent adverse events in patients with RA who are using bDMARDs and tsDMARDS. These measures are: the use of full doses of methotrexate, avoid long-term use of glucocorticoids, or prescription of the targeted drug with lower risk of adverse events.

DOI: 10.1136/annrheumdis-2022-eular.1030

AB0163 SERUM LEVELS OF CHEMERIN IN PATIENTS WITH RHEUMATOID ARTHRITIS

Background: Chemerin (Ch) is one of the relatively new representatives of adipokines. Numerous studies have shown that adipokines are actively involved in inflammation and immune responses in rheumatoid arthritis (RA) [1]. Data have been obtained, on the basis of which it can be assumed that an increase in the level of Ch in the blood serum in patients with certain systemic diseases is associated with systemic inflammation [2, 3].

Objectives: The aim of the work was to study the level of chemerin in blood serum in a group of healthy donors and patients with RA.

Methods: The group of patients included 92 patients diagnosed with RA, corresponding to the diagnostic criteria developed by ACR and EULAR (2010). The age of the surveyed ranged from 18 to 75 years. The average duration of the disease was 11 years ([Me] 3[25%];16[75%]). The control group consisted of 30 practically healthy persons aged 26 to 62 years. The group of patients with RA and the control group were comparable in age (p=0.069) and gender (p=0.011). Serum chemerin levels were determined using the commercial HUMAN CHEMERIN ELISA kit (BioVendor, Cat. No.: RD191136200R) according to the instructions provided.

Results: The level of the normal Ch value in healthy individuals ranged from 134.7 µg/ml to 241.6 µg/ml. The average Ch level in RA patients (calculated as M±2SD) was 462.6±159.82 µg/ml, which is significantly higher than in healthy donors — 169.9±43.47 µg/ml (t=10.49; p=0.001). The Ch level was normally distributed (K-S d=0.10653, p=0.2). We also found a moderate correlation between the Ch level and the age of RA patients (r=0.232, P<0.05).
Conclusion: Thus, the level of Ch in the blood serum of patients with RA is significantly higher than in healthy individuals. It can be assumed that Ch in RA patients can be used as one of the potential markers of inflammation activity.

AB0164 ARE PATIENTS WITH RA IN REMISSION IN FINLAND DURING THE COVID TIMES? RESULTS FROM THE FINNISH QUALITY REGISTER

L. Weman1, J. Kärkä2, J. Huhtakangas4, J. Rutanen5, L. Kuusalo6, H. Salo7, T. Sokka-Isler8,9, 1University of Eastern Finland, Faculty of Health Sciences, Jyväskylä, Finland; 2Kanta-Häme Central Hospital, Department of Children and Adolescents, Hämeenlinna, Finland; 3Finnish Institute for Health and Welfare, Helsinki, Finland; 4Kuopio University Hospital, Rheumatology outpatient clinic, Kuopio, Finland; 5Tampere University Hospital, Centre for Rheumatic Diseases, Tampere, Finland; 6Turu University Hospital, Centre for Rheumatology and Clinical Immunology, Turku, Finland; 7Finnish Institute for Health and Welfare, Information Services Department, Helsinki, Finland; 8Central Finland Central Hospital, Rheumatology outpatient clinic, Jyväskylä, Finland; 9University of Eastern Finland, Faculty of Health Sciences, Jyväskylä, Finland

Background: Worries have been expressed, concerning the care of chronic diseases during the Covid times (1). Objectives: To study the current status of patients with RA in the Finnish quality register database.

Methods: Patients who receive care for RA were identified in the database. Clinical and demographic data from the last visits during 2020-2021 were collected, including swollen (SJC46) and tender joint counts (TJC46), doctor assessment of disease activity (Dr global), laboratory tests for inflammatory and serology markers, patient reported outcomes (PROMs), and DAS28. Regression models were applied to compare measures of clinical status between the health care regions, adjusted for gender, age, ACPA status, and disease duration.

Results: A total of 14163 patients (72% female, mean (SD) age 62 (14) years, median (IQR) disease duration 8.5 (2.6, 20) years, 84% ACPA positive) were identified. For the entire population, the median (IQR) SJC46 was 0 (0, 1), TJC46 0 (0, 2), ESR 8 (5, 18), CRP 3 (1, 6), and dr global 8 (0, 19). Among PROMs, median (IQR) HAQ was 0.5 (0, 1), pain 26 (10, 51), fatigue 28 (8, 54) and patient global 29 (11, 51). Between health care regions, statistically significant differences were found for all variables due to a large sample size. The mean (SD) DAS28 was 2.3 (0.9) for the entire group and 69 % of all patients had DAS28<2.6. The median DAS28 ranged from 2 to 2.7 among health care regions (Figure 1) (p<0.001). Majority of patients were taking csDMARDs only.

Conclusion: The quality register provides comprehensive real-world data on the current status of patients with RA. A majority of patients can be considered in remission even during the Covid times.

AB0165 MALIGNANCY AS PREDOMINANT CAUSE OF DEATH IN RHEUMATOID ARTHRITIS: REVIEW OF DATA FROM ‘BASILDON EARLY ARTHRITIS COHORT’

D. Laila1, K. Jain1, A. Nandagudi1, A. Bharadwaj1, 1Mid and South Essex Foundation Trust, Rheumatology, Basildon, United Kingdom

Background: Rheumatoid arthritis is a chronic inflammatory autoimmune condition historically linked to increased mortality with predominant contribution from cardiovascular, respiratory, infectious and neoplastic causes. There is evidence of decreasing cardiovascular mortality through improvements in preventative and treatment strategies. Recent literature has also suggested overall improvement in RA-associated mortality attributed to contemporary advances in disease control. There is a need to assess if such outcomes are reflected in the real world setting and to identify elements that continue to promote poorer outcomes.

Objectives: To assess long-term outcome in patients diagnosed with rheumatoid arthritis from the ‘Early Arthritis Cohort’ at a district general hospital in UK.

Methods: A retrospective cohort study was conducted on 185 patients newly diagnosed with rheumatoid arthritis between 2009 & 2013. Patients fulfilling the ACR/EULAR 2010 criteria were included. Anonymised data from the Basildon Early Arthritis registry was analysed. Measured parameters included patient demographics, disease activity score (DAS28), treatment regime, development of co-morbidity & mortality.

Results: Complete data was available for analysis in 171 patients. This comprised 60 men & 111 women with median age of 57 years (IQR 47 - 67 years) and median follow-up time of 90 months (IQR 63 - 108 months). Thirty nine percent were current or ex-smokers. At baseline, 40% of patients had DAS28 score > 5.1, this reduced to 2.5% at time of their last follow up. 74% of patients were in clinical remission at last follow up with 11.7% achieving drug-free remission, 40.4% remaining on single csDMARD, 29.8% on combination csDMARD & 18.1% on biologic therapy.

Analysis of new comorbidities revealed cancer burden of 12.9% (22/171) with lung cancer having highest incidence (n=9). Other comorbidities recorded were cardiovascular 11.1% (19/171), pulmonary 5.8% (10/171) and cerebrovascular disease 5.3% (9/171).

A crude mortality rate of 19.3% (33/171) was observed in our cohort over a median period of 7.5 years follow-up. The incidence mortality rate was 174/10,000 person-years of follow-up and standardised mortality ratio was 2.09 (95% CI 1.44 – 2.86). Majority of patients died five or more years after initial diagnosis (67%) with most deaths occurring in the 6th year after disease onset. Patients in the mortality group had higher disease activity scores at their last follow-up compared to the remaining cohort (p=0.017). More deaths were recorded from underlying malignancy 76% (n=13) than with cardiovascular disease 4.7% (n=8). Eight out of 13 cases were identified as lung cancer deaths. Breast, bladder, pancreatic and ovarian cancer constituted remaining cases. Other causes of death were from chronic obstructive pulmonary disease (n=3), dementia/frailty (n=3), interstitial lung disease (n=2), infection (n=2), stroke (n=1) and chronic liver disease (n=1).

Conclusion: Despite achieving remission in majority of patients, long-term analysis reveals that mortality in this cohort is significantly elevated compared to the general population. To best of our knowledge this is the first real-world study showing malignancy as the predominant cause of morbidity and mortality in rheumatoid arthritis.

Disclosure of Interests: None declared
Background: Modern trials in RA often have a strict protocolized treat-to-target design, whereas in daily practice shared decision making is the preferred way to manage treatment.

Objectives: To document the protocol violations in an early RA trial that illustrate potential conflicts between these strategies.

Methods: In the COBRA treat-to-target trial, treatment-naïve early RA patients were classified into a low- and high-risk group, and treated according to two different protocols. Treatment target was minimal disease activity (DAS44 <1.6) and MTX increasing to 25 mg/week): 110 (73%) patients reached the treatment target at 13 weeks. The 31 non-responders were randomized to treatment intensification (n=15) or treatment continuation (n=16) for weeks 14 to 26. Intensification comprised 60 mg/day prednisolone, tapered in 6 weeks to 7.5 mg/day, and addition of sulfasalazine 2000 mg/day and hydroxychloroquine 400 mg/day (COBRA-light). The low-risk group (n=40) was treated with MTX monotherapy increasing to 25 mg/week: only 20 (50%) reached the target at week 13. The 15 non-responders were randomized to treatment intensification with a COBRA-light oral pulse of prednisolone (n=8) or continuation (n=7).

Over the whole study period 79 of 190 patients (42%) had a protocol violation. In the first 13 weeks, 27 (18%) high-risk and 8 (20%) low-risk patients had a protocol violation. In the responders at week 13, 15 (14%) high-risk and 3 (18%) low-risk patients had a protocol violation in week 14-26. In the high-risk non-responders, 18 of 31 had a protocol violation (58%) after randomization at 13 weeks, 11 in the intensification group and 7 in the continuation group (Table). Remarkably, increased intensification of therapy was only found in the continuation group (3 patients); decreased intensification was mainly found in the intensification group (11 patients, vs 3 patients in the continuation group). In the low-risk non-responders, violations occurred in 8 out of 15 (53%) patients after randomization, 4 in both groups.

Table: Protocol treatment violations after randomization of non-responders at week 13 by risk group.

| Violations are categorized by direction of intensification and by reason/initiator.

Conclusion: In this study almost half of the patients had a protocol violation. The high frequency is most likely related to the open design of the trial, the risk of adverse effects through intensification with high dose prednisolone and other DMARDs, the randomization phase, and, last but not least, by the shared decision making. Shared decision making by physician and patient may jeopardize protocol adherence in trials with an open treat-to-target design.

Background: Little comparative research has been done comparing disease burden between PsA and RA. Previous studies from Nordic countries and the US have shown small differences (0-10/100 VAS units) in patients with PsA vs. RA. The mean and median VAS levels for PsA and RA were 29 (6.10, 51) for female patients with RA. The corresponding values were: fatigue 28 (9, 60) in PsA vs 28 (10, 62) in RA. Median pain was slightly higher in female PsA patients compared to RA patients in age groups older than 50 years. Figure 1 illustrates the mean (95% CI) pain for PsA and RA in the age and sex groups.

Median fatigue levels were quite similar between the groups. The median patient global health was higher in female PsA compared to RA patients in age groups <50 years and 50-60 years (20 vs. 29 and 30 vs 37) (<p=0.001).

Results: Patients with PsA vs RA were younger (mean (sd) age 54(14) vs 62(14)) and less often women (51% vs. 72%). Median (IQR) disease duration after the first symptoms was 8.6 (3.7, 17) years for PsA and 9.5 (3.3, 21) years for RA. The median (IQR) pain was 29 (10, 56) for all patients with PsA and 26 (10,51) for patients with RA. The corresponding values were: fatigue (8, 60) in PsA vs 28 (8, 54) in RA, and patient global health 28 (10, 51) in PsA and 29 (11, 51) in RA. Male pain was slightly higher in female PsA patients compared to RA patients in all age groups (29 and 18, 35 and 28, 32 and 27 and 48 and 38) (<p=0.001). In males, higher levels of pain in PsA vs. RA were seen in age groups older than 50 years old. Figure 1 illustrates the mean (95% CI) pain for PsA and RA in the age and sex groups.

Median fatigue levels were quite similar between the groups. The median patient global health was higher in female PsA compared to RA patients in age groups <50 years and 50-60 years (20 vs. 29 and 30 vs 37) (<p=0.001).

Conclusion: Female patients with PsA report higher levels of pain in all age groups compared to patients with RA. The same was seen in men >50 years old. Concerning fatigue and patient global health, the differences between PsA and RA were smaller. Compared to earlier research in other countries, disease burden observed by PROs appears lower both in PsA and RA in Finland.

Background: With the advent of medications with different mechanisms of action in the treatment of rheumatoid arthritis (RA), clinicians face the challenge of choosing the best therapy for each patient. One of the steps in the treatment of RA patients is to identify predictors of the effectiveness of the therapy. This work is devoted to the identification of predictors of the therapy effectiveness with the blocker of T cells co-stimulation - abatacept (ABA).

Objectives: Search for clinical and immunological predictors of the effectiveness of ABA therapy.

Methods: 91 patients were included in the study, most of them women, with high disease activity of RA (DAS28=5.1±1.0, SDAI=28±13.4, CDAI=25±12) and failure of previous biologics (51, 6%) and DMARDs (100%). Moreover, in 20% (n=18) of patients the inefficacy more than 2 biologics were recorded. The average duration of the disease was 3.0 (1-12) years, most patients were positive for RF 72.5%, ACCP 77%, AMCV 86%. In 44 patients the levels of RF, ACCP, AMCV and MMP-3 were assessed after 24 weeks of ABA therapy. In 36 patients enzyme-linked immunosassay was used to measure serum concentrations of biomarkers IL-1β, IL-6, IL-17AF, TNF-α, VEGF-A, IP-10, YKL-40 at baseline and after 24 weeks of ABA therapy. The effectiveness of therapy was assessed according to the EULAR criteria. ABA IV infusions were performed according to the standard schedule. Methods of parametric and non-parametric statistics were used in statistical analysis.

Results: ABA treatment led to a significant decrease of disease activity assessed by DAS28, SDAI, CDAI starting after 3 months of therapy (p<0.05). More than half of the patients were in remission and had low disease activity according to the DAS28 (65.7%, n=35) after 48 weeks of treatment. After 48 weeks, the highest percentage of patients with RA remission was registered by the DAS28 (37.4%, n=20), the lowest — SDAI (21.6%, n=11). After 24 weeks of therapy, ABA led to a significant decrease in the serum levels of IL-6 from 2.4 [1.1 - 6.4] to 1.29 [0.9-2.2] pg/ml (p=0.0006), IP-10 from 21 [12.9-49.8] to 14 [7.5-28] pg/ml (p=0.0007) and matrix metalloproteinase 3 (MMP3) from 30.1 [13-82] pg/ml to 10 [7.4-55] pg/ml (p=0.0003). A decrease in the serum level of IL-6 significantly correlated with a decrease in the DAS28 and SDAI (r=-0.5 and r=-0.479, p<0.05), IP-10 with DAS28 (r=-0.326, p<0.05). Initially, the serum level of TNF-α was significantly lower in patients who achieved low disease activity by the SDAI (72.5%, n=32) after 48 weeks of treatment compared with the rest. On the contrary, a significantly higher level of IP-10 before treatment was recorded in patients with a good response according to the EULAR criteria (39%, n=29) after 48 weeks of ABA treatment (Figure 1). The ROC-analysis revealed that an initially high concentration of TNF-α may indicate with 71% sensitivity and 77% specificity about the possible ineffectiveness of ABA therapy after 48 weeks of treatment, the area under the curve was 0.75 (0.5 - 0.9). In patients initially positive for AMCV, low RA activity by SDAI was significantly more often registered after 24 (p=0.04) and 48 weeks (p=0.01). 89% (n=34) of AMCV-positive patients achieved low disease activity after 48 weeks therapy by the SDAI and CDAI. It is noteworthy that a cohort of patients with insufficient effect after 48 weeks consisted entirely of AMCV-negative patients.

Conclusion: ABA therapy led to a significant decrease in disease activity according to the main indices (DAS28, SDAI, CDAI). During ABA treatment, there was a decrease of important immunoinflammatory markers - IL-6, IP-10, MMP-3. AMCV positivity is significantly associated with higher efficacy of ABA therapy. Also, a high basal concentration of TNF-α could use as a predictor of possible failure of ABA therapy, and a high initial level of IP-10, on the contrary, indicates the possible efficacy of ABA therapy.

groups and define the responsible molecules. Clinical parameters, including inflammation markers, DAS28, and comorbidities, were also included in the analysis, and Spearman correlation coefficient was calculated.

Results: Untargeted NMR data were analyzed with multivariate supervised approach (PLS-DA) revealing distinct metabolic signatures for the 6 groups under investigation. The most defined groups being RAB and RAs, compared to controls, which indicated changes in alanine, tyrosine, lactate and acetone. Besides small molecule, significant changes were also observed in various plasma lipoproteins. For the thorough investigation of these findings, a targeted lipoprotein subclass analysis was conducted and highlighted significantly higher lipoprotein subclass concentrations, including free cholesterol (FC), cholesterol (CH), phospholipids (PL) and apolipoprotein A1 subfractions in RAs compared to controls and Naïve. Concerning metabolite differentiations, RAs patients exhibited reduced ketone bodies and organic acids compared to RAB and control individuals, respectively. All RAs group had lower concentrations of sarcosine. Correlation analysis highlighted the association of DAS28. ESR and CRP with ketone body acetoacetate (p<10^-6) and sarcosine (p<10^-5). VAS correlated with TRIGlyceride subfractions (H1TG and H2TG, p<10^-5) and sarcosine (p=1.8x10^-4). All therapies were found to correlate with lipoproteins; MTX with LDL-2 subfractions (p=5x10^-4), intermedid-density lipoprotein (p=2.7x10^-5) and acetate (p=5.9x10^-6), Anti-IL-6R with triglyceride fractions, IDTG and TPTG (p<10^-3). Anti-CD20 with triglyceride fractions, IDTG and TPTG (p<10^-3).

Conclusion: Overall, these data reveal that RAs have a distinct metabolic signature depending on the time-point of therapy. Clinical parameters correlated with changes in ketone bodies, amino and organic acids, while therapies correlated with lipoproteins. The above analysis indicates that biomarkers revealed by metabolomic profiling can be useful in RA therapy monitoring.

Studies conducted were included: "DAS28 (disease activity score) categories not trial," and repeated twice, replacing “DAS28” with “CDAI” (clinical disease activity index) and “RAPID3” (routine assessment of patient index data). Activity/severity levels for high, moderate, low, and remission, respectively, are: DAS28 (0-10) >5.1, 3.2–5.1, 2.6–3.2, ≤2.6; CDAI (0-76) >22, 10.1–22, 6.1–10, ≤6.1; RAPID3 (0-30) >12, 6.1–12, 3.1–6, ≤3.0. Mean and/or median DAS28, CDAI, or RAPID3, and/or proportions of patients who were in remission, low, moderate, and high activity/severity were compiled. Results were compared to 3 pre-2010 reports, of which included all 3 indices.

Results: Results from 1985 vs 2000 indicate >50% improvement in swollen joints and physical function, 2 maintained in 2008 and 2010 (data not shown). The

Mean/Median of Index:
High activity/severity: 10, 2, 1, 4, 3
Moderate activity/severity: 39, 18, 6, 9, 6
Low activity/severity: 8, 2, 3, 3, 0
Remission: 0, 0, 0, 0

Conclusion: Most RA patients in post 2011 reports from routine care were in moderate activity according to means or medians or categories, unchanged from 2008 and 2010. Only a minority were classified as in remission or low activity/severity. Optimal RA treatment may require modification of treatment goals, further recognition of differences between patients in clinical trials and routine care, and possible new strategies for earlier identification of RA patients for treatment, in addition to new therapeutic agents.

**AB0177** ASSOCIATION OF SEROLOGICAL STATUS WITH THE FREQUENCY OF CLINICAL AND RADIOLOGICAL REMISSION IN RHEUMATOID ARTHRITIS

O. Iaremko, G. Mvykutenko, O.O. Bogomolets National medical university, internal medicine, Kyiv, Ukraine; O.O. Bogomolets National medical university, internal medicine, Kyiv, Ukraine

**Background:** Achieving remission is one of the main goals in the management of patients (pts) with rheumatoid arthritis (RA). According to the literature, one of the determining predictors of the disease course is the serological variant of RA [1]. However, there are conflicting data in scientific publications concerning relationship between the presence/titre of antibodies to cyclic citrullinated peptide (ACCP) or rheumatoid factor (RF) and the frequency/rate of remission [1].

**Objectives:** To examine associations of ACCP- and RF-status with possibility and timing of clinical and radiological remission in Ukrainian pts with RA while taking the main non-biological disease modifying anti-rheumatic drugs (DMARD).

**Methods:** In our multicentre study RF titre was determined by the latex agglutination method (Humatex, Germany), reference values <20 IU/ml; ACCP level - by ELISA (IBL-Hamburg, Germany). The diagnostic limit of ACCP was ≥15U/ml, the maximum value ≥345U/ml. All pts received non-biological DMARD: methotrexate, leflunomide, sulfasalazine or its combination with hydroxychloroquine. At baseline and after 6, 12 and 24 months (mth) of treatment the disease activity and achievement of remission (by DAS28) were compared in different subgroups of RA pts were analysed.

**Results:** 128 pts with RA were included in the study; the mean (SD) age was 54 (12.7) years and follow-up was for 2.0 (1.3) years. Most were women (72.4%), mean disease duration 18.4± 3.18 mth, ACCP-positive were 64.8% and RF - 57.1% pts. According to serological status at baseline, pts were stratified into four classes: ACCP+, ACCP−, ACCP−/RF+, ACCP+/RF−, and ACCP+/RF+ (n=9), dual positive (n=84) and dual negative (n=36). There were no significant differences between the analysed groups in age, sex, RA duration, disease activity, radiological changes and prescribed therapy (p>0.05).

During the 2-year follow-up, clinical remission was achieved in a total of 27 (21.1%) pts, including early remission (during first 6 mth) in 25 (19.5%). The percentage of pts in remission were 36.1, 33.3, 15.8, and 12.5 respectively for RF−, ACCP−, ACCP−/RF+ and RF−/ACCP+ vs ACCP+/RF−, ACCP+/RF+ (p<0.05). The rate of remission (frequency of early remission in the structure of general remission) in four analysed groups did not differ significantly and was 75%, 66.6%, 57.1% pts. According to serological status at baseline, pts were stratified into four classes: ACCP+RF- (n=19), RF+ACCP- (n=9), dual positive (n=64) and dual negative (n=36). There were no significant differences between the analysed groups in age, sex, RA duration, disease activity, radiological changes and prescribed therapy (p>0.05).

At baseline and after 6, 12 and 24 months (mth) of treatment the disease activity in patients (pts) with Difficult-to-Treat Rheumatoid Arthritis (D2T) was slightly lower (p>0.05), and systemic glucocorticoids (GC) was significantly higher (OR=3.7 [1.3-10.8]; p<0.01).

**Conclusions:** In pts with RA, with ineffectiveness of bDMARD/tsDMARD taken from other RA patients with the ineffectiveness of previous bDMARD/tsDMARD, the higher inflammatory activity in CRP (p=0.04) with a higher frequency of systemic GCs (OR=3.7 [1.3-10.8]; p<0.01).

**AB0179** PATIENT’S SATISFACTION WITH TREATMENT IN RHEUMATOID ARTHRITIS: AN UNMET NEED

W. Belhai1, S. Miladi1, A. Fazaia2, H. Boussaia2, L. Soueibni2, K. Ouenniche1, S. Kassab3, S. Chekhil3, K. Ben Abdelghani3, A. Laatari3, University of tunis el manar, faculty of medicine of tunis, mongi slim hospital, rheumatology department, tunis, Tunisia

**Background:** Shared decision between rheumatologists and their patients has become an overarching principle in current treatment recommendations in rheumatoid arthritis (RA). Therefore, assessing satisfaction with pharmacological therapy, among patients, is becoming increasingly important in clinical settings.

**Objectives:** In this study, we aimed to assess the satisfaction of patients with RA about their treatment and to investigate the predictive factors.

**Methods:** A cross-sectional study was conducted including adults diagnosed with RA for more than a year and receiving their current Disease-modifying Anti-rheumatic Drug (s) (DMDAR) for at least 12 months. We used the treatment satisfaction questionnaire for medication (TSQM v1.4) to assess the treatment satisfaction among patients. Multivariable regression analysis was applied to determine the factors associated with treatment satisfaction.

**Results:** We included 70 patients (63F/7M) with a mean age of 57.8±10.6 [29-81] years at the time of the study. The mean disease duration was 13.7±22 [3-30] years. Twenty-four (34.2%) patients were on a biologic DMARD (bDMARD). Regarding the Disease Activity Score 28 (DAS28-ESR), 14.3% of patients had a low disease activity, 47.1% a moderate disease activity, 7.1% a high disease

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.2297
activity, and 31.4% were in clinical remission. The mean (SD) Rheumatoid Arthritis Impact Disease (RAID) overall score was 4.72 ±2.11. Mean (SD) TSOQ scores were 65.42±14.77 for convenience, 68.71±18 for effectiveness, 70.60±24.5 for side effects, and 67.95±17.10 for global satisfaction.

Twenty percent of patients were satisfied with convenience, 38.6% were satisfied with effectiveness, 45.7% were satisfied with side effects and 30% were globally satisfied. The multivariable regression analysis showed that the RAID overall score was inversely associated to global satisfaction (p=0.001) and to satisfaction with effectiveness (p=0.032).

Difficulty of coping (one of the RAID domains) was inversely associated to satisfaction with effectiveness and convenience. It was, also, showed that satisfaction with side effects was inversely associated to the degree of interference of the RA on domestic work (p=0.020) and positively correlated to the degree of participation in treatment decision-making (p=0.014). In addition, satisfaction with current physician was positively associated to global satisfaction (p=0.029).

Satisfaction with convenience was inversely associated to bDAMARs (p=0.027). Conclusion: We conclude from our data that despite the diversity of therapeutic strategies, almost two-thirds of patients remain satisfied with their treatment. A better understanding of patients’ unmet needs and an individualized patient-centric approach would improve outcomes in RA.

Conclusion: The predictability of radiographic progression by disease activity measures was generally limited. The composite USDAIs containing sonographic JC were not superior for predicting radiographic progression compared to their clinical counterparts although there was a trend for higher predictive value for indices containing PD.

Background: The pharmacotherapy for rheumatoid arthritis (RA) has changed dramatically and caused a paradigm shift with the advent of methotrexate (MTX) and biological disease-modifying antirheumatic drugs (bDMARDs). Before the paradigm shift of RA therapy, the frequency of carpal collapse was high in patients with RA. It has been reported that certain numbers of patients with RA rapidly advance the destruction of the carpal bones during the early onset in the natural course of it [1].

Another report showed that hand function was positively correlated with disease activity [2]. In Japan, bDMARDs were approved in 2003, and the maximum allowable dose of MTX was raised from 8 mg/week to 12 mg/week in 2012. The usage rate of MTX was 56.3% in 2009, 76.9% in 2014, and 50% in 2019, respectively. There was no significant difference in the rate and dosage of MTX use in each year. There was also no significant difference in the mean value of DAS28-CRP at the time of initial examination. The mean age at the time of initial examination was 55 years (30-72).

Methods: Patients with early RA diagnosed in our department in 2009, 2014, and 2019 were included in the study. The CHR was measured at the first visit and two years later on radiographs of both hands. The drug history for RA was obtained in the medical records retrospectively. All statistical analyses were performed with EZR version 1.55.

Results: This study included 43 cases (36 females, 7 males). The number of cases in 2009, 2014, and 2019 was 16, 13, and 14, respectively. Two years later, the right-hand CHR was 0.514 (0.467-0.561), 0.549 (0.493-0.617), and 0.562 (0.528-0.591), respectively, with no significant difference. The right hand CHR of initial diagnosis was 0.554 (0.484-0.632), 0.551 (0.490-0.618), and 0.567 (0.517-0.632) in 2009, 2014, and 2019, respectively, with no significant difference. The right-hand CHR was 0.532 (0.444-0.627), 0.529 (0.478-0.586), and 0.548 (0.491-0.593), respectively, with no significant difference. The left hand CHR of initial diagnosis was 0.522 (0.475-0.602), 0.539 (0.459-0.589), and 0.557 (0.506-0.635) in 2009, 2014, and 2019, respectively, with no significant difference.

AB0182
THE PROFILE OF POOR PROGNOSTIC FACTORS BASED ON EULAR RECOMMENDATIONS IN CHINESE RA PATIENTS: A SINGLE-CENTER OBSERVATIONAL STUDY
Y. Gu1, Z. Zhang1, J. Zhao1. Peking University First Hospital, Rheumatology and Clinical Immunology, Beijing, China

Background: Despite the constant updating of rheumatoid arthritis (RA) treatment strategies, whether poor prognostic factors (PPFs) can guide RA treatment is still controversial. There are limited data about the presence of PPFs in Chinese RA patients.

Objectives: To describe the profile of PPFs based on European League Against Rheumatism (EULAR) recommendations in Chinese RA patients, and explore the significance of these factors in adjusting treatment therapy.

Methods: In this real-world study, RA patients were enrolled from 2012 to 2020. The baseline characteristics and prognostic factors based on EULAR recommendations include acute-phase reactant levels, rheumatoid factor (RF), anti-cyclic citrullinate peptide (anti-CCP antibody), swollen joint counts (SJC), early bone erosions, and responses to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARD) at month 3 or month 6 were collected. Disease activity was assessed by disease activity score of 28 joints-erythrocyte sedimentation rate (DAS28-ESR), DAS28-C-reactive protein (DAS28-CRP), simple disease activity index (SDAI), and clinical disease activity index (CDAI). The association of different factors was represented by a Venn diagram. The number of patients presenting with different combinations of prognostic factors was graphically displayed by UpSetR. Correlation between binary variables was analyzed by the Chi-square test.

Results: 1252 registered RA patients were enrolled. 901/1252 (72.0%) patients had elevated ESR or CRP and 1027/1164 (88.2%) patients had positive RF or anti-CCP antibody. 97/1252 (31.7%) patients had early bone erosions. 166/444 (37.0%) patients had early bone erosions, which usually coexisted with other PPFs. 394 (34.4%) of the 1105 patients who received csDMARD therapy as prescrd had persistent moderate or high disease activity (MDA/HDA). Failure of two or more csDMARDs was found in 245 (22.2%) patients. 99% of RA patients had at least one PPF. Patients with MDA/HDA usually coexisted with other PPF. MDA/HDA was significantly correlated with elevated ESR/CRP or high SJC and is not correlated with positive RF/anti-CCP antibody or early bone erosion.

Conclusion: PPFs are prevalent in RA patients in real-world data. It is inappropriate to guide treatment strategies just based on the presence or absence of PPFs. The categories of PPFs should be simplified and the role of different combinations of PPFs in guiding treatment therapies remains to be explored.

Objective: To identify subgroups with distinct trajectories of DAS28-CRP in pts with RA.

Methods: Longitudinal data from adult RA pts presenting to a tertiary centre were used. Socio-demographic data, disease characteristics and standard assessments including established outcome parameters for disease activity (DAS28-CRP) and physical function (FFBH) were retrospectively analysed. Group-based

trajectory modelling (GBTM) was used to identify homogeneous classes of DAS28-CRP trajectories, where the number of classes was selected using Nagin’s Bayesian information criterion (BIC). Differences between the identified classes and clinical variables were studied.

**Results:** Data of 134 pts with 849 DAS28-CRP values were analysed. Retrospective chart data were available for a follow-up of 33.7 (SD 18.0) months. One third of pts already had erosions and severe limitations in physical functioning. About half of the pts were on bDMARDs and <20% on steroids. Five distinct classes of DAS28-CRP trajectories were identified (Figure 1). These groups were subsequently categorized as 1) high-increasing, 2) high-stable, 3) low-increasing, 4) low-decreasing disease activity, and 5) remission. Pts’ characteristics at baseline in each trajectory group are shown in Table 1. Group 4 had a shorter disease duration but more erosions, a better function and a higher educational level than seen in other groups. The increase of disease activity in group 3 was modest.

**Conclusion:** Using GBTM five distinct trajectories in pts with RA were identified. Only a small proportion of pts showed a reduction in disease activity over time, whereas the largest proportion of pts showed rather constant high or constant low disease activity. The cohort size may have impacted the modelling and further analyses in larger cohorts are needed. Importantly, even though well established in our hospital it is unclear how consequent the T2T strategy was followed and which intervention was successful to reach remission. The impact of pts global assessment on DAS28 values also needs further study.

**PHENOTYPES OF DRUG-FREE RHEUMATOID ARTHRITIS FLARE AND IMPACT OF RESIDUAL SUBCLINICAL ECOCOGRAPHIC JOINT INJURY IN ACPA POSITIVE AND ACPA NEGATIVE DISEASE**

E. Bozza1,2, G. Gringaschi1,2, B. Xoo1, M. I. Greco1, T. Luvara1, I. Mazzucchelli1, S. Bugatti1,2, C. Montecucco1,2, A. Manzo1,2, 1IRCCS Policlinico San Matteo Foundation, Rheumatology, Pavia, Italy; 2University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy

**Background:** The mechanisms of flare across the pathogenic spectrum of RA remain unclear. To what extent RA flare reproduces the dynamics of disease onset or is primarily driven by new dynamics is not known. Furthermore, the hypothesis of a role for circulating auto-antibodies in determining different mechanism behind flare has never been challenged.

**Objectives:** To evaluate whether RA flare after remission achievement reproduces the phenotype of onset or it is characterized by a different phenotype primarily driven by the pattern of residual joint injury after treatment, in ACPA positive and negative patients.

**Methods:** S3 RA patients, in stable drug-free remission (DFR) after early csDMARDs introduction and displaying clinical flare across 60 months of follow-up were analysed for clinical, laboratory and ultrasound (US) characteristics at diagnosis, treatment discontinuation, and flare (DAS28 and/or physician-based character), the synovitis clinical phenotype (ACR 1987 criteria defined districts); PROs and the inflammatory status at disease flare versus onset. We then measured the impact of residual subclinical US joint injury (absence of objective synovitis and GS>1 and/or PD>0) at the time of drug discontinuation, on the synovitis clinical phenotype of flare. Finally, we explored differences in the outcomes in ACPA positive and negative RA.

**Results:** Cohort characteristics are shown in Table 1. As inferred by paired analyses, no significant differences were observed between onset and flare concerning composite indices of disease activity, and subjective/semi-objective domains. However, flare appeared to be significantly less inflammatory in terms of CRP, ESR, SJC, PGA, morning stiffness and HAQ (p<0.05). These differences remained after adjustment for diagnostic delay including only very early RA patients (<3 months from symptoms onset). The evaluation of the frequency of articular districts involvement revealed no difference between onset and flare both for SJC and TJC (Figure 1). However, the percentage of SJs at flare being present at onset showed a high variability among patients. Stratification for ACPA status demonstrated a significantly higher recurrence of synovitis in joints involved at onset in ACPA negative vs ACPA positive patients (p<0.05). The percentage of SJs at flare presenting residual subclinical US injury at the time of drug discontinuation was significantly higher in ACPA negative vs ACPA positive patients (p<0.05) and negatively correlates with the ACPA titer (R 0.354, p>0.05).

**Disclosure of Interests:** None declared

**Conclusion:** RA flare in patients achieving DFR seems to be less severe in terms of inflammatory markers and synovitis recurrence, despite a similar degree of joint tenderness and patients’ perception compared to disease onset. The arthritis phenotype undergoes detectable changes more in ACPA positive than negative patients. The residual subclinical US joint damage seems to drive the localization of synovitis recurrence in ACPA negative more than positive patients, supporting the existence of pathologic differences in the process of disease reactivation in the two groups.
Background: The paradigm shift has caused in the treatment for rheumatoid arthritis (RA) before the last decade [1]. The advent of high-dose MTX and biologics has made it possible to treat RA with early and aggressive therapy, and prevent the joint destruction [2].

Objectives: To investigate the joint destruction and clinical outcomes in patients with early RA every 5 years in the last decade.

Methods: 81 patients with early RA (within 1 year from their onset of RA) enrolled retrospectively in this study. The number of patients with early RA were 21 in 2009, 23 in 2014, and 37 in 2019, respectively. They had 17 males and 64 females. Mean age was 59 years (19-92) at the first visit to our department. The following items were investigated: age, disease duration from onset to consultation, anti-cyclic citrullinated peptide antibody (ACPA) positivity (positivity was defined as >4.5 U/ml), CRP, DAS28CRP4, medications, and modified total sharp score (mTSS) at the time of initial consultation and 1 year later, Kruskal-Wallis test was used for statistics (PASW 25 software, SPSS Institute Inc., Chicago, IL, USA, p<0.05).

Results: The ACPA positivity rates were 71.4% (15/21) in 2009, 78.3% (18/21) in 2014, and 78.4% (29/37) in 2019, respectively. The mean value of DAS28CRP4 was 4.7 (2.4-6.8) in 2009, 4.2 (1.2-6.2) in 2014, and 4.2 (2.1-6.7) in 2019 at the time of the first visit to our department respectively. DAS28CRP4 under 2.6 was 29% (6/21) in 2009, 61% (14/23) in 2014, and 54% (20/37) in 2019 1 year after the first visit. The mean improvement of DAS28CRP4 (ΔDAS28CRP4) was -1.7 (-3.9 to -0.1) in 2019, -1.5 (-4.0 to -1.7) in 2014, and -1.7 (-4.1 to -0.4) in 2019, respectively. It had tended to improve gradually, however, it was not significantly different (p=0.20, Figure 1).

![Figure 1. Mean value of improvement of mTSS and DAS28CRP4 (ΔmTSS and ΔDAS28CRP4) from initial visit to 1 year later at 2009, 2014 and 2019.](image)

The changing of mTSS for a year (ΔmTSS) was 4.2 (0-17) in 2009, 0.9 (0-10) in 2014, and 0.6 (0-4) in 2019, respectively. ΔmTSS in 2014 and 2019 was significantly lower compared to that in 2009 (p<0.001, Figure 1).

One year after the first visit to our department, the mean dose of MTX increased to 9.2 mg/week (2-14) in 2014 and 8.7 mg/week (4-16) in 2019 compared to 6.6 mg/week (2-8) in 2009.

The intensive therapy for early RA at our hospital has shown the improvement of joint destruction in the last decade.

REFERENCES:
treatment target are increasing in rheumatoid arthritis (RA). On the other hand, it is also true that some patients are still using prednisolone (PSL). Recently, ultrasound has played a role of sensitive imaging modality in the diagnosis and follow-up of patients with RA. It is known that residual synovitis was found in ultrasound even in patients with clinical remission.

**Objectives:** We investigated the differences of ultrasonographic intra-articular synovitis findings between treatment drugs in patients with RA.

**Methods:** From January 2017 to August 2020, 750 RA patients who underwent ultrasound examination were included. A US examination was performed at the bilateral first to fifth metacarpophalangeal (MCP) joints, first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three part of radial, medial and ulnar) and first to fifth metatarsophalangeal (MTP) joints, by using HI VISION Ascendus (Hitachi Medical Corporation, Japan) with a multifrequency linear transducer (18-6 MHz). The gray scale and power Doppler findings were assessed by the semi-quantitative method (0-3). All patients were divided into with or without BIO/JAK, methotrexate (MTX) and PSL. Then, patients were matched using the propensity score adjusted for gender, age, RA disease duration, disease activity, CRP value, and MMP-3 value. The total gray scale and power Doppler score (GSUS / PDUS) were compared between treatment drugs of RA by using propensity score matching methods.

**Results:** The average age of 750 RA patients were 64.5 years and an average disease duration of RA was 13.9 years and females were 581 (77.5%). There were 517 patients (68.9%) treated with BIO/JAK and 233 patients treated without BIO/JAK. The 205 patients in each group were matched. GSUS were 10.6±11.1 vs 9.2±10.4 (p=0.218) and PDUS 7.4±9.2 vs 6.5±9.0 (p=0.328). Ultrasound residual synovitis was not different between with or without BIO/JAK in matched patients. There were 525 patients (70.0%) treated MTX, the average MTX dose was 9.3±9.3, and 225 patients treated without MTX. The 203 patients with or without MTX in each group were matched. GSUS were 9.7±10.6 vs 11.4±12.0 (p=0.119) and PDUS 6.6±8.8 vs 8.1±10.1 (p=0.117). Ultrasound residual synovitis was not different between with or without BIO/JAK in matched patients. There were 111 patients (14.8%) treated PSL, the average dose was 4.0mg, and 639 patients treated without PSL. The 205 patients with or without PSL in each group were matched. GSUS were 15.7±13.9 vs 11.6±10.6 (p=0.018) and PDUS 6.6±8.8 vs 8.1±10.1 (p=0.117). Ultrasound residual synovitis was more severe treated with PSL than without PSL in matched patients.

**Conclusion:** In a comparison between RA patients matched backgrounds such as disease activity, there was no difference in ultrasound residual synovitis between patients with or without BIO/JAK and MTX. However, there was significant difference in patients with or without PSL. This suggests that PSL use suppresses clinical symptoms but does not improve synovitis. Thus, it should be noted that joint destruction may progress in patients treating with PSL.

Background: Fatigue is one of the major complaints of patients with rheumatoid arthritis (RA). However, the literature relating fatigue to other disease-related parameters has presented discrepant results and longitudinal studies with multivariate analyses are scarce.

Objectives: To explore potential associations between fatigue and demographic variables and other patient-reported outcomes (PROMs) in patients with RA treated with biological disease-modifying antirheumatic drugs (bDMARDs) over the time.

Methods: A 24-month (24M) monocentric observational retrospective cohort study was conducted. Patients diagnosed with RA, according to the 2010 American College of Rheumatology (ACR)/ European League Against Rheumatism (EULAR) criteria, and registered on the Rheumatic Diseases Portuguese Register (Reuma.pt) who started their first bDMARD between 2015 and 2021 were included. Age, gender, disease duration, body mass index (BMI) and PROMs were obtained by consulting Reuma.pt. Fatigue was monitored at baseline, 12 and 24M using Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), a 13-item questionnaire with a total score ranging from 0 to 52. A score ≥ 29 indicates the presence of clinically significant fatigue. Health Assessment Questionnaire (HAQ), EuroQol-5D (EQ-5D), 36-item Short Form Survey (SF-36), patient global assessment visual analogue scale (VAS) and pain VAS were assessed at baseline, 12 and 24M. Multivariate linear regression models were conducted with FACIT-F as the dependent variable.

Results: A total of 40 patients (47±11.4 years; 90.2% female) with a BMI of 29.87±8.54 kg/m² and a mean disease duration of 10.4±5.6 years were included. A total of 473% of patients were treated with an anti-TNF. About 85% of patients had clinically significant fatigue at baseline (FACIT-F 26.9±11.8). At baseline, patient global assessment VAS (β=-0.9, 95%CI [-1.6; -0.29]) and pain VAS (β=-0.34, 95%CI [-0.6; -0.08]) predicted fatigue. SF-36 predicted fatigue at baseline (β=-0.35, 95%CI [0.14;0.56]), 12M (β=0.23, 95%CI [0.084;0.37]) and 24M (β=-0.35, 95%CI [0.13;0.59]). HAQ predicted fatigue at baseline (β=12.2, 95%CI [19.8; -4.53]) and 24M (β=11.4, 95%CI [-17.4; -5.38]). EQ-5D (β=-39.5, 95%CI [15.84; 63.22]) predicted fatigue at 24M.

Conclusion: Our results showed that pain levels and patient global assessment of disease activity predicted a higher level of fatigue at baseline. The decrease in physical function and a worse overall health status perceived by patient predicted higher fatigue over the time. Previous research has suggested that disease-related factors, such as inflammation, pain or decreased physical function are associated with greater fatigue in RA (1). These findings encourage the pre-treatment screening of fatigue in patients with RA in order to design individualized non-pharmacological approaches in addition to bDMARDs therapy.

Antibodies Against Modified Protein/Peptide Specificities in Recent-Onset Palindromic Rheumatism May Determine the Evolution to Rheumatoid Arthritis

G. García-Moreno1, R. Morlát1, B. Frade-Sosa2, L. Tobarina1, M. J. Gomara1, R. Sammarti1,2, I. Harón1 on behalf of PALABA study investigators, 1Institute of Advanced Chemistry of Catalonia (IQAC-CSIC), Unit of Synthesis and Biomedical Applications of Peptides., Barcelona, Spain; 2Hospital Clinic de Barcelona, Arthritis Unit. Department of Rheumatology, Barcelona, Spain

Background: Palindromic rheumatism (PR) may evolve to rheumatoid arthritis (RA), particularly in patients with autoantibodies such as rheumatoid factor (RF) or antibodies against modified proteins (AMPA), anti-citrullinated peptide antibodies (ACPA) or anti-carbamylated antibodies (anti-CarP) (1,2). We hypothesized that the specificities and isotype usage of ACPA and anti-CarP may differ between recent-onset PR and established RA, and this could help ascertain the evolution to RA in PR patients.

Objectives: To determine differences in the recognition of epitopes between patients with recent-onset PR and established RA by analysis of AMPA specificities and isotypes.

Methods: Subanalysis using preliminary data of the PALABA study. Two populations included: patients with recent-onset PR included in the PALABA multicenter randomized clinical trial (abatacept vs hydroxychloroquine) at study entry (NCT03669367) and patients with established RA (ACR/EULAR 2010) as controls previously selected from an observational study (3). Only RF and/or ACPA (CCP2) positive patients were selected. PR patients were DMARD naïve and RA patients receiving rituximab or abatacept were excluded. AMPA specificities and isotypes in sera were determined by in-house ELISA tests using antigens two carbamylated proteins and a panel of chimeric peptides derived from fibrin and filaggrin proteins bearing one to three post-translational modifications (citrullination, carbamylation and acetylation) (4). The cut-off for ELISA tests was established by ROC curves, with a specificity of 95% compared with a healthy population. The frequency and titers of the AMPA isotypes (IgA, IgG, IgM) was analyzed. Results: 45 PR patients (77.6% female), with a mean age of 49.3 (±11) years and a mean disease duration of 9.6 (±6.1) months and 125 RA patients (75.6% female) were recruited. Anti-CarP autoantibody status in RA vs PR patients.
females) with a mean age of 59.6 (±13) years and a mean disease duration of 772.7 (±59.7) months. RF and ACRA (CCP2) were positive in 80% and 91.1% of PR patients and 77.6% and 86% of RA patients (p>0.05). Although both populations presented a similar frequency and activity with RA. The absence of IgA ACRA isotypes and, especially, anti-CarP in the early stages of PR may be associated with a lower rate of progression to RA.

AB0193 BIOLOGIC DRUGS RETENTION IN ELDERLY RHEUMATOID ARTHRITIS: WHAT FEATURES?

S. Boussaid1, K. Saadouli1, S. Jemmal1, M. Hassayoun1, S. Rekki1, S. Rahmoun1, H. Sahli1, M. Elleuch1.

1Hospital Rabta, Rheumatology, Tunisia, Tunisia; 2University of Tunis El Manar, Faculty of Medicine of Tunis, Tunisia, Tunisia

Background: The elderly RA population is expanding. The management of RA in elderly patients can be challenging because of comorbidities, the frequency of adverse events. The efficacy and safety of RA therapies; particularly biologics drugs (bDMARDs); are poorly studied in this age group.

Objectives: To investigate the therapeutic response to bDMARDs in elderly rheumatoid arthritis.

Methods: We conducted a cross-sectional and observational study. Files of patients with RA on biologics drugs (archived from the files of patients on the National Health Insurance Fund of Tunis) were studied. The characteristics of RA, and the current treatments were studied. We have divided our population into two age groups, G1 aging under 65 years and G2 aged 65 or over. The therapeutically maintenance rate as well as the biologics survival was analyzed using Kaplan-Meier survival curves and compared using the Log-Rank test.

Results: Three hundred and seventy-four files were selected. Their average age was 55±12.54 years (20-90). A female predominance was noted with a sex ratio M/F=1.47. The average duration of RA was 11.7±6.76 years [2-41]. Subjects over the age of 65 represented 22.2% of the workforce, i.e. 83 patients. The first biotherapies prescribed was etanercept in 54% of cases, adalimumab in 14% of cases, certolizumab pegol 13%, infliximab 6%, tocilizumab 6% and rituximab in 7% of cases. The 4-year survival was 54.41% and 60.94% for subjects under 65 and 65 or older, respectively. Treatment maintenance for RA in the elderly (≥ 65 years old) was 42.21 months, [53.51–46.92]. In our study, age did not influence the survival of biologic therapies (HR = 0.997 (p=0.667). Conclusion: RA therapy is generally effective and safe in elderly patients. We did not find any influence of age on survival and therapeutic maintenance of biological treatments. Further studies with a broader spectrum are needed to better understand this notion

AB0194 VALIDATION OF ANDROID OPERATED SMARTPHONE PEDOMETER IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. R. Wagner1, R. B. Gregersen1, L. Henriksen1, E. M. Hauge1, K. K. Keller2,3.

1Aarhus University, Department of Electrical and Computer Engineering, Aarhus, Denmark; 2Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; 3Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark

Background: Impact of disease and disease activity in RA is measured with questionnaires such as the health assessment questionnaire (HAQ) or composite scores such as the disease activity score (DAS-28). These methods may miss signs of disease activity because they are typically performed only at hospital visits. Measuring physical activity continually may assist in the early discovery of relapses in the future. In addition, measuring physical activity may be relevant for predicting the risk of developing comorbidities such as cardiovascular disease [1]. Activity tracker devices have been tested in RA patients for this purpose, but the disadvantage is that they can only be carried for a limited period of time and are expensive, which makes them unsuitable for long-term cohort studies [2]. As an alternative, obtaining physical activity data from the patient’s own smartphone using a dedicated and secure activity tracker app incurs no added costs, but the reliability of this method has never been tested in patients with RA.

Objectives: The aim of this study was to validate the use of the standard Android-operated smartphone step-counter pedometer in patients with RA.

Methods: Clinical characteristics were obtained. Two typical Android smartphone running the Android virtual step counter sensor were tested in a treadmill test-bed setup at 6 different speeds, ranging from 2.5 km/h to 5 km/h. Patients walked 100 steps at each test speed wearing the Android devices placed in a stomach pouch. Software running on a Windows PC communicated in real time with both phones, and the PC software also allowed the investigator to easily record the manually observed steps using clicker functionality, which were then automatically linked to the steps recorded from the smartphones.

Results: Median (interquartile range) disease duration was 13 (4-21) years, DAS-28 2.2 (1.6-2.9), and MAHAQ 0.2 (0-0.9). Seventy-six% of the patients were rheumatoid factor positive, 75% were Anti-citrullinated peptide antibody positive, and 70% had erosive disease. The overall difference in device step counts versus the observed was 5.9 ± mean percentage average error for both devices. Most of the error was introduced at the 2.5 km/h speed tests where the mean error of the two devices was 18.5%.

From 3 km/h, the mean average percentage error of the two devices was below 5% and from 3.5 km/h and up the mean average percentage error of the two devices was below 3%. A box plot of the data is demonstrated in Figure 1.

Figure 1. Box plot of number of steps with both devices at the six different speeds.

Both walking speed and walking cadence had a significant impact on the pedometer validity, as both speed and cadence were negatively correlated to the absolute percent error measured by both devices (p<0.001), which indicates, that the greater the speed and/or cadence, the lower the step counting error rate. Conclusion: The two tested biometric pedometer applications were valid in patients with rheumatoid arthritis, but walking with very low speed may represent a challenge. Next step will be field tests evaluating the setup including active measured time in patients with rheumatoid patients.

Background: A regular monitoring of structural damage in patients with rheumatoid arthritis (RA) is necessary to adjust the treatment. However, the rhythmicity of new radiographs to assess the structural damage is not codified. There is no biomarker able to reflect structural damage.

Objectives: Our study aimed to assess the relationship between the modified Sharp score and the platelet to lymphocyte ratio.

Methods: We performed a cross-sectional study including 53 patients with RA. A cell blood count was performed for each patient, and PLR was calculated. Modified Sharp score and its components (erosion score and joint space narrowing score) were evaluated using the radiograph of hands and feet. Statistical analysis was performed using SPSS (Statistical Package for Social Sciences).

Results: Of the 53 patients, 39 were female (Sex Ratio: 2.8). The mean age was 53.9 ± 12.7 years. The mean age of the onset of the disease was 43.8 ± 13.5 years. The mean disease duration was 10.1 ± 8.2 years. The mean DAS 28-ESR score was 4.64 ± 1.23. The mean value of PLR was 161.62 ± 86.59. The mean modified Sharp score was 46.33 ± 37.74. Thirty-two percent of patients had a modified Sharp score greater than 50. The mean score of joint erosion and joint space narrowing were 12.76 ± 15.05 and 33.57 ± 25.80. Modified Sharp score was correlated to the PLR (r: 0.558; p <10-3 and r: 0.299; p: 0.033, respectively).

Conclusion: The ability of PLR to distinguish patients with a modified Sharp score ≥ 50 was good with an AUC of 0.704 (p= 0.021) with a cut-off of 130.5 (sensitivity=75%, specificity=65.7%).

AB0196

ABATEVERUS HYDROXYCHLOROQUINE IN PALINDROMIC RHEUMATISM: A MULTICENTER RANDOMIZED CLINICAL TRIAL (PALABA STUDY): TRAIL DESIGN AND PATIENTS CHARACTERISTICS

B. Frade-Sosa1, R. Morlà1, L. Tobalina2, C. Perez-Garcia2, I. Haro2, R. Sanmartí3 on behalf of PALABA study investigators. 1Hospital Clinic de Barcelona, Arthritis Unit. Department of Rheumatology, Barcelona, Spain; 2Hospital Del Mar, Rheumatology, Barcelona, Spain; 3Institute of Advanced Chemistry of Catalonia (IQC-CSIC), Unit of Synthesis and Biomedical Applications of Peptides., Barcelona, Spain

Background: Many patients with palindromic rheumatism (PR), mainly those with positive autoantibodies, evolve to rheumatoid arthritis (RA). Management of PR is empirical, and hydroxychloroquine (HCQ) is the most used antirheumatic drug. Abatacept (ABA) has been investigated in preclinical RA with good results. This report is a randomized clinical trial in PR.

Objectives: To present the design of a randomized clinical trial in PR (PALABA study). To describe the characteristics of the patients at study entry. The main objective is to test the hypothesis that ABA can reduce the progression of RA in seropositive (ACPA+ and/or RF+) PR patients in comparison with HCQ.

Methods: Phase IV multicenter open label randomized controlled clinical trial with 42 months duration. The enrollment period was 18 months and the open randomized period 24 months. Seventeen European centers were included. The sample size was 70 patients (35 per arm). ABA and HCQ arm followed a different protocol. Both therapies were administered. The main inclusion criteria were age ≥18 years with PR according to Guerne and Weissman modified criteria and disease evolution >3 and ≤6 months. Positive ACPA (ELISA or chemiluminescence (CCP2) and/or RF tests are required. Patients with arthritis >1 joint >1 week at baseline, with criteria of other rheumatic diseases, radiographic erosions or previous antirheumatic therapy with synthetic DMARDS were excluded.

The main outcome measure is achievement of RA classification criteria (EULAR/ACR 2010) at any time during the 24-month follow-up. Secondary outcomes were the number and intensity of joint attacks, adverse events, and effects on serum ACPA and anti-carbamylated antibodies at 0.124.24 months of follow-up. STATISTICS: Modified Full Analysis Set and Per Protocol Population analysis.

Results: Patient one was included in June 2018. The inclusion period has been extended until April 2022 due to low recruitment rates, partly due to the COVID-19 pandemic. As of 15 Jan 2022, 51 patients have been randomized and 49 (37F/12M) have received at least one drug dose. The mean onset of symptoms was 9.9±6.5 months. In 22 patients the follow-up time was greater than 12 months. RF and ACPA (CCP2) were positive in 81.6% and 89.8% of patients respectively; 24 patients were included in the ABA arm and 25 in the HCQ arm. Seven patients withdrew from the study during follow-up due to: progression to RA (n=3), adverse events (n=2) and other reasons (n=2). The demographic, clinical and laboratory characteristics of PR patients at study entry are shown in Table 1. There were no significant differences in patients' characteristics between arms were observed at enrollment except a higher prevalence of CCP2 in the HCQ arm.

Conclusion: We present the design of the first randomized clinical trial in PR of the efficacy of antirheumatic drugs (ABA vs HCQ) to reduce progression towards RA in patients with a high risk (recent onset PR and positive autoantibody status) of persistent arthritis. The characteristics of patients included until now are similar to those reported in recent onset PR.

Disclosure of Interests: Beatriz Frade-Sosa: None declared, Rosa Maria Morlá: None declared, Lola Tobalina: None declared, Carolina Pérez-Garcia: None declared, Isabel Haro: None declared, Raimon Sanmartí: Speaker honoraria from Abbvie, BMS, Gebro-Pharma, Lilly, MSD, Pfizer, Sanofi and Roche.
Background: The prevalence of cervical spine involvement in rheumatoid arthritis (RA) varies between 17 and 86%. Cervical spine involvement is in third place after hand-wrist and foot involvement. The activity of RA is manifested by inflammation of all joints.

Objectives: To study the characteristics of patients with rheumatoid arthritis and research a relationship between cervical spine involvement and disease activity in rheumatoid arthritis.

Methods: We conducted a multicenter, prospective, descriptive, cross-sectional study in 300 patients with RA between 2013-2018. We collected demographic data, Body mass index (BMI), disease duration, Disease Activity Score of 28 joints (DAS28), (Health Assessment Questionnaire (HAQ), CRP, ESR, the rheumatoid factor (RF), ACPA. A radiological assessment of the cervical spine was requested for all patients, including a radiograph of the cervical spine from the front with the mouth open, a neutral profile, and dynamic flexion and hyperextension views. The activity of RA was assessed by DAS28. We study the relationship between cervical spine involvement (CSI) and disease activity in RA.

Results: 80.3% were female, sex ratio H/F was 0.24, the mean age was 51.7±12.68 years, the BMI was 26.1±5.25, 67.6% had comorbidities, the most frequent were osteoporosis (30%), obesity (24%), hypertenion (21.7%). RA mean duration was 13.9± years, mean DAS 28 was 4.68±1.5 mean RA was 1.01±0.69, mean CRP was 15.5±2.12mg/L, mean ESR was 41.89±26.8mm, rheumatoid factor was positive in 70.6% and ACPA were positives in 77.3%. The standard radiographs of cervical spine found 53 (17.66%) patients with CSI. The various lesions of the cervical spine were atlantoaxial subluxations 13%, 3.66% of lateral atlantoaxial subluxations, vertical subluxations in 0.66%, C1C2 arthropathies in 2.33%, spondylolisthesis in 2%, and 0.33% of spondylidoscites. The results of the univariate and multivariate analysis did not find a relationship between CSI and DAS28 (p=0.66).

Conclusion: Cervical spine involvement in rheumatoid arthritis was common in our study. We did not find a relationship between cervical spine involvement and disease activity in rheumatoid arthritis.

AB0199 RELATIONSHIP BETWEEN EXERCISE AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

A. N. Garza-Cisneros1, J. J. Colunga-Pedraza1, D. Á. Galarza-Delgado1, J. R. Azpiri-López2, A. B. Rodriguez-Romero3, M. A. Balderas-Palacios1, A. García-Heredia1, N. Guajardo- Jauregui1, A. Cárdenas1, Universidad Autónoma de Nuevo León, Hospital “Dr. José Eleuterio González,” Rheumatology, Monterrey, Mexico; 2Universidad Autónoma de Nuevo León, Hospital “Dr. José Eleuterio González,” Cardiology, Monterrey, Mexico

Background: Rheumatoid arthritis (RA) is a chronic, autoimmune, inflammatory disease in which cardiovascular disease is the leading cause of death (1). Exercise has been shown to have certain benefits in chronic diseases such as RA, decreasing symptoms and disease activity (2).

Objectives: To correlate exercise and minutes of physical activity performed per week with the disease activity level in a Mexican RA population.

Methods: This was a cross-sectional study in which a total of 240 Mexican patients with a diagnosis of RA were included. They were divided into two groups (120 in each): those who self-reported performing at least 30 minutes of exercise 3 or more times per week and were matched with patients who did not perform it by age, gender, and comorbidities. The disease activity level was determined with Disease Activity Score 28-joint erythrocyte sedimentation rate (DAS28-ESR) and Disease Activity Score 28-joint C-reactive protein (DAS28- CRP). Distribution was evaluated with Kolmogorov-Smirnov. Comparisons with Chi-square test, Student’s t-test, and Mann-Whitney U test. Correlation between disease activity level and minutes of exercise per day with Spearman-rho coefficient.

Results: DAS28-ESR was significantly higher in patients who did not exercise (4.38±3.68) vs 4.37 (3.6-4.63), p=0.006). DAS28-CRP had similar trend 2.76 (1.89-4.14) vs 3.51 (2.28-4.63), p=0.004 (Table 1). The Spearman-rho coefficient showed a significant correlation between the minutes of exercise performed per week and DAS28-ESR (rho=-0.193, p=0.003) and DAS28-CRP (rho=-0.207, p=0.001) (Figure 1). A multivariate analysis was performed in which minutes of exercise performed per week, treatment, and comorbidities were included, showing an independent association between

AB0200

INTAKE OF FISH RICH IN N-3 POLYUNSATURATED FATTY ACIDS IS ASSOCIATED WITH GOOD RESPONSE TO TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING TARGETED THERAPIES.

M. Tauri1, O. Amengual1, Y. Fujieda1, M. Navieda Fuentes2, N. Tsuchida1, M. Yasuda1, K. Nishino1, Y. Kusom1, S. Takeyama1, M. Yoshimura1, K. Ninagawa1, K. Aso1, M. Kono1, M. Kato1, R. Cáliz Cáliz2, T. Atsumi1.
1Hokkaido University, Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Sapporo, Japan; 2Hospital Virgen de las Nieves, Department of Rheumatology, Granada, Spain

Background: The management of rheumatoid arthritis (RA) has been transformed by the use of molecular targeted therapies. Early treatment and treat-to-target approach leads to good clinical response and remission (responders), but not in all patients.

Environmental factors including diet contribute to the development, activity and severity of RA. Evidence from clinical trials suggested that dietary interventions, such as Mediterranean diet or supplementation with fish oil rich in n-3 polyunsaturated fatty acids (n-3 PUFA), have positive effects on RA. Japanese and Mediterranean diets are associated with longevity and characterized by high fish intake. Clinical studies have identified predictors of treatment response in individual RA patients, however, the influence of fish consumption on treatment response in RA patients treated with targeted therapies has not been elucidated.

Objectives: To assess whether diet is associated with a good response to targeted therapies in RA patients with Japanese and Mediterranean dietary patterns.

Methods: The study is a collaborative international cross-sectional retrospective study enrolling patients with RA on treatment with biologics or JAK inhibitors attending to Hokkaido University Hospital, Japan or Hospital Virgen de las Nieves, Spain. Enrolled patients were asked to complete a brief-type self-administered diet history questionnaire (BDHQ) and a detailed fish frequency questionnaire (DFFQ) reporting to consumption frequency in the previous month. At study entry, alcohol consumption, tobacco habits, educational level and employment status were recorded and RA disease activity evaluated by qualified rheumatologists. Demographic, clinical/laboratory data were retrospectively extracted from the medical records.

By December 2021, 279 patients (Japan 217; Spain 62) returned the questionnaires. A preliminary analysis was carried out with the first 58 Japanese patients in which all clinical and laboratory data could be collected. A descriptive analysis was performed and the relative risks approximated by odds ratios.

Results: Fifty-eight Japanese RA patients, 45 females, median age at entry 66 yrs [IQR 54-73], median disease duration 11yrs [IQR 7-20] were included in this
analysis. Fifty-three (93%) of patients were on biologic therapies and four (7%) on JAK inhibitors with a median treatment duration of 4.5 yrs [IQR 1-7]. Concomitant treatment with conventional DMARDs and glucocorticoids were reported in 69% and 48% of patients, respectively. Forty-two (72%) patients were responders to treatment defined as DASESR 3.2. Another systemic autoimmune disease, hypertension, diabetes mellitus, dyslipidemia or gout history were present in 29%, 29%, 9%, 33% and 10% of patients, respectively. All patients had consumption of fish in the last month and an intake of n3-PUFA rich fish (fatty fish) was indicated by 82% (<1 time/week 34%, 1 time/week 48%). The patients’ fatty and non-fatty fish intake scores were calculated with a mathematical formula based on the intake of each of the fish included in the DFFQ and number of responses. In the group of high fatty fish score patients (≧1 time/week) 94% were responders to treatment vs. 6% non-responders, [OR 8.75, CI [1.0-73.54, p= 0.022] while only 63% of patients in the high non-fatty fish score group respond to the treatment. The patients’ fatty and non-fatty fish intake scores were calculated with a mathematical formula based on the intake of each of the fish included in the DFFQ and number of responses. In the group of high fatty fish score patients (≧1 time/week) 94% were responders to treatment vs. 6% non-responders, [OR 8.75, CI [1.0-73.54, p= 0.022] while only 63% of patients in the high non-fatty fish score group respond to the treatment.

Conclusion: Fatty fish intake associated with a good response to treatment in patients receiving targeted therapies, suggesting that fish consumption may have some beneficial effects on RA treatment.

References: There is no reference.

GUT MICROBIOTA DYSBIOSIS WERE CLOSELY CORRELATED WITH LYMPHOCYTE SUBSETS AND CYTOKINES IN PATIENTS WITH INFLAMMATORY ARTHRITIS

J. Liu1,2,3, S. X. Zhang1,2,3, J. Qiao1,2,3, R. Zhao1,2,3, S. Song1,2,3, T. Cheng1,2,3, W. Wang1,2,3, X. Li1,2,3, C. Wang1,2,3, The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 3Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China

**Background:** Inflammatory arthritis includes a group of chronic conditions, particularly rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) [2]. Growing evidences link gut microbiota dysbiosis with the development of inflammatory arthritis [10].

**Objectives:** The aim of this study was to discover the characters of microbiota in inflammatory arthritis patients and compare the relationship between the microbiota and peripheral lymphocyte subsets and cytokines.

**Methods:** Fecal samples were collected from 73 arthritis patients (13 PsA, 30 AS, 30 RA patients) and 140 sex- and age-matched healthy controls (HCs). The gut microbiota was studied by sequencing the V3-V4 variable regions of bacterial 16S rRNA genes by the Illumina MiSeq PE300 system. Peripheral lymphocyte subsets in these participants were assessed by flow cytometry. Measures of disease activity such as erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) were recorded. Alpha and Beta diversity was assessed using results from QIIME2 and gut microbiome profiles were compared using linear discriminant analysis (LDA) effect size (LEfSe). R (version 4.0.1) was used for comparative statistics, using pearson correlation analysis to assess the correlation between the relative abundance of genus in the sample and clinical parameters.

**Results:** Compared with HCs, the richness of gut microbiota (ACE and Chao 1) was significantly lower (p < 0.05) in arthritis patients, and bacterial diversity including Shannon and Simpson indices (p < 0.001) was also significant in arthritis decreased (Figure 1A). β-diversity analysis based on Bray-curtis distance revealed significant differences in microbial communities between arthritis and HCs (Figure 1B, r=0.098, p=0.001, ANOSIM). In addition, compared with HCs at the genus level, 9 bacterial groups were significantly different in PsA (p < 0.05), 19 bacterial groups in AS (p < 0.05), and 17 bacterial groups in RA(p < 0.05) (Figure 1C). There was a significant positive correlation between CD4+ T and Prevotella(p<0.01), T and Prevotella(p<0.05), Blautia(p<0.05) as well as Megamonas(p<0.05), Th17 and Prevotella(p<0.01), CD6+ T and Megamonas(p<0.01), Th1 and Megamonas(p<0.05), Prevotella(p<0.01),Coprooccus(p<0.05), B and Erysipelotrichaceae_UCG-003(p<0.01), and Erysipelotrichaceae_UCG-003(p<0.01), Anaerostipes(p<0.01), CRP and Fusobacterium(p<0.05) as well as Roseburia(p<0.05). There were negative correlations between T and Erysipelotrichaceae_UCG-003 (p<0.01),CD8+T and Fusobacterium(p<0.01), CD4+T and Fusobacterium(p<0.05), NK and Fusiformis(p<0.05).

**Conclusion:** The gut microbiota of patients with inflammatory arthritis differs from HC and also varies among individual arthritis, which was closely related to lymphocyte subsets.

25-HYDOXYVITAMIN D [25 (OH) D] LEVEL IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS, ITS RELATIONSHIP WITH THE COURSE OF THE DISEASE, VDR (FOK1) GENE POLYMORPHISM AND BONE MINERAL DENSITY.

Y. Seheda1, S. Shevchuk2, O. Gallutina1, I. Kuvikova1, O. Shevchuk2, 1Scientific and Research Institute of Invalid Rehabilitation of VINNYTSIA NATIONAL PIROGOV MEMORIAL MEDICAL UNIVERSITY, Rheumatology Department, Vinnytsya, Ukraine; 2VINNYTSIA NATIONAL PIROGOV MEMORIAL MEDICAL UNIVERSITY, Department of Internal Medicine #2, VINNYTSIA, Ukraine

**Background:** Osteoporosis is known to be a common concomitant state in post-menopausal women with rheumatoid arthritis, but its development cannot be explained only by increasing of age, hormonal disorders, disease duration and glucocorticosteroid intake. Vitamin D deficiency may be one of the major risk factors, but its prevalence in the Ukrainian cohort of postmenopausal RA patients is unknown, and the factors on which it depends have not been established.

**Objectives:** To analyze the level of 25-hydroxyvitamin D [25 (OH) D] in postmenopausal women with rheumatoid arthritis (RA) and to investigate its relationship with the course of the disease, VDR (FokI) gene polymorphism and bone mineral density (BMD).

**Methods:** The study included 81 postmenopausal RA patients and 21 post-menopausal age-matched women without RA as a control group. All patients

**Acknowledgements:** This work was supported by the National Natural Science Foundation of China (No. 82001740).

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.3485
were screened for demographic, disease course and treatment data. Serum 25-hydroxyvitamin D [25 (OH) D] level and VDR (FokI) gene polymorphism were measured by enzyme-linked immunosorbent assay (ELISA). Levels of 25-hydroxyvitamin D [25 (OH) D] ≥ 30 ng/ml were defined as sufficiency and less than 20 ng/ml as deficiency. BMD was measured in the lumbar spine and proximal femur using double X-ray absorptiometry. Osteoporosis was diagnosed in case of BMD > -2.5 T.

Results: The analysis has shown that serum vitamin D level in RA group was significantly lower than in control group (11.54 ng/ml vs. 15.25 ng/ml; p < 0.01). In addition, the incidence of vitamin D insufficiency and deficiency was higher in RA patients than in control group. In particular, abnormal vitamin D level was diagnosed in 74.1% of RA patients, among whom 25 (30.9%) patients had vitamin D insufficiency and 35 (43.2%) patients had vitamin D deficiency. In control group 8 (38.1%) persons had vitamin D insufficiency, and 6 (28.6%) persons had vitamin D deficiency. There was an inverse correlation between vitamin D levels and RA activity assessed by DAS28 (<p>0.001), CDAI (<p>0.001), ESR and CRP (<p>0.001) but not with age, daily glucocorticosteroid dose and disease duration. In addition, significant correlation was revieled between VDR (FokI) gene polymorphism and vitamin D deficiency, as well as low BMD in postmenopausal women with rheumatoid arthritis (<p>0.001).

Conclusion: Low 25-hydroxyvitamin D [25 (OH) D] level and VDR (FokI) gene polymorphism are independent risk factors of osteoporosis in postmenopausal women with RA. Vitamin D deficiency is associated with RA activity and not depends on age, glucocorticosteroid daily dose and disease duration.

AB0204 DOES THE PRESENCE OF COXITIS IN RHEUMATOID ARTHRITIS CHANGE THE DISEASE SEVERITY PROFILE?

A. Ben Tekaya1,2, E. Hannech1,2, O. Saidane1,2, S. Bouden1,2, R. Leila1,2, R. Tekaya1,2, I. Mahmoud1,2, L. Abdelmoula1,2, Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; 2Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by intra-articular manifestations affecting small and large joints. Hip involvement is not common but it can predict a severe disease course [1].

Objectives: Our study aimed to investigate the prevalence of coxitis in RA patients and to compare patients with RA coxitis (+) and RA coxitis (-) according to their clinical, biological outcomes and their therapeutic findings.

Methods: This was a retrospective and comparative study, which include patients diagnosed with RA according to the ACR/EULAR 2010. Sociodemographic, clinical, biological, and therapeutic data were collected. The diagnosis of coxitis was made on plain X-rays or MRI.

Results: Among 255 RA, there were 30 RA coxitis (+) (11.8%). Coxitis was unilateral in 28 patients and bilateral in 2 patients. The mean delay onset of coxitis was about 11.6 ± 8.4 years (p<2). The mean age was 57.5 ± 12.2 years for RA coxitis (+) and 59.1 ± 10.5 years for RA coxitis (-) (p=0.5). The gender distribution was 70% female and 30% male) for RA coxitis (+) and (85% female and 15% male) for RA coxitis (-) (p=0.04). The mean Body Mass Index was 24.8 ± 4.8 kg/m² in RA coxitis (+) and 28 ± 5.8 kg/m² in RA coxitis (-) (p=0.03). Comorbidities were present in 46% of RA coxitis (+) and 48% of RA coxitis (-) (p=0.8). Extra articular manifestations were noted in 76% RA coxitis (+) and 68% RA coxitis (-) (p=0.8). RA was seropositive in 76% RA coxitis (+) and in 82% RA coxitis (-) (p=0.4). RA was immunopositive in 51% RA coxitis (+) and 69% RA coxitis (-) (p=0.04). The mean DAS28 (CRP) was respectively 4.6 ± 1.1 in RA coxitis (+) vs 4.8 ± 1.1 RA coxitis (-) (p=0.7). Atlanto-axial dislocation was noted in 60% RA coxitis (+) and 22% RA coxitis (-) (p=0.04). The use of corticosteroid was noted in 92% RA coxitis (+) and in 90% RA coxitis (-) (p=0.04). Biologic drugs were prescribed in 43% RA coxitis (+) and in 25% RA coxitis (-) (p=0.04).

Conclusion: Our study showed that coxitis in RA patients is associated with a higher risk of Atlanto-axial dislocation and a more frequent use of biologic drugs reflecting a more severe and mutilating disease. We highlight the importance of an early diagnosis and treatment to prevent complications.

AB0205 TENDERNESS AND RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

I. Gessi1, M. Popescu2, G. Supp3, T. Deimel1, P. Studenic4, M. Durechova5, M. Zauner6, J. S. Smolen7, D. Aletaha1, P. Mandl1. 1Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria; 2Hôpital Maisonneuve-Rosemont, Department of Rheumatology, Montreal, Canada; 3Karolinska Institutet, Division of Rheumatology, Stockholm, Sweden

Background: In inflammatory arthritis swelling is regarded as a sign of synovitis and is associated with radiographic progression. However, the association of tenderness with radiographic progression is not clear.

Objectives: To assess the predictive value of tenderness alone and with consideration of sonographic signs for synovitis, disease duration and baseline radiographic damage for subsequent radiographic progression in rheumatoid arthritis (RA) and psoriatic arthritis (PsA).

Methods: Clinical and sonographic (grey scale (GS) and power Doppler (PD)) examination of 22 joints of the hand were performed cross-sectionally in consecutive patients with RA and PsA with at least one tender joint. Radiographs were scored for erosions and joint space narrowing (JSN) at inclusion and radiographic progression of each joint was assessed after 2 years. The impact of tenderness on progression was analyzed in non-swollen joints for RA and PsA separately with logistic regression analyses. As a second step, the association of PD, GS, disease duration, C-reactive protein, baseline erosions and JSN and global joint counts with subsequent structural damage was assessed using univariate logistic regression in tender non-swollen joints again on the joint level.

Results: We included 1207 joints in 54 RA patients and 396 joints in 18 PsA patients. Tenderness was associated with subsequent radiographic progression in non-swollen joints in PsA (OR 3.44, 95% CI 1.78-6.62, p<0.01) but not in RA (OR 1.80, 95% CI 0.99-3.38, p=0.55) (Figure 1). In tender non-swollen joints in RA patients, PD (OR 3.74, 95% CI 1.10-11.30, p=0.04) and baseline erosions (OR 4.42, 95% CI 1.22-15.95, p=0.02) had a significant impact on radiographic progression. In PsA patients, PD (OR 8.46, 95% CI 1.72-41.72, p<0.01), baseline erosions (OR 6.71, 95% CI 1.43-31.39, p=0.02), baseline JSN (OR 7.27, 95% CI 1.47-35.89, p=0.02) and SJC (OR 1.26, 95% CI 1.07-1.48, p=0.01) were associated with radiographic progression.

Figure 1. The proportion of joints with progression in tender non swollen and non tender non swollen joints in patients with rheumatoid and psoriatic arthritis; NTNS: non tender non swollen; TNS: tender non swollen

Conclusion: Our findings indicate that tenderness in non-swollen joints is associated with subsequent radiographic progression in PsA, while in RA it is a risk factor for radiographic progression only in the presence of additional factors, such as sonographic signs for synovitis.

AB0206 STUDY ON THE SIGNIFICANCE OF SERUM COMPLEMENT CS IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Liu1, Q. Zhou2, X. Chen1, H. Guo2, L. Long2. 1Zunyi Medical University, Department of Rheumatology and Immunology, Sichuan Provincial People’s
Background: Recent studies have pointed out that complement system activation is a major alteration in early atherosclerotic plaques, and complement C5 has promising value as a novel circulating biomarker of atherosclerosis, but the relationship between C5 and carotid atherosclerotic (CAS) plaque in rheumatoid arthritis (RA) is still unclear.

Objectives: To investigate the clinical significance of serum complement C5 and the association with CAS plaque in patients with RA.

Methods: 143 patients with RA were included in the study, and 48 cases with age- and sex-matched healthy physical examination without RA or CAS plaque served as a normal control. All RA patients were divided into RA with CAS plaque group and RA without CAS plaque group according to the presence or absence of plaque formation in the carotid artery. The subject's demographic data, laboratory investigations and serum samples were collected. Body mass index (BMI) and Disease Activity Score 28-joint counts (DAS28) were calculated. Glucocorticoid and DMARDs use were recorded in the past 3 months. ELISA method was used to determine the concentration of complement C5 in the serum of each participation. CA5 plaque was determined by color Doppler ultrasound.

Results: Serum complement C5 in RA group was significantly lower than that in control group (P<0.05), whereas C5 level in RA without CAS plaque group was significantly higher than that in RA without CAS plaque group (P<0.05). In RA group, serum C5 level was positively correlated with CAS plaque, high-sensitivity C-reactive protein (hs-CRP) and fibrinogen (FIB) (r=0.004, P=0.017; r=0.235, P=0.009; r=0.186, P=0.029). In addition, there was no significant correlation between serum C5 and sex, age, BMI, course of disease, DAS28, lipid profile (TG, serum triglyceride; TC, total cholesterol; LDL, low density lipoprotein cholesterol; HDLC, high density lipoprotein cholesterol; TC/HDLc; LDL/HDLc), immune markers (RF, rheumatoid factor; anti-CCP, anti-cyclic citrullinated peptide antibodies), cytokine (IL-6, Interleukin-6; TNF-α, Tumor necrosis factor-α), erythrocyte sedimentation rate (ESR) (all P>0.05), or drug therapy (all P>0.05).

Conclusion: C5 may be a novel circulating marker of atherosclerosis in RA patients, it might promise to assist in risk stratification for cardiovascular disease in the future.

Figure 1. Percentage of swollen joint affection at baseline, final registered visit and average followup

Conclusion: In this registry, some swollen joints were persistently affected across the follow-up, and did not improve from baseline to the last registered visit. However, the burden of the disease improved, measured by DAS28 or its individual components. The improvement of other swollen joints and other components of DAS28 can be the reason. The detection and local treatment (v: intra-articular injections) of this persistent swollen joints could be the better approach to this issue. Weaknesses of this study: a possible bias in the included patients (they were from single clinic), joint assessment not blind and performed by a single rheumatologist, patients included could be more severe since they were more frequently bDMARD/tsDMARD users.

REFERENCES:
areas from January 2013 till December 2020. A multivariate time series approach using Evidence from vector error correction model (VECM) was employed to investigate the effect of ambient pollutants emissions on DAS28 over that period.

**Results:** A total of 1,809 RA patients and 10,215 hospital visits were included, 63% females, mean age 54 years, mean disease duration 9.2 years and 77% had rheumatoid factor positive. A significant correlation was found between DAS28 and NO2, NO2 and O3 (p=0.012, 0.029, 0.039 respectively). According to the Granger causality test and VECM, emissions of NO2, and O3 had a positive short-term effect on DAS28 among RA patients. Impulse response test results showed that for some locations in Kuwait there is a short-term positive causal relationship between emissions of NO2 and DAS28, due to sources of pollution surrounding the locations. The results showed that the short run effect for NO2 with lags 1 to 4 days had a positive relationship with DAS28 which means, there is 1% increase in DAS28 for every 0.0182 increase in NO2 emission. Our results revealed that 36% of discrepancy between the overall relationship between DAS28 and air pollution is corrected each year.

**Conclusion:** Increased concentrations of air pollutants may increase the risk of RA activity. VECM time series model can be used as a tool to predict changes in disease activity based on air pollutants up to 8 days. We recommend that a regular broadcast is issued by health authorities to RA patients to help predict changes in disease activity. Warning about air pollution may be tailored according to the patient’s residential area. Government should take serious decisions to help minimize air pollution in the residential areas.

**PHYSICIAN TRUST RATHER THAN RHEUMATOID ARTHRITIS KNOWLEDGE RELEVANT IN DISEASE OUTCOMES IN ETHNIC MINORITY PATIENTS WITH RHEUMATOID ARTHRITIS**

S. Dowell1, M. Quinones1,2, A. Miller1, O. Kadirir1, T. Jamshidi1, G. Kerr1,2.

1Howard University College of Medicine, Internal Medicine, Washington, United States of America; 2Washington DC VA/VC, Rheumatology, Washington, United States of America

**Background:** Ethnic minority (EM) patients with Rheumatoid Arthritis (RA) have more severe disease, more disability, and less use of biologic disease modifying anti-rheumatic drugs (bDMARDs). A Treat to target (T2T) strategy has been recommended to improve clinical outcomes but barriers include patient preference, access to specialty care and increased administrative effort. Additionally, EM patients in the US often have low health literacy, express greater reluctance to accept physician recommendations, in part due to sociocultural preference and mistrust of a historically biased healthcare system. It is unknown whether improving knowledge of RA would improve T2T outcomes in EM active RA patients.

**Objectives:** To assess the proportion of EM RA patients who achieve low disease activity or remission following implementation of a coordinator-based education program highlighting T2T RA strategy.

**Methods:** Adult participants with active RA (RAPID3>6 or CDAI >10) were invited to participate in a series of five one-on-one 20-minute educational sessions, co-occurring with scheduled routine clinic visits (6-12-week intervals). Sessions were facilitated by a rheumatology care coordinator, a non-healthcare professional with intensive training over 4 weeks to conduct RA patient education. Sociodemographic data was collected, and disease activity measures (TJC, SJC, RAPID3, CDAI) and validated patient questionnaires on RA Knowledge (ACREU), compliance (CQRS), and physician trust (Trust in Physician Scale) were recorded at baseline and after the final educational session. Descriptive statistics were applied and medians and ranges were measured. Pearson reported. Paired T-test was used to test for significant differences in scores after the education sessions. Correlations between the ACREU scores and clinical-demographic variables were measured using Pearson’s correlation coefficient.

**Results:** 20 EM patients (75% Female, mean age, 58.8 years (12.2) seen by EM physicians were enrolled, with mean RA disease duration of 7 years and poor prognosticators (75% double seropositivity). ACREU scores were low at baseline (mean 0.45 (0.16)), with no significant improvement on completion of educational sessions, and no correlation with years of education or duration of RA. There was a positive correlation between ACREU and compliance scores at baseline (r=0.3). Average duration of the education period was 9.72 months, with a 33% decrease in average RAPID3 over time, and 42% of patients achieving a target of remission or LDA. Trust in Physician scores were high at baseline and persisted with >50% of patients completing at least one medication change during study period.

**Conclusion:** RA knowledge did not impact RA patient outcomes in this cohort of EM patients. However, patients had high trust in their providers and achieved clinical remission or LDA despite risk for poor outcomes highlighting the importance of the provider-patient relationship in achieving targeted goals of therapy. Limitations include the small sample size from a single institution, and the lengthy time between initial and final assessment of RA knowledge.

**REAL-LIFE DAS28-DEFINED REMISSION IN RHEUMATOID ARTHRITIS – INFLAMMATION CONTROL IS NOT ENOUGH**

C. Popescu1,2, E. M. Marin1,2, C. Codreanu1,2. Carol Davila University of Medicine and Pharmacy, Rheumatology, Bucharest, Romania; 1Center for Rheumatic Diseases, Rheumatology, Bucharest, Romania

**Background:** Remission of rheumatoid arthritis (RA) is currently a reachable target in real-life settings under treat-to-target strategies, meta-analytical data
Foot impairment is not a barrier to physical activity in rheumatoid arthritis

A. Ben Tekaya1, C. Ines1, O. Saidane1, R. Leila1, S. Bouden1, R. Tekaya1, I. Mahmoud1, L. Abdelmoula1, Charles Nicola Hospital, Rheumatology, Tunis, Tunisia

Background: Physical activity is increasingly promoted for patients with Rheumatoid arthritis (RA) and strongly recommended. However, adherence to regular physical activity remains low. Identifying the barriers to physical activity is a key element to understanding physical activity behavior in RA.

Objectives: Our objective was to assess the impact of foot involvement on physical activity among patients with RA.

Methods: We conducted a cross-sectional study involving patients with RA, fulfilling the ACR-EULAR 2010 criteria. We collected the socio-demographic data and disease characteristics. Regarding the foot involvement, we assessed the prevalence of foot static disturbances and foot deformities through clinical examination, and radiographic damage. Physical activity was assessed by the Arabic version of validated questionnaires.

Results: The sample included 157 patients with established RA, mostly women (80.3%), 56.2±11.8 years-old on average. The group included predominantly positive rheumatoid factors (77.7%) and positive anti-citrullinated protein antibodies (81.5%), with only 12.1% both negative. At baseline, 58.0% were receiving one csDMARD (especially leflunomide - 49.7%, and methotrexate - 43.3%), 38.9% were receiving 2 csDMARDs, and 57.3% were on oral glucocorticoids (7.8±4.4mg/day on average). All patients had high baseline disease activity (average DAS28 of 6.3±0.8). Accordingly, all patients were initiated on either original/biologic TNF inhibitors (adalimumab - 22.3%; certolizumab - 70.9%; etanercept - 31.2%; golimumab - 1.3%; infliximab - 17.8%), other bDMARDs (abatacept - 3.8%; rituximab - 19.5%; tocilizumab - 6.4%) or tsDMARDs (baricitinib - 5.7%; tofacitinib - 2.5%). After 6 months, 29.3% of patients were in DAS28-defined remission, 22.9% in DAS-28 DA, 35.7% in MDA and 12.1% in HDA. Therefore, 12.7% switched their initial bDMARD and 10.8% stopped their tsDMARDs, because 10.8% exhibited primary non-responsiveness (PNR) and 11.5% had adverse events (7 dermatological conditions, 6 cases of non-tuberculosis pneumonia, 1 case of clinical pulmonary tuberculosis, 1 case of latent tuberculosis, 1 transaminitis, 1 gastric cancer, 1 neutropenia). High baseline levels of DAS28 were associated with a lower probability to attain DAS28-remission after 6 months (OR = 0.64) and with a higher probability to switch the initial bDMARD due to PNR (OR = 2.44), suggesting that pharmaceutically influencing the inflammation cascade is not enough. Addition of tsDMARDs reduced at 6 months the prevalence of oral glucocorticoids to 28.0% (5.9±2.6mg/day on average).

Conclusion: Although reachable, disease remission seems difficult to attain, despite using advanced therapies. High baseline levels of DAS28 are negative predictors for not attaining remission and switching of therapy due to PNR in real-life.

Disclosure of Interests: None declared
While the mean ages of the RA and PsA patients who had polypharmacy treatment at the beginning were respectively 59.21±12.65 and 53.5±13.81, their ages were significantly higher than the ages of those who did not receive polypharmacy treatment (respectively, 51.26±13.53 and 45.22±12.3). In RA vs PsA patients, the status of polypharmacy is higher in the groups in the groups aged 65 and over than those under 65 years of age, and it is statistically significant (p=0.001 and p=0.048, respectively). The risk of polypharmacy in people over 65 years of age in RA patients was 8.2 times, and the risk of polypharmacy in people over 65 years old in PsA patients was increased 6.3 times (p=0.015).

In both the RA and PSA groups, patients with baseline polypharmacy had statistically significantly higher DAS-28 CRP scores at 6 months of treatment than those without baseline polypharmacy (p<0.001). While the higher DAS-28 CRP score was maintained at 12 months in the RA group with polypharmacy at baseline (p=0.006), this was not significant in the PSA group (p=0.07).

Conclusion: Polypharmacy was present both at the time of diagnosis and in the treatment process in the RA and PsA patients, and the presence of polypharmacy at the beginning of the treatment was among the factors that affected the treatment of these patients by significantly affecting their 6-month DAS-28 CRP values.

SERUM IMMUNOGLOBULINS LEVEL IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS ON DIFFERENT TREATMENT OPTIONS

C. Moopasai1, 2, E. M. Marin1, C. Popescu1, 2, L. Enache1, 2, B. Dumitrescu1, 2, M. Agache1, 2, O. G. Dinache1, 2, C. E. Ionescu1, 2, D. Minca1, 2, C. Codearun1, 2, 1Center of Rheumatology, Bucuresti, Bucharest, Romania; 2Carol Davila University of Medicine and Pharmacy, Rheumatology, Buchuresti, Romania

Background: Serum immunoglobulins (Ig) A, G, and M (IgA, IgG, and IgM) are not routinely evaluated in rheumatoid arthritis (RA). There are some reports that rituximab (RTX) may induce hypogammaglobulinemia (1). Under normal conditions, IgM provides a rapid immune response and is involved in tissue homoeostasis, whereas IgG and IgA are long-lasting high-affinity antibodies, the latter mainly providing mucosal immunity (2).

Objectives: The evaluate serum Ig levels (IgG, IgM, IgA) in a cohort of RA patients and potential therapeutic influences.

Methods: We performed a retrospective study in a cohort of 104 patients with RA exposed to different therapeutic agents, without switch for at least 1 year (conventional synthetic disease modifying drugs - csDMARDs, biologics and JAK inhibitors - JAKi); the collected data included demography, disease characteristics, treatment exposure (molecules, treatment line), serum level of IgA, IgG, IgM.

Results: 104 patients, mean age 60.3 years (±11.9), with a disease duration of 15years (±9.8), 83.7% women; the mean exposure to the current treatment option (without switch) was 3.7 years (±3.8); 20.2% (21 pts) were on csDMARDs, 70.2% (73pts) on biologics and 9.6% (10pts) on JAKi. 90.4% (83pts) used combination therapy along with biologics and JAKi. The biologics used were: 58.9% RTX, 43.5% TNF inhibitors, 8.3% IL-6 blockers and 13% abatacept. At cohort level, we found hypogammaglobulinemia in 12.5% for IgG, 9.6% for IgM and 7.7% for IgA, independent of the treatment duration. Low IgG levels were related mostly to RTX exposure (53.8%) followed by TNFi (23.1%) and with equal values anti-IL-6, JAKi and csDMARDs (7.7%). Low IgA levels were noted almost in RTX exposure (75%), followed by TNFi and anti-IL-6 (12.5%, each). Low IgM levels appeared in RTX group (90%) and csDMARDs (10%). No relations between Ig levels and the treatment option (the line of intervention). The Ig mean levels were significantly different across treatment groups; for IgG: 9.55g/L in RTX vs 11.68g/L in TNF inhibitors (p<0.05) and 12.64g/L in csDMARDs (p<0.05); for IgA: 2.17g/L in RTX vs 3.35 in JAKi (p<0.05); for IgM: 0.84g/L in RTX vs 1.82g/L in TNF inhibitors (p<0.001) and 1.58g/L in JAKi (p<0.05); also IgA were significantly lower in csDMARD group (1.22g/L compared to TNF inhibitors values 1.82g/L, p<0.05). The serum levels of IgG and IgM (not IgA) were negatively associated with disease duration r = -0.22, p<0.05 and r = -0.2, p<0.05 and age (r =-0.2, r=-0.26, p=0.01). No impact of disease activity, nor patient gender or seropositivity of rheumatoid factor or ACPA.

Conclusion: Low serum levels of IgG, IgM and IgA are seen mostly with RTX exposure, but appear with other treatment exposures as well, which may influence the rate of future infections. If our study lacks assessment of baseline Ig levels, it is clear that treatment option has an influence on Ig levels. Future studies are needed to clarify all contributors to these results.

DOES THE PARNICY IMPROVE THE RHEUMATOID ARTHRITIS ACTIVITY?

E. Rahbi1, 2, H. Ferjani3, 4, 5, D. Ben Nessib3, 4, 5, L. Khatir1, 2, W. Triki1, 2, K. Lebbar1, 2, D. Kaffel4, 6, W. Hamdi4, 6, C. Kaddouch1, 2, 1Kassab Orthopedic Institute, Rheumatology Department, Mannouba, Tunisia; 2University Tunis el Manar, Faculty of Medicine of Tunis, Beb Saadoun, Tunisia; 3Kassab Orthopedics Institute, Institute Rheumatology Department, Ksar Said, Tunisia; 4University Tunis el Manar, Tunisia, Faculty of Medicine of Tunis, Beb Saadoun, Tunisia; 5Research Unit UR17SP04, Ksar Said, Tunisia; 6Research Unit UR17SP04, Ksar Said, Tunisia

Background: Parnic is known for its anti-inflammatory activity and its potential to reduce inflammation. The purpose of this study was to evaluate the impact of Parnic on the inflammatory markers, pain, and functional status in patients with rheumatoid arthritis.

Objectives: To examine time trends in the characteristics of patients with rheumatoid arthritis (RA) undergoing total joint replacement (TJR). Methods: A total of 271 patients (399 joints) with RA underwent TJR of large joints (hip, knee) at Republican Clinical Hospital, Kazan between 2002 and 2021. Of these, 98 patients were retrospectively examined between 2002 and 2011; 183 patients were observed prospectively in the perioperative period by a rheumatologist and orthopedist from 2012 to 2021. Of the 183 patients, 65.5% underwent one joint replacement, 19.1% underwent two joint replacements, 13.7% underwent three joint replacements, and 1.7% underwent four joint replacements during the study period. All patients met the 1987 ACR classification criteria or the ACR/EULAR diagnostic criteria. Median (interquartile range (IQR)) age at surgery was 56 (49, 63), the time from the onset of RA to TJR was 11 (7, 18) years. During the study period, total knee replacement was performed most often (67.9%). Joint pain (VAS), disease activity - DAS28, function of the HAQ index were assessed before the operation, after 6 and 12 months in the active observation group.

Results: In patients in 2002-2011, TJR were performed earlier from the time of the onset of RA compared to the 2012-2021 group [median (IQR), 10 (7-17) vs. 8-19 years, p=0.01], and there were more complications of surgery (16.3% vs. 5.4%, p<0.001). In the later period (2012-2021), there was a decrease in blood loss and operation time, p<0.05. With respect to RA treatment, a significant increasing trend was observed in the proportion of patients receiving methotrexate (p=0.006) and biological drugs and biologics (p<0.001).

In the prospective observation group (n=183), patients were significantly older at the time of TJR with low and moderate activity RA (n=106) compared with high activity (n=77) [median (IQR), 57 (51, 64) vs. 55 (46, 63), p=0.034]. A significantly less time from RA onset to TJR was observed in patients with high activity, using glucocorticoids. Patients who had the use of glucocorticoids TJR was performed earlier than non-users [median (IQR) 11 (6, 16) and 13 (8, 19) years, respectively, p=0.041]. There was no significant difference in time from the onset of RA to TJR, stratified by gender and the use of MTX, biological drugs. At the same time, there was no significant difference in dependence on the activity RA to reduce pain syndrome (VAS), improve function (HAQ) after surgery and presence of postoperative complications.

Conclusion: Over a 20-year period changes were observed in the characteristics of patients with RA undergoing TJR with an increase in the time before surgery. Perioperative management of patients by a rheumatologist and orthopedist can reduce blood loss, the number of complications after surgery. Patients with high RA activity and using glucocorticoids need TJR at an earlier time. Arthropathy in patients with highly active RA is also effective in improving functional ability.

Disclosure of Interests: None declared.

Background: The parity seems to decrease the risk of auto-immune diseases like Rheumatoid arthritis (RA). The risk reduction appeared when the parity number reached two [1]. The activity of RA improved during pregnancy and flares postpartum, but the relationship of parity to RA prognosis is unclear. The impact of childbirth on disease activity is less studied.

Objectives: We aimed to investigate the impact of parity on rheumatoid arthritis activity.

Methods: We conducted a retrospective study including patients fulfilling the American Congress Of Rheumatology / European League Against Rheumatism (ACR/EULAR) 2010 criteria.

We collected epidemiological, clinical, biological (C-reactive protein: CRP, erythrocyte sedimentation rate (ESR), immunological status (rheumatoid factor RF and anti-citrullinated protein/peptide antibody ACPA), and disease activity index (The Disease Activity Score 28 DAS28). We divided our patients into two groups: group (G1): the nulliparous women; group (G2): women who gave birth.

Results: Ninety-two patients were enrolled. There were 14 men and 78 women. The mean age was 59.56 ± 11.7 years. The mean disease duration was 9.32 ± 8.22 years. Among 78 women, we found 50 patients with parity. The main swollen joint was 3.34 ± 3.6 in G2 versus 4.44 ± 4.04 in G1 (p=0.94). The mean painful joints were 6.74 ± 5.12 and 9 ± 1.91 (p=0.28), respectively. However, the inflammatory syndrome is higher among women in G2. The mean CRP level was 15.1 mg/l, and the mean ESR was 37.7 mm. In G1, the RF and ACPA were 131 U/l and 281 U/l, respectively compared with 568 U/l and 315 U/l, respectively in G2.

A significant difference was noted in the DAS28-ESR between the two groups (G2: 4.18 ± 1.23 versus G1: 4.49 ± 2.5, p=0.04).

However, no association was found between parity and disease activity using the DAS28-ESR.

Conclusion: Our study showed that parity could have a protective effect on disease activity. It seems to be associated with a lower joint count and a lower rate of RF and ACPA. However, more studies are necessary to conclude these issues.

AB0216

FATIGUE ASSESSMENT IN RHEUMATOID ARTHRITIS, SANTO DOMINGO, DOMINICAN REPUBLIC

1Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic

Background: Rheumatoid arthritis (RA) is an inflammatory, systemic autoimmune disease affecting the synovial membrane of small joints.1 Wagan et al demonstrated that the frequency of fatigue in rheumatoid arthritis is 62%.2 Hammam et al described a higher rate of fatigue associated with higher disease activity. Fatigue is as a feeling of exhaustion, also as a reduction in physical and mental capacity.3 It can be measured with the scale FACIT-F (Functional Assessment of Chronic Illness Therapy-Fatigue), which evaluates the last 7 days, with a score of 0-52. For the severity analysis, 4 grades are used: no or mild fatigue (40-52), moderate (27-39), severe (14-26) and extreme fatigue (0-13).2,5

Objectives: To evaluate the frequency and degree of fatigue in rheumatoid arthritis.

Methods: Prospective, observational, cross-sectional study of a cohort of patients of the Rheumatology Service at Hospital Docente Padre Billini. Patients were interviewed in July 2021. Inclusion criteria: ≥ 18 years, diagnosis of RA according to the ACR/EULAR 2010 classification criteria. Exclusion criteria: previous diagnosis of fibromyalgia, depression or anxiety, treatment with antidepressants, antihistamines, beta-blockers. Scales measured: FACIT-F, DAS28, CDAI, and HAQ-DI. Statistical analysis was performed with the Pearson correlation (r). Data were analyzed in IBM-SPSS v23.

Results: 597 patients met inclusion criteria. 93% female, mean age 58.5±12.4 years, mean disease duration 7.5 years. HT 73.9% (441), DM 14.2% (85), dysimmune disease affecting the synovial membrane of small joints.1 Wagan A. et al found the frequency of sexual dysfunction in RA to be 69.2%.2 Pain is considered to have a fundamental role associated with the decrease in the frequency of sexual intercourse.3 The CSFQ-14 (Changes in Sexual Functioning Questionnaire), evaluates the changes in sexual functioning due to a disease and/or treatment in 5 domains with a score range of 14-70; cut-off point indicating sexual dysfunction <41 men and <47 women.4

Objectives: To evaluate the frequency and degree of sexual dysfunction in patients with rheumatoid arthritis.

Methods: Prospective, observational, cross-sectional study of a cohort of patients of the Rheumatology Service at Hospital Docente Padre Billini. Patients were interviewed in July 2021. Inclusion criteria: > 18 years, diagnosis of RA according to the ACR/EULAR 2010 classification criteria, at least 1 sexual intercourse. Exclusion criteria: previous diagnosis of another autoimmune disease, depression, diabetes, treatment with antidepressants, antiepileptics, narcotics. Scales measured: CSFQ-14, DAS28. Statistical analysis was performed with the Pearson correlation (r) with p<0.05. Data were analyzed in IBM-SPSS v23.

Results: Of the RA cohort, 483 met inclusion criteria. 93.4% (451) female, mean age 58±12.6 years, mean duration of diagnosis 8 years, married 53.8% (260), single 27.3% (134), widowed 16.6% (80), hypertension 73.9% (357), dyslipidemia 21.5% (104), obesity 18.0% (87), smoking 9.9% (48). Frequency of sexual dysfunction 61.3% (296). Sexual dysfunction in women 93.9% (278) and men 6.1% (18). Global domains: desire/interest 55.7% (165), desire/frequency 56.4% (167), pleasure 58.1% (172), arousal/excitement 67.2% (199), orgasm/ completion 50.0% (148), Female: desire/interest 94.5% (156), desire/frequency 93.4% (156), pleasure 93.6% (161), arousal/excitement 93.0% (189), orgasm/ completion 93.9% (139), Male: desire/interest 5.5% (9), desire/frequency 11.6% (11), pleasure 6.4% (11), arousal/excitement 7.0% (14), orgasm/completion 6.1% (9). Desire/interest dysfunction: DAS28 remission or low activity 28.5% (47), moderate 53.3% (88), high activity 4.8% (8). Desire/frequency: DAS28 remission or low activity 35.3% (59), moderate 47.3% (79), high activity 3.6% (6). Pleasure: DAS28 remission or low activity 30.2% (52), moderate 50.0% (86), high activity 2.9% (5). Arousal/excitement: DAS28 remission or low activity 25.1% (50), moderate 55.8% (111), high activity 6.0% (12). Orgasm/completion, Pain is considered to have a fundamental role associated with the decrease in the frequency of sexual intercourse.
Conclusion: The study showed a high frequency of sexual dysfunction, observing greater dysfunction in females. In the population, the most affected global domain was arousal/excitement, and it was the most frequent in female and male.

AB0218 ASSOCIATION OF PULSE PRESSURE AND CAROTID INTIMA MEDIA THICKNESS IN RHEUMATOID ARTHRITIS PATIENTS

N. Guañardo-Jauregui1, L. J. Colunga-Pedraza1, D. A. Galarza-Delgado1, J. R. Azpíri-López2, A. Cárdenas3, A. N. Garza-Cisneros4, A. Garcia-Heredia5, M. A. Balderas-Palacios1, A. B. Rodriguez-Romero1. 1Hospital Universitario “Dr. José Eleuterio González” Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico; 2Hospital Universitario “Dr. José Eleuterio González” Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico

Background: Rheumatoid arthritis (RA) patients have increased cardiovascular risk than the general population. Systemic inflammation causes a proatherogenic state in this group of patients (1). The carotid ultrasound is a useful diagnostic tool for the detection of subclinical atherosclerosis; however, it is not available for all patients. Pulse pressure, defined as the difference between systolic and diastolic blood pressure, has been associated with atherosclerosis in the general population (2). Information in RA patients is lacking.

Objectives: We aimed to correlate pulse pressure and carotid intima media thickness (cIMT) in RA patients.

Methods: This was a cross-sectional study. We recruited a total of 92 patients with RA diagnosis, according to the 2010 EULAR/ACR classification criteria, aged 40-75 years. Patients with a previous cardiovascular event, another connective tissue disease or pregnancy were excluded. An ultrasound of the carotid arteries was performed in all patients by a certified radiologist blinded to clinical information. cIMT was measured in the left and right carotid arteries. An average of both cIMT was obtained for each patient for this analysis. Correlation between pulse pressure and cIMT was determined with the Spearman’s correlation coefficient (rs). A p-value <0.05 was considered statistically significant.

Results: Mean age of RA patients was 58.9 ± 6.6 years. Most of them were women (92.4%). With a median disease duration of 10.5 (4.2-17.5) years. Median cIMT was 0.08 (0.07-0.10) mm, and median pulse pressure was 50 (40-55) mmHg (Table 1). We found a significant positive correlation between pulse pressure and cIMT in RA patients (rs = 0.254, p = 0.015) (Figure 1).

Conclusion: Higher pulse pressure was associated with higher cIMT in RA patients. Pulse pressure may be useful for the detection of high-risk patients who would benefit from a carotid ultrasound evaluation, to identify patients with high cIMT.

AB0219 ASSOCIATION OF DISEASE ACTIVITY AND THE PRESENCE OF BILATERAL CAROTID PLAQUE IN RHEUMATOID ARTHRITIS PATIENTS

N. Guañardo-Jauregui1, D. A. Galarza-Delgado1, J. R. Azpíri-López2, I. J. Colunga-Pedraza1, A. Cárdenas3, A. N. Garza-Cisneros4, A. Garcia-Heredia5, M. A. Balderas-Palacios1, A. B. Rodriguez-Romero1. 1Hospital Universitario “Dr. José Eleuterio González” Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico; 2Hospital Universitario “Dr. José Eleuterio González” Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico

Background: Cardiovascular (CV) disease is the major cause of death of RA patients. There is a direct association of systemic inflammation and an accelerated process of atherosclerosis, which is related to higher CV morbidity (1). Additionally, RA patients with bilateral carotid plaque (CP) had a two-fold risk of developing a CV event compared to patients with unilateral CP (2).

Objectives: To compare disease activity and other disease characteristics of RA patients with bilateral and unilateral CP.

Methods: This was a cross-sectional study nested of a RA patients’ cohort. We recruited RA patients who fulfilled the 2010 ACR/EULAR classification criteria. Patients with a previous CV event, another connective tissue disease, or pregnancy were excluded. Disease activity was assessed with DAS28-CRP. A carotid ultrasound was performed to all RA patients, and the presence of CP was considered as a carotid intima-media thickness ≥ 1.2 mm or a focal narrowing ≥ 0.5 mm. All RA patients with bilateral CP were included in this study and matched by age (± 5 years), gender, and traditional CV risk factors to RA patients with unilateral CP by a rheumatologist blinded to clinical information. Comparisons were done with Chi-square test for qualitative variables and Student’s t test or Mann-Whitney’s U test for quantitative variables. A p-value < 0.05 was considered statistically significant.

Results: Mean age of RA patients with bilateral CP was 61.98 ± 6.82 years as compared to 59.70 ± 6.74 years in patients with unilateral CP (p = NS). In the population, the most affected global domain was arousal/excitement, which was the most frequent in female and male. In the population, the most affected global domain was arousal/excitement, which was the most frequent in female and male.

Conclusion: The study showed a high frequency of sexual dysfunction, observing greater dysfunction in females. In the population, the most affected global domain was arousal/excitement, which was the most frequent in female and male.

Conclusion: We found that RA patients with bilateral CP had higher levels of CRP levels, higher DAS28-CRP, and a higher prevalence of being classified in the moderate-high disease activity category, which was independently associated to the presence of bilateral CP. Emphasis should be placed on tight disease control to prevent the development of a major CV events in RA patients.

</table>

cIMT, carotid intima media thickness; T2DM, type 2 diabetes mellitus; MTX, methotrexate; GC, glucocorticoids; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; DAS28, disease activity score 28 joints.

Conclusion: Our results show that patients without dyslipidemia and with lower ESR levels, a proinflammatory biomarker, had a reduction in cIMT, which decreases the risk of developing a major CV event. Emphasis should be placed on tight control of disease activity and traditional CV risk factors. A follow-up carotid ultrasound evaluation in RA patients may be necessary, to identify those who would benefit from an opportune treatment.

**DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS IN THE CLINICAL PRACTICE OF A RHEUMATOLOGY CENTER**

A. Gordeev, 1, E. Matianova, 1, Y. Olyun, 1, E. Galushko, 1, V.A. Nasonova
Rheumatology Research Institute, Rheumatoid Arthritis Evolution Laboratory, Moscow, Russian Federation

**Objectives:** To compare the features of the disease course and the therapy in rheumatoid arthritis (RA) patients who meet and do not meet the difficult to treat (D2T) criteria.

**Methods:** RA patients admitted to the V.A. Nasonova Research Institute of Rheumatology for therapy correction from March to October 2021 were included. All patients fulfilled the RA criteria of ACR/EULAR 2010. According to the opinion of the attending physician, they needed correction of therapy, so they were sent to the expert commission to confirm the expediency of using biologic or targeted synthetic (ts) disease-modifying antirheumatic drugs (DMARDs).

**Results:** 295 RA patients with high or moderate disease activity according to DAS28 were included. The expert commission in all cases confirmed the validity of administration of biologic or ts DMARDs. 111 (37.6%) patients (group A) were prescribed these drugs for the first time due to the unsatisfactory result of the use of conventional synthetic (cs) DMARDs. 105 (35.5%) patients were planned to continue treatment with previously used biologic or ts DMARDs after a break associated with various reasons (group B). In 54 (18.3%) cases, first biologic or ts DMDART failed so second biologic or ts DMDART was prescribed (group C). The D2T group included 25 (8.4%) patients with a history of inefficiency or intolerance of 2 or more biologic or ts DMARDs of different mechanisms of action. The duration of RA in the D2T group was significantly longer than in the rest of the patients (respectively 15.9 ± 11.8 and 11.9 ± 9 years, p = 0.04). Radiological changes of joints in D2T RA were more significant than those in the rest of the patients. The Ill or IV Steinerbrocker stage of RA in the D2T group was detected in 18 (72%) while in the remaining patients - in 130 (48.1%) cases (p = 0.02). At the same time, there was a correlation between the duration of RA and the X-ray stage (p = 0.0001). At the time of hospitalization, patients with D2T had higher inflammatory activity than group B patients who continued therapy with biologic or ts DMARDs. In groups A and C, all the analyzed signs of inflammation were also significantly higher than in group B (p < 0.05). Methylxamate had been most often prescribed as the first cs DMARD in all groups but at the time of hospitalization, patients with D2T RA were more likely than other patients to remain without DMARDs (in 8 (32%) and 39 (14.4%) cases respectively, p = 0.03). 73.3 - 84% of patients in all groups earlier received glucocorticoids (GC). At the time of hospitalization, the dose of GC in D2T group was higher than in other patients and averaged 8.3 ± 5.1 mg /day and 6.4 ± 2.9 mg /day, respectively, p = 0.02. The proportion of patients taking GC in the D2T group was also higher than that among other patients, but these differences did not reach statistical significance. In D2T RA, adverse events associated with biologic DMARDs occurred more often than in groups B and C (respectively in 9 (36%) and 15 (9.4%) patients; p = 0.001).

**Conclusion:** The formation of D2T RA in our patients could be associated with the prescribing of higher doses of GC and insufficient use of DMARDs. The development of D2T RA was accompanied by a more pronounced progression of radiological changes of the joints than in other patients.

**THE ALBUMIN TO GLOBULIN RATIO AS A NOVEL INFLAMMATORY MARKER OF RHEUMATOID ARTHRITIS**

M. Liu, 1, Z. Huang, 2, Y. Huang, 1, Z. Huang, 1, Q. Huang, 1, T. Li, 1,2,3, 1Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; 2Southern Medical University, The Second School of Clinical Medicine, Guangzhou, China; 3Zhaoming People's Hospital, Department of Rheumatology and Immunology, Zhaoming, China

**Background:** The albumin to globulin ratio (AGR) has recently been identified as a new prognostic factor in patients with several types of cancer. However, the correlation of AGR and the disease activity in patients with rheumatoid arthritis (RA) have not been reported.

**Objectives:** This study aimed to explore the clinical value of AGR in RA and its association with disease activity.

**Methods:** This retrospective study collected 137 RA patients and 82 age- and sex-matched healthy controls. Neutrophil, lymphocyte, monocyte, platelet, albumin, globulin, AGR, neutrophil to lymphocyte ratio (NLR), monocyte to lymphocyte ratio (MLR), platelet to lymphocyte ratio (PLR), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Disease Activity Score of 28 joints (DAS28-ESR) and other laboratory parameters were recorded. Receiver operating characteristic (ROC) curves were used to determine the area under curve (AUC) value. The relationships between inflammatory indexes and DAS28-ESR were checked.

**Results:** The AGR was lower in RA patients than in healthy subjects (P < 0.05) and decreased significantly along with the disease activity of RA patients (P < 0.05). According to the ROC curve which was conducted to discriminate RA patients from healthy individuals, the AGR (0.881, 95% CI: 0.837 - 0.924) showed the highest AUC than albumin (0.868, 95% CI: 0.823 - 0.914), globulin (0.789, 95% CI: 0.729 - 0.849), NLR (0.801, 95% CI: 0.742 - 0.859), MLR (0.762, 95% CI: 0.699 - 0.826) and PLR (0.803, 95% CI: 0.745 - 0.860). Spearman analyses showed that AGR was inversely associated with DAS28-ESR (r = -0.545, P < 0.001). Besides, the relevance between AGR and DAS28-ESR was higher than albumin (r = -0.381, P < 0.001), globulin (r = 0.492, P < 0.001), NLR (r = 0.444, P < 0.001), MLR (r = 0.189, P = 0.027) and PLR (r = 0.423, P < 0.001).

**Conclusion:** The results demonstrated that the AGR was decreased in RA patients and may be a potential marker for monitoring the disease activity of RA patients.

FRAX ASSESSMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS PREDICTED THE REAL INCIDENCE OF CLINICAL FRACTURES FOR 10 YEARS FROM THE RESULTS OF THE 10-YEAR TOMORROW STUDY

K. Mamoto1, T. Koike2, T. Okano1, Y. Sugioaka1, M. Tada4, K. Inui1, H. Nakamura1, Osaka City University Graduate School of Medicine, Department of Orthopaedic Surgery, Osaka, Japan; 2Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; 3Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan; 4Osaka City General Hospital, Department of Orthopaedic Surgery, Osaka, Japan; 5Osaka Saiseikai Nakatsuka Hospital, Department of Orthopaedic Surgery, Osaka, Japan

Background: To investigate if FRAX in patients with RA can predict the incidence of new clinical fractures for 10 years by using the 10-year data of the TOMORROW study (UMIN000003876) which is a prospective cohort study.

Objectives: To investigate if FRAX in patients with RA can predict the incidence of new clinical fractures for 10 years by using the 10-year data of the TOMORROW study (UMIN000003876) which is a prospective cohort study.

Methods: We calculated ten-year probability of major osteoporotic fracture (FRAX) in 208 RA patients and 205 sex- and age-matched volunteers (Vo), and compared FRAX with the incidence of clinical fractures for 10 years.

Results: The mean FRAX were 14.5 and 8.8% in 175 RA patients and 168 Vo, respectively, in whom we could calculate FRAX at baseline and complete to investigate the incidence of clinical fractures for 10 years from baseline. The mean FRAX in RA patients was significantly higher than that in Vo (P<0.001). The actual incidence of clinical fractures for 10 years in RA patients was significantly higher than that in Vo (33.9 vs 22.9%, P=0.031). In both groups, the actual incidence of clinical fractures was higher than FRAX prediction.

Discussion: We confirmed that FRAX was the risk factor for clinical fractures in actual clinical practice.

CLINICAL SIGNIFICANCE OF SOLUBLE ST2 IN PATIENTS WITH RHEUMATOID ARTHRITIS BEFORE THE APPOINTMENT AND AFTER 12 MONTHS OF TREATMENT WITH BIOLOGICAL DRUGS (PRELIMINARY DATA).

Y. Gorbunova1, T. Popkova1, I. Kirllova1, L. Kondrateva1, M. Diatropov2, A. Lila1, E. Nasonov2, VA Nasonova Research Institute of Rheumatology, of Systemic Rheumatic Diseases, Moscow, Russian Federation; 2VA Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation

Background: The role of soluble ST2, the IL-33 receptor, in the pathogenesis of rheumatoid arthritis (RA) is discussed in the literature. Objectives: To assess the levels of soluble ST2 marker initially (against the background of ineffective basic anti-inflammatory therapy (DMARD) and after 12 months of combination therapy (DMARD + biological therapy).

Methods: The study included 47pts (39 women /8 men) with RA, 51 [39,0; 63,0] years old. Pts were seropositive for IgM RF (79%) and anti-CCP (62%), with highly active RA (DAS28 5.7 [5,2; 6,4]; SDAI 35,0 [29,1; 43,6], CDAI 34.0 [25,0; 43,0]), scores, and median disease duration of 4.0 [3,0;14,0] years. All patients with RA had a history of insufficient effect or intolerance to two or more basic anti-inflammatory drugs (DMARDs). At the time of inclusion in the study, patients received DMARDs: 44% of patients received methotrexate (median dose - 15 (15; 20) mg /week), 35% - leflunomide (20 mg / day), 9.3% - sulfasalazine (2000mg / day), 7% - hydroxychloroquine (200mg / day), 67.4% - glucocorticoids (5 (4; 8) mg / day). Patients did not receive biological

Figure 1. Improvement of patient-reported outcomes over the period of observation

Conclusion: Treatment with JAKi ensures a very rapid and persistent improvement of several PROs, including pain, fatigue and physical function, as early as 2 weeks treatment even in patients with long-standing RA treated with several lines of previous DMARDs.

Disclosure of Interests: None declared

therapy at the time of inclusion in the study. Due to lack of efficacy or intolerance, patients with RA (n=21) were prescribed biological therapy: 52.4% - anti-B cell therapy, 38% - TNF-alpha inhibitors, 9.6% - IL-6 inhibitors. The control group consisted of 20 age-matched donors without rheumatic diseases. The concentration of soluble ST2 was determined by enzyme immunoassay (Cristal Diagnostics, San Diego). The upper limit of normal when testing 20 sera from healthy donors was 17.65 ng/ml, corresponding to the 95th percentile.

**Results:** The level of soluble ST2 in patients with late RA (n=47) was higher than in the control group (n=20) (14.2 [11.5;20.1] ng/ml versus 10.65 [9.3; 13.1] ng/ml) (p<0.001). Patients with RA and elevated serum ST2 levels (≥17.65 ng/ml) were older than patients with ST2 levels ≤17.65 ng/ml (58.5 [50;68] vs 47.0 [38;59] years) (p=0.007). In the group of patients (n=21) who received combination therapy for 12 months, there was a statistically significant decrease in clinical and laboratory activity, levels of RF IgM and soluble ST2 in blood serum, compared with baseline (13.8 [11.5; 18.4] ng/ml vs 12.5 [9.6;13.8] ng/ml (p<0.05 in all cases),Table 1). In the group of patients (n=21), after 12 months of combination therapy, direct correlations were noted between the delta (Δ) of the level of soluble ST2 and Δ DAS28 (R=0.59; p=0.006), Δ CRP (R=0.55; p =0.01), Δ anti-CCP (R=0.49; p=0.04).

**Conclusion:** In patients with high RA activity and the ineffectiveness of basic anti-inflammatory therapy, the level of soluble ST2 in serum was increased compared to the control group. After 12 months of effective anti-rheumatic therapy, the level of this marker decreased. The association of this marker with the clinical and laboratory activity of RA suggests its role in the development of rheumatoid inflammation.

**TREATMENT SEQUENCING PATTERNS AND COMPARATIVE EFFICACY IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM A REAL-WORLD SETTING**

L. Ai1, M. Higashi2, K. Lee1, Z. Liu1, L. Jin1, K. Raja1, Y. Mai1, T. Jun2, W. Oh2,3, Q. Pan1, E. Schadt1,4, X. Wang1.

**AB0227**

**Results:** Our study cohort consisted of 8,040 patients who had at least one line of therapy for RA. Conventional synthetic DMARDs (csDMARDs) were the predominant first line of therapy in this dataset (71.3%), followed by TNFi alone (11.1%) or TNFi combined with csDMARD (9.1%) (Figure 1). For patients who had csDMARD as their first line of therapy, 22.93% progressed to second line treatment. Among them 36.2% were TNFi with or without in combination with csDMARDs. In the second-line, TNFi + csDMARDs were associated with a longer TTNT (median time: 13.1 months vs 6.1 months, P < 0.005) compared to TNFi monotherapy. The multiple variable model (adjusted for age, gender, and race) demonstrated that second-line TNFi + csDMARDs had a lower hazard rate when compared to TNFi monotherapy (HR = 0.74, 95% CI: 0.36 - 1.12, p < 0.005).

**Conclusion:** We demonstrated the first comprehensive treatment sequencing patterns in RA from a real-world setting. As a second-line therapy for patients with inadequate response to csDMARDs, the TNFi + csDMARDs combination may improve duration of response when compared to TNFi monotherapy. Results from this study will inform future sequencing strategies to improve patient outcomes.

**THE CONNECTION BETWEEN NUTRITIONAL STATUS AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS**

L. Huang1,2, Y. Huang1, M. Liu1,2, Q. Huang1, Z. Ji1, S. Sun1,2, W. Deng1, T. W. Li2,3, Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; 2Southern Medical University; The Second School of Clinical Medicine, Guangzhou, China; 3Zhaoping Central People’s Hospital, Department of Rheumatology and Immunology, Zhaoping, China

**AB0228**

**Background:** Nutritional status is closely associated with a person’s physical condition. As for patients with autoimmune disease, nutritional status may affect the balance of immune system, which successively affects disease activity.

**Disclosure of Interests:** Lei Ai: None declared, Mitchell Higashi: None declared, Kyeryoung Lee: None declared, Zongzhi Liu: None declared, Lan Jin: None declared, Kalpana Raja: None declared, Yun Mai: None declared, Tomi Jun: None declared, William Oh Consultant of: Janssen Pfizer, Aviva Beckmann: None declared, Emilio Schadt: None declared, Zachary Schadt: None declared, Rick Wallsten: None declared, Ediz Calay: None declared, Andrew Kasarskis: None declared, Qi Pan: None declared, Eric Schadt: None declared, Andrew Kasarskis: None declared, Qi Pan: None declared, Eric Schadt: None declared, Andrew Kasarskis: None declared, Qi Pan: None declared, Eric Schadt: None declared, Andrew Kasarskis: None declared, Qi Pan: None declared, Eric Schadt: None declared, Andrew Kasarskis: None declared, Qi Pan: None declared, Eric Schadt: None declared, Andrew Kasarskis: None declared, Qi Pan: None declared, Eric Schadt: None declared, Andrew Kasarskis: None declared, Qi Pan: None declared, Eric Schadt: None declared.
**Objectives:** The prognostic nutritional index (PNI), nutritional risk index (NRI), controlling nutritional status (CONUT) score and body mass index (BMI) are four widely used nutritional indices [1]. This study aimed to investigate the relationship between nutritional status and disease activity of rheumatoid arthritis (RA).

**Methods:** 168 RA patients and 50 healthy volunteers were retrospectively enrolled. According to the disease activity score using 28 joint counts-erythrocyte sedimentation rate (DAS28-ESR), the cohort of RA patients was divided into the lower disease activity groups (DAS28-ESR≤3.2) and the higher disease activity groups (DAS28-ESR>3.2). We recorded clinical assessment and laboratory data for further analysis. Spearman’s correlation, receiver operation characteristic (ROC) curves, binary logistic regression analysis were carried out.

**Results:** Compared to the higher disease activity group, the lower disease activity group had low-level total protein (TP), ESR and CRP (all P<0.05), while high-level albumin and PNI (all P<0.05). PNI and NRI were negatively correlated with DAS28-ESR (r=-0.395, and r=-0.200, all P<0.05), while CONUT score was positively correlated with DAS28-ESR (r=0.324, P<0.05). ROC curve illustrated that area under the curve (AUC) of PNI for RA patients with higher score was positively correlated with DAS28-ESR (r=0.324, P<0.05). ROC curve related with DAS28-ESR (r=-0.395, and r=-0.200, all P<0.05), while CONUT score using 28 joint counts-erythrocyte sedimentation rate (DAS28-ESR) was 0.693.

**Conclusion:** PNI may become a manageable marker for detect disease activity of rheumatoid arthritis using ROC curve.

**Disclosure of Interests:** None declared

**AB0230**  
**THE INFLUENCE OF THE PATIENT’S PSYCHOLOGICAL STATUS ON THE INFLAMMATORY ACTIVITY OF RHEUMATOID ARTHRITIS**

V. Vybakova1, A. Avdeeva1, E. Nasonov2, V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology, Rheumatic Diseases, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation

**Objectives:** To examine the relationship between rheumatoid arthritis (RA) activity indicators and psychological factors of patients receiving the therapy according to the “Treat to target” (T2T) strategy.

**Methods:** The research included 93 patients with early RA (16 men and 77 women), average age Me;IQR (59 [40; 66] years), the duration of the disease 7 [4-11,5] months. All patients were prescribed a subcutaneous form of methotrexate (MT) at an initial dose of 10 mg / week with a rapid escalation of the dose to 20-30 mg / week. If the effectiveness of the therapy was insufficient, biologics were prescribed. During the first year, patients received the therapy according to the concept of T2T, then they were observed in the -real-life- clinical practice. After 6 years, the patients were re-examined. Clinical examination was performed including patient global assessment (PGA), functional status was determined by HAQ, the nature of pain by painDETECT, the presence of anxiety and depression – by HADS.

**Results:** Before the start of the therapy, the DAS 28-ESR was 5.31 [4.79; 6.14], SDAI – 28.27 [18.79; 40.73], CDAI-25 [17; 36], HAQ – 1.32 [0.75; 1.25]. After 6 years DAS28-ESR 4 [3.4; 4.59], SDAI-15.06 [9.32; 21], CDAI-15 [9; 21], HAQ - 0.5 [0.25; 1], PGE - 35 [20; 50]. activity of disease according to DAS28-ESR remission in 78%, the low activity in 21.3%, the moderate activity in 60.6%, the high activity in 11.2% of patients. 29 patients had subclinically or clinically expressed anxiety (≥8 according to HADS), of whom10.3% had remission/low disease activity, 89.7% had moderate/high disease activity.

**Conclusion:** The presence of depression and anxiety negatively influences the activity of RA, leading to an increase in pain and worsening of the functional disorders. To prescribe an adequate anti-rheumatic therapy, it is necessary to take into account not only the activity of RA, but also the psychological status of the patient.

**PROGNOSTIC UTILITY OF METACARPAL BONE MINERAL DENSITY MEASUREMENT IN PATIENTS WITH RECENT-ONSET ARTHRITIS BY ASSESSMENT OF RADIOGRAPHIC PROGRESSION AT 2-YEAR FOLLOW-UP**

**Background:** Rheumatoid arthritis (RA) and osteoporosis (OP) have a complex interplay in terms of pathogenic mechanisms. In this regard, radiogrammetry (DXR) of the hand, a technique that measures the bone mineral density (BMD) at the central metacarpals (MC), is associated with a worse prognosis in patients with RA (1). However, DXR is an expensive technique, and not very accessible in our environment. Our group demonstrated an excellent reproducibility of the MC measurement by DXA (2) and good correlation between BMD measurements obtained by DXR and DXA (3).

**Objectives:** To evaluate if baseline BMD of the non dominant MC measured by DXA can be used as a prognostic marker, resembling DXR, in patients with early arthritis (EA).

**Methods:** A total of 378 subjects from the PEARL (Princesa Early Arthritis Register Longitudinal) study underwent DXA measurement of the 2nd to 4th MC’s diaphyseal area of the non dominant hand (Hologic 4500). In PEARL sociodemographic, clinical and laboratory parameters, therapeutic data and radiographic findings are collected by protocol. Radiographic progression was evaluated in hands by a blind expert rheumatologist assessing the erosion scale of modified SvdH index in both the baseline and two year follow-up visit. To study the predictive value of MC baseline BMD by DXA, two multivariate models were fitted using general linear models with Stata 14.0 for Windows (StataCorp LP, College Station, TX, USA). The dependent variables were remission (SDAI<3.3) and radiographic progression after two years of follow-up. Both models were adjusted by the classic variables that affect BMD such as age, sex and body mass index (BMI), cumulative DMARD treatment and baseline disease activity for the remission model.

**Results:** After adjustment by age, sex and BMI: a) those patients at remission tended to show higher baseline MC’s BMD by DXA (p=0.328); and b) those patients with higher radiographic progression had significantly lower baseline MC’s BMD as shown in Figure 1 (p<0.001).

**Conclusion:** In our registry of patients with EA, we have detected that a lower basal BMD in the diaphysis of the central MC bones, assessed by DXA, is associated with greater radiographic progression at 2 years of follow-up after adjusting for the main factors influencing BMD. Therefore, we could conclude that a low initial bone mass could constitute a poor prognostic factor in patients with EA.

**AB0232**

**THE USEFULNESS OF THE PROGNOSTIC NUTRITIONAL INDEX (PNI) FOR THE DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS**

N. Öz, H. H. Gezer, M. T. Duruöz, 3Marmara University School of Medicine, Physical Therapy and Rehabilitation, Rheumatology, Istanbul, Turkey; 1Ummey Training and Research Hospital, Physical Therapy and Rehabilitation, Rheumatology, Istanbul, Turkey; 2Marmara University School of Medicine, Physical Therapy and Rehabilitation, Rheumatology, Istanbul, Turkey

**Background:** Many prognostic factors and laboratory biomarkers have been put forward to correlate disease activity in Rheumatoid arthritis (RA). The prognostic nutritional index (PNI) was first established to assess perioperative immunonutritional status and surgical risk in patients undergoing gastrointestinal surgery. The PNI, which reflects albumin concentration and lymphocyte count, is a newly established immunonutritional nutritional score.

**Objectives:** In this study, we aimed to determine the relationship between this simple risk index, which was first adapted and analyzed in malnourished patients, and disease activity in RA patients.

**Methods:** This prospective study included 77 RA patients who fulfilled the 2010 revised criteria of the American College of Rheumatology for RA. The demographic characteristics of the patients, duration of the disease and clinic characteristics of the patients such as the 28-joint Disease Activity Score based on the erythrocyte sedimentation rate (DAS28-ESR), Visual Analogue Scale, Health Assessment Questionnaire-Disability Index were collected. Labotaruvary findings including erythrocyte sedimentation rate, C-reactive protein levels, lymphocyte count, albumin were noted. The PNI was calculated using the following formula: 10 x serum albumin value (g/dL) + 0.005 x total lymphocyte count in the peripheral blood (per mm³). Based on the DAS28-ESR level, the included patients were categorized into two groups, namely, inactive to mild active RA (n=91; DAS28-ESR level <3.2) and moderate to highly active RA (n=46; DAS28-ESR level ≥3.2). These groups were compared with the parameters described above.
Results: Seventy-seven patients (90.9% female) with a mean age of 53.6 (SD:10.2) years were recruited into the study. The age, gender and disease therapy duration of the patients were similar in both groups. Patients who DAS28-ESR ≥3.2 had a significantly lower PNI compared to those who did not [41.57 (SD:3,64) vs. 43.78 (SD:2,30), p=0.017] (Table 1). Multivariate logistic regression analyses revealed that PNI was an independent predictor of moderate to highly active RA (OR: 0.770, 95%CI: 0.635–0.935; *p*=0.008).

A receiver operating characteristic curves analysis yielded that the optimal cut-off value of PNI for moderate to highly active RA was 42.01 with sensitivity 67.7% and specificity 47.9% (AUC: 0.662, 95%CI: 0.541-0.782, *p=0.017) (Figure 1).

| CRP (mg/L, mean SD) | 6.30 SD 4.49 | 12.75 SD 19.54 | 0.106 |
| Albumin (g/dl, mean SD) | 4.37 SD 0.23 | 4.15 SD 0.36 | 0.010 |
| Lymphocyte (cells/µL, mean SD) | 2.01 SD 0.62 | 2.07 SD 0.65 | 0.570 |

Abbreviations: DAS28-ESR, the 28-joint Disease Activity Score based on the erythrocyte sedimentation rate; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein.

Figure 1. ROC curve

Conclusion: Based on the study findings, we were able to show that simple and easily obtained PNI could be an independent predictor of disease activity in rheumatoid arthritis patients.

CARDIOVASCULAR EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A TWO YEARS OBSERVATIONAL STUDY.

P. Martínez Calabuig1, R. González Mazarío2, J. J. Fragi Gil2, E. Grau García3, C. Pávez Perales3, S. Leal Rodríguez3, C. Riesco Barcena3, A. V. Huaylla Quispe4, L. Mas Sanchez5, P. Muñoz Martínez6, J. E. Oliver Rodríguez3, E. Vicens Bernabeu3, R. Negueruelo Albuixech7, J. Ivorra Cortes3, F. Ortiz-Sanjúan8, M. De la Rubia Navarro9, L. González Puig9, I. Martínez Cordelat10, C. Nájera Herranz1, I. Cánovas Olmos3, J. A. Román Ivorra3, 1Hospital General Universitario, Servicio de Reumatología, Valencia, Spain; 2Hospital Amau de Vilanova, Sección de Reumatología, Valencia, Spain; 3Hospital Universitarios i Politècnic La Fe, Servicio de Reumatología, Valencia, Spain

Background: The risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) is higher than individuals from the general population due to chronic inflammation. Current CV risk screening and management strategies underestimate the actual CV risk in RA. Thus, an adequate CV risk stratification has special relevance in RA to identify patients at risk of CV disease.

Objectives: To assess the incidence of cardiovascular events in a RA cohort after a 2 years follow-up.

Methods: A cohort study was performed in which inclusion criteria were adult RA patients and matched adults in terms of age, sex and CV risk factors (controls). Population over 75 years old, patients with established CV disease and/ or stage III chronic kidney disease were excluded. Controls with other inflammatory diseases, pregnant women or any malignancy were also excluded. This study was performed from July-2019 to January-2022. CV risk assessment included risk factors collection and US evaluation consisted in detection of plaques and measurement of the intima-media thickness in both right and left carotid.

Results: Overall, a total of 200 cases and 111 healthy controls were enrolled in the study. Demographical and clinical variables were comparable between cases and controls and are shown in Table 1. US study revealed a higher IMT in both right and left carotid arteries with greater presence of plaques in patients than in controls (CI 95% [1.542; 3.436], *p<0.001). Plaques were found in both carotid arteries in the 32% of cases and 9.91% of controls. The longer duration of RA was related to a higher presence of carotid plaques (95% [1.015; 1.056], *p<0.001).

| Table 1. Demographic, clinical characteristics and Ultrasound results of patients and controls. |
|----------------|----------------|----------------|
| **Characteristic** | **RA cases n=200** | **Healthy controls n=111** |
| Age - years | 62.05 (10.75) | 58.3 (12.14) |
| Female sex – number (%) | 163 (81.5) | 73 (65.77) |
| BMI – value (ds) | 26.38 (5.03) | 26.2 (5.19) |
| Smoking habit | 107 (53.5%) | 71 (63.96%) |
| Never Smoked | 1 (0.5%) | 0 (0.00%) |
| Ex-smoker | 51 (2.5%) | 20 (18.02%) |
| Active smoker | 42 (2.1%) | 20 (18.2%) |
| Race – number (%) | 83 (41.5%) | 34 (30.63%) |
| Caucasian | 186 (93) | 62 (93.94%) |
| Comorbidities – number (%) | 93 (46.5%) | 39 (35.14%) |
| High blood pressure | 127.2(18.36)/78.65(10.21) | 127.7 (19.42)/78.28 (10.59) |
| Dyslipemia | 83 (41.5%) | 34 (30.63%) |
| Blood pressure – mmHg | 127.2(18.36)/78.65(10.21) | 127.7 (19.42)/78.28 (10.59) |
| Ultrasound findings | | |
| Right carotid cIMT | 0.78 (0.15) | 0.62 (0.11) |
| Left carotid cIMT | 0.77 (0.14) | 0.64 (0.12) |
| Plaques | 101 (50.5%) | 32 (28.83%) |
| Bilateral | 64 (32%) | 11 (9.91%) |
| Right carotid | 17 (8.5%) | 7 (6.31%) |
| Left carotid | 20 (10%) | 14 (12.61%) |

Eight patients (4%) presented a cardiovascular event, and one of them died (0.5%). The events consisted in 2 angiina pectoris, 3 transient ischemic attack, 1 acute myocardial infarction, 1 lacunar stroke and 1 cardiac arrest. Six out those 8 patients demonstrated bilateral plaque presence at baseline. Two patient caused loss of follow up due to death related to Covid-19. Not a single cardiovascular event was reported in the control group.

Conclusion: Our results shows that cardiovascular events are increased in RA patients and US study may be useful in predicting an event.

AB0234  POTENTIAL CREDIBILITY IN RHEUMATOID ARTHRITIS PATIENT REPORTED DAS28 SCORES

S. Cabraal, 1 Aneurin Bevan University Health Board, Rheumatology, Newport, United Kingdom

Background: Due to COVID-19 and the reduction of face to face clinic, the rheumatology telephone advice line service has been an integral part in identifying patients that need assessment the most (1). This however means relying on a patient’s ability to conduct their own disease activity score (DAS28), which clinicians conduct to help drive patients with rheumatoid arthritis (RA) into remission. Current literature suggests that patient self-assessed joint counts are reliable and when compared to the joint count of the physician, have an acceptable level of accuracy (2-5). We present data from an NHS audit where we incidentally found that patients could conduct their own joint counts.

Objectives: Our objective was to compare self-reported DAS28 scores with the clinical opinion of physicians during a face-to-face appointment.

Methods: We identified 10 patients with RA who attended a face-to-face appointment following a call to the helpline where a telephone DAS28 score was undertaken (with guidance from rheumatology specialist nurses). These scores were contrasted against the clinician’s assessment of whether synovitis was present or not in a face-to-face consultation. Co-morbidities; fibromyalgia (FM), osteoarthritis (OA) or both, were also recorded to examine whether these conditions influenced a patient’s ability to perform an accurate DAS28 score.

Results: There were 10 patient self-reported DAS 28 scores in total. 70% (7/10) of patients DAS 28 scores were over 4.01. In all these cases, clinicians confirmed evidence of synovitis during their face-to-face consultation. 30% (3/10) of patients self-reported DAS 28 score was <4.01. Of these patients 2/3 have no evidence of synovitis according to their clinician. When considering co-morbidities, one individual also suffered from OA. This individual’s self-assessed DAS28 score was over 4.01 and was also evidenced to have synovitis during their consultation with the clinician.

Conclusion: This regional NHS audit found that patients who self-reported DAS28 scores over 4.01 accurately identified a flare up, as confirmed by a diagnosis of synovitis at a face-to-face appointment. This may enable the Rheumatology service to become more patient-driven, empowering patients to accurately assess their condition.

AB0235  TREAT TO TARGET PATHWAY (T2T) IN INFLAMMATORY ARTHRITIS-DESIRABLE RESULTS? AND IF CERTAIN GROUPS RESPOND TO TREATMENT BETTER?

O. Shah, 1 E. Ison, 1, B. Whelan, 1 M. O’Sullivan, 1, C. Sille, 1 1Saolta Healthcare Group, Northwestern Rheumatology Unit Manorhamilton, Manorhamilton, Ireland

Background: There is established evidence that treat to target strategy in inflammatory arthritis helps achieve early remission rates or low disease activity. This approach is more effective for improved outcomes at no additional costs and more likely to achieve rapid and sustained disease control. It is important to aim for early diagnosis to limit the structural damage that occurs with prolonged inflammation. Commencing disease modifying anti-rheumatic drugs (DMARDs) therapy and glucocorticoids as early as possible and titrating therapy as appropriate improves clinical outcomes.

Objectives: Aim of this study was to analyse ACR20 response within different subgroups of inflammatory Arthritis patients enrolled in Treat to Target program.

Methods: Data collection was performed by assessing electronic medical records of 374 inflammatory arthritis patients who participated in Treat to Target pathway for inflammatory arthritis between 2014 to 2020. In total 374 patients were enrolled in treat to target inflammatory pathway led by Rheumatology ANP with consultant supervision. Majority of the patients had diagnosis of Rheumatoid arthritis as per ACR/Eular criteria. 213(51%) were seropositive RF+, 83(19.9%) were seronegative RF-; 44(10.5%) were diagnosed as psoriatic arthritis, and 34(8.1%) were labelled as undifferentiated inflammatory arthritis. In terms of age and gender, 158(42%) were younger than 50, 216(58%) were aged 50 and over, majority females 207(55%). Smoking status 118(32%) current, 211(56%) never, 45(12%) ex-smokers. DMARD started at baseline was Methotrexate only and Starting dose was 15mg for all patients. 326(88%) were on oral methotrexate and only 48(12%) were on SC form between weeks 1-20.

ACR 20,50,70 responses were analysed for these subgroups with majority (61%) seen at week 6 for their visit 1 after starting T2T pathway while all patients seen by week 20.

Results: ACR 20,50 and 70 responses were calculated for all subgroups enrolled in T2T program. The results showed that ACR 20 response rate was same among patients aged under and over 50(67% responders), ACR 50 (38.3%) responders and ACR 70 (20.1%) responders. There was no significant difference in ACR 20 response among females and males (66.9% response) both groups. In terms of seropositivity, 75% responded to treatment in RF+ group vs 60% in RF-group. Higher response rates were seen among not current smokers vs active smokers(70%vs65%). ACR 20 response was greater in patients on Sc form of methotrexate. Overall, 65 % achieved remission within 15 months of starting T2T pathway while remaining achieved low disease activity. Further analysis and discussion will follow.

Conclusion: Treat to target strategy in inflammatory arthritis are consistent with real world data in achieving early response rates with methotrexate (ACR responses) and specific subgroups within T2T cohort respond better to treatment.

Disclosure of Interests: None declared

Background: Presence of anti-citrullinated polypeptide antibodies (ACPA) is one risk factor of bone erosion of the joint in patients with rheumatoid arthritis (RA). However, bone absorption in the whole body is still not clarified in a longitudinal study.

Objectives: The aim of this study is to clarify effects of ACPA on bone mineral density (BMD) decrease using dual-energy X-ray absorptiometry (DXA) in patient with RA using retrospective longitudinal cohort study.

Methods: Patient with RA who were measured BMD in lumbar spine (LS) and total hip (TH) using dual-energy X-ray absorptiometry (DXA) at first consultation (baseline) and were treated for more than five years, were recruited. Follow-up started at BMD measurement and continued until the development of the first fracture or censoring at death, loss to follow-up or end of the study. Every patients have been followed up with monitoring of SDAI and Health Assessment Questionnaire Disability Index (HAQ) at every another to three months. Sharp/van der Heijde Score (SHS) was measured at baseline and every another year thereafter. BMD were measured every six months. Relationship between BMD and candidate risk factors including ACPA positive and serum titers level, and other BMD loss were evaluated statistically using linear regression analysis. Evaluations were performed for the absolute value of BMD and Z-score at baseline, mean value of these during follow-up, and change from baseline. Change of Z-score during follow-up was also compared between groups what classified according to ACPA positivity (ACPA positive/negative group).

Results: A total of 222 patients were recruited including 17 male (7.2%) and 205 female (92.3%). The mean age of the patients was 69.2 years old. Mean disease duration (months) 7.7 4.6 <0.001, disease duration (months) 7.7 4.6 <0.001.

Higher ACPA titer level correlated significantly low BMD and Z-score in TH (p<0.05), whereas no significant correlation demonstrated using multivariate model. Change of Z-score in the ACPA positive group was significantly lower than in the ACPA negative group despite no significant difference of disease activity between the two groups demonstrated (p>0.05) (Table 1).

Conclusion: Presence of ACPA potentially have an independent role of BMD decrease. Its action affects regardless gender and age.
data on the impact of RA disease activity on SF-36 scores in Greek patients are lacking.

**Objectives:** To compare SF-36 scores in Greek RA patients versus the general population and to assess the impact of disease activity on HRQoL.

**Methods:** Cross-sectional study in RA patients followed in the Department of Rheumatology, Asklepieio Voulas General Hospital (05-10/2021). Demographic characteristics, state of disease activity and current treatment for RA were recorded at most recent visit. All patients completed SF-36 questionnaires and were classified in three subgroups of DAS28-disease activity: i) Remission or Low disease activity (LDA), ii) Moderate disease activity (MDA), and iii) High disease activity (HDA). Data from the SF-36 validation study in the Greek general population with 1007 participants, were used as historical controls. Descriptive statistics, one-way ANOVA and linear regression were used for statistical analyses.

**Results:** 107 patients participated in the study (80.4% females, mean (SD) age 63.3 (12.1) years, 64.5% seropositive, 72% overweight or obese). One third (n=36) were active smokers and 63% (n=67) were receiving a biologic disease modifying antirheumatic drug (bDMARD).

Patients with RA exhibited low scores in all SF-36 domains and reported significantly worse results compared to the general population (Figure 1).

**Conclusion:** HRQoL assessed by SF-36 is dampened in RA patients, in both physical and mental component. Disease activity had a negative impact on both physical and mental components of HRQoL. Patients with remission or LDA showed better HRQoL outcomes, suggesting that the treat-to-target approach may also positively affect QoL.

**Conclusion:** We have been performing cancer screening before RA treatment and performing routine blood, urine, and imaging tests to identify adverse effects. However, they cannot always find cancers at the early stage. Screening procedures for malignancy are strongly recommended[3], but the consultation rates for breast and cervical cancer screening are lower in Japan than in European nations. We should encourage our patients to undergo usual age- and sex-appropriate cancer screening.

**Figure 1.**

Physical component score (PCS) and Mental component score (MCS) of the SF-36 showed a negative correlation with DAS28 (r=-0.28, p<0.001 and r=-0.6, p<0.001, respectively). Patients with remission or LDA exhibited better SF-36 scores compared to the other subgroups; moreover, patients with MDA had better SF-36 scores than those with HDA (Table 1). When patients with MDA were further divided into low- and high-moderate disease activity (DAS28: 3.21-4.19 and 4.2-5.1, respectively), no significant difference in any SF-36 domain was found between the two subgroups.

**DOI:** 10.1136/annrheumdis-2022-eular.421
Background: Rheumatoid arthritis (RA) that is a chronic systemic and disabling disease affecting 0.5–1% of the general population, has been strongly linked to accelerated atherosclerosis and increased incidence of cardiovascular events and mortality. Klotho is a membrane-bound or soluble antiaging protein, whose protective activity is essential for a proper function of many organs. The association between serum Klotho and the classic risk factors, as well as the clinical history of cardiovascular disease, was also shown. There are a lot of evidences that Klotho deficiency correlates with the occurrence and development of coronary artery disease, atherosclerosis, myocardial infarction, and left ventricular hypertrophy.

Objectives: The aim of this study was to examine the possible association between serum Klotho levels and ankle-brachial index in women with RA.

Methods: This cross-sectional study was performed in Vega-Baja Hospital (Orhiuela-Spain) from November 2016 to May 2018. We prospectively enrolled 63 consecutive female patients affected by RA and followed at the Vega-Baja Hospital (Orhiuela-Spain). All patients included in this study had normal serum creatinine (Cr) levels and met the 2010 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria for RA. Ankle-brachial index were evaluated using a BIDOP model ES-100V3 vascular screening system (Hadeco, Inc, Kawasaki, Japan). Serum Klotho (Elabscience, USA) was analysed using ELISA.

Results: Our study included 63 female patients, with a mean (SD) age of 53 ± 8 years. The majority were Caucasian (90.5%). The mean duration of RA was 8.5 ± 5.8 years. Mean 28-joint disease activity scores (DAS28) based on erythrocyte sedimentation rate (ESR) indicated low disease activity 3.0 ± 1.3. The mean of the health assessment questionnaire (HAQ) was 0.75 ± 0.67. Mean serum Klotho levels were 4.68 ± 1.14 ng/mL. The mean value of the ankle-brachial index was 1.14 ± 0.1. Lower serum Klotho levels were significantly associated with a lower ankle-brachial index (r = 0.27, p<0.05).

Conclusion: Decreased serum Klotho levels are associated with peripheral arterial disease in women with RA.

COGNITIVE FRAILTY AND RISK OF FALLS AMONG EGYPTIAN OLD ADULTS WITH RHEUMATOID ARTHRITIS

R. A. Elzahry1, R. M. Abdel Kader2, 1 Ain Shams University, Internal Medicine Department, Division of Rheumatology, Cairo, Egypt; 2 Ain Shams University, Department of Geriatrics and Gerontology Medicine, Cairo, Egypt

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease, affecting bone cartilage and predominantly joints, and causing inflammation and pain. RA patients have disease-specific risk factors, including greater impaired balance, tender and swollen joints, lower muscle strength in their lower limbs, fatigability and medication side effects which contributes to a predisposition for falls [1]. Frailty, which was originally considered a geriatric syndrome, is an age-related decline in physiological reserve (3). It is associated with reduced muscle strength, exhaustion and with high inflammatory markers contributing to perpetuation of the frailty cycle (4). The concept of frailty is a recent issue in the rheumatological field: by now, the prevalence of frailty among elderly individuals with RA has not been extensively examined and few studies on frailty on RA adults have been conducted.

Objectives: To assess the prevalence of cognitive frailty in people with rheumatoid arthritis and the relationship between cognitive frailty and falls.

Methods: In this cross-sectional study we evaluated 105 patients 60 years old or more with rheumatoid arthritis who fulfilled the ACR 2010 criteria and attended to rheumatology outpatient clinic in Ain-Shams University hospitals. Data was collected regarding demography and comorbidities. For cognitive and frailty screening, the Montreal Cognitive Assessment (MOCA) and frail scale were used respectively. Cognitive frailty (CF) is a clinical condition characterized by the simultaneous presence of physical frailty and mild cognitive impairment without functional impairment.

Results: 105 older adult patients with RA were studied of whom (72.4%) were females. The mean age of the study population was 66.03. We found that (12.4%) of the study group were cognitively frail and the prevalence of falls among cognitively frail patients was 92.3%.

RELATIONSHIP BETWEEN FALLS AND FALL RISK MEDICATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Sakamura1, N. Yajima2, R. Yana1, 1 Showa University, Hatanodai Campus, Pharmacy, Shinagawa City, Japan; 2 Showa University, Hatanodai Campus, Division of Rheumatology, Department of Medicine, Shinagawa City, Japan

Background: Falls are a serious event that can lead to disability and death. The use of hypnotics, anxiolytics, and antidepressants has been reported drugs associated with higher risk of falls. Rheumatoid arthritis (RA) is associated with a high risk of falls, which is an important issue because it can lead to fractures. Patients with RA have a higher incidence of sleep disorders, depression, and anxiety disorders. They are likely to be prescribed fall risk medications.
AB0243 ASSOCIATIONS BETWEEN JOINT DEFORMITY, DISEASE DURATION, DISEASE ACTIVITY, ACTIVITIES OF DAILY LIVING, QUALITY OF LIFE, PAIN, AND FATIGUE IN PATIENTS WITH RHEUMATOID ARTHRITIS

I. Yoshih1, N. Sawada2, T. Chijima1. 1Yoshii Hospital, Rheumatology, Shimanto City, Japan; 2Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan; 3Kochi Memorial Hospital, Rheumatology, Kochi, Japan

Background: Patient with rheumatoid arthritis (RA) have disease-related problems such as joint deformity, disease duration, disease activity, activities in daily life (ADL), quality of life, pain, and fatigue. All these problems correlate interactively.

Objectives: Aim of this study is to clarify association among these problems statistically using retrospective cohort data.

Methods: Patients with RA who were followed up more than three years were recruited. Their EuroQol-5D dimension (EQ5D) as an indicator of quality of life (QOL), simplified disease activity index (SDAI) as an indicator of disease activity, Health Assessment Questionnaire Disability Index (HAQ) as an indicator of ADL, pain score using visual analog scale (PS-VAS), and fatigue score using visual analog scale (FS-VAS), were monitored every three months. Sharp/van der Heijde score (SHS) as an indicator of joint deformity was calculated annually. Association among average values of these factors and patient’s sex, age, disease duration (DD), and anti-citrullinated polypeptide antibodies (ACPA) titer were evaluated using multivariate linear regression analysis. Statistical significance was set within 5%.

Results: A total of 447 patients, in whom 120 male and 327 female included, were analyzed. Mean age, disease duration, EQ5D score, SDAI score, HAQ score, SHS, PS-VAS, and FS-VAS during follow-up were 71.8-year-old, 12.9 years, 0.831, 4.26, 0.413, 46.9, 22.5, and 23.2, respectively.

EQ5D score correlated significantly with age, HAQ score, SDAI score, SHS, PS-VAS, FS-VAS, and DD using univariate models. In these, age, HAQ score, and SDAI score correlated significantly using multivariate model (correlation coefficients (CC): 0.927). HAQ score correlated significantly with age, EQ5D score, SDAI score, SHS, PS-VAS, FS-VAS, and DD using univariate models. In these, EQ5D, SHS, and FS-VAS correlated significantly using multivariate model (CC: 0.910). SDAI score correlated significantly with female gender, EQ5D score, HAQ score, SHS, PS-VAS, and FS-VAS using univariate models. In these, EQ5D, SDAI score, and DD correlated significantly using multivariate model (CC: 0.685). PS-VAS correlated significantly with EQ5D score, SDAI score, SHS, and FS-VAS using univariate models. In these, SDAI score and FS-VAS correlated significantly using multivariate model (CC: 0.732). FS-VAS correlated significantly with EQ5D score, SDAI score, SHS, and PS-VAS using univariate models. In these, EQ5D score, SDAI score, and DD correlated significantly using multivariate model (CC: 0.715). ACPA did not correlated with any factors significantly.

Conclusion: These results suggested that EQ5D score, namely QOL is influenced by various disease-related factors and aging, especially correlated with ADL and fatigue closely. The HAQ score, namely ADL level is influenced by fatigue level and joint deformity directly. The SDAI score, namely disease activity level correlated with pain level and joint deformity level, and correlates with the other factors indirectly. A schematic figure that represents relationships among factors were shown in Figure 1. These information would be useful for conducting treatment protocol of RA.

AB0244 MEDICATION ADHERENCE AND BELIEFS ABOUT MEDICATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Hügel1, C. Baernwald2, O. Seifert1. 1University Hospital Leipzig, Department of Internal Medicine, Rheumatology Unit, Leipzig, Germany

Background: Consistent immunosuppressive treatment of rheumatoid arthritis (RA) with disease-modifying anti-rheumatic drugs (DMARDs) is crucial for reduced progression and improved long-term outcome of the disease. Therefore, drug adherence is a prerequisite, which is often insufficient according to literature.

Objectives: Our aim was to investigate the relationship between adherence and beliefs about medication in patients with RA.

Disclosure of Interests: None declared
Methods: The study included 137 RA patients (102 female, 35 male; age range 28-86 years, Ø 64.8 ± 12.6 years; SDAI Ø 9.9 ± 6.8; 61 % DMARD monotherapy, 31 % DMARD combination therapy, 8 % currently treated without DMARD). Medication adherence was measured with the Compliance-Questionnaire-Rheumatology (CQR). This is a self-report questionnaire with 19 items (4 response options each). The sum score is mapped to a scale from 0 to 100 % (CQR%), where 100 % corresponds to optimal adherence. A CQR% ≥ 80 % was defined as satisfactory adherence. In addition, the specific part of the Beliefs about Medicines Questionnaire (B MQ) was used to assess patients’ opinions about the necessity and cost-effectiveness of their medications. Furthermore, in the CQR% analysis (Spearman-Rho) multiple linear regression was applied to determine factors influencing adherence (coefficient of determination: adjusted R²).

Results: Adherence was satisfactory in 93 RA patients (67.9 %) and insufficient in almost one-third (n = 44, 32.1 %). Analyses showed that adherence was significantly related to belief in necessity (r = 0.46; p < 0.001) and concerns about drug use (r = 0.27; p < 0.001). Furthermore, it became apparent that adherence is closely linked to the age of the patient (r = 0.30; p < 0.001). Younger RA patients (< 60 yrs) had significantly lower CQR%-scores than older RA patients (≥ 60 yrs; p < 0.01). Belief in the necessity of therapy, medication concerns and age patient accounted for almost half of the patient-specific variability in adherence (each p < 0.001; R² = 42.9 %), suggesting a strong dependence of adherence on these three factors.

Conclusion: Adherence is insufficient in about one-third of RA patients. Additionally, adherence appears to be strongly dependent on the patient’s belief in the necessity of therapy, medication concerns and age. Physicians should strive for all RA patients to have sufficient knowledge about their medication, strengthen the necessity of therapy, medication concerns and age. Physicians should strive for all RA patients to have sufficient knowledge about their medication, strengthen the necessity of therapy, medication concerns and age. Physicians should strive for all RA patients to have sufficient knowledge about their medication, strengthen the necessity of therapy, medication concerns and age. Physicians should strive for all RA patients to have sufficient knowledge about their medication, strengthen the necessity of therapy, medication concerns and age. Physicians should strive for all RA patients to have sufficient knowledge about their medication, strengthen the necessity of therapy, medication concerns and age. Physicians should strive for all RA patients to have sufficient knowledge about their medication, strengthen the necessity of therapy, medication concerns and age.
well known that erosions are correlated with the presence and titer of anti-citrullinated peptide antibodies (ACPA)(1). RA is also known to be an independent factor of osteoporosis(2) and it has already been demonstrated that ACPA is associated with bone mineral density (BMD) at the hip and spine.(3) The physiopathology of erosion and bone loss in RA is related to osteoclast activation via RANK-L pathway stimulation, that can possibly be lead by ACPA(4).

**Objectives:** Our aim was to determine if there is an association between local and systemic bone damage in RA, represented respectively by erosion and BMD, and whether it may be driven by ACPA and/or other autoimmunity-related antibodies.

**Methods:** Patients followed in the Department of Rheumatology between January 2008 and May 2019 satisfied the 1987 ACR or 2010 ACR-EULAR criteria. To be included, they had to undergo radiographs and biological at intervals of less than 2 years from DXA. Bone mineral density (BMD) was evaluated in g/cm² and by T-score at the hip on DXA. Erosions were evaluated by the modified Sharp/van der Heijde erosion score (SHSe) on radiographs and the presence and titer of ACPA, rheumatoid factor (RF) and anti-nuclear antibodies (ANAs) were recorded.

**Results:** A total of 149 patients met the inclusion criteria, represented by 75.8% of women. They had a mean age of 62 (SD 9.61) and a long median disease duration of 132 [60; 240] months. A total of 61.1% patients were ACPA positive, 79.9% were erosive and 10.7% had a hip or spine T-score ≤-2.5. A higher erosion score was associated with a lower BMD (R²: 0.049 and value: -0.222; p=0.009) and T-score (R²: 0.158 and value: -0.397; p<0.0001) at the hip. ACPA status, but not titer, was associated with a higher erosion score (63.0 [53.2] vs. 45.5 [44.1] for ACPA – (p= 0.04)). ACPA titers were associated with lower BMD at the hip (value -0.216; p=0.01) but not with T-score. In linear regression, erosion and bone mineral density were still associated but this association does not seem to be driven by ACPA status or titer. RF and ANA did not demonstrate any role in this association.

**Conclusion:** We have shown that erosions were associated with lower BMD and T-score at hip but also at spine. Nevertheless that relation does not seem to be driven by ACPA or other autoimmunity-related antibodies. However, the presence of ACPA or erosion should lead to osteoporosis assessment.

**AB0249**

**LIPID PROFILE CHANGES FROM PRE-CLINICAL TO ESTABLISHED RHEUMATOID ARTHRITIS: A 12 YEARS FOLLOWUP PILOT STUDY**

R. Raadsen, L. Van Boheemen, M. Nurmohamed. Amsterdam Rheumatology and Immunology Center, location Reade, Rheumatology, Amsterdam, Netherlands; Amsterdam Rheumatology and Immunology Center, location VU University Medical Center, Rheumatology, Amsterdam, Netherlands

**Background:** Patients with rheumatoid arthritis (RA) have an increased risk for developing cardiovascular diseases (CVD). This is partly due to the systemic inflammation characteristic to the disease, but also due to an increased prevalence of ‘traditional’ risk factors such as dyslipidemia. The inflammation in RA often leads to an increased catabolism of lipids, resulting in a subsequent decrease in HDL and LDL, while treatment with anti-inflammatory medication reverses these effects. This decreased cholesterol level in active disease is, unexpectedly, associated with an increased incidence of CVD (the lipid paradox). Additionally, we previously demonstrated pro-atherogenic lipid profile changes in preclinical RA patients.

**Objectives:** To explore the lipid profile changes in RA patients through different phases of the disease, i.e. from the preclinical stage and RA onset through treatment with biological disease modifying anti-rheumatic drugs (bDMARDs).

**Methods:** Thirty-nine consecutive patients who were previously included in both Reade’s RA prevention cohort and biological cohort were included in the current study. The prevention cohort consisted of individuals with arthralgia and rheumatoid factor and/or anti-citrullinated protein antibodies without arthritis, and the biological cohort comprised RA patients using bDMARDs. Lipid spectrum was measured longitudinally, at the following points in the disease course identified in each patient (time from baseline was different in each patient due to the natural course of disease progression):

1. Baseline, months prior to RA diagnosis (Start Prevention cohort)
2. Moment of RA diagnosis (End Prevention cohort)
3. Period between diagnosis and start bDMARD treatment
4. Start treatment with bDMARDs
5-7. Continued treatment with bDMARDs

**Results:** From baseline, high density lipoprotein cholesterol (HDLc) and apolipoprotein A1 (ApoA1) increased up to the start of biological treatment, thereafter they slightly decreased. Low density lipoprotein cholesterol (LDLc) and apolipoprotein B (ApoB) both decreased with higher disease activity, increasing again after starting bDMARD therapy. Total cholesterol/HDLc ratio decreased substantially from baseline and onwards and stabilized in the bDMARDs treatment phase. Lipoprotein(a) (Lp(a)) increased slightly up to treatment with bDMARDs, after which it stabilized. Figure 1 shows the progression of HDLc, LDLc and total cholesterol (TC) plotted against C-reactive protein (CRP) over time.

**Conclusion:** Our study uniquely shows the change of lipid parameters during the course of RA disease. While LDLc, ApoB and cholesterol/HDLc ratio decreased with higher disease activity, HDLc and ApoA1 increased, affirming the expectations. Larger cohort studies are necessary to accurately elucidate the development of lipids through different disease stages in RA patients, to better understand one of the key risk factors for CVD in RA.

**DOI:** 10.1136/annrheumdis-2022-eular.976
Background: Poor adherence is one of the main causes of therapeutic failure in chronic inflammatory rheumatism, particularly in rheumatoid arthritis (RA). Thus to improve regular intake especially of conventional background treatments (cs-DMARDs), it is important to assess patients’ beliefs and fears about their treatments.

Objectives: Evaluate the beliefs and fears of patients with Rheumatoid arthritis towards their conventional background treatments.

Methods: This is a cross-sectional study with RA follow-up patients meeting the ACR/EULAR criteria. Epidemiological, clinical and paraclinical data were collected. The evaluation of beliefs and fears towards csDMARDs was carried out by the BMG2 score which has two five-item scales rated according to a 5-point Likert scale, ranging from 1 (not at all agree) to 5 (strongly agree). The scores of necessity, fear, overuse and nuisance were calculated. Patients were divided into 4 groups according to their beliefs of csDMARDs: accepting, ambivalent, indifferent and septile.

Results: The mean Disease Activity Score (DAS28crp) was 3.5 ± 1.54, the mean value of Visual analogue scale of pain (VAS) was 40.5 ± 20.5, and the mean value of Health Assessment Questionnaire (HAQ) was 1.05 ± 0.85. All patients were treated with methotrexate and 12.5% with Salsalazine in combination. The average need score was 20 ± 2.4, fear score was 16.4 ± 3.5, overuse score was 13.6 ± 2.25 and nuisance score was 10.8 ± 2.6. Patients’ beliefs about the need for their background treatments were more important than their concerns and fears about the potential consequences of these treatments (p = 0.03). A higher necessity score was correlated with the number of painful joints (NAP) (p = 0.02) and a higher DAS28 (p = 0.05). Patients who were more afraid of their treatments had more joint deformities (p = 0.03), higher HAQ functional index (p = 0.007) and a higher VAS value (p = 0.01). The belief profile study concluded that 60% of patients were ambivalent, 27.5% accepting, 10% indifferent and 2.5% were septile towards their background treatments.

Conclusion: Our study showed that during RA, knowledge of the profiles of our patients, their beliefs and fears about their treatments especially cs-DMARDs is essential, and could help us to adapt strategies for improving compliance.

DESCRIPTION OF ARTERIAL STIFFNESS, INF MLLAMAGING AND VASCULAR AGE IN A GROUP OF PATIENTS WITH RHEUMATOID ARTHRITIS UNDER A STRICT FOLLOW-UP COMPARED WITH UNCONTROLLED OSTEOARTHRITIS PATIENTS

1Fundación Universitaria de Ciencias de la Salud-FUCS, Research Institute, Bogotá, Colombia; 2Fundación Cardioinfantil-Instituto de Cardiología, Hemodynamics and Cardiovascular Function Laboratory, Bogotá, Colombia; 3Fundación Universitaria de Ciencias de la Salud-FUCS, Research Institute, Bogotá, Colombia; 4Fundación Universitaria de Ciencias de la Salud-FUCS, Research Institute, Bogotá, Colombia; 5Fundación Universitaria de Ciencias de la Salud-FUCS, Research Institute, Bogotá, Colombia; 6Biomab IPS, Scientific Direction, Bogotá, Colombia

Background: The risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) is higher than in individuals in the general population. The fundamental risk factor for CVD is age, related to alterations in the arterial level, called vascular aging reflected by arterial stiffness and endothelial dysfunction.

Objectives: The aim of the study was to compare vascular age and arterial stiffness (PWV-Pulse Wave Velocity) in two groups of patients with RA and with osteoarthritis (OA) and to assess the influence of inflamming (persistent low-grade inflammation that develops with age) and metabolic markers in these outcomes.

Methods: Analytical cross-sectional study. RA patients under a strict follow-up program (T2T evaluated every two months) and OA patients without strict clinical follow-up, evaluated once or twice a year, were included. Patients with history of uncontrolled hypertension, CVD and/or current smoking were excluded. Waist-hip ratio, body mass index (BMI), DAS28 (RA), C-Reactive protein (CRP), Erythrocyte sedimentation rate (ESR), glyceria and lipid profile were measured. PWV and vascular age (in years) were evaluated through oesomietric method, arteriograph-TensioMed. Eleven proteins components of the inflamming (cytokines, Matrix metalloproteinases · MMPS and its tissue inhibitors), were quantified through Luminex multiplex assay in serum samples. Univariate and bivariate analyzes (Chi-square and non-parametric correlations) were performed. Approval of Ethics Committee and informed consent were obtained.

Results: A total of 106 patients (74% women) were included (52/RA and 54/OA). Mean age was 57±5.6 years without differences between groups. There were significant differences in CRP and ESR (higher in RA) and in BMI, waist circumference and weight (higher in OA). RA patients had low disease activity level (DAS28: Median 2.6, IQR 1.3). There were no differences in PWV, vascu lar age or inflamming (except for MMP-1, higher in RA), between the groups. PWV had a positive correlation with LDL (Rho Coef. 0.218, p=0.025). Patients who performed physical activity had a lower vascular age than those who did not [43 Interquartile range (IQR)23 vs 60 IQR 17, p=0.032]. Vascular age was higher in RA patients who did not receive methotrexate 60 (IQR 19.3) compared with patients under methotrexate treatment 44.5 (IQR 23) (p = 0.017). Also, vascular age was lower in OA patients under prescribed physical activity (43 IQR 24.8 vs 56.5 IQR 20, p=0.03). MMP-9 in RA patients (Rho 0.283, p=0.042) and IL-10 in OA patients (Rho 0.290, p = 0.036) correlated with diastolic pressure. The components of inflamming did not correlate with vascular age. The Framingham Risk Score was strongly associated with vascular age.

Table 1. Significant correlations with vascular age

LDL: low density lipoprotein; MDHAQ: multidimensional health assessment questionnaire.

Conclusion: In RA strictly controlled patients, there are no differences in endothelial dysfunction, vascular age or inflamming, when comparing with uncontrolled overweight OA patients. Physical activity, LDL levels and coffee consumption correlate with vascular age in OA and RA patients. OA patients under physiatrists follow-up and RA patients under methotrexate treatment or low MDHAQ levels have lower vascular age levels.

* FATIGUE IN RHEUMATOID ARTHRITIS: DOES PATIENT AGE INFLUENCE?*

S. Rodriguez-Muguruza1, S. Castro1, M. J. Poveda1, S. Paredes2, D. Taverner2, R. Fontova2, 1Hospital Universitari de Tarragona Joan XXIII, Rheumatology, Tarragona, Spain; 2Hospital Universitari Sant Joan de Reus, Rheumatology, Reus, Spain; 3Hospital Universitari de Tarragona Joan XXIII, Rheumatology, Tarragona, Spain

Background: Fatigue in RA has a multi-causal pathway. It is recommended that it should be measured in all RA studies using a validated instrument. Fatigue in elderly patients could have a different perception than in younger patients, identifying the associated factors could be a key to the management of this complex symptom.

Objectives: To compare fatigue and its associated factors in young and elderly patients with RA from two university hospitals.

Methods: A cross-sectional analysis was performed in 167 RA patients diagnosed according to the 2010 ACR-EULAR criteria. Patients were divided into two groups based on age (≥60 and <60) for comparative purposes. Fatigue was assessed using 4 instruments: the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ), the fatigue subscale of the Short-form 36 survey (fatigue-SF36), the Visual Analogic scale of fatigue (VAS) and the Functional Assessment of chronic illness Therapy Fatigue Scale (FACT-F). To compare the mean of fatigue between groups we used a T-Test. To determine in each group of patients (young and elderly patients) the relationship between the 4 subscales of fatigue (assessed by BRAF-MDQ) and the other variables (DAS28, CPR, ESR, hemoglobin, vitamin D, HAQ, RAID [Rheumatoid Arthritis Impact of Disease], SF36, Hospital Anxiety and depression Scale [HAD] and Brief Pain Inventory) a Spearman correlation was performed. A value of p < 0.05 was accepted as statistically significant.

Results: A total of 167 patients were included, 81 (48.5%) young and 86 (51.5%) elderly patients. We found fatigue (using 4 instruments) has not significant differences in young and elderly patients (Table 1). In young and
elderly patients, physical, living, cognitive and emotional fatigue were corre-
lated to RAID, SF36, HAID and pain but they were not associated to CRP,
ESR, hemoglobin and vitamin D. In young patients, all dimensions of fatigue
were associated with DAS28. Furthermore, in elderly patients we found a rela-
tion between physical (p-value 0.044) and living fatigue (p-value 0.012)
with DAS28, nevertheless cognitive and emotional fatigue (p-value 0.078 and
0.079 respectively) were not related.

</table>

Conclusion: In young and elderly patients, all dimensions of fatigue appear to be
related with subjective but not with objective variables. In young patients, all
dimensions of fatigue were associated with DAS28 but in elderly patients only
physical and living fatigue were correlate to disease activity. This results could
indicate that it is important to evaluate fatigue in a multidimensional perspective
in elderly patients.

INTOLERANCE TO METHOTREXATE IN RHEUMATOID ARTHRITIS: AN ASSESSMENT WITH THE MISS
(METHOTREXATE INTOLERANCE SEVERITY SCORE)
H. Hachichi1, S. Abdelkadi2, M. Brahmi1, Y. Mohamed1, Taher Star University
Hospital, Rheumatology, Mahdia, Tunisia; Taher Star University Hospital,
Rheumatology, Mahdia, Tunisia

Background: Methotrexate (MTX) is a cornerstone in the treatment of rheuma-
toid arthritis (RA), in monotherapy or in combination with biological agents.
Its prolonged use requires regular clinical and biological monitoring. The purpose
of our study is to assess intolerance to MTX and its consequences.

Objectives: The purpose of our study is to assess intolerance to MTX and its
consequences.

Methods: This is a cross-sectional study with RA follow-up patients meet-
ing the ACR/EULAR 2010 criteria. An assessment of MTX intolerance was
conducted using the Arabic version of the MISS (Methotrexate Intolerance
Severity Score). It is a questionnaire containing 12 items covering four areas:
abdominal pain, nausea, vomiting and behavioral disorders. A score of six
indicates an intolerance.

Results: Forty patients were included: 35 women (87.5%) and 5 men
(12.5%) of average age 51.7 years ±12.7 years. The average duration of dis-
ease progression was 12.2 years 9.2 [1-40 years]. All patients were treated
with methotrexate and supplemented with folic acid. 50% of patients were
under 10mg/week of MTX, 27.5% under 15mg/week and 22.5% under 20mg/week.
Patients had been on this treatment for an average of 8.7 years [1-25 years],
The majority of them (97.5%) received corticosteroids in combination,
12.5% received Salazopyrine and 27.5% received biotherapy. Methotrexate
intolerance was observed in 16 patients (42.1%). Nausea was observed in
13 patients (81.2%), vomiting in 5 patients (31.2%), abdominal pain in 11
patients (68.8%) and behavioral disorders in all patients. As a result of this
intolerance, 18.8% of patients had to stop their treatment, 12.5% decreased
the dose on their own, 6.2% took the MTX irregularly, 12.5% switched from
the oral route to the intramuscular route and 50% continued to take their
treatment in the usual way. The study of correlations did not reveal statisti-
cally significant associations between MTX intolerance and age, sex, dose
and duration of MTX, the associated intake of salazopyrin, biotherapy and
other symptomatic treatments.

Conclusion: The occurrence of an intolerance to MTX is common in
patients followed for RA, which may lead to poor adherence to therapy or
even a discontinuation of treatment thus decreasing the effectiveness of
management. Hence the need to systematically detect this intolerance and
react in time.

C. Garaffoni1, A. Marangoni2, M. Govoni3, C. A. Sciriá3, 1Rheumatology
Unit, University of Ferrara and Azienda Ospedaliera-Uneversità S.Anna,
Department of Medical Sciences, Ferrara, Italy; 2University of Milano-Bicocca,
School of Medicine and Surgery, Milan, Italy

Background: Cardiovascular disease (CVD) risk in patients with chronic inflam-
matory arthritis (IA), including rheumatoid arthritis (RA), psoriatic arthritis (PsA)
and ankylosing spondylitis (AS), is substantially increased compared to the
general population. New evidence strengthens the notion that the excess risk of
CVD morbidity and mortality in patients with IA is related to both traditional (e.g.
hypertension, diabetes, smoking) and novel CVD risk factors, including chronic
inflammation, leading to an accelerated atherosclerosis. How to minimize such
increased CVD prevalence is still underdood, and whether more intensive
traditional risk factor control or disease specific risk factor should be targeted is
still matter of debate.

Objectives: The aim of this systematic review was to identify intervention tar-
genring CVD or inflammatory arthritis associated with improvement of CV risk
outcomes (estimated CV risk, CV events, endothelial function, arterial stiffness,
subclinical atherosclerosis) in adult patients with diagnosis of inflammatory
arthritis (RA, PsA and AS).

Methods: Two independent reviewers retrieved randomized controlled trials of
interest from systematic searches of Medline, Embase and Cochrane database
(20th April 2020). Data extraction was performed using standard template; the
guadity of each included trials was assessed with the Revised Cochrane risk
of-bias tool for randomized trials (RoB 2) [1]. Systematic review was conducted
following the Preferred Reporting Items for systematic reviews and Meta-analysis
(PRISMA) statement.

Results: Out of total of 4823 articles, 27 met the inclusion criteria. Among these,
most (n=22) involved RA patients, one trial was based on mixed IAs patients and
the remaining (n=4) were performed on spondyloarthritids pop-
ulation. Total number of patients was 8045. Overall risk of bias was high in
most of per protocol analysis trials (90%) and in 26.7% of intention-to-treat
analysis trials. Four trials evaluated major adverse cardiovascular events (MACE)
icidence and one of these demonstrated a significant reduction in
incidence of MACE in RA patients underwent a treat-to-target strategy of
CV risk factor. The same study also demonstrated a significant reduction in
progression of subclinical atherosclerosis (carotid Intima-media thickness
cIMT), while other trials (n=8) exploring effect of rosuvastatin, enalapril,
tocolizumab and TNF-inhibitors failed to reach a similar result. Endothelial dys-
function, predominantly measured as reduce flow mediated dilatation (FMD),
was widely used as surrogate outcome of CVD and it appeared to be signifi-
cantly improved by treatment with statins, ACE-inhibitors, anakinra and tocili-
zumab. Treatment with pioglitazone, anakinra or tocilizumab in three trials
significantly ameliorated arterial stiffness, estimated with pulse wave velocity
(PWV), Cardio-ankle vascular index (CAVI) or augmentation index (AI). Two
studies explored how a reduction of estimated CV risk could be achieved
after treatment with enalapril and tight-control strategy aiming to SDAI ≤ 3.3.
Results of both trials didn’t demonstrate any variation in QRS3K3-2018 and
Framingham risk score, respectively.

Conclusion: Optimal CVD management in IA patients remains undefined and it
should be implemented as stated in international guidelines. Randomized con-
trolled trials exploring efficacy of prevention strategy are few and predominantly
focused on surrogate outcome measures of cardiovascular risk.

REFERENCES:
al. RoB 2: a revised tool for assessing risk of bias in randomised trials. BMJ,
Patients were stratified into those who were adherent to the treatment and those who weren't, according to their CQR score. Additional information regarding the quality of life (QOL-RA), disease activity (DAS28 ESR), and functionality (HAQ) was recovered from electronic clinical charts. Data was gathered on a database stored in REDCap. T-test and Chi-squared test were used for comparisons and a multiple logistic regression with backward selection was performed to build the final fitted model.

**Results:** Data from a total of 564 patients were included in the analysis. Our population was constituted of 79.1% women with a mean age of 53 ± 13.1; the CQR mean score was 77.7 ± 9.26 and treatment adherence, defined as a CQR score of ≥ 80.7, was seen in 49.3% of the cases. Mean DAS28 ESR, QOL-RA, and HAQ scores were 3.3 ± 1.62, 724 (± 1.43), and 0.671 (± 0.716), respectively; with a reported preserved quality of life (QOL-RA > 7) in 60.5% of patients. Monotherapy (42.7%) and combined therapy (49.6%) were the two most common treatment schemes, being MTX the more frequent DMARD (58.9% oral, 20.9% subcutaneous). Noncompliant patients showed higher mean disease activity (3.52 ± 1.66) vs 3.08 ± 1.54); p < 0.001) and lower quality of life (6.94 ± 1.43) vs 7.56 ± 1.33; p < 0.001) scores. Having a higher DAS28 score (OR 1.19), drug dispensing delay (OR 1.71), and infection as an adverse effect (OR 2.53) were recognized as risk factors for an impaired treatment adherence after adjustment for the effects of possible confounders. Complete results of the multiple logistic regression model are shown in Table 1.

AE: adverse effect. Bold values indicate a p value < 0.1

**Conclusion:** In our study population, there were evident trends regarding the effects of dispensing delays, adverse effects, and barriers to access to the healthcare system on reducing treatment adherence. Moreover, there was a subtle association of treatment adherence with the DAS28 score, as well as with a better quality of life. Taken together, these results suggest the need for the implementation of educational programs that will support a comprehensive approach that considers not only patient-related factors but also the proper functioning of the healthcare system itself. Further research with a follow-up period could assess the long-term effects on several clinical outcomes and explore if proposed trends change with time.

**DOI:** 10.1136/annrheumdis-2022-eular.1256
Background: Sarcopenia is a muscle disease which is characterized by loss of muscle mass and function. This condition is associated with chronic disease and ageing which predicts inability, hospitalization and death.

Objectives: Describe sarcopenia prevalence and risk factors in patients with rheumatoid arthritis (RA) over 65 years of age.

Methods: Design:
A case-control study.

Subjects: Cases: Recruitment was performed by random sampling between patients over 65 years of age with RA (ACR/EULAR 2010 criteria) attended at 4 Spanish University Hospitals. Controls: Recruitment of subjects without rheumatoid disease was performed asking for case patients who attended to medical center with a similar-age (age of range +5 years) and same-gender person from same social or family environment.

Variables: The main variable was sarcopenia which was defined according to European Working Group on Sarcopenia in Older People (EWGSOP) 2019. Sarcopenia risk factors assessed were: economic status, malnutrition, measured with Mini-Nutritional Assessment (MNA), dual-energy x-ray absorptiometry (DEXA) in spine and hip to osteoporose screening, toxic habits, comorbidities and Charlson index, physical activity measured with Global physical activity questionnaire (GPAQ) and Short Physical Performance Battery (SPPB).

Other variables were: haemoglobin, calcium, D and B12 vitamins, total proteins, albumin, C reactive protein, body mass index (BMI), polymedication, quality of life measured with EQ-5D and RA related factors, activity disease measured with DAS28, SDAI and CDAI; physical function measured with HAQ (Health assessment questionnaire) and global functional status according ACR criteria.

Statistical analysis:
Descriptive and multivariative analysis was performed to identify factors associated to sarcopenia in RA.

Results: 76 patients and 76 controls were included in the study, 120 were women (78,9%), with media ± SD of age 74,7 ± 8,98 of media and 32 (21,1%) were men, with age 70,1 ± 3,78 of media. In comparison with controls, RA patients presented more frequency of sarcopenia (30 [19,53%] vs 6 [3,94%]; p=0,005), RA patients who presented sarcopenia, were upper average age (p=0,001), worse results in Short Physical Performance Battery (SPPB) (p=0,037), higher DAS28 (3,55 ± 1,09 vs 2,78 ± 1,05; p=0,017), higher score HAQ (1,18 ± 0,79 vs 1,69 ± 0,68; p=0,024), worse score in EQSD (0,27 ± 0,28 vs 0,54 ± 0,25; p=0,001) and Visual analogic scale VAS EQSD (45,7 ± 17,4 vs 56,9 ± 17,6; p=0,035).

By the way, RA patients presented lower levels of total proteins (p=0,018), worse results in MNA (p=0,001) and they performed less physical activity by GPAQ (p=0,011). Multivariate models (Table 1) identified as independent predictors of sarcopenia in RA: age (p=0,014), proteins levels (p=0,044) and disease activity measured by DAS28 (p=0,030), This model could explain 37% of sarcopenia in RA (R2=0,37).

**ADHERENCE TO TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS**

P. Postnikova1, P. Kovalenko1, I. Dydykina1, A. Abolyoshina1, A. Smirnov2, A. Litik.1 V.A. Nasonova Research Institute of Rheumatology, Rheumatoid Arthritis Evolution Laboratory, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, Laboratory of Instrumental Diagnostics, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation

Background: Adherence is defined as the degree of agreement between a patient’s behavior (taking medication, changing lifestyle, or adhering to treatment recommendations) and the prescriptions of a physician or medical staff. The patient’s adherence to treatment is an important factor influencing the effectiveness of therapy, the course of the disease. In Russia, a universal questionnaire was developed to assess the level of adherence to drug therapy, medical care, lifestyle changes, and general adherence to treatment.

Objectives: To analyze the adherence to treatment, medical care and recommendations for lifestyle changes in patients with RA.

Methods: The cross-sectional study included 88 women with RA (ACR/EULAR 2010), the mean age -63.0±8.1 years, the duration of the disease - 22.4±9.3 years. Adherence was assessed using the Russian questionnaire, which determines the low, average, and high levels of adherence to drug therapy, medical care, recommendations for lifestyle changes, and general adherence to treatment. All patients completed The Hospital Anxiety and Depression Scale (HADS) for the detection of anxiety and depression symptoms and HAQ (Health Assessment Questionnaire) to explore functional disability. All patients took a clinical examination, assessment of the anamnestic data, X-ray of hands, feet.
M. Cazzato, O. Mazzarella, L. Bazzichi, F. Subir, E. Villa, E. Laurino, F. D'Alessandro, M. Mosca. Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy. Azienda Ospedaliero Universitaria Pisana, Pisa, Italy, Pisa, Italy

Background: The COVID-19 pandemic has impacted on face to face assessments of patients with rheumatic diseases, including rheumatoid arthritis (RA) and telemedicine has offered a valid opportunity to follow these patients. DEDICARE is a Patient Support Program (PSP) which has been active at our center since 2016, which allows the telemonitoring of PROs (Patient Reported Outcomes) for patients being treated with abatacept. Since 2016, 98 RA patients followed at our Unit entered the DEDICARE program. During COVID-19 pandemic these patients continued their monitoring using this PSP.

Objectives: To evaluate the impact of the first COVID wave on PROs and CROs (Clinical Reported Outcomes) in patients with RA included in the DEDICARE programme

Methods: Data collected in the dedicated platform three months before (from December 2019 to February 2020, pre-lockdown), during (from March 2020 to May 2020, lockdown) and after (from June 2020 to August 2020, post-lockdown) the first lockdown period in Italy were compared. In detail DAS28 (CRP, ESR), SDAI and CDAI were evaluated before and after the lockdown period; while VAS-pain, Global Health (GH); Patient Global Assessment of Disease Activity (PGA); Health Assessment Questionnaire (HAQ); Functional Assessment Chronic Illness Therapy (FACIT) were evaluated pre, during e post lockdown with the DEDICARE platform.

Results: 36 RA patients, all females, were included in the study; mean age was 62.4 (32-85) years; mean disease duration 15.5 (5-38) years; 18 were ACPA and RF+. All patients were treated with abatacept, 13 as monotherapy and 23 in association with csDMARDs. No patients had COVID19 disease during the evaluated period.

A significant worsening of global health and patient global assessment of disease activity was observed; while no differences were observed regarding the CROs and other PROs (Figure 1)

Conclusion: In the present study we were able to compare PROs in patients with RA before and after the first COVID wave in Italy. While no significant changes in disease activity were observed, patients experienced an increased perception of disease activity and a decline in their overall health status which began during the lockdown and continued over the following 3 months.

This may highlight a discordance between the patient and the physician perception of the disease, which may partly due to the psychological impact of pandemic on the general perception of health particular in patients with chronic diseases. Since this discrepancy may have consequences on disease management, and particularly on treatment adherence, there is a need to promote studies to better understand the reasons for these discrepancies and to improve the patient perception of their disease particularly in difficult situations such as COVID 19 pandemic.

ASSOCIATION BETWEEN INFLAMMATION AND DEPRESSIVE SYMPTOMS IN RHEUMATOID ARTHRITIS PATIENTS.

Instituto Nacional de Rehabilitación “Luis Guillermo Ibarra Ibarra”, Quintana Roo, Mexico;2Instituto Nacional de Rehabilitación “Luis Guillermo Ibarra”, Departamento de Mastología, Mexico City;3Hospital Júarez de México, Departamento de Reumatología, Mexico City, Mexico

Background: Rheumatoid arthritis (RA) is an autoimmune, progressive disease characterized by an inflammatory process mediated by CD4+ T lymphocytes leading to damage of the synovial membrane1. Its prevalence is estimated between 0.2 and 1.2% worldwide, affecting women in the fourth and fifth decades2. In 2013, the Mexican College of Rheumatology estimated a 1.6% prevalence3 in Mexico. RA may affect patients’ social, psychological, emotional and physical areas. Among its psychological implications, depression is one of the most important (with a prevalence of 40%) beyond the general population4. Several studies assess either prevalence or prognosis, despite its higher prevalence and a lesser likelihood of remission in these patients. Some investigations looked for a relationship between inflammation and depressive symptoms considering only clinical or biochemical parameters, despite the evidence supporting better results with imaging methods, such as musculoskeletal ultrasound (MSU).

Objectives: To identify the association between MSU demonstrated inflammation and the presence of depressive symptoms in RA patients.

Methods: In 2021 a cross-sectional study on RA patients (according to ACR/EULAR 2010 criteria) was conducted. The subjects were from the Instituto Nacional de Rehabilitación “Luis Guillermo Ibarra Ibarra” and Hospital Júarez de México Rheumatology out-patient clinic. Each patient underwent a clinical (SDAI, CDAI, and EVA), psychological (PHQ9 and InCaViSa questionnaires), and MSU assessment (7 joints score). Data described with central tendency and dispersion measures for quantitative variables and frequencies and proportions for qualitative variables.

Results: Fifty-two patients (94% women) were evaluated, with a mean age of 56.06 ± 12.31 years and duration of disease 13.66 ± 9.44 years. Depression prevalence was 54%. Patients with disease activity had the highest depression scores (p=0.009), those with triggering events in the last six months (p=0.177), the leading event was the death of a close relative in 30% of the patients. A moderate correlation between the depression score (PHQ9) and clinical disease activity scores (SDAI, CDAI, and VAS) was found (r=0.553 [p<0.001], 0.559 [p<0.001], 0.492 [p<0.001], and 0.57 [p<0.001], respectively) were found. Furthermore, we found a moderate correlation between depression scores and psychological, social and physical quality of life. A mild correlation between MSU synovitis and depression scores (r=0.315 [p=0.03]) found.

Conclusion: Patients with disease activity reported higher depression scores in comparison to remission patients. We demonstrated a relationship between depressive symptoms, social factors, disease perception and ultrasound synovitis. It is crucial to conduct longitudinal studies with a large number of patients, including a control group, and perform an adequate stratification of the demographic characteristics of the patients and their confounding variables.

CARDIOMETABIC COMORBIDITIES MAY IDENTIFY A MORE SEVERE SUBSET OF RHEUMATOID ARTHRITIS, RESULTS FROM A “REAL-LIFE” STUDY

P. Rusci1, A. Conforti1, C. Di Muzio2, D. Currado2, L. Navarini3, V. Pavlovich1.

1Center Biotechnological and Applied Clinical Sciences, Uqella, Italy;2Campus Bio Medico University of Rome, Department of Medicine, Rome, Italy;3Alma Mater Studiorum - Università di Bologna, Department of Biomedical and Neuroromotor Sciences, Alma Mater Studiorum, Bologna, Italy

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease associated with a significant increased rate of cardiometabolic comorbidities contributing to an increased risk of morbidity and mortality of these patients1.2. RA patients with cardiometabolic comorbidities might differ from those without in their clinical presentation and prognosis.

Objectives: This “real-life” cross-sectional study was designed to describe disease features of RA consecutive participants affected by cardiometabolic comorbidities than those without, among those attending recruiting centers from January 1, 2011 to December 31, 2012. Our purpose was also the identification of possible associations between these diseases and clinical characteristics of patients (i.e., fulfillment of ACR1987 criteria, ACPA positivity, presence of extra-articular manifestations, remission, and bDMARD failure).

Methods: Consecutive RA patients were assessed, all fulfilling 2010 ACR/EULAR criteria for RA. We have defined the participant as having such comorbidities if affected by 2 or 3 among high blood pressure (HBP), type 2 diabetes (T2D), and/or dyslipidaemia. The presence of cardiometabolic comorbidities for each participant was verified by reviewing the clinical charts, interview, and extensive medical examinations. Patients with and without cardiometabolic comorbidities were grouped and compared. After that, regression models were built to assess the influence of the presence of cardiometabolic comorbidities on RA features of disease severity.

Results: 757 consecutive RA participants were evaluated [(female 56.6%, age 64.7 ± 12.3 years, median disease duration 6 years (IQR 12)]. Among assessed participants, 13.5% showed cardiometabolic comorbidities. These were older (63.9 ± 13.1 vs 70.4 ± 9.0 years, p<0.001) and characterised by a longer disease duration with 64.7% vs 50% between 5 and 10 years (p=0.003). They were more often affected by extra-articular manifestations (8.2% vs 17.7%, p=0.029) and frequently displayed smoking habit (36.6% vs 50%, p=0.003). A lower percentage of patients with these comorbidities was in remission (15.7% vs 8.5%, p=0.048) and they showed a higher prevalence of history of bDMARD failure (40.4% vs 78.6%, p<0.001).

Finally, regression models showed that cardiometabolic comorbidities were significantly correlated with RA features of disease severity. Participants with cardiometabolic comorbidities more frequently fulfilled ACR1987 criteria in both univariate (OR: 1.47, 95%CI: 1.15-1.91, p=0.002) and multivariate analyses (OR: 1.48, 95%CI: 1.15-1.91, p=0.002). These participants had a higher probability of ACPA positivity in both univariate (OR: 1.52, 95%CI: 1.10-2.09, p=0.009) and multivariate analyses (OR: 1.47, 95%CI: 1.06-2.04, p=0.020). Cardiometabolic comorbidities also predicted the presence of extra-articular manifestations in both univariate (OR: 3.26, 95%CI: 1.77-5.89, p<0.001) and multivariate analyses (OR: 2.41, 95%CI: 1.33-4.47, p=0.005). Participants with cardiometabolic comorbidities had a higher probability of previous bDMARD failure in both univariate (OR: 1.73, 95%CI: 1.24-2.43, p=0.003) and multivariate analyses (OR: 7.17, 95%CI: 3.61-14.2, p<0.001). Cardiometabolic comorbidities resulted to be a negative predictor of being in remission in both univariate (OR: 0.53, 95%CI: 0.39-0.79, p=0.041) and multivariate analyses (OR: 0.61, 95%CI: 0.41-0.96, p=0.035).

Conclusion: We described disease features of RA participants with cardio- metabolic comorbidities, identifying a disease subset characterised by clinical features of disease severity and to be considered as “difficult-to-treat”. Thus, cardiometabolic comorbidities may represent a considerable burden for RA patients requiring an appropriate management which should focus, in addition to cardiovascular risk prediction, on targeting these metabolic components.

AB0262

PATIENTS WITH RHEUMATOID ARTHRITIS WHO DEVELOP SARCOPENIA FALL FREQUENTLY: 5-YEAR DATA FROM THE CHIKARA STUDY

Y. Yamada1, M. Tada1, K. Mandai1, N. Hidaka2, H. Nakamura3, 1Osaka City University School of Medicine, Orthopedics, Osaka, Japan;2Osaka City General Hospital, Orthopedics, Osaka, Japan;3Saiseikai Nakatsu Hospital, Orthopedics, Osaka, Japan

Background: Patients with rheumatoid arthritis (RA) are likely to have sarcopenia due to decreased muscle mass and physical function. Some patients develop sarcopenia even if disease activity is well controlled. We previously reported that 13.2% of RA patients without sarcopenia at baseline developed sarcopenia over a year2.3.

Objectives: The aim was to longitudinally investigate sarcopenia status and the characteristics of RA patients using data from the prospective, observational CHIKARA study.

References:

Disclosure of Interests: None declared.

Methods: Body composition, laboratory data, disease activity, physical function (HAQ), treatment, and history of falls and fractures were investigated in 100 RA patients who participated in the CHIKARA study at baseline and at 5 years. They were divided into 4 groups depending on their sarcopenia status: no sarcopenia developed (N group; sarcopenia absent at baseline and 5 years); sarcopenia developed (S group; sarcopenia absent at baseline, but present at 5 years); cured (C group; sarcopenia present at baseline, but absent at 5 years); and persistent (P group; sarcopenia present at baseline and at 5 years).

Results: Seventy RA patients completed the survey. There were no differences among the 4 groups in disease activity, physical function, and treatment. The N group, accounting for 67.1% of all patients, was young and had high body mass index, muscle mass, fat mass, estimated bone mass, and body metabolic rate at baseline. On the other hand, the S group, accounting for 4.3% of all patients, fell significantly more frequently (p=0.035), 3.3 times during 5 years. The P group, accounting for 18.6% of all patients, had significantly higher MMP-3 at baseline (p=0.006). The C group accounted for 10.0% of all patients (Table 1).

Data are shown as mean ± standard deviation (SD) or median (25th, 75th percentile). GC: glucocorticoids; MMP-3: matrix metalloproteinase 3; DAS: disease activity score; HAQ: health assessment questionnaire; BMI: body mass index; SMI: skeletal muscle mass index; BMR: body metabolism rate; Δ: change during 5 years.

Conclusion: Overall, 4.3% of RA patients developed sarcopenia and fell frequently during 5-year follow-up. Patients who develop sarcopenia require special care because they are at high risk of falls.

Ab0263 CLINICAL AND LABORATORY FACTORS ASSOCIATED WITH THE RHEUMATOID CACHEXIA.

1Federal State Budgetary Institution “Research Institute of Clinical and Experimental Rheumatology named after A.B. Zavodovsky”; Laboratory of Methods of Treatment and Prevention of Joint Diseases, Volgograd, Russian Federation

Background: Rheumatoid arthritis (RA) is associated with reduced physical performance capacity, leisure activities and self-service [1]. These changes are the result of the destruction of the joints, as well as the decrease in muscle strength, which is known as sarcopenia. However, patients with RA beneﬁt with a rheumatoid cachexia (RC), a speciﬁc form of sarcopenia, characterized with a decrease in fat-free mass index and an increase in fat mass index [2]. RC leads to a dramatic decrease in the life quality and increase in mortality rate [3].

Objectives: To study the clinical and laboratory factors associated with the RC.

Methods: 110 patients (102 females and 8 males) were enrolled in our study. All patients fulﬁlled the 2010 ACR/EULAR classiﬁcation criteria for RA. Standard clinical, laboratory and instrumental examinations were performed. Additionally, hsCRP, ACPA, CTX-1, P1NP and 25(OH)D were deﬁned. Dual-energy X-ray absorptiometry with Total Body program was performed. The diagnosis of RC was based on the criteria: fat-free mass index less than 10th percentiles with fat mass index above 25th percentiles [2]. Statistical analysis was performed using a software package “Statistica 12.0”. Parametric parameters are presented as Mean±std.dev. (95% CI), non-parametric as Me (Q1-Q3). Intragroup analysis of quantitative indicators was carried out using Student’s or Mann-Whitney test. The multiple logistic regression analysis was performed with a stepwise direct search procedure. Results are presented as odds ratio (OR) and 95% conﬁdence interval (95% CI). ROC curve was plotted to assess the diagnostic signiﬁcance of quantitative signs in predicting rheumatoid cachexia.

Results: Mean patients age was 53.7±12.07 (10.8-13.7) years. More than 85% had severe of terminal progression of the RA. Most patients were RF (77.3%) and ACPA (67.3%) positive, had moderate disease activity (3.79 [2.89-4.40]), cartilage erosions (79%) and II (56.4%) functional class. RA was diagnosed in 25 patients. Prevalence of RC was lower in RF-negative patients (OR 0.11 (95% CI 0.01-0.83). Also, prevalence of RA was associated with the duration of RA (1.06 (1.01-1.11)). Mean cumulative dose of glucocorticoids (GCs) was higher in patients with RC (8.5 g [8.2-17.5 g]), than without (5.8 g [3.6-13.7 g] (Z=1.98; p=0.047). Mean daily dose of GCs was lower in patients with RC (5 mg [4-6 mg] and 8 mg [5-10 mg] (Z=2.58; p=0.01)). The median duration of RA was higher among patients with RC (14.0 years) [9.0-22.0) vs 8.0 years [3.0-16.0] (Z=-2.18; p=0.029). ROC-curve was employed to assess the significance of the RF-negativity and RA duration in the diagnosis of the RC. Results are presented in Figure 1.

Figure 1. ROC-curve for the RC based on the duration of RA and the presence of RF

The optimum cut-off point of 9.5 years of RA was defined using Youden’s J, with a sensitivity of 88% and specificity of 53%.

Conclusion: RC is associated with the duration of RA, positivity for RF, higher cumulative dose of GCs and lower daily dose of GCs. Due to clinical practice, higher doses of GCs are usually prescribed as a “bridge-therapy” at the start of the treatment or while switching the therapy. On the other side, patients with low daily dose of GCs are more often hormone dependent, with high total cumulative dose. With the sensitivity of 88% patients with the duration of RA 9,5 years and more have RC.

Ab0264 ASSOCIATION BETWEEN DIFFERENT HLA DRB1 ALLELES AND SEVERITY IN RHEUMATOID ARTHRITIS.

M. Rojas-Giménez1, J. Calvo Gutierrez2, C. López-Medina3, R. Ortega Castro2, M. L. Ladehesa Pineda1, A. Escudero Contreras2, Reina Sofia University Hospital, 14004 Córdoba, Spain; Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), 14004 Córdoba, Spain; Córdoba University

Method: We performed a case-control study comparing 78 patients with rheumatoid arthritis (RA) and 93 controls. Both groups were matched for age, gender, and smoking status. The diagnosis of RA was based on the American College of Rheumatology and the European League Against Rheumatism criteria. Genotyping for the HLA DRB1*0101, *0401, *1001, *0901, and *0301 alleles was performed using PCR and restriction fragment length polymorphism analysis. The severity of RA was assessed using the Disease Activity Score (DAS-28). The associations between the HLA DRB1 alleles and the DAS-28 were analyzed using the chi-square test.

Results: The frequency of the HLA DRB1*0101 allele was significantly higher in the RA group than in the control group (p=0.003). The HLA DRB1*0101 allele was associated with a higher risk of severe RA (DAS-28 > 5.1) compared to the control group (OR=3.79, 95% CI: 1.60-9.00, p=0.002). The frequency of the HLA DRB1*0401 allele was significantly lower in the RA group than in the control group (p=0.04). The HLA DRB1*0401 allele was associated with a lower risk of severe RA compared to the control group (OR=0.32, 95% CI: 0.12-0.84, p=0.02).

Discussion: Our findings suggest that the HLA DRB1*0101 allele may increase the risk of severe RA, while the HLA DRB1*0401 allele may protect against severe RA. Further studies are needed to confirm these findings and to investigate the mechanisms underlying the association between HLA DRB1 alleles and RA severity.

**Objectives:** To evaluate the association between different HLADRB1 alleles and the development of serious complications in patients with rheumatoid arthritis (RA).

**Methods:** We performed an observational, longitudinal and retrospective study of a cohort of 134 patients with established RA (ACR/EULAR 2010) from the registry of our department, older than 18 years and without other associated autoimmune pathologies except secondary Sjogren's syndrome and who had the requested HLADRB1 genotyping. Patients with ≥ 1 of the following HLA-DRB1 alleles were considered positive shared epitope carriers (SE+): *01:01, *01:02, *04:01, *04:04, *04:05, *10:01, *03:01, *07:01.

**Results:** A total of 134 patients (91 SE+ and 43 SE-) were included. The main differences between the different alleles are shown in Table 1. The most frequent alleles were *01:01 (n=18), *03:01 (n=15) and *07:01 (n=17).

**Conclusion:** Our results suggest that RA patients carrying the *0405 and *0701 alleles have a higher risk of mortality compared to the control group.

**Disclosure of Interests:** None declared

**RHEUMATOID ARTHRITIS PATIENTS HOSPITALIZED FOR A SERIOUS INFECTION HAVE HIGH INCIDENCE OF SEPsis WHILE THOSE ON bDMARDS HAVE LOWER MORTALITY COMPARED TO THOSE ON csDMARDS**

E. Tzagarakis1, I. Fleur2, I. Facconi2, E. Kalioggiannaki2, S. Ilia3, G. Brissoulis3, P. Sioridoulopoulou1, V. Verzelino General Hospital of Heraklio, 2nd Internal Medicine Dept., Heraklion, Crete, Greece; 2University Hospital of Heraklion, Crete, Greece; 3University Hospital of Heraklion, Crete, Pediatric Intensive Care Unit, Heraklion, Crete, Greece

**Background:** The treatment of rheumatoid arthritis (RA) includes conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDS) and biologic DMARDs (bDMARDS). RA is associated with an increased risk of serious infections (SI) and the use of bDMARDS almost doubles this risk. SI can lead to sepsis, a life-threatening condition manifested by organ failure caused by a dysregulated host response to a pathogen. bDMARDS target pro-inflammatory cytokines which mediate the inflammation cascade activated both in RA and sepsis. However, very few data exist regarding the incidence of sepsis in patients with a SI while on treatment with bDMARDS.

**Objectives:** To assess the outcomes of sepsis and death in RA patients with a SI and compare them between patients on bDMARD and csDMARDs. Secondary aims were the comparison of subgroups of patients treated with different bDMARD classes (Tumor necrosis factor inhibitor (TNFi) vs. non-TNFi) and subgroups based on age (geriatric vs. younger patients).

**Methods:** Single-center retrospective analysis of adult RA patients registered in the University of Crete Rheumatology Clinic Registry (UCRCR), who were hospitalized for ≥1 SI between 2004-2020. Patients were assigned to “bDMARD group” if they were receiving bDMARDS at the time of the SI or “Control group” if there was no bDMARD exposure at least 3 months before the SI. Demographics, RA characteristics, and comorbidities were retrieved from UCRCR database, while details regarding hospitalization were sought in the patients’ electronic and paper files. Together with the “Sequential Organ Failure Assessment” (SOFA) criteria at admission and during 72-92 hours of hospitalization used to define the diagnosis of sepsis, we also analyzed the criteria of septic shock and in-hospital mortality.

**Results:** A total of 117 hospitalizations for SI in RA patients were included: 66 in patients receiving bDMARDS and 51 in the control group (65% bDMARD-naive and 35% bDMARD-experienced). The majority of the patients (76%) were women in both groups, however, patients on bDMARD were younger than control patients [70 (IQR 62-77) and 78 (IQR 68-82) years old respectively, p=0.002]. Other demographics, disease characteristics, disease activity at baseline, and comorbidities did not differ between the two groups, except for a higher prevalence of one or more previous hospitalizations for infection in patients on bDMARDS.

During hospitalization, 14 patients (12%) died. Mortality was significantly higher in the control group versus the bDMARD group (56.9% vs. 40.9% respectively, p=0.025). Sepsis criteria were fulfilled in 56 patients (47.9%) at admission and/or at 72-96 hours of hospitalization. Sepsis was marginally more frequent in the control group versus the bDMARD group (58.9% vs. 40.9% respectively, p=0.087). In the subgroup analysis based on the type of bDMARD, no statistical difference was found for the outcomes of sepsis or death between patients on TNFi versus those on non-TNFi. However, in the subgroup of patients ≥65 years old, there was a tendency for a lower incidence of sepsis or death in patients on TNFi compared to those on non-TNFi or the control group (14% vs 33%, vs 85% respectively (p=0.120) for the outcome of sepsis and 7% vs. 21%, vs. 71% (p=0.138) for the outcome of death).

**Conclusion:** In the present study, we found a high incidence of sepsis (47.9%) and mortality (12%) in RA patients hospitalized for a serious infection. Older age is the most significant predictor of adverse outcomes, however, patients on bDMARDS showed lower mortality and a tendency for a lower incidence of sepsis compared to the control group.

**DOI:** 10.1136/annrheumdis-2022-eular.2064
Background: Women with inflammatory arthropathies (IA) have fertility problems and complications during pregnancy and frequently biological therapy (BT) is required for the disease control.

Objectives: To evaluate pregnancy in women with IA in a multidisciplinary unit composed of Rheumatologists and Obstetricians: describe disease evolution, complications and treatment.

Methods: Retrospective and descriptive study of the evolution of pregnancy in patients with IA [Rheumatoid Arthritis (RA), Spondyloarthritis (SpA), Psoriatic arthritis (PsA) and Juvenile Idiopathic Arthritis (JIA)] and follow-up in a multidisciplinary unit for more than 15 years (until December 2021). Demographics, maternal disease, until time conception, previous abotions and presence of antibodies were collected. In addition, during follow-up, treatment, abortions, cesarean sections (C-section), preterm births, disease activity and maternal/fetal complications were collected.

Results: We registered 49 pregnancies (39 women): 27 RA (55.1%), 9 SpA (18.4%), 9 PsA (18.4%) and 4 JIA (8.1%). Maternal age at diagnosis was 26.8±6.7 years and average age at childbirth/abortion was 34.5±5.3 years. It took an average time of 9±7.7 months to conceive. 82% received fertility treatment with in vitro fertilization techniques. Anti-Ro antibodies were registered in 6.3% of patients and 28.6% had at least 1 antiphospholipid antibody. At the time of gestational desire/gestation 24 women (13 RA, 5 SpA, 3 PsA, 3 JIA) were receiving BT: 14 corticosteroids (CZP), 5 adalimumab (ADA), 4 etanercept (ETN), 1 patient was being treated with baricitinib (BARI). During pregnancy, ADA was changed to CZP in 3 women and BT was stopped in 6 cases (3 ETN, 2 ADA, 1 CZP) as well as BARI. In 2 cases, ADA was stopped at week 17 of pregnancy (medication indication). Pregnancy was completed with BT (CZP) in 15 cases. 9 abortions were registered prior to follow-up in the unit (0.23 abortions/mother) and 3 (2 RA, 1 PsA) during follow-up (0.07 abortions/mother); 2 (1 RA, 1 PsA) of them in women with CZP RA patient had positive antiphospholipid antibodies and was a smoker and the other one had moderate disease activity by the time of the abortion. C-section was performed in 26.1% of cases. Premature birth (<37 weeks) happened in 8.2% (n: 4) of the pregnancies: 2 in women with CZP. A total of 19 different fetal/maternal complications were registered during discharge and follow-up: 8 in the BT group (42.1%) compared to 11 (57.9%) in the group without BT, being Intrauterine Growth Restriction (IUGR) more frequent among women with BT. Infections were not more common in patients with BT, Table 1.

Regarding concomitant treatment, low dose prednisone was used in 32.7% of pregnancies, hydroxychloroquine in 44.9%, sulfasalazine in 8.2% and acetylsalicylic acid in 51%. We didn’t find differences in the use of these treatments between the two groups. Median DAS28 among RA patients with available data was under 2.6 throughout pregnancy as well as previously and posteriorly. No differences in median DAS28 were found between women with BT and without BT. SpA patients had BASDAI lower than 4 in both groups during pregnancy and previously.

Conclusion: In our series, as described in the literature, women with IA are older and more likely to have preterm births compared to general population. Appropriate disease control was maintained during pregnancy, also previously and afterwards. We registered more IUGR, low birth weight (LBW) and diabetes mellitus (DM) among women with BT but lower rate of infections. Given the low number of patients with BT no statistically significant conclusions about complications can be drawn. Therefore, more studies among pregnant women with BT are necessary.

AB0268

SURVEY OF ELDERLY RHEUMATOID ARTHRITIS (RA) PATIENTS: REAL-WORLD DATA OF PRE-OLD (65 TO 74 YEARS) AND OLD (≥ 75 YEARS) RA PATIENTS

1 Ishikawa Prefectural Central Hospital, Division of Nephrology and Rheumatology, Kanazawa, Japan; 2 Ishikawa Prefectural Central Hospital, Division of Nephrology and Rheumatology, Kanazawa, Japan; 3 Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan; 4 Kanazawa University Hospital Department of General Medicine, Kanazawa, Japan

Background: The number of patients (pts) with rheumatoid arthritis (RA) is highest in persons in their late 60s, and the age at onset has increased in recent years. In many countries, including Japan, ‘elderly’ is defined as 65 years or older, but recently, the Japan Geriatrics Society and Japan Gerontological Society have advocated a newer classification of elderly: pre-old as 65 to 74 years, old as 75-89 years and super old as ≥90 years. Disease activities, renal functions, treatments, and other parameters in thus classified elderly RA pts have not been investigated yet.

Objectives: Elderly pts with RA were classified, and then disease activities, treatments, renal functions and other parameters compared between the groups to clarify the real-world picture of pre-old and old RA pts.

Methods: We enrolled 359 RA patients (85 males, mean age 65.0 ± 13.6 years) treated at our hospital and affiliated hospitals. They were divided into three groups: 65 to 74 years as a pre-old (group I), 75 years or older as an old (group II). Urine examination, serum Cr, eGFR, BUN, other biochemical tests, serological tests, disease activity, treatment, smoking, and comorbidities were evaluated. Difficult-to-treat RA pts (D2TR) were evaluated according to EULAR criteria.

Results: Group C contained 148 pts (28 males, mean age 51.7 ± 9.6 years), Group I 123 pts (28 males, mean age 70.1 ± 2.9 years) and Group II 88 pts (29 males, average age 80.2 ± 4.5 years). Among the three groups, the frequency of males was 33.0% in group II, which was significantly higher than in the other groups. There was no significant difference in disease activity among the three groups. There was a significant difference in eGFR among the three groups (77.3 ± 17.3 ml/min in group C, 69.4 ± 15.8 ml/min in group I, 62.7 ± 18.7 ml/min in group II). There was a significant difference in frequencies of treatment with NSAIDs (40/133 (30.0%) in group C, 23/102 (22.5%) in group II, 9/67 (13.4%) in group III), methotrexate (MTX) (87/148 (58.8%) in group C, 62/103 (60.4%) in group I, 28/88 (31.4%) in group II). There was no significant difference in frequencies of treatment with prednisolone (55/148 (30.2%) in group C, 55/123 (43.1%) in group I, 45/88 (51.1%) in group II), with biologics (44/148 (29.7%) in group C, 29/123 (23.6%) in Group I, 26/88 (29.5%) in Group II) and with JAK inhibitor (15/148 (10.1%) in Group C, 7/123 (5.7%) in Group I, 5/88 (5.7%) in Group II). There was no significant difference in D2TR pts among the three groups (21/148 (14.2%) in Group C, 12/123 (9.8%) in Group I, 13/88 (14.8%) in Group II). There were significant differences in the frequencies of stage IV and comorbidities among the three groups.

Conclusion: In the pre-old and old RA pts, renal function was lower than in the control group. MTX was administered even in them, but less frequently. We were able to clarify the current situation that JAK inhibitors and biologics are actively used even in pre-old and old RA pts with impaired renal function, and the frequency of D2TR RA pts could be suppressed to almost that in the control group. Patients with impaired renal function are more likely to develop side effects of MTX, and it is necessary to pay particular attention to pre-old and old RA patients.

UTILITY OF DAS28-GT IN THE ASSESSMENT OF DISEASE ACTIVITY AND CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS

M. Lesturgie Telarek1, A. Delomeau1, E. Sorbets2, Y. Allamore3, J. Avouac3.

1 Cochin Hospital, Rheumatology, Paris, France; 2 Hôtel Dieu Hospital, Cardiology, Paris, France

Background: gGT has been identified as a maker of systemic inflammation and cardiovascular (CV) risk. The composite index DAS28-GT has been developed to allow an evaluation of both joint disease activity and CV risk.

Objectives: To assess the value of the DAS28-gGT in a population of patients with rheumatoid arthritis (RA) requesting cardiologic assessment.

Methods: Retrospective analysis of RA patients referred to cardio-metabolic day hospitalization in the Rheumatology department of Cochin hospital between February 2021 and January 2022. Criteria for referral were age > 50 years and presence of at least one CV risk factor. DAS28-GT index was calculated as follows: 0.56 * [TJ-28+0.28 *SJ-28+2 & + (γGT) +0.14 * GH]. This index was analysed according to disease activity measured with the DAS28-CRP. CV risk assessed by the Framingham score and the decision taken by the cardiologist (requirement of complement of examinations and/or therapeutic intervention).

Results: We included 22 RA patients (17 women), with a mean age of 66±10 years, a disease duration of 21±12 years. Rheumatoid factor was positive in 15 patients, anti-CCP antibodies in 17, and bone erosions in 16. 15 patients received methotrexate, 13 corticosteroids (dose < 10 mg per day), 15 targeted biologic therapies and 3 JAK inhibitors. The mean DAS28-CRP was 2.5±0.9 and the mean DAS28-GT was 7.9±1.90. 2 patients had a DAS28-GT < 5.5, defined in our previous study as high probability of RA remission and low probability of CV risk. These two patients were in remission and their Framingham score was < 10% (low CV risk). No complementary exploration was requested by the cardiologist.

8 (6 women, 2 men) had a DAS28-GT index between 5.5 and 7.5, defined in our previous study as high probability of RA remission or low disease activity (LDA) and increased probability of CV risk. As expected, all patients were in remission or in LDA. This population were at higher CV risk: 2 patients had a Framingham score > 20% (high risk), 3 patients a score ranging from 10 to 20% (intermediate risk), and 3 patients a score < 10%. One patient presented carotid atheroma. 4 patients required additional CV explorations and 3 patients necessitated escalation of blood pressure therapy.

Twelve patients (9 women, 3 men) had a DAS28-GT index > 7.5, defined in our previous study as high probability of active RA and/or increased probability of CV risk. 4 patients were in remission, 3 were in LDA and 5 presented moderate disease activity. One patient had a Framingham score > 20%, 4 had a score ranging between 10 and 20% and 6 had a score < 10%. The score was not applicable in an 80-year-old patient. Three other patients had coronary artery disease, including a patient who presented both coronary artery disease and carotid atheroma. 5 patients requested additional CV explorations and 4 patients required CV therapy escalation (introduction of statin and aspirin in 2 patients and increased blood hypertension therapy in 2 patients). Among these 12 patients, 3 with the highest DAS28-gGT values presented CV complications: a 64-year-old woman with a DAS28-gGT of 12.8 (DAS28-CRP, 2.89) had carotid atheroma and intermediate lesion of the right artery on coroscanner justifying a coronarography; a 61-year-old woman with a DAS28-gGT of 10.67 (DAS28-CRP: 4.62) had atrial fibrillation and aortic stenosis requiring Transcatheter Aortic Valve Implantation; and a 77-year-old woman with a DAS28-gGT of 10.35 (DAS28-CRP: 3.89) had ischemic chest pain necessitating rapid explorations in cardiology.

Conclusion: The DAS28-gGT allowed a reliable classification of patients according to RA activity and CV risk. This index may be relevant for CV risk stratification decision making to refer RA patients to a cardiologist. Its validation is in progress in a prospective cohort.

AB0270

EFFECT OF METHOTREXATE USE ON JOINT AND LUNG DISEASE OUTCOMES IN PATIENTS HAVING RHEUMATOID ARTHRITIS WITH INTERSTITIAL LUNG DISEASE

M. Yoshida1, T. Zoshima2, M. Kawano1.

1 Kanazawa University Graduate School of Medicine, Rheumatology, Kanazawa, Japan

Background: Intestinal lung disease (ILD) is a frequent complication of rheumatoid arthritis (RA). Although methotrexate (MTX) is an anchor drug for RA management, its use may worsen lung disease severity in patients with RA related ILD (RA-ILD). The safety and efficacy of MTX use in RA-ILD treatment have not been elucidated.

Objectives: We aimed to clarify the clinical characteristics of patients with RA-ILD and the effect of MTX use on joint and lung disease outcomes.

Methods: In this retrospective study, we included patients with RA-ILD who visited our department from 2011 to 2019 and underwent chest computed tomography (CT). RA was diagnosed using the 1987 ACR criteria or the 2010 ACR/EULAR classification criteria. During the abovementioned period, we defined the baseline as the time of the first chest CT scan; moreover, the final observation was defined as the time of the final chest CT scan in patients who underwent CT more than once, or as the final visit in those without a second chest CT scan. We excluded patients whose RA-ILD status could not be fully evaluated using chest
CT scans due to other causes, including respiratory infections. Severe infections were defined as infectious events requiring hospitalization.

To identify the clinical characteristics of patients with RA-ILD, we compared the features of RA with versus without ILD at baseline. To clarify the effect of MTX use on RA-ILD outcomes, we compared the outcomes of patients with RA-ILD with versus without MTX use. Furthermore, we investigated factors associated with RA disease activity or ILD deterioration using multivariate analyses.

**Results:** In this study, we included 452 patients (mean age, 60.2 years; females, 78.5%; mean observational period, 775 months), 325 (71.9%) of whom underwent chest CT more than two times.

Patients with ILD (ILD: n=90, 19.9%) were older and had a higher RF positivity rate than those without ILD. Moreover, patients with ILD were treated with lower MTX use (20.2% vs. 52.9%, p<0.001; 1.46 vs. 3.53 mg/week, p<0.001) and TNF inhibitors exposure (21.1% vs. 13.1%, p=0.044) than those without ILD, albeit with similar uses of prednisolone and other bDMARDs, including tocilizumab and abatacept. DAS28-PCR was higher in patients with than in those without ILD at baseline (4.60 vs. 3.42, p=0.063) and at the final observation (2.42 vs. 2.09, p=0.025). Linear regression analysis showed that baseline age and ILD were significantly associated with DAS28-PCR at the final observation ([b]=0.206 and 0.173, respectively). Kaplan Meier analysis revealed that patients with ILD experienced severe infections and respiratory infections more frequently than those without ILD (log-rank test, p<0.001 and p<0.001). Seventeen patients (20.2%) with ILD were treated with MTX. At baseline, these patients had similar ages and RF/ACPA positivity rates, as well as prednisolone and tDMARDs exposures, with higher tDMARD exposure (41.2 vs. 13.4%, p=0.016) compared to that in ILD patients without MTX use. DAS28-PCR was comparable in patients with and without MTX use at baseline, but was lower at the final observation in MTX-treated patients with ILD (1.41 vs. 2.73, p=0.001). Kaplan Meier analyses revealed no differences in the frequencies of severe infections, respiratory infections, or ILD deterioration between patients with and without MTX use. Cox regression analysis demonstrated that the risk factors for ILD deterioration included baseline age (hazard ratio [HR] 1.088; 95% confidence interval [CI] 1.037-1.147), but not MTX use (HR 1.668; 95% CI 0.472-5.876).

**Conclusion:** RA-ILD were treated with lower MTX use, which resulted in higher RA disease activity. In contrast, patients with RA-ILD treated with MTX had lower RA disease activity without ILD deterioration. As RA-ILD is undertreated, further studies are needed to assess the clinical significance of alexithymia in this category of patients.

the root mean square of successive R-R intervals (RMSSD), and c) the proportion of NNSQ (pairs of successive R-R intervals that differ more than 50 milliseconds) divided by the total number of R-R intervals (PNNS).

**Results:** Thirty minutes of DB increased HRV and was the optimal dose of DB in healthy participants. In patients with RA and SLE 30 minutes of DB increased all HRV-parameters similarly across two days indicating reliability, see Figure 1. The effect of DB remained for at least 30 minutes after the intervention. In our cohort the first ILD symptom appeared 7.4 years after RA diagnosis.

**Conclusion:** DB increases HRV in healthy participants and in patients with RA. HRV-parameters similarly across two days indicating reliability, see Figure 1. The mean time between diagnosis and initiation of biotherapy was 54 months (±5734). The first biologic prescribed for rheumatoid arthritis was Rituximab (94%), Infliximab was the first choice for spondyloarthritides (71%). Conventional treatment was combined with biotherapy in 78% versus 21% just treated by a biological treatment, the switch rate was high in the group receiving monotherapy with a significant difference (P=0.0008). The first cause of switch was therapeutic escape in (82.36%), followed by inefficacy in (11.76%) and a paradoxical reaction such as skin psoriasis in (5.85%). Switching was made to an Anti TNF alpha in 14 patients to and another therapeutic class in 3 patients.

**Conclusion:** Regular monitoring of the efficacy and tolerance of biological treatment is an integral part of the management of chronic inflammatory rheumatism.

**IDENTIFICATION OF RED FLAGS FOR INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS**

P. Cornigliano1, E. De Martinis2, E. Cela3, P. Triggianese3, M. S. C. Chimenti3, A. Lucano3, P. U. Calabria3, J. Ora4, F. Cavalli5, F. Garaci6, R. Floris7, P. Regiani1, A. Bergamini1, 1University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy; 2University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy; 3University of Rome Tor Vergata, Department of Diagnostic Imaging and Interventional Radiology, Rome, Italy; 4Tor Vergata Hospital Foundation, Radiosurgery, Rome, Italy; 5University of Rome Tor Vergata, Department of Diagnostic Imaging and Interventional Radiology, Rome, Italy; 6University of Rome Tor Vergata, Respiratory Medicine, Department of Experimental Medicine, Rome, Italy

**Background:** Interstitial lung disease (ILD) in Rheumatoid Arthritis (RA) can be subclinical or underestimated. Data from the literature report male sex, seropositivity and old age as known risk factors for ILD in RA. However, the correct timing for referral to pneumologists and eligibility for CT chest scan is undefined.

**Objectives:** To identify potential red flags of ILD diagnosis for referral to a multidisciplinary team analyzing clinical and radiological findings associated with the establishment of ILD.

**Methods:** Retrospective study on CT chest scan from RA patients evaluated and categorized into usual interstitial pneumonia (UIP), nonspecific interstitial pneumonia (NSIP) and unclassifiable RA-ILD (Un-ILD), by two radiologists.

**Results:** 80 CT chest scans from RA patients (F 59, age 66.6 ± 11.4, disease duration 78 ± 4.4) were evaluated. 36.5% of patients had performed CT chest scan for suspect of ILD, 11.2% for probable pulmonary infection, 8.7% for oncological screening or follow up, 13.7% for COPD disease, 8.7% for screening or active TBC, 3.7% for screening or previous pluriets and 175% for other reasons. A RA-ILD pattern was identified in 35% of patients, with a defined UIP pattern in 17.8%, a defined NSIP pattern in 42.8% and a 39.3% of Un-ILD, while 65% of patients had a non-ILD lung involvement by CT-scan. The mean age at ILD diagnosis was 67.2 years and the mean time between RA diagnosis and onset of ILD symptoms was 74 years. In the multivariate analysis female sex (HR=0.33; p=0.006) and disease duration (HR=0.8; p=0.06) were protective factors for ILD diagnosis. Age (HR=1.1; p=0.03), use of leflunomide (HR=10.1; p=0.03) were negative prognostic factors for ILD. Pulmonary clinical symptoms as dry cough (HR=17.6; p=0.02), bivascular inspiratory crackles (HR=11.5; p=0.01) and pleural rubs (HR=18.1; p=0.03) predicted ILD while negative predictors were the presence of linear opacities (HR=99.9; p=0.006), interstitial abnormalities (HR=12.1; p=0.07) and cystic areas (HR=33.3; p=0.06) at chest CT scan.

**Conclusion:** In our cohort the first ILD symptom appeared 74 years after RA diagnosis. Clinical variables and radiological abnormalities were identified as highly predictive of ILD diagnosis and may represent red flags for an early diagnosis and referral to pneumologists and radiologists in a multidisciplinary approach.

**AB0275**

**THE FREQUENCY, PREVALENCE OF CORONARY ARTERY DISEASE AND PRE-MATURE CAD IN PSA AND RA PATIENTS**

**Background:** An increased incidence of coronary artery disease (CAD) is known in inflammatory arthritis patients compared to the normal population. In the Veterans With Premature Atherosclerosis (VITAL) registry, the frequency of premature CAD in patients with rheumatoid arthritis (RA) compared to the healthy population in approximately 135,000 patients, while a similar situation was observed in Psoriatic arthritis patients. Aims: To study the prescription profile of biological agents (bDMARD) during chronic inflammatory rheumatic diseases, their impact on disease activity, frequency and causes of switch.

**Methods:** This is a retrospective study including 106 patients followed for chronic inflammatory rheumatism treated by biological agents.

**Results:** We included 106 patients, sex ratio (0.44), mean age was 41.5 ± 11.9. 64.4% were followed for spondyloarthritides (41 cases of ankylosing spondylitis, 10 cases of psoriatic arthritis, 11 cases of spondyloarthritides and chronic inflammatory bowel disease). 35.6% of the cases had rheumatoid arthritis. Sero-positive in 32% (labeled with Sjogren’s syndrome in 75% of cases, lupus in 19% of cases, vasculitis in 2% of cases). The mean time between diagnosis and initiation of biotherapy was 54 months (±5734). The first biologic prescribed for rheumatoid arthritis was Rituximab (94%), Infliximab was the first choice for spondyloarthritides (71%). Conventional treatment was combined with biotherapy in 78% versus 21% just treated by a biological treatment, the switch rate was high in the group receiving monotherapy with a significant difference (P=0.008). The first cause of switch was therapeutic escape in (82.36%), followed by inefficacy in (11.76%) and a paradoxical reaction such as skin psoriasis in (5.85%). Switching was made to an Anti TNF alpha in 14 patients and to another therapeutic class in 3 patients.

**Conclusion:** Regular monitoring of the efficacy and tolerance of biological treatment is an integral part of the management of chronic inflammatory rheumatism.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.2907
of RA patients had premature CAD, 18/32 (56.3%) PsA patients had premature CAD (Table 1).

Conclusion: While the frequency of premature CAD is 10% in the normal population, CAD has a premature character in two-thirds of RA patients and 55% of PsA patients (2). In a large community-based study, the frequency of premature CAD was found to be increased in RA patients compared to the normal population, but no similar difference was observed in PsA patients (1). In real-life data in which we examined a large group of patients using bDMARDs, it is seen that the subtype of CAD is of pre-mature character in both RA patients and PsA patients.

Background: According to international recommendations, co-morbidities must be taken into account in the management of patients with inflammatory arthritis.

Objectives: To evaluate the distribution of pre-treatment comorbidities in the bDMARD cohort including patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA).

Methods: The Hacettepe University biological database (HUR-BIO) was established in 2005. 581 (75.4% female) patients with RA and 520 (69.4% female) patients with PsA enrolled up to 2021 were analyzed. Diagnosis of RA and PsA was established in 2005. 581 (75.4% female) patients with RA and 520 (69.4% female) patients with PsA enrolled up to 2021 were analyzed. Diagnosis of RA and PsA was established in 2005. 581 (75.4% female) patients with RA and 520 (69.4% female) patients with PsA enrolled up to 2021 were analyzed. Diagnosis of RA and PsA was established in 2005. 581 (75.4% female) patients with RA and 520 (69.4% female) patients with PsA enrolled up to 2021 were analyzed. Diagnosis of RA and PsA was established in 2005. 581 (75.4% female) patients with RA and 520 (69.4% female) patients with PsA enrolled up to 2021 were analyzed. Diagnosis of RA and PsA was established in 2005. 581 (75.4% female) patients with RA and 520 (69.4% female) patients with PsA enrolled up to 2021 were analyzed. Diagnosis of RA and PsA was established in 2005.

Results: The burden of comorbidities in patients with RA before bDMARDs is more pronounced than in patients with PsA. Although, cardiovascular risk factors were similar, with the exception of hypertension and smoking, the age-adjusted CCI was 3.96 times higher in patients with RA than in patients with PsA.

Conclusion: The burden of comorbidities in patients with RA before bDMARDs is more pronounced than in patients with PsA. Although, cardiovascular risk factors were similar, with the exception of hypertension and smoking, the age-adjusted CCI was 3.96 times higher in patients with RA than in patients with PsA.

*p1, bDMARD initiation visit comparison **p2, last visit comparison
Background: Patients with Rheumatoid arthritis (RA) have an increased risk of infections due to the disease itself, and/or immunosuppressive therapy. The risk of herpes zoster (HZ) including disseminated HZ is also increased.

Objectives: In an unselected series of RA patients we assessed a) prevalence, b) general features and c) predictive factors of HZ.

Methods: Study of 393 RA patients included in the prospective vaccination program of the Preventive Medicine and Rheumatology department of a University hospital, from October 2011 to October 2016. The minimum follow-up was of 12 months; therefore, it was made until December 2020. HZ vaccination is not included in our vaccination program.

RA was diagnosed according to the ACR/EULAR 2010 criteria. HZ diagnosis included characteristic skin rash and blisters, paresthesia and local pain, in one (localized) or more dermatomes (generalized).

Vaccination program in our hospital includes vaccination for Influenza, Streptococci, Rhinovirus, Varicella Zoster Virus, Haemophilus influenzae, Pneumococci.

Patients with serious infections-related hospitalization were compared with healthy ones using the incidence rate method at a follow-up of 12 months; therefore, it was made until December 2020.

Results: We studied 393 patients (310 women), mean age 61.5±11.9 years. They were followed-up during a mean period of 82.6±15.2 months (range: 50 months-9 years).

HZ infection was observed in 31 of 393 patients (7.9%) (26 women); mean age 69.7±11.2 years. Prevalence of HZ in this period (12months) was 7.88% with an annual incidence rate of 0.73/100 patients/year. A comparison between patients with and without HZ was performed (Table 1).

HZ locations were intercostal (n=6), dorsal (5), abdominal (3), lumbar (3), facial (3), cervical (1), gluteus (1) (submmamary fold (1), intermmamary fold (1) and upper extremity (1). Main HZ complications were post-herpetic neuralgia (n=7), visual alteration in facial HZ (n=1) and disseminated HZ (n=1).

HZ treatment was antiviral agents (n=23) (brivudine=7; acyclovir 6; famciclovir; valaciclovir), topical (n=2) and none (n=6).

Predictive factors for HZ (Figure 1) were older age (>65 years), hypertension and treatment with high prednisone dose and antiTNF.

Conclusion: HZ is a relative frequent complication of RA. In our series, although are usually localized, post-herpetic neuralgia is relatively frequent. Probably to include HZ vaccine in our vaccination program of RA may be useful.

Disclosure of Interests: None declared

Results: We studied 392 RA patients (309 women/83 men); mean age 63.1±13.7 years. After a mean follow-up of 7.1±2±3.6 months, in 88 of 392 patients (22.4%) (60 women) 167 serious infections-related hospitalizations were required. The median (IQR) number of hospitalizations was 15 [1-2]. The main serious infections were respiratory (44 patients; 78 hospitalizations), urinary (33 patients; 48 hospitalization), cutaneous (19 patients; 28 hospitalizations), abdominal (17 patients; 20 hospitalizations), septic arthritis (7 patients; 8 hospitalizations), maxillofacial (2 patients, 2 hospitalizations), bacterial endocarditis (2 patients, 2 hospitalizations) and genital (1 patient; 1 hospitalization). Patients with serious infections-related hospitalization were older, with a longer RA, with more co-morbidities (hypertension, hypercholesterolemia diabetes mellitus, and Intestinalstitial lung disease) and with more conventional and biological DMARDS (Table 1).

The predictive factors for hospitalization were hypertension and Diabetes Mellitus, RA related intestinal lung disease and treatment with biologic DMARDS.

Figure 1. Predictive factors for serious infections-related hospitalization

Conclusion: Despite to be included in a vaccination program up to 22% of patients required hospitalization due to serious infection. The main predictive factors were co-morbidities, intestinal lung disease and treatment with biologic DMARDS. Serious infections in RA remain to be an unmet need.

AB0282

THE 2016 REVISED ACR FIBROMYALGIA CRITERIA IDENTIFY A HIGHER PREVALENCE OF FIBROMYALGIA IN RHEUMATOID ARTHRITIS PATIENTS: A CROSS-SECTIONAL STUDY FROM INDIA.

D. Malujtte, 1 S. Upadhyaya 1, R. Handa, 1 S. J. Gupta 1, S. Budmuru 1.

1Indraprastha Apollo Hospitals, Rheumatology, New Delhi, India

Background: Fibromyalgia (FM) prevalence in rheumatoid arthritis (RA) is reported around 5-50% as per older American College of Rheumatology (ACR) FM Criteria, while in India reported around 15% (1). The Revised 2016 ACR FM criteria has greater sensitivity and specificity of 94% and 91% respectively compared to older criteria (2). To best of our knowledge, no study has evaluated the prevalence of FM in RA as per revised 2016 ACR FM criteria.

Objectives: 1) To study prevalence of FM as per revised 2016 ACR FM criteria in RA patients.
2) To compare Disease activity, Disability status, Quality of life, Anxiety and Depression in RA with and without FM.

Methods: This cross-sectional study included 200 RA patients and equal number of controls. FM was diagnosed using revised 2016 ACR FM Criteria. Disease activity, quality of life and functional disability in RA patients was assessed using disease activity scores (CDAI, SDAI, DAS-28 CRP, WHO-Qol BREF and Health Assessment Questionnaire CRD HAQ-DI). Presence of depression and anxiety was determined using validated Hospital Anxiety and Depression Scale (HADS).

Results: FM was present in 31% and 4% of RA patients and healthy controls respectively in our study using 2016 ACR FM criteria. This is significantly higher compared to the 15% and 2.5% in RA and healthy control populations respectively of the study by Dhir V. et studying a similar population of Indian patients, using 1990 ACR FM criteria. RA patients with FM were older, predominantly females, had longer disease duration, were more on steroids, had higher disease activity and more functional disability. In a multivariable linear regression analysis, FM was important predictor of DAS28 score & CDAI, even after adjusting for other independent variable like disease duration, CRP, SJC, functional disability. RA patients with FM had a poorer quality of life and had higher prevalence of anxiety and depression. No difference was noted in use of disease modifying agents, biological or ts-DMARDs in RA patients with or without FM.

COMORBIDITIES ARE MORE IMPORTANT THAN JAK INHIBITORS: VENOUS THROMBOEMBOLISM IN RHEUMATOID ARTHRITIS

G. Sandal Uzun1, M. Bahap0, O. Yucel1, Y. Kaygusuz2, E. Bilgin1, L. Kılıç1, A. Akdogan1, O. Karadag1, Ş. A. Bilgen1, S. Kinaz1, A. İ. Ertenli1, U. Kalyoncu1, 1Ankara, Hacettepe University, Faculty of Medicine; Division of Rheumatology, Ankara, Turkey; 2Hacettepe University, Faculty of Pharmacy, Department of Clinical Pharmacy, Çanakkale, Turkey

Background: The risk of Venous thromboembolism (VTE) is increased and is an important cause of mortality and morbidity in rheumatoid arthritis. In addition to the underlying Rheumatoid arthritis(RA), there are a number of predisposing risk factors for VTE(1).

Objectives: In this study, we aimed to evaluate the demographic and clinical features of rheumatoid arthritis patients with VTE.

Methods: Patients who were referred to Hacettepe University Medical Rheumatology department from January 2021 to December 2021 retrospectively analyzed. A total 981 RA patients were detected according to the ICD code(M05, M06, MO07). RA diagnosis was confirmed in 400 patients according to 2010 ACR/ EULAR criteria. Venous thrombosis was confirmed by ICD code(I26,I74,I82), computed tomograph, lower extremity venous doppler and medical treatment report in these 400 patients with RA. Thromboembolism was detected in 58 patients during follow-up. The patients' clinical characteristics, serological features, co-morbidities, and treatment were systematically analysed.

Disclosure of Interests: None declared

Background: Fatigue is a major symptom suffered by patients with rheumatoid arthritis (RA), with a high prevalence (40%-70%). Different questionnaires and scales (BRAF, FACIT, SF36v, MDHAQ, VAS...) have been validated, but none have been standardized to measure it. In observational studies, the VAS (0-10) scale was reported as a good measure for fatigue; cut-off 5/10 indicates high level. A residual fatigue in low activity/remission of the disease has been described in a significant percentage of patients. The level of brain-derived neurotrophic factor (BDNF) in serum has been reported to be elevated in patients with RA, their connection with cognitive and depressive disorders in rheumatic diseases. Chronic inflammation, prolonged pain, early disability of patients with multi-morbidities. RA patients with multimorbidity may have an increased risk of VTE. In the management of RA, comorbidities should be taken into account.

References:
[1] Kettic, Boutigny A, et al. Risk of venous thromboembolism in rheumatoid arthritis (RA), with a high prevalence (40%-70%). A residual fatigue in low activity/remission of the disease has been described in a significant percentage of patients.

Disclosure of Interests: None declared.

patients - all these factors contribute to the development of depressive and cognitive disorders in this category of patients. Still, the mechanisms of these disorders remain poorly understood. Recently, the role of brain-derived neurotrophic factor (BDNF) as one of the factors of cognitive and depressive disorders in various pathological conditions has been widely discussed in the literature.

Objectives: To study cognitive and depressive disorders in RA patients and their association with serum BDNF levels.

Methods: 79 women with RA, aged 21 to 74 years, on average (M ± SD) 48.7 ± 10.2 were examined. Diagnosis RA was established according to EULAR / ACR criteria (2010). Patients' cognitive function was assessed by the MMSE (Mini Mental State Examination). The presence and severity of depression were determined by the QIDS-SR16 (Quick Inventory of Depressive Symptomatology Self-Report). Serum BDNF was detected by enzyme-linked immunosorbent assay (ELISA) using standard BDNF Quantikine ELISA kits (R&B Systems, USA). The control group consisted of 30 age matched healthy women.

Results: It was found that the level of BDNF in the serum of women with RA was 1.5 times higher than in healthy individuals and was 16.8 ± 10.8 ng/ml and 11.3 ± 4.89 ng/ml, respectively. Cognitive disorders (MMSE < 28 points) were registered in the majority (78.5%) of patients with RA, while in the control group, there were only 10%. The mean MMSE values in RA patients and the control group were 27.2 ± 1.45 and 29.1 ± 0.99, respectively. Depressive disorders (QIDS-SR16 ≥ 6 points) were reported in 53% of patients, while in the control group, it was 3.3%. It was found that depressive disorders in RA patients were associated with BDNF levels (r = 0.208; p<0.05) and age (r = 0.159; p<0.05). There was no significant association between BDNF levels and MMSE in RA patients. In the control group it was found negative correlation (-0.257; p<0.05). We found also close negative correlation between MMSE and age in patients with RA (r = -0.669; p<0.001). A significant relation with age was also registered in the healthy group (r = -0.257; p<0.05).

Conclusion: Patients with RA had an increased level of BDNF compared with the control group. Most of them had cognitive and depressive disorders. Depressive disorders in RA patients are associated with higher levels of BDNF in the blood and with age. No association of cognitive impairment with BDNF has been established in patients. Cognitive disorders in RA patients are most closely associated with age. Moderate association between MMSE and BDNF levels was established in control group.

regression models for estimating the increment in the mean outcome disease activity scores, DAS28- CRP and SDAI in continuous, provided beta coefficients equal to -0.17 (Standard Error, SE: 0.06) with a p-value equal to 0.06 for DAS28- CRP and a beta coefficient of -1.13 (SE: 0.37) with a p-value equal to 0.04.

Conclusion: Increasing frequency of consumption of a food group composed by olive oil, black and green olives is significantly associated to a lower risk of disease activity, as measured by both DAS28-CRP and SDAI, after adjustment for socio-demographic factors, therapy, disease duration and severity. Robust regression models allowed to quantify the mean reduction of DAS28-CRP in 0.17 points and that of SDAI in 1.19 points.

AB0287 INFLUENCE OF COPING ON RHEUMATOID ARTHRITIS RELATED PAIN

O. Saidane1, M. Haddad2, A. Ben Tekaya1, R. Leila1, S. Bouden1, R. Tekaya1, I. Mahmoud1, L. Abdelmoloula1. 1Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia

Background: Most patients with rheumatoid arthritis (RA) have chronic pain. Nowadays dealing with pain is no more focused on traditional treatment only.

Objectives: Our study aimed to assess the impact of coping strategies on the chronic pain in RA subjects.

Methods: We performed a 6-month study including patients followed for RA according to ACR / EULAR 2010 criteria. The visual analogue scale (VAS) was used to assess the perception of pain. Coping was assessed by the Brief COPE questionnaire according to which five grouped strategies were identified: Problem solving that includes active coping and planning. Cognitive restructuring that combines humour, acceptance and positive reinterpretation. Support seeking that combines the search for instrumental support, the search for emotional support and religion. Avoidance that includes denial, blame, substance use and behavioural disengagement. Distraction that includes distraction and expression of feelings.

Results: We included 65 RA patients with 58 women and 7 men, the sex ratio was 0, 12 H/F. Mean age of the patients was 58, 6 [24 – 73 years]. Disease duration was superior to 10 years in 66, 2% of patients. RA was immunopositive in 87%, the average of VAS was 5 ± 2,2. The perception of pain was positively associated with coping strategies based on problem solving, negatively associated to cognitive restructuring and distraction (Table 1).

Table 1. Impact of coping strategies on chronic pain RA subjects

AB0288 ECHOCARDIOGRAPHIC FINDINGS BY SPECKLE TRACKING IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. A. Rosal Arteaga1, S. Cerpa-Cruz2, E. Purón González1, G. Martínez-Bonilla1, V. Gonzalez-Díaz3, J. J. Hernandez-del Río3, M. E. Ventura Valenzuela1, S. Contreras Sánchez1. 1Hospital Civil Fray Antonio Alcalde, Rheumatology, Guadalajara, Mexico; 2Hospital Civil Fray Antonio Alcalde, Echocardiography, Guadalajara, Mexico

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory joint disease characterized by infiltration of the synovial membrane by B cells, T cells, and monocytes. Among the most important extra-articular manifestations are those of the cardiovascular system. Cardiovascular involvement in this group of patients is highly relevant as it is an important cause of morbidity and mortality (1, 2). Subclinical involvement is underestimated and currently, conventional cardiovascular risk stratification methods are insufficient to detect early stages of cardiovascular disease. Speckle tracking has emerged as a tool to measure early myocardial dysfunction and has been shown to be useful as a predictor of cardiovascular events. Normal reference values have recently been published (3).

Objectives: To describe the echocardiographic findings by speckle tracking (ST) of the left atrium (LA) and left ventricle (LV) in patients with RA without prior known cardiovascular disease and to compare it with healthy controls. To establish if there is an association of echocardiographic findings with characteristics of the disease.

Methods: Thirty-four patients with RA without a history of previous cardiovascular disease and 50 healthy controls were included. Echocardiographic measurements were made by Speckle Tracking of the LA in its 3 phases and of the LV expressed as Global Longitudinal Strain (GLS), in addition to conventional measurements. Quantitative variables were expressed as proportions, continuous data were reported as means and standard deviations. Both groups were compared with t-test and a linear regression model was used to evaluate age and RA presence in relation to the abnormality or normality of Speckle tracking findings. SPSS was used for statistical analysis.

Results: A significant difference was found in LA global longitudinal strain compared to controls (45.14% vs 57.34%, p=0.020), LA conduit strain (25.69% vs 36.74%, p=0.002) and LV global longitudinal strain (-176% vs. -22.62%, p<0.000). There was no significant difference in LA contractile strain and LA strain rate. In the echocardiographic measurements by conventional technique, no differences were found in the measurement of the LV ejection fraction or LA volume index, but LA ejection fraction was lower in the RA group (53.8% vs 78.2%, p=0.000). Rheumatoid arthritis was associated with LA speckle tracking abnormality in the reservoir, conduit, and LV global longitudinal phases.

Conclusion: The patients with rheumatoid arthritis presented subclinical echocardiographic alterations of myocardial deformation measured by speckle tracking both in the left ventricle (assessed as GLS) and in the left atrium, these were associated with RA regardless of age.

AB0289 DEPRESSION AND METABOLIC DISORDERS PREVENT REMISSION IN RHEUMATOID ARTHRITIS

A. Aleksandrova1, L. Shilova1, V. Aleksandrova2, I. Alekhiina3, N. Aleksandrova3. 1Volgorad State Medical University, Department of Hospital Therapy, Volgorad, Russian Federation; 2Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zboroovsky», Department of Clinical and Laboratory Diagnostics, Volgorad, Russian Federation; 3Stavropol State Medical University, Department of Hospital Therapy, Stavropol, Russian Federation

Background: Epidemiological data and clinical observations suggest an increased risk of depressive disorders in rheumatoid arthritis (RA) patients with metabolic syndrome (MS) [1, 2].

Objectives: To study the prevalence of depressive symptoms depending on the presence of MS components in RA patients and to evaluate their combined effect on achieving remission of RA.

Methods: 100 RA patients aged 18 to 69 years old (91% women; mean duration of disease 9 [3.5,15] years; body mass index (BMI) 28.6 [IQR 25.1-32.8]) were examined. MS was confirmed in RA patients with three or more harmonized National Cholesterol Education Program Adult Treatment Panel III (NCEP-ATPIII; 2004) criteria. RA patients were assigned a binary MS score (“yes/no”) and a categorical MS score (from 0 to 5 criteria) was calculated. The severity of depression in patients with RA was determined using the Beck Depression Inventory (BDI).

Disclosure of Interests: None declared

Results: 46% of RA patients met the criteria for MS. The presence of three categorical signs of MS was noted in 26%, four - in 16% and of all five signs - in 4% of cases. The combination of elevated fasting glucose, elevated triglycerides (TG), and decreased high-density lipoproteins (HDL) was the most frequent (19.6%; 9/46). The combination of the four MS criteria (increased waist circumference (WC), elevated TG, decreased HDL, and arterial hypertension) occurred in 17.4% (8/46) of cases. RA patients with MS had more severe systemic inflammation (C-reactive protein 9.3(3.9; 23.1) versus 3.35(2.3; 12.0) mg/L (p < 0.028), higher levels of TG (p = 0.001) and total cholesterol (p = 0.003), and higher BMI (p = 0.018) and WC (p = 0.007).

Depression scores of BMI ≥10 were noted in 64 RA patients: 26% were mild, 28% were moderate and 10% were severe. Symptoms of depression were more frequent in RA patients with longer duration (p = 0.025, p = 0.012) and high activity (p = 0.37; p = 0.001) of the disease. There were statistically significant differences in the incidence of depression (BMI ≥10 points) depending on the absence or presence of MS in RA patients (Phi-square=0.42; association coefficient q = 0.65). When comparing groups of RA patients stratified by the presence of MS, significant differences in the severity of depressive disorders according to BMI were found (RA without MS: 8.35 ± 5.1 points; RA with MS: 23.6 ± 12.8 points, p < 0.001). In RA patients without MS, only mild (26%) and moderate (9.3%) depression were detected. In RA patients with MS, depressive symptoms from mild to severe were present in almost equal proportions. Two-factor analysis of variance showed significant differences in BDI and MS on DAS28-ESR activity in RA patients (p = 0.05), the presence of MS had a significant effect on BDI depression (p = 0.001), and there was no relationship between MS and the degree of disease activity (p = 0.33).

Re-examination (6-7 months later) of patients with initially moderate RA activity (n = 58) revealed that remission of the disease was not achieved in 25% of patients from the group with no signs of depression and MS. In the group of RA patients with MS and BMI ≥10 there were almost two times more cases of deterioration (63.3%) (p = 0.025) by G2 with Yates correction = 4.7, p = 0.03).

Conclusion: Progression of depression against the background of marked metabolic disorders can lead to a decrease of RA patients’ quality of life and complications in disease prognosis [3, 4, 5]. This requires an early multidisciplinary treatment and increased knowledge of the risks associated with depression and MS among health care professionals and patients. Identification and correction of symptoms of depression and MS in RA patients should be a part of the optimal patient care.

COMPARATIVE FEATURES AND LONGITUDINAL BEHAVIOUR OF RHEUMATOID ARTHRITIS-ASSOCIATED UIP VERSUS IDIOPATHIC PULMONARY FIBROSIS: A SINGLE CENTRE COHORT STUDY

C. Mazeda1, J. Antao2, M. Ferreira3, R. Aguilar1, A. Barcelos1, P. G. Ferreira4,
1Centro Hospitalar Baixo Vouga, Rheumatology, Centro Académico Clínico Esga Moniz, Aveiro, Portugal; 2Universidade de Aveiro, Centre for Research and Development in Mathematics and Applications, Aveiro, Portugal; 3Centro Hospitalar Baixo Vouga, Radiology, Aveiro, Portugal; 4Centro Hospitalar e Universitário de Coimbra, Pneumology, Coimbra, Portugal

Background: Intestinal lung diseases (ILDs) are a group of heterogeneous lung disorders with variable prognosis. Idiopathic pulmonary fibrosis (IPF) is the main idiopathic interstitial pneumonia and rheumatoid arthritis (RA) is the commonest cause of connective tissue disease related-ILD. In fact, ILD is the most frequent form of respiratory involvement in RA, with 10% patients having clinically significant disease, frequently imposing serious morbidity mortality. RA-ILD can potentially comprise different disease patterns with distinct prognosis, with usual interstitial pneumonia (UIP) being the most frequent radio-histological pattern. Several studies have suggested that the RA-UIP disease course and survival may be clinically similar to IPF.

Objectives: This study aimed to investigate comparative clinical features, longitudinal behaviour and healthcare resource utilization between local cohorts of RA-UIP and IPF patients.

Methods: Retrospective and descriptive study including all IPF and RA-ILD cases diagnosed and followed in the ILD outpatient clinic of secondary hospital between 2015 and 2020. All patients with RA diagnosis met classification criteria of 2010 ACR/EULAR and IPF patients were diagnosed according to 2018 ATS/ERS/JRS/ALAT clinical guidelines. Socio-demographic, clinical data and longitudinal lung function (functional vital capacity (FVC) and lung diffusion capacity for carbon monoxide (DLCO)) were collected. A statistical analysis was performed; p-value <0.05 was statistically significant.

RESULTS:

Table 1. Baseline clinical characteristics of all patients are listed in table.

In RA-UIP group, 86% of patients reported preceding articular symptoms, with lung disease being diagnosed after a median of 11 years (IQ range 2-13). All patients had a UIP/probable UIP pattern in HRCT. Regarding baseline FVC and DLCO, the RA-UIP group revealed better lung function compared to the IPF group. All patients with RA-UIP received some form of immunomodulation treatment. Around 78.4% of patients were on low dose prednisolone. Additionally, 64.2% received treatment with mycophenolate mofetil, 21.4% with rituximab, 7.1% with azathioprine and 7.1% with nintedanib or pirfenidone. From the global population study only 27.3% of IPF patients were on low dose prednisolone. Additionally, 64.2% were treated with antifibrotics (nintedanib or pirfenidone). Given the high global population study only 27.3% and 14.3% of IPF and RA-UIP patients, respectively, were referred for respiratory rehabilitation. There were significant differences between the FVC groups (p = 0.002) and DLCO groups (p = 0.003) decline over time between groups. Comparing to RA-UIP, IPF patients experienced a greater number of acute exacerbations (4 vs 27±0.006) and had more respiratory-related emergency visits. IPF patients also had a higher rate of hospitalizations, most of them respiratory-related. There was a clear trend towards higher mortality during follow-up in the IPF group compared to the RA-UIP group (40% vs 21.4%; p = 0.23), although not reaching statistical significance.

Conclusion: RA-UIP patients appear to be less symptomatic and have a shorter symptomatic period at diagnosis. IPF patients had worse lung function at diagnosis. IPF patients showed a higher tendency to acute exacerbations and had a greater unplanned health care resources utilization. There was also a non-significant trend towards higher mortality during follow-up in the IPF group compared to the RA-UIP group (40% vs 21.4%; p = 0.23), although not reaching statistical significance.

COMORBIDITIES PROFILES IN SEROPOSITIVE RHEUMATOID ARTHRITIS VERSUS SERONEGATIVE RHEUMATOID ARTHRITIS

E. Hannech1,2, A. Ben Tekaya1,2, O. Saidane1,2, S. Bouden1,2, R. Leila1,2, R. Tekaya1,2, I. Mahmoud1,2, L. Abdelmoula1,2, 1Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; 2Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia

Disclosure of Interests: None declared

Background: Patients with seropositive rheumatoid arthritis (RA) (positive Rheumatoid Factor (RF)) are more susceptible to extra-articular manifestations [1]. The role of RF in the occurrence of comorbidity is not clear. 

Objectives: We compare comorbidities among patients with seropositive RA versus patients with seronegative RA.

Methods: We conducted a retrospective study in our rheumatology department including 255 patients with established RA according to the ACR/EULAR 2010 criteria. Patients were divided in two groups according to their Rheumatoid Factor (RF) profile: seropositive RA (positive RF), seronegative RA (negative RF).

Comorbidities were investigated and compared between the two patient groups.

Results: There were 206 seropositive RA and 49 seronegative RA. Gender distribution was similar in the two groups: 82% female and 18% male in seropositive RA; 85% female and 15% male in seronegative RA (p=0.5). Smoking was noted in 15% patients with seropositive RA and in 11% patients with seronegative RA without any difference (p=0.5).

Comorbidities were noted in 40% of seropositive RA and in 45% of seronegative RA without any significant difference (p=0.6). Obesity (BMI ≥ 30kg/m²) was noted in 31% of seropositive RA and in 36% of seronegative RA (p=0.7). Diabetes was noted in 18% seropositive RA and in 26% seronegative RA patients (p=0.1). Hypertension was noted in 31% seropositive RA patients and in 30% seronegative RA (p=0.8). Heart disease was present in 6% seropositive RA and in 7% seronegative RA (p=0.9). Dyslipidemia was noted in 40% seropositive RA and in 20% seronegative RA (p=0.1). Gastrointestinal comorbidities were observed in only seropositive RA patients (11%). Respiratory comorbidities were noted in 27% seropositive RA and in 28% seronegative RA without any significant difference (p=0.6). Regarding mental health problems, depression was noted in 7% seropositive RA and in 14% seronegative RA without any significant difference (p=0.4).

Conclusion: Our study showed that comorbidities were comparable in seropositive and seronegative RA. It seems that RF does not influence the prevalence of comorbidities in RA patients.

INDICATIONS AND THERAPEUTIC IMPLICATIONS OF HAND AND WRIST JOINT ULTRASOUND IN RHEUMATOID ARTHRITIS

S. Ben Dhia1, S. Miladi1, A. Fazaa1, H. Bousaa1, L. Souabni1, K. Ouenniche1, S. Kassa1, S. Chekili1, K. Ben Abdelghani1, A. Laatar1, 1Mongi Slim Hospital, Department of Rheumatology, La Marsa, Tunisia

Background: Ultrasound (US) has been increasingly used in the recent years for the diagnosis and follow-up of rheumatoid arthritis (RA) [1]. It is considered as a complement to physical examination with high sensitivity, specificity, and accuracy in detecting synovial thickening, synovial hypervascularization as well as cortical bone erosions [2].

Objectives: To explore rheumatoid cachexia association with bone, vertebral fractures, and structural joint damage in RA patients.

Methods: We conducted a retrospective study in our rheumatology department including 255 patients with established RA according to the ACR/EULAR 2010 criteria and recruited from December 2021 at our rheumatology department. Patients with seropositive rheumatoid arthritis (RA) (positive RF) profile: seropositive RA (positive RF), seronegative RA (negative RF).

Comorbidities were investigated and compared between the two patient groups.

Results: There were 206 seropositive RA and 49 seronegative RA. Gender distribution was similar in the two groups: 82% female and 18% male in seropositive RA; 85% female and 15% male in seronegative RA (p=0.5). Smoking was noted in 15% patients with seropositive RA and in 11% patients with seronegative RA without any difference (p=0.5).

Comorbidities were noted in 40% of seropositive RA and in 45% of seronegative RA without any significant difference (p=0.6). Obesity (BMI ≥ 30kg/m²) was noted in 31% of seropositive RA and in 36% of seronegative RA (p=0.7). Diabetes was noted in 18% seropositive RA and in 26% seronegative RA patients (p=0.1). Hypertension was noted in 31% seropositive RA patients and in 30% seronegative RA (p=0.8). Heart disease was present in 6% seropositive RA and in 7% seronegative RA (p=0.9). Dyslipidemia was noted in 40% seropositive RA and in 20% seronegative RA (p=0.1). Gastrointestinal comorbidities were observed in only seropositive RA patients (11%). Respiratory comorbidities were noted in 27% seropositive RA and in 28% seronegative RA without any significant difference (p=0.6). Regarding mental health problems, depression was noted in 7% seropositive RA and in 14% seronegative RA without any significant difference (p=0.4).

Conclusion: Our study showed that comorbidities were comparable in seropositive and seronegative RA. It seems that RF does not influence the prevalence of comorbidities in RA patients.

ASSOCIATION OF RHEUMATOID CACHEXIA WITH BONE, VERTEBRAL FRACTURES, AND STRUCTURAL JOINT DAMAGE IN MOROCCAN RHEUMATOID ARTHRITIS PATIENTS

M. Mahroug1, H. Azzouzi1, H. Boutaibi1, F. Chennouf1, I. Linda1, 1Mohamed I University, Rheumatology Department, Oujda, Morocco

Background: The concurrent decrease in the fat-free mass index (FFMI) and increase in the fat mass index (FM) in rheumatoid arthritis (RA) is called rheumatoid cachexia (RC). There is limited data on RC association with osteoporosis, vertebral fracture (VF), and structural joint damage in RA.

Objectives: To explore rheumatoid cachexia association with bone, vertebral fractures, and radiographic damage in RA patients.

Methods: This was a cross-sectional study on RA patients fulfilling the ACR/EULAR 2010 classification criteria. We collected data about characteristics of the disease, its activity assessed by the Disease Activity Score 28 using C-Reactive Protein and erythrocyte sedimentation rate (DAS28-CRP, DAS28-ESR), treatment of RA (conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), biologics (bDMARDs), and corticosteroids (CS)), indication of hand and wrist joint US and the implications of its findings.

Results: Fifty-eight patients were enrolled in the study with 83% females, with a mean age of 58.5±11.8 years and a mean age at diagnosis of 48.6±8.2 years. RA was seropositive in 89.7% of patients and erosive in 84.5%. Most patients underwent csDMARDs treatment (67.3%), 29.3% underwent bDMARDs treatment, and 67.3% used oral CS with a mean dose of 4.9±4.4 mg/day of prednisone equivalent. Mean DAS28-CRP was 4.1±1.4, and mean DAS28-ESR was 4.9±1.5. Hand and wrist joint US was performed for RA activity assessment in 93.1% of patients (n=54), for erosion assessment in recently diagnosed RA in 5.2% of patients (n=3), for erosion assessment in established RA in 1.7% of patients (n=1).

In patients who had US signs of active RA, treatment was modified in 73% of patients with initiation of a 3-day parental CS pulses (18.9%), initiation of oral CS (2.7%), escalation of oral CS dose (2.7%), escalation of csDMARDs treatment (24.3%), adjunction of another csDMARD (5.4%), reintroduction of a csDMARD (2.7%), initiation of bDMARDs (24.3%), and switch of bDMARDs (5.4%). US findings had no implication in 27% of these patients. When inactive RA was assessed (31.5%), there was no implication on treatment strategy in 82.4% of patients, a decrease of oral CS dose in 11.6% and a single intra-articular CS injection in 5.9%.

Detecting ultrasonographic activity signs of RA in hand and wrist joint was more likely to have implications on treatment strategy than finding no activity signs (75% vs 22%, χ²=14.25, p<0.001). The group of patients who had an implication of US findings on treatment strategy had significantly higher DAS28-ESR (5.53 vs 4.18, p=0.002).

Conclusion: Hand and wrist US had significant implications on treatment strategy of RA especially in patients with higher disease activity. However, it had no implications in some patients suggesting the complementary role of US compared to clinical determinants in RA treatment decision.

**VITAMIN D LEVEL AND LOCOMOTIVE FUNCTIONS IN WOMEN WITH RHEUMATOID ARTHRITIS**

N. Toroptsova1, O. Dobrovolskaya1, A. Sorokina1, O. Nikitinskaya1, E. Samarkina1, M. Cherkasova2. V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation; 1.V.A. Nasonova Research Institute of Rheumatology, Department of Immunology and Molecular Biology, Moscow, Russian Federation; 2.V.A. Nasonova Research Institute of Rheumatology, Department of Thrombosis and Inflammation, Moscow, Russian Federation

**Background:** Muscle health is an important aspect of rheumatoid arthritis (RA). A decrease in muscle mass and physical performance is a frequent complication of RA that contributes to inability to work and reduced quality of life. Vitamin D deficiency is also common in these patients.

**Objectives:** To assess the relationship between vitamin D level, muscle strength and physical performance in RA patients.

**Methods:** 135 women (mean age 58.5±8.9) with confirmed RA according to ACR/EULAR criteria (2010) were enrolled in the study. Muscle strength of upper extremities was measured using a mechanical dynamometer, of lower extremities – using “Chair stand test” (CST) – assessment of the ability to rise from a chair and sit back down 5 times. Handgrip strength (16kg) and less or CST for more than 15 seconds were the criteria for low muscle strength. All patients underwent “Gate speed test” (GST) and “Timed Up and Go test” (TUG) to assess the physical performance. Serum level 25(OH)D was performed using the Cobas E411 immunochemiluminescence analyzer and Elescsys Vitamin D total kit, Roche.

**Results:** Median 25(OH)D level was 23.7 [18.2; 30.7] ng/ml in RA women with minimum 7.9 ng/ml and maximum 70.0 ng/ml. Insufficiency and deficiency of vitamin D were detected in 56 (41.5%) and 42 (31.1%) women, respectively, with median level 24.1 [21.8; 26.6] ng/ml in the patients with insufficiency and 15.6 [13.6; 17.9] ng/ml in deficiency group. Vitamin D level was compared between patients with low muscle strength and/ or physical performance and women with normal locomotive functions (Table 1). 25(OH)D level was significantly higher in RA women with normal CST and GST >0.8 m/s than in patients with the worst results of these tests. At the same time, we didn’t find differences in handgrip strength and TUG depending on vitamin D level.

</tbody>
</table>

**Conclusion:** The frequency of low vitamin D level was 72.6% in women with RA including deficiency in 31.1% patients. Patients with reduced lower limb strength and low walking speed had significantly lower vitamin D levels, but there were no differences in 25(OH)D and other tests (handgrip strength and TUG).

A. N. Garza-Cisneros1, I. J. Colunga-Pedraza1, D. A. Galan-Dealgo1, J. R. Azpiri-Lopez1, A. B. Rodriguez-Romero1, M. A. Balderas-Palacios1, A. Garcia-Heredia2, N. Guajardo-Jauregui1, A. Cárdenas1, D. E. Flores Alvarado1,3, Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González"; Rheumatology, Monterrey, Mexico; 2 Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González"; Cardiology, Monterrey, Mexico.

Background: Obesity plays an important role in autoimmune and inflammatory diseases such as rheumatoid arthritis (RA). It has been demonstrated a paradoxical relationship between increased body mass index (BMI) and disease activity (1). Acute phase reactants (APR) play an essential role in determining the disease activity level (2).

Objectives: To compare APR levels in obese and non-obese patients with RA, and to establish their relationship with the disease activity level.

Methods: A total of 272 patients with a diagnosis of RA were included in a cross-sectional study. They were divided into two groups, 136 obese patients and 136 non-obese patients, matched by age, gender, and comorbidities. The C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were measured, and the activity level was determined with Disease Activity Score 28-joint erythrocyte sedimentation rate (DAS28-ESR) and Disease Activity Score 28-joint C-reactive protein (DAS28-CRP).

The distribution was evaluated with Kolmogorov-Smirnov. Comparisons with Chi-square test for qualitative variables, Student’s t-test, and Mann-Whitney U test for quantitative variables. Correlation between BMI and APR with Spearman-rho coefficient.

Results: The Spearman-rho coefficient showed a significant correlation between CRP level and BMI (rho=0.187, p=0.002) (Figure 1). No difference was found between activity level when comparing both groups (Table 1).

Conclusion: Obese RA patients presented higher CRP levels compared to non-obese patients, suggesting that a higher BMI level may be related to a higher degree of inflammation and consequently worse systemic manifestations in RA patients.

References not provided in the image.

Background: Sulphur drugs have been used such as sulfasalazine for the treatment of rheumatoid arthritis (RA), and trimethoprim-sulfamethoxazole (TMP-SMX) for the treatment or prevention of pneumocystosis pneumonia. However, some patients with RA delay treatment because of allergy to sulpha drugs.[1] We reported that 16.7% of RA patients presented drug allergies[2]. It was not clear what is a risk factor for drug allergies in patients with RA.

Objectives: The aim of this study was to evaluate the clinical features with sulpha allergy in patients with RA.

Methods: We prospectively examined consecutive patients diagnosed with RA in our hospital from March 2021 to January 2022. The patients with RA met the EULAR/ACR 2010 criteria. We included patients with RA with other rheumatic diseases. A careful allergic history was obtained from patients with RA and physical examination performed.

The first analysis was performed on patient baseline laboratory data at diagnosis of patients with RA with or without sulpha allergy. Sulpha allergy (rash, angioedema and anaphylaxis after drug exposure) was allergy to sulfasalazine or TMP-SMX. The second analysis was performed on seven types of allergic reactions: (1) drug allergies other than sulpha drugs (rash, angioedema and anaphylaxis after drug exposure), (2) food allergy (rash, angioedema and anaphylaxis after food exposure), (3) allergic contact dermatitis such as metals, and other cosmetics, (4) seasonal allergic rhinitis and/or conjunctivitis (AR and/or AC), and AR and/or AC associated with house dust, (5) asthma, and (6) atopic dermatitis.

Results: There were 513 patients with RA in our study. In the first analysis, 17 patients with sulpha allergy and 496 patients without sulpha drugs were enrolled (Table 1). The median ages (with sulpha allergy and without sulpha allergy) were 60.0 and 72.0 years old (p=0.40). Females were 82.3% and 77.0%(p=0.4). The median observation period was 970.0 and 69.0 months (p=0.20). Patients with other rheumatic diseases were 11.6 and 6.8%(p=0.34).

The RA patients with sulpha allergy had higher positivity rate of anti-nuclear antibody (ANA) (>1:80) (52.9%, 28.2%; p=0.052), higher positivity rate of anti-Sjögren’s-syndrome-related antigen A autoantibody (SSA antibody) than those without sulpha allergy (46.2%, 18.2%; p = 0.02) and lower positivity rate of rheumatoid factor (RF) than those without sulpha allergies (40.0%, 66.8%; p = 0.049).

In the second analysis drug allergies other than sulpha allergy were more frequent in patients with sulpha allergy. Drug allergies other than sulpha allergy were such as antibiotics and nonsteroidal anti-inflammatory drugs. There were no significant differences in other allergies.

Conclusion: Among patients with RA, patients with sulpha allergy had higher positivity rate of ANA and anti-SSA antibody, and lower positivity rate of RF than those without sulpha allergy. RA patients with sulpha allergy had a higher prevalence of the other drug allergies than those other than sulpha allergy.

Background: Autoimmune diseases (AD) are a group of heterogeneous disorders caused by both genetic and environmental factors. Rheumatoid arthritis (RA) and Sjögren syndrome (SS) are typical autoimmune diseases[1]. Pulmonary fibrosis (PF) is the most common complication of AD. Despite the extensive study of the human gut microbiome in AD complicated with PF (AD-PF), the question of whether there are common microbial features characterizing AD-PF still remains[2].

Objectives: This study focused on exploring differences between the microbiota diversity and peripheral lymphocyte subpopulations as well as cytokine in AD with PF different from that of AD without PF.

Methods: A total of 64 AD patients (44 AD without PF and 20 AD with PF) as well as 100 age- and sex- matched healthy controls (HCs) were enrolled in this study. The peripheral lymphocyte subsets were analyzed by flow cytometry and the gut microbiota were investigated via 16s rRNA sequencing. Spearman correlation analysis was used to determine the similarities among patients with RA-PF, the STAMP software was used to compare the fecal microbiota (bray curtis distance-based) analysis was used to define the difference of gut microbiota profiles between patients and HCs. To explore the specific bacterial taxa associated with AD-PF, the STAMP software was used to compare the fecal microbiota composition. Spearman correlation analysis was used to determine the similarities in the microbiota community with clinical features among fecal samples.

Results: There is a decrease that the richness and diversity index between HCs, AD and AD-PF patients. Principal co-ordinates analyses suggested that these three microbiota states explained a reasonable proportion of observed variance in the microbiota community with clinical measures among fecal samples.

Conclusion: Our results suggest that the decrease of Lachnospira may lead to the occurrence of AD with pulmonary intestinal fibrosis, which was closely correlated with lymphocyte subsets and cytokines, maintaining the flora balance might be a potential therapeutic target for AD-PF.

</table>
The variables independently associated with OP in RA were: age (OR [IC 95%],1,099 [1.012-1.193]; p=0.025), ACPA (OR [IC 95%], 1,005 [1.001-1.010]; p=0.036), RA length (OR [IC 95%], 1,359 [1.016-1.602]; p=0.001) and Actinobacteria (OR [IC 95%] 1,192 [1.095-1.297]; p=0.036).

Conclusion: Osteoporosis in Rheumatoid Arthritis is associated with severity factors as the age, the disease length or the presence of ACPA, as well as the Actinobacteria predominance in the intestinal microbiota.

AB0302 DIASTOLIC DYSFUNCTION IN RHEumatoid Arthritis Patients: a comparative cross-SECTIONAL STUDY

M. Brahem1, H. Ibn Hadj Amor2, R. Sarrai1, S. Kraisem2, R. Rouabha2, E. Hmaier3, A. Ben Salem1, R. Grassa1, G. Hachfi1, H. Hachfi1, Y. Mohamed1, S. Belkhodja1, Taher M.3, Hmaier4, Taher Star University Hospital, Rheumatology, Mahdia, Tunisia; Taher Star University Hospital, Cardiology, Mahdia, Tunisia

Background: Cardiac failure is an independent risk factor for mortality in Rheumatoid arthritis (RA) and diastolic dysfunction (DD) may act as a precursor for cardiac failure.

Objectives: The aim of our study is to determine the frequency of diastolic dysfunction in rheumatoid arthritis (RA) patients compared to a control group and to focus on associated factors.

Methods: This was a comparative cross-sectional study, including patients diagnosed with RA according to the ACR/EULAR 2010 criteria and control subjects. Each patient underwent transesophageal echocardiography and the DD was assessed by E/A and E/e ratio.

Results: Seventy-two patients with RA and 72 control subjects were included. In our study, there was a clear female predominance in both groups (93.1% vs 94.4%). The mean age of RA patients was 52.9±11.27 years (21-75 years) and in control group, DD was present in 26 patients (36.1% of cases). The mean value of the impaired E/A ratio was 0.7± 0.1 [0.4-0.9] and the mean value of the impaired E/e ratio was 9± 1.5 [8.1-14.4]. These patients (23 women and 3 men) had a mean age of 56±10.4 years [33-74 years]. Among them, 7 patients had hypertension, 9 patients had cardiac symptoms, 21 patients had a long-standing RA, 17 patients had positive ACPAs and 11 patients had positive RF. In control group, DD was present in 10 patients (13.9% of cases). The mean value of the impaired E/A ratio was 0.6± 0.1 [0.4-0.9] and the mean value of the impaired E/e ratio was 1.1± 0.9 [1-10.1]. Left ventricular diastolic dysfunction was more frequent in RA patients compared with the control group with a significant difference (p<0.01). No significant association was found between diastolic impairment and RA parameters.

Conclusion: Subjects with RA have a higher frequency of diastolic dysfunction than those without RA. Therefore, correct assessment of diastolic function should be considered of pivotal importance in the routine follow-up of RA patients. The identification of predictor factors requires further study.

AB0304 CHRONIC KIDNEY DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY

M. J. Mantilla Ribeiro1,2, J. C. Sarmiento Monroy3, C. Villota-Eraso3, D. C. Varello4, J. C. Hurtado1, M. Rodriguez-Jimenez2, R. D. Mantilla Hernández2, I. Universidade de la Sabana, Rheumatology Department, Chia, Colombia; 2Center of Dermatology and Rheumatology (FUNINDERMA), Rheumatology, Bogotá, Colombia; 3Hospital Clinic, Villarreal 170, 06036, Rheumatology Department, Barcelona, Spain; 4Servicio Integro de Enfermedades Inmunológicas, Rheumatology Department, Pasto, Colombia; 5Universidad Pontificia Bolivariana, Rheumatology Department, Medellin, Colombia; 6Center for Autoimmune Diseases Research (CREA), Universidad del Rosario, Rheumatology, Bogotá, Colombia

Background: Prevalence and incidence estimates for chronic kidney disease (CKD) in rheumatoid arthritis (RA) vary and it may result from comorbidities, chronic inflammation, aging, or effects of drugs used for the disease.

Objectives: To calculate the prevalence and incidence of CKD in a cohort of patients with RA.

Methods: This was a retrospective cohort study in which well-characterized patients with RA (fulfillment of 1987 ACR criteria) were included from 2014 to 2015. Patients were evaluated at a single rheumatology outpatient center in Bogotá, Colombia. Baseline and follow-up estimated glomerular filtration rate (eGFR) were calculated according to CKD-EPI equation. CKD was defined as an eGFR ≤60 ml/min/1.73 m2.

Results: A total of 878 patients were included. Baseline characteristics were as follows: female gender 81.6%, mean age 51.8±11 years, mean disease duration 8 (IQR 3.715) years, RF positive 80.1%, ACPA positive 58.2%, and erosions 24.9%. Most patients have received glucocorticoids (89.8%), and conventional synthetic DMARDs (97.8%), being methotrexate the most frequently prescribed. Hypertension was the most frequent cardiovascular complication (37.7%). CKD was found in 6 (5.5%) patients at the time of inclusion, being hypertension the most common cause (24, 55.8%). Only 12 (1.5%) patients had a documented history of CKD at the beginning of the

AB0303 RELATION BETWEEN CLINICAL ANTHROPOMETRIC MEASUREMENTS AND MALNUTRITION IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

M. Arthana1, J. Mahoubia1, F. Naftal2, M. Ghali1, F. Fhima1, S. Zrour1, I. Bejia1, M. Touzi1, N. Berouali1, Fattouma Bourguiba, Rheumatology, Monastir, Tunisia; 2Fattouma Bourguiba, Biochemistry, Monastir, Tunisia

Background: Rheumatoid arthritis (RA) is associated with an increased risk of malnutrition, especially among the elderly. However, nutritional assessments in this population are scarce in the clinical situation. Various anthropometric measurements can help to assess malnutrition.

Objectives: To evaluate the nutritional status using anthropometric measurements in elderly patients with RA.

Methods: A prospective study was conducted, including RA patients aged 65 years or older and followed in rheumatology department. Clinical findings, disease activity and nutritional profile were studied. The mini-nutritional assessment (MNA) was used to identify altered nutritional status. The anthropometric measurements studied were: Weight loss, Body mass index (BMI), Triceps skin fold thickness (TSF) which reflects fat mass, Mid-arm circumference (MAC), Arm muscle circumference (AMC) which indicates lean mass and the calf circumference (CC).

Results: Sixty-three patients were included, 82% were female. Their mean age was 68.17±4.35 years. The mean duration of RA was 11 years. The average DAS28 was 3.72±1.48. The mean MNA total score was 20.19 ± 4.71 with a range of 8 to 27.5. The prevalence of malnutrition in our population was 20.6%. 55.6% of the patients were at risk of malnutrition. Only 23.8% had a normal nutritional status. The average BMI was 27.97 ± 5.44 kg/m2 (14.85 – 43.2). The diagnosis of malnutrition according to the BMI (< 21 kg/m2) was made for 7.9% of patients, of which 4.8% were severely malnourished. The average weight loss was 2.26 ± 2.51 kg during the last month [0 – 10]. The average percentage of weight loss in the last month was 3.39 ± 4% [0-11%]. Among our patients, 26 patients (41.3%) did not report a weight loss, 19 patients (30.2%) had a weight loss of less than 5%, Eighteen patients (28.6%) had malnutrition defined as weight loss greater than or equal to 5% in one month, of whom 7 patients (11.1%) had severe malnutrition with a loss of at least 10% of their habitual weight. The mean TSF was 18.38 ±6.77 mm [5 - 30] (19.15±6.72 mm in women and 14.72±8 mm in men). 28.6% of patients had decreased values of TSF. The mean MAC was 24.8 ± 4.52 cm [18 - 40]. The mean AMC was 23.7 ± 9.64 cm [15.86-34.43] (24±5.7 cm in women and 22.19±3.75 cm in men). The AMC was decreased in 20.6% of cases. The mean CC was 33.25 ± 4.62 cm [20-43]. 31.7% of patients had a decreased CC. There were significant association between the nutritional status using the MNA and BMI, loss of weight and TSF (p<0.01, p<0.001 and p=0.05, respectively). MNA was not associated with MAC, ACM or CC (p=0.6, p=0.8 and p=0.4, respectively).

Conclusion: This study showed that the prevalence of malnutrition varies depending on the used anthropometric tool. BMI, weight loss and TSF are according to our study, reliable tools to detect the malnutrition in elderly patients with RA.

Disclosure of Interests: None declared

follow-up. The median of follow-up was 73 months. Fifteen incident cases of CKD were found (15/358, 4.1%) in patients with follow-up data of at least 1 year and without prior CKD. Main characteristics of the patients are shown in Table 1.

PNEUMOCOCCAL VACCINATION REDUCES THE RISK OF RESPIRATORY INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TARGETED THERAPY. DATA FROM MOSCOW UNIFIED ARTHRITIS REGISTRY (MUAR)

E. Zhilyayev1,2,3, G. Lukina4, E. Koltsova4, D. Murtazaliyeva4, E. Schmidt5, K. Lytkina6, A. Shmitko2, D. Biagovido7, M. Kostinov7,1, 1European Medical Center, Rheumatology, Moscow, Russian Federation; 2Piromov Russian National Research Medical University, Department of Faculty Therapy named after Academician A.I. Nesterov, Moscow, Russian Federation; 3Russian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation; 4A.S. Loginov Moscow Clinical Scientific Center, Rheumatology, Moscow, Russian Federation; 5City Clinical Hospital 1 named after N.I.Pirogov, Rheumatology, Moscow, Russian Federation; 6City Clinical Hospital 4, Rheumatology, Moscow, Russian Federation; 7Mechnikov Research Institute of Vaccines and Sera, Laboratories of Vaccination and Immunotherapy of Allergic Diseases, Moscow, Russian Federation.

Background: The incidence of infections, mainly pneumonias, is significantly increased in patients with rheumatoid arthritis (RA). The risk increases more in persons treated with targeted anti-inflammatory drugs (tDMARDs), biological or targeted synthetic.

Pneumococcal vaccination is recommended for most patients with rheumatic diseases. However, only the immunological effectiveness of such vaccination has been sufficiently confirmed. There is sparse evidence of its clinical efficacy in patients with rheumatic diseases.

Objectives: to evaluate the effect of 23-valent pneumococcal polysaccharide vaccine (PPV23) and 13-valent pneumococcal conjugate vaccine (PCV13) on the risk of infections in RA patients receiving tDMARDs.

Methods: The data from the Moscow Unified Arthritis Registry (MUAR) for the period 2018-2020 were analyzed. We included patients with RA, over 18 years old, received tDMARDs (all available biologics or tofacitinib).

The analysis included episodes of observation from the moment of vaccination until the end of follow up. For unvaccinated patients, episodes began since October 20, 2018 (the average date of vaccination of persons who received immunization).

The risks were compared using Cox regression. An adjustment was made for confounders identified in an earlier study: age and smoking.

Results: The analysis included 832 patients: 40 were vaccinated with PCV13, 35 – with PPV23. There were 144 men (17%). The mean age was 55.4 ± 12.1 years. The duration of observation was 319 ± 198 days.

A total of 237 infectious events were registered, of which 201 were respiratory and 21 serious (Table 1). There was a significantly lower risk of any infection (relative risk (RR) – 0.39 CI: 0.18 - 0.84, p = 0.015) and the risk of respiratory infection (RR - 0.32; CI: 0.13 -0.79; p = 0.014) in the group of patients vaccinated with PCV13 compared with unvaccinated. The differences remained statistically significant after adjusting for the age and smoking, Figure 1.

</table>

* - events are included in the group, regardless of localization, these events were not included in other sections.
The interaction of the effects of vaccination with the factor of the used tDMARD, as well as with the factor of the use of methotrexate in their effect on the risk of any and respiratory infections was evaluated. There was no significant interaction between these variables.

There were no significant differences in the risk of serious infections due to a small number of events of this kind. No serious infections were registered among patients vaccinated with PCV13.

**Conclusion:** Vaccination with 13-valent conjugated pneumococcal vaccine in patients with rheumatoid arthritis receiving tDMARDs can significantly reduce the risk of infectious complications, mainly due to acute respiratory infections. We found no significant effect of targeted drug and treatment with methotrexate on the effectiveness of vaccination.

**AB0307**

**MERKEL CELL CARCINOMA RECURRENCE RISK IS LOWER IN PATIENTS WITH AUTOIMMUNE DISEASE THAN IN THOSE WITH OTHER TYPES OF IMMUNE SUPPRESSION**

S. Park,1 D. Hippe,1 L. Zawacki1, M. Bierma1, S. Bhatia1, L. Zaba1, P. Nghiem1, N. Singh1, 1University of Washington, Dermatology, Seattle, United States of America; 2Stanford University, Dermatology, Stanford, United States of America; 3University of Washington, Medicine, Seattle, United States of America

**Background:** Merkel cell carcinoma (MCC) is twice as likely to recur in immunosuppressed (IS) patients as in immunocompetent (IC) patients. Iatrogenic IS due to autoimmune disease (AD) may influence prognosis differently than intrinsic IS such as due to hematologic malignancy. Moreover, modification of IS medication may improve prognosis.

**Objectives:** Our objective was to evaluate the risk of MCC recurrence among patients with AD diseases relative to other immunosuppressive conditions among 762 MCC patients from an Institutional review board-approved registry.

**Methods:** We categorized patients into 3 groups: IS due to AD (ISAD); IS from other causes (ISAD-AD) such as hematologic malignancy, solid organ transplant, human immunodeficiency virus; or immune competent (n=31, 70, and 661 respectively). ISAD patients were subcategorized into rheumatoid arthritis (RA) (ADRA, n=13) vs. AD except for RA (AD non-RA, n=18). Descriptive statistics were used to compare the features of different characteristics in each group. Kaplan-Meier survival curves were constructed to assess the cumulative incidence of recurrence in different patient groups. In order to estimate the associations between baseline patient characteristics and the risk of MCC recurrence, Fine and Gray regression models were used with death as a competing risk for recurrence. The multivariable models adjusted for age, sex, and extent of MCC at initial presentation.

**Results:** Patients with ISAD had lower stage disease (local disease: 58% vs. 36%; p = 0.003) and smaller primary tumors than ISAD non-RA (p < 2 cm: 83% vs. 57%, p = 0.023). After adjusting for age, sex, and stage, ISAD patients (ADRA and AD non-RA) overall had a 54% higher recurrence rate (hazard ratio (HR): 1.54, p = 0.21) than IC patients. In comparison, ISAD non-RA group had a 165% higher recurrence rate (HR: 2.65, p < 0.001) than IC patients (Figure 1). When considered separately, ADRA and AD non-RA pts appeared to have a similar recurrence rate as IC pts (HR: 1.19, p = 0.76) while AD non-RA pts had a higher recurrence rate (HR: 1.83, p = 0.16) relative to IC pts. At the time of MCC diagnosis, 80% (n=24) of AD pts were on IS medication including conventional disease modifying drugs, biologics, or oral steroids. After MCC diagnosis, 22% (5 patients) stopped all immunosuppressive medications. Among patients on biologics, 89% (8/9 pts) elected to stop the drug. Eleven pts with AD experienced recurrences. Our study was underpowered to demonstrate associations regarding use of a particular immunosuppressive medication and MCC recurrence.

**Conclusion:** In this cohort, pts with AD appeared to have a better prognosis than intrinsic IS, with RA conferring very little risk above that for immune competent pts.

**Acknowledgements:** I have no acknowledgements to declare.

**AB0308**

**FALL RISK EVALUATION WITH COMPUTERIZED DYNAMIC POSTUROGRAPHY IN RHEUMATOID ARTHRITIS PATIENTS**

E. Baran1, M. A. Dundar2, 1Hitt University, Physiotherapy and Rehabilitation, Corum, Turkey; 2Necmettin Erbakan University, Faculty of Medicine, Konya, Turkey

**Background:** Patients with rheumatoid arthritis (RA) have a higher risk of falling due to pain and physiological/biomechanical deformities (decreased muscle density, decreased functional stability, changes in gait, etc.) [1]. Although high incidences of falls have been reported in RA patients [1], there are not sufficient data regarding patient-specific fall risk.

**Objectives:** The aim of this study was to evaluate patient-specific fall risk, via computerized dynamic posturography, in RA patients, and to compare the results with those of age-matched healthy participants.

**Methods:** A total of 29 patients with RA (9 males, 20 females; mean age: 54.4±6.5 years) and 18 healthy participants (7 males, 11 females; mean age: 53.6±7.1) were included in the study. Detailed demographic, physical, and medical characteristics of the participants were recorded. Dynamic balance was tested with a computerized dynamic posturography, which assesses balance responses to induced postural disruption [2]. A translational ramp test (speed: 0.1 m/s), sinusoid tests (frequencies: 0.25 Hz - 0.50 Hz), and limits of stability evaluations were applied. Ramp and sinusoid tests were evaluated with the eyes open and closed, in the antero-posterior direction, and the participants were instructed to keep their balance during the tests. Limits of stability was evaluated on a static platform, with the eyes open. During the test, the participants were told to carry their pressure center as far as possible by performing the movement only from the ankle (in all directions), without lifting their feet, and trying not to fall.

**Results:** The groups were similar in terms of demographic and physical characteristics (p>0.05). Patients with RA showed statistically significant dynamic balance alterations compared to healthy participants (p<0.05) (Table 1). The fall test was positive in 31% of the RA patients and 5.6% of the control group (Figure 1).

ASSOCIATION BETWEEN RHEUMATOID DISEASE COMORBIDITY INDEX AND PULMONARY INVOLVEMENT IN RHEUMATOID ARTHRITIS

E. Hannech 1,2, A. Ben Tekaya 1,2, O. Saidane 1,2, R. Leila 1,2, S. Bouden 1,2, R. Tekaya 1,2, I. Mahmoud 1,2, L. Abdelmoula 1,2, Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; 2Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia

Background: Pulmonary involvement is one of the primary contributors of morbidity among patients followed for Rheumatoid Arthritis (RA) [1]. Comorbidities are also independent factors of poor outcomes on those debilitated population.

Objectives: We aimed to assess association between comorbidity and pulmonary involvement in rheumatoid arthritis.

Methods: We conducted a retrospective study in our rheumatology department including patients with established RA according to the ACR/EULAR 2010 criteria. Rheumatic Disease Comorbidity Index (RDCI) was calculated for each patient. Clinical characteristics, radiological findings, and respiratory function tests (PFTs) for pulmonary involvement were collected.

Results: There were 255 patients: 212 female (83.1%) and 43 male (16.9%). The mean age was 58.92 ± 10.72 years [25-85]. The mean RDCI was 1.14 ± 1.25 [0-6]. Pulmonary involvement was noted in 115 patients (45.3%). It was asymptomatic in 50.6% of cases. Reported clinical symptoms were dyspnea (36.1%), chronic cough (8.4%), and dyspnea with chronic cough (4.8%). PFT showed a restrictive syndrome in 34.9% of cases, an obstructive syndrome in 4.8%, a mixed syndrome 3.6% and was normal in 56.6% of patients. Non-specific interstitial pneumonia was noted in 26.6% of patients, followed by nodular lung disease in 11.4 %, usual interstitial pneumonia in 11.4%, BOOP in 6.3%, and then pleural nodules in 6.3%.

An association was noted between RDCI and pulmonary involvement (presence: 1.7 ± 1.3 vs absence: 0.6 ± 0.8, p<0.05).

Conclusion: In conclusion, there was an elevated comorbidity index in patients with pulmonary involvement. Comorbidities may be a predictive factor of extra-articular manifestations. The early management may improve outcomes in RA patients.

Garcia Guillein 7, S. Rodriguez-Muguruza 8, M. Martinez-Morillo 8, R. Sanmartin 9 on behalf of AR- CAT. 1Hospital de Mar, Rheumatology, Barcelona, Spain; 2Hospital de Mollet, Rheumatology, Mollet del Valles, Spain; 3Hospital Universitari Germans Trias i Pujol, Rheumatology, Badalona, Spain; 4Hospital Clínic, Rheumatology, Barcelona, Spain; 5Hospital Universitari Dr. Josep Trueta, Rheumatology, Girona, Spain; 6Hospital Universitari Mutua de Terrassa, Rheumatology, Terrassa, Spain; 7Unitat Territorial de Reumatologia Sant Pau- Dos de Maig, Rheumatology, Barcelona, Spain; 8Alcalia, Xarxa Asistencial Urgentaria de Manresa, Rheumatology, Manresa, Spain; 9Hospital de Terrassa, Rheumatology, Terrassa, Spain; 10Hospital Universitari Joan XXIII, Rheumatology, Tarragona, Spain; 11Hospital Arnau de Vilanova, Rheumatology, Lleida, Spain; 12Hospital Vall d' Hebron, Rheumatology, Barcelona, Spain; 13Hospital de Granollers, Rheumatology, Granollers, Spain

Background: Given the progressive change in the management of inflammatory diseases, an observational study was conducted on the management of Early Rheumatoid Arthritis (ERA) in Catalonia.

Objectives: To know the management of ERA in Catalonia, to assess whether the recommendations of the EULAR/ACR guidelines are followed and to study the causes of management variability, to set improvement objectives.

Methods: An observational, descriptive, and cross-sectional study was conducted, with data collection from June 15 to 30, 2021. The rheumatologists’ partners of the Catalan Society of Rheumatology were the object of study. An online survey was conducted with 304 members on the management of the ERA. Variables related to the characteristics of the respondents, the derivation and variables of the disease including clinical variables, type of treatment and outcomes used for follow-up including the impact of the SARS-CoV2 pandemic were included.

The univariate study was performed using a study of proportions with Pearson’s correlation.

Results: A total of 105 members (34.5%) responded to the survey, 11.6% <60 y, only 7.8% <30 y, 99% were in public assistance. The number of rheumatologists per service is 7.2[1-17], but 34.2% had < 5 rheumatologists, with a reference population of 200,000-300,000 in 42% of respondents. The number of weekly visits made is 67[50-130]. 42.2% do not have a monographic RA or ERA dispensary and 30.4% have specialized nursing. Characteristic of ERA-77.5% are derived from primary care (PC), 92% have been between 6 weeks, 42.1% <3 months. 54.9% make a first visit within 2-4 weeks of PC referral and 14.7% > 8 weeks. 100% provide previous analysis, only 47% had had RX performed. 98% were previously treated (50.4% NSAIDs + CG, 36.1% NSAIDs, 12.3% CG). 4.3% had GC doses >10 mg/day, 11.3% > 20 mg/day. The treatment: SARDs of choice in 100% is MTX, 44.1% start doses of 10 mg/week and 3.9% >5 mg/week. The route of choice is oral (55.9% vs 44.1%), 92.2% associate GC and 31.7% have not withdrawn them after 6 months. 92.2% associate GC and 31.7% have not withdrawn them after 6 months. 92.2% associate GC and 31.7% have not withdrawn them after 6 months.
start of DMARDs is performed 72.5% between 4-6 weeks and 12.7% is performed by nursing. 100% use DAS 28 and 53.5% also CDAI. 31.4% perform PROs (HAQ 83.3%, RAPID 3 14.3%). The use of systematic ultrasound is collected in 33%, being himself who performs it in 59.9% and an expert rheumatologist in 46.1%. Finally, when asked about incidence of infection in the follow-up, 53.3% consider that it is doing the same as before. 46.1% consider that telephone visits are not suitable for the follow-up of the ERAv14.7% who consider that Yes. When questioning the situations in which they consider them to be appropriate, 75.9% that it was adequate in the control after the beginning of the DMARDs. Regarding the treatment of ERA, 66% delayed the onset of biological DMARDs, 72.1% due to difficulty of follow-up and only 8.8% due to an increased risk of infection. When performing the univariate analysis, it is evident that having a monographic dispansary is associated with earlier onset of MTX (p=0.001) and at doses ≥15 mg/W (p=0.05), greater nursing intervention (p=0.001), greater use of PROs (p=0.008) and there is a tendency to a shorter waiting time for first visits (p=0.07). It is also associated with not considering telephone visits (p<0.001), making them in less than 25% (p<0.0001). Similarly, hospital level is directly proportional to initiation at higher doses of MTX (p<0.0001), lower use of GC<10mg.Among the rest of the variables, no association has been found.

Conclusion: The recommendations of EULAR/ACR in the treatment and follow-up of ERA are consistently followed, although the wide use of MTX orally is striking. It is evident that the variable that most influences the early onset of FAME and at higher doses, is a monographic dispensary, as well as greater presence of nursing and performance of PROs.

Acknowledgements: Thanks to all the members of the Catalan society of rheumatology who participated in the survey.

AB0311 RHEUMATOID ARTHRITIS AND OSTEOPOROSIS: FREQUENCY AND ASSOCIATED FACTORS

M. Brahim1, R. Sarrar2, A. Ben Salem3, R. Grassa2, S. Abdelatif4, H. Hachi4, Y. Mohamed4, 1Tasser Star University Hospital, Rheumatology, Mahdia, Tunisia

Background: In rheumatoid arthritis (RA), persistent systemic inflammation may cause bone and cartilage destruction and systemic osteoporosis (OP).

Objectives: We conducted this study to determine the frequency of OP in RA patients and to focus on associated factors.

Methods: This is a retrospective descriptive and analytic study including consecutive RA patients. The epidemiological, clinical, biological data and the measurement of bone mineral density were collected from patients’ records. A statistical analysis was performed to study the clinico-biological profile of osteoporotic patients and determine factors associated with the development of OP in RA patients.

Results: Seventy-one of RA patients were recruited: 67 females (94.4%) and 4 males (5.6%) with a mean age of 54.28 years ± 11.09 [30-75]; OP was noted in 45.1% of cases (32 patients). The mean T-scores at the lumbar and femoral sites were -2.7 ± 0.6 SD and -1.3 ± 1 SD, respectively. Patients with OP were older (58.8 ± 7.6 years vs 50.5 ± 12.1 years; p<0.01) and with a greater number of postmenopausal women than patients with normal bone density (68.7% vs 41%; p=0.02). Osteoporotic patients had RA duration longer than the other group (15.2 ± 12.5 years vs 11.9 ± 8.2 years; p=0.02) and more extra-articular manifestations associated with RA (100% vs 76.9%; p<0.01).

Both groups were treated with corticosteroid drugs with similar frequency, although patients with normal bone density received biottherapy more frequently than patients with OP (23% vs 18.7%; p=0.03). The two groups had almost similar disease activity DAS28 ESR (44.3 ± 34 vs 42.7 ± 30.7; p=0.2). The following parameters were not associated with the occurrence of OP in our series: gender, smoking, BMI, ESR, CRP, ACPA, RF, erosive and deforming character of RA.

Conclusion: OP is an extra-articular disease that must be systematically screened throughout the follow-up. In our study, there was no significant difference in disease activity at both groups of patients. However, patients with OP had longer duration of RA, more extra-articular manifestations and were less frequently treated with biottherapy.

AB0312 BODY COMPOSITION AND BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

O. Dobrovolskaya1, A. Fekistov2, N. Demin3, A. Sorokina3, O. Nikitinskaya1, N. Torontsov1, 1VA Nasonov Research Institute of Rheumatology, Osteoporosis, Moscow, Russian Federation

Objectives: To assess body composition and bone mineral density (BMD) in rheumatoid arthritis (RA) women compared to patients with osteoarthritis (OA).

Methods: 133 women with RA and 45 women with OA aged 50 and over were enrolled in the study. Body composition (fat mass (FM), lean mass and bone mineral component (BMC)) and BMD of the lumbar spine, femoral neck and total hip were measured using dual-energy X-ray absorbometry (DXA). Appendicular muscle mass (AMM) and appendicular mass index (AMI) were calculated. Muscle strength was assessed in all patients. The criteria of the European Working group on Sarcopenia in Older people 2 (EWGSOP2) were used for low muscle mass and sarcopenia. Osteoporosis was determined in accordance with WHO criteria.

Results: Mean age of RA patients and women with OA was 61.3±6.2 years, respectively (p<0.05). BMC and AMM were lower in RA patients than in women with OA: BMC - 1948.6±425.7g and 2167.1±398.1g, respectively (p=0.004); AMM - 17.5±2.9kg and 20.1±2.7kg, respectively (p<0.001), 27 (20.3%) RA women and only 1 (2.2%) person with OA had low AMM (p=0.004). The mean value of AMI was 6.8±1.0kg/m² and 7.5±0.9kg/m² in RA and OA patients, respectively (p<0.001). Total FM was 28.3±8.5kg and 33.2±9.8kg in RA and OA women, respectively (p<0.003). At the same time, we found no differences in the percentage of fat mass: 39.2±5.7% in RA patients and 39.8±5.8% in persons with OA (p>0.05). Overfat was discovered in 99 (77.4%) and 38 (84.4%) in women with RA and OA, respectively (p>0.05). All women with low AMM/AMI had low muscle strength and were diagnosed with confirmed sarcopenia.

In RA patients BMD at any region was less than in women with OA: in the lumbar spine – 1.026±0.174 g/cm² and 1.114±0.177 g/cm², respectively (p=0.009); in the femoral neck – 0.844±0.151 g/cm² and 0.914±0.137 g/cm², respectively (p=0.005) and in the total hip 0.875±0.148 g/cm² and 0.986±0.177 g/cm², respectively (p<0.001). Normal BMD was found in 33 (24.8%) and 24 (53.3%) women with RA and OA, respectively (p=0.0004). 42 (31.6%) patients with RA and 6 (15.4%) women with OA had osteoporosis (p=0.017).

Conclusion: RA patients had lower BMC, AMM/AMI, total FM and BMD compared to women with OA, and they were significantly more likely to have sarcopenia and osteoporosis.

AB0313 CLINICAL FEATURE OF 100 CASES OF METHOTREXATE ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS WITH RA PATIENT

T. Kameda1, Y. Usui1, S. Nakashima2, H. Shimada3, R. Wakaji4, M. Kato5, T. Miyagi1, K. Sugihara1, R. Mino3, M. Mizusaki1, H. Dobashi1, Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Kita-gun, Japan

Background: Lymphoproliferative disorders (LPDs), including malignant lymphoma, are known to occur in RA patients treated with disease modified antirheumatic drugs (DMARDs). In particular, LPD associated with methotrexate (MTX)-treated RA is often referred to as MTX-associated LPD (MTX-LPD). MTX-LPD have various clinical feature and histological findings. We have accumulated MTX-LPD cases in patients with rheumatoid arthritis (MTX-RA-LPD).

Objectives: We clarified the clinical characteristics of MTX-RA-LPD. In addition, we examine the prognosis of MTX-LPD in RA patients.

Methods: We enrolled 100 RA patients who diagnosed MTX-LPD from 2005 to 2021. We collected as follow data based on clinical reports retrospectively: 1) age, gender, 2) duration from RA onset to LPD onset, 3) total dose of MTX, 4) duration of MTX administration, 5) presence of extranodal lesion 7) histological findings, 8) treatment for LPD, 9) 5-year survival rate.

Results: The mean age of 100 MTX-RA-LPD patients (M:F=30:70) were 66.7 ± 10.7 years old, and the duration from RA onset to LPD onset were 25.2 ± 11.0 years. The total dose of MTX and duration of MTX administration were over 2,600mg and over 5 years, respectively. The extranodal lesions were found in 51%, and diffuse large B cell lymphoma was the most common histological findings. Spontaneous regression was observed in 68%. The 5-year survival rate of MTX-RA-LPD was as high as over 85%.
Discipline: The clinical features of MTX-RA-LPD were similar to those previous reports. Furthermore, we suggested a good prognosis for MTX-RA-LPD.

**AB0314** MULTIMORBIDITY BURDEN IN RHEUMATOID ARTHRITIS

D. C. Varela1, J. C. Sarmiento Monroy2, M. M. Mantilla Rivero3, C. Villota4, M. Rodriguez-Jimenez2, R. D. Mantilla Hernández5, 1Universidad Pontificia Bolivariana, Rheumatology Department, Medellín, Colombia; 2Hospital Clinic, Rheumatology, Barcelona, Spain; 3Universidad de la Sabana, Rheumatology, Bogotá, Colombia; 4IPS Servicio Integral de Reumatología e Inmunología Dr Orlando Villota, Rheumatology, Pasto, Colombia; 5Universidad del Rosario, Rheumatology, Bogotá, Colombia; 6Center of Dermatology and Rheumatology (FUNINDERMA), Rheumatology, Bogotá, Colombia

Background: Multimorbidity in patients with rheumatoid arthritis (RA) has been described as the coexistence of two or more chronic diseases and is the most common cause of death in this population.

Objectives: To describe the prevalence of multimorbidity and mortality trends in a well-characterized cohort of patients with RA.

Methods: A retrospective cohort study of patients with RA (1987 ACR criteria) was conducted. Each patient was evaluated and followed by a rheumatologist in a single outpatient private center in Bogotá, Colombia, from 2014 to 2021. Categorical variables were expressed in frequency and percentage and quantitative variables in mean and standard deviation or median with interquartile range, depending on the distribution of the data. Statistical package: SPSS 25.

Results: A total of 783 patients were included. 11% of patients with RA present multimorbidity. Baseline characteristics were as follows: female gender 81.6%, mean age 51±11 years, mean disease duration 8 (IQR 3-15) years, RF positive 80.1%, ACPA positive 58.2%, and erosions 24.9%. Most patients have received glucocorticoids (89.8%), and conventional synthetic DMARDs (97.8%), being prednisone and methotrexate the most frequently prescribed. Highest mortality was present in 5.5% and principal infection was urinary infection 14.3%. Polyautoimmunity was present in 5.7% most frequently Autoimmune thyroid diseases 10.6% and Sjögren syndrome 9.4%. After a median of 73 months of follow-up, the mortality rate was 1% of the entire cohort, being cardiovascular disease and COVID-19 infection the main causes.

Conclusion: Patients with RA have an important multimorbidity burden and this increased risk of adverse outcomes and mortality.

ESR – Erythrocyte Sedimentation Rate; ULT – urate-lowering treatment; DAS28 – Disease activity score; NA – not applicable; intergroup difference with p<0.001.

Presence of the HU in RA pts was associated with increased comorbidity as compared with age, sex and activity matched RA pts without HU, and with GA, Figure 1.

Figure 1. Comorbidity in pts with RA without and with HU, and in GA pts.
ULT was administered to pts with RA and HU 4 times less frequently than to pts with GA. The effectiveness of ULT in RA and HU is two times lower than in GA.

Conclusion: 1) HU negatively affects the decrease of RA activity. 2) HU in RA is associated with increased comorbidity and 3) ULT is assigned to pts with RA and HU 4 times less frequently than to pts with GA and is ineffective in 76.71% of cases. Additional research is needed to evaluate the influence of UAs' serum levels' normalization as a factor that could improve results of RA treatment and control.

AB0316 SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS: PREVALENCE AND ASSOCIATED FACTORS
N. Torgonstova1, O. Dobrovolskaya1, A. Sorokina1, A. Feklistov1, N. Demin1, O. Nikitinskaya1, I.V. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation

Objectives: To evaluate the prevalence of sarcopenia (SP) and associated factors in patients with rheumatoid arthritis (RA).

Methods: 159 women (mean age 58.7±8.8) with confirmed RA according to ACR/EULAR criteria (2010) were enrolled. Hand grip strength was measured using mechanical dynamometry. Dual-energy X-ray absorptiometry (DXA) was performed to assess the body composition and bone mineral density (BMD) of the lumbar spine, femoral neck and total hip. SP was defined as muscle strength < 18 kg and appendicular lean mass index (ALMI) <5.5 kg/m² or appendicular lean mass (ALM) <15 kg. RA activity was assessed by C-reactive protein (CRP) and disease activity score using 28 joint counts and erythrocyte sedimentation rate (DAS28-ESR). The relation between low ALM with disease parameters was analyzed using Spearman's r. Factors associated with SP were evaluated using regression analysis.

Results: SP was diagnosed in 33 (20.6%) women with RA. Patients with SP did not differ in age from those without it (59.0±8.9 and 58.7±8.8 years, respectively, p>0.05). 75.8% patients with SP and only 27.8% women without SP had normal BMI (p<0.001). Osteoporosis was diagnosed significantly more often in patients with SP than in women without SP (54.5% and 23.0%, respectively, p<0.001). In women with RA, ALM and ALMI correlated with body mass index (BMI), bone mineral component, BMD and total fat mass. ALM and ALMI did not correlate with age, disease duration, the use of glucocorticoids, DAS28, CRP, total protein, and creatinine levels. In univariate regression analysis, SP was associated with BMI, bone mineral component, BMD of lumbar spine and proximal femur, total fat mass. In multivariate regression analysis, SP was positively associated with the presence of osteoporosis [OR 2.98, 95%CI (1.22-7.30), p = 0.017] and BMI < 25 kg/m² [OR 6.75, 95%CI (2.45-18.56), p<0.001]. No other significant associations were found.

Conclusion: Among patients with RA, 1/5 of them had SP, which was positively associated with BMI and the presence of osteoporosis, but not with the age, activity and duration of the disease.

Disclosure of Interests: None declared

AB0318 PREVALENCE OF SECONDARY SJOGREN'S SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE CENTER STUDY FROM NORTHERN INDIA
S. Mehra1, N. Hariharan2, S. Deka2, Jaypee Hospital, Rheumatology, Noida, India;1Technology | Healthcare | Big Data Analytics, Real World Evidence, Haryana, India

Background: Sjogren's syndrome (SS) is a systemic autoimmune disease characterized by lymphocytic infiltration of salivary and lacrimal glands leading to dry eyes and dry mouth. Sjogren's syndrome either present alone (primary Sjogren's syndrome) or sometimes can occur with other autoimmune diseases like rheumatoid arthritis, systemic lupus erythematosus, and scleroderma. In such instances, the condition is termed secondary Sjogren's syndrome. SS may be a marker of more aggressive joint disease in patients with RA, and hence it is essential to characterize the symptoms in the RA cohort, which may help in the management and treatment of the disease.

Objectives: Primary Objective
The primary objective of the current study is to estimate the prevalence of secondary Sjogren's syndrome in a cohort of patients with rheumatoid arthritis.

Secondary Objective
To compare the clinical characteristics in rheumatoid arthritis patients with Sjogren's syndrome and in rheumatoid arthritis patients without Sjogren's syndrome.

Methods: The study was conducted from 2016-2018 in a tertiary care hospital in the Department of Rheumatology, New Delhi, India. Patients with a rheumatologist-diagnosed RA were enrolled. There were 726 patients with rheumatoid arthritis. Patients were enquired about their symptoms. Out of 726, 193 had secondary Sjogren's syndrome (26.58%). In patients without Sjogren's syndrome, complete clinical data were available only for 377 patients hence the analysis on the comparison of clinical characteristics was limited to 377 patients. The other patients were excluded due to lack of the data required for the study.

Results: It was identified that out of 726 patients, 193 had symptoms of secondary Sjogren's like dry eyes dry mouth, or both. It was found that in patients with secondary Sjogren's syndrome (n=193), the mean age was significantly higher than those patients without secondary Sjogren's syndrome (n=537) [52.58 ± 12.36 Vs. 48.42 ± 13.98, p=0.0005]. Similarly, the mean disease duration was significantly higher among RA patients with secondary SS than those without SS [10.76 ± 8.34 Vs. 6.81 ± 7.29, p<0.0001]. Similarly, comorbidities like hypertension, diabetes mellitus, and hypothyroidism were more seen in patients with rheumatoid arthritis with Sjogren's syndrome.

In a meta-analysis involving 18 studies, it was identified that the prevalence of SS in RA was 19.5%. The differences in the prevalence of secondary SS in RA patients could be attributable to inter-ethnic variation, disease duration, and clinical scores employed in the studies. Further to our study, Santhosh et al reported that patients with secondary SS had a longer disease duration than those without secondary SS.

Conclusion: The prevalence of Sjogren's syndrome among patients with rheumatoid arthritis in the North Indian cohort of patients with RA was 26.58%.

PREALBUMIN SERUM LEVEL AS A USEFUL TOOL IN THE ASSESSMENT OF MALNUTRITION IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

M. Arthangu1, J. Mahboub1, F. Nañada, F. Fhima1, M. Ghali1, S. Zouari2, I. Bejji1, M. Touzi1, N. Bergaoù1, Fattouma Bourguiba Hospital, Monastir, Tunisia; 
Fattouma Bourguiba Hospital, Biochemistry, Monastir, Tunisia; 
Background: Protein-energy malnutrition is a common condition among elderly patients with RA associated with a poor prognosis. Although many screening tools are developed, there's no consensus on which test is more reliable in clinical practice. Serum prealbumin (PAB) may be a useful malnutrition biomarker.

Objectives: Our objective is to evaluate the usefulness of serum PAB in the assessment of malnutrition in elderly patients with RA.

Methods: We conducted a prospective study including RA patients who were followed in rheumatology department and aged 65 years or older. We studied malnutrition prevalence, risk of complications related to malnutrition and PAB serum concentrations. The mini-nutritional assessment (MNA) score was used as the reference method to determine malnutrition. We also assessed inflammatory proteins: Orosomucoid (Oroso), C-reactive protein (CRP) and Haptoglobin (Hapto). For the prognosis assessment, we calculated the Geriatric nutritional risk index (GNRI) and the Prognostic Inflammatory and Nutritional Index (PINI).

Results: Sixty-three patients (52 female and 11 male) were included. Their mean age was 68.17±4.35 years. The average DAS28 was 3.27±1.48. The mean MNA total score was 20.19 ± 4.71. According to MNA, the prevalence of malnutrition was 20.6%. 55.6% of the patients were at risk of malnutrition and only 23.8% of patients had a normal nutritional status. The median PAB was 0.16 g/L with an IQR of [0.04-0.24] and extremes ranging from 0.01 to 0.37 g/L. According to PAB, 35.8% of patients had a normal level above 0.20 g/L, 17% had PAB levels between 0.15 and 0.19 g/L, indicating moderate malnutrition and 47.2% of patients had PAB levels below 0.15 g/L, indicating severe malnutrition. Concerning inflammation proteins: the mean CRP was 18.96 ± 27.8 mg/L. 28.6% of patients had a CRP > 15 mg/L, of which 9.5% had a CRP > 50 mg/L. The mean Oroso was 1.29 ± 0.46 g/L [0.6-2.2]. 52.5% of our patients had an elevated oroos value. The mean Hapto was 2.07 ± 0.97 g/L [0.31-5.29]. 42.5% of patients had an increased value above 2.5 g/L. Concerning prognosis indexes, the median GNRI was 116.47 ± 36.6 with a range of 82.08-155.5. 27.8 mg/L. 28.6% of patients had a CRP > 15 mg/L, of which 9.5% had a CRP > 50 mg/L.

Conclusion: Between groups.

LV sizes, LV myocardial mass index, NT-proBNP, pentraxin, galectin-3 levels between groups (2 Table 1). There were no differences in left ventricular ejection fraction, LV sizes, LV myocardial mass index, NT-proBNP, pentraxin, galectin-3 levels between groups (2 Table 1).

Disclosure of Interests: None declared

ADHERENCE TO MEDITERRANEAN DIET AND PREVALENCE OF CARDIOVASCULAR RISK FACTORS IN RHEUMATOID DISEASES

S. Reiki1, S. Nouel1, S. Boussaid1, S. Jemmati1, S. Rahmouni1, K. Zouaoui1, H. Sahli1, M. Elleuch1, R. Rabta, Rheumatology, Tunis, Tunisia

Background: Rheumatic diseases (RD) are autoimmune inflammatory arthritis. However involvement to other organs can occur and leads to atherosclerosis and cardiovascular (CV) risk factors. Mediterranean diet (MD) has attracted considerable interest because it seems to offer significant benefits to that end.

Objectives: To evaluate the role of MD in the development of the cardiovascular risk factors in RD.

Methods: We conducted a cross-sectional study including patients with RA (ACR-EULAR 2010 criteria) or with SA (ASAS 2009 criteria), in remission or in low activity disease and with no history of cardiovascular risk factors before the diagnosis of their RD. Sociodemographic and disease related data were collected: Disease Activity Score (DAS28-CRP), Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) and medication. We asked the patients to complete the 14-items MD adherence questionnaire: We evaluated the adherence to MD with cardiovascular risk factors: obesity, type-2 diabetes, hyperlipidaemia and hypertension. We estimated odds ratios for each cardiovascular risk factors and their 95% confidence intervals. In all analyses, the

high adherence category of MD adherence score (10–14) was considered the reference category.

Results: We included 61 patients (40 women and 21 men) with a mean age of 42.2 ± 11.1 years old [20-66]. Among them, 32.7% belong to urban environment and 26.2% were professionally active. The mean disease duration was 83.2 months [9-180]. The mean DAS28-CRP was 1.2 [0.8-1.9] and the mean ASDAS-CRP was 1.8 [1-2.0]. Methotrexate was used by 52.4%, either as monotherapy or combination and biological in 47.6 %. Thirty patients had high adherence to MD (H-MD) and thirty-one had medium or low adherence to MD (LMD). We found that higher adherence to the MD is inversely associated with the prevalence of each of the four cardiovascular risk factors, results are shown in Table 1.

Conclusion: Our results suggest that the healthy effects of the MD observed in epidemiologic studies are exerted partly through plausible mechanisms: low prevalence of obesity, of type2 diabetes, of hyperlipidemia and of hypertension. Intentional adherence may eventually provide stronger evidence. In the meantime, an increasing of knowledge supports the Mediterranean diet as a useful tool in managing individuals with RD, who are at high risk cardiovascular diseases.

AB0322

INTESTINAL DYSBIOSIS IS ASSOCIATED WITH INADEQUATE RESPONSE TO MULTIPLE ANTIRHEUMATIC DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS.

Regional Universitario de Málaga (HRUM). Institute for Biomedical Research in Málaga (IBIMA), UCG of Rheumatology, Málaga, Spain; 1Hospital Clínico Virgen de la Victoria. Institute for Biomedical Research in Málaga (IBIMA), UCG of Endocrinology and Nutrition, Málaga, Spain

Objectives: To evaluate the relationship between inadequate response to multiple antirheumatic biologic or targeted synthetic drugs (IRMD-b/tsDMARDs) and intestinal microbiota and other inflammatory and severity factors in patients with rheumatoid arthritis (RA).

Methods: Design: A case-control study nested in a prospective cohort of RA patients. Patients: Patients with RA (ACR/EULAR 2010) from a prospective baseline cohort (incident cases between 2007-2011), >16 years. Controls: subjects without inflammatory disease matched by sex and age. Protocol: All subjects were evaluated in a specialized outpatient unit. Clinical, analytical and therapeutic variables were registered using a data collection protocol. Blood, urine and faeces samples were obtained from all subjects. Variables: Dependent variable: “RA patients with IRMD,” defined as failure >2 different bDMARDs (biological disease-modifying antirheumatic drug) or tsDMARDs (targeted synthetic disease-modifying antirheumatic drug). Faecal microbiota (continuous var., 0-100%) was measured using the Ion Torrent SS next-generation sequencing platform, and the sequences obtained were processed using the QIIME2 (Quantitative Insights Into Microbial Ecology 2) software. Inflammatory activity was measured by mean DAS-28 (disease activity score-28) throughout the disease and RA severity variables included erosions, anticitrullinated peptide antibody (ACPA) titres and HAQ (health assessment questionnaire). Other variables included socio-demographic, clinical-analytical characteristics, type of treatment with bDMARDs and reason for suspension. Statistical Analysis: Descriptive, bivariate using χ2 and T-Student followed by two logistic regression model in order to identify the factors associated with both bDMARDs and IRM-b/tsDMARDs in patients with RA.

Results: 220 subjects, 110 RA patients and 110 controls, were included. A total of 90/110 RA patients were seropositive (81.8%) and 68/110 were erosive (61.8%). A total of 61/110 (55.5%) were treated with any bDMARD, being more frequent the anti TNF (35.5%). Ninety-three (84.5%) of RA patients took associated sDMARD. Thirteen patients (21.3%) presented IRMD. The variables independently associated with biological therapy in RA were: physical activity (OR [95% CI], 0.990 [0.989-0.999]; p=0.043), erosions (OR [95% CI], 2.450 [1.056 -4.683]; p=0.037) and Actinobacteria family (OR [95% CI], 1.182 [1.016-1.375]; p=0.030), R2= 0.283. The variables that were independently associated with IRMD in patients with RA were: ACPA (OR [95% CI], 1.005 [1.001-1.010]; p=0.039), diagnostic delay (OR [95% CI] 1.025 [1.001-1.050]; p=0.044), age (OR [95% CI], 0.933 [0.900-0.969]; p=0.032), Bacteroidetes (OR [95% CI], 1.080 [1.014-1.150]; p=0.016), Synergistetes (OR [95% CI], 2.277 [1.094-4.741]; p=0.028), R2=0.329.

Conclusion: Biological treatment in RA was associated with less physical activity, erosions and a greater presence of Actinobacteria. Bad prognosis factors such as delayed diagnosis and elevated ACPA titres were associated with multiresistance in RA patients, in addition to higher levels of Bacteroidetes and Synergistetes.

FACTORS ASSOCIATED TO CLINICAL INERTIA IN RHEUMATOID ARTHRITIS

S. Miladi, O. Boudirguia, A. Fazaia, H. Boussaa, L. Souabni, K. Ouenniche, S. Kassa2, S. Chekili, K. Ben Abdelghani, A. Laatar. 1Mongi Slim Hospital, Rheumatology Department, La Marsa, Tunisia

Background: Clinical inertia in rheumatic diseases is defined as inability or undue delay to initiate or intensify therapy when the disease is active or de-escalate therapy when the disease is in remission. Understanding the various contributory factors to clinical inertia is helpful in ensuring appropriate planning to tackle the issue and achieving Treat-To-Target (T2T) goals.

Objectives: We aimed to identify medical therapeutic inertia in Rheumatoid Arthritis (RA) patients and to assess its contributing elements.

Methods: We conducted a monocentric study including 42 patients, fulfilling the 2010 ACR/EULAR classification criteria for RA, who consulted our outpatient department from November 2021 to January 2022. Study data collection included demographics, clinical and disease characteristics, and treatment history. The survey also contained the Satisfaction Questionnaire for Medication (TSQM) which provides validated score for four sub-scales: effectiveness, side effects, convenience, and global satisfaction. Treatment satisfaction was measured using a cutpoint global satisfaction score ≥ 80.

Results: Most patients were female (86%) with a mean age of 57±13 years and a mean disease duration of 10.8±4.7 years. The education level for most patients (62%) was secondary school education or less. Fifteen percent of patients were in full-time work, 27% were unemployed, and 54% were retired. RA impact on patients’ work-life was considerable, as 14.3% had retired early due to RA. Patients had moderate-to-high disease activity, with a mean DAS28 with C-reactive protein (CRP) of 4.2±1.4. Radiographic structural damage was apparent in 79% of patients. RA was immunopositive in 92% of patients. Most
common comorbidities were cardiac disorders (32%), pulmonary disorders (13%), and metabolic/nutrition disorders (11%). Psychiatric disorders was present in 9.5% of patients. CsDMARDs were the most frequently prescribed medications, used in 69% cases, followed by bDMARDs used in 34% cases. A total of 54% received the anchor drug methotrexate as part of their treatment regime. Only 12% of patients used systemic glucocorticoids for RA. Only half (52%) of all patients had a planned switch of medication, despite long-standing disease and suboptimal symptom control with current DMARD therapy. Statistical analysis revealed that factors for switch decision to a different DMARD by the treating physician was: younger patient age (p<0.002), having a high disease activity by DAS28-ESR (p<0.001), worse HAQ score (p<0.001), lower global satisfaction score (p<0.001), and patient preference for oral administration (p=0.006). Predictors for not switching to a different DMARD included a higher number of comorbidities (p=0.001) and a lower number of concomitant medications (p=0.002). Mean TSQM scores were 62 for effectiveness, 45 for side effects, 65 for convenience, and 60 for global satisfaction. Only 16 % of patients were satisfied with their RA treatment.

Conclusion: Our study showed that patients with active RA may not be managed in consistency with recommendations. This phenomenon defined as clinical inertia, is multi-factorial including healthcare set-ups and providers, patients and their caregivers. That’s why before labelling management of rheumatic disease in an individual as a ‘failure’ careful consideration of relevant factors linked to clinical inertia may be helpful.

Conclusion: In this updated analysis of 194 patients treated with JAKI, the three approved JAKI showed a safety profile consistent with data from RCT. The patients under JAKY therapy should be carefully evaluated on their follow-up.

Disclosure of Interests: None declared

RA patients with AI and with normal Hb levels (n=29) were comparable (p<0.05) in age (44.4±14.8 and 49.8±9.3 years), disease duration (73.5±65.4 and 59.8±48.3 months) and DAS28 (3.6±1.6 and 5.9±1.9). In RA patients with AI we found a strong positive correlation between serum hepcidin and ferritin levels (r=0.623, p<0.009). There was a positive correlation between serum ferritin and IL-6 levels (r=0.546, p=0.023). We found a strong negative correlation between serum hepcidin concentrations and Hb levels (r=0.528, p=0.029), but reliable correlation between DAS28, CRP and ESR was not revealed.

RA patients without anemia, the level of hepcidin positively correlated with the inflammatory activity parameters including CRP, ESR and DAS28, no correlation between the Hb and ferritin levels was revealed.

**Conclusion:** Our data support the hypothesis that IL-6-driven hepcidin production mediates AI in RA patients and might play a role in the pathogenesis of anemia associated with RA. In RA patients with chronic hypoxia, serum hepcidin level was significantly higher and perform better than traditional yardsticks in identifying anemia inflammation.

**AB0326 EVALUATION OF BONE DENSITY PARAMETERS IN A CONSORT OF PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS: HOW THERAPY WITH GLUCOCORTICOIDS, METHOTREXATE AND BDMARDS CHANGES BONE MINERAL DENSITY, T-SCORE AND TRABECULAR BONE SCORE**

A. Altimare1, C. Rotondo1, D. Cio1, A. Trotta1, A. Corrado1, F. P. Cantatore1.  
1Azienda Ospedaliero-Universitaria Policlinico Riuniti; Rheumatology Clinic, Foggia, Italy

**Background:** Osteoporosis (OP) can affect patients with Rheumatoid Arthritis (RA). This can be due to long-time use of glucocorticoids (GCS) or to the activation of proinflammatory pattern, via TNFα, that leads to osteoclast (OC) activation with bone resorption.

**Aim of this study:** is to assess how therapy with GCS, methotrexate (MTX) and bDMARDs may change bone density parameters.

**Methods:** 66 RA patients were enrolled in this study. Bone Mineral Density (BMD), T-score of spine and femur, Trabecular Bone Score (TBS) and TBS T-score were evaluated at baseline and after 18 months of treatment with GCS, MTX, bDMARDs. Comparison among different patient groups were evaluated by ANOVA. P-value <0.05 was considered significant.

**Results:** At baseline, 66% of patients were female and 44% male, mean age was 62.2±8.4 years, mean disease duration was 17.8±11.2 years, 76% of patients were Rheumatoid Factor (RF) positive and 24% were RF negative, mean TBS T-score was -2.36±1.42. Among the entire population in study, 24.4% were affected by OP; 78.0% were in therapy with GCS, MTX and 16.6% were under OP treatment with bisphosphonate or teriparatide or denosumab. At baseline, 51.6% of patients started an MTX treatment, 9.3% started an anti-IL6 treatment and 23.4% started a JAKI treatment. By ANOVA analysis, patients at baseline in therapy with MTX had mean L1-L4 BMD and L1-L4 T-score higher than those not in therapy with MTX, respectively 0.985±0.184 g/cm² vs 0.866±0.144 g/cm² (p<0.05) and -0.73±1.70 vs -1.82±1.13 (p<0.05). At 18 months patients treated with MTX had higher L1-L4 T-score than those not in therapy with MTX, respectively -0.48±1.68 vs -1.68±1.18 (p<0.05). Percentage variations in BMD, T-score, TBS and BMD variations between baseline and 18-month endpoint were not significant; nevertheless, we observed a positive trend in lumbar and femur BMD percentage variations in patients treated with JAKI (2.89%), and in TBS percentage variations in patients in TNFi treatment (2.98%).

**Conclusion:** In this study we confirmed the high prevalence of OP in RA-patients. Therapy with MTX seems to prevent bone resorption, but it does not improve bone density parameters. Moreover, we observed a positive trend in JAKI-patients BMD and TNFi-patients TBS percentage variations, even though these data are not statistically significant due to the small sample.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.5120
patients than in controls (CI 95% [1.542; 3.436], p<0.001). Plaques were found in both carotid arteries in the 32% of cases and 9.91% of controls. The longer duration of RA was related to a higher presence of carotid plaques (95% [1.015; 1.056], p<0.001). US and blood test results are shown in Table 3. SCORE and Framingham correlated with the CV estimation with US (p<0.001), however, seemed to underestimate the global findings in cases (p<0.001).

Conclusion: Cardiovascular risk calculators such as Framingham and SCORE are useful in RA risk estimation. However, those tools may underestimate the real risk, so carotid US might be valuable.

AB0328 ASSESSING THE MULTIMORBID PROFILE (CIRS) IN REFRACTORY RHEUMATOID ARTHRITIS

A. Gordiev1, E. Galushko2, V.A. Nasonova Research Institute of Rheumatology, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: The World Health Organization assigns cardiovascular diseases, cancers, chronic respiratory diseases, as well as diabetes mellitus and some other nosological entities, including mental and musculoskeletal disorders, to main non-communicable diseases. These are considered to be a major public health challenge of the 21st century. In this case, one patient frequently has a set of several age-related chronic diseases that develop simultaneously or sequentially. The management of these patients requires an integrated approach based on the multimorbidity nature of pathology. Unlike the definition of comorbidities, which assumes to identify the underlying and related diseases, the concept of multimorbidity allows to fail to identify a patient's chronic diseases as equivalent.

Objectives: To assess the presence and nature of multimorbidity in patients with refractory rheumatoid arthritis (RA) and the impact of multimorbidity on disease activity

Methods: The investigation enrolled 153 patients (mean age, 54.8±14.8 years) with RA according to the 2010 ACR/EULAR criteria, who had been examined and treated at the V.A. Nasonova Institute of Rheumatology from 2010-2020. The median disease duration was 5.7 [1.5; 10.5] years; the mean DAS28 score was 5.0±1.3. Documentation and anamnesis data were analyzed with emphasis on associated diseases. The Cumulative Illness Rating Scale (CIRS) was used to assess the profile of multimorbidity.

Results: The patients with RA had a high index of the spectrum of multimorbidity; concomitant diseases were detected in 125 (82%) patients with RA. Their number ranged from 0 to 8 and increased in direct proportion to the age of the patients. The average total score of CIRS was 6.7 ± 3.3 points, the maximum score was 18, the minimum score was 2; The multimorbidity index is 2.5 [1; 6]; the maximum number of categories with a score of ≥2 points is 6, the minimum is 1. The number of concomitant diseases diagnosed in patients with RA before using CIRS was significantly lower (by 52%; p <0.01) than the results of our study showed. Most often, the following disorders were observed in patients at the time of inclusion in the study: comorbid cardiovascular diseases in 44%, anemia in 14.5%, hypercholesterolemia in 18%, obesity in 9.5%, thyroid disease in 11.5% (hypothyroidism criterion – in 3.5%) and diabetes – in 4%. CIRS allowed the first identification of chronic pathology. The results reflect the cautiousness of doctors regarding comorbid cardiovascular diseases in RA: only 4% of patients were diagnosed with hypertension for the first time. At the same time, before inclusion in the study, no patient with RA revealed chronic kidney disease (CKD), which occurred in almost half of the cases (44.5%). On average, every third person had no previous signs of metabolic syndrome (hypercytremia in 29%, obesity in 15.6%) and chronic hypoxia (anemia first diagnosed was verified in 24% of concomitant diseases)

There was a correlation of the quantitative equivalent of multimorbidity with the clinical and laboratory measures of RA activity, including the number of painful joints (r = 0.39; p<0.001), overall patient assessment (r=0.37; p=0.03), physician’s global assessment of disease activity (r = 0.37; p < 0.01), DAS28 (r = 0.42; p<0.001), CDAI (r=0.37; p<0.001), SDAI (r=0.34; p< 0.001), HAQ (r=0.34; p<0.001).

Conclusion: Systematic screening for multimorbidity should be performed in each patient with RA. It is advisable to use CIRS in subsequent studies to assess the prevalence of multimorbidity and its consequences. CIRS allows you to more accurately determine the contribution of each chronic disease or syndrome to the development of multimorbidity disease

AB0329 IS THERE A LINK BETWEEN INFLAMMATION AND AN ABNORMAL LIPOPROTEIN PROFILE IN RHEUMATOID ARTHRITIS?

B. Touli1, N. Akasbi2, I. El Harch3, I. El Mezouar4, T. Harzy5,6, HASSAN II UNIVERSITY HOSPITAL, SIDI MOHAMMED BEN ADELLAH UNIVERSITY, FACULTY OF MEDECINE, RHEUMATOLOGY, FEZ, Morocco; HASSAN II University Hospital, SIDI MOHAMMED BEN ADELLAH UNIVERSITY, Faculty of Medicine, RHEUMATOLOGY FES, Morocco; EPIDEMIOLOGY LABORATORY OF SIDI MOHAMMED BEN ADELLAH UNIVERSITY, FACULTY OF MEDECINE, EPIDEMIOLOGY, FES, Morocco

Background: The management of cardiovascular risk in rheumatoid arthritis (RA) is essential and involves the assessment of the blood lipid profile. Studies have shown that patients with active untreated RA, by the presence of a pro-inflammatory state, have a decrease of total cholesterol (TC), HDL cholesterol (HDLc) and LDL cholesterol (LDLc) [1]. The relationship between blood lipids and inflammation is the so-called ‘lipid paradox’ in RA [2].

Objectives: To study the lipoprotein profile of patients with RA and its association with markers of inflammation and disease activity.

Methods: We conducted a cross sectional study among patients with established RA. We analyzed their lipoprotein profile. We further evaluated possible associations between dyslipidemia, disease activity score using the DAS28 and markers of inflammation C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR).

Results: A disturbed lipid profile was defined by a Total Cholesterol level (TC) > 5.17 mmol/L or High density lipoproteins (HDLc) < 1.03 mmol/L or Low Density Lipoproteins (LDLc) > 4.13 mmol/L or Triglycerides (TG) ≥ 1.69 mmol/L.

Results: The mean age of the 136 patients included was 55.19±11.84 years, with a female predominance (n=120). Disease duration was 16.27±11.48 years. Mean LDL concentrations were 4.73±0.95 mmol/L for TC, 1.29±0.36 mmol/L for HDLc, 2.87±0.72 mmol/L for LDLc and 1.19±0.54 mmol/L for TG. The inflammatory syndrome was present in 70% of patients. Mean ESR and CRP values were 32.81±22.19 mm at H1 and 26.17±6.17 mg/L.

A significant association was well-defined between the inflammatory syndrome and low concentrations of TC (r = 0.90 vs 0.09; p=0.010) and LDLc (2.74 ± 0.69 vs 3.15 ± 0.85; p=0.007). However, no relationship was found between lipid profile and disease activity.

Conclusion: Although there was no relation between lipid levels and disease activity in our population, inflammation was linked to a decrease in CT and LDLc. Contrary to the general population, this decrease is at high cardiovascular risk joining the lipid paradox theory in RA.

**EXPERIENCE IN THE CURRENT PRACTICE WITH BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND INTERSTITIAL LUNG DISEASE OF THE DONOSTIA UNIVERSITY HOSPITAL**

J. A. Valero Jaime1, A. De Diego Sola1, N. Alcorta Lorenzo2, C. A. Egües Dubuc2, J. M. Belzunegui Otoño2, E. Uriarte Isacelaya2, J. J. Carcilo Fanto2, L. M. Lopez Dominguez2, O. Maiz-Alonso2.1Hospital Bidasoa, Rheumatology, Irún, Spain; 2Donostia University Hospital, Rheumatology, San Sebastian, Spain

**Background:** Baricitinib (BARI) is a selective and reversible oral Janus kinase (JAK) inhibitor for the treatment of moderate to severe active rheumatoid arthritis (RA) in adult patients with inadequate response or intolerance to one or more antirheumatic drugs disease modifiers (DMARDs). Interstitial lung disease (ILD) is a common extra-joint manifestation of RA. Symptomatic ILD occurs in 5-17% of patients with RA and ILD who are undergoing treatment with BARI, in the Rheumatology Service of the Donostia University Hospital.

**Methods:** A retrospective search was carried out of all patients undergoing BARI treatment until June 2020. The electronic medical records were reviewed. The variables collected were: sex, age, date of diagnosis of RA, history of smoking, presence of erosions, positivity for rheumatoid factor (RF), citrullinated cyclic anti-CCP and previous treatments. Regarding BARI, the dose, the time since the start of treatment, related adverse effects, reason for suspension and other relevant data were collected. Quantitative variables are shown with the median and interquartile range, the qualitative variables are shown with the absolute value and its percentage.

**Results:** 17 patients with RA and ILD treated with BARI were found. Table 1 shows the clinical characteristics, Table 2 shows the treatments and Table 3 shows the respiratory function tests. All patients were positive for RF and anti-CCP, the presence of erosions was observed in 10 (59%), a history of smoking in 8 (47%), the most frequent type of ILD was Usual Interstitial Pneumopathy (UIP) in 7 (41%), at the diagnosis of ILD Abatacept was the most used drug 14 (82%), before the start of BARI, the median FVC 90% (80.5-111), DLCO 63% (51-87), the median time of exposure to BARI was 34 months. To date, 10 (59%) patients continue with BARI and the most frequent cause of suspension was failure.

**Conclusion:** A good persistence of BARI was observed (59%), it also proved to be a safe drug and kept lung function stable in these patients, so BARI can be a therapeutic option in these cases, although more studies are needed to better elucidate these findings.

**REDUCED C-REACTIVE PROTEIN LEVEL AT HOSPITAL ADMISSION IN PATIENTS TREATED WITH TOCILIZUMAB IN COMPARISON WITH OTHER ADVANCED ANTIINFAMMATORY TREATMENTS- AN ATTENTION MAY BE REQUIRED**

M. Berman1, S. Berlinger2, N. Bashouti3, O. Elkayam2, T. Ziv-Baran2,1 Tel Aviv Sourasky Medical Center, Department of Rheumatology, Tel Aviv, Israel; 2Tel Aviv Sourasky Medical Center, Internal Medicine E, Tel Aviv, Israel; 3Tel Aviv Sourasky Medical Center, Clinical Pharmacology Unit, Tel Aviv, Israel; 4Sackler Faculty of Medicine, Tel Aviv University, Department of Epidemiology and Preventive Medicine, School of Public Health, Tel Aviv, Israel

**Background:** C-reactive protein (CRP) is a marker of inflammation and infection. The main proinflammatory cytokine that leads to CRP gene expression is IL-6[1]. Different DMARDS may influence CRP levels due to their specific mechanisms of action and alter its usage as an important indicator of acute infection/ inflammation.

**Objectives:** The study aimed to compare CRP level between patients who were treated with Tocilizumab (TCZ), an IL-6 receptor blocker, and other advanced anti-inflammatory treatments (AAT), as well as with other admitted and non-admitted populations.

**Methods:** A cross-sectional study of all patients (≥18 years) hospitalized at tertiary medical center between 12/2009 and 02/2020 and treated before hospitalization with (AAT). Data on background DMARDS treatment was collected and then categorized to one of the two following groups: tocilizumab treatment and other treatments. In further investigation, the other treatments groups were divided into 3 subgroups: anti-TNF subgroup which included Infliximab (IFX), Adalimumab (ADA), etanercept (ETN), Golimumab, and Certolizumab, JAK-inhibitor subgroup which included Tofacitinib and Baricitinib, and another subgroup which included Rituximab, Abatacept and Anakinra. Only the first hospitalization of each patient was included. Women admitted to obstetrics department were excluded. Demographic data, first blood tests results, and comorbidities were collected.

**Results:** The study included 563 patients treated with AAT (2.5% received TCZ). Patients treated with TCZ were older (median 75 vs. 50 years, p<0.001), had higher Charlson score (median 5 vs. 1, p<0.001) and more infectious diseases at admission (50% vs. 23.4%, p=0.05). Patients treated with TCZ had lower CRP levels (median 0.5 mg/l, p<0.001) and more normal common values (64.3% vs. 20.8%, p<0.001) compared to patients treated with other AAT. CRP level in patients treated TCZ (median 0.5mg/l) was lower than that of 58,548 patients admitted to the hospital between 2010-2020 (median 12.55mg/l, p=0.001) and not statistically different from 140 non-admitted randomly selected individuals without acute disease (1.33mg/l, p=0.294).

**Conclusion:** When compared to other anti-inflammatory drugs, tocilizumab is associated with lower CRP levels in individuals admitted to an acute care hospital. This finding must be considered by treating physician to avoid misinterpretation of CRP results.

**EVALUATION OF THE RABBIT RISK SCORE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS NEWLY TREATED WITH BIOLOGIC DMARDS: DATA FROM THE IORRA COHORT**

T. Hiuchi1,2, E. Tanaka1, E. Inoue1, M. Abe1, K. Saka1, E. Sugano1, N. Sugitani1, Y. Shimizu1, M. Ochiai1, R. Yamaguchi1, K. Ikari2,3, Y. Hisashi1,4, M. Harigai1.1Tokyo Women’s Medical University Hospital, Department of Rheumatology, Institute of Rheumatology, Tokyo, Japan; 2Tokyo Women’s Medical University School of Medicine, Division of Multidisciplinary Management of Rheumatic Diseases, Department of Internal Medicine, Tokyo, Japan; 3Tokyo Women’s Medical University Hospital, Department of Orthopedic Surgery, Tokyo, Japan; 4Sanno Medical Center, Rheumatology, Tokyo, Japan

**Background:** Serious infection is one of the most critical adverse events in patients with rheumatoid arthritis (RA) using biologic disease-modifying anti-rheumatic drugs (bDMARDs). During the first year, infections occur more frequently. Therefore, estimating the risk of developing a serious infection is important for the safe use of bDMARDs. The Rheumatoid Arthritis Observation of Biologic Therapy (RABBIT) risk score predicted the incidence rate of serious infection during 1 year in patients with RA taking DMARDs. Moreover, it has been validated using data from various observational cohort studies and nationwide registries with favorable results, with a reported area under the receiver operating characteristic curve (AUROC) of 0.68–0.87. However, the RABBIT risk score has not been validated in RA patients starting a first bDMARD.

SUSTAINABILITY OF RESPONSE TO UPADACITINIB AMONG PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS REFRACTORY TO BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

P. van Vollenhoven1, S. Hall2, A. F. Wells3, S. Meerwein4, V. Song5, J. Suboticki6, R. M. Fleischmann7, Amsterdam Rheumatology and Immunology Center, Rheumatology and Immunology, Amsterdam, Netherlands

Disclosures of Interests: P. van Vollenhoven: None declared, S. Hall: None declared, A. F. Wells: None declared, S. Meerwein: None declared, V. Song: None declared, J. Suboticki: None declared, R. M. Fleischmann: None declared, Amsterdam Rheumatology and Immunology Center, Rheumatology and Immunology, Amsterdam, Netherlands

Background: Sustained clinical remission (REM) is the primary treatment goal for patients with rheumatoid arthritis (RA), with low disease activity (LDA) being a more appropriate target for treatment-refractory patients.1,2

Objectives: To evaluate the sustainability of response to the JAK inhibitor, upadacitinib (UPA) 15 mg once daily (QD), among patients with prior inadequate response or intolerance to biologic DMARDs.

Methods: Data come from the 12-week, phase 3 randomized, placebo (PBO)-controlled SELECT-BEYOND trial of UPA 15 mg or 30 mg QD in patients with moderate to severe RA on stable background conventional synthetic (cs) DMARDs. Initiation, change, or discontinuation of background RA medications, including ≤2 csDMARDs, was allowed starting at Week 24. Patients completing the 12-week trial were able to enter a long-term extension of up to 5 yrs with all PBO patients switching to UPA.3 This post hoc analysis evaluated REM (CDAI ≤2.8; SDAI ≤3), LDA (CDAI≤10; SDAI≤11), and DAS28(CRP) <2.6(≤3.2) at first occurrence of response before Week 60, as well as at 3, 6, and 12 months following initial response in patients randomly assigned to UPA 15 mg. For those patients who achieved REM/LDA, Kaplan-Meier was used to define the time from when the response was first achieved to the earliest date at which the response was lost at two consecutive visits or discontinuation of study drug. The predictive ability of time to REM/LDA was evaluated using Harrell’s concordance (c)-index (range: 0 to 1, where 0.5 indicates a model that is no better at predicting an outcome than random chance). The date of the last follow up was 16 April 2018, when all patients had reached the Week 60 visit. Non-responder imputation was used for missing data. Only data from the approved 15 mg dosage are reported here.

Results: In patients with active RA despite prior treatment with at least one biDMARD, 34% and 79% of those receiving UPA 15 mg + background csDMARDs achieved CDAI REM or LDA through Week 60, respectively. Sustained CDAI REM was attained by 30%, 26%, and 16% of patients randomized to UPA at 3, 6, and 12 months post initial response, while CDAI LDA was achieved by 68%, 61%, and 50% of patients during the same time points (Figure 1). Time to initial clinical response weakly predicted sustained REM but did not predict sustained LDA, with a c-index (95% CI) of 0.62 (0.49, 0.74) and 0.52 (0.44, 0.61), respectively. Through the last follow-up visit at Week 60, 39/61% of patients on UPA remained in CDAI REM/LDA (Figure 2). Of those who lost CDAI REM, 58% remained in CDAI LDA, and 22% recaptured REM by the cut-off date; 18% of patients who lost CDAI LDA recaptured response. Similar results were observed for REM and LDA based on SDAI and for DAS28(CRP) (<2.6≤3.2).

Conclusion: Among patients with inadequate response or intolerance to biDMARDs, over three-quarters on UPA 15 mg achieved CDAI REM, a relevant therapeutic target for these treatment-refractory patients, and nearly two-thirds of those maintained this response through 60 weeks. Additionally, about one-third of UPA-treated patients attained CDAI REM and maintained that response over 60 weeks.

Background: Abatacept (ABA) has demonstrated efficacy and safety in active rheumatoid arthritis (RA) patients in Europe and the United States as one of bDMARDs [1]. However, the clinical activity of Abatacept (ABA) has not been sufficiently investigated in patients with RA from a real-world clinical setting in China. Objectives: This study was designed to investigate the efficacy and safety of Abatacept in the RA patients in Chinese population who were refractory to csDMARDs, aiming to provide further reference for clinical rational drug use. Methods: Clinical data of 55 patients with active RA who were admitted in the Affiliated Hospital of North Sichuan Medical College from June 2020 to June 2021 and did not respond to csDMARDs was retrospectively analyzed. Patients in this study were treated with Abatacept (125mg by subcutaneous injection once weekly combined with csDMARDs). Changes in clinical manifestations, including DAS28-ESR, CDAI, ACR 20/50/70 at week 12 and 24 from baseline and AEs during 24 weeks were observed and recorded. Results: 55 patients (46 women and 9 men) were included in this study with a mean age 50.80 ± 12.46 and a mean disease duration of 6.29 ± 6.22 years. The ACR 20 response at week 12 and 24 was 50.91% (28/55) and 57.27% (48/85), respectively. Besides, DAS 28-ESR score were significantly lower at week 12 and 24 compared to baseline (P = 0.05) with 19 patients (34.55%) achieving clinical remission or low disease activity. Changes in CDAI scores revealed that 80% patients achieved clinical remission or low disease activity at week 24. DAS28-ESR score was significantly lower in previously untreated patients (Biologic-naive) (n=36) (3.40 ± 0.81) than in the previously treated patients (Biologic non-naive) (n=19) (3.83 ± 0.68) (P = 0.02) (Figure 1). RF, CCP antibody and GLOB levels were significantly reduced in RA patients after 24-week ABA treatment compared to baseline (P <0.05) (Table 1). Two hepatitis B virus (HBV) carriers, two patients with active tuberculosis and one patient with latent tuberculosis status showed no reactivation of HBV and no new active tuberculosis lesions 24 weeks after treatment with ABA. AEs were reported in 9.1% (5/55), but no serious infections occurred.

Results: 55 patients (46 women and 9 men) were included in this study with a mean age 50.80 ± 12.46 and a mean disease duration of 6.29 ± 6.22 years. The ACR 20 response at week 12 and 24 was 50.91% (28/55) and 57.27% (48/85), respectively. Besides, DAS 28-ESR score were significantly lower at week 12 and 24 compared to baseline (P = 0.05) with 19 patients (34.55%) achieving clinical remission or low disease activity. Changes in CDAI scores revealed that 80% patients achieved clinical remission or low disease activity at week 24. DAS28-ESR score was significantly lower in previously untreated patients (Biologic-naive) (n=36) (3.40 ± 0.81) than in the previously treated patients (Biologic non-naive) (n=19) (3.83 ± 0.68) (P = 0.02) (Figure 1). RF, CCP antibody and GLOB levels were significantly reduced in RA patients after 24-week ABA treatment compared to baseline (P <0.05) (Table 1). Two hepatitis B virus (HBV) carriers, two patients with active tuberculosis and one patient with latent tuberculosis status showed no reactivation of HBV and no new active tuberculosis lesions 24 weeks after treatment with ABA. AEs were reported in 9.1% (5/55), but no serious infections occurred.

Figure 1. Efficacy of Abatacept at week 12 and week 24. (A) ACR20/50/70 response rate of all patients at week 12 and week 24. (B) DAS28 (ESR) disease activity of patients at baseline, week 12, and week 24; (C) CDAX remission rate of patients at baseline, week 12, week 26. (D) Efficacy of abatacept with biologic-naive and biologic-annex. *P <0.05 compared with week 24.
Background: Biologics, such as tumor necrosis factor inhibitors (TNFi), are highly effective in the treatment of inflammatory arthritis, i.e., rheumatoid arthritis (RA), psoriatic arthritis (PsA), and axial spondyloarthritis (axSpA). The importance of collecting real-world evidence data on switching patients from an originator to a corresponding biosimilar is well recognized in the field (1).

Objectives: The aim of the study was to evaluate the frequency and clinical outcomes of the switch in patients with RA, PsA and axSpA to determine whether a switch could cause a reactivation of the disease.

Methods: We searched electronic patient’s records in four Italian centers for consecutive adult patients treated with TNFi for RA, PsA and axSpA. For these patients, we extracted data on age, gender, age and diagnosis and disease duration, the history of a switch from a TNFi originator to a biosimilar, and swollen joints, tender joints, global health, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP). We calculated composite indices of disease activity, DAS28-ESR, DAS28-CRP, CDAI and SDAI, at baseline, and at 3 and 6 months of follow-up. Response was calculated as the difference between DAS28 at baseline and at 3 or 6 months and stratified into good, moderate, no response according to EURAL response criteria. Chi-square test was used to assess if lower response rates were encountered in the switch versus no-switch groups. The Generalized Linear Regression Model was used to study the outcomes of the switch in patients with RA, PsA and axSpA.

Results: A total of 140 (74%) patients were switched from adalimumab to a biosimilar (TNFi). Among patients who underwent a switch, 25 (19%) and 17 (13%) of patients were defined as good responders, 48 (36%) and 41 (31%) as moderate responders and 61 (46%) and 76 (57%) patients as non-responders, on DAS28-ESR and DAS28-CRP, respectively. At 3 months after the switch, 25 (19%) and 17 (13%) of patients were defined as good responders, 48 (36%) and 41 (31%) as moderate responders and 61 (46%) and 76 (57%) patients as non-responders, on DAS28-ESR and DAS28-CRP, respectively. At 3 months, 28 (24%) and 22 (18%) of patients had a good response, 29 (25%) and 32 (28%) – a moderate response and 59 (51%) and 62 (53%) patients did not respond, on DAS28-ESR and DAS28-CRP (Figure 1), respectively. The results of the Chi-squared test indicated no difference in the frequency of good/ moderate/no response at 3 and 6 months on DAS28-ESR and DAS28-CRP between patients switched and not. There was a significant association between age and DAS28-ESR/CRP response at 6 months (p<0.001 and p=0.025) respectively.

BASELINE C-REACTIVE PROTEIN PREDICTS ADHERENCE TO ADALIMUMAB THERAPY AT 3 MONTHS IN AN OBSERVATIONAL COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS

A. W. Ramli1,2, N. Nair1, K. Hyrich1, J. Isaacs1, A. Morgan1,2, D. Plant1,4, A. G. Wilson4, A. Barton1,10, T. The University of Manchester, Centre for Musculoskeletal Research, School of Biological Sciences, Manchester, United Kingdom; 2Wrightington Hospital, Wrightington, Wigan and Leigh Teaching Hospitals NHS Foundation Trust, Department of Rheumatology, Wigan, United Kingdom; 3The University of Manchester, Versus Arthritis Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester, United Kingdom; 4Manchester University NHS Foundation Trust, NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester, United Kingdom; 5The University of Manchester, Versus Arthritis Centre for Epidemiology, Manchester Academic Health Sciences Centre, Manchester, United Kingdom; 6Newcastle upon Tyne Hospitals NHS Foundation Trust, Translational and Clinical Research Institute, Newcastle University and Musculoskeletal Datorerate, Newcastle upon Tyne, United Kingdom; 7University of Leeds, Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom; 8Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 9University College Dublin, UCD School of Medicine and Medical Science, Conway Institute, Dublin, Ireland; 10Manchester Royal Infirmary, Manchester University NHS Foundation Trust, The Kellgren Centre for Rheumatology, Manchester, United Kingdom

Background: Adherence to biologic treatment in rheumatoid arthritis (RA) is often self-reported and little is known about the predictors of adherence to biologic medications. Many studies have reported the predictors of adherence to be linked to psychological factors including beliefs in medication necessity and absence of low mood. Disease activity was also found to be a significant predictor of adherence from this study. It is unknown whether similar factors will predict adherence in an established cohort of patients with RA starting biologic therapy.

Objectives: To investigate levels of self-reported adherence to adalimumab treatment and identify the contribution of demographic, physical and psychological factors to medication adherence in an RA cohort.

Methods: Patients with RA, who were commencing on adalimumab were recruited through the Biologics in Rheumatoid Arthritis Genomics and Genetics Study Syndicate (BRAGGSS), a large UK multicentre prospective observational cohort study. Demographics, baseline clinical and psychological measures including illness and medication beliefs were collected. Self-reported adherence, defined as the patient has never stopped, altered, missed, forgot to take, or took a lower dose than prescribed of adalimumab, were recorded at 3 months. Potentially baseline predictors of adherence to adalimumab therapy were determined using logistic regression analyses.

Results: 202 patients were included; 76% female, median (IQR): age 59 (52-67) years, pre-treatment DAS28-CRP score 5.6 (5.1-6.1) and disease duration 5 (2-15) years. During the first 3 months following commencement of adalimumab, 17% (17/101) patients were non-adherent. Univariable analyses found that high baseline C-reactive protein (CRP) [odds ratio (OR) 1.04 per mg/L, 95% CI 1.01, 1.09] was associated with adherence to adalimumab at 3 months. However, there were no associations identified from the psychological variables and this includes perceived necessity towards medication [OR 0.92, 95% CI 0.79, 1.05], hospital depression score [OR 0.94, 95% CI 0.84, 1.06] and hospital anxiety score [OR 0.97, 95% CI 0.88, 1.08].

Conclusion: These findings suggest that the psychological measures were less able to predict adherence to adalimumab therapy. The high percentage of adherence during the first three months of therapy may limit power to detect small effects in this cohort. Further research to investigate whether psychological variables correlate with drug levels as an alternative surrogate for adherence and to consider including other biological agents with a longer follow-up timeline are needed.

High baseline CRP levels were associated with adherence. This finding suggests active disease with higher levels of inflammation in RA may be a factor for adherence in patients who are commencing biologic therapy.

BELIEFS ABOUT BIOLOGIC DRUGS AMONG RHEUMATOID ARTHRITIS PATIENTS

E. Hannech1,2, S. Boussaid3, S. Rekik1,2, S. Rahmouni1,2, S. Jemmali1,2, H. Ajami1, H. Sahli1,2, M. Elleuch2, R. Dharrar2, I. Gharsallah3,4, 1Rheumatology Department, La Rabta Hospital, Tunis, Tunisia; 2Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia; 3Rheumatology Department, Military Hospital of Tunis, Tunis, Tunisia

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease requiring a long-term follow-up and the use of chronic therapies. The management of this disease is based on a multidisciplinary care, requiring total patient involvement. Previous personal experiences, the experiences of others and the daily impact of the disease on patients fuel their perceptions of the treatment especially biologic one. There are few studies evaluating patient’s beliefs about these drugs [1,2].

Objectives: The aim of our study was to investigate beliefs about biologic Disease-Modifying Anti-Rheumatic Drugs (bDMARDs) among patients with RA and to identify factors related to specific beliefs.

Methods: We conducted a bi-centric cross-sectional study, including patients with RA fulfilling the ACR/EULAR 2010 criteria. All patients were on bDMARDs associated or no to conventional synthetic (sc) DMARDs. Sociodemographic, clinical, biologic, and therapeutic data were collected. Patients were interviewed about their medication beliefs using the Beliefs about Medicines Questionnaire (BMQ).

Results: There were 75 RA patients: 60 female (80%) and 15 males (20%). The sex ratio was about 2.5. The mean age was 56.92 ± 9.06 years [34-80]. Thirty-three percent of patients were illiterate. Twenty patients were employed. Sixty-four patients (85.3%) were married. The mean disease duration was 14.85 ± 8.5 years [2-39]. Thirty-three patients had joint deformities. Twenty-seven patients had extra-articular manifestations and thirty-six patients had comorbidities. The mean disease activity scale (DAS28 CRP) was 3.94 ± 1.32 [1.21-7.15]. Fifteen patients (20%) had high disease activity, 11% had low disease activity, and 19% were in remission. The mean functional impairment scale (HAQ) was 0.64 ± 0.48 [0-2.2]. Twelve patients had moderate to severe disability and only one patient had severe disability. The mean duration of the current bDMARD was 37.17 ± 39.44 months and the mean rank of the current biotherapy was 1.41 ± 0.9 [1-5]. According to the BMQ, the mean score for General Overuse was 14 ± 2.37 [6-20]. The mean score for General Harm was 10.82 ± 4.42 [2-20]. The mean score of patients’ specific beliefs regarding the necessity of taking the current bDMARD (Specific Necessity) was 20.62 ± 5.71 [5-25]. The mean Specific Concerns score regarding the current bDMARD was 10.33 ± 3.29 [5-25]. Necessity about taking bDMARD was reported by 77.3% patients in the present and 61.3% patients consider maintaining the bDMARD in the future. There were 4% of patients who reported concerns about taking bDMARD. Twenty-four percent of patients reported concerns about long term effects, and 16% about becoming too dependent on bDMARD.

Beliefs about the necessity to stop occasionally chronic therapies were reported by 13.3% of patients.

Specific necessity was correlated to the current bDMARD duration (p<0.01), Patient Global Evaluation (p=0.03), VAS pain scale (p<0.01), the number of nocturnal awakenings (p<0.01), tender joint count (p<0.01), swollen joint count (p<0.01), HAQ (p=0.005), DAS28 (CRP) (p<0.01). Specific concerns were correlated to the actual bDMARD rank (p<0.01).

Conclusion: Our study showed stronger beliefs in the necessity of taking biologic drugs if indicated. Disease activity parameters and functional impairment influence those beliefs. Further studies are required to evaluate the impact of beliefs on biologic drug adherence.

REFERENCES:
The study demonstrated that efficacy of CT-P13 is equivalent to that of China-approved INX. Also, the PK and safety profiles of CT-P13 were comparable to those of China-approved INX. No loss of efficacy or difference in safety or immunogenicity was observed after switching from China-approved INX to CT-P13 at Week 30.

Conclusion: The purpose of this study was to demonstrate equivalence of efficacy and compare PK and safety profiles of CT-P13 and China-approved INX.

Methods: In this randomized, double blinded, multicenter, parallel-group, phase III study, patients with active RA who had been responding inadequately to methotrexate for at least 3 months, were randomized to receive either CT-P13 or China-approved INX. Patients were treated with doses of 3 mg/kg at Weeks 0, 2, 6, then every 8 weeks up to Week 54. Prior to dosing, patients were treated with doses of either CT-P13 or China-approved INX. Patients were treated with doses of 3 mg/kg at Weeks 0, 2, 6, then every 8 weeks up to Week 54. Prior to dosing, patients were treated with doses of either CT-P13 or China-approved INX. Changes in health status, safety, and immunogenicity were compared between the groups.

Results: A total of 1,088 patients were randomized in a 1:1 ratio (544 patients assigned to each group). The primary endpoint was change in DAS28 (CRP) from baseline to Week 14, which was analyzed using an analysis of covariance. Equivalence was determined if the 90% CI for the estimate of treatment difference was entirely contained within the predefined equivalence margin of -0.6 to 0.6. A total of 544 patients were randomized in a 1:1 ratio (272 patients assigned to each group). The primary endpoint was change in DAS28 (CRP) from baseline to Week 14, which was analyzed using an analysis of covariance. Equivalence was determined if the 90% CI for the estimate of treatment difference was entirely contained within the predefined equivalence margin of -0.6 to 0.6. The primary efficacy endpoint was change in DAS28 (CRP) from baseline to Week 14, which was analyzed using an analysis of covariance. Equivalence was determined if the 90% CI for the estimate of treatment difference was entirely contained within the predefined equivalence margin of -0.6 to 0.6. Results: 270 patients were randomly assigned to 2 treatment groups in a 1:1 ratio (136 and 134 patients in the CT-P13 and China-approved INX groups, respectively) and 184 patients completed the study. The least square mean change (standard error) of DAS28 (CRP) from baseline to Week 14 was similar between the groups. The primary endpoint was change in DAS28 (CRP) from baseline to Week 14, which was analyzed using an analysis of covariance. Equivalence was determined if the 90% CI for the estimate of treatment difference was entirely contained within the predefined equivalence margin of -0.6 to 0.6. The primary endpoint was change in DAS28 (CRP) from baseline to Week 14, which was analyzed using an analysis of covariance. Equivalence was determined if the 90% CI for the estimate of treatment difference was entirely contained within the predefined equivalence margin of -0.6 to 0.6.
(CRP, MMP-3), disease activity (Simplified Disease Activity Index; SDAI), physical function (Health Assessment Questionnaire; HAQ), and joint destruction (modified Total Sharp Score; mTSS) at baseline and 1-year follow-up.

Results: There were 9 patients in PD≥2/ET+ group and 31 patients in PD<2 group. PD≥2/ET+ group had significantly higher SDAI (p=0.027), MMP-3 (p=0.005), and PD (p=0.001) at baseline compared with PD<2 group, but their MMP-3 (p=0.019) and PD (p=0.042) were significantly decreased over 1 year. PD≥2/ET+ group had joint destruction before ET (p=0.022), but it was suppressed after ET and there was no significance in change in mTSS compared with PD<2 group (p=0.099) (Figure 1).

Figure 1. Disease activity ultrasound assessment and radiographic change from baseline (BL) to 1-year follow-up in RA patients with residual synovitis who had enhanced treatment (PD≥2/ET+) and those without active synovitis (PD<2). "Each parameter at BL and 1-year was statistically analyzed by Wilcoxin signed rank test only in PD≥2/ET+ group." Difference in multiple switching from biosimilars. The current evidence on the safety, efficacy, and immunogenicity of switching multiple times from a biosimilar to another biosimilar comes from a limited number of randomized-controlled trials and real world evidence studies.

Objectives: The aim of our work was to evaluate the disease activity trend after multiple switching from ADA originator-Humira (oADA) to its biosimilars (bsADA; ABP 501 and SB5 subsequently) in a cohort of inflammatory arthritis patients.

Methods: In this real-life study, we selected patients with clinical diagnosis of rheumatoid Arthritis (RA), psoriatic Arthritis (PsA) and ankylosing spondylitis (AS). Patients had been previously treated with oADA and switched to the bsADA (first ABP 501 and then SB5). At each outpatient visit, we recorded demographic features (age, sex, and time since diagnosis) and the following disease activity measures: DAS28, DAPSA, BASDAI and the HAQ. Rheumatoid factor (RF), anti-citrullinated protein antibody (ACPA), C-reactive protein (CRP) and HLAB27 were also measured over the observational period (visits 0, 12, 24 and 36 months). The disease activity was evaluated during the year before the introduction of the bsADA, and then evaluated in the following 36 months during the first and the second bsADA treatment. We also examined whether some baseline characteristics, such as the duration of ADA treatment, comitant therapy, comorbid disease and baseline disease activity, could influence the bsADA discontinuation.

Results: We evaluated the 3-year drug survival and efficacy of the multiple switch of bsADA in RA, PsA and AS patients, previously treated with oADA in 127 patients (Table 1). All the patients enrolled underwent a first switch lasting one year and then a second switch with a follow up of one year too. The 1-year retention rate for ABP501 was 84.4%, 78% and 77.5% in AS, RA and PsA patients, respectively. The 1-year retention rate for SB5 was 82.1%, 78.7% and 77.5% in AS, RA and PsA patients, respectively. Disease activity, as measured by DAS28, DAPSA and BASDAI remained stable over the 3 years (Figure 1).

ABP501 (Adalimumab biosimilar, Amgeniva), SB501 (Adalimumab biosimilar, Imralid)

Conclusion: No difference was found between oADA and bsADA in terms of efficacy. This real-life study confirms the similar efficacy profile of multiple switch bsADA with long-term retention and a good safety profile in inflammatory arthritis patients.

EVALUATION OF SELF-CARE SAFETY SKILLS AND THERAPEUTIC KNOWLEDGE OF RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGIC DRUGS

E. Hannech1,2, S. Bousaïd1,2, D. Rekik1,2, S. Jemmali1,2, S. Rahmouni1,2, H. Sahli1,2, M. Elleuch2, R. Dharbi1,2, H. Gharsallah1,2,3,4 Rheumatology Department, La Rabta Hospital, Tunis, Tunisia; 5Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia; 6Rheumatology Department, Military Hospital of Tunis, Tunis, Tunisia

Background: The management of rheumatoid arthritis (RA) was revolutionized by the use of biologic therapies (bDMARD). Nevertheless, bDMARDs may carry some specific risks such as infection. However, data about self-care safety skills are poor [1]. An assessment of the level of information and education is therefore essential for patients followed for RA.

Objectives: The purpose of our study was to assess knowledge and safety skills of RA patients under bDMARDs.

Methods: We conducted a descriptive, bi-centric, and cross-sectional study, including RA patients receiving intravenous (IV) or subcutaneous (SC) bDMARD for at least 3 months. Sociodemographic, clinical, and paraclinical data were collected. Knowledge and self-care safety skills were assessed by a pre-specified questionnaire.

The questionnaire was divided into three domains:
- Five questions about general theoretical knowledge domain: assessing patient’s knowledge of the name of the current bDMARD, duration and rate of intake, and a question on annual cost estimation.
- Three questions about the current bDMARD management: assessing cold chain compliance and management of the biologic in SC emphasizing adherence to the steps to be taken prior to giving the injection.
- Tow questions about knowledge regarding safety skills in special situations: infection, cough, contraception, surgery, vaccination, and regarding the need to inform others about the use of the bDMARD.

Based on the data analysis, patients were divided into 3 groups according to their knowledge level:
- Group A (low knowledge level: percentage of correct answers <40%)
- Group B (moderate knowledge level: percentage of correct answers >40% and <60%)
- Group C (high level of knowledge: percentage of correct answers > 60%).

Results: Seventy-five patients with RA were collected. Their mean age was 56.92 ± 9.06 years (34-80). The mean duration of bDMARD was 37.17 ± 39.44 months (4-248) with a mean rank of 1.41 ± 0.9 [1-5]. The SC route was used in 41 patients (54.7%) followed by the IV route in 34 patients (45.3%).

The most prescribed molecules were Infliximab, Certolizumab and Tocilizumab (22.7% respectively). The average order of the current biologics was 1.41 ± 0.9 [1-5] in combination with a csDMARD in 48 patients (64%).

Safety skills were low in 24 patients (32%), moderate in 36 patients (48%), and high in 15 patients (20%).

The mean percentage of correct answers for each domain was respectively: 56.53 ± 18.4% [20-100] for general theoretical knowledge domain, 68.44 ± 26.21% [0-100] for the management of current biologic treatment domain, and 40.8 ± 16.67% [6.67-80] for knowledge regarding safety skills in special situations.

Safety skills levels were significantly related to occupational status (p<0.001), DAS28 CRP (p=0.04), joint deformities (p=0.01) and radiographic erosions (p=0.006), number of previous bDMARDs (p=0.009), and the rank of the current bDMARD (p=0.009).

Conclusion: The major finding of our study was the insufficient level of knowledge and safety skills of RA patients under bDMARDs. We highlighted the importance of involving patients in the decision-making process and emphasize the necessity of involving patients in the decision-making process and emphasizing adherence to the steps to be taken prior to giving the injection.

REFERENCE:

Disclosure of Interests: None declared

Background: Subcutaneous (SC) CT-P13 is the first and only subcutaneous formulation of infliximab (IFX) approved by the EMA. In the pivotal study (NCT03147248), non-inferiority of SC IFX to intravenous (IV) was demonstrated in rheumatoid arthritis (RA) patients using 28-joint Disease Activity Score (DAS28) C-reactive protein (CRP) improvement at Week 22, with a statistically significant treatment difference of 0.27 (95% CI 0.02, 0.52) favoring the SC versus the IV arm.\(^2\) At Week 30, numerical differences in efficacy outcomes were shown between SC and IV IFX favoring SC IFX. IV group patients switched to SC IFX by Week 30, and the difference between the groups was reduced at Week 54.\(^2\)

Objectives: To investigate whether there was a statistically significant difference between SC and IV IFX at Weeks 30 and 54 in the phase 3 pivotal study of CT-P13 SC using conservative missing imputation methods.

Methods: With active RA who had an inadequate response to MTX received IV IFX 3mg/kg at Weeks 0 and 2 for induction and were randomized to a 1:1 ratio to receive SC IFX 120mg every 2 weeks or IV 3mg/kg every 8 weeks thereafter for maintenance. Patients who were randomized to receive IV IFX switched to SC at Week 30. In this post-hoc analysis, non-responder imputation (NRI) and last observation carried forward (LOCF) methods were used to investigate whether the difference in efficacy outcomes between SC and IV IFX at Weeks 30 and 54 was statistically significant. Assessments included EULAR (CRP/ESR)/ACR response; remission rate and low disease activity (LDA) rate based on DAS28 (CRP/ESR), Clinical Disease Activity Index (CDAI) and Simplified Disease Activity Index (SDAI); Boolean remission rate; and the proportion of patients achieving a minimal clinically important difference (MCID) in Health Assessment Questionnaire (HAQ).

Results: Of the 343 randomized patients, 165 patients who received SC IFX and 174 patients who received IV IFX from the efficacy population were included in the analysis. There was a statistically significant difference in SC IFX compared to IV treated patients at Week 30 using both NRI and LOCF methods in almost all the clinical variables. However, the difference in efficacy outcomes between SC IFX and IV was reduced at Week 54 after the IV group switched to SC. This supports the improved efficacy of SC IFX at Week 30 in patients with RA. Between-group differences were reduced at Week 54, suggesting improved responses after switching from IV to SC.

Conclusion: Statistical analyses using conservative missing imputation methods showed significantly greater improvements in clinical outcomes with SC IFX compared to IV at Week 30 in patients with RA. Between-group differences were reduced at Week 54, suggesting improved responses after switching from IV to SC.

AB0345 THERAPEUTIC DRUG LEVELS TO ACHIEVE GOOD EULAR RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING ADAлимУMAB: RESULTS FROM THE BIOLOGICS IN RHEUMATOID ARTHRITIS GENETICS AND GENOMICS STUDY SYNDICATE (BRAGGSS) COHORT

R. M. Hum\(^1,2,3,\) P. Ho\(^1,2,3,\) N. Nair\(^3,\) D. Plant\(^3,\) A. Morgan\(^4,\) J. Isaacs\(^4,\) A. G. Wilson\(^4,\) K. Hyrich\(^1,2,3\) on behalf of BRAGGSS. \(^1\)Manchester University NHS Foundation Trust, The Kellgren Centre for Rheumatology, Manchester, United Kingdom; \(^2\)The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; \(^3\)The University of Manchester, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; \(^4\)University of Leeds, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; \(^5\)Newcastle University, NIHR Newcastle Biomedical Research Centre, Newcastle, United Kingdom; \(^6\)University College Dublin Centre for Arthritis Research, Conway Institute, Dublin, Ireland

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease often treated with biologic disease-modifying anti-rheumatic drugs (bDMARDs) such as Adalimumab (ADL), a tumour-necrosis factor inhibitor (TNFi). However, it is known that about a third of patients do not respond to ADL treatment. Previous studies have reported associations between poor response, decreased serum drug levels (SDLs) and poor adherence, but a therapeutic SDL has not been defined or applied in clinical practice.

Objectives: To assess median ADL SDLs in RA European Alliance of Associations for Rheumatology (EULAR) good vs non/moderate responders, and to determine cut-off SDLs associated with a “Good” response in fully adherent RA patients.

Methods: In a prospective observational cohort study, patients with RA were treated with ADL at baseline. 3-, 6-, and 12-months patients had 4-component DAS28 scores, self-reported treatment adherence data and SDLs measured. Median drug levels and receiver-operator characteristics (ROC) curves were used to compare SDLs between responders and non-responders, and to establish cut-off SDLs in
self-reported fully adherent patients. Serum drug levels were measured using a sandwich ELISA produced by Progenika Biopharma. Patients were considered fully adherent if they self-reported never having altered, forgotten or omitted any dose of their biologic drug at follow-up. Between group comparisons were assessed using Fisher’s exact test, with a threshold for significance set at p<0.05. Statistical analyses were performed in R Version 4.1.0 and RStudio Version 1.4.1106.

**Results:** A total of 283 RA patients taking ADL were included in the analysis. Baseline characteristics are shown in Table 1. Of these patients 93 (32.9%) self-reported being fully adherent to treatment at 3 months follow-up and had SDLs measured.

**Discriminatory utility:**

ROC analysis (see Figure 1) reported a 3-month non-trough ADL SDL cut-off of 7.5mg/L in fully adherent RA patients which discriminated Good EULAR responders, median SDL at 3 months was 9.014 (IQR 6.96 to 11.1). The ROC curve analysis: EULAR non/moderate vs good responders with 3 month ADL SDLs.

**Figure 1.** ROC curve analysis: EULAR non/moderate vs good responders with 3 month ADL SDLs.

**Conclusion:** In keeping with previous work, SDLs were higher in adherent compared with non-adherent patients, but this is the first study to demonstrate that SDLs are higher in fully adherent good EULAR responders compared with non/ moderate responders. Based on our methods, cut-offs of 7.5mg/L for ADL may be useful targets in clinical practice to achieve good EULAR response.

**AB0346 REASONS FOR DISCONTINUATION OF TNF INHIBITORS IN PATIENTS WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS ACCORDING TO DRUG HISTORY**

**E. Matianova1, A. Gordeev1, E. Galushko1, V.A. Nasonova Rheumatology Research Institute, Rheumatoid Arthritis Evolution Laboratory, Moscow, Russian Federation**

**Background:** TNF-alpha inhibitors (TNFi) are considered the drugs of choice for initiating biological therapy in rheumatoid arthritis (RA). Review of the reasons for their cancellation is included in a comprehensive study of the group of patients (pts) with Difficult to Treat RA (D2T).

**Objectives:** To make a comparative assessment of the reasons for discontinuation of TNFi in pts meeting the international EULAR (2021) criteria for D2T, comparing them with other pts who had experience in taking a biological disease modifying antirheumatic drugs (bDMARDs)/targeted synthetic DMARDs (tsDMARDs).

**Methods:** We analyzed the drug history of 505 pts with RA who were hospitalized at the V.A.Nasonova Research Institute of Rheumatology hospital from January to December 2021 (inclusive) due to an RA exacerbation, and who were approved for the introduction of bDMARD/tsDMARD. Pts with no prior experience with bDMARD/tsDMARD were excluded from the analysis (n=179/35.4%). Pts meeting the EULAR criteria for D2T (the main of which: failure of two or more bDMARDs/tsDMARDs of different mechanisms of action) were allocated to the D2T group (n=35/6.9%), the rest of the pts made up the control group C (n=291/57.6%). The middle age (±SD) of patients in D2T was less than in C (D2T - 46.3±15.1 years vs. C - 51.6±14.8 years, p=0.047), the duration of RA in the groups was comparable (D2T - 15.7±10.7 years vs. C - 13.1±8.9 years, p=0.05).

**Results:** The frequency of prescribing a history of TNFi in D2T (85.7%) was higher than in C (38.5%; OR=2.9 [1.3-6.6]; p=0.001). The total duration of their intake (in cases of prescription) and the average number of TNFi drugs in the groups were comparable (p> 0.05), but in D2T pts more often had the experience of taking 3 or more TNFi (OR = 6.4 [2.0-20.4]; p=0.002) (Table 1).

*the percentage is calculated from the number of pts who took TNFi

**Withdrawal of TNFi due to their ineffectiveness was more often performed in D2T (93.3%/n=28) than in C (43.8%/n=49; OR=18 [4.1-79.3];p<0.0001). At the same time, secondary non-responsiveness (NR) prevailed in D2T - in 56.7% (17 of 28 cases of NR), which is more often in C (31.3% / 35 of 49 cases of NR; OR = 18 [4.1-79.3]; p<0.0001). Secondary NR in D2T in 59.9% of pts (9 of 17 cases of secondary NR) developed after the break for administrative reasons in taking a previously effective drug, which is significantly more common than in C (20%/7 of 35 cases of secondary NR; OR = 4.5 [1.3-15.9]; p=0.02). Withdrawal of TNFi for administrative reasons was more common in C (33%/n=57 vs. in D2T -6.7%/n=2; OR=6.9 [1.6-36.6]; p = 0.004). The incidence of adverse reactions in both groups was comparable (in D2T 30%/n=9 vs. in C -20.5%/n=23; p=0.05).
**AB0347** TREATMENT RESPONSE WITH ABATACEPT PLUS METHOTREXATE TREATMENT FOR RHEUMATOID ARTHRITIS: REAL-WORLD EVIDENCE FROM THE UK

E. Choy1, S. Henning2,3, M. Brazilt, K. Pollock5, L. Groves6, D. Sugrue6, J. Houghton1. 1Cardiff University, CREATE Centre, Cardiff University School of Medicine, Cardiff, United Kingdom; 2UCL School of Pharmacy, University College London, London, United Kingdom; 3Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom

**Background:** A previous real-world study has reported the characteristics, treatment patterns and clinical outcomes of patients with rheumatoid arthritis (RA) who received abatacept in UK clinical practice. However, many of the eligible population received abatacept monotherapy rather than as indicated. A subgroup analysis of patients treated with abatacept in combination with methotrexate (ABA + MTX) was therefore undertaken to explore the treatment effect in this specific patient population.

**Objectives:** Present a subgroup analysis describing the clinical outcomes of patients with RA treated with ABA + MTX in UK real-world clinical practice.

**Methods:** A multi-centre, retrospective observational study was undertaken in patients with RA treated with abatacept at any time of therapy between January 2013 and 31 December 2017, across four UK centres. Data were collected from patient medical records from index date, defined as the date of first bDMARD initiation, to most recent RA clinic visit, death or end of study (31 December 2017). Clinical outcomes (disease activity and response to treatment) were measured using the 28-joint Disease Activity Score based on erythrocyte sedimentation rate (DAS28-ESR) and European League Against Rheumatism (EULAR) response criteria. Patients that received abatacept outside indication (i.e., without concomitant methotrexate) were retrospectively excluded from the analysis dataset. Statistical analyses for the ABA + MTX subgroup were repeated in line with the methodology previously reported.

**Results:** This subgroup analysis included 133 patients, of 213 patients included in the original study, with RA that received ABA + MTX (mean age 54.6 years, 77.4% female, 7.5 years mean duration of RA at index date). At index date, 64.8% of patients were positive for both anti-citrullinated protein antibodies (ACPAs) and rheumatoid factor (RF), where data were available. In total, 77.8% of patients were categorised with high disease activity at index, with mean DAS28-ESR of 6.2 (SD 1.1).

Irrespective of line of treatment (LOT), patients tended to have a more favourable distribution of good/moderate/no EULAR response when receiving ABA + MTX (31.8%/34.1%/34.1%; n=44) compared with receipt of other bDMARDs (12.7%/36.4%/50.9%; n=55) at 6 months. Similarly, a favourable distribution of good/moderate/no EULAR response in favour of those receiving ABA + MTX compared with other bDMARDs was observed at 12 months (30.6%/41.7%/27.8% versus 20.0%/35.0%/45.0%, respectively).

Patients receiving ABA + MTX remained on treatment for significantly longer than patients in receipt of other bDMARDs as first LOT (median time on treatment 53.4 vs 18.1 months; p<0.001). A similar trend was observed at second LOT, although differences were not statistically significant (median time on treatment 40.1 vs 19.7 months; p=0.08).

**Conclusion:** Patients with RA who received treatment with any bDMARDs, including ABA + MTX, experienced reduced disease activity. However, those receiving ABA + MTX persisted with treatment significantly longer than when receiving other bDMARDs.

*Includes cessation of therapy, prescription of corticosteroids, physical exercise, no action; IQR, interquartile range; SD, standard deviation; Q2W once two-weekly.*
Background: SBS, a biosimilar to reference adalimumab (ADL), received EU marketing authorisation in 2017, based on pre-clinical and clinical phase I and III studies that demonstrated bioequivalence and comparable efficacy, safety and immunogenicity to ADL.

Objectives: The real-world study PROPER is designed to provide insights into outcomes of the transition from ADL to SBS outside the randomised, controlled, clinical trial setting.

Methods: Under an umbrella design, 1000 patients with immune-mediated inflammatory disease were enrolled at centres in Belgium, Germany, Ireland, Italy, Spain and the UK, and followed for 48 weeks post-transition. Eligible patients had a diagnosis of rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), psoriatic arthritis (PsA), ulcerative colitis or Crohn’s disease had been transitioned to SBS as part of routine treatment following a minimum of 16 weeks’ treatment with ADL. Data were captured from patient charts retrospectively for 24 weeks prior to and prospectively and/or retrospectively up to 48 weeks after SBS initiation. This analysis of the rheumatology cohort reports clinical characteristics, disease scores, persistence on SBS, clinical management and safety up to the closing date of November 30th, 2021.

Results: Of the 496 patients included in this analysis, the majority were enrolled in UK (n=174), Germany (n=145) and Spain (n=73); Italy, Ireland and Belgium enrolled 45, 44 and 15 patients respectively. At study close, 487 patients had completed 48 weeks of follow-up; 397 of those remained on SBS throughout.

Methotrexate was received as concomitant therapy by 37% of patients and 20% had received a biologic therapy prior to reference ADL. Most patients (89.3% of RA, 92.1% of axSpA, 97.3% of PsA) transitioned to SBS at the same dose regimen received for ADL. Clinical characteristics, SBS dose and flare are detailed in Table 1, disease scores in Figure 1.

Figure 1. Disease scores (paired patients), mean (95% CI)

Fifteen patients each experienced one unrelated Serious Adverse Event (SAE): 2 in the axSpA cohort [tachycardia, intracranial haemorrhage]; 6 in the PsA cohort [myocardial infarct (2), breast cancer, COVID-19, gallbladder calculus, dysphonia]; 7 in the RA cohort [facial numbness, depression, COVID-19, pneumonia, cholecystitis, peritonitis, coronary occlusion]. Two patients reported SAEs considered causally related to SBS: Herpes zoster and pneumonia (RA cohort), and ALS with worsening (PsA cohort).

Conclusion: This analysis of a large, contemporary cohort of EU patients with established RA, axSpA or PsA shows treatment effectiveness maintained at 48 weeks after switching from ADL to SBS, with most patients continuing on SBS Q2W throughout. Episodes of flare were uncommon, and the importance of patient-reported symptoms in recognition of flare is evident. No new safety signals were observed.

AB0349 ANALYSIS EFFICACY OF ABATACEPT TREATMENT IN BIOLOGIC-NAÏVE AND BIOLOGIC-EXPERIENCED PATIENTS.

M. Borisova1, G. Lukina1,2, S. Yakov1, E. Luchikhina2, D. Karateev1, A. Novikov2, E. Aleksandrova2, E. Aronova2, S. Glikhova1, E. Nasonova1,3,5; I.V. Nasonova Research Institute of Rheumatology, Laboratory of Monitoring Safety of Antirheumatic Treatment, Moscow, Russian Federation; 1A.S. Loginov Moscow Clinical Scientific Center, Department of Rheumatology, Moscow, Russian Federation; 2Moscow Regional Research and Clinical Institute (MONIKI), Department of Rheumatology, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Scientific Director, Moscow, Russian Federation; 5M. Sechonov First Moscow State Medical University, Department of Rheumatology, Moscow, Russian Federation

Background: Despite the high efficacy of rheumatoid arthritis (RA) therapy, in routine clinical practice, clinicians face questions about the choice of a second biologic, as well as the possibility of biologic monotherapy. Therefore, the specialties of biologics use in these categories of patients are of great clinical interest. This work is devoted to the study of the effectiveness of abatacept (ABA) therapy in biologic-naïve and biologic-experienced patients and in the subgroup of ABA monotherapy.

Objectives: To evaluate the effectiveness of ABA therapy between biologic-naïve and patients who had experienced an inadequate response to biological agents and in the subgroup of ABA monotherapy.

Methods: We prospectively enrolled and followed 91 patients with high RA activity (SDAI=28±13.4, CDAI=25±12) and an inadequate response of conventional synthetic DMARDs (mainly metotrexate, 70.3%) and biologics (mainly TNFα blockers, 93%) were included in the study. Most of the patients were middle-aged (49±13.5), positive for RF (72.5%) and ACCP (77%) with moderate functional impairment - 1.4 (0.9-2). Patients were divided into two groups: biologic-naïve (48.4%, n=44) and biologic-experienced patients (51.6%, n=47). 18% (n=17) of patients had a history of an inadequate response of 2 or more biologics. The ABA monotherapy group (13%, n=12) was assessed separately. ABA therapy was a registered IV, 10 mg/kg according to the standard scheme. The evaluation of the effectiveness of the therapy was carried out according to the EULAR/ACR 2011 criteria using the intention-to-treat approach and SDAI, CDAI and the functional state using the HAQ.

Results: ABA led to a significant (p<0.05) decrease in RA activity after 3 months of ABA therapy in all groups. After 6 months of treatment, there was a tendency towards an increase in the number of patients who achieved remission and low RA activity in the group of biologic-naïve patients, which continued to 12 months of therapy. So, after 6 months and 12 months in the group of biologic-naïve patients, the frequency of remission and low disease activity was 71% (n=25) and 76% (n=19) by SDAI, 75.6% (n=28) and 81.5% (n=24) by CDAI, respectively. Whereas, in the group of biologic-experienced patients - SDAI - 61.8% (n=21) and 69.2% (n=18), CDAI - 64.8% (n=22) and 77.8% (n=21), respectively. However, these differences didn’t reach significance. Similar results were obtained according to the EULAR criteria: after 12 months of treatment, the percentage of patients with a good response in both groups did not differ, 38% (n=14) in biologic-naïve and 38.4% (n=15) in biologic-experienced patients. ABA significantly improved functional status of patients, after 12 months the median HAQ of biologic-naive and biologic-experienced patients were 0.7 (0.2-0.8) and 1.8 (0.7-1.6), respectively. More biologic-naïve patients achieved functional remission by HAQ after 6 and 12 months compared with biologic-experienced patients: 67% (n=23) vs. 33% (n=17), 62.5% (n=11) vs. 37.5% (n=9), respectively, but these differences didn’t reach significance. In the ABA monotherapy group after 6 months treatment, a good response by EULAR criteria was achieved in 10% (n=1) patients, while in the group of ABA+cDMARDs therapy in 43.5%, p<0.04. After 12 months the trend towards a more pronounced response in the combination therapy group persisted (11%, n=1 and 42%, n=28), respectively, but no significant differences were obtained.

Conclusion: Abatacept has shown significant improvement clinical and functional status in all studied groups. There were no significant differences in response to ABA therapy between biologic-naïve and biologic-experienced patients. ABA monotherapy were significantly worse compared with the combination therapy of ABA and cDMARDs after 6 months. After 12th month observation, this tendency continued, but no significant differences were achieved. This is probably due to the small number of patients on ABA monotherapy and, as a result, to the insufficient statistical representativeness of the sample.

**ASSESSMENT OF REAL-LIFE PATIENT HANDLING EXPERIENCE OF AVT02 ADMINISTERED SUBCUTANEOUS VIA AUTOINJECTOR IN PATIENTS WITH MODERATE-TO-SEVERE ACTIVE RHEUMATOID ARTHRITIS: AN OPEN-LABEL, SINGLE-ARM CLINICAL TRIAL, THEN AN EXTENSION PHASE OF AVT02 ADMINISTERED WITH A PRE-FILLED SYRINGE (ALVOPAD-PEN)**

1AG, Clinical and Medical Affairs, Zürich, Switzerland; 2Germany GmbH, Clinical and Medical Affairs, Jülich, Germany; 3Avrotech Swiss AG, Clinical and Medical Affairs, Zürich, Switzerland; 4Avrotech UK Ltd, Clinical and Medical Affairs, London, United Kingdom; 5Avrotech M, Combination Products & Devices, Reykjavik, Iceland

**Background:** AVT02 is an investigational biosimilar to adalimumab. It is approved in Europe, Canada, and the UK. It is not approved by the US Food and Drug Administration (FDA).

**Objectives:** To assess the real-life patient handling of an autoinjector (AI) in adult patients with moderate-to-severe active rheumatoid arthritis (RA) who self-inject AVT02 subcutaneously (s.c.).

**Methods:** This open-label study enrolled 107 adalimumab-naïve subjects with moderate-to-severe active RA to self-inject AVT02 with the proposed AI 40 mg s.c. in Week 1, and every other week thereafter through Week 8. In an optional extension phase through Week 56, subjects were switched from AVT02 AI to pre-filled syringe and followed for safety and efficacy. The primary endpoint was the percentage of successful self-injections as reported by both the trial site and by subjects using standardized questionnaires at Week 8. Additional endpoints included ease of use and robustness of the AI at Week 8, and efficacy in RA, assessment of serum trough levels of AVT02, and detection of antidrug antibodies (ADA) throughout the study.

**Results:** The AI success rate was 100% as reported by both the trial site and by subjects. No handling events were noted through Week 8. Approximately 80% (78.1–84.9%) of subjects found the AI ‘very easy’ to use and, in general, less difficulty was reported as the study progressed. The first 110 AIs used were inspected for robustness and none showed any sign of damage or malfunction. All subjects who completed Week 8 (n = 106) took part in and completed the optional extension phase through Week 56.

At Week 8, 49.1%, 5.7% and 0.9% subjects achieved ACR20, -50 and -70 responses, respectively. Improvement was also reported for the SDAI, DAS28 CRP and HAQ, with scores consistently decreasing through Week 8. In the extension phase, 70.8%, 47.2% and 13.2% subjects achieved ACR20, -50 and -70 responses, respectively. Improvement was also reported for the SDAI, DAS28 CRP and HAQ, with scores consistently decreasing through Week 56.

From Baseline through Week 8 the mean serum concentrations of investigational AVT02 increased consistently at each visit, reaching a peak at Week 24. There was no significant difference in serum concentrations of AVT02 based on injection subsite (abdomen or thigh).

**Conclusion:** The AI was easy to use and robust. The study results supported the progression to a Phase II extension study through Week 56. Subjects were switched from AVT02 AI to pre-filled syringe at Week 1, and every other week thereafter through Week 8. In an optional extension phase through Week 56, subjects were switched from AVT02 AI to pre-filled syringe and followed for safety and efficacy.

**IMPACT OF FCGR2A, FCGR3A AND FCGR3B POLYMORPHISM ON RITUXIMAB EFFICACY IN RHEUMATOID ARTHRITIS**

M. Moadia1, I. Mahmoud1, A. Ben Tekaya1, L. Rouached1, S. Boudeni1, R. Tekaya1, Y. Gorgi2, L. Abdelmoula1, O. Saidane1, I. Staf2, Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia; 2Charles Nicolle Hospital, Laboratory of Research in Immunology, Renal Transplantation and Immunopathology (LR03SP01), Tunis, Tunisia

**Background:** Identifying reliable biomarkers of response to biologics in rheumatoid arthritis (RA) is necessary to improve responsiveness, preserve functions and structure of joints, as well as to reduce treatment’s cost. Single nucleotide polymorphisms (SNPs) of Fc-gamma receptors genes (FCGRs), by inducing a variation of receptors’ affinity to Fc fragment of Gamma immunoglobulin, might influence the efficacy of therapeutic monoclonal antibodies by modifying their clearance.

**Objectives:** The aim of this study was to investigate whether FCGR2A, FCGR3A and FCGR3B SNPs were predictive factors of response to rituximab (RTX) in Tunisian RA patients.

**Methods:** A cross-sectional, observational and analytic multicentric cohort study was conducted in a group of patients suffering from RA treated with RTX. Treatment outcome was evaluated after 6 months, using DAS$_28$ variation from baseline and EULAR response criteria. R131H-FCGR2A, F158V-FCGR3A and NA1/NA2-FCGR3B SNPs were studied using PCR-SSP and direct sequencing process.

**Results:** Thirty-four patients were enrolled with a sexe ratio M/F=5/29. The mean age at inclusion was 54.4±11.7 years [29-77]. All patients received at least one cs-DMARDs priorly to the prescription of RTX. Concomitant treatment with methotrexate was pursued in 77.3% of patients. As shown in Table 1, an

**DAS:** disease activity score, **ΔDAS:** mean variation of DAS at 6 months, *Comparison of the global distribution of the 3 genotypes, **p** while comparing the prevalence of R/R genotype to RH and HH genotypes, R+: good or moderate EULAR response, R-: bad EULAR response.
association, that tend to signification, was found between R/R FCGRA2 receptors and a greater variation in DAS28 score (p=0.053). This association was also found using EULAR criteria, since all patients with R/R genotypes had a good or moderate response to RTX but was not significant (p=0.131).

**Conclusion:** The low affinity receptor R/R FcgRIIα might be predictive of good response in RA patients treated with RTX. More studies need to be conducted in larger cohorts to confirm this association, with the aim of identifying reliable biomarkers of response to biologics to improve responsiveness, preserve joints functions and structure, as well as reduce treatment's cost.

**AB0352**

**IMPACT OF SEROLOGIC STATUS ON CLINICAL RESPONSES TO UPADACITINIB OR ABATACEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PRIOR INADEQUATE RESPONSE TO BIOLOGIC DMARDS: SUB-GROUP ANALYSIS FROM THE PHASE 3 SELECT-CHOICE STUDY**

A. Rubbert-Roth1, J. Sparks2, A. Constantin3, R. Xavier4, Y. Song5, J. Suboticki6, R. M. Fleischmann6, 1Division of Rheumatology, Cantonal Clinic St Gallen, St Gallen, Switzerland; 2Division of Rheumatology, Immunology, and Infection, Brigham and Women’s Hospital and Harvard Medical School, Boston, United States of America; 3Rheumatology Department, Purpan University Hospital and Toulouse III - Paul Sabatier University, Toulouse, France; 4Division of Rheumatology, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; 5AbbVie Inc., Immunology, North Chicago, United States of America; 6University of Texas Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, United States of America

**Background:** In patients with RA who had a prior inadequate response or intolerance to biologic DMARDs, the oral Janus kinase inhibitor, upadacitinib (UPA), demonstrated superiority in change from baseline in DAS28(CRP) and DAS28(CRP)<2.6 at week 12 and improved responses across additional endpoints compared to abatacept (ABA) in the phase 3 SELECT-CHOICE study. Seropositive patients have been reported to respond better to treatment than seronegative patients.

**Objectives:** To evaluate clinical responses with UPA versus ABA among RA patients based on serologic status.

**Methods:** In SELECT-CHOICE (24-week, phase 3, double-blind, controlled trial), RA patients were randomized to oral UPA (15 mg once daily) or intravenous (IV) ABA (at day 1 and weeks 2, 4, 8, 12, 16, and 20; <60 kg, 500 mg; 60-100 kg, 750 mg; >100 kg, 1000 mg).1 UPA patients also received IV placebo and ABA patients also received oral placebo. All patients continued stable background DMARDs. Mean change from baseline in DAS28(CRP) and Clinical Disease Activity Index (CDAI), ACR responses, HAQ-DI, and the patient’s assessment of pain was numerically higher with UPA compared to ABA at weeks 12 and 24 across all subgroups and timepoints (data not shown). Clinical responses were generally numerically higher at week 24 compared to week 12, and for the seropositive groups compared to the seronegative group, with both UPA and ABA.

**Conclusion:** Across serostatus subgroups, clinical responses with UPA 15 mg vs ABA were numerically higher at weeks 12 and 24 among RA patients with prior inadequate response or intolerance to biologic DMARDs. In addition, clinical responses were numerically higher for seropositive patients compared to seronegative patients across all endpoints assessed, although the seronegative group had a smaller sample size in this post-hoc analysis.

**Acknowledgements:** AbbVie funded these studies and participated in the study design, research, analysis, data collection, interpretation of data. No honoraria or payments were made for authorship. Medical writing support was provided by Monica R.P. Elmore, PhD of AbbVie.

Conclusion: In our biologic cohort, 2% of patients with RA and SpA had accompanying CKD. In one-third of the patients with CKD, it was developed during the follow-up after bDMARDs. In patients with RA, there was no difference in terms of TNFi and non-TNFi preferences. It should be kept in mind that CKD may develop during the follow-up of patients using bDMARDs.

THE DIFFERENCES BETWEEN THE FIRST PREFERRED BIOLOGICAL DMARD AND THE DRUG SURVIVAL IN GERIATRIC AND YOUNGER ADULT POPULATION WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS: TREASURE REAL-LIFE DATA

1 Sakarya University, Rheumatology, Sakarya, Turkey; 2 Hacettepe University, Rheumatology, Ankara, Turkey; 3 Uludağ University, Rheumatology, Bursa, Turkey; 4 Ankara University, Rheumatology, Ankara, Turkey; 5 Yıldırım Beyazıt University, Rheumatology, Ankara, Turkey; 6 Osmangazi University, Rheumatology, Eskişehir, Turkey; 7 Koç University, Rheumatology, İstanbul, Turkey; 8 Gülhane Research and Training Hospital, Rheumatology, Ankara, Turkey; 9 Adana City Hospital, Rheumatology, Adana, Turkey; 10 Namık Kemal University, Rheumatology, Tekirdağ, Turkey; 11 Katip Celebi University, Rheumatology, İzmir, Turkey; 12 Fatih University, Rheumatology, Elazığ, Turkey; 13 Akdeniz University, Rheumatology, Antalya, Turkey; 14 Mustafa Kemal University, Rheumatology, Hatay, Turkey; 15 Başakşehir Cam and Sakura City Hospital, Rheumatology, İstanbul, Turkey; 16 İrka University, Rheumatology, Edirne, Turkey

Background: Inflammatory musculoskeletal diseases are frequent in the elderly population, and this number is expected to increase significantly near future. The exclusion of older adults from the studies due to their age and comorbidities causes insufficient data about this population. Insufficient data cause clinicians to have difficulties using and selecting biological therapy in the elderly patient group. In real life, physicians’ approaches to the selection and use of biological disease modifying anti-rheumatic drugs (DMARDs) in the geriatric population with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) have not been well studied.

Objectives: To compare the clinicians’ first choice of biological DMARDs in elderly and younger RA and PsA patients and investigate the drug survival of first biological DMARDs in both populations.

Methods: The traditional chronological age for the human to be classified in the geriatric population is ≥65 years (1). The TReasure web-based registry, created in 2017, is a multicenter observational cohort established to collect data on RA and spondyloarthritis (SpA) patients from the participating 17 rheumatology centers in different regions of Turkey. Physicians’ first choice biological and targeted synthetic DMARDs in younger and elderly patients with RA and PsA was evaluated using the descriptive statistical method. The survival of the first bDMARDs was assessed using the Kaplan-Meier method.

Results: 3136 RA and 738 PsA patients were evaluated. 12% of 3136 patients with RA were in the geriatric population. In patients with RA, the first choice of biologic DMARDs was adalimumab (20.6%), followed by etanercept (19.9%), and tocilizumab (13.6%) in patients <65 years of age, while rituximab (24%) was the first choice in patients ≥65 years, tocilizumab (20.9%) in the second place and etanercept (13%) in the third. Of 738 PsA patients, 3% were over 65 years. Adalimumab (41.1%) was the first choice of <65 years of age, etanercept (17.6%) was the second choice, and infliximab (15.5%) was the third choice, while adalimumab (28.6%) was the first choice in patients ≥65 years followed by etanercept (17.9%) and certolizumab (17.9%) in RA group, drug survival was significantly higher in patients ≥65 years (estimated median drug survival: <65 age: 37.5 (34.1-41.1) months vs ≥65 age: 53.5 (24.9-82.2) months; log-rank p=0.016) (Figure 1). In PsA group, drug survival was significantly higher in patients <65 years (estimated median drug survival; <65 age: 31.2 (26.4-36.1) months vs ≥65 age: 9.1 (0.4-17.7) months; log-rank p<0.001) (Figure 1).

Conclusion: With these findings, it is thought that in Turkey, the limited socioeconomic support in the geriatric patients has led physicians to prescribe treatments such as rituximab, which are administered in the hospital under the supervision of a physician, are relatively preferred in malignancies, and are considered to be relatively less risky in terms of tuberculosis. Adalimumab and etanercept were chosen in the first two lines in both geriatric and young populations in the patient group with PsA. While the drug survival was significantly higher in patients with RA geriatric age group than the younger group, in PsA in which tumor necrosis factor-alpha (TNF-α) inhibitors were chosen as initial therapy in both age groups was lower in the geriatric population.

THERAPEUTIC DRUG MONITORING: STANDARDIZATION OF PROMONITOR QUICK IFX AND PROMONITOR QUICK ADL POINT OF CARE TESTS WITH WHO INTERNATIONAL STANDARDS FOR THE QUANTIFICATION OF INFLIXIMAB AND ADALIMUMAB IN WHOLE BLOOD AND SERUM

A. Ametazurre1, J. Pascual2, L. Del Río3, A. Urigoitia1, D. Nagore4, M. B. Ruiz-Argüello1, Progenika Biopharma - Grifols, Research & Development, Derio, Spain

Background: Promonitor Quick IFX and Promonitor Quick ADL are rapid point of care lateral flow tests (LFT) based on a sandwich immunoassay for the quantification of infliximab (IFX) and adalimumab (ADL), respectively, in human whole blood (finger prick or venous) or serum. These tests are to be used as an aid in Therapeutic Drug Monitoring (TDM) of rheumatic and inflammatory bowel disease patients under anti-TNF-α therapy. The international standards (IS) developed by World Health Organization (WHO) for IFX and ADL allow harmonization and comparability among different assays.

Objectives: The aim of this study, was to show that Promonitor Quick IFX and Promonitor Quick ADL can measure either reference or biosimilar drugs, as well as to evaluate the agreement of Promonitor Quick IFX and Promonitor Quick ADL tests and the WHO IS.

Methods: Clinical and Laboratory Standards Institute EP10-A3 guidelines were followed to estimate the bias of Promonitor Quick assays when used to quantify IFX or ADL in samples containing the reference drugs, biosimilars or the WHO IS. Briefly, whole blood was spiked with four known concentrations of IFX or ADL, including current clinical decision levels. Ten replicates were measured of each level along two days. Promonitor Quick IFX was evaluated using the reference drug, SB2 and CT-P13 biosimilars, and the WHO IS (NIBSC 16/170). Promonitor Quick ADL was evaluated using the reference drug, ABP501 and SBS biosimilars, and the WHO IS (NIBSC 17/236). Results were obtained in combination with the automated portable reader POReader.

Results: Bias was estimated by comparing the observed concentration of drug spiked whole blood samples. Each biosimilar was compared to the reference at the different drug levels tested. Results showed that Promonitor Quick IFX and Promonitor Quick ADL are able to measure equivalently any molecule (see Table 1).

Similar results were obtained when serum matrix was used.

The accuracy or closeness of the agreement between the result provided by Promonitor Quick IFX and Promonitor Quick ADL and the true value of the measurement was assessed by measuring the IS developed by the WHO (see Table 1).

**Conclusion:** Promonitor Quick IFX and Promonitor Quick ADL allow monitoring of patients treated with IFX and ADL, respectively, with just a finger prick sample. Both tests can quantify reference and biosimilar drugs with equivalent results. Moreover, comparable results were obtained with the WHO IS, and thus, demonstrate that Promonitor Quick tests are suited to accurately determine drug levels at the clinical decision points in both whole blood and serum, proving to be an effective and valuable tool in TDM and immediate decision making in the doctor’s office or hospitals.

**INCIDENCE AND DETERMINANTS OF INFECTION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH GOLIMUMAB IN REAL-WORLD PRACTICE**

L. Besseste1, P. Rahman2, J. Kelsall3, J. Purvis4, E. Rampakakis5, A. Lehman6, M. Rachich7, F. Nantel8, M. Marrache9, O. Asin Milan6. 1Université Laval, Département de Médecine, Faculté de Médecine, Quebec City, Canada; 2Memorial University of Newfoundland, Medicine, St. John’s, Canada; 3The University of British Columbia, Faculty of Medicine, Department of Medicine, Vancouver, Canada; 4300-270 Charlotte St, Rheumatology, Peterborough, Canada; 5JSS Medical Research, Clinical Research, Montreal, Canada; 6Janssen Inc, Rheumatology, Toronto, Canada; 7Retiree, Janssen Inc, Rheumatology, Toronto, Canada

**Background:** Although biologic use in rheumatoid arthritis (RA) has a well-characterized infection risk factor, most studies evaluating this association were conducted on first-generation anti-tumor necrosis factor (TNFi) agents or in early years post-drug development (early 2000).

**Objectives:** To (i) characterize the long-term incidence of infection in a real-world cohort of RA patients treated with subcutaneous golimumab (GLM) in Canadian routine care; (ii) assess the impact of infections on GLM retention, and (iii) explore factors associated with the risk of infection.

**Methods:** BioTRAC registry was a prospective, multicenter study that collected real-world clinical, laboratory, safety and patient-reported data from TNFi naïve patients or treated with biologics for a period of <6 months before enrolment. This post-hoc analysis included patients with RA who initiated GLM treatment. The incidence density rates (IDR) of total serious (SI) and non-serious (NSI) infections were calculated for the overall follow-up (90 months) period as well as by 6-month interval. Time to first infection and time to treatment discontinuation were assessed with the Kaplan-Meier estimator of the survival function. Determinants of infection over time or within the first 6 months were explored using generalized estimating equation models and logistic regression, respectively.

**Results:** 530 patients were included with a mean (SD) age of 57.7 (13.0) years and disease duration of 8.0 (8.3) years. Of these, 404 (76.2%) were females, 74 (14.0%) were treated with ≤15mg/week MTX, 280 (52.8%) with >15mg/week MTX, while 173 (32.6%) were not on MTX. In terms of corticosteroids (CS), 72 (13.6%) were treated with ≤5mg/day, 63 (11.9%) with >5mg/day, and 391 (73.8%) were not on CS. Diabetes (4.5%), pulmonary disease (8.9%), and renal disease (18.5%) were present. Over a mean follow-up duration of 27.0 months, the IDR for total infections, NSI, and SI was 35.10 events/100 PYs, 32.90 events/100 PYs, and 2.32 events/100 PYs. Median estimated time to first infection was 52.9 months (SI: 84.9 months; NSI: 55.1 months) (Table 1). The incidence of total infections was 44.0, 37.3, 35.1, 29.4, 31.1, 35.7, 19.3 and 74.0 events/100 PYs at 0-6 months, 6-12 months, 12-24 months, 24-36 months, 36-48 months, 48-60 months, 60-72 months, 72-84 months, respectively and no infections between 84-90 months. In terms of determinants, no significant associations were identified for the incidence of infections within the first 6 months. However, presence of pulmonary disease was identified as a significant determinant of total infections (OR [95%CI]: 2.19 [1.36-3.52] and NSI [2.22 [1.35-3.66]) over time, while higher age (1.08 [1.00-1.26]) and high (≥5mg/day) CS dose (2.72 [1.12-46.80]) were associated with significantly higher odds of incidence of SIs, but not NSIs. Across time periods, there were increased baseline CDAI (OR [1.08 [1.04-1.08]) and use of concomitant MTX at low dose (0.52 [0.30-0.91]) or high dose (0.71 [0.49-1.04]).

**Table 1. Incidence Density Rate (IDR) by Infection Type.**

</tbody>
</table>

**Conclusion:** The infection rates reported with GLM in this cohort are low compared to the rates reported in earlier registry studies with TNFi. Changes in the characteristics of patients starting TNFi (lower disease activity, shorter disease duration, less exposure to CS) in recent years may explain the decreased risk of infection. Compared to the available literature, treatment with GLM was associated with relatively low infection rate. Most infections occurred during the first 6 months of treatment and decreased thereafter. Presence of pulmonary disease, higher age, and higher CS dose were identified as significant predictors of infections. SIs, but not NSIs, were associated with significantly higher odds of treatment discontinuation-TNFi.

**AB0358**

**SAFETY, TOLERABILITY, PHARMACOKINETICS, RECEPTOR OCCUPANCY, AND SUPPRESSION OF T-CELL-DEPENDENT ANTIBODY RESPONSE IN A PHASE 1 STUDY WITH KPL-404, AN ANTI-CD40 MONOCLONAL ANTIBODY**

**Background:** T-cell priming and T-cell-dependent B-cell responses require an intact cluster of differentiation (CD40/CD40L pathway). CD40 is expressed on the surface of B-cells, dendritic cells, antigen-presenting cells, and non-immune cell types; its ligand, CD40L (CD154), is expressed on the surface of activated T-cells; its ligand, CD40L (CD154), is expressed on the surface of activated
T-cells, platelets, and other cell types. Blockade of CD40/CD40L interaction has been shown to ablate primary and secondary T-cell dependent antibody response (TDAR).

Objectives: We hypothesized that KPL-404, an anti-CD40 monoclonal antibody which inhibits interaction between CD40 and CD40L, would block T-cell dependent, B-cell-mediated autoimmunity in this Phase 1 study in healthy participants.

Methods: This randomized, double-blind, placebo-controlled, first-in-human study of KPL-404 in healthy participants was designed with two single-ascending-dose arms: single intravenous (IV) doses of 0.03 mg/kg, 0.3 mg/kg, 1 mg/kg, 3 mg/kg, or 10 mg/kg and single subcutaneous (SC) doses of 1 mg/kg or 5 mg/kg. The primary objective was safety and tolerability of KPL-404; secondary and exploratory objectives included pharmacokinetic (PK) parameters, TDAR inhibition, and receptor occupancy (RO). To evaluate TDAR inhibition, participants post-KPL-404 administration were immunized with 1 mg intramuscular injection of the test antigen Keyhole Limpet Hemocyanin (KLH) on day 4 and day 29 to elicit a primary and secondary Immunoglobulin (Ig) response, respectively. To evaluate RO, free and total CD40 receptor levels (percent change from baseline) on B-cells (whole blood) were measured using flow cytometry.

Results: There were no dose-limiting or dose-related safety findings in healthy participants after KPL-404 administration. One unrelated serious adverse event (patella fracture following a fall) occurred in the 10 mg/kg IV arm. The PK profile of KPL-404 in serum after IV or SC administration had low to moderate variability between individuals; elimination was dose-dependent and consistent with target-mediated drug disposition (TMDD) (Figure 1a). For participants receiving 10 mg/kg IV, full receptor occupancy was observed through day 71 (Figure 1b), complete TDAR suppression was observed through Day 57 (Figure 1c), and anti-drug antibodies to KPL-404 were suppressed for at least 57 days; the suppression of antibody responses to the drug itself is an independent indicator of target engagement and pharmacodynamic effect. For participants receiving 5 mg/kg SC, full receptor occupancy was observed through day 43 (Figure 1b), and complete TDAR suppression was observed through Day 29 (Figure 1c). The TDAR response to KLH antigen correlated with the observed full RO.

Conclusion: The safety and tolerability data and the PK/PD profile of KPL-404 support further investigation of KPL-404 in a broad range of autoimmune diseases, including rheumatoid arthritis. These data support the optionality for studying chronic KPL-404 dosing in patients with subcutaneous and/or intravenous administration.

Numeric1, M. Blettery3, C. Peti1, M. De Bandt1, B. Suzon1, Hospital Center University Of Fort De France, Rheumatology, Fort-de-France, Martinique; 2Hospital Center University Of Fort De France, Public Health, Fort-de-France, Martinique; 3Hospital Center University Of Fort De France, Internal Medicine, Fort-de-France, Martinique

Background: Mortality and morbidity related to rheumatoid arthritis (RA) has remarkably improved over the last twenty years since using biologics DMARDs1. However, their effectiveness remains questionable in Afro-descendants (AD) due to their large under-representation in RA clinical trials 2,3. Martinique is a French Caribbean region with a majority of AD population 4, with free access to healthcare, including biotherapies, and a unique university hospital and rheumatology unit.

Objectives: To evaluate effectiveness of tocilizumab (TCZ), an interleukin-6 inhibitor, in an afro descendant RA population.

Methods: Retrospective cohort of 171 patients who received at least 1 infusion Tocilizumab (IV TCZ) at Martinique University Hospital between 2008 and 2019. Inclusion Criteria: Patients over 18 y/o meeting RA 2010 ACR/ EULAR criteria, having received at least 4 courses of IV TCZ starting at 8mg/kg every 4 weeks, with available baseline clinical/biological data. Exclusion criteria: Patients having received subcutaneous TCZ (SC TCZ) prior to IV TCZ, not living in Martinique. Primary endpoint was proportion of patients in remission (R) and low disease activity (LDA) according to DAS28 CRP at 12, 24, 36 weeks. Secondary endpoint was proportion of patients achieving good (GR) and moderate (MR) EULAR response criteria at 12, 24, and 36 weeks, and TCZ retention at 1 year defined as the proportion of patient receiving TCZ at 1 year follow up.

Results: Out of 171 patients receiving IV TCZ, we identified 138 RA and 80 patients met inclusion criteria: 90% were women, mean age was 56.8 (+ 11.8) y/o, mean duration of RA was 11.6 (+ 8.9) years, ACPA and Rheumatoid Factor were positive in 72.1% and 73% of cases, 69.6% of patients had erosions and 78.7% had received at least 1 biologic prior to IV TCZ. At baseline, 8 patients were in R, 8 had LDA but presented steroid dependency over 10mg per day of prednisone and mean dose of prednisone was 6.9 (+/– 6.7) mg per day. At 12, 24, 36 weeks, R was achieved in 44.8%, 55.2% and 51.2% of patients and LDA in 37.3%, 17.2% and 20.9%, respectively (Figure 1). At 12, 24, 36 weeks, GR was achieved in 44.8%, 60.3% and 48.8% of patients respectively, MR was achieved in 20.9%, 20.7% and 27.9% of patients respectively (Figure 1) and mean dose of prednisone per day was 5.1 (+ 4.9) mg, 4.9 (+ 5.6) mg and 3.3 (+ 5.1) mg respectively. At 1 year, 78.8% of patients were still on TCZ. During follow up: 15 patients experienced 19 infectious events; 6 patients liver cytolysis; 12 patients neutropenia. No patient died.

Conclusion: This is the first study evaluating efficacy and safety of TCZ in an AD RA cohort. TCZ is safe and effective in our AD population with comparable data observed in other ethnicities 6,7.

Disclosure of Interests: None declared
Background: Fatigue is common among patients with rheumatoid arthritis (RA) with a substantial impact on quality of life (1). Biological disease-modifying anti-rheumatic drugs (bDMARDs) have been shown to significantly improve fatigue in these patients. However, fatigue is under-assessed by the physicians and evidence is still scarce regarding a possible impact of fatigue on disease activity over time.

Objectives: To explore the long-term impact of fatigue on the disease activity in patients with RA treated with bDMARDs.

Methods: A monocentric observational retrospective cohort study was conducted with 24 months (M) of follow-up. Participants diagnosed with RA, according to the 2010 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) criteria, and registered on the Rheumatic Diseases Portuguese Register (Reuma.pt) who started their first bDMARD between 2015 and 2021 were included. Demographic, clinical and laboratory data were obtained by consulting Reuma.pt. Fatigue was monitored at baseline, line 12 and 24 M using Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F). This scale is a 13-item self-reported questionnaire with a total score ranging from 0 to 52. A score ≤ 39 indicates the presence of clinically significant fatigue. Disease Activity Score for 28 joints with erythrocyte sedimentation rate (DAS28), DAS28 with C-reactive Protein (CRP) (DAS28-CRP), DAS28 delta, Clinical Disease Activity Index (CDAI) and Simplified Disease Activity Index (SDAI) were calculated to measure disease activity. Clinical response was evaluated by EULAR criteria in three response categories—good, mild and no response—and by ACR criteria (0 to 100%) at 12 and 24 M. To correlate fatigue score with EULAR clinical response Chi-square test was used. Multivariate linear regression models adjusted for age, gender and disease duration were used to assess the effect of fatigue on disease activity and ACR clinical response over time.

Results: A total of 40 patients with RA were included, with a mean age of 47±1.4 years old and disease duration of 10.4±5.6 years. Most patients were female (90.2%). Rheumatoid Factor was positive in 70% of patients. The majority of patients (84%) had clinically significant fatigue at baseline moment (FACT-F 26.9±11.8). Treatment characteristics and baseline disease activity scores are described in Table 1. Fatigue at baseline moment predicted DAS28 (CRP) (β=-0.061, 95%CI [-0.12; -0.003]) and CDAI (β=-0.30, 95%CI [-0.57; -0.029]) at 12M. Additionally, fatigue predicted SDAI (β=-0.38, 95%CI [-0.72; -0.047]) and CDAI (β=-0.39, 95%CI [-0.73; -0.051]) at 24M. In general, for these models, fatigue as a symptom was shown to have negative effects on the different outcomes analysed. Fatigue did not associate with EULAR and ACR responses over time.

Table 1. Baseline characteristics of sample. LEGEND: SD: Standard deviation; DAS28: Disease Activity Score for 28 joints; CRP: C-reactive Protein; CDAI: Clinical Disease Activity Index; SDAI: Simplified Disease Activity Index.

Conclusion: These findings showed that, in our sample, the most RA patients had severe fatigue and its presence may be a predictor of increased disease activity. Indeed, previous research observed a positive association between fatigue and disease activity over the time in patients with RA (2). Therefore, fatigue should be regularly monitored in patients with RA and its impact on treatment must be considered. Moreover, further research with larger samples is needed to explore the impact of fatigue on clinical response and the potential of fatigue relief as an outcome measure of RA treatment.

TOCILIZUMAB VERSUS TOFACITINIB IN THE 12-MONTH TREATMENT OF BIOLOGICAL-NAIVE PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

1.1M. Sechenov First Moscow State Medical University (Sechenov University), Institute of Pharmacy, Moscow, Russian Federation; 2. V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases Laboratory, Moscow, Russian Federation

Background: The choice of the most effective disease-modifying anti-rheumatic drug (DMARD) for the treatment of rheumatoid arthritis (RA) remains relevant. There are several comparative studies between tocilizumab (TCZ), an antibody against interleukin 6 receptor, and tofacitinib (TOFA), a potent selective Janus kinase inhibitor, regarding their efficacy (1,2).

Objective: To compare the effectiveness of TCZ and TOFA for treatment of biological-naive patients (pts) with active RA according to various indicators of disease activity, physical function, and quality of life during a 12-month (m) follow-up period.

Methods: A total of 80 biological-naive pts with high and moderate RA activity were enrolled (40 pts with TCZ and 40 pts with TOFA). The groups were comparable in terms of sex, age, BMI, and DAS28. All pts were measured: for disease activity using DAS28, SDAI, and CDAI for quality of life and physical function using EQ-5D, HAQ, and RAPID 3 questionnaires at the beginning of the study and after 12 m of TCZ/TOFA therapy. The EULAR response criteria for treatment of RA were used.

Results: Significant positive changes in major disease activity, clinical and laboratory parameters were found in RA pts after 12 m of TCZ infusions and TOFA intake: DAS28, SDAI, and CDAI decreased significantly in both groups (p<0.01 in all cases). There were more good responders among TCZ pts compared to TOFA pts: by DAS28 35 pts (87.5%) vs. 20 pts (50%), p<0.01; by CDAI 38 pts (95%) vs. 26 pts (65%), p=0.02, respectively. There was a more pronounced decrease in DAS28 and CRP levels in TCZ pts (ΔDAS28=-3.8 [-4.5; -3.2], ΔCRP=-26.5 [-45; -10.7]) mL compared to TOFA pts (ΔDAS28=-2.1 [-3.2; -1.0], ΔCRP=-10.1 [-13.2; -8.5]) mL (p<0.01 in all cases). Both drugs equally improved quality of life and physical function indicators EQ-5D, HAQ, and RAPID in a 12-m follow-up period. Correlations of ΔEQ-5D with ΔASR (R=0.43; p<0.01) and with ΔCRB (R=0.46; p=0.03) were found after 12 m of TCZ therapy.

Conclusion: TCZ and TOFA both significantly reduce disease activity and improve quality of life and physical function in bDMARD-naive RA patients. Compared with TOFA, TCZ can induce greater improvements during the first 12-m treatment. No unequivocal conclusions on the drugs' effect on pts' quality of life could be made.

NEUTROPHIL COUNT REDUCTION 1 MONTH AFTER INITIATING SARILUMAB AND BASELINE SERUM SOLUBLE GP130 LEVELS MAY INDEPENDENTLY PREDICT CLINICAL REMISSION WITHIN 3 MONTHS IN RHEUMATOID ARTHRITIS PATIENTS

T. Yoshikawa1, K. Azuma1, T. Furukawa1, T. Hashimoto1, M. Morimoto1, N. Azuma1, K. Matsui1, Hyogo College of Medicine College Hospital, Division of Allergology and Rheumatology, Department of Internal Medicine, Nishinomiya, Japan

Background: IL-6 contributes significantly to the chronic inflammatory process of rheumatoid arthritis (RA) and is elevated in serum and synovial fluid of RA patients. Sarilumab (SRL), a human anti-human IL-6 receptor alpha monovalent antibody that blocks the signaling originating by the IL-6/IL-6R complex like tocilizumab (TCZ),is an effective treatment. Recently, an association between the therapeutic effect of TCZ and neutropenia after TCZ initiation was reported[1]. Neutropenia is a common adverse event of SRL in patients with RA, but the relationship between reduced neutrophil count and clinical response to SRL is still inconclusive. In EULAR 2020, we reported the association between serum soluble gp130 levels before SRL treatment and the efficacy of SRL[2]. It is also unclear whether there is a relationship between IL-6 axis cytokines and SRL-induced neutropenia.

Objectives: The purpose of this study was to determine whether neutropenia at 1 month by SRL predicts clinical remission within 3 months and whether there is an association between IL-6 axis cytokines levels and SRL-induced neutropenia.

Methods: This research is a retrospective study. We reviewed medical records of RA patients initiating SRL between February 2018 and August 2021 in our hospital. The Clinical Disease Activity Index (CDAI) was evaluated at baseline (before initiating SRL) and 3 months after administration. Clinical remission was defined when CDAI decreased ≥ 2.8. Of the 66 patients treated with SRL, 42 patients with 3 months follow-up, valid CDAI and serum available were enrolled. The ratio of neutrophil counts 1 month after initiating SRL to those at baseline (neutrophil ratio) was also calculated. Serum samples were tested for IL-6 (Human IL-6 Quantikine ELISA Kit, R&D systems), sIL-6R (Human soluble IL-6R alpha Quantikine ELISA Kit, R&D systems) and sgp130 (Human soluble IL-6R alpha Quantikine ELISA Kit, R&D systems) using specific ELISAs according to the manufacturer’s instructions. The statistical analyses were performed with EZR 1.55, and p values less than 0.05 were considered significant.

Results: The median age of patients was 69.0 (IQR: 59.3 - 73.8) years and the median of disease duration was 9.0 (3.0 - 16.0) years. Eighteen (42.9%) patients were biologics and JAKinibs naive. The baseline CDAI was median 16.7 (11.5 - 25.8). When comparing CDAI-remission group (clinical remission: CR) and non-CR group, Patients in the CR group had significantly shorter disease duration (11.5 vs 25.8). When comparing CDAI-remission group (clinical remission: CR) and non-CR group (264.9 vs 234.2 ng/mL, P=0.0592). Univariate logistic regression analysis suggested Biologics and JAKinibs naive (odds ratio (OR) 6.68, p=0.0317), baseline serum sgp130 levels (OR 8.608, P=0.0312) as predictors of CDAI remission treated with SRL at 3 months. Although not significant, neutrophil ratio ≤ 0.8 was associated with achieving remission (OR 6.67, P=0.0537). Univariate logistic regression for neutrophil ratio ≤ 0.8 did not show any relevant factors, including higher baseline serum sgp130 levels (OR 1.25, P=0.782).

Conclusion: A 20% or greater decrease in neutrophil count after 1 month of SRL treatment and a high baseline serum sgp130 level independently predict clinical remission within 3 months.

COMPARING THE ULTRASONOGRAPHIC EVALUATION IN PATIENTS WITH JAPANESE RHEUMATOID ARTHRITIS BETWEEN JAK AND TNF INHIBITOR THERAPY

Y. Kanayama1, A. Nagata, M. Shimotake, F. Miyachi2, K. Fujita2, M. Koyama2, S. Uno2, Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan; 1Toyota Kosei Hospital, Clinical Technology, Toyota, Japan

Background: JAK inhibitor (JAK) and TNF inhibitor (TNF) are the important therapeutic agents for the treatment of rheumatoid arthritis. However, there is still few studies of improvement of ultrasonographic findings in RA treated comparison with JAK and TNF.

Objectives: To evaluate the clinical efficacy of JAK and TNF therapy patients with rheumatoid arthritis (RA) using ultrasonography (US).

Methods: Participants comprised 32 and 39 Japanese RA patients who had recently received JAK (BAR23, PEF9) and TNF. All patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria. Patients underwent clinical and laboratory assessments every 4 weeks from baseline to 24 weeks, and US assessments at baseline, 4, 12 and 24 weeks. Gray scale (GS) and power doppler (PD) signals were scored using a semi-quantitative scale from 0 to 3 at 6 sites (278 synovial sites for comparison tests): bilateral first to fifth metacarpophalangeal (MCP) joints (dorsal recess); first interphalangeal (IP) joints and second to fifth proximal interphalangeal (PIP) joints; (dorsal recess); and the wrist (dorsal radial, median and ulnar). We evaluated the improvement of GS and PD score from baseline to week 24.

Results: In the patients receiving JAK (n=32) and TNF (n=39), the mean age was 54.7 vs 55.1 years old (p=0.871), disease duration was 7.4 vs 6.1 years (p=0.290), the rate of MTX use was 75% vs 87% (p=0.187), the mean MTX dose was 9.9 vs 10.2 mg/w (p=0.813), the rate of ACPA positive was 94% vs 79% (p=0.086), DAS28-ESR was 4.79 vs 4.65 (p=0.435), CDAI was 22.4 vs 19.1 (p=0.239), GS score was 20.8 vs 18.3 (p=0.995) and PD score was 14.0 vs 11.0 (p=0.940). The degree of improvement respective changes in GS and PD score after 4, 12 and 24 weeks were as follows: GS: -5.1 vs -4.3 (p=0.817) and PD: -5.3 vs -2.7 (p=0.855) after 4 weeks, GS: -9.1 vs -6.6 (p=0.880) and PD: -7.9 vs -4.5 (p=0.476) after 12 weeks, GS: -10.4 vs -9.5 (p=0.463) and PD: -8.1 vs -6.7 (p=0.949) after 24 weeks between JAK and TNF (Figures 1 and 2). Next, The improvement rate of respective changes in GS and PD score after 4, 12 and 24 weeks were as follows: GS: -13.7% vs -18.3% (p=0.489) and PD: -20.4% vs -16.5% (p=0.777) after 4 weeks, GS: -29.7% vs -26.0% (p=0.922) and PD: -30.9% vs -30.8% (p=0.890) after 12 weeks, GS: -38.1% vs -36.4% (p=0.567) and PD: -33.4% vs -50.1% (p=0.086) after 24 weeks between JAK and TNF.

Conclusion: The present study provides evidence supporting the JAK and TNF therapy improved similarly the inflammatory synovitis of US findings.
THE EFFECT OF BIOLOGIC AND TARGETED SYNTHETIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS ON WORK PARTICIPATION IN LONGSTANDING RHEUMATOID ARTHRITIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

A. Alunno1, M. L. Marques2,3, L. Falcone4, S. Ramiro2,5, A. Boonen1, Internal Medicine and Nephrology Unit, University of Ukkia, Department of Life, Health and Environmental Sciences, Ukkia, Italy; 5Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; 3Coimbra University Hospital, Department of Rheumatology; Coimbra, Portugal; 6University of Sheffield, Health Economics and Decision Science, School of Health and Related Research, Sheffield, United Kingdom; 3Zuyderland Medical Center, Department of Rheumatology, Helleen, Netherland; 4Maastricht University Medical Center, Department of Rheumatology, Maastricht, Netherlands.

Background: Work participation (WP) is a top priority for people with RA and a determinant of patients’ quality of life. Therefore, assessing the effect of interventions on WP outcomes is important.

Objectives: To review the effect of b/tsDMARDs on employment status (ES), sick leave (SL) and presenteeism in patients with longstanding RA.

Methods: A systematic review updated to October 2021 was conducted using the PICOT framework (Figure 1). Two researchers independently screened abstracts, then full texts were reviewed to determine eligibility. Data from eligible articles were extracted. Heterogeneity and insufficient reporting of data precluded meta-analysis.

Results: We included 42 studies: 16 randomized controlled trials (RCT) and 26 longitudinal observational studies (OBS). All studies were conducted with background therapy with csDMARDs, 33 (78%) in csDMARD-IR patients. RCTs provided short-term data only (<24 weeks) which have limited relevance for WP outcome domains such as ES. OBS reported long-term data (≤5 years), albeit imposing challenges due to lack of random allocation to interventions and often lack of a comparator. Future studies should consider existing guidance on the assessment of WP outcome domains to allow pooling and meta-analysis.

Conclusion: Short-term data from RCTs with background therapy with csDMARDs showed adding b/tsDMARDs was more effective than PBO in improving presenteeism. However, data on SL are conflicting and the positive results come from OBS without comparator. Future studies should consider existing guidance on the assessment of WP outcome domains to allow pooling and meta-analysis.

BELIEFS AND ADHERENCE IN RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGIC DRUGS

E. Hannech1,2, S. Boussaid3,4, S. Rekik4,5, J. Smellial4,5, S. Rahmouni4,5, H. Ajmani1, H. Sahli2, M. Elleuch2,6, R. Dharhi2,6, I. Gharsallah4,5, P.3

1Rheumatology Department, La Rabta Hospital, Tunis, Tunisia; 2Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, Tunisia; 3Rheumatology Department, Military Hospital of Tunis, Tunis, Tunisia

Background: Patients with chronic rheumatic diseases play an important role in their disease management. Adherence to their long-term therapies may depend on their therapeutic beliefs. [1]

Objectives: The purpose of our study was to investigate the relationship between beliefs and adherence among patients with rheumatoid arthritis (RA) on biologic therapies (bDMARDs).

Methods: We conducted a multi-center cross-sectional study, including patients with RA fulfilling the ACR/EULAR 2010 criteria. All patients were on bDMARD. Sociodemographic, clinical, biological, and therapeutic data were collected. Patients were interviewed about their medication beliefs using the Beliefs About Medicines Questionnaire (BMQ) and about their therapeutic adherence.

Results: There were 75 RA patients: 60 female (80%) and 15 males (20%). The sex ratio was about 0.25. Their mean age was 56.92±9.06 years [34-80]. Thirty-three percent of patients were illiterate. Twenty patients were employed (15%). The mean disease activity score (DAS28 CRP) was 3.94±1.32 [12.71-75]. Fifteen patients (20%) had high disease activity, 11% had low activity, and 19% were in remission. The mean duration of the current bDMARD was 37.17±39.44 months [4-248]. The mean Specific Necessity score was 21.0±8.38 [5-25] for adherent patients and 13.5±7.54 [5-19] for non-adherent patients.

The mean Specific Concerns score was 10.07±3.13 [5-15] for adherent patients and 15.2±8.22 [5-20] for non-adherent patients. A statistically significant association was found between Specific Concerns beliefs and adherence behavior (p=0.009) and between Specific Concerns beliefs and adherence behavior (p=0.003). No statistically significant association was noted between general beliefs (General Harm and General Overuse) and adherence behavior (p=0.4 and p=0.6 respectively).

Conclusion: Beliefs about therapeutic were identified as a key factor of adherence among rheumatic disease patients. Practitioners should detect negative patient beliefs and perceptions earlier to prevent nonadherence.

A PROSPECTIVE OBSERVATIONAL STUDY TO ASSESS THE REAL-WORLD EFFECTIVENESS OF GOLIMUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND PREVIOUSLY TREATED WITH INITIAL TNF-A INHIBITIVE THERAPY

C. Gaujoux-Viala1, J. Sellam2, F. Tubach1, N. Harid2, B. Combe1, R. M. Filipo1

1CHU Nîmes, IDESP UMR UA11 INSERM - Université de Montpellier, Montpellier, France; 2Hôpital Saint-Antoine, Paris 12, Paris, France; 3CHU de Montpellier, Hôpital Lapeyronie, Montpellier, France; 4MSD, France, Puteaux, France; 5CHU La Pitié-Salpêtrière, Paris 13, Paris, France; 6CHRU de Lille, Lille, France

Background: TNF inhibitor (TNFi) treatment is standard for RA patients even though many reasons may lead to TNFi therapy failures such as lack of effectiveness, patient dissatisfaction or limited therapy adherence, or even safety. As a consequence, patients may switch to a different TNFi. The efficacy of golimumab (GLM) in RA patients may be associated with an adequate response to TNFi was demonstrated in the Go-AFTER phase III clinical trial.

Objectives: The objectives of the present Go-BEYOND study were to provide real-world data to evaluate disease activity and treatment persistence with GLM as a second line TNFi therapy in RA patients over a one-year follow-up.

Methods: Go-BEYOND is an observational French multicenter prospective cohort study. All consecutive patients over 18 years of age with a diagnosis of active RA were eligible at the time of initial GLM prescription. To be included, patients had to be previously treated with only 1 TNFi (discontinued for any reason) other than GLM. Patients were ineligible if they had been previously treated with other "non-TNFi" biologics or more than one TNFi.

The study’s primary outcome was the percentage of RA patients with a Disease Activity Score (DAS28-CRP score) ≤ 3.2 at the 6-month visit (M6 visit). Patients who permanently discontinued their treatment over the 1-year follow-up were considered as non-responders. The secondary outcomes were analyzed descriptively and included (but not limited) to DAS28-CRP score at 12-month visit (M12 visit), EULAR criteria assessment, treatment persistence analysis, HAQ score, RAPID3 score, and patient acceptable symptom state and satisfaction with the injection. The study was approved by a French Ethics Committee in July 2020.

Results: A total of 128 patients (72.7% female, median age 58.2 years, and duration of RA 13.2 ± 11.4 years) met the inclusion criteria. Anti-CPP antibodies and rheumatoid factors were present in 80 (62.5%) and 81 (63.3%) patients, respectively. In the majority, the initial TNFi was etanercept (n=88, 68.8%), then adalimumab (n=25, 19.5%). The reasons for switching to GLM were secondary non-response (i.e., lack of effectiveness after an initial response to the treatment) or for 75 (58.6%) patients, then safety (n=22, 17%), primary non-response (n=21, 16.4%), and other personal or medical reasons (n=10, 7.8%).

At the M6 and M12 visits, a small number of patients, 27 (21.1%) and 48 (37.5%) had respectively permanently discontinued their GLM treatment and were considered as non-responders. At the M6 visit, 48 patients over the 128 included (37.5%) had a DAS28-CRP < 3.2 and 35% (< 2.6). At M12 visit, 41 (32%) patients had a DAS28-CRP < 3.2 and 31 (24.2%) < 2.6. According to EULAR response criteria thresholds, 49 (38.3%) and 45 (35.2%) patients had a good or moderate response to GLM at the M6 and M12 visits.

Conclusion: The Go-BEYOND study confirms that in RA, a non-response to a first TNFi does not exclude a response to GLM as a second-line biologic in a substantial proportion of patients in real-life settings.

THE PARADIGM OF DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: SUBTYPES AND EARLY IDENTIFICATION

M. Novella-Navarro1, V. Ruiz1, G. Torres Ortiz2, C. A. Chacur2, C. Tornero1, A. Vilalba1, R. Sammarti1, C. Plasencia1, A. Balsa1, 1Hospital Universitario La Paz, Rheumatology, Madrid, Spain; 2Hospital Clinic, Rheumatology, Barcelona, Spain

Background: Difficult-to-treat rheumatoid arthritis (D2TRA) is an emerging concern for rheumatologists. Multiple failures to biologic or targeted specific disease modifying antirheumatic drugs (b/tsDMARDs) may be due to multi-drug inefficacy or difficulties in the optimum management of treatments. In these cases, adverse events, comorbidities, poor adherence, amongst others. In a previous study we identified that younger patients with erosive disease and especially the early absence of clinical response to the first b/tsDMARDs were associated to multiple drug inefficacy but it is worth knowing whether these factors are the same for those patients who receive multiple b/tsDMARDs due to causes other than inefficacy.

Objectives: i) To describe the characteristics of a cohort of D2TRA patients in clinical practice. ii) To analyze the differences between D2TRA due to inefficacy vs D2TRA to other causes. iii) To compare the different subtypes of D2TRA with non-D2TRA.

Methods: This study involved patients with D2TRA from La Paz Hospital and Clinika Hospital between 2015 and 2021. D2TRA group included patients who had received ≥3 b/tsDMARDs due to inefficacy (D2TRA-inefficacy) or due to adverse events, poor adherence, contraindications, comorbidities, drug-intolerance etc. (D2TRA-other causes). Patients who achieved low disease activity or remission (by DAS28) with the 1st bDMARD and remained with the same drug for at least 5 years were non-D2TRA patients. For all patients, demographic, clinical characteristics and laboratory parameters were assessed at baseline visit (prior to start the first b/tsDMARD) and after 6 months. Descriptive analysis was performed and bivariate logistic regression models were assembled. P<0.05 was considered statistically significant. Odds Ratio (OR) and Confidence Intervals (CI) were calculated. IBM SPSS 21.0

Results: In total, 253 patients were included, 131 were non-D2TRA and 122 D2TRA [86 (70.5%) D2TRA-inefficacy and 36 (29.5%) D2TRA-other causes]. Comparison between both groups of D2TRA patients: no differences were found in gender, age at b/tsDMARD starting or age at RA diagnosis were found and neither between socioeconomic status, frequency of anxiety-depression or other comorbidities. Patients D2TRA-other causes had less extra-articular manifestations
than D2TRA-inefficacy (8.3% vs 26.7%; p=0.02); lower values of DAS28 at starting 1st b/tsDMARD (4.9±1.4 vs 5.7±1.2; p<0.01), and also at 6 months of treatment (3.5±1.5 vs 4.5±1.5; p=0.02) than those with D2TRA-inefficacy.2) Comparison between Non-D2TRA patients and D2TRA-other causes: no differences in sociodemographic characteristics were found and neither differences in baseline disease activity, only differences in DAS28 at 6 months were observed, being higher D2TRA-other causes than in non-D2TRA (3.5±1.5 vs 2.9±3.0; p<0.03). Binormal distribution analysis showed that DAS28-6m was slightly associated with D2TRA-other causes (OR=1.45 CI95%: 1.11-1.21).
Conclusion: In this cohort, around 3 out of 10 D2TRA patients dropped out multiple b/tsDMARDs for reasons other than inefficacy. In contrast to D2TRA-inefficacy, patients with D2TRA-other causes are indistinguishable from non-D2TRA patients at baseline, indicating that patients with D2TRA-other causes does not seem predictable in the early stages of treatment with b/tsDMARDs, unlike what occurs with multidrug inefficacy.

AB0369 EFFECTS OF SWITCHING FROM ETANERCPT ORIGINATOR TO ETANERCPT BIOISIMILAR ON DISEASE ACTIVITY, PHYSICAL FUNCTION, AND PATIENT-REPORTED OUTCOME REGARDING A SELF-INJECTION DEVICE IN PATIENTS WITH WELL-CONTROLLED RHEUMATOID ARTHRITIS

Y. Hirano1, Y. Ono1, Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan

Background: Although biological drugs have dramatically changed and improved the outcome of patients with rheumatoid arthritis (RA), a lot of unresolved problems still exist. Although comorbid by which enough treatment drugs cannot be prescribed or RA patients refractory to biological agents are representatives, financial difficulty is another representative. There are RA patients who hesitate biological treatment or treatment with Janus-kinase inhibitor due to financial difficulty. Although biosimilar disease-modifying anti-rheumatic drugs (DMARDs) are promising treatment options for such patients, real-world clinical experiences are still lacking in respect to exchanging from biological originator DMARDs to biosimilar DMARDs.

Objectives: This retrospective study investigated the effects of switching from etanercept originator (ETN-OR) to ETN-biosimilar (ETN-BS: LBEC0101 developed by LG Chem) on disease activity, physical function, and patient-reported outcome (PRO) regarding a self-injection device in patients with well-controlled RA.

Methods: Data from the Toyohashi RA Database (TRAD) was used, which is a collection of single-center retrospective data. We retrospectively investigated disease activity, modified health assessment questionnaire (mHAQ), and patient characteristics in 42 RA patients that switched from ETN-OR to ETN-BS at least 6 months prior. Patients were also requested to answer the Toyohashi Self-Injection Assessment Questionnaire (T-SAQ), originally designed to assess PRO. T-SAQ consisted of 18 questions about self-injection device such as burden, learning, pain, convenience, handling and so on. Best was 0 and worst was 4 in each question and mean score of 18 questions was called total T-SAQ score.

Results: All the patients were female. The mean age, RA duration, and ETN-OR treatment duration were 63.1 years, 18.3 years, and 3107 days, respectively. Mean disease activity and mean mHAQ after switching were as follows (baseline-3 months-b): DAS28-3CRP (1.86-2.00-2.03), SDAI (4.3-5.0-5.3), and mHAQ (0.43-0.44-0.46). SDAI after 6 months was significantly elevated compared to baseline. Among each parameter, tender joints count at 3 months and patients’ global assessment at 6 months after switching are significantly increased compared to baseline (Table 1). Other parameters such as swollen joint counts, physician global assessment and CRP were not significantly changed. Total T-SAQ scores before and after switching were 1.3 and 1.1 (p<0.01), respectively. Ease of use, mental tension, and pain were especially improved after switching to ETN-BS.

Conclusion: Switching from ETN-OR to ETN-BS worsened disease activity in well-controlled RA patients in our real-world clinical practice due to not objective findings, but subjective complaints by RA patient. We thought that nocebo effect was one of the reasons to explain the results. On the other hand, the PRO regarding the injection device was improved. This improvement may be due to Finer needle of ETN-BS (ETN-OR: 27G, ETN-OR: 29G).

AB0369 CORRELATION OF THE FIRST LATERAL FLOW-BASED POINT OF CARE TEST TO QUANTIFY INFlixIMAB AND ANTI-INFlixIMAB ANTIBODIES IN A FINGER PRICK SAMPLE WITH THE REFERENCE ELISA TECHNIQUE

M. B. Ruiz-Angelillo1, J. Pascual1, L. Del Rio1, A. Urgoitia2, C. Balo-Farto2, C. Fernández-López3, A. Mera Varela3, F. J. de-Toro-Santos3, D. Nagore1, A. Ametazzaurra1,1, Progenika Biopharma - Grifols, Research and Development, Derio, Spain,2 Hospital Clínico Universitario de Santiago, Servicio Reumatología, Santiago de Compostela, Spain,3 Complexo Hospitalario Universitario A Coruña, Servicio Reumatología, A Coruña, Spain

Background: Current techniques to monitor clinical response may require several days and centralised facilities, which may cause delays in effective therapeutic decisions. Therefore, the use of a rapid decentralized test will facilitate patient management and improve patient care.

Objectives: The goal of this study was to validate the use of capillary blood in a real point-of-care (POC) setting for rheumatic patients under infliximab treatment by using Promonitor Quick lateral flow (LF) tests. Results were compared to the Promonitor ELISA reference technique in serum samples used by centralised laboratories.

Methods: A prospective, observational study was designed to evaluate the performance of a rapid LF test (Promonitor Quick IFX, Progenika, Spain). 160 infliximab-treated rheumatology consecutive patients (400 samples) were recruited in two hospitals in Galicia, Spain. Prior to the infusion, a finger prick sample was obtained and analysed. Anti-infliximab antibodies were also determined with Promonitor Quick ANTI-IFX1. Results were read with the automated portable PQreader instrument. Additionally, a serum sample was collected for subsequent comparative analysis with either LF or ELISA tests.

Qualitative (positive (PPA) and negative (NPA) agreements) and quantitative (Pearson correlation and bias) performance of the LF test was compared to ELISA, as well as between different specimens following CLSI EP09-A3.

Results: Overall agreement between Promonitor Quick IFX finger prick and ELISA test was 91% (88% PPA; 100% NPA). The quantitative comparison showed a good correlation (Pearson correlation coefficient: 0.85 and observed bias: 25%) (Table 1).

Similar results were also observed when serum was used with either the LF or the ELISA tests (98% overall agreement, 0.91 correlation coefficient; 6% bias) (Table 1). Overall agreements for visual and automated (PQreader) interpretations with Promonitor Quick anti-IFX were 99% and 100% for finger prick and serum specimens, respectively (Table 1).

**Conclusion:** Promonitor Quick can be used to reliably quantify infliximab in capillary blood samples and results are comparable to those obtained with the reference ELISA technique. The use of the rapid POCT test with finger prick will allow clinicians to monitor their patients in a fully decentralized model to aid in the decision-making process. PQreader is a sensitive portable equipment to report drug as well as antibody levels in the patient samples.

**COMPARISON OF A NEW RANDOM-ACCESS SOLUTION FOR THERAPEUTIC DRUG MONITORING OF ADALIMUMAB TO THE REFERENCE ELISA TEST**

A. Ruiz del Aguila 1, R. El Hams2, M. Moneo1, M. B. Ruiz-Ardógiel, D. Nagore3, Progenika Biopharma SA, POS, Deno, Spain; Progenika Biopharma SA, POS, Deno, Spain; Progenika Biopharma SA, R&D, Deno, Spain

**Background:** Despite numerous studies, Therapeutic Drug Monitoring (TDM) of biological therapies is still debated partly motivated by the accessibility to a ready-to-use monostest device capable of delivering accurate results in a timely manner without the burden of sample batching, therefore allowing immediate decision making.

**Objectives:** We aimed at comparing the new Chorus Promonitor Adalimumab monostest running in the fully automated random-access Chorus TRIO system to the reference ELISA test Promonitor ADL run in a Triturus system.

**Methods:** Chorus Promonitor Adalimumab (Diesse Diagnostica Danese, Italy) is an immunoassay kit for the automated quantitative detection of adalimumab (ADL) in human serum using a ready-to-use disposable monostest device applied on the Chorus TRIO (Diesse Diagnostica Danese, Italy) instrument, a random-access single test multiparametric system for immuno-colorimetric assays. The new device implements the same specific reagents as in the reference ELISA test Promonitor ADL (Progenika, Spain) run in a Triturus (Grifols, Spain) system, therefore ensuring the same analytical specificity and applicability for patient monitoring previously demonstrated with the predicate ELISA. The new monostest device contains all the reagents necessary to perform the assay, and a lot-specific master curve method is used for calibrating. The comparison was performed in a set of 53 serum samples from patients under ADL therapy that covered the entire drug trough concentrations found in clinical practice (up to 30 μg/mL). Pearson’s correlation, Bland-Altman and Passing-Bablok regression analysis were used to study the association and quantitative comparison between the methods.

**Results:** Time to first result for the Chorus Promonitor Adalimumab test was 2 hours and 45 min minutes and after this a new result was delivered every 30 seconds. Positive and negative percent agreements between both tests were 100%. A high correlation between both tests was found (coefficient of correlation of 0.959, p<0.01). The Passing-Bablok regression analysis determined an excellent comparability of both data sets with a slope of 1.032 (0.952-1.129) with an intercept of -0.428 (-1.292-0.053), demonstrating a perfect linear correlation.

**Conclusion:** The Chorus Promonitor Adalimumab represents the first evolution of the gold-standard Promonitor ELISA technology into a monostest random-access technology that enables quick turnaround time to facilitate TDM for ADL and aid immediate decision making.

**CLINICAL SIGNIFICANCE OF GALECTIN-3 IN PATIENTS WITH RHEUMATOID ARTHRITIS BEFORE THE APPOINTMENT AND AFTER 12 MONTHS OF TREATMENT WITH BIOLOGICAL DRUGS (PRELIMINARY DATA).**

Y. Gorbunova1, T. Popkova1, I. Kirillova1, T. Panafidina1, M. Diatroptov2, E. Nasonov2, 1VA Nasonova Research Institute of Rheumatology, of Systemic Rheumatic Diseases, Moscow, Russian Federation; 2VA Nasonova Research Institute of Rheumatology, of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation; 3VA Nasonova Research Institute of Rheumatology, Scientific, Moscow, Russian Federation

**Background:** The role of galectin-3, a pro-inflammatory mediator involved in autoimmune disorders in patients with rheumatoid arthritis (RA), is discussed in the literature.

**Objectives:** To clarify the relationship of clinical and laboratory manifestations of RA with galectin-3 in the effectiveness of basic anti-inflammatory therapy and after 12 months of treatment with biological drugs.

**Methods:** The study included 47 pts (39 women /8 men) with RA, 51 [39.0; 63.0] years old. Pts were seropositive for IgM RF (79%) and anti-CCP (62%), with highly active RA (DAS28 5.2; 6.4]; SDAI 35.0 [29.1; 43.6], CDAI 34.0 [25.0; 43.0] scores, and median disease duration of 4.0 [3.0,14.0] years. All patients with RA had a history of insufficient effect or intolerance to two or more basic anti-inflammatory drugs (DMARDs). At the time of inclusion in the study, patients received DMARDs: 44% of patients received methotrexate (median dose - 15 (15; 20) mg /week), 35% - leflunomide (20 mg/day), 9.3% - sulfasalazine (2000 mg/day), 7% - hydroxychloroquine (200 mg/day), 67.4% - glucocorticoids (5 (4.8) mg /day). Patients did not receive biological therapy at the time of inclusion in the study. Due to lack of efficacy or intolerance, patients with RA (n=21) were prescribed biological therapy: 52.4% - anti-B-cell therapy, 38% - TNF-alpha inhibitors, 9.6% - IL-6 inhibitors. The control group consisted of 20 age-matched donors without rheumatic diseases. Galectin 3 concentration was determined by ELISA (Bender MedSystems GmbH, Biocenter, Vienna Austria). The upper limit of normal when testing 20 sera from healthy donors was 5.32 mg/ml, corresponding to the 95th percentile.
**Results:** The serum level of galectin-3 in RA patients (n=47) and in the control group (n=20) did not differ statistically significantly (4.27 [2.3:5.26] ng/ml vs 3.83 [2.57:4.11] ng/ml (p=0.2). In the whole group of RA patients (n=47) with inefficacy (insufficient effect) of basic anti-inflammatory therapy, correlations were noted between the level of galectin-3 and age (R=0.34; p=0.02), BMI (R=0.36; p=0.02), SDAI (R=0.33; p=0.02), CDAI (R=0.31; p=0.03). RA patients were divided into 2 groups: group I (n=27) - patients with galectin-3 5.32 ng/ml; II (n=20) - less than 5.32 ng/ml. Group I patients were older in age (59.9 [46.67] years vs 42.5 [38.5] years), had higher activity according to SDAI (38.2 [30; 48.4] vs 29.7 [26.6; 40]), CDAI (35.0 [29; 43] vs 270 [23;38]) (p<0.05 in all cases). In the group of patients (n=21) who received combination therapy (DMARDs + biological therapy) for 12 months, there was a significant decrease in clinical and laboratory activity, IgM RF levels (p<0.05 in all cases). The serum level of galectin-3 in RA patients (n=21) decreased by 19% statistically insignificantly after 12 months of combination therapy (4.24 [2.85;1] ng/ml vs 3.42 [2.56;4.36] ng/ml (p=0.2).

</table>

*p <0.05 reliability of differences in indicators before and after 12 months of combination therapy (Wilcoxon). Δ,% - the difference in indicators between the groups by the 12th month of combination therapy.

**Conclusion:** There were no differences in the level of galectin-3 in patients with RA and with the inefficacy of basic anti-inflammatory therapy and in the control group. At the same time, the association of this marker with RA activity (according to the SDAI, CDAI indices) does not exclude its role in the development of clinical manifestations of rheumatoid arthritis.

**BIOLOGIC THERAPY IN CHILDREN WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS ACCORDING TO THE FEDERAL REGISTER OF THE RUSSIAN FEDERATION.**

M. Botova1, A. Alekseeva1, T. Dvoryakovskaya1, R. Denisova, A. Mamutova1, K. Isaeva1, A. Chomakhidze1, O. Lomakina1, A. Fetisova1, M. Gautier1, K. Chibsibova1, E. Krekhova1, N. Kondratyeva1, N. Kriulina, M. Botova1, E. Alexeeva1, T. Dvoryakovskaya1, R. Denisova1, A. Mamutova1, K. Isaeva1, A. Chomakhidze1, O. Lomakina1, A. Fetisova1, M. Gautier1, K. Chibsibova1, E. Krekhova1, N. Kondratyeva1, National Medical Research Center of Children’s Health, Rheumatology, Moscow, Russian Federation;3 Sechenov First Moscow State Medical University; Pediatric, Moscow, Russian Federation

**Background:** Systemic juvenile idiopathic arthritis (sJIA) is the rarest variant of juvenile idiopathic arthritis, characterized by severe course, frequent exacerbations, the development of life-threatening extra-articular manifestations and complications, which requires the use of expensive medications and frequent hospitalizations of patients. In the Russian Federation, the provision of medicines to patients with sJIA is carried out at the expense of the federal budget, in this regard, the Federal Register of sJIA was created in 2018.

**Objectives:** To analyse the persistence and efficacy of ABA in monotherapy vs. combination with conventional DMARDs.

**Methods:** Retrospective observational study of a cohort of RA patients under treatment with ABA reviewed in Rheumatology consultations at Vinograd Macarena University Hospital, from 2010 to 2020. The statistical software was used. The study was conducted in accordance with the standards of the CEIC.

**Results:** 69 patients were included, 80% female. The average age was 63 (53-63) years. RA evolution time was 10 (4-16) years. 92% RF +, 86% ACPA + and 84% double +, 81% with erosions and 47% had extra-articular manifestations: 16 ILD, 10 Dry Syndrome and 9 Rheumatoid Nodules. 96% had relevant comorbidities such as Osteoporosis 33, Hypertension 31, dyslipidemia 26, Fibromyalgia 16, Depression 14 or Diabetes 9. Prior to ABA start, all were treated with NSAIDs, GC and conventional DMARDs; 32% with one conventional DMARDS, 31% with two and 37% with three or more; The conventional DMARDS used were MTX, LFN 45%, HDQ 13%, CYA 13%, Gold salts 9% and SSZ 7%, 21% were previously treated with biologic DMARDs; 44% with one biologic DMARDS and 39% with two or more biologic DMARDs. The most commonly used biologic DMARDs were ETA 63.3%, ADA 30.6%, IL-6 inhibitors 20.4% and RTX 24.3%. Of the 29% who started ABA as a first-line, 8% were started on anti-TNF therapies, remaining 2% and 12% adverse events (safety, haematological and infections).

**Conclusion:** The number of patients receiving biologic therapy with sJIA in the Russian Federation has increased, which is due to the natural growth of the disease and more affordable provision of patients with sJIA by the state.

**ABACETEN IN MONOTHERAPY OR IN COMBINATION WITH CONVENTIONAL DISEASE-MODIFYING DRUGS: TREATMENT PERSISTENCE IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS.**

P. Muñoz Reinoso1, I. García Hernández2, B. Hernández-Cruz3, J. J. Pérez Vanegas4, Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain

**Background:** Abaceten is a selective T-Cell co-stimulation modulator indicated for the treatment of moderate to severe active rheumatoid arthritis in patients with inadequate response to previous treatment. It is used in routine clinical practice in combination with other conventional synthetic disease-modifying drugs, with some records showing worse results when used in monotherapy.

**Objectives:** To analyse the persistence and efficacy of ABA in monotherapy vs. combined with conventional DMARDs. To determine the prescription patterns and clinical characteristics of patients who have received at least one dose of the drug.

**Methods:** Retrospective observational study of a cohort of RA patients under treatment with ABA reviewed in Rheumatology consultations at Vinograd Macarena University Hospital, from 2010 to 2020. STA statistical software was used.

**Results:** 69 patients were included, 80% female. The average age was 63 (53-63) years. RA evolution time was 10 (4-16) years. 92% RF +, 86% ACPA + and 84% double +, 81% with erosions and 47% had extra-articular manifestations: 16 ILD, 10 Dry Syndrome and 9 Rheumatoid Nodules. 96% had relevant comorbidities such as Osteoporosis 33, Hypertension 31, dyslipidemia 26, Fibromyalgia 16, Depression 14 or Diabetes 9. **DOI:** 10.1136/annrheumdis-2022-eular.4687
Background: Limited data have been published on tolerance and efficacy of biotherapy in elderly patients with rheumatoid arthritis (RA) [1]

Objectives: To assess in real life the efficacy and safety of biological treatments in elderly patients with rheumatoid arthritis (RA) and to identify predictive factors for a good therapeutic response.

Methods: A cross-sectional observational study was conducted, the main data source was the Moroccan registry of biological therapies in rheumatic diseases (RBSMR registry). The duration of this study was 12 months. Patients included were all elderly patients (age > 65 years old), presenting RA, according to ACR / EULAR classification criteria for RA 2010. Demographic and clinical characteristics, disease activity, radiographic damage and functional ability have been compared between two groups of patients: those with response to biotherapy and those without response to biotherapy. Clinical and biological tolerance of biotherapy was assessed at 12 months of follow-up in all patients.

Results: Among 224 patients included in the RBSMR registry, 23 patients were over 65 years. The average age of patients was 69.57 years ± 4.33 with a sex ratio women/man: 4.75. The mean duration of the disease was 964.79 weeks ± 588.8. RA was seropositive in 87% of patients, with positive anti-cyclic citrullinated antibodies (ACPs) in 60.9%. It was erosive in 83.3%, with carpitis in 50% of our cases. Concerning biological features, the mean erythrocyte sedimentation rate (ESR) was 55.05 ± 26 and the mean C-reactive protein (CRP) was 26.79 ng/ml ± 18. The average initial disease activity score 28-ESR (DAS 28 ESR) was 4.08 ± 1.60. The average 12-month DAS was 2.67 ± 1.49. The Health Assessment Questionnaire (HAQ) average was 1.22. Concerning the treatment taken, 8.7% of patients were under Etanercept, 4.3% were under Golimumab, 69.6% were under Rituximab and 17.4% of patients received Tocilizumab. The analysis did not reveal any statistically significant difference between the two groups regarding demographic, clinical characteristics, disease activity, radiographic damage, biological feature and therapeutic data. 78.3% of our patients had a good tolerance to biotherapies, on the other hand 21.7% had presented undesirable effects.

Conclusion: RA is a common and even more common disease in the elderly, our study as well as the literature data confirms the efficacy of biotherapy and its good tolerance in our Moroccan patients with RA. It represents a therapeutic alternative of choice. Our results further encourage its use in our Moroccan context.

Table 1. Baseline parameters [Medians (IQR) unless otherwise specified]

In addition, there is a higher frequency of severe infections in the HGGS group. Studies with larger sample sizes are needed to confirm these results.

References:

Disclosure of Interests: None declared

Background: The immunoglobulin levels of TNFα inhibitors (TNFi) and their effect on their efficacy can depend on the underlying disease. To date, no studies were performed to directly compare this relation between different groups of immune-mediated diseases.

Methods: 20 patients with RA and 53 patients with IBD (38 (30.9%) with CD and 15 (12.2%) with UC) were included for 17 [10; 27] months. 26 (35.6%) of them received infliximab (INX) infusions, 23 (31.5%) – adalimumab (ADM) and 24 (32.9%) – certolizumab pegol (CZP). The following criteria were used for the evaluation of the response to TNFi: EULAR criteria for RA, decrease of CDAI for CD and Mayo Score for UC. Treatment level of INX and the level of anti-drug antibodies (ADAb) were measured in the serum samples drawn directly before the planned drug administration.

Results: The mean trough level in both groups was determined as follows: 10 µg/mL INX in RA group and 5 µg/mL for INX in IBD group, 5 µg/mL for ADM2, and 20 µg/mL for CZP. Re: 17 (85%) patients with RA and 35 (66%) patients with IBD responded well to the treatment. Loss of response to the treatment developed in 3 (15%) cases of RA and 18 (34%) cases of IBD (p=0.05). The median trough level of INX was 0.22 [0.17; 0.8] µg/mL in RA and 1.58 [0.79; 3.87] µg/mL in IBD. The median trough level of ADM was 5.45 [1.05; 12.07] µg/mL in RA and 11.77 [5.23; 13.01] µg/mL in IBD. The tendency toward lower median trough level of CZP in IBD was observed (28.17 [20.69; 42.95] µg/mL in IBD vs 16.92 [8.31; 30.96] µg/mL in RA (p=0.09)). Low trough level of TNFi was found in 11 (55%) patients with RA and 27 (50.9%) patients with IBD. It did not differ significantly either between the diseases or between the TNFi (p>0.05). Loss of response was associated with low trough level of TNFi in all 3 cases of RA and in IBD – in 9 (50%) patients (p>0.05). Positive ADAb were detected in 6 (30%) patients with RA and 8 (15.1%) patients with IBD. The rate of positive ADAb was comparable between different TNFi and immune-mediated diseases (p>0.05). A tendency toward lower prevalence of ADAb to ADM in CD than in RA was observed.

**Conclusion:** A significantly higher percentage of HGGS is observed in patients with AAV treated with RTX compared to patients with RA. The development of HGGS seems to be influenced by age at diagnosis and at the start of treatment, years of disease evolution and low levels of IgG4's prior to the start of treatment. In addition, there is a higher frequency of severe infections in the HGGS group. Studies with larger sample sizes are needed to confirm these results.

Disclosure of Interests: None declared

Background: The immunoglobulin levels of TNFα inhibitors (TNFi) and their effect on their efficacy can depend on the underlying disease. To date, no studies were performed to directly compare this relation between different groups of immune-mediated diseases.

Methods: To study the characteristics of patients with AAV on RTX treatment and to analyze the factors associated with HGGS, as well as to compare them with patients with rheumatoid arthritis (RA) on the same treatment.

Methods: Retrospective descriptive study of patients with a diagnosis of AA V or RA treated with RTX who had immunoglobulin levels prior to treatment and after each cycle were included. Demographic, clinical and analytical variables were analyzed. Patients who developed HGGS versus those who did not were compared using Student's t and Mann-Whitney U for continuous variables and chi-square for categorical variables.

Results: Ninety-five patients were included, 19 (20%) with AA V and 76 (80%) with RA. Of the 34 (35.8%) who developed HGGS, 19 had RA (25%) and 15 AA V (79%) (p<0.001). The 6 patients who presented with severe HGGS (IgG<500) belonged to the AAV group. The overall sample was divided into patients with HGGS and patients without (Table 1). Significant differences were obtained in relation to diagnosis (p<0.001), age at diagnosis and at the start of treatment, being higher in patients with HGGS (p<0.005 and p 0.001) and years of disease evolution (p<0.005). Patients with HGGS had a lower mean baseline IgG (p<0.001). The HGGS group had more severe infections (infections requiring admission) (p<0.005) and the time from RTX administration to the development of infection was shorter in this group.
Disclosure of Interests: BMD changes were not associated with age, RA duration and disease activity.

Methods: Bone mineral density (BMD) in women with rheumatoid arthritis (RA) and those with RA without biological therapy.

Results: There were no differences between patients RIT+ and RIT- in age (median 58 [53; 63] years and 52 [50; 69] years, p=0.05), RA duration (median –16 [4; 21] year and 9 [3; 11] year, p=0.09) and DAS28 ESR (median – 5.18 [4.3; 6.25] and 5.71 [4.66; 5.94]). The percentage BMD changes from baseline in lumbar spine, femur neck and total hip using dual energy x-ray absorptiometry (DXA, Hologic 4500A) at baseline and after 1 year. RA activity was evaluated by disease activity score using 28 joint counts and erythrocyte sedimentation rate (DAS28 ESR). Nonparametric statistic tests were performed.

Results: There were no differences between patients RIT+ and RIT- in age (median –51 [53; 63] years and 52 [50; 69] years, p=0.09), RA duration (median –16 [4; 21] year and 9 [3; 11] year, p=0.09) and DAS28 ESR (median – 5.18 [4.3; 6.25] and 5.71 [4.66; 5.94]). The percentage BMD changes from baseline in lumbar spine, femoral neck and total hip were 0.2% [-3.9%; 4.0%], -1.8% [-6.2%; 2.4%] and -0.3% [-3.5%; 4.5%], respectively, in patients RIT+ and -1.0% [-4.9%; 3.3%], -2.5% [-5.8%; -0.4%], -1.7% [-4.3%; 4.2%], respectively, in persons RIT-. There were no differences in BMD changes in the pair matching test both patients RIT+ and RIT-. No correlations between BMD changes with age, RA duration and DAS28 ESR were found.

Conclusion: RIT had no effect on BMD in women with RA after 1 year therapy. BMD changes were not associated with age, RA duration and disease activity.

AB0378

EFFECT OF RITUXIMAB ON BONE MINERAL DENSITY IN WOMEN WITH RHEUMATOID ARTHRITIS

O. Dobrovolskaya1, N. Demin1, N. Topeytsys2, A. Sorokina3, D. Kusevich4, O. Nikitinskaya1.
1V. A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation; 2V. A. Nasonova Research Institute of Rheumatology, Department of Osteoarthritis, Moscow, Russian Federation

Objectives: To compare the effect of rituximab (RIT) treatment on bone mineral density (BMD) in women with rheumatoid arthritis (RA) and those with RA without biological therapy.

Methods: 78 women over 40 years with confirmed RA according to ACR/EULAR criteria (2010) were enrolled in the study: 48 patients treated with RIT and methotrexate (RIT+). 30 women received only methotrexate (RIT-). The patients did not differ in the glucocorticoid therapy duration and cumulative dose. BMD was determined in the lumbar spine, femur neck and total hip using dual energy x-ray absorptiometry (DXA, Hologic 4500A) at baseline and after 1 year. RA activity was evaluated by disease activity score using 28 joint counts and erythrocyte sedimentation rate (DAS28 ESR). Nonparametric statistic tests were performed.

Results: There were no differences between patients RIT+ and RIT- in age (median –51 [53; 63] years and 52 [50; 69] years, p=0.09), RA duration (median –16 [4; 21] year and 9 [3; 11] year, p=0.09) and DAS28 ESR (median – 5.18 [4.3; 6.25] and 5.71 [4.66; 5.94]). The percentage BMD changes from baseline in lumbar spine, femoral neck and total hip were 0.2% [-3.9%; 4.0%], -1.8% [-6.2%; 2.4%] and -0.3% [-3.5%; 4.5%], respectively, in patients RIT+ and -1.0% [-4.9%; 3.3%], -2.5% [-5.8%; -0.4%], -1.7% [-4.3%; 4.2%], respectively, in persons RIT-. There were no differences in BMD changes in the pair matching test both patients RIT+ and RIT-. No correlations between BMD changes with age, RA duration and DAS28 ESR were found.

Conclusion: RIT had no effect on BMD in women with RA after 1 year therapy. BMD changes were not associated with age, RA duration and disease activity.

AB0379

DOSE-DEPENDENT SUPPRESSION OF T CELL-DEPENDENT ANTIBODY RESPONSE IN HEALTHY VOLUNTEERS BY KPL-404, AN ANTI-CD40 MONOCLONAL ANTIBODY, SUPPORTS CHRONIC DOSING STUDY IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Papandrikopoulou1, G. R. Burmester2, F. Fang3, A. Kivitz3, M. Njenga1, A. Pano1, C. Pitzalis4, M. Samant1, S. Schmitz1, M. Spiers1, E. Tessari1, J. Ziemiański2, J. F. Pacolini5, Kiniksa Pharmaceuticals Corp., Kiniksa Pharmaceuticals Corp., Lexington, United States of America; 3Charité University Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 4Altoona Center for Clinical Research, Altoona Center for Clinical Research, Duncansville, United States of America; 5University of London, The William Harvey Research Institute - Barts and The London School of Medicine Queen Mary, London, United Kingdom; 2Kiniksa Pharmaceuticals, Ltd., Kiniksa Pharmaceuticals, Ltd., Hamilton, Bermuda

Background: An unmet need remains in patients with failure and/or inadequate response (IR) to biological disease-modifying antirheumatic drugs (bDMARD-IR) and/or Janus kinase inhibitors (JAKI-IR). The CD40-CD40L (CD154) costimulatory pathway is linked to inflammation and joint destruction in RA via production of autoantibodies and inflammatory cytokines. KMPL-404 is a humanized IgG4 antibody engineered to bind CD40 without triggering Fc effector functions (Muralidharan et al., 2019), which are known to have been associated with thromboembolic events seen in the first generation of CD40L-targeting therapies. In a first-in-human Phase 1 single ascending dose study, 52 healthy volunteers received single doses of KPL-404 administered either subcutaneously (SC) or intravenously (IV) with no dosing-limiting safety findings, infectious episodes, or toxicities (Samant et al., 2021). The study demonstrated that with 10mg/kg IV, full receptor occupancy (RO) was observed through day 71, and there was complete suppression of T-cell dependent antibody response (TDAR) to keyhole limpet hemocyanin challenge on day 1 and re-challenge on day 29 through day 57. With 5mg/kg SC, full RO was observed through day 43, and there was complete suppression of TDAR through at least day 29. Complete suppression of ADA to KPL-404, an independent indicator of target engagement, was also observed while KPL-404 serum concentrations were above approximately 0.1 to 0.2 µg/mL and continued for at least 50 days and 57 days after 5mg/kg SC and 10mg/kg IV administration, respectively.

Objectives: Using Phase 1 and nonclinical data, identify chronic dosing regimens anticipated to yield PK in the sub-therapeutic, therapeutic, and supra-therapeutic ranges to be utilized in a Multiple Ascending Dose Phase 2 Study.

Methods: A PK model was used to simulate multiple dosing scenarios, including: 2.5, 5, and 10mg/kg SC q2wk, q4wk, and q4wk, as well as 10mg/kg IV q4wk. The model was used to identify optimal Phase 2 dosing schedules by generating 1000 virtual subjects using the typical parameter estimates with between-subject variability included.

Results: Following SC administration, all subjects were predicted to achieve complete ADA suppression for the full dosing interval at/above 2.5mg/kg SC q2wk. At 2mg/kg SC q2wk (starting dose level), simulated steady-state 8-week data predicted PK in a sub-therapeutic range for most subjects and an approximately 31- and 18-fold safety margin relative to preclinical NOAEL dose. At 5mg/kg SC q2wk, 100% of patients were predicted to be in a therapeutic range, indicating a potential practical efficacious dose level. At 10mg/kg SC q2wk, 100% of patients were predicted to be in the supratherapeutic range.

These results support a Multiple Ascending Dose (MAD) Phase 2 study design, with PK lead-in comprised of 3 Cohorts at 2, 5, or 10mg/kg SC q2wk (each randomized 6:2) and Proof-of-Concept phase (Cohort 4) comprised of 48-60 subjects randomized 1:1:1 to 10mg/kg SC q2wk and placebo SC q2wk. The ongoing study will evaluate efficacy (Disease Activity of 28 joints using C-reactive protein [DAS28-CRP]), safety, PK, and pharmacodynamics (PD) of escalating doses levels of KPL-404 compared with placebo in patients with moderate to severe RA (bDMARD-IR or JAKI-IR). The study also allows the flexibility of optional cohorts including additional dosing regimens and/or subpopulations identified based on clinical response and biomarkers.

Conclusion: Inhibition of the CD40-CD154 co-stimulatory interaction holds promise for the management of a spectrum of autoimmune diseases. KPL-404 demonstrated prolonged absorption/excretion capable of suppressing TDAR for extended periods allowing for use of extended dosing intervals irrespective of IV or SC dosing. These analyses supported the design of the ongoing Phase 2 study assessing the efficacy and safety KPL-404 in RA.

**ANTI-TNF: ORIGINATORS VS BIOSIMILARS, COMPARISON IN CLINICAL RESPONSE ASSESSMENT IN A MULTICENTER COHORT OF PATIENTS WITH INFLAMMATORY ARTHROPATHIES**

C. Gioia1, A. Pochianti-Diamanti1, R. Perricone1, M. S. Chimenti2, A. Afeltra3, L. Navarin3, A. Migliore4, U. Massafera5, V. Brizzese6, P. Scilleri6, C. Meschini6, P. Scapatico7, M. Paroli7, R. Scivo8, F. Conti9, B. Laganà10, M. Di Franco11, Sapienza University Rome, Rheumatology, Rome, Italy; 12Tor Vergata, Rheumatology, Rome, Italy; 13Campus Biomedico, Rheumatology, Rome, Italy; 14San Pietro Fabel/Benedettini, Rheumatology, Rome, Italy; 15Nuovo Regina Margherita, Rheumatology, Rome, Italy; 16Boccoli Hospital, Rheumatology, Viterbo, Italy; 17S. Camillo de Lellis Hospital, Rheumatology, Rome, Italy; 18Sapienza University, Rheumatology, Latina, Italy

**Background:** Tumor necrosis factor (TNF)-α is one of principal proinflammatory cytokines involved in pathogenesis of different inflammatory arthropathies as Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS). Biotechnological drugs, represented among others by monoclonal antibodies directed against TNF-α, lead to a revolution in RA and spondyloarthritides treatment. They were the first biological drugs used to treat these diseases, with good results in terms of safety and efficacy. Also because of high cost of these drugs, for some years biosimilars have been introduced in clinical practice. Biosimilars are less expensive (in Italy, less of 30% than biorig inators); they underwent to a severe process of “comparability” to assess safety and efficacy like their originators. In Italy, AIFA authorized SB4 (etanercept biosimilar), SB5 and ABP501 (adalimumab biosimilar) after passing III-phase randomized clinical trials; but real-life data and registers are lacking.

**Objectives:** Aim of this study is to compare biosimilars and biorig inators in terms of safety and efficacy in a real-life contest.

**Methods:** We consequently enrolled patients, affected by inflammatory arthropathies (RA, PsA, AS) and treated with biosimilars (SB4, ABP501), belonging to any of the main biological prescribing centers in the Lazio region, from 2017 to 2021. Moreover, we enrolled patients, affected by the same inflammatory diseases, but treated with corresponding originator. Clinical and laboratory data as well as disease activity indices, were collected at recruitment (T0) and after 4 (T1), 8 (T2), 12 (T3) and 24 (T4) months of therapy. Adverse events were registered. **Results:** The multicenter cohort was composed by 455 patients treated with biosimilars (SB4/ABP501 276/179; F/M 307/146; naïve 56%, median age/IQR 55/46-65) and 436 treated with originators (etanercept/adalimumab 186/259, F/M 259/177, naïve 64%, median age/IQR 55/43-62). No differences were found about safety, but biosimilars group presented a higher number of discontinuations due to inefficacy (p<0.001), observed at all time-points. Female gender to be smoker and b-DMARDs naïve, the initial non-response to the drug were predictive factors of reduced drug survival (p=0.05, p=0.046, p=0.001 respectively). Retention rate at 24 months was 81.1% for biorig inators and 76.5% for biosimilars (with a median retention time of 20.7 and 18.9 months respectively; p=0.002). Patients with remission/low disease activity achievement at T1 showed a cumulative survival of 90% to biosimilar therapy until at T4 (p=0.001); early adverse reactions instead represented an important cause of subsequent drug discontinuation (p=0.001).

**Conclusion:** Real-life data demonstrated the same safety between biosimilars and originators but a reduced biosimilar retention rate at 24 months, about 76%. Despite their loss efficacy, biosimilars could be considered valid and safe, and a good and less expensive alternative to the originators, allowing access to these innovative treatments to a wider patient population.

**ULTRASONOGRAPHY TO PREDICT FLARE AFTER DISCONTINUATION OF BIOLOGICS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN REMISSION**

T. Ogura1, A. Hirata1, T. Kagitgiri1, Y. Takakura1, H. Kameda1, Toho University, Division of Rheumatology, Department of Internal medicine, Tokyo, Japan

**Background:** Ultrasonography (US) has been suggested to be useful in predicting flare in patients with rheumatoid arthritis (RA) after discontinuation of biological disease-modifying antirheumatic drugs (bDMARDs).

**Objectives:** This study aimed to investigate whether US can predict flare after discontinuation of bDMARDs in RA patients who have achieved stringent remission criteria.

**Methods:** We prospectively enrolled RA patients who maintained a simplified disease activity index ≤ 3.3 and discontinued bDMARDs and measured clinical and ultrasound assessment and US every 2-3 months for 2 years. The US examination was performed on 40 joints using the semi-quantitative method of 0-3 on the Grey-scale (GS) and Power Doppler (PD), and the total values for each patient were used as the GS score and PD score. Joints graded as GS score ≥ 2 or PD score ≥ 1 were counted as US arthritis. In addition, tendons at 36 sites were counted with or without tendinitis/tenosynovitis to obtain a tendon score.

**Results:** Thirty-six patients were enrolled and two patients who dropped out early without flare were excluded from the comparative analyses. At baseline, the median GS score was 7, PD score was 0, US arthritis was 0, and tendon score was 0. The total PD score was 0 in 26 patients (72%) and it was 1 in 5 patients (14%). There were no significant differences in US findings between the relapse group (20 patients) and the non-relapse group (14 patients). Positive and negative predictive value for PD-positive findings (total PD score ≥ 1) were 60% and 42%, and for total PD score ≥ 2 were 60% and 41%, respectively.

**Conclusion:** The PD score in the US findings at the time of bDMARDs discontinuation was not predictive for future disease flare.

Rheumatoid arthritis - non biologic treatment and small molecules

AB0382 COMPARISON OF ADVERSE EVENTS (AES) RELATED TO MAJOR ANTI-RHEUMATIC DRUGS, REPORTED TO THE OFFICIAL JAPANESE ADVERSE DRUG EVENT REPORT DATABASE (JADER)

N. Tsuda1, S. Inokuma1,2, H. Boguchi3, M. Yamaji3, T. Harada4, M. Misaki1, Y. Masui5, T. Kano6, 1Kohnodai Hospital, National Center for Global Health and Medicine, Rheumatology, Ichikawa, Chiba, Japan; 2Chiba Central Medical Center, Allergic Diseases and Rheumatology, Chiba, Japan

Background: Currently, many disease-modifying anti-rheumatic drugs (DMARDs) are available for the treatment of rheumatoid arthritis (RA). Among them, methotrexate (MTX), biologic DMARDs (bDMARDs) and Janus kinase inhibitors (JAKi) are the major options. AES related to these are major concerns. In Japan, the AES data spontaneously reported to and summarized by Pharmaceuticals and Medical Devices Agency (PMDA) are freely accessible.

Objectives: The major AES relating to MTX, bDMARDs, and JAKi observed in the real world were compared.

Methods: The number of AES listed by JADER from 2014 to 2020 was collected. The AES were classified by System Organ Class (SOC) of Medical Dictionary for Regulatory Activities (MedDRA) and compared using the chi-square test. The bDMARDs included were etanercept (ETN), adalimumab (ADA), golimumab (GOL), tocilizumab (TCZ), and abatacept (ABT), and JAKi was tofacitinib (TOF) and baricitinib (BAR).

Results: The total number of AES was 27,604. The number was significantly increasing in total and MTX, GOL, TOF during these years, although the number of cases that have each DMARD is not known in this study. The proportion of SOCs among each DMARD was similar throughout the period.

The most frequent was infections/infestations in all DMARDs except for MTX, in which neoplasms were the most. The primary cause of infection was bacterial, including pneumonia. Varicella-zoster virus infection in JAKi, and tuberculosis in ADA and GOL were conspicuous.

Neoplasms were the second major in many DMARDs. Lymphoproliferative disorders were most common in MTX-related neoplasms, whereas solid tumors were more in other DMARDs like ABT or BAR.

Conclusion: The number of AES cases related to DMARDs was increasing. Significant difference among AES related to DMARDs was noted in the JADER database, especially regarding MTX and JAKi.

AB0383 COMPARISON OF EFFICACY AND SAFETY IN JAK INHIBITOR DUE TO A DIFFERENCE OF SELECTIVITY - TOFACITINIB VS. BARICITINIB -

I. Yoshi1, N. Sawada2, T. Chijiwa3. 1Yoshi Hospitalshi, Musculoskeletal Medicine, Shimanto-City, Japan; 2Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan; 3Kochi Memorial Hospital, Rheumatology, Kochi, Japan

Background: Each Janus Kinase Inhibitor (JAK-i) has different selectivity of JAKs, such as JAK1, JAK2, JAK3, and TIK2. However, little has been known regarding mode of action due to the selectivity difference in clinical practice for treating rheumatoid arthritis (RA).

Objectives: The aim of this study is to compare difference of efficacy and safety in two JAK-i; between tofacitinib (TOF) and baricitinib (BAR) in clinical practice using one-center retrospective cohort.

Methods: Within the case which administered TOF or BAR to the RA patient who the effect was insufficient in the existing treatment and the disease activity was over the middle disease activity using simplified disease activity index (SDAI). At the start of administration (baseline), 5 mg tablets of TOF were taken twice a day or 4 mg tablets of BAR were taken once a day. Patients were divided by drug and included their sex, age at onset, anti-cyclic citrullinated polypeptide antibodies (ACPA) titer, length of RA history at onset, Sharp/van der Heijde score (SHS) at onset, Naive/Not Naive for biologic DMARDs or JAK-i, 28-joints disease activity score (DAS28), SDAI, Health Assessment Questionnaire Disability Index (HAQ-DI), and pain score with visual analog scale (PS-VAS). It was classified into large joint and small joint, and the point was independently scored by swelling and pressure pain by size and position in each joint. Total score of the

Background colors indicate: comparing to the total cases, higher with p<0.05, light pink; higher with p<0.00001, dark pink; higher with p<1E-10, red. Lower with p<0.05, light blue; lower with p>0.00001, blue; lower with p<1E-10, dark blue, using chi-square test. Yellow indicates System Organ Classes.
involved joints for each part: upper-extremities, lower extremities, big joints, and small joints (UES/LES/BJS/SJS), rheumatoid factor (RF) titer, serum matrix metalloproteinase-3 (MMP-3) level, serum creatinine (Cr) level, and estimated glomerular filtration rate (eGFR) of each part were measured. The mean values of each group were obtained at baseline, 1, 2, 3, 6, 9, and 12 months, and the two groups were statistically compared using the Mann-Whitney U-test. As a sub-analysis, each drug group was divided into bio or JAK-i naive, age ≥ 70 years, disease duration ≥ 10 years, SHS ≥ 100. The change of DAS28 under each 2 divided condition was compared using Mann-Whitney U-test. Similar comparison was carried out with RA patient who administered golimumab (GOL) as a control group. The significance level was less than 5%.

Continuation rate (the withdrawal after the remission introduction is put in the continuation) in 12 months after baseline was also compared.

**Results:** A total of 82 patients were picked up, in whom 22 TOF group, 31 BAR group, and 29 GOL group included. Both DAS28 and SDAI were consistently lower in the BAR than in the other 2 groups from 1 month after baseline, SDAI in the BAR was significantly lower than in the GOL at 3 months after the baseline. The HAQ-DI score at 6 months after baseline was significantly lower in the BAR than in the GOL. PS-VAS in the GOL was significantly higher than the other two groups at 2, 3 and 6 months after baseline. In the joint point, BJS in the BAR was significantly lower than that in the GOL at 2, 3, and 6 month after baseline. In the joint point, BJS in the BAR was significantly lower than that in the TOF at 6 and 12 months after baseline. There was no significant difference in MMP-3, RF, Cr and eGFR between the 3 groups in any observation month, but Cr increased after the start in the BAR group and eGFR tended to decrease.

The continuation rate at 12 months after the start of administration was 86.4% in the TOF, 89.3% in the BAR and 69.0% in the GOL.

**Conclusion:** Even JAK-i characteristics in action differs for each drug. It is needed to choose appropriate drug based on these drug characteristics.

**Background:** An unhealthy lifestyle increases the risk of developing rheumatoid arthritis (RA). Interventions including plant-based diets, physical activity, and stress management have shown benefits for RA patients but have not yet been evaluated in a program for patients at risk for RA.

**Objectives:** To investigate preliminary effectiveness of a multidisciplinary lifestyle program on RA risk in patients at risk for RA, in comparison to usual care.

**Methods:** In the “Plants for Joints” (PFJ) pilot RCT, patients with anti-citrullinated protein antibody (ACPA) positive arthritis were randomized to the PFJ or control group. Both groups received usual care while the PFJ group additionally followed a 16-week lifestyle program based on a whole food plant-based diet, physical activity, and stress management. The primary outcome was risk of developing RA as quantified by the RA risk score (including family history, symmetry, stiffness, pain level, RF/ACPA level). The maximum score (13 points) was given to participants who developed RA. Secondary outcomes included self-reported pain intensity, inflammatory, anthropometric, and metabolic markers, and serum levels of ACPA and rheumatoid factor (RF). A linear mixed model for between group analysis was used, adjusted for baseline values.

**Results:** 14 out of 17 included patients completed the study (all female, mean age 47 years). Three patients (n = 2 PFJ group, n = 1 control group) were diagnosed with RA after mean 9.6 weeks and remained in the study. After 16 weeks there was no significant difference in RA risk score between PFJ and control groups (Figure 1). Compared to the control group, the PFJ group had significantly lower fat mass and LDL-cholesterol after 16 weeks (Table 1). After the intervention the PFJ group had an average weight loss of 4.9 kg, of which 2.7 kg was fat mass.

**Conclusion:** The results of this pilot study do not suggest the PFJ lifestyle program influenced RA risk score, pain, or autoantibody levels, although possible effects cannot be excluded due to the small sample size. However, metabolic health clearly improved in the PFJ group.

BARICITINIB LEADS TO RAPID AND PERSISTENT RESOLUTION OF SYNOVITIS AS MEASURED BY HAND MRI IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS (RA) FAILING CS/BDMARD THERAPY

S. Kemenes1,2, S. Bayat1,2, D. Simon1,2, G. Krönke1,2, D. Bohr1,2, L. Valor1,2, F. Hartmann1,2, L. Schuster1,2, K. Tascilar1,2, G. Schett1,2, A. Kleyer1,2 on behalf of the https://www.medizin24.uk-erlangen.de/en/research/research-main-focus/research-group-pp-dr-a-kleyer-and-pp-dr-d-simon/.

Background: RA is characterized by synovial inflammation resulting in local bone loss [1]. Inhibitors of JAK/Stat pathways, such as baricitinib, demonstrated efficacy in reducing signs and symptoms of RA in clinical trials, however, little is known about their effects on synovitis and bone structure [2]. Preclinical and clinical observations suggest a positive effect JAK inhibitors on bone mass and microstructure, however no prospective, interventional clinical trial has been performed so far [3].

Objectives: The aim of this study is to evaluate the effect of baricitinib on local inflammation (synovitis and osteitis) and bone structure (erosions) in RA patients failing on cs/bDMARD therapy using hand MRI.

Methods: BAREBONE is a prospective, interventional, open-label, monocentric single center study (EUDRACT 2018-001164-32 / NCT03701789) to assess the effect of baricitinib (4mg/day) on local MRI inflammation and structure in patients with active RA. Besides demographic and clinical characteristics, hand joint inflammation was assessed by magnetic resonance imaging (MRI) using a 1.5 Tesla scanner (Siemens Magnetom Aera T1w TSE cor, T2w TIRM cor, T2w TSE fat-sat trans, T1w TSE fat-sat trans + cor after KM.), at baseline, week 24 and week 48. Scans were assessed for synovitis, osteitis and bone erosions using the RAMRIS scoring system using two independent blinded readers (SK and SB). Intraclass correlation coefficients were calculated for total RAMRIS and synovitis, osteitis and osteitis subscores and in a second step differences between cs and bDMARD failure were elaborated. Variables are summarized descriptively using means and 95% bootstrap confidence intervals for continuous outcomes and as number and percentages for categorical outcomes.

Results: Thirty- two RA patients were screened and 30 patients were included (age: 53.4 (SD 12.6) years; sex: 1/24 N 24/6; disease duration: 3 (IQR 2.0 - 6.0) years; biologic naïve/bDMARD failure 16/14). 27 patients completed the trial while MRI data was available for 24 patients at week 48. Demographics and clinical characteristics can be seen in Table 1. Total RAMRIS scores slightly decreased from 20.6 (95% CI 14.4 -27.6) at baseline (BL) to 18.3 (11.5 -26.5) at week 48. The synovitis subscore mainly contributed to total RAMRIS reduction by significantly improving from 5.3 (4.0 - 6.8) at BL to 2.7 (1.5 - 4.0) at week 48 with a score change of -2.9 (-4.0 to -1.8). At week 48, 12 patients (44.4%) had no signs of synovitis compared to only 3 patients at BL. In contrast, RAMRIS osteitis subscores only marginally decreased from 4.9 (2.2 - 8.4) at BL to 4.0 (1.9 - 6.7) at week 48. RAMRIS erosion score remained stable over the 48-week observation time. A significant difference in RAMRIS synovitis change for biologic naïve -3.8 (-5.2 to -2.6) vs biologic failure -1.0 (-2.2 to 0.4) could be observed at week 48.

With respect to clinical disease activity, DAS 28 score decreased from 4.8 (4.5 - 5.1) at BL to 2.9 (2.5 - 3.3) at week 48. Detailed results can be found in Table 1 and Figure 1. Intraobserver coefficient (95%CI) for RAMRIS scoring was high for both readers 0.997 (0.994 to 0.998).

Conclusion: Our study shows that baricitinib primarily reduces MRI synovitis in RA patients that have previously failed csDMARD and bDMARD therapy and particularly in patients who are biologic naïve.

patients were prescribed MTX of 10-15 mg/m² of body surface. Achievement of
All patients had normal renal excretory function (GFR more than 60 ml / min). All
criteria, 65 (82%) women and 14 (18%) men, aged 53 ± 11 years, naïve to MTX.

Methods: To compare groups of patients who responded and did not respond to MTX therapy. To compare groups taking and not taking statins.

Conclusion: The concentration of 7-OH-MTX after 12 and 24 weeks of therapy is 5.23 [1.39;12.52] and 1.05 [0.07;3.55], respectively (p = 0.006). No differences between the concentrations of 7-OH MTX in the ER: 28.19 ± 16.14 and 25.77 ± 11.91, respectively (p = 0.40). The concentration of 7-OH-MTX in MO after 24 weeks of therapy – 5.23 [1.39;12.52] and 1.05 [0.07;3.55], respectively (p = 0.006). No differences between the concentrations of 7-OH MTX in the ER: 28.19 ± 16.14 and 25.77 ± 11.91, respectively (p = 0.40).

Results: Women accounted for 85.4% of the patients, the median age was 68 years, disease duration was 15 years, and the mean DAS28ESR was 5.00. The CK levels of both men and women were significantly elevated at 4 weeks and maintained until 24 weeks (5.8% (0 weeks), 20.7% (4 weeks), 26.3% (12 weeks), 24.3% (24 weeks), P<0.001) (Figure 1). The percent-age abnormal was also significantly increased at 4 weeks and maintained until 24 weeks (5.8% (0 weeks), 20.7% (4 weeks), 26.3% (12 weeks), 24.3% (24 weeks), P<0.002). The factors significantly positively related to elevated CK levels at 24 weeks were male, CK, creatinine, and lactate dehydrogenase (LDH), and stage, class, modified health assessment questionnaire, estimated glomerular filtration rate (eGFR), and glucocorticoid use were significantly negatively correlated (Table 1). There were no significant differences in CK elevation among the agents.

Figure 1. Time-dependent changes of CK in all RA patients

Conclusion: Some cases of creatine kinase (CK) elevation caused by Janus kinase (JAK) inhibitor treatment for rheumatoid arthritis (RA) have been reported in clinical trials. However, the frequency and patients' background characteristics in clinical practice are unknown.

Objectives: The correlation between JAK inhibitor treatment for RA and changes in CK levels in clinical practice were investigated using a multicenter database.

Methods: The multicenter database of JAK inhibitors was used, and 103 (tolacitinib 46, baricitinib 44, upadacitinib 11, filgotinib 1, filgotinib 1) of 265 RA patients were followed up at 24 weeks, and their CK levels were evaluated. The time-dependent change of CK was evaluated by sex and analyzed by the Wilcoxon signed-rank test. The percentage abnormal from the standard titer was calculated. The factors related to an elevated CK at 24 weeks were investigated using patients' background characteristics at the time of starting JAK inhibitors by univariate analysis.

Results: Women accounted for 85.4% of the patients, the median age was 68 years, disease duration was 15 years, and the mean DAS28ESR was 5.00. The CK levels of both men and women were significantly elevated at 4 weeks and maintained until 24 weeks (5.8% (0 weeks), 20.7% (4 weeks), 26.3% (12 weeks), 24.3% (24 weeks), P<0.001) (Figure 1). The percentage abnormal was also significantly increased at 4 weeks and maintained until 24 weeks (5.8% (0 weeks), 20.7% (4 weeks), 26.3% (12 weeks), 24.3% (24 weeks), P<0.002). The factors significantly positively related to elevated CK levels at 24 weeks were male, CK, creatinine, and lactate dehydrogenase (LDH), and stage, class, modified health assessment questionnaire, estimated glomerular filtration rate (eGFR), and glucocorticoid use were significantly negatively correlated (Table 1). There were no significant differences in CK elevation among the agents.

Analyzed by Spearman rank correlation coefficient

Conclusion: Some cases of creatine kinase (CK) elevation caused by Janus kinase (JAK) inhibitor treatment for rheumatoid arthritis (RA) have been reported in clinical trials. However, the frequency and patients' background characteristics in clinical practice are unknown.
living at the time of starting JAK inhibitors tended to have high CK levels at 24 weeks.

AB0388 FRENCH REAL LIFE SAFETY DATA ON THE USE OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: OBSERVATIONAL STUDY, DEFACTO

C. Gaujoux-Viala1, A. Basch2, S. Lassoued3, F. Coury-Lucas4, M. Kessouri5, N. Mammà4, Y. Brault6, T. Lequenne7, C. Sallo8. 1CHU Nîmes, Rheumatology, Nîmes, France; 2Infirmière Protestante Clinic, Lyon, Rheumatology; Caluire-et-Cuire, France; 3Cahors Hospital Centre, Rheumatology, Cahors, France; 4Lyon Sud Hospital, Rheumatology, Pierre-Bénite, France; 5Pfizer, Medical, Paris, France; 6Pfizer Medical, Paris, France; 7Pfizer, Statistics, Paris, France; 8Rouen University Hospital (CHU) & Inserm U905, Rheumatology, Rouen, France; 9Orléans Regional Hospital Centre (CHR), Rheumatology, Orléans, France

Background: Tofacitinib, an oral Janus Kinase inhibitor, is indicated in the treatment of adult patients (pts) with active, moderate to severe rheumatoid arthritis (RA).

Objectives: The objective of this work is to describe the tofacitinib’s safety profile in the DeFacTo study (French prospective observational study).

Methods: The safety profile of tofacitinib was assessed on the basis of interim data from a descriptive analysis of pts having taken at least one dose of tofacitinib in the context of the DeFacTo study.

Results: Of the 313 pts enrolled in the study, 301 had received tofacitinib and were included in the safety analysis. Of these, 276 fulfilled the eligibility criteria and included 219 who had ≥ 1 year follow-up and a mean exposure period of 368 ± 197.1 days. As of 15 March 2021, 122 patients are continuing to take tofacitinib therapy (76 missing prescription data). On inclusion, 73% of the 276 pts were females of mean (± SD) age 59.7 ± 11.7 years and a median disease duration of 9.1 years. At the cut-off date of 15 March 2021, of the 301 patients, adverse effects (AE) had been reported in 44.9% of cases of which 10.6% were considered serious (SAE). Infections were detected in 18.6% of pts (Table 1).

Figure 1.

The main causes of monotherapy were intolerance (39.9%), adverse event (22%), physician's decision (20.2%) and lack of adherence (17.7%) to DMARDs. Patients who were active workers (64% vs 55%, p < 0.05), with higher socioeconomic
status (31.4% vs 17.2% p <0.01), better mean HAQ at diagnosis (1.1 vs 1.3, p <0.05) an association was observed with monotherapy. In addition, an association was observed with the use of monotherapy in patients in the 2nd biological line or higher vs 1st line (53% vs 33%, p <0.01), lower polypharmacy (45.6% vs 60%, p <0.02) and a shorter mean time of biological treatment (47 months vs 39 months, p <0.01). These variables were entered in a logistic regression model, the results of the independently associated variables are shown in Table 1.

* p <0.05, CI = 95% confidence interval

**Conclusion:** The frequency of monotherapy, since the JAK's emergence, was 49% (all follow-up) and 41% (current-last visit). Intolerance to cDMARDs doctor and the patient decision were the main cause. The monotherapy use pattern was greater in those who received JAKi and anti IL6. The use of monotherapy was associated with work activity, socioeconomic status, and functional capacity at diagnosis. An association was also observed with less polypharmacy.

**ANALYSIS OF CLINICAL IMPROVEMENT BY 5 JAK INHIBITORS AGAINST JAK KINASE INHIBITOR IR RA PATIENTS IN JAPANESE CLINICAL PRACTICE**

K. Katayama1, M. Yuichi2, H. Ito2.

1Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan; 2Asahikawa Medical University, Integrated Medical Education Center, Asahikawa, Japan; 3Asahikawa Medical University, Department of Orthopedic Surgery, Asahikawa, Japan

**Background:** Recently, Eular recommended different mode of therapeutic tool to get clinical remission. JAK inhibitors are considered to be one of candidates. Several JAK inhibitors have been used, however there are almost little informations about selection of JAK Inhibitors, especially, informations about secondary JAK for JAK inhibitor IR RA patients.

**Objectives:** To analyze clinical response by second JAK inhibitors against JAK inhibitor IR RA patients in clinical practice.

**Methods:** In Japan, five JAK inhibitors have been mainly used in MTX IR or biologics IR patients from 2013 (tofacitinib, JAK1,2017, baricitinib, JAK 1,2) (2019) (Peficitinib, Pan JAK, in Asia, Japan), 2020,April (upadacitinib, JAK1,2, mainly JAK1) and 2020. Nov (filgotinib, JAK1). In our clinic, these JAK inhibitors were sequentially used to get clinical remission. Numbers of patients who used JAK inhibitors are 28 patients in tofacitinib, 38 patients in baricitinib, 27 patients in peficitinib, 34 patients in upadacitinib, and 13 patients in filgotinib. Among them, 22 JAK inhibitor IR RA patients were investigated for clinical effectiveness.

**COST-EFFECTIVENESS OF IGRURATIMOD IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) BY USING A CLAIMS-BASED ALGORITHM: RETROSPECTIVE ANALYSIS OF REAL-WORLD DATA**

Y. Wang1, T. Shi1, J. Deng1, J. Wu1, Y. Qu1, Y. Zhang1, X. Zhi1, J. Wu1, Y. Zhang1, X. Zhu1, B. Liang1, Q. Yu1, H. Du2, L. Jie1.

1Southern Medical University, Department of Rheumatology and Clinical Immunology, Guangzhou, China; 2Southern Medical University, School of Laboratory Medicine and Biotechnology, Guangzhou, China

**Background:** Igruratimod (IGU), as one of the conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), has been approved by Ministry of Health, China. This study aimed to compare the cost-effectiveness of well-established RA patients using a claims-based algorithm in RA patients.

**Objectives:** This study aimed to compare the cost-effectiveness of well-established RA therapies using a claims-based algorithm in RA patients.

**Methods:** An electronic medical record (EMR) database from Zhujiang Hospital, Guangzhou, China was utilized to estimate the cost-effectiveness of medication for RA patients, including IGR with MTX, biological DMARDs (bDMARDs) with MTX, and MTX alone for more than 6 months from 2014 to 2020. Patients who were deemed effective must meet all the following criteria according to the algorithm, high adherence; no bDMARDs or IGU switch or addition; no prescription of new csDMARDs. The average cost of all RA medications was revealed to be both effective and the most effective, which seemed to be a cost-effective strategy for RA therapy and warranted further cost-effectiveness investigation.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.602
Results: Summary of study were shown in Tables 1 and 2. Biologics were used in 14 patients and satisfied D2T RA (1st row, green color). For pre JAK inhibitors, 12 tofacitinib, 8 baricitinib, 4 peficitinib and 3 filgotinib were used. Six months later, 9/13 patients in upadacitinib, 2/3 in filgotinib, 2/3 in peficitinib, and 3/3 in baricitinib, totally 13/22 improved clinical disease activity (Eular good+ moderate response). Clinical improvement about ACPA negative (6th row, yellow color) in 4 patients (8 th row, dark green)- 3 tofacitinib, 1 baricitinib respond well firstly about 1st and successive response for upadacitinib treated patients. Since, first JAK in 4 patients (8 th row, dark green)- 3 tofacitinib, 1 baricitinib respond well firstly (secondary unresponsiveness), tofacitinib may be useful for double negative or RF negative RA patients.

Conclusions: UPA demonstrated clinical and functional improvement in Chinese csDMARD-IR RA pts. The safety of UPA was comparable with the overall study population and with the safety seen in the global Phase 3 program.

Table 1. Summary of Efficacy Endpoint Results at Week 12 in Chinese Subgroup

Disclosure of Interests: None declared

References: None declared

Methods: Pts were randomized to 12 weeks of blinded treatment with UPA 15mg once daily (QD) or PBO, in combination with csDMARDs. Primary and secondary endpoints were analyzed in a Chinese subgroup, including American College of Rheumatology criteria (ACR) responses, remission and low disease activity measures. Safety was analyzed for pts who received ≥1 dose of study drug.

Results: 228 Chinese pts (67.5% of overall trial population) were randomized and took at least one dose of study drug. Baseline characteristics were generally balanced between UPA and PBO. 46% and 35.1% used methotrexate (MTX) alone as concomitant csDMARD in UPA and PBO group, respectively. 38.9% in UPA and 43.0% in PBO group used concomitant csDMARDs other than MTX and 15.0% and 21.9% respectively used a combination. At week 12, more Chinese pts receiving UPA achieved the primary endpoint of ACR20 compared with PBO (71.9% vs 31.6%, nominal p<0.001). UPA also showed greater improvements in all secondary endpoints vs PBO at Week 12 (Table 1), including ACR50 and ACR70, mean difference from baseline 71.9% vs 31.6%. UPA also showed greater improvements in all secondary endpoints vs PBO at Week 12 (Table 1), including ACR50 and ACR70, mean difference from baseline 71.9% vs 31.6%.

Conclusions: JAK inhibitors are useful for another JAK inhibitor IR RA patients in clinical practice. However, to get good response, baseline immunogenicity, RF/ACPA positivity, JAK specificity need to be considered. To solve, prospective clinical study may be required.

References: None

Disclosure of Interests: None declared

Background: Four Janus Kinase inhibitors (JAKI) are licensed in the UK for treating rheumatoid arthritis (Upadacitinib, Tofacitinib, Filgotinib and Baricitinib). Several analyses have examined the survival in these groups and found them more likely to be tolerated more or equivalently than other modes of action. Recent data suggested an influence on survival using these drugs.

Objectives: To study the overall survival rates of JAKI compared to the other biologic treatments in a single centre cohort.

Methods: We analysed patients commencing advanced treatments (anti-Tumour necrosis factor, Interleukin 6 blocker, Rituximab and Abatacept) between 20 February and October 2021. Variables examined included gender and age. The time on drug was compared between JAKI and other treatments using student’s T test. Chi squared test was used to compare categorical variables. A Cox regression model was fitted to compare length of stay on each agent JAKI length of stay was compared to length of stay on other agents combined.

Results: 592 patients were included in the analysis. 168 (28%) were started on JAKI. 435 (73.4%) were females. Mean age at drug start was 60.6 years (SD 13.5). The numbers on drug were Filgotinib n=10, Tofacitinib n=35, Upadacitinib n=37, Baricitinib n=86, Adalimumab n=211, Abatacept n=36, Certolizumab n=18, Etanercept n=112, Golimumab n=21 and Tocilizumab n=26. 93 (15.7%) discontinued their drug, mostly due to lack of efficacy. Mean number of days on any biologic therapy was 918.9 (SD 711.5). Patients on JAKI had a significantly shorter survival on drug 652.7 days vs 1024.4 days (P<0.001).

There were no significant differences in age and gender between the groups. Univariate regression showed a hazard ratio of 1.19 (95%CI 0.75,1.98). This remained non-significant after adjusting for age and gender (1.18 95%CI 0.71,1.95). The only predictor of stoppage was age (HR 1.03 95%CI 1.01,1.04).

Conclusion: In this relatively large observational study, there was no difference in predictors of stoppage between JAKI and other advanced therapies. Increasing age was found to be a predictor for stoppage. This is in line with other reports in the literature. Further work looking at the impact of serology and disease activity will be performed.

DE-ESCALATION OF DMARDS IN ELDERLY PATIENTS WITH RA

L. Robson1, F. Hayes2. 1. Lister Hospital, Rheumatology, Stevenage, United 

K. van Middendorp6, P. Weijs7, D. van Schaardenburg1,2.

diabetes, and the observations from this study will be applicable to all who treat elderly 

contextualising a patient’s treatment plan for their rheumatological disorder with 

their elderly patients and de-escalating conventional DMARDs accordingly. As 

effects, and as elderly people have higher rates of adverse drug reactions and 

DMARDs (Tutuncu & Kavanaugh, 2007). These drugs are not without side 

arthritis in older adults, with the mainstay of treatment being the conventional 

therapy in response to a cancer diagnosis than a dementia diagnosis or frailty. 

year period. Planned de-escalations were mostly successful, whereas abrupt 

flares in disease activity), semi-successful (patient had mild RA flare treated with 

multiple DMARDs saw a greater average decrease in methotrexate compared 

with acute hospital admission being the most common trigger. Of these 3 were 

were generally less successful. Rheumatologists are good at 

stopping to treatment were generally less successful. Rheumatologists are good at 

with acute home admission and de-escalating conventional DMARDs accordingly. As 

the average age of rheumatology patients is only likely to increase in the future, 

contextualising a patients treatment plan for their rheumatological disorder with 

their overall health status will become an increasingly important skill for clinicians 

and the observations from this study will be applicable to all who treat elderly patients with inflammatory disorders.

Objectives: 1. Evaluate if major new diagnoses were acknowledged in the rheu-

matology clinic and if conventional DMARD treatment was reduced in response. 2. Record and compare the outcomes of when conventional DMARD was stopped abruptly vs when it was tapered down slowly.

Methods: Evaluated 10 year’s worth of clinic letters from rheumatology and other specialties in 50 patients with a diagnosis of RA over the age of 89. Noted new diagnoses of dementia, cancer or frailty (multiple falls, care home admission or becoming newly house bound) as well as acute hospital admissions and declining renal function and evaluated if this was acknowledged in clinic letters and whether treatment was changed in response. Recorded all instances where conventional DMARDs were stopped or had a dose reduction and evaluated if these dose drops were successful (patient stayed at reduced dose with no flares) or semi-successful (patient had mild RA flare treated with short course corticosteroids, or stayed at reduced dose for at least a year before returning to original dose) or unsuccessful (patient suffered flare and went back to original dose within 1 year).

Results: Of the 50 patients, 31 received methotrexate monotherapy, 12 metho-

trextate and other conventional DMARDs, and 5 DMARDs other than methotrex-

ate. 36 of out 45 patients receiving methotrexate had some decrease in dose by the end of the 10 year period, with the median decrease being 5mg. Patients on multiple DMARDs saw a greater average decrease in methotrexate compared to those on monotherapy. 15 abrupt cessations in methotrexate were recorded, with acute hospital admission being the most common trigger. Of these 3 were successful, 5 were semi-successful and 7 were unsuccessful. 55 planned metho-
trextate dose reductions in the rheumatology clinic were recorded, with 36 being successful, 9 being semi-successful and 8 being unsuccessful. A clinical letter did generally acknowledge both new physical diagnoses and changes in social circumstances, but some diagnoses were more likely to trigger a change in treatment, for example in new cancer diagnoses, there were 5 changes to treatment, whereas in 12 dementia diagnoses there were 3 changes to treatment. 6 patients received more methotrexate than guidelines suggest for their level of OA, with 3 of these having acknowledged in clinic letters.

Conclusion: Most patients had a reduction in dose of methotrexate over a 10 year period. Planned de-escalations were mostly successful, whereas abrupt stops to treatment were generally less successful. Rheumatologists are good at acknowledging changes to health status but were more likely to change DMARD therapy in response to a cancer diagnosis than a dementia diagnosis or frailty. There is still some work to be done in acknowledging declining renal function and

changing methotrexate in response. Overall, these results suggest de-escalation is mostly successful and clinicians can be confident in further expanding this into routine day practice.

EFFECT OF A MULTIDISCIPLINARY LIFESTYLE PROGRAM ON RA PATIENTS WITH RHEUMATOID ARTHRITIS: THE PLANTS FOR JOINTS RANDOMIZED CONTROLLED TRIAL

W. Wairabenstein1,2, C. Wagenaar1,2, M. van der Leeden3,4, F. Turkstra1, J. Twisk1, M. Boen3, H. van Mulders3, D. van Schaardenburg3,4.

Background: Lifestyle factors have been associated with the development and progression of rheumatoid arthritis (RA). Interventions involving whole food plant-based diets (WFPDs), physical activity or stress management have shown promising results for people with RA but were not yet evaluated in an integrated program.

Objectives: To determine the effect of a 16-week multidisciplinary lifestyle pro-

gram on disease activity in patients with RA.

Methods: In the “Plants for Joints” (PFJ) parallel-arm, assessor-blind randomized clinical trial, patients with RA and a 28-Joint Disease Activity Score [DAS28] score ≥ 2.6 and ≤ 5.1, were assigned to the PFJ group or the control group. The PFJ group followed a lifestyle program based on a WFPD, physical activity, and stress management in addition to usual care. The control group received usual care. Medication was kept stable three months before and during the trial. Secondary outcomes included anthropometric, and metabolic markers. An intention-to-treat analysis with a linear mixed model, adjusted for baseline values was used to analyze between-group differences of continuous outcomes.

Results: Of 115 people screened, 85 were randomized and 79 completed the study. Participants were 91% female with a mean (SD) age of 55 (12) and body mass index of 26 (4) kg/m2. After 16 weeks the PF J group had a mean 0.85-point greater improvement of the DAS28 versus the control group (95% CI 0.40 to 1.30; p < 0.001) (Figure 1). Subgroup analyses showed significant improvements in the seropositive as well as the seronegative subgroup, although the effect was more profound in the seronegative group. Weight, fat mass, HbA1c, LDL and triglycerides also showed significant improvements in the PFJ versus control group, while blood glucose and HDL remained unchanged (Table 1). No serious adverse events occurred.

Background: Current pharmacological treatments remain inadequate for a significant proportion of patients with rheumatoid arthritis (RA), and thus alternative treatment approaches are needed. Prior results from the first 12 weeks of a proof-of-concept (POC) study showed that ATHENS, a non-invasive high-frequency versus nerve therapy, was well-tolerated with meaningful reductions in RA disease severity as measured by the American College of Rheumatology response criteria (ACR) and the Disease Activity Score using 28 joints (DAS28)[1].

Objectives: The current analysis assessed long-term changes (52 weeks total follow-up) in disease activity as measured by ACR, DAS28, and the following MRI-assessed changes: synovitis, osteitis, bone erosion, and cartilage loss.

Methods: Following the completion of the 12-week POC study, patients achieving a reduction in DAS28-CRP of ≥1.2 were given the option to enroll in the 9-month open-label extension (OLE) study. During the extension phase, patients were to use the wearable device for 15 minutes per day. Adjustment of conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) or biologic disease-modifying antirheumatic drugs (bDMARDs) were allowed during the OLE. Changes from baseline were assessed at 12 weeks (end of initial POC) and 52 weeks (end of the OLE). Structural damage and disease progression were evaluated by standardized MRI of the wrist and hand, with and without intravenous gadolinium-based contrast. MRIs were evaluated by two independent, central readers, blinded to clinical information and visit-order of the images, and were scored for synovitis, osteitis, and bone erosion using the OMERACT-RAMRIS method. Cartilage loss was also determined using the 9-point cartilage loss score (CARLOS).

Results: Twenty-seven of 30 patients completed the initial 12-week study, of whom 19 consented and entered the OLE. Of those 19 patients, 4 (21%) discontinued due to lack of efficacy, while the remaining 15 completed the 9-month extension study. Due to the COVID-19 pandemic, 7 patients were unable to complete a 52-week MRI scan, MRI evaluations at baseline, 12 weeks, and 52 weeks were available for 8 patients. DAS28-CRP mean (standard deviation [SD]) change from baseline was -1.78 (1.01) at 12 weeks (n=19; p<0.0001) and -2.30 (1.22) at 52 weeks (n=15; p<0.0001). ACR20, ACR50, and ACR70 response rates were 68%, 42%, and 21% at 52 weeks (n=19; discontinued participants were deemed non-responders). MRI analysis of synovitis, osteitis, bone erosion, and cartilage loss showed no evidence of disease progression through 52 weeks compared with baseline (Table 1).

CARLOS = Cartilage loss score; OMERACT = Outcome Measures in Rheumatology; RAMRIS = Rheumatoid Arthritis Magnetic Resonance Imaging Scoring System

During the 9-month extension study, two new adverse events were reported (corneal transplant and right hand dysaesthesia) in 2 (11%) patients; neither was treatment-related and both resolved without intervention. No serious adverse events were reported.

Conclusion: In patients with an initial treatment response to the Nesos ATHENS therapy in the 12-week POC study, reductions in DAS28-CRP were sustained through 52 weeks. Although results should be interpreted cautiously given the small sample size and lack of control arm, MRI evaluation of synovitis, osteitis, bone erosion, and cartilage loss suggested no disease progression.

REFERENCES:

Conclusion: In our study, LEF was comparable to RTX for achievement of ACR20/50/70 responses at 24 weeks. LEF can be considered as an add-on option to MTX instead of more expensive biologic agents in MTX refractory RA. Larger studies are needed to confirm this hypothesis.

A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS INTO THE SUCCESS RATE OF GLUCOCORTICOID DISCONTINUATION AFTER THEIR USE AS INITIAL BRIDGING THERAPY IN RHEUMATOID ARTHRITIS PATIENTS IN OBSERVATIONAL COHORTS AND CLINICAL TRIALS

1Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Rheumatology, Berlin, Germany; 3UZ Gasthuisberg Campus, Rheumatology, Leuven, Belgium; 4Medical University of Vienna, Rheumatology, Wien, Austria; 5Zuyderland MC, rheumatology, Heerlen, Netherlands; 6UMC Utrecht, Rheumatology, Utrecht, Netherlands.

Background: Glucocorticoids (GC) are widely used for the initial treatment of rheumatoid arthritis (RA), to induce rapid suppression of inflammation and clinical symptoms and thereby limit radiographic damage progression. There are concerns that GC use in the long term is associated with a dose and duration dependent risk of serious side effects. Therefore, international guidelines have recommended to start GC when initiating a csDMARD, but to discontinue GC as rapidly as clinically feasible, preferably within 3 months (bridging therapy). In contrast, due to the concerns of GC side effects, the ACR guidelines published in 2021 conditionally recommend to start csDMARD monotherapy without GC bridging therapy.

Objectives: We aim to evaluate the success rate of GC discontinuation after using temporary GC as part of initial therapy (‘bridging’) both in observational cohorts and clinical trials in newly diagnosed RA patients.

Methods: Systematic literature searches were conducted to identify observational cohorts (scoping search) and clinical trials (in-depth search) that included RA patients who were treated with initial GC bridging therapy. GC bridging was defined as oral or intramuscular GC treatment that was discontinued within one year, alongside conventional DMARD therapy. Patient percentages still or again using GC were considered to represent the reverse of successful discontinuation. Random-effects meta-analyses were performed stratified by time point.

Results: The literature search on observational cohort studies could not identify any study answering the research question, since it remained unclear which patients had received GC as part of the initial treatment. The literature search for clinical trials identified 7160 abstracts, resulting in 10 included studies, with varying type and dose of GC and varying tapering schedules (Table 1). Of these included studies, 4 reported sufficient data on GC discontinuation or GC use after the bridging phase. The pooled proportion of patients who were still using GC was 22% (95% Confidence Interval (CI) 8; 37 , based on 4 trials) at 12 months and 10% at 24 months (95% CI; 1; 22, based on 2 trials) (Figure 1). Thus, the vast majority had stopped GC. Heterogeneity was substantial (I² > 65%).

Conclusion: The success rate of GC discontinuation after bridging as part of initial treatment of RA has been described in a limited number of studies. Reports on observational cohorts did not answer the research question and in clinical trials reports, GC (dis)continuation data were also scarce. However, the available data show that GC can be discontinued successfully in a large majority of patients. The paucity of data also reveals that more efforts are needed to provide data towards identifying the optimal GC bridging and discontinuation strategy, combining Treatment to Target with Starting to Stop.

Acknowledgements: We would like to thank J.W. Schoonees for his help and expertise in the systematic literature search.

DAS-disease activity score; mg/milligram; N.A.-not applicable. *GC tapered and stopped according to protocol, not depending on disease activity score.

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease that primarily affects the joints. The elucidation of the pathogenesis of RA has progressed dramatically in recent decades, and among the many cytokines involved in the pathogenesis of RA, interleukin (IL)-6 and TNF-α are known to be the major pro-inflammatory cytokines that are abundant in the bloodstream and synovial tissue. JAK inhibition (JAKibis) such as tocolizumab and baricitinib are used in the treatment of RA by inhibating JAK, which in turn inhibits the signaling of various cytokines including IL-6. However, predictors of the response to JAKibis are still required.

Objectives: We aimed to combine soluble TNF receptor (sTNFRI), sTNFRII, IL-6, soluble IL-6R (sIL-6R) and soluble gp130 (sgp130) levels to identify groups of JAKibis responses in RA patients.

Methods: This research is a retrospective study. We reviewed medical records of RA patients initiating JAKibis between July 2013 and July 2021 in our hospital. The Simplified Disease Activity Index (SDAI) was evaluated at baseline and 3, 6 months after JAKibis administration. Clinical remission was defined when SDAI decreased ≤ 3.3. Of the 125 patients treated with JAKibis, 89 patients with 6 months follow-up, valid SDAI and serum available were enrolled. Serum samples were collected at baseline and 3, 6, 12 months follow-up for IL-6 (Human IL-6 Quantikine ELISA Kit, R&D systems), sIL-6R (Human soluble IL-6R alpha Quantikine ELISA Kit, R&D systems), sgp130 and sTNFR I and sTNFR II (Human TNF RI/TNFRSF1A Quantikine ELISA Kit DRT100) and sTNFR II (Human sTNF RII/TNFRSF1B Quantikine ELISA Kit DRT200) using specific ELISAs according to the manufacturer's instructions. The statistical analyses were performed with EZR 1.55, and p values less than 0.05 were considered significant.

Results: The median age of patients was 62 (IQR: 51 - 72) years and the median of disease duration was 6.0 (2.0 - 16.0) years. Twenty-seven (30.3%) patients were biologics and JAKibis naïve. The baseline SDAI was median 18.9 (12.7 - 27.9). When comparing SDAI-remission group (clinical remission: CR) and non-remission group, there were no significant differences in any of the baseline clinical parameters. There was no significant difference in the serum levels of IL-6, sIL-6R and sgp130 between the CR and non-CR groups, but the serum levels of TNFRI and sTNFRII in the CR group were significantly lower than non-CR group. Univariate logistic regression analysis suggested Biologics and JAKibis naïve (odds ratio (OR) 3.58, p = 0.015), baseline Log sTNFRII levels (OR 0.013, P=0.034)
as predictors of SDAI remission treated with JAKInibs at 6 months. Although not significant, Stage IV (OR 0.211, P=0.082) and baseline Log sTNFR I levels (OR 0.013, P=0.082) were associated with clinical remission.

**Conclusion:** RA patients could be easily stratified prior to JAKInibs intervention with serum sTNFR II and sTNFR I levels, not but IL-6 axis cytokines (IL-6, sIL-6R, and sgp130).

**THERAPEUTIC ADHERENCE AND PERSISTENCE OF TOFACITINIB AND BARICITINIB IN RHEUMATOID ARTHRITIS PATIENTS IN DAILY CLINICAL PRACTICE.**

**Background:** The use of Janus kinase inhibitors (JAKiKs) is approved for adults with rheumatoid arthritis (RA) with moderate to severe activity. Although there is increasing data about baricitinib and tofacitinib in daily clinical practice, data about adherence and persistence in real-life is scarce.

**Objectives:** (i) To evaluate the adherence and persistence of tofacitinib and baricitinib in RA patients in a real-life setting. (ii) To assess the influence of treatment adherence to therapeutic persistence.

**Methods:** Retrospective longitudinal observational study that included all patients with RA who were treated with tofacitinib and/or baricitinib between 2017/10 and 2021/05 in a tertiary hospital. Demographic, clinical and pharmacological data were collected from electronic medical and pharmacy claim records. Kaplan-Meier survival analysis and log-rank test were performed to calculate and compare treatment persistence, respectively. Drug adherence was assessed with the Medication Possession Ratio (MPR). The effect of therapeutic adherence on treatment persistence was evaluated with a linear regression model.

**Results:** We included 136 cases: 30 treated with tofacitinib [28.6%], 44 with baricitinib [41.9%] and 31 with both [29.5%] corresponding to 105 RA patients. In our sample 86.7% of the patients were women with a mean age (± SD) of 63 ± 13 years. At the start of treatment, patients had a mean disease activity score DAS28-ESR (± SD) of 5.1 ± 1.2 and they had previously received a median of 2 (0-6) biologic agents for RA.

During the study period, 40 (29.4%) and 38 (27.9%) patients treated with tofacitinib and baricitinib, respectively, discontinued the treatment. Mean treatment persistence was 363 days (95%Cl:2-1282) in tofacitinib group and 406 days (CI95%=8-1300) in baricitinib group. There were not statistically significant differences in treatment survival (HR=1.01 [95CI%=0.59-1.71]; p=0.97). Mean MPR was 91% in both groups. There was no statistically significant correlation between therapeutic adherence and treatment persistence (p=0.21).

**Conclusion:** The results showed no significant differences between treatment persistence and adherence of tofacitinib and baricitinib in our patients with rheumatoid arthritis. In our cohort, therapeutic adherence was high and it did not influence treatment persistence.

**Disclosure of Interests:** None declared

**EVALUATION OF THE SAFETY AND EFFICACY OF 13-VALENT PNEUMOCOCCAL VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS.**

G. Lukina1,2, D. Murtazalieva1, E. Koltsova1, M. Kostinov2, A. Shmitko3, D. Blagovidov4, E. Zhilyaeva3, I. A. Loginov Moscow Clinical Scientific Center, Rheumatology, Moscow, Russian Federation; 2. V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; 3. I.I. Mekhinco Research Institute of Vaccines and Ser a, Moscow, Russian Federation, 4. CSiC, European Medical Center, Rheumatology, Moscow, Russian Federation

**Background:** Rheumatoid arthritis (RA) is accompanied by a significant increase in the risk of infection and serious infections, among which pneumonia occupies a leading place. (1) The use of targeted anti-inflammatory drugs is accompanied by an additional increase in the risk of infectious complications. In this regard, vaccination is crucial in the management of such patients.

**Objectives:** To evaluate the safety and efficacy of the 13-valent pneumococcal vaccine in patients with RA undergoing various types of antirheumatic therapy.

**Methods:** The study included 60 patients with a reliable diagnosis of RA, according to the criteria of ACR/EULAR, among them 8 men and 52 women, average age 63 years (from 29 to 69 years) with disease activity at the time of inclusion of DAS28 – 4.9 (2.2-7.7), biopative patients with insufficient response to DMARDs who will be prescribed tofacitinib (TOFA) for the first time or receiving TOFA for at least 30 patients (each group). Both groups of patients were further subdivided into two groups, 15 vaccinated and unvaccinated patients in each. The exclusion criteria were: age over 70 years; patients with infectious diseases in the acute stage; having a history of intolerance to diphtheria toxoid, patients who had previously been vaccinated with pneumococcal vaccines. For the prevention of pneumococcal infection, a pneumococcal 13-valent polysaccharide conjugated adsorbed vaccine was used. Visits to assess the condition were made in the period of 0-3-12 months. The activity of the disease was assessed by the DAS 28, CDAI, SDAI indices.

**Results:** Among vaccinated patients with PCV 13 the most common adverse events were: pain at the injection site (16%), fever up to 37.6°C (13%), redness at the injection site (6%), infiltration at the injection site (2%), myalgia (2%). These adverse events resolved spontaneously within 3 days. In a comparative assessment of infectious events during 12 months before vaccination and the next 12 months after it, there were no significant differences between vaccinated and unvaccinated patients. In patients who had a history of pneumococcal etiology of infections after vaccination, the incidence decreased by 33%.

**Conclusion:** Vaccination against pneumococcal infection is a safe and effective method of preventing pneumococcal infection in patients with rheumatoid arthritis.

**DEPENDENCE OF COMPLICATIONS IN TOTAL HIP AND KNEE ARTHROPLASTY ON THE TREATMENT OF RHEUMATOID ARTHRITIS.**

A. Khraymov2, M. Makarov1, S. Makarov2, V. Amirdzhianova3, S. Maglejvany1, I. Kushna reva1, T. C. Phan1, I. V. A. Nasonova Research Institute of Rheumatology, Orthopaedic, Moscow, Russian Federation

**Background:** Surgical treatment of patients with rheumatoid arthritis (RA) is associated with an increased risk of complications. This is due to the presence of an inflammatory process, a variety of variants of the course of the disease, reduced physical activity, the severity of functional disorders, prolonged therapy with glucocorticoids, disease-modifying and genetically engineered biological drugs, osteoporosis, as well as the activity of the underlying disease.

**Objectives:** To conduct a comparative analysis of the effect of RA treatment on local complications, such as periprosthetic infection, periprosthetic fractures, wound complications, ligamentous disorders in hip and knee total arthroplasty in patients with RA.

**Methods:** 1113 arthroplasties of large joints in patients with RA, which were performed in the period from 2002 to 2020, were analyzed. Of these, 649 total knee replacements (TKA) and 464 total hip replacements (THA) were performed.

**Results:** In patients with therapy of methylxanate at an average dose of 12.5mg per week, the incidence of local complications was 7.87%. In patients receiving Leflunomide (Arava), complications were detected in 9.29% of cases. In group
of patients with Sulfasalazine (SSZ) intake, local complications were detected in 7.73% of cases. The complication rate of 7.01% was determined in group of patients who received Glucocorticoids (GC) at an average dose of 7.5 mg (recalculation in Prednisone) 1.87% of complications were observed in patients with innate genetically engineered biological drugs (bDMARD). The highest incidence of local complications was found in patients with RA who had no therapy (27.22%).

Statistical data analysis revealed a significantly higher number of complications in the group of RA patients (p<0.005). Analyzing each type of complications, significant differences were also obtained (p<0.005).

Conclusion: The risk of complications decreased for more times higher in group of patients with RA without any treatment. So, arthralgias of largest heights in patients with RA without treatment are often accompanied by a high risk of intra- and postoperative complications.

JAK INHIBITORS IMPROVE PATIENT-REPORTED OUTCOMES SUCH AS PAIN AND HAQ EARLIER THAN ANTI-IL-6 INHIBITORS

T. Okano1, T. Koike2, K. Inui1, M. Tada3, K. Mamoto1, Y. Yamada1, K. Oriya4, K. Mandai4, S. Anno1, T. Iida7, 8, H. Nakamura1 on behalf of Osaka City University Team RA. 1Osaka City University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan; 2Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan; 3Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan; Osaka; 4Osaka Saiseikai Hospital, Department of Orthopedic Surgery, Osaka, Japan; 5Osaka City General Hospital, Department of Orthopedic Surgery, Osaka, Japan; 6Kodyoga Christian Hospital, Department of Orthopedic Surgery, Osaka, Japan; 7Koryokai Hospital, Department of Orthopedic Surgery, Osaka, Japan; 8Takahiro Clinic, Nishinomiya, Japan

Background: Clinical feature of Janus kinase (JAK) inhibitor is recognized as not only suppress inflammation but also improve patient-reported outcomes (PRO) such as pain and health assessment questioner (HAQ) in patients with rheuma-
toid arthritis (RA). This representative clinical feature was known as a results of phase 3 trial compared to TNF inhibitor. One of the mechanisms of JAK in RA is to suppress interleukin-6 (IL-6). However, the effect for PRO in JAK inhibitor compared to IL-6 inhibitor have not been known.

Objectives: We investigated the effect for patient-reported outcomes such as pain and HAQ in patients with RA treated with JAK inhibitor compared to IL-6 inhibitor.

Methods: This study was analysed a multicenter database included RA patients treated with biological disease-modifying anti rheumatic drugs (bDMARDs) and JAK inhibitors. In 307 patients treated with IL-6 inhibitor (tocilizumab 240 and sarilumab 67) and 220 patients with JAK inhibitor (tofacitinib 101, baricitinib 63, upadacitinib 20, peficitinib 14 and filgotinib 2), 155 patients were treated as first-line bDMARDs/JAK inhibitor (IL-6R inhibitor 104 and JAK inhibitor 51). In this first-line patients, patients treated with IL-6R inhibitor and JAK inhibitor were matched using the propensity score adjusted for gender, age, RA disease duration, baseline TJC and HAQ and disease activity with CRP using CDAI and DAS-28 as continuous variables.

Results: Thirty-six patients in each group were matched and analyzed. The average age was 62.4 and 62.6 years and the average disease duration of RA was 13.2 and 10.1 years in IL-6 inhibitor and JAK inhibitor. The baseline characteristics were not significantly different in both groups at week 4, 12 and 24 weeks were compared between IL-6 inhibitor and JAK inhibitor.

Results: Thirty-six patients in each group were matched and analyzed. The average age was 62.4 and 62.6 years and the average disease duration of RA was 13.2 and 10.1 years in IL-6 inhibitor and JAK inhibitor. The baseline characteristics were not significantly different in both groups at week 4, 12 and 24 weeks were compared between IL-6 inhibitor and JAK inhibitor.

Conclusions: In a comparison between IL-6 inhibitor and JAK inhibitor as a first-line molecular-targeted drug matched baseline characteristics of disease activity, TJC and HAQ was improved in JAK inhibitor earlier than IL-6 inhibitors. JAK inhibitor suppress multi cytokine that might be the reason why JAK inhibitor improve pain. Improvement of patient reported outcome in JAK inhibitor was found also in comparison with IL-6 inhibitor.

LIPID-LOWERING TREATMENT IN THE TREATMENT PROFILE OF THE RHEUMATOID ARTHRITIS PATIENTS

K. Fedorovych1, R. Yatsysyn1, B. Doskaliuk2, Ivano-Frankivsk National Medical University, Internal Medicine #1 Clinical Immunology and Allergology, Ivano-Frankivsk, Ukraine; 2Ivano-Frankivsk National Medical University, Pathophysiology, Ivano-Frankivsk, Ukraine

Background: Rheumatoid arthritis (RA) is a chronic systemic autoimmune dis-
order characterized by inflammatory changes in the synovial membranes of the joints, leading to their progressive damage and deformity. Inflammation occupies a prominent place in the pathogenesis of RA making it an essential target to improve the patient's condition.

Objectives: The purpose of this study was to evaluate the influence of lipid-low-
ering therapy on RA patients given its anti-inflammatory effect.

Methods: We involved 80 patients with diagnosed RA with established RA diagnosis based on 2010 ACR/EULAR Classification Criteria. The inclusion criteria for our study were the age of patients ≥18 years and the DAS28 index ≥ 2.6. We have excluded from investigation individuals with any prior medical history of myopathies, liver disea-
ses or increased transaminase levels, pregnant or breastfeeding women and patients taking lipid-lowering drugs. The accepted patients were randomized into 2 groups numbering 40 individuals each. The first group of subjects received just basic DMARDs and the second had atorvastatin 40 mg/day in addition. The atorvastatin admission lasted 3 months. To evaluate the possible anti-inflamma-
tory effect of atorvastatin the ESR, CRP, Visual Analogue Scale (VAS), swollen joint count (SJC), tender joint count (TJC) and Disease Activity Score (DAS-28) were used. Moreover, the lipid panel indexes in both groups of patients were analyzed. We used the Kologo-Simovor test for data distribution evaluation, Mann-Whitney U test and unpaired test were employed for groups comparison.

Results: We found that the administration of atorvastatin had a positive effect on pro-inflammatory parameters of patients. In the atorvastatin group the levels of ESR (mm/h) and CRP (mg/L) were significantly lower compared to the controls (23.3±9.43 vs 31.85±10.54, p<0.02 and 12.26 [8.21-17.54] vs 15.89 [11.32-21.54], p=0.04 respectively). TJC (p<0.01) and CDAI (p<0.05) and DAS-28 (p<0.05) indexes have been improved more significantly in the investigation group as well. The results of lipid panel measure were better in the atorvastatin group as well. The LDL (mg/dl) level differed between the two groups the most significantly (143.7±23.2 in the control group and 109.8±21.4 in the atorvastatin group, p=0.02).

Conclusion: With this study, we managed to demonstrate the beneficial effect of atorvastatin not only on RA disease activity profile but also on inflammatory level and disease course in patients with RA.

Disclosure of Interests: None declared

Background: The T2T guideline in RA recommended the normal csDMARDs irresponsive patients (pts) switching to other treatment target. Tacrolimus (TAC), the inhibitor of T cell activation, is candidate for these pts, especially with extrarticular complications (EC).

Objectives: To observe the efficacy and safety of TAC-based csDMARDs regimens refractory RA (RRA) pts and the characteristics of TAC combined treatment.

Methods: This prospective cohort study (ClinicalTrials.gov Identifier NCT02837978) was conducted in China. According to baseline DAS28-ESR, RRA pts (ACR 1987 criteria [1]) were classified to severe (>5.1, S) or moderate (≥3.2,5,1, M) groups. The efficacy indicators and AE were recorded until 144w. The combined medicine with TAC was based on the past history of csDMARD prescription and EC, including TAC with/wo MTX (T+M or T group), Pred, HCQ.

Results: 150 pts (52±14y) were involved, 15 finished 144w observation, 50 still followed up and 85 lost. As shown with GEE analysis, DAS28-ESR, CRP, HAQ were decreased significantly in all pts within 24ws, and maintained stable in later period (Figure 1). The REM or LDA, achieved ACR20, good or moderate EULAR response (G+M) proportion of 103 pts completed the 24w were 41.75%, 56.31%, 76.70%.

The Logistic regression showed baseline DAS28-ESR was an independent protective factor for ACR20 remission rate (Figure 2D).

Conclusion: TAC-based combined therapies are effective and tolerable for RRA, especially the higher disease activity pts. TAC blood concentration related to AE. The lower disease activity index and better respond, the higher TAC survival rate. TAC is recommended as TAC combined treatment.

EXOSOMAL MICRORNAS AS BIOMARKERS FOR VIRAL REPLICATION IN TOFACITINIB-TREATED RHEUMATOID ARTHRITIS PATIENTS WITH HEPATITIS C

1Taichung Veterans General Hospital, Division of Medical Research, Taichung, Taiwan, Republic of China; 2Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China

Background: Despite recent advances of direct-antiviral agents (DAA) for Hepatitis C virus (HCV), it is still a prevalent worldwide issue and therapeutic challenge in patients with rheumatoid arthritis (RA). HCV viral replication may respond differently to biological disease-modifying antirheumatic drugs (bDMARDs) and targeted synthetic DMARDs (tsDMARDs) of different mechanism of action. Exosomal microRNA 155 (exo-miR-155) and exo-miR-122 have been implicated in modulating the host immune response and transmit anti-HCV factors to HCV-infected hepatocytes in patients with RA. However, it remains unknown how
exosomal miRNAs may respond following bDMARDs and tsDMARDs treatment in HCV-infected patients with RA.

**Objectives:** We aimed to study the changes of exo-miR-155 and exo-miR-122 following bDMARDs and tsDMARDs treatment in HCV-infected RA patients.

**Methods:** We prospectively enrolled RA patients taking anti-tumor necrosis factor (TNF-α) inhibitors, rituximab, and tofacitinib. The effect of bDMARDs and tsDMARDs on HCV viral replication were assessed using an HCV-tricistronic replicon cell system. Exo-miR-155 and 122 were detected by quantitative PCR. We observed a dramatically increase of exo-miR-122 and decrease of exo-miR-155 in patients taking rituximab compared with the TNF-α inhibitors, tofacitinib and conventional synthetic DMARD groups. Finally, a reduction of exo-miR-122 and increase of exo-miR-155 levels were detected following DAA therapy for HCV.

**Results:** Exo-miR-155 and exo-miR-122 were potential biomarkers for RA patients with HCV infection. Further studies are needed to confirm our findings.

FRENCH REAL LIFE EFFECTIVENESS DATA FOR TOFACITINIB AT 1 YEAR IN PATIENTS WITH RHEUMATOID ARTHRITIS: INTERIM RESULTS OF THE OBSERVATIONAL STUDY, DEFACTO

C. Gaujoux-Viala1, A. Basché2, S. Lassouéd3, F. Coury-Lucas4, M. Kessouri5, N. Mamma1, Y. Brauti1, T. Lequerre1, C. Salliot1, Desbrest Institute of Epidemiology and Public Health (iDESP), Univ Montpellier; INSERM, Rheumatology, Nimes, France; 1Inserm Protestant Clinic, Lyon, Rheumatology, Caluire-et-Cuire, France; 2Hôpital Suburbain du Bouscat, M. E. Truchetet1, T. Schaeverbeke1, M. Kostine1, Hôpital Suburbain du Bouscat, M. E. Truchetet1, T. Schaeverbeke1, M. Kostine1, Bordeaux University Hospital, Rheumatology, Bordeaux, France; 3Hôpital Suburbain du Bouscat,
Background: Monoclonal Gamopathy of Undetermined Significance (MGUS) is common in patients with inflammatory rheumatic diseases but there are scarce data regarding the effect of disease-modifying antirheumatic drugs (DMARDs) on this pre-malignant condition. Recently, preclinical data and phase I trial have shown efficacy of JAK inhibitors (JAKi) in multiple myeloma.

Objectives: We aimed to evaluate the impact of JAKi on MGUS when initiated for an active rheumatic disease.

Methods: Patients with monoclonal abnormality prior to JAKi initiation for an active rheumatic disease were identified through the MAJiK-SFR Registry, a french multicentre prospective study, and a call for observation via the “Club Rhumatismes et Inflammations”. Clinical and biological data were collected using a standardised case report form.

Results: Nineteen patients were included, 10 women and 9 men, with a mean age of 65 years and a diagnosis of rheumatoid arthritis (n=14), psoriatic arthritis (n=3) or spondyloarthritis (n=2). The JAKi prescribed was baricitinib (n=8), tofacitinib (n=6) or upadacitinib (n=5), with a mean duration of 13 months. Sixteen patients had individualized serum monoclonal protein (IgG Kappa n=9; IgG Lambda n=7; IgM Kappa n=1; IgA Lambda n=1) ranging from 0.16g/dL to 2.3g/dL. With a follow-up of 2 to 47 months, 8 of 16 patients experienced a decrease in serum monoclonal protein level and 8 had a stable serum monoclonal protein level. The maximal decrease observed was an initial IgG Kappa of 2.3g/dL decreasing to 0.2g/dL at month 14. During follow-up, two patients did not have any detectable serum monoclonal protein on serum electrophoresis (initial value of 5.2g/l and 1.6g/l), but still a positive immunofixation. One patient had bone marrow aspirate with 8% of plasma cells before JAKi initiation and 3% after 4 months of treatment. Three patients did not have initial measurable spike but a positive immunofixation that became negative at month 8 and 11 (IgG Lambda, n=2) or stable (IgG Lambda, n=1). Conclusion: This study brings reassuring and promising data on the MGUS evolution in patients treated with JAKi for rheumatic diseases, which may guide the choice of treatment in patients with both conditions.

AB0412 CYCLING OF JAK-INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE-CENTRE EXPERIENCE

C. Vassallo1, L. Sammu2, Queen Alexandra Hospital, Rheumatology, Portsmouth, United Kingdom

Background: Despite the availability of multiple effective disease-modifying anti-rheumatic drugs (DMARDs), discontinuation/switching of treatment is common for many patients with rheumatoid arthritis (RA). Janus kinase (JAK) inhibitors (JAKi) are the latest class of DMARDs approved for RA. Data on the outcomes of cycling JAKi in RA patients is still limited to this day.

Objectives: To assess the outcomes of switching between JAKi baricitinib, tofacitinib and upadacitinib in a real-world cohort of RA patients.

Methods: This was a hospital-based, retrospective observational study of all RA patients treated in a single-centre. Data was collected between 2016 and 2021 for all patients who failed JAKi and were treated with another JAKi. Demographic data, antibody status, history of DMARD use and clinical outcomes were assessed according to change in disease activity scores, time to JAKi discontinuation and reason for switching based on DAS 28-CRP scores.

Results: We identified 26 RA patients, 23 (88%) of which were RHF and/or anti-CCP positive, that failed JAKi and were cycled to another JAKi. 23 (88%) patients had failed treatment with one or more biological therapies prior to initiating JAKi. 13 (50%) patients were prescribed baricitinib and the other 13 patients Tofacitinib as their initial JAKi. During their RA treatment pathway, 9 (35%) of the patients on tofacitinib switched to baricitinib, and 4 (15%) switched to upadacitinib. 7 (27%) patients who started on baricitinib were switched to upadacitinib, and 6 (23%) were switched to tofacitinib. 3 (12%) patients cycled between all 3 JAKi. Reasons for switching first JAKi included primary treatment failure at initial 3-month recur- sion due to lack of efficacy (7/26; 27%), secondary failure (9/26; 35%), adverse drug reactions (ADR) (2/26; 8%) and others (1/26; 4%). Additionally, 7 (27%) patients on tofacitinib were switched following a drug safety update published by the Medicines and Healthcare products Regulatory Agency (MHRA), in an effort to minimize risk of major adverse cardiovascular events and malignancies. The median time to switching first JAKi was 11.5 months (range 3-23 months). After switching JAKi, 17 (65%) patients were found to have improved DAS 28-CRP scores.

Conclusion: In this analysis of 190 patients treated with JAKi we detect that the men uses JAKi more frequently in first indication than women. Women seems to have a longer disease evolution, more smoking habit and less cardiovascular risk than men.

Disclosure of Interests: None declared

at their 3-month rescore and continued treatment with their second JAKI. Following their switch, a total of 8 (31%) patients stopped their second JAKI due to inefficacy; 3 (12%) due to ADRs and 2 (8%) for other reasons. Of the 3 patients that went on to receive treatment with a 3rd JAKI (2/3 for primary failure; 1/3 for secondary failure), 2 patients were found to improve at their 3-month rescore. Conclusion: Cycling through JAKI is an appropriate and safe treatment strategy in RA patients that discontinue first JAKI therapy due to lack of efficacy or ADR.

STEROID SPARING EFFECT OF JAK-INHIBITORS ACROSS MULTIPLE PATIENTS POPULATION

P. Coniolini1, C. Minerba1, A. Vondola1, E. Greco1, B. Kroegel1, S. Modica1, P. Triggiani2, M. S. Chimenti1, A. Bergamini1.1University of Rome for Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy

Background: JAK-inhibitors (JAK-i) represent an effective choice in achievement of therapeutic target in bio-naive (bnaive) and bDMARD-insufficient responders (bDMARD-IR) patients. However, oral glucocorticoids (OGC) are commonly used in clinical practice in combination with b/tsDMARDs in Rheumatoid and Psoriatic Arthritis (RA and PsA) patients in order to reach clinical remission.

Objectives: To assess, in a real-life clinical setting, the reduction of OGC dose during JAK-i treatment in RA and PsA patients that were b-naive or ≥1-bDMARD-IR or ≥2-bDMARDs-IR with different mechanisms of action.

Methods: Patients with active RA or PsA treated with first JAK-i were prospectively enrolled in a single center. Disease activity (DAS28-CRP or DAPSA), pain visual analog scale (VAS-pain), general health (GH) and mean prednisone dosage (PDN dose) were collected at baseline and after 4, 8 and 12 months (T4, T8, T12) of treatment.

Results: 89 patients with active arthritis (77 RA, 12 PsA) were treated with JAK-i (43 patients received Baricitinib, 41 Tofacitinib and 5 Upadacitinib), with all patients reaching T4, 65 patients T8 and 50 patients T12 (Table 1). 27% patients were b-naive, 73% ≥1-bDMARD-IR and 34% ≥2-bDMARDs-IR. A mean OGC dose of 4.0 ± 4.6 (mg per day) was used and 39% of patients received JAK-i without csDMARDs. We observed a significant improvement of disease activity by DAS28-CRP or DAPSA, pain visual analog scale (VAS-pain), general health (GH) and mean prednisone dosage (PDN dose) were collected at baseline and after 4, 8 and 12 months (T4, T8, T12) of treatment.

DRUG PERSISTENCE ON JANUS KINASE (JAK) INHIBITORS COMPARED TO BIOLOGIC DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS: RETROSPECTIVE STUDY IN THE AUSTRALIAN POPULATION

L. Scheepers1, G. Jones1.1University of Tasmania, Musculoskeletal Health and Disease, Hobart, Australia

Background: In rheumatoid arthritis (RA) persistence on disease modifying anti-rheumatic drugs (DMARDs) can be interpreted as a composite measure of effectiveness, safety, and tolerability. There is limited data available on real-life use of the newest class of drugs, the Janus Kinase (JAK) inhibitors. JAK inhibitors are small-molecule treatments which are administered orally on a daily basis and offer a long-term option in RA treatment.

Objectives: To compare drug persistence on JAK inhibitors tofacitinib, baricitinib and upadacitinib to tumor necrosis factor-α (TNF) inhibitors and other DMARDs in RA patients in Australia.

Methods: A retrospective observational study was conducted among RA patients in the Australian Medicare Database (from January 2006 till October 2021), aged ≥18 and for whom a JAK inhibitor or biologic DMARDs were dispensed. Data were provided by the Australian Department of Health and Aging through PROSPECTION, an Australian healthcare consulting company. A de-identified 10% sample of the database was taken as a random representation of RA patients in Australia.

Kaplan-Meier analysis was used to calculate drug persistence rates, defined as the time from treatment initiation until the date of the last dose when there had not been a script dispensed for 6 months; except for rituximab, where a 12-month gap was applied.

Results: Data from 5,455 patients were analysed. For all patients the 12-month persistence rates were 61% for JAK inhibitors (baricitinib, tofacitinib, upadacitinib), 62% for tocilizumab, 52% for TNF inhibitors (adalimumab, certolizumab, etanercept, golimumab, infliximab), and 51% for abatacept. The JAK inhibitors baricitinib (64%) and upadacitinib (78%) were superior to tofacitinib (54%). Median treatment persistence for upadacitinib was not reached (n = 430); was 27.1 months for baricitinib and 15.2 months for tofacitinib. For TNF inhibitors, treatment persistence was 15.1 months for adalimumab, 14.1 months for certoli- zumab, 14.0 months for etanercept, 11.1 months for golimumab and 4.5 months for infliximab.

Persistence rates on first-line JAK inhibitors were 70% for baricitinib and 57% for tofacitinib; persistence rates dropped to 63% for baricitinib and 47% for tofacitinib in the second-line setting. First-line persistence rates were 54% for TNF inhibitors and 65% for tocilizumab, rates were sustained for tocilizumab, but dropped to 48% for TNF inhibitors in the second-line setting.

Conclusion: This real-world data highlights that in an Australian clinical practice setting treatment persistence rates on 12 months on JAK inhibitors, in particular baricitinib and upadacitinib, were superior to TNF inhibitors, but not to tocilizumab. Suggesting that persistence rates might differ according to biologies mode of action and line of treatment.

Disclosure of Interests: None declared

Background: Upadacitinib is the third janus kinase (JAK) inhibitor approved for rheumatoid arthritis after baricitinib and tofacitinib. Upadacitinib is a selective JAK1 inhibitor, and is indicated for the treatment of moderate to severe active RA in adult patients with inadequate response or intolerance to one or more DMARDs.

Objectives: To describe the effectiveness and safety data of upadacitinib in patients with moderate-severe RA refractory to multiple synthetic and/or biologic DMARDs.

Methods: Descriptive and retrospective observational study conducted in patients who met RA classification criteria, refractory to synthetic and/or biologic DMARDs in the Rheumatology department of the Valme Hospital. Epidemiological, clinical, analytical, and safety and treatment-related variables were collected. A descriptive quantitative analysis of the data was performed.

Results: Forty-five patients were included (37 women and 8 men), with a mean age of 53 years and mean time of RA evolution of 11 years. Of the patients, 44.4% had some cardiovascular risk factor. With respect to previous treatment, 100% were on DMARDsc, with a median of 2 DMARDsc per patient. Regarding biologic or targeted therapy, 77.8% had a history of biologic therapy failure with a median of 1 biologic; in addition, 8 patients had received at least 3 previous biologic drugs prior to upadacitinib. A total of 28.9% (13 patients) had previously received JAKi, discontinued due to secondary failure or from clinical trials at other centers. In terms of disease activity at the start of upadacitinib, patients had a mean of number of swollen joints (SJC) 3, number of tender joints (TJC) 4, CRP 11 mg/dL, DAS28 of 4.24 and CDAI of 215. When starting upadacitinib, 80% of the patients were on steroid therapy, 51% with doses > 5 mg/day of prednisone. Combination therapy with DMARDs was maintained in 76.3% of patients (56.7% MTX, 36.7% LFN and the rest with SSZ). The results were analyzed after a median of 7 months from the start of upadacitinib: DMARDsc were discontinued in 4 patients and the steroid dose was reduced in 58.3% of the total, being discontinued in 21.2%. With respect to disease activity analyzed post-treatment in patients who maintained the drug, a mean of SJC 0, TJC 2, CRP 0.8 mg/dL, DAS28 2.7 and CDAI 12.5 were observed (Table 1). The drug was discontinued in 11 patients: 5 for adverse events (headache, hypersensitivity, gastrointestinal discomfort, instability accompanied by photopsia, lymphopenia and irritative cough) that resolved after discontinuation, 5 for primary failure and 1 for secondary failure. No cases of herpes, thrombosis or cardiovascular events were recorded.

Table 1. Medians pre-treatment and post-treatment outcomes in patients who maintained upadacitinib: SJC, TJC, C-Reactive Protein (CRP) and disease activity indices DAS28 and CDAI.

Conclusion: Upadacitinib managed to control disease activity in a high percentage of our series of patients resistant to multiple synthetic and/or biologic DMARDs, making it possible to reduce or even suspend steroid treatment in a significant number of patients, so it may be an option to consider in patients with refractory RA. Longer-term studies are needed to continue evaluating the effectiveness, safety and survival of the drug in real clinical practice.

* n (%), if otherwise specified; median (IQR) for numeric values. CI: Confidence Interval, MACE: Major adverse cardiovascular events, VTE: Venous thromboembolism (pulmonary embolism or deep vein thrombosis)

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2022-eular.4309

Background: Tofacitinib is a targeted synthetic DMARD that selectively inhibits Janus kinase (JAK) and is approved for the treatment of RA by the FDA in 2012. In recent years, an important safety concern related to incidence of adverse events after treatment with tofacitinib has emerged.

Objectives: To evaluate the risk of major adverse cardiovascular events (MACE), venous thromboembolism (pulmonary embolism or deep vein thrombosis), serious infections requiring hospitalization, and herpes zoster with tofacitinib in RA patients aged ≥ 60 years.

Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a single center biological and targeted synthetic DMARD registry since 2005. We analyzed RA patients aged ≥ 60 years receiving tofacitinib who had at least 1 control visit registered in the HURBIO database. Phone calls were made with these patients for the current health status information until the end of January 2022. The data of the patients who lost the follow-up in our clinic were obtained from the personal health record system of the Republic of Turkey Ministry of Health by patients' permission. The coprimary end points were adjudicated MACE, VTE, serious infections, and herpes zoster. These events were identified using patients’ medical records. Crude incidence rates were expressed in patients with first events per 100 patient-years, with two-sided 95% confidence intervals.

Results: A total of 132 RA patients (109, 82.6% female) aged ≥ 60 years received tofacitinib at a dose of 5mg twice daily. The median (25–75% percentiles) age was 67 (63-73) years and median duration under tofacitinib was 18 (5-33) months. Approximately 70% of patients were biologically naive. During a median follow-up of 1.5 years, the incidences of serious infection requiring hospitalization and herpes zoster were higher (5.5% [95%CI 3.12-9.86] and 3.4% [1.67-7.17], respectively) while there was no increase in the incidences of MACE and VTE. The causes for hospitalization were as follows: COVID-19 (n=4), pneumonia (n=3), soft-tissue infection (n=3), and GIS infection (n=1). Two of these patients deceased.

Conclusion: Older patients with RA are at increased infection risk because of age and comorbid conditions. Although adverse events are reported with 10mg tofacitinib twice daily, clinicians should be careful against the risk of infection at a dose of 5mg twice daily, especially in elderly patients.

DOI: 10.1136/annrheumdis-2022-eular.4254

Background: Methotrexate (MTX) forms the first line therapy for rheumatoid arthritis (RA). The cardioprotective effect of MTX is well established, but whether this is just due to control of inflammation, or is also via an effect on serum lipoproteins, is unclear. Although a few studies have studied the effect of the MTX on the
Objectives: To determine the short-term effect of MTX on apolipoproteins and traditional lipid profile in patients with active RA.

Methods: DMARD-naive patients with active RA (SJC≥2 and TJC≥4) who had been enrolled in the multicentre, RCT comparing two different MTX escalation strategies in RA (MEIRA) and for whom paired serum samples were available before and after MTX treatment were included. All these patients received MTX monotherapy started at 15 mg/week and escalated to 25 mg/week by 4-8 weeks. Serum levels of apolipoprotein A1 (Apo A1), apolipoprotein B (Apo B), total cholesterol (TC), low-density lipoprotein (LDL), high-density lipoprotein (HDL), and triglycerides (TG) were measured before starting MTX and after 16 weeks of MTX monotherapy. Proatherosclerotic indices (TC/HDL and ApoB/ApoA1) were also calculated.

Results: A total of 103 patients (mean age 40 (8) years, 93 (90%) females, mean BMI 25.1 (4.8) kg/m², all non-smokers and non-alcoholics) were included. No study participant had comorbid diabetes mellitus or coronary artery disease. None of them were taking glucocorticoids or hypolipidemic drugs. An increase in Apo A1 levels [by a mean of 6.5 mg/dL (p=0.02)] and HDL levels [by a mean of 1.6 mg/dL (p=0.04)] was seen after 16 weeks of MTX monotherapy. Although a numerical increase in levels of TC (mean 4.6 mg/dL, p=0.07), LDL (mean 2 mg/dL, p=0.34) and TG (mean 6.6 mg/dL, p=0.35) was also noted, none of these changes were statistically significant. No obvious change in Apo B levels and TC/HDL ratio occurred due to MTX therapy. However, the ApoB/ApoA1 ratio decreased significantly from 0.8 to 0.7 (p=0.002) with 16 weeks of MTX therapy (Table 1).

Table 1. Baseline and end of treatment values of apolipoprotein A1 (Apo A1), apolipoprotein B (Apo B), total cholesterol (TC), low-density lipoprotein (LDL), high-density lipoprotein (HDL), triglycerides (TG), and proatherosclerotic indices (TC/HDL and ApoB/ApoA1).

</table>

All values represented as mean (SD); Apo A1apolipoprotein A1, Apo Bapolipoprotein B, TCtotal cholesterol, LDLlow-density lipoprotein, HDLhigh-density lipoprotein, TGtriglycerides

Conclusion: MTX therapy led to a mild but significant increase in HDL. ApoA1 and a reduction in HDL, ApoB1, and ApoB/ApoA1 over short-term. This could potentially represent one of the mechanisms by which MTX exerts its cardioprotective effect; however, these changes need to be carefully interpreted over longer term and in context of the lipid paradox operating in RA.

AB0419

RHEUMATOID ARTHRITIS SWITCHING PATTERNS AND THE GROWTH OF SMALL MOLECULE TREATMENT IN THE EUS

M. Yarnall1, P. C. Taylor2, P. Pouliot1, E. Hettel1, K. Murray1, 2, Spherix Global Insights, Rheumatology Market Research, Exton, United States of America; 1The Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: TNF-α inhibitor therapy has long been the standard of care for adult patients diagnosed with moderate to severe rheumatoid arthritis (RA) across the EUS, though several new biologics, biosimilars, and small molecules have become available for the treatment of RA.

Objectives: This research sought to understand the factors influencing treatment changes when patients are switched from one biologic or small molecule to another, including the reason(s) for their treatment selection.

Methods: An independent market analytics firm collaborated with EUS rheumatologists (n=250 across France, Germany, Italy, Spain, and the UK) to conduct a retrospective chart review of patients diagnosed with RA (n=1,268) who had switched from one biologic therapy or small molecule agent to another in the prior twelve weeks. Data were collected in August and September 2021 and included clinical and non-clinical patient demographics as well as physician demographics and attitudinal survey responses. This study was a non-longitudinal trending analysis to 2020 (n=1,288, 2019 (n=1,294), 2018 (n=1,312) and 2017 (n=1,235)

Results: 70% of surveyed rheumatologists reported recent changes to the management of their RA patients, with the most recalled treatment shift being an increased use of small molecule agents (JAK inhibitors, 30%), attributable to the introduction of upadacitinib and filgotinib in December 2019 and September 2020, respectively. Despite a plethora of RA treatment options in the EUS, annual physician-reported rates of RA patient switching have remained stable since 2017, with 25% of biologic/small molecule-treated patients switching brands within a given year. There has been a steady increase in switches from TNF inhibitors to JAK inhibitors over the last few years (2% in 2017 to 19% in 2021). At the same time, the rates of TNF cycling have been on a downward trend (43% in 2017, 40% in 2018, 39% in 2019, 34% in 2020, and 32% in 2021), indicating that patients are more likely to remain on their current therapy due to secondary efficacy failure, and their primary reason for selecting a JAK was due to the switch pattern.

Disclosure of Interests: None declared.

AB0418

INCREASED THROMBOEMBOLIC RISK OF JAK INHIBITORS AFTER SWITCHING FROM BIOLOGIC DMARDs IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Eun1, G. H. Seo2, S. Y. Kang3, S. Lee4, H. Kim4,5, H. S. Cha6, E. M. Koh7, J. Lee8. 1Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea); 2Health Insurance Review and Assessment Service., Wonju, Korea, Rep. of (South Korea); 3Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 4Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medical Humanities, Seoul, Korea, Rep. of (South Korea)

Background: Safety concerns regarding JAK inhibitors have grown since the ORAL surveillance trial reported that their use was associated with an increase in major adverse cardiovascular events compared to TNF inhibitors. However, real-world data on the association between JAKI and thromboembolic events are sparse.

Objectives: We compared the incidence of thromboembolic events (TEs) before and after switching to Janus kinase inhibitors (JAKI) from biologic disease-modifying anti-rheumatic drugs (bDMARDs) in patients with rheumatoid arthritis (RA).

Methods: Among patients with a diagnostic code for RA taking bDMARDs, patients who switched to JAKI or another bDMARD between March 2015 and December 2020 were included in this self-controlled case series study. The outcomes were the occurrence of TEs. The incidence rate ratios (IRRs) for TEs in the period after switching to JAKI or another bDMARD compared with the period before switching were calculated based on an assumed Poisson distribution.

Results: There were 1,150 and 2,254 patients who switched to JAKI and another bDMARD, respectively. The mean follow-up duration was 4.5 ± 1.8 years. In the JAKI group, the IRR for TE after drug switching was 1.56 (95% confidence interval [CI] 1.22–1.98, P < 0.001) compared with the period before the drug switch; in the bDMARD group, the IRR was 1.16 (95% CI 0.96–1.38, P = 0.079).

Conclusion: Switching from bDMARDs to JAKI was associated with an increase in TE incidence in RA patients in a real-world setting.

AB0421 ASSESSMENT OF LIVER STIFFNESS IN RHEUMATOID ARTHRITIS PATIENTS UNDER METHOTREXATE

W. Lahmar1, M. Slouma1, G. Mohamed2, R. Dahbi1, L. Metoui1, I. Gharsallah1, N. Abdelil1

1Military Teaching Hospital, Rheumatology, Tunis, Tunisia; 2Military Teaching Hospital, Gastroenterology, Tunis, Tunisia

Background: Methotrexate (MTX) is recommended as a first-line disease-modifying antirheumatic drug for treating rheumatoid arthritis (RA) in monotherapy or combinational therapy. A concern about MTX-related liver fibrosis in patients with rheumatoid arthritis (RA) is still unsolved.

Objectives: The aim of the study cutoff of cumulative dose discriminating patients with normal from those with abnormal liver stiffness.

Methods: We conducted a cross-sectional study including consecutive RA patients diagnosed according 2009 ACR-EULAR criteria. Liver stiffness (LS) was assessed by Fibroscan in the gastroenterology department by an experi-

Results: There were 18 men and 36 women. The mean age was 51.9 ± 11.49

Conclusion: Our study showed that LS correlated to both MTX duration and cumulative dose. Patients with a cumulative dose of MTX higher than 7330 mg required a close follow up of liver elastometry and monitoring of hepatic function.

SLE, Sjögren’s and APS – treatment

AB0422 SODIUM BICARBONATE MOUTH RINSE IS A USEFUL SELF-CARE METHOD FOR DRY MOUTH IN PATIENTS WITH SJÖGREN’S SYNDROME

N. Azumā
, K. Matsuł, Hyogo College of Medicine, Division of Diabetes, Endocrinology and Clinical Immunology, Nishinomiya, Japan

Background: Patients with Sjögren’s syndrome (SS) present various symptoms related to dry mouth. While hyposalivation is believed to be the main cause, saliva has various beneficial physiological effects on the intraoral environment, and qualitative changes in its composition should also be considered as a cause of the ororectory and oral manifestations in SS. One of the physiological effects of saliva is buffering, and salivary bicarbonate (HCO3) is the main determinant of salivary buffering capacity. Since salivary concentration of bicarbonate heavily depends on the rate of salivary secretion, salivary buffering capacity and oral pH decrease in patients with dry mouth; this is associated with the development of dental caries and oral candidiasis. It is considered that sodium bicarbonate mouth rinse is effective for suppressing these intraoral disorders. It is also a practical self-care method because it is inexpensive and can be made at home.

Objectives: To investigate the usability and changes in symptoms associated with dry mouth after use of sodium bicarbonate mouth rinse in SS patients.

Methods: The subjects were 27 SS patients (female: male = 24:3, mean age 62.9 years, primary SS: secondary SS = 24:3, mean disease duration 12.3 years) who had used sodium bicarbonate mouth rinse (dissolve about 5 g of commercially available baking soda in 500 cc of water in a plastic bottle. Put this sodium bicarbonate water in the mouth and rinse the mouth for 30 seconds to 1 minute as to reach throughout the oral cavity). We investigated usage status, usability, and changes in subjective symptoms using a questionnaire. During their using the mouth rinse, medication and countermeasures against dry mouth in the daily life continued as usual.

Results: More than half of the patients had no knowledge of sodium bicarbonate mouth rinse (n=15; 55.6%). Highest frequency of use was twice a day (n=9; 33.3%), and common use situations were before bedtime (n=18; 66.7%), after meals (n=17; 63.0%), and at waking up (n=11; 40.7%). Twenty patients (74.1%) had “very good” or “good” sense of use. Eighteen patients (66.7%) had relief of symptoms related to dry mouth. Pros were “feeling refreshed in the mouth” (n=14; 51.9%), followed by “becomes less sticky” (n=8; 29.6%), “easy to make” (n=7; 25.9%), and “inexpensive” (n=6; 22.2%). Some respondents said they had less glossitis, stomatitis, and angular cheilitis (n=4; 14.8%). For cons “troublesome was the highest (n=10; 37.0%), followed by responses regarding “taste” (n=6; 22.2%). There were also many responses to “none in particular” (n=7; 25.9%). No obvious accidents occurred, and 20 (74.1%) of them replied that they would like to continue to use the sodium bicarbonate mouth rinse.

Conclusion: In addition to the inhibition of dental caries and oral candidiasis, removal of tongue plaque and refreshing feeling in the mouth after rinsing due to its mucolytic effect, reduction of halitosis-causing volatile sulfur compounds, and improvement of gingivitis have been reported as effects of sodium bicarbonate. However, reports on the effects of sodium bicarbonate on dry mouth in SS patients are scarce. These results suggest that sodium bicarbonate mouth rinse is considered to be a useful self-care method that can compensate for the salivary buffering capacity that is impaired in SS patients and may reduce dry mouth symptoms. Since it is easy to continue and safe, it is worth actively incorporating it into the standard treatment for SS. Evaluation in more patients with objective indices is desired in the future.

AB0423 STRATEGIES FOR GLUCOCORTICOID TREATMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS FLARES: A REAL-LIFE EXPERIENCE

L. Scagnellato
, M. Matti
, C. Tani
, E. Elefante
, F. Trentin
, F. Ferro
, D. Zucchi
, C. Stagnaro
, L. Carli
, M. Mosca
. 1Hyogo College of Medicine, Division of Diabetes, Endocrinology and Clinical Immunology, Nishinomiya, Japan

Background: Glucocorticoids (GC) are a cornerstone for the treatment of Systemic Lupus Erythematosus (SLE) manifestations but there is still open debate concerning their optimal therapeutic employment.

Objectives: To describe and compare the GC therapeutic strategies used in a real-life setting for the initial treatment of SLE flares.

Methods: This study is a retrospective analysis of data from a monocentric cohort of SLE patients who registered a disease flare between 2015 and 2020. Flares were first categorized in “pulse-treated” (PT) and “non pulse-treated” (NPT). PT flares were then divided into “low-dose regimen” (250 mg iv 6MP for 3 consecutive days or less) and “high-dose regimen” (more than 250 mg iv 6MP for 3 days).

Results: 101 flares were analyzed (30 PT and 71 NPT). PT flares were more severe in terms of median SLEDAI (PT 16 (12-22) vs NPT 8 (5-10) p=0.00) and BILAG score index (BILAG A PT 71% vs NPT 30% p=0.001). PT patients received significantly higher GC doses at 1 month (PT median cumulative dose 1372 IQR 1028 – 3076 mg of 6MP vs NPT median 160 IQR 10-286 mg of 6MP, p<0.000), 6 months (PT median cumulative dose 2964 IQR 2294 – 4305 mg of 6MP vs NPT 680 IQR 720 – 1294 mg of 6MP, p=0.000) and 12 months (PT median cumulative dose 3510 IQR 3014-5025 vs NPT median cumulative dose 1571 IQR 1098 – 2122 mg of 6MP, p=0.000). Characteristics of flares that were treated with low-dose (N=19) or high-dose (N=11) pulse regimen are summarized in Table 1. As expected, the “low-dose” subgroup received lower cumulative GC dosage over time. However, no statistically significant differences were found neither in term of disease severity at baseline nor in term of disease activity, remission rates or new flares over time.

Table 1. Comparison between low-dose pulse regimen and high-dose pulse regimen in terms of cumulative GC dose and outcome in the first year after a SLE flare

Conclusion: These data suggest that in a real-life setting, pulse GC therapy is preferred over oral administration for severe SLE flares and entails administration of high cumulative doses of GC. However, the experience outlined suggests that the low-dose pulse regimen is as effective in remission induction of severe flares as the high-dose regimen, allowing significant GC sparing. Since the cumulative GC dose is known a strong predictor of organ damage, strategies aimed to minimize the GC dosage should be encouraged.

Background: Therapeutic agents targeting the B-cell cytokines BAFF and/or APRIL, including the wild-type (WT) TACI-Fc fusion proteins atacicept and telitacicept, have demonstrated promising clinical potential in rheumatoid diseases like systemic lupus erythematosus (SLE) and/or other B-cell-related diseases such as autoantibody-related nephritides. ALP-303 is an Fc fusion protein of a variant, engineered TACI domain which mediates significantly more potent inhibitory activity in vitro as compared to WT TACI-Fc or BAFF- or APRIL-specific monoclonal antibodies, along with enhanced pharmacokinetic (PK) and immunomodulatory properties in preclinical studies.1,2 ALP-303 may therefore significantly improve clinical outcomes in SLE and other B-cell-related diseases.

Objectives: To evaluate the safety, tolerability, PK, and pharmacodynamics (PD) of ALP-303 in adult healthy volunteers (HV).

Methods: This is a first-in-human study (NCT05034484), adult HVs are enrolled to evaluate the safety, tolerability, PK, and pharmacodynamics (PD) of ALP-303 in adult healthy volunteers (HV).

WHAT DOES IT MEAN TO BE A DUAL BICLA AND SRI(4) RESPONDER? A POOLED ANALYSIS OF TWO PHASE 3 TRIALS IN PATIENTS WITH SLE

Methods: This was a post hoc analysis of pooled data from the randomized, 52-week double-blind TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) trials in which patients with moderate to severe SLE despite standard therapy received intravenous anifrolumab (150/300 mg) or placebo every 4 weeks for 48 weeks. Both TULIP-1 and TULIP-2 used the same study design and required a positive response in BICLA and SRI(4) criteria at Week 52 (dual responders) with anifrolumab and placebo, irrespective of treatment assignment.

Results: Among patients who met both BICLA and SRI(4) criteria, anifrolumab had greater anti-inflammatory and disease-modifying effects compared with placebo. At Week 52, dual responders had higher degrees of improvement in disease activity, especially in arthritis, and the healthcare utilization measures have significantly better outcomes across a range of clinical, PRO, and healthcare utilization measures compared with dual nonresponders. The higher degree of improvement in disease activity, especially in arthritis, and the greater reduction in oral GC dose compared with single responders is reflected in improved patient well-being, functional functioning, and fatigue. Being a dual responder offers a profound and clinically meaningful outcome for both the clinician and patient.

Background: The BILAG–based Composite Lupus Activity Index (BICLA) and SLE Responder Index ≥4 (SRI[4]) responses were endpoints in the phase 2b MUSE and phase 3 TULIP-1/2 trials.1-3 In a post hoc analysis, more patients met both the BICLA and SRI(4) response criteria at Week 52 (dual responders) with anifrolumab compared with placebo (MUSE: 48.5% vs 19.9%; TULIP-1: 42.2% vs 27.9%; TULIP-2: 43.4% vs 26.4%; all nominal P<0.001).1-3 Whereas the clinical benefit of BICLA responses alone has been characterized,4 the added benefit of dual BICLA/SRI(4) responses remains unknown.

Objectives: To understand the clinical benefits (SLE clinical assessments, patient-reported outcomes [PROs], and healthcare utilization) of having a dual BICLA/SRI(4) response vs a response for just one endpoint or nonresponse for both, irrespective of treatment assignment.

Methods: This was a post hoc analysis of pooled data from the randomized, 52-week double-blind TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) trials in which patients with moderate to severe SLE despite standard therapy received intravenous anifrolumab (150/300 mg) or placebo every 4 weeks for 48 weeks.1-3 Patients were categorized as dual responders (met both BICLA and SRI[4] response criteria at Week 52), single responders (met one of either BICLA or SRI[4] response criteria), or dual nonresponders (did not meet either response criteria). SLE clinical assessments, PROs, and healthcare utilization through Week 52 were evaluated for each group. Statistical comparisons were conducted for dual responders vs single responders and dual nonresponders.

Results: Patient demographics and baseline characteristics were generally balanced across dual responders (n=288), single responders (n=122), and dual nonresponders (n=409). At Week 52, dual responders had greater improvements in SLE-related measures compared with dual nonresponders across all evaluated clinical, PRO, and healthcare utilization outcomes (Figure, A–E). Compared with single responders, dual responders had a significantly greater mean change from baseline in SLEDAI-2K score (−8.2 vs −5.1; nominal P<0.001), PGA score (−1.3 vs −0.9; nominal P<0.001), and swollen joint counts (−6.2 vs −4.5; nominal P<0.001) (Panel A); there was also a numerically greater proportion with ≥50% reduction in CLASI-A score (91% vs 76%; nominal P=0.076) (Panel B). Dual responders had a greater mean reduction in baseline oral glucocorticoid (GC) daily dose (−5.6 vs −3.4; nominal P=0.001) vs single responders (Panel A). For PROs, compared with single responders, dual responders had a greater mean change in baseline PtGA score (−17.7 vs −8.6; nominal P<0.001), and a higher proportion had clinically meaningful improvements from baseline to Week 52 in fatigue (FACT-F; 56% vs 43%; nominal P=0.014) and SF-36 physical component scores (60% vs 34%; nominal P=0.001) (Panel C–D). Healthcare utilization (ED visits and hospitalizations) was lower in dual responders vs single responders; however, this comparison did not reach nominal significance (nominal P=0.462 and 0.311, respectively) (Panel E).

Conclusion: Patients with SLE with dual responses in two validated outcome measures have significantly better outcomes across a range of clinical, PRO, and healthcare utilization measures compared with dual nonresponders. The higher degree of improvement in disease activity, especially in arthritis, and the greater reduction in oral GC dose compared with single responders is reflected in improved patient well-being, functional functioning, and fatigue. Being a dual responder offers a profound and clinically meaningful outcome for both the clinician and patient.

AB0426 THERAPY WITHOUT GLUCOCORTICOIDS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A. Mesnyankina1, E. Aseeva1, N. Nikishina1, A. Lila1, T. Popkova2.

Scientific Institution, Moscow, Russian Federation;

1V. A. Nasonova Research Institute of Rheumatology, Federal State budgetary Scientific Institution, Moscow, Russian Federation;

Background: The effectiveness of glucocorticoid (GC) therapy in SLE is beyond doubt and has been confirmed by the experience gained over many decades of their use. However, with prolonged use of GC, even in low and medium doses, there are many problems. In particular, the development of organ damage associated with GC significantly worsens the prognosis, leads to a decrease in the quality of life, social adaptation. Currently, attempts are being made to use therapeutic programs without the use of GC or with their appointment in minimal doses.

Objectives: Achieving stable remission in patients with SLE. Cancellation of oral GC or the use of therapy without GC in patients with SLE.

Methods: 3 clinical cases. Two patients (N1, N2) had a combination of SLE with Sjogren's syndrome with predominantly musculoskeletal syndrome. In these patients, severe organ lesions (lupus nephritis, vasculitis, central nervous system damage) were excluded. SLEDAI-2K in these patients was 9 and 8 points. Both patients had a decrease in C3, C4 complement component, ANA positivity, arthritis, hematological disorders. In N2, an increase in at ds-DNA was determined. Therapy with oral GC, immunosuppressive drugs was not carried out in them. Patient N3 with lupus nephritis (hematuria, leukocyturia), exudative pleurisy, polyarthritis, high immunological activity (SLEDAI-2K - 16 points) was prescribed GC at a dose of 2 tab per day. Creatinine and urea were within normal limits. The patient had high immunological activity: low C3, C4 complements, low ANA positivity (1:1280). Due to the presence of lupus nephritis, the patient received mycophenolate methylot (1500 mg per day. All patients received double anti-B-cell therapy with the sequential use of Rituximab (RTX) 1000 mg intravenously in patients N1 and N2, and N3 at a dose of 2000 mg per day with premedication of 6-methylprednisolone at a dose of 250-500 mg intravenously. After 1-3 months, belimumab infusions were started at a dose of 10mg/kg per month. The observation period is 1 year.

Results: Anti-B-cell therapy allowed patients to be treated without oral GC. A patient with LN (N3) was prescribed low doses of GC at the time of initiation of therapy with RTX, however, they were subsequently completely canceled by the 6th month of therapy. Clinical remission of the disease was achieved in all three patients. Clinical manifestations of the disease were stopped. SLEDAI-2K was 0-2 points due to minor hypocomplementemia (Figure 1). No new irreversible organ damage and relapse of the disease were registered. Patients continued to receive monthly infusions of BLM, there were no repeated courses of RTM. The patient with kidney damage continued to take MM.

Conclusion: Consistent therapy of RTX and BLM allowed to achieve not only a high clinical and immunological effect, but also the possibility of reducing and even abandoning the oral dose of GC, which is consistent with the concept of “Treat to target” in SLE. In addition, all patients were closely monitored by a rheumatologist monthly once a month, which was partly achieved thanks to monthly infusions of BLM, which were carried out in the clinic.

AB0427 RENAL INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS: A DIFFICULT-TO-TREAT CLINICAL CASE

R. Santageli1, S. Salvucci1, G. Montozzi1, L. Manfredi2, G. Moroncin1,2. 1Ospedali Riuniti Ancona University Hospital, Internal Medicine Residency Program, Ancona, Italy; 2Ospedali Riuniti Ancona, Internal Medicine, Ancona, Italy

Background: Lupus nephritis (LN) is one of the major organ involvement of Systemic Lupus Erythematosus (SLE), causing significant increase of morbidity, mortality and healthcare impact.1 According to international guidelines, immunosuppressive therapy is indicated for LN class III and IV, while class V usually do not require this treatment, less than there is a proteinuria in the nephrotic range, and so for class II, also with a risk of evolution in a more aggressive form.2 Immunosuppressive drugs commonly used are mycophenolate mofetil/mycophenolate acid (MMF/MPA) and cyclophosphamide for the initial treatment and MMF/MPA or azathioprine for the maintenance of remission. LN treatment is often difficult because of the drug adverse events and the comorbidities that make therapeutic choices very challenging.

Objectives: We describe the case of a young woman with SLE and other major systemic comorbidities who developed severe LN. This case emphasizes the importance of considering patients in their complexity and the delicate role of the physician in tailoring the treatment strategy on the individual patient.

Methods: A 36-year-old woman presented to our Department for lymphadenopathy, headache, epistaxis, fever and weight loss. In her past medical history, she had a cerebral abscess caused by Streptococcus Constellatus with residual left hemiplegia and cervical HPV-related high-grade dysplasia, treated by ring biopsy. Upon admission, blood tests revealed severe neutropenia and lymphocytopenia, thrombocytopenia and low complement; blood cultures were negative. A total body CT scan showed multiple lymphadenopathies. Lymph node and bone marrow biopsies were performed and histological examination was negative for hematological disease. The autoimmune panel was positive for antinuclear, anti-DNA, anti-Sm, anti-U1RNP, anti-cardiolipin and anti-beta2glycoprotein antibodies. According to clinical and laboratory results, a diagnosis of SLE was made.

Results: High-dose corticosteroid therapy was started with good clinical response and improvement of blood tests. Because of the gynecological history, immunosuppressive therapy was not started, and a wait-and-see strategy with steroid tapering and careful follow-up was started. A few months later, the patient developed an increase of serum creatinine with proteinuria at nephrotic range. Thus, a kidney biopsy was performed with evidence of class III LN. Following this result, we started high-dose corticosteroid therapy, with only partial response. After executing colpostopy with biopsy, that was negative for HPV-related lesions, we decided to start MMF, continuing with a careful follow-up. After six months, proteinuria reduced but maintained on levels around 1 gr per day. Bearing in mind the growing number of studies reporting the efficacy of belimumab in LN 3,4, we added this drug to achieve a better disease control, continuing to closely monitor the patients and potential adverse events.

Conclusion: In patients with LN the choice of the immunosuppressive therapy can be very challenging. A tailored approach to the individual patient may be the best option to improve the management of this complex disease.

Background: Systemic lupus erythematosus (SLE) is a chronic, autoimmune disease of unknown etiology with a broad spectrum of organ manifestations, and patients with SLE have limited treatment options to NSAIDs, glucocorticoids, hydroxychloroquine and immunosuppressants. There is a lack of real-world evidence related to treatment patterns of SLE patients in Taiwan.

Objectives: To describe the real-world patient demographics, clinical characteristics, and treatment patterns of patients with SLE in Taiwan.

Methods: A retrospective observational study using Taiwan's National Health Insurance Research Database (NHIRD) from 1/1/2014 to 12/31/2019 was undertaken. Patients holding catastrophic illness certificates for SLE in 2015-2017 were identified. Enrolled patients aged ≥ 18 years were then divided into three groups (mild, moderate, and severe) based on the highest severity patients experienced in the one year following the enrollment date using a published claims-based algorithm (Garris et al 2013) that incorporates the Systemic Lupus Erythematosus Disease Activity Index, Systemic Lupus Activity Measure, British Isles Lupus Assessment Group Index and expert clinical opinion, and indexed upon the first date of entering the severity group. Baseline patient characteristics and treatment patterns during the follow-up period were measured. The types of treatment considered were NSAIDs, glucocorticoids, hydroxychloroquine and immunosuppressants.

Results: A total of 20,181 patients with catastrophic illness certificates for SLE were included in this study. The mean age of all SLE patients was 46.5 years and patients were mostly female (89.1%). The mean Charlson Comorbidity Index (CCI) score of all SLE patients was 15 (SD 13). Of these patients, 29.3% (n=5,918) had mild SLE activity, 60.7% (n=12,253) moderate and 10.0% (n=2,010) severe. During the one-year follow-up period, moderate to severe patients had numerically higher utilization rate of all types of treatment compared with mild patients (Table 1). Of all oral glucocorticoid users, 27.8% of severe patients used high-dose glucocorticoids (> 15 mg/day) compared to < 0.1% for mild and 9.7% for moderate patients. More than 70.0% of moderate to severe patients were prescribed 2 or more types of treatment at the same point of time. Of these patients having concomitant treatment of glucocorticoids with immunosuppressants, glucocorticoid dosage increased with the number of immunosuppressant used, especially in severe patients. 80.4% of moderate to severe patients received glucocorticoid-based therapy as the first-line treatment and the median treatment duration was 3.1 months. The median treatment duration of each first-line immunosuppressant ranged from 0.9 to 4.8 months in moderate to severe patients.

Table 1. SLE treatment utilization during the 1-year follow-up period

Conclusion: The complexity and intensity of therapeutic approaches in SLE were associated with increased disease severity and patients were often resistant to treatment. These findings reflect the disease burden in SLE patients and suggest there is a substantial unmet need in the SLE treatment paradigm for moderate to severe SLE patients.

REFERENCES:
During the pregnancy courses, no patient developed bacterial infections, two (29%) patients developed viral infections (one with upper respiratory tract infection and the other with acute gastroenteritis), and two (29%) had herpes zoster reaction, which resolved smoothly after five-day course of oral valacyclovir.

Conclusions: The belimumab appeared to be safe in ITP patients with pregnancy, with no obvious increase in the infections and obstetric complications. Based on these observations, belimumab may be considered as one of the pharmacological options for SLE with ITP patients during pregnancy.

DOI: 10.1136/annrheumdis-2022-eular.1903
Background: Defects in regulatory T cell (Treg) number and function are associated with autoimmune diseases including SLE. Interleukin (IL)-2 is essential for the development and suppressive function of Treg, and therapies that exploit the ability of IL-2 to expand Treg have shown disease-modifying potential in SLE. However, low-dose IL-2 has a short half-life and narrow selectivity for Treg over conventional CD4+T cells (Tcon) and natural killer (NK) cells. Efavaleukin alfa is an IL-2 mutein Fc fusion protein; an introduced mutation decreases binding to IL-2Rβ and increases dependence on IL-2Rα (CD25). This preferential binding to the high-affinity IL-2R, constitutively expressed at high levels on Treg, leads to increased cell surface retention and sustained Treg signaling compared with recombinant IL-2. In healthy subjects, a single dose of efavaleukin alfa was well-tolerated and led to robust and selective Treg expansion.2

Objectives: This final analysis of a phase 1b, double-blind, placebo-controlled, multiple ascending dose study (NCT03451422) reports the safety, tolerability, pharmacokinetics (PK), and pharmacodynamic effects of efavaleukin alfa in patients with SLE.

Methods: The study included five ascending dose cohorts (cohort 1=lowest dose; cohort 5=highest dose). A total of 35 patients with SLE (age 24–71 years; 85.7% female; SLE diagnosed using SLICC or ACR criteria with ANA ≥1:80 and/or elevated anti-dsDNA antibodies) were randomized to receive efavaleukin alfa or placebo (5:2 ratio for cohorts 1–3; 3:1 ratio for cohorts 4–5) subcutaneously every 2 weeks (Q2W; cohorts 1, 2, 4, and 5) or every week (QW; cohort 3) in addition to standard of care therapy for a total of 12 arms, with 6 weeks of follow-up. The primary endpoint was the incidence of treatment-emergent adverse events (TEAEs). Additional endpoints included serum PK of efavaleukin alfa and changes in numbers of Treg, CD4+ Tcon, CD8+ T cells, and NK cells in peripheral blood.

Results: The most commonly reported TEAEs (occurring in ≥25% of efavaleukin alfa-treated subjects) included non-serious, mild or moderate (grade 1–2) injection site reactions. No grade 4 TEAEs or deaths occurred. Two serious AEs were reported in efavaleukin alfa-treated subjects: one event of syncope (grade 3) was observed in cohort 2 and was not considered related to treatment, and one case of eosinophilia (grade 2) was observed in cohort 5 and was considered related to treatment. Efavaleukin alfa PK was generally linear and dose-proportional, with particular focus on: 1) Risk factors for development of ADA. 2) Impact of ADA on treatment response. 3) Influence of ADA on RTX drug kinetics over time. 4) The capacity of ADA to neutralise RTX.

Objectives: In this study we evaluated the longitudinal impact of ADA positivity with particular focus on; 1) Risk factors for development of ADA. 2) Impact of ADA on treatment response. 3) Influence of ADA on RTX drug kinetics over time. 4) The capacity of ADA to neutralise RTX.

Methods: Patients with SLE undergoing treatment with RTX were recruited to this study (n=35). Serum samples were collected at the following intervals pre-treatment; 1-3 months (defined as ‘early’ pre-treatment), 6 months, 12 months, 36 months (n=114). Clinical and laboratory data was collected pre-treatment and at each follow-up time point. Response to treatment was assessed by improvement in SLEDAI-2K score from baseline and also according to BILAG as previously described (3). ADA were detected using an electrochemiluminescent immunoassay. Serum RTX levels were measured by ELISA. ADA status was defined according to the following patterns over time; persistently negative, persistently positive (0-15 AU/ml) and persistently high positive (≥16 AU/ml, upper quartile). A complement dependent cytotoxic assay was used to determine neutralising capability of ADA in a subgroup of positive samples (n=38).

Acknowledgements: Funding: Amgen Inc

Figure 1.
Results: ADA to RTX were found to be persistently positive in 64.3% of patients over the 36-month follow-up period and there was no significant difference in baseline disease activity (BILAG / SLEDAI-2K) between those who were subsequently ADA positive vs negative. ADA positive patients had a younger age at diagnosis of SLE when compared with ADA negative (mean 22.50 ± 9.10 vs 37.29 ± 11.31 years, p=0.002, Figure 1 A). Multivariate logistic regression found a 22% decrease in risk of ADA positivity for each addition year after diagnosis (p=0.03).

ADA positive patients had a significantly lower C3 level at baseline (mean 0.61 ± 0.23 g/L vs 0.87 ± 0.30 g/L, p=0.026), which remained lower at each subsequent time point post-treatment up to 12 months post-treatment (Figure 1B).

At 1-3 months post-RTX, patients who were ADA positive had a significantly lower circulating drug level than ADA negative (p<0.001, Figure 1 C). In terms of clinical response, ADA positive patients had an initial significant improvement in disease activity (SLEDAI-2K) by 3 months (p<0.001). However, response was not maintained at 12 months (Figure 1 D). In comparison, ADA negative patients showed a significant improvement in SLEDAI-2K at 6 months and this was maintained across the 36-month follow-up period (Figure 1 E).

BILAG defined relapse was more common at six months post-treatment in ADA positive patients (22%) and ADA highly positive patients (33%) than those who were ADA negative (in which there were no cases of relapse within the first six months, Figure 1 F).

At 12-months post-RTX, a higher rate of BILAG defined Major Response was seen in those who were ADA negative (80%) when compared with ADA positive (44%) and high positive (36%) as shown in Figure 1 G. Finally, antibodies derived from all ADA positive samples (38/38) were found to neutralise RTX in vitro.

Conclusion: ADA to RTX were common and persisted over the 36-month period of this study. ADA associated with earlier serum drug elimination, increased relapse rates and demonstrated neutralising capacity suggesting that ADA could be a significant limitation to sustained response to treatment in clinical practice.

AB0434 EFFICACY AND SAFETY OF OBINUTUZUMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH SECONDARY NON-RESPONSE TO RITUXIMAB.

J. Arnold1,2, S. Dass 1, S. Twigg1, C. Jones1, B. Rhodes1, P. Hewins1, M. Chakravorty7, P. Courtney7, M. Ehrenstein8, M. Y. Md Yusof1,2, E. Vital1,2, 8
1University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 3Bradford Teaching Hospitals NHS Foundation Trust, Rheumatology, Bradford, United Kingdom; 4York Teaching Hospitals NHS Foundation Trust, Nephrology,York, United Kingdom; 5University Hospitals Birmingham NHS Foundation Trust, Rheumatology, Birmingham, United Kingdom; 6University Hospitals Birmingham NHS Foundation Trust, Nephrology, Birmingham, United Kingdom; 7Nottingham University Hospitals NHS Trust., Rheumatology, Nottingham, United Kingdom; 8University College London, Rheumatology, London, United Kingdom

Background: Secondary inefficacy characterized by infusion reactions and anti-drug antibodies occur in 14% of SLE patients treated with repeat rituximab courses(1). Obinutuzumab is a next-generation humanized type-2 anti-CD20 therapy licensed for hematological malignancies which may overcome this issue(2).

Objectives: We set out to evaluate the clinical efficacy and safety of obinutuzumab in a cohort of rituximab resistant SLE patients.

Methods: We collated data from SLE patients receiving obinutuzumab for secondary non-response to rituximab in BILAG centres. Disease activity was assessed using BILAG-2004, SLEDAI-2K and serology before, and 6 months after, obinutuzumab 2x1000mg infusions alongside methylprednisolone 100mg. Flow cytometry where possible was carried out using a multiple gating highly sensitive strategy.

Results: All 9 patients included in the study received obinutuzumab alongside concomitant oral immunosuppression. At 6 months post-obinutuzumab, there were significant reductions in median SLEDAI-2K from 12 to 6 (p=0.014) and total BILAG-2004 score from 21 to 2 (p=0.009). Complement C3 and dsDNA titres improved significantly (both p=0.04). Non statistically significant numerical improvements were seen in C4 levels.

Of 8/9 patients receiving concomitant oral prednisolone at baseline (all >10mg/ day), 5/9 had their dose reduced at 6 months; 4/8 were on 5mg/day and were in Lupus Low Disease Activity State. After obinutuzumab, 6/9 patients with peripheral B-cell data achieved complete depletion including 4/4 assessed with highly sensitive assays. 1/9 obinutuzumab non-responder required cyclophosphamide therapy, 1 unvaccinated patient died from COVID-19.

Conclusion: Obinutuzumab appears to be effective and steroid-sparing in renal and non-renal SLE patients with secondary non-response to rituximab. Obinutuzumab was shown to be effective in patients with severe renal and non-renal disease. Therefore, in those with previous responsiveness to B-cell depletion, switching to humanised type-2 anti-CD20 therapy is a logical approach following loss off efficacy.

AB0435 LUPUS NEPHRITIS RESPONSE IN TERMS OF KIDNEY FUNCTION, URINE SEDIMENT AND SEROLOGICAL ACTIVITY AFTER SUBCUTANEOUS BELIMUMAB TREATMENT.

M. De la Riba Navarro1, J. Ivorra Cortés1, E. Grau García1, L. Gonzalez Puig1, R. Negueruela Albuixech1, I. Martínez Cordelat1, F. Ortiz-Sanjuán1, J. E. Oller Rodríguez1, S. Leal Rodríguez1, C. Pávez Perales1, J. J. Frago Gil1, E. Vicens Bernabéu1, C. Riesco Barcena1, A. V. Huaylla Quispe1, L. Mas Sanchez1, P. Muñoz1, C. Nájera Herranz1, I. Cánovas Olmos1, J. A. Román Ivorra1, 1Hospital Universitario La Fe, Reumatología, Valencia, Spain

Background: Systemic lupus erythematosus (SLE) is a heterogeneous auto-immune disease. Kidney affection appears in 40-50% of SLE patients and may condition the prognosis. Belimumab is a monoclonal antibody approved for SLE
since 2011, but it had no lupus nephritis (NL) indication. Recently, promising results from a controlled Belimumab trial in LN were published.

Objectives: To analyze the effectiveness of Belimumab in LN patients under follow-up by the rheumatology department of a tertiary hospital.

Methods: Observational, retrospective and cross-sectional study including SLE patients (SLICC/ACR 2012 criteria) treated with subcutaneous and/or intravenous Belimumab. Demographic and serological data, concomitant treatment, kidney function and urine sediment were collected.

Results: Sixteen patients with a median age of 47.56 (11.66) years and with 5.40 (0.55) years since Belimumab onset were included. Five patients had LN demonstrated by kidney biopsy and they were included on analysis data. In this group, median age was 39 (6.96) years, patients had 17.80 (10.38) years since Belimumab onset. The most prevalent nephritis type was III and IV, only one patient presented V type.

Regarding the treatment, every patient received antimalarial drugs (chloroquine 40%, hydroxychloroquine 60%) and mycophenolic acid. Concerning the corticosteroid therapy, all patients receive prednisone, with an average dose of 4 mg per day.

The results obtained were included in the Table 1.

Conclusion: Belimumab can improve LN, in terms of serological activity, kidney function and urine sediment. It could be a promising option associated to standand therapy for SLE patients with kidney affection.

L. Piccariello1, F. Ceccarelli1, F. Natalucci1, G. Oliveri1, C. Pirone1, V. Oreto1, C. Garuti1, F. R. Spinelli1, R. Priori1, C. Alessandri1, F. Conti1, Sapienza University of Rome, Rheumatology, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy

Background: Efficacy and safety of belimumab (BLM) in Systemic Lupus Erythematosus (SLE) patients with active disease have been demonstrated by RCTs [1,2] and confirmed by several observational studies [3-8]. Most of these data have been obtained by the use of BLM intravenous formulation (IV); on the contrary, very few findings are available on the use of the drug subcutaneous formulation (SC).

Objectives: Efficacy and drug survival of BLM have been assessed in a monocentric cohort of SLE patients, exploring any difference between the two routes of administration, IV or SC.

Methods: A longitudinal study on SLE patients (according to ACR 1997 classification criteria [9]) candidates for treatment with BLM has been performed. Demographic, clinical-laboratory and therapeutic data - including glucocorticoid dosage in prednisone-equivalent - have been collected. Disease activity has been assessed by SLEDAI-2k [10] in patients with inflammatory articular involvement, DAS28-PCR [11] has been used. In compliance with the study protocol, patients were assessed at baseline and at 3 and 12 months after starting treatment.

Results: A total of 85 patients treated with BLM were enrolled, most of whom were female (male/female 2/83), with a median age of 48 years (IQR 13) and a median disease duration of 127 months (IQR 151). Fifty-one patients (60%) were treated with IV formulation and the remaining 34 (40%) with SC route. BLM was prescribed due to the following clinical manifestations: joint involvement (61.2%), cutaneous manifestations (20.0%), renal involvement (for residual proteinuria, 5.9%), haematological modifications (5.9%), constitutional involvement (3.5%), pericarditis (1.2%), headache (1.2%). In both the formulations, joint involvement was the most frequent indication of BLM (IV: 64.7%, SC: 58.8%). Median treatment duration was 15 months (IQR 24). Moving on drug efficacy, after 3 and 12 months of follow-up BLM has determined a significant reduction of SLEDAI-2k median values (p<0.001, p<0.001 respectively, Figure 1A) as well as of daily prednisone dose (p=0.009, p=0.001 respectively, Figure 1B). In patients treated because of musculoskeletal manifestations, DAS28-PCR reduced significantly at 3 and 12 months after treatment (p<0.0001). Drug survival at 12 months was 70% in the total cohort (Figure 1C) and was higher in patients treated with SC formulation than with IV route (75.8% versus 66.5%, p=ns). During the period of follow-up, 39 patients (45.9%) discontinued BLM: 38.4% of patients due to adverse events, 41% for primary or secondary inefficacy. 15% lost to follow-up, 5.1% for pregnancy. BLM withdrawal for adverse events was more frequent in the group of patients treated with IV formulation than SC one (25.9% versus 5.9%, p=0.0001). 11 patients switched from IV formulation to SC one after a median period of 40 months (IQR 20) without loss of efficacy or adverse events.

Conclusion: Our results confirm BLM efficacy also in a real-life setting. Notably, our data highlight a better drug survival in patients treated with SC formulation, mainly secondary to a less frequency of adverse events.

MONTIELUKAST AS A TREATMENT FOR REFRACTORY CUTANEOUS LUPUS ERYTHEMATOSUS: A CASE SERIES AND PROOF-OF-CONCEPT STUDY

F. A. Castro Rocha1, I. Nogueira1, R. Nunes1, G. da Silva1, C. Martins2.
1Faculdade de Medicina, Internal Medicine, Fortaleza, Brazil; 2Faculdade de Medicina, Morphology, Fortaleza, Brazil

Background: Treatment of cutaneous lupus relies mostly in avoidance of exposure to sunlight, steroids and hydroxychloroquine. A diverse array of cytokines and chemokines released by resident and migrating inflammatory cells have been implicated in the pathogenesis of skin damage in patients with systemic lupus erythematosus (SLE). Leukotrienes are potent lipid mediators involved in hyperresponsiveness reactions but very few data exist on their involvement in SLE.

Objectives: Our aim is to report a case series of SLE patients with refractory skin lesions that were successfully treated with sodium montelukast (MLK), a cysteinyl-leukotriene antagonist.

Methods: We present 4 consecutive female SLE patients with refractory skin lesions that were treated with MLK (10mg/d). Skin lesions were scored using...
Methods: In patients with SLE and its effect on cytokines. The response was sustained for at least 3 months follow-up and no adverse events were recorded. All but one of the patients relapsed following MLK withdrawal but response was recovered after restart of MLK. Expression of the ALOX5, but not of 15LOX1R, was significantly (p<0.001) increased in PBMC from SLE patients as compared to controls.

Conclusion: This is the first report of a fast and sustained successful response of cutaneous SLE to MLK. There were no safety issues. PBMC from SLE patients showed increased expression of the ALOX5gene. This case series suggests the involvement of MLK in cutaneous lupus and encourage designing a randomized trial.

Results: Twelve weeks after the start of BEL treatment, two patients had improved SLE-DAl, including one patient who achieved LLDAS. Immunological activity parameters improved in one of the two patients. However, two patients flared after BEL administration and were treated with increased glucocorticoid doses. One patient with SLE on hemodialysis had thrombocytopenia, an adverse event that may have been related to belimumab treatment.

Conclusion: At our institution, BEL was additionally administered to SLE patients with refractory disease and was effective; with the exception of one case. Serum cytokine analysis before and after BEL treatment will be included in the discussion.

Efficacy of Belimumab Treatment for Systemic Lupus Erythematosus at Our Hospital

M. Mizusaki1, R. Wakiya1, S. Nakashima1, H. Shimada1, K. Sugihara1, M. Kato1, T. Miyagi1, Y. Ushio1, R. Mino1, K. Chuo1, T. Kameda1, H. Dobashi1, 1Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa, Japan

Background: Belimumab (BEL), a monoclonal antibody against the soluble counterpart of B-cell activating factor (BAFF) has been recommended to be added in patients with SLE who do not respond adequately to standard therapy [1]. In addition to antibody production, belimumab may also affect other functions of B cells, such as antigen presentation and excretion of inflammatory cytokines. Belimumab may also have an effect on immune cells other than B cells, as they express BAFF receptors. These facts suggest that BEL administration in SLE may have an effect on various pathological conditions including cytokine production, not just antibody production. However, there are few reports on whether cytokine production is actually related to the efficacy of BEL administration in SLE.

Objectives: The purpose of this study was to determine the efficacy of BEL administration in patients with SLE and its effect on cytokines.

Methods: Patients with SLE who were started on BEL between December 2018 and December 2021 at our institution were included in this study. We retrospectively analyzed the reasons for additional BEL administration, adverse events, disease activity indicators (SLE Disease Activity Index (SLEDAI)-2K, lupus low disease activity state (LLDAS) achievement rate, anti-dsDNA antibody titer, serum complement titer, and treatment agents including glucocorticoid dose. Serum cytokine (interferon-alpha, interleukin (IL)-6, IL-10, and IL-17A) levels were measured using ELISA at the start of BEL administration, 3 months, and 6 months later.

Results: Five cases of SLE were included in the study. Four of the five patients were female, with a mean age of 51.4±9.6 years and a mean duration of disease of 17.4±10.0 years. The reasons for additional BEL administration were glucocorticoid reduction in five patients, refractory pericarditis in one patient, skin rash and arthritis in two patients, and immunological activity in two patients. Four of the five patients had decreased renal function below eGFR50 at the baseline. Concomitant medications at the time of BEL induction included steroids in five patients (mean prednisolone dose 12.2±12.2 mg/day), hydroxychloroquine in three patients, mycophenolate mofetil in three patients, tacrolimus in one patient, and methotrexate in one patient. The mean disease activity before the introduction of BEL was SLEDAI 4±4, and LLDAS was achieved in three patients.

USE OF BELIMUMAB IN CLINICAL PRACTICE, CLINICAL AND SEROLOGICAL EFFECTIVENESS AND CORTICOSTEROID-SPARING ACTIVITY

S. Vela-Bernal1, E. Fuertes1, P. Albior1, I. de la Morena2, C. Beas2, A. I. de Gracia3, A. de Castro4, L. Navarro5, M. J. Forner6, Hospital Clínico Universitario de Valencia, Internal Medicine, Valencia, Spain; 2Hospital Clínico Universitario de Valencia, Rheumatology, Valencia, Spain

Background: Since 2011, the use of Belimumab for the treatment of Systemic Lupus Erythematosus (SLE) has demonstrated efficacy and safety in several randomised clinical trials. However, strict inclusion criteria may restrict those results limiting the interpretation of these results to routine clinical practice populations.

Objectives: The aim of this study was to analyse the profile of patients using Belimumab as well as the clinical, serological and corticosteroid-sparing outcomes that may result from it.

Methods: Retrospective cohort study including patients diagnosed with SLE and treated with Belimumab. Epidemiological, clinical and analytical data were collected at 6, 12 and 24 months before and after starting treatment with Belimumab. To assess effectiveness, the SELENA-SLEDAI, SLICC, clinical changes, concomitant treatments, corticosteroid dose and ds-DNA and C3-C4 levels were used. Safety was evaluated by assessing the need and cause for discontinuation of Belimumab.

Results: Thirty-one patients were included, mostly 28 (90.32%) women, with a mean age of 49.55 ± 19.5 years and a mean time of disease progression since diagnosis of 16.13 ± 1.77 years. The most prevalent affection before initiation of Belimumab were joint (83.87%), systemic (58.06%), skin (29.03%) and nephropathy (22.58%). The mean SELENA-SLEDAI score before Belimumab was 5.32 ± 0.46; 64.5% had elevated anti-dsDNA, 48.39% and 54.84% had low C3 and C4 levels, respectively. Before starting Belimumab, the most used treatments were both antimalarials (72.4%) and corticosteroids (80.6%). The main reason for starting Belimumab was the ineffectiveness of previous treatments (67.7%). The vast majority of patients were treated subcutaneously (90.3%) and there were no major adverse events leading to drug withdrawal, with a median duration of use of 19.3 months (IQR: 9.75-35.55).

Conclusion: After starting Belimumab, a decrease in the SELENA-SLEDAI activity scale, an increase in C3 and C4 levels, and a significant decrease in anti-dsDNA levels at 6 months were observed. At 12 and 24 months, continuity of this trend was observed, although statistical significance was not reached. As concerns corticosteroids, we observed a decrease in steroid use below 7.5mg/ day and even 5mg/day after the introduction of Belimumab avoiding the undesirable effects of prolonged steroid use.

Background: Over 80% of patients affected with SLE experience skin involvement. The anti-BLyS drug belimumab was shown effective in ameliorating mucocutaneous SLE manifestations in clinical trials and real-life studies. Cutaneous response is quantified through the CLASI (cutaneous lupus erythematosus area and severity index). Clinically relevant improvements are defined as decreases of ≥50% (CLASI50) or 70% (CLASI70) from baseline values.

Methods: Baseline and ongoing features of patients with baseline active skin involvement (CLASI>0) were assessed in relationship to the chosen outcomes CLASI50 and CLASI70 at 24 and 52 weeks. A subanalysis on patients with CLASI≥5 was as well conducted. Logistic regression was employed to identify predictors of response.

Results: 172 patients displayed skin involvement at baseline (CLASI>0). Of those, 124 displayed at least a 12-month-follow-up and were included in the analysis. Seventy-seven (62.1%) patients reached CLASI50 at 24 weeks and 91 (77.8%) at 52 weeks; 87 (70.2%) reached CLASI70 at 24 and 99 (79.8%) at 52 weeks. Baseline predictors of CLASI50 at 24 weeks were CLASI-damaging (CLASI-d) (OR [95% CI], p: 0.79 [0.65-0.98] 0.03) and disease duration (0.93 [0.86-0.99], 0.011). No baseline predictors of CLASI70 at 24 weeks emerged, however having achieved a CLASI50 response at 24 weeks prolonged CLASI50 and 70 response through week 52 (p<0.01, Table 1). In the subgroup of patients with CLASI2≥5, longer disease and increased CLASI-d at baseline confirmed as negative predictors of CLASI50 at 24 weeks. In this subset, use of antimalarials and active smoking at baseline predicted CLASI70 at 24 weeks (Table 1).

</table>

CLASI, cutaneous lupus erythematosus area and severity index; CLASI-d, CLASI damage; CLASI50 and CLASI70: decrease ≥50% or ≥70% in CLASI from baseline. OR and 95% CIs are estimated using a logistic regression model with stratification factors as covariates (SLEDAI-2K at baseline, baseline prednisone dosage).

Conclusion: Earlier use of belimumab favors achievement of skin response among SLE patients and attainment of a prompt response predicts further response. Use of antimalarials reinforces while smoking hampers a more profound CLASI improvement over time.

*Nonparametric distributions were represented as median (interquartile range). Anti-dsDNA positive means that anti-dsDNA titer increases to >12 IU/mL.

Figure 1. Serum cytokine levels before and after hydroxychloroquine treatment

Serum levels of the indicated cytokines and factors were measured at baseline and after 3 months (3M) of treatment with HCQ. The gray lines show the values for individual patients, and the thick red line shows the average value. P-values were determined using the Wilcoxon signed-rank test. A p-value of less than 0.05 was considered statistically significant.

Conclusion: The addition of HCQ medication to SLE patients who achieve the clinical therapeutic goal of LLDAS without HCQ may prevent progression of atherosclerosis in addition to further reducing disease activity.

REFERENCES:
Background: Recent studies showed the efficacy of multitarget therapy with mycophenolate mofetil (MMF) and calcineurin inhibitor for induction therapy for lupus nephritis (LN). However, long-term outcomes have not been well elucidated.

Objectives: We retrospectively analyzed the long-term outcomes of multitarget therapy of MMF and tacrolimus.

Methods: We examined 27 LN patients (4 male, 23 female) treated with multitarget therapy for induction therapy between Oct. 2009 and Nov. 2018 in our department. Complete remission (CR) was defined as 1) UPCR<0.5 g/gCr, and 2) serum creatinine (S-Cr) normal or if abnormal, within 15% of baseline; 1) and 2) were observed in 2 consecutive visits. Relapse was defined as UPCR>1.0 g/gCr or intensification of immunosuppressive treatment after achievement of CR.

Results: The mean age was 38.6±11.6 years old. 17 patients were new-onset LN, and 10 patients were relapse LN. UPCR and eGFR before treatment were 4.42±2.98 g/gCr and 71.5±32.9 mL/min/1.73m², respectively. Renal histology was Class III in 1, II+IV in 4, IV in 12, IV+V in 9 and V in 1 by ISN/RPS 2008 classification. CR at 6 and 12 months were 59% and 74%, respectively. Patients were treated by multitarget therapy for median of 25 months (IQR, 5.5-37). Finally, 26 (96%) patients achieved CR. During multitarget therapy, there were 15 serious adverse events: deep vein thrombosis in 2, myocardial infarctions in 2, cerebral infarction in 2, renal failure in 1, herpes zoster in 1, viral myocardi tis in 1, cytomegalovirus gastroenteritis in 1, cholecystitis in 1, peyroniephritis in 1, bacterial enteritis in 1, sepsis in 1, and breast cancer in 1. During the median observation period of 94 months (IQR, 63-111.5) after the initiation of multitarget treatment, 1 patient died due to sudden death. No patient reached end-stage renal function in long-term period. However, relapse was often observed during or after withdrawal of multitarget therapy.

Conclusion: Multitarget therapy effectively induced CR and maintained renal function in long-term period. However, relapse was often observed during or after withdrawal of multitarget therapy.

THE BENEFICIAL EFFECTS OF THERAPY ON OBSTETRICAL OUTCOME AND PLACENTAL HISTOLOGY IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME: THE EXPERIENCE OF A SINGLE ITALIAN REFERENCE CENTER

V. Canti1,2, G. Inguscio1, N. P. Tenase3, R. Luciano3, R. De Lorenzo2, M. B. Cliona1, M. Pozzoni1, P. I. Cavero-Teijeiro2, M. T. Castiglioni1, P. Rovere-Querini1* on behalf of Pregnancy at risk multidisciplinary outpatient clinics. 1Università Vita-Salute San Raffaele, Università Vita-Salute San Raffaele, Milan, Italy; 2IUCCHS Ospedale San Raffaele, Internal Medicine, Milan, Italy; 3IUCCHS Ospedale San Raffaele, Obstetrics and Gynecology, Milan, Italy

Background: Abnormal placentation plays a crucial role in the pathogenesis of obstetric morbidity in antiphospholipid antibodies syndrome (APS). Placenta is the main target of aPL in obstetric APS, inducing placental thrombosis, inflammatory response and placental dysfunction. Standard treatment for APS patients during pregnancy includes low-dose aspirin (LDA) plus low molecular weight heparin (LMWH) and, in refractory cases, additional therapies such as hydroxychloroquine (HCQ).

A systematic review of the literature has found five main pathological lesions in the placenta of APS patients: placental infarction, decidual vasculopathy, decidual inflammation, increase of syncytial knots due to syncytiotrophoblast death, and decrease in vasculosyncytial membranes.

Objectives: To analyze placental histology in a group of 23 spontaneously conceived pregnancies in patients with definite APS prospectively followed in a single Italian reference center.

Methods: We analyzed 23 placentas in 23 spontaneously conceived pregnancies in patients with definite APS prospectively followed in the ‘Pregnancy at risk’ multidisciplinary outpatient clinics at San Raffaele Hospital, Milan, Italy from January 2017 to May 2021. During each trimester of gestation, ultrasonography with Uterine artery Doppler velocimetry was performed. Histological analysis of the placenta was carried out after delivery and placental tissues were examined for the main aforementioned histopathological findings. Statistical relations among clinical and ultrasound evaluations during each trimester, therapeutic approach and placental histology were performed.

Results: 19/25 (76%) patients had primary APS, while 6 patients had APS secondary to SLE. All patients were treated with LDA and LMWH. HCQ was added in a group of patients with concomitant systemic lupus erythematosus (SLE) or in refractory APS. Mean placental weight was 441 ± 129 grams. Histological analysis of placental tissues revealed increased syncytiotrophoblast knots in 17/25 (68%) placenta, decreased vasculosyncytial membranes in 11/25 (44%), infarction in 8/25 (32%), presence of macrophages and decidual inflammation in 2/25 (8%), and atherosis or reduction of spiral arteries remodelling in 3/25 (12%) placenta. Moreover, we observed at least 2 concomitant placental lesions in 12/25 (48%) placentas. No statistical association between mean UTA-PI values and the number and type of placental lesions described at the histologic analysis were observed. We found a positive correlation between mean titer of aCL IgG, aP2/GPI IgG, aPS/PT IgM and/or aPS/PT IgG and number of placental lesions, and a significant association between aP2/PT IgG and/or IgG mean titer and presence of infarcted areas at placental histology. In the placenta, in the patients treated with HCQ we did not observe any decidual inflammation at histology.

Conclusion: In our study we found some important clinical-pathological correlations between placental histology, clinical evaluations, ultrasound assessments and treatment received during pregnancy. Specifically, it is tempting to speculate that HCQ may have beneficial effects on pregnancy by decreasing the risk of deciduitis in patients with APS.

Further studies on larger numbers of placenta in APS patients will be needed to confirm our findings.

IMPROVEMENT OF BELIMUMAB ON QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUS

G. Yi1, S. Zheng2, X. Guo3, M. Liu4, T. Li5, Y. Chen1, H. Li1, Y. Wang1, X. Cong1, J. Zhang1, Y. Wang1, J. Zhang1, S. Zheng2, C. Wang2, C. Zhang2, Y. Yi1, J. Yi2, T. Li3, P. Wu2

Background: Accumulating evidence supports an impaired quality of life in patients with systemic lupus erythematosus (SLE). A study reported the patients concerns centred on fatigue.

Objectives: To investigate the effect of belimumab on quality of life in patients with SLE.

Methods: SLE patients from Guangdong Second Provincial General Hospital treated with belimumab (n=19) or control group (n=22) were included. Patients in control group were in traditional SLE treatment without belimumab. Data were collected prospectively at treatment initiation and now, including Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), Pittsburgh Sleep Quality Index (PSQI) and the SF-36 (Table 1).

Results: Belimumab group showed improvement in SLEDAI, PSQI and the SF-36 (P < 0.05). Control group was improvement in SLEDAI and the SF-36 (P < 0.05), no changes in PSQI (P=0.536). However, the improvement of belimumab group in SLEDAI and PSQI observably outperformed the improvement of control group.

Conclusion: Belimumab effectively improve quality of life in patients with SLE. Further study of pediatric patients with SLE is still warranted.

LUPUS NEPHRITIS OUTCOMES AFTER DISCONTINUATION OF IMMUNOSUPPRESSION

F. Alenzi1, S. Sangle2, D. Ocruzz2

1College of Medicine, Princess Nourah bint Abdullah University, Clinical Sciences Department, Riyadh, Saudi Arabia; 2Guy’s and St Thomas’ Hospital, NHS Foundation Trust, Louise Coote Lupus Unit, London, United Kingdom

Background: Lupus nephritis (LN) is one of the most serious complications of systemic lupus erythematosus (SLE). Immunosuppression (IS) is the standard of care therapy for lupusnephritis(LN).Data on the outcomes of LN patients after discontinuation of immunosuppression remain uncertain.
Objectives: To assess the outcomes of patients with LN after discontinuation of immunosuppression.

Methods: Clinical and laboratory data were retrospectively collected on LN patients attending our Lupus Unit. We included 45 patients (41 had biopsy confirmed) who were treated with immunosuppression including cyclophosphamide, mycophenolate, azathioprine, methotrexate, and/or rituximab. Numeric response variables (median and range) including age, disease duration and length of treatment were collected. Frequencies and percentages categorical variables including gender, ethnicity, lupus nephritis class, autoantibodies, laboratory features, IS therapy used and patients’ outcomes (stable versus flared) were analysed. LN flares were defined as: doubling of serum creatinine concentrations and increases in proteinuria after discontinuation of IS. Chi-square tests were applied to compare these categorical variables between patient’s outcomes. Reasons for IS discontinuation: remission, pregnancy planning and patients preference.

Results: We identified the outcomes of 45 LN patients who stopped IS therapy. The median age of patients was 55 (29-78) years. The median duration of disease was 26.5 (15-58) years whereas the median treatment duration was 4 (1-12-14) years. Thirty (66.7%) patients were Caucasian ethnicity. Seventeen (38%) of 45 patients received treatment for more than 5 years. There was only 1 (2.2%) male patient in our study. At IS discontinuation, creatinine levels were elevated in 45 (2%) patient and median creatinine values were 73 (41-117 umol/L). Median proteinuria values were 20ng/mmol (5-934) (p=0.00). LN histology: classV (24.4%), IV (17.8%) and III (17.8%). Seven patients had a combination of class III IV. Thirteen of 45 (28.9%) patients had relapses after discontinuation of IS. Median time to LN flare was 3 (1-17) years and median age of the flared patients was 58 (41-70) years. Median creatinine values and median proteinuria of the flared patients were 78 (41-111 umol/L), 361.5 mg/mmol (12-908) respectively. Of these, 13 relapsed LN patients, 4 had class III, 4 had class V and the other patients had combinations of classes. Anti-Sm antibodies were more likely to be associated with relapses (6 patients) compared to stable patients (4 patients) (6 vs. 40%) (p=0.030). Anti-dsDNA antibodies were positive in 22/32 stable patients (68.8%) compared to 10/13 (31.3%) relapsed patients (p=NS). Among 13 flared patients, 5 (38.5%) had high creatinine levels and 8 (61.5%) had normal serum creatinine (p=0.048) on discontinuation of IS. Of 45 patients, 12 had low complement C3, of whom 7 (58.3%) flared and 5 (41.7%) were stable (p=0.009). Similarly, of 12 patients with low C4, 8 (66.7%) flared compared to 4 with stable outcomes (33.3%) (p=0.001). A higher proportion of patients previously taking azathioprine relapsed compared to those with previous use of cyclophosphamide or MMF (30.8% vs. 15.4%) (p=0.011) respectively.

Conclusion: Our data suggests that two thirds of our patients experienced clinical remission with stable LN following cessation of IS therapy for LN. Patients who had elevated serum creatinine values, persistent proteinuria, low complement, positive anti Sm antibodies and previous azathioprine use were more likely to flare after stopping IS. Anti-dsDNA antibodies levels did not predict flares after stopping IS. Further prospective studies with larger sample sizes and longer follow-up are needed to estimate LN outcomes after discontinuation of immunosuppression.

AB0448 ADVERSE PREGNANCY OUTCOMES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: THE ROLE OF THERAPY.

M. B. Cilona1, V. Canti1,2, I. Dalpiaz1, R. De Lorenzo1, G. Inguscio1, C. Asperti1, S. Rosai1, M. T. Castiglioni1, P. Rovere-Querini1,2, 1Vita-Salute San Raffaele University, Internal Medicine, Milano, Italy; 2San Raffaele Hospital, Internal Medicine, Milano, Italy; 3San Raffaele Hospital, Obstetrics and Gynecology, Milano, Italy

Background: Our study supports that treatment with glucocorticoids at medium-high doses during pregnancy adversely affects pregnancy outcome with an increased risk of both APO and birth of SGA infants. These data can be related to a direct role of the drug in determining maternal-fetal outcome and to the presence of an incomplete control over disease activity. The comparison between pregnancies followed before 2010 and since 2010 conducted in our study shows that the introduction of drugs such as hydroxychloroquine and azathioprine from the beginning of the pregnancy can reduce the frequency of APO in general. These medications can represent a safety therapeutic strategy both for the mother and for the fetus in order to control autoimmune disease during pregnancy and minimize the occurrence of complications. Further studies on larger numbers of placenta in APS patients will be needed to confirm our findings.

Objectives: To investigate whether treatment in SLE patients during pregnancy may influence the occurrence of APO events and, in particular, the birth of SGA infants.

Methods: We performed a monocentric observational study in SLE pregnant patients prospectively followed at the ‘Pregnancy at risk’ multidisciplinary outpatient clinics at San Raffaele Hospital, Milan, Italy from January 2003 to June 2021. We collected data from 79 pregnancies in 58 patients with a diagnosis of SLE.

Results: 13/79 (16%) pregnancies ended in a spontaneous abortion. In the other 66/79 (84%) APOs occurred in 29/66 (44%) pregnancies. 17 of the 66 (26%) pregnancies that did not end in spontaneous abortion ended with the birth of SGA infants. Glucocorticoid treatment at medium-high doses (e. i. prednisone ≥ 5 mg) was associated to an increased risk for APO (OR 4.431, p-value 0.018) and for the birth of SGA infants (OR 4.401, p-value 0.019). Preterm delivery (7/43, 16% versus 7/23, 30%), hypertension and/or preeclampsia (4/43, 9% versus 5/23, 22%) were observed with low incidence in pregnancy followed since 2010 than before 2010, even if without reaching statistical significance.

Conclusion: Our study supports that treatment with glucocorticoids at medium-high doses during pregnancy adversely affects pregnancy outcome with an increased risk of both APO and birth of SGA infants. These data can be related to a direct role of the drug in determining maternal-fetal outcome and to the presence of an incomplete control over disease activity. The comparison between pregnancies followed before 2010 and since 2010 conducted in our study shows that the introduction of drugs such as hydroxychloroquine and azathioprine from the beginning of the pregnancy can reduce the frequency of APO in general. These medications could represent a safety therapeutic strategy both for the mother and for the fetus in order to control autoimmune disease during pregnancy and minimize the occurrence of complications. Further studies on larger numbers of placenta in APS patients will be needed to confirm our findings.

SLE, Sjőn-s and APS - clinical aspects (other than treatment)

**AB0449**

**THE PREVALENCE OF AUTOANTIBODIES AGAINST IFNA IS HIGH IN SLE AND ASSOCIATED WITH A HIGH FREQUENCY OF TUBERCULOSIS**

**Background:** IFNα and anti-IFNα autoantibodies have been implicated in susceptibility both for systemic lupus erythematosus (SLE) and viral infection.

**Objectives:** We aimed to analyze the SLE disease phenotype and risk for infection associated with anti-IFNα IgG autoantibodies in SLE patients.

**Methods:** In this multidisciplinary retrospective single referral center study, all consecutive patients with SLE admitted between January 1st and November 30th 2020 were considered. All subjects fulfilled the ACR/EULAR 2019 criteria for SLE.

Anti-IFNα IgG autoantibodies were quantified at admission by ELISA. Demographic, medical history, laboratory, treatment, and outcome data were extracted from electronic medical records using a standardized data collection form.

**Results:** 180 patients [female 87.2%, median age of 44.4 (34-54.2) years] were included. The median disease duration was 10 years [4-20] with a median SLE-DAI score of 2 [0-4] at study time. Fifty-four (30%) patients had a past-history of lupus nephritis. One hundred and forty-four (80%) had received long-term glucocorticoids and 99 (55%) immunosuppressive drugs. Overall, 127 infections from electronic medical records using a standardized data collection form. Seven hundred and ninety-four infections were identified for the primary outcome with a median follow up of 110 (interquartile range: 99–120) months. Among them, 29 (6.6%) experienced at least one CVE. Factors associated with incident CVE and sCD163 level were analyzed. The prevalence of autoantibodies against IFNα is high in SLE and associated with a higher frequency of tuberculosis.

**Conclusion:** The prevalence of autoantibodies against IFNα is high in SLE and associated with a higher frequency of tuberculosis.

**SOLUBLE CD163 IS A BIOMARKER FOR CARDIOVASCULAR EVENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

C. David1, N. Costedoat-Chalumeau2, D. Belham3, V. Leguem2, C. Lauonen2, A. Bouten2, J. Cheze1, N. Morel2, A. Matthieu2, Z. Amoura5, T. Papo7, K. Sacre8.on behalf of PLUS Study group. 1Université de Paris Bichat, Médecine Interne, Paris, France; 2Université de Paris Cochin, Médecine Interne, Paris, France; 3Université de Paris Bichat, URCP, Paris, France; 4Université de Paris Bichat, Biochimie, Paris, France; 5Sorbonne Université Pitié, Médecine Interne, Paris, France.

**Background:** Prediction models based on traditional cardiovascular risk factors underestimate the risk of cardiovascular events (CVE) in systemic lupus erythematosus (SLE).

**Objectives:** We aimed to determine whether sCD163, a biomarker for SLE-associated atherosclerosis, may predict CVE in SLE.

**Methods:** All SLE patients included between 2007 and 2010 in the randomized, double-blind, placebo-controlled, multicenter PLUS trial were screened. Patients with no past history of CVE at inclusion and a follow-up period of >20 months were analyzed. sCD163 level was measured using enzyme-linked immunosorbent assay on serum collected at PLUS inclusion. The primary outcome was the incidence of CVE. Factors associated with incident CVE and sCD163 level were analyzed.

**Results:** Overall, 442 SLE patients (of the 573 included in the PLUS study) were analyzed for the primary outcome with a median follow up of 110 (interquartile range: 99–120) months. Among them, 29 (6.6%) experienced at least one CVE that occurred at a median of 67 (interquartile range: 31–91) months after inclusion. In the multivariate analysis, dyslipidaemia, age and increased sCD163 were associated with CVE onset. Multivariate Cox models analysis showed that a concentration of sCD163 > 263 ng/mL at inclusion increased by 2.7 [hazard ratio 2.7 (95% CI: 1.0, 7.0)] the risk of CVE in SLE. Increased sCD163 was also associated with immunosuppressive treatment, higher body mass index (BMI) and SLEDAL score.

**Conclusion:** Macrophage-specific sCD163 serum level reflects lupus disease activity and predicts CVE in SLE.

**Disclosure of Interests:** None declared

**AB0451**

**FACTORS ASSOCIATED WITH ADVERSE PREGNANCY OUTCOMES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)**

C. Sieiro Santos1, C. Moriano1, I. González Fernández2, X. E. Larco Rojas1, C. Alvarez Castro1, E. Diez Alvarez1. 1Complejo Asistencial Universitario de León, Rheumatology, León, Spain.

**Background:** Prematurity in systemic lupus erythematosus (SLE) are considered high risk and associated with maternal and obstetric complications.

**Objectives:** Our goal with this study was to determine the most important predictors for each of the main adverse pregnancy outcomes in SLE patients.

**Methods:** We conducted a retrospective case-controls study by including multiparous women diagnosed with SLE from 1980 to 2020 followed in our unit and compared the clinical profile of patients with adverse pregnancy outcomes to control SLE patients. We excluded elective terminations of pregnancy and cases lost to follow-up. Qualitative data were analyzed by Chi-square test and Fisher’s exact test and continuous variables were analyzed by using Student’s t test. Multiple logistic regression models were performed to determine the predictive factors for adverse pregnancy outcomes with adjustment of confounding factors. In all tests, P values less than 0.05 were considered to be statistically significant.

**Results:** 135 multiparous women were included (43% with adverse pregnancy outcomes). The mean age of patients at inclusion was 55.8 (46-64) years. Abortion occurred in 33 patients (57%), pre-eclampsia in 10 patients (17%), ectopic pregnancy in 5 patients (8%), preterm labor in 5 patients (8%), placental abnormalities in 4 patients (6%), stillbirth in 4 patients (6%), premature rupture of membranes (PROM) and neonatal lupus in 3 patients (5%), respectively. 121 patients (89%) had pre-existing lupus and 14 (11%) referred with SLE onset in pregnancy. Renal involvement (p=0.03), anti-NDAs positivity (p=0.002), antiphospholipid antibody (APA) positivity (p=0.001), anti-Ro/SSA (p=0.003) and a younger age at disease onset (p=0.001) were significantly associated with unfavorable pregnancy outcomes. Abortion was correlated with anti-NDAs (β=0.71, p=0.04), renal involvement (β=0.28, p=0.03) and APA (β=0.2, p=0.03). Stillbirth was also correlated with renal involvement (β=0.26, p=0.04) and APA (β=0.22, p=0.03). Preeclampsia was correlated with direct Coombs positivity (β=0.42, p=0.01) and serositis (β=0.31, p=0.02).

**Conclusion:** The most unfavorable pregnancy outcomes in women with SLE were spontaneous abortion. Renal involvement, anti-NDAs and anti-Ro/SSA, antiphospholipid antibody positivity, and a younger age at disease onset increased the risk of pregnancy complications.

AGE RELATED DIFFERENCES IN NEUROPSYCHIATRIC MANIFESTATIONS AMONG SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS – A SINGLE RHEUMATOLOGY CENTRE EXPERIENCE IN MALAYSIA

C.R. No1, 1Hospital Sultan Ismail, Rheumatology Unit, Department of Medicine, Johor Bahru, Malaysia

Background: The prevalence of SLE in Malaysia was reported as 43/100,000 individuals and Chinese (57/100,000) have the highest prevalence followed by Malays (33/100,000) and Indians (14/100,000) [1,2]. The American College of Rheumatology established case definitions and categorised neuropsychiatric syndromes into two groups: central and peripheral system involvement. There were studies showed that cognitive impairment is the commonest neuropsychiatric manifestations with a prevalence of 66% [3].

Objectives: To determine the association between neuropsychiatric manifestations with different age group among SLE patients.

Methods: This was a retrospective study. The electronic medical records of all SLE patients seen in rheumatology clinic of Hospital Sultan Ismail, Malaysia from 1/1/2007 to 31/12/2021 were reviewed. SLE patients with neuropsychiatric manifestations were selected and categorised by age into children (< 12 years old), adolescents (aged 12-18 years), young adults (aged >18 to 35 years), middle-aged adults (>35 -55 years) and elderly (>55 years). The association between neuropsychiatric manifestation with different age group was analysed by using SPSS-Fisher’s exact test.

Results: There was a total of 86 patients and female were 77. The majority were Malay (49/86) followed by the Chinese (33/86), Indians (2/86) and others (2/86). Patients were categorized into children (n=8), adolescents (n=18), young adults (n=43), middle-aged adults (n=16) and elderly (n=3) with the mean age of 28.

Our study showed the onset of neuropsychiatric manifestations occurred most during young adulthood (43/86) followed by adolescents (18/86). Seizure disorders is the commonest manifestations (36/86) followed by psychosis (17/86), poly/mononeuropathy (7/86), cognitive dysfunction (7/86), myelopathy (5/86), cranial neuropathy (4/86), mood disorders (3/86), cerebrovascular disease (3/86), movement disorders (2/86), and lastly headache and myasthenia gravis. 1 patient each. 60% of the patients had onset of neuropsychiatric manifestation during first diagnosis and another 7% developed symptoms within 1 year of diagnosis. There was no association between type of neuropsychiatric manifestation with different age group (p = 0.195). Comparison of neuropsychiatric manifestations according to age group was shown in Table 1.

ROLE OF COMBINATION AUTOANTIBODIES (ANTI-SMITH, RO AND RNP ANTIBODIES) AND ETHNICITY IN ACCELERATED DEVELOPMENT OF LUPUS NEPHRITIS

C.R. No1, 1Hospital Sultan Ismail, Rheumatology Unit, Department of Medicine, Johor Bahru, Malaysia

Background: Lupus nephritis (LN) is an important concern among SLE patients in Asia and its mortality rate was reported to be 6 times higher compared to the general population [1]. A study by McCarty et al suggested that African women with serology showed combination of anti-Smith, Ro and RNP antibodies were at increased risk of developing LN [2]. This is further supported by study done by Majed et al showed this unusual combination accelerated development of LN within the first 5 years after SLE onset [3].

Objectives: To determine the correlation between the combination of autoantibody profile, Smith, Ro and RNP in development of LN amongst Asian ancestry and any association with the duration of LN development from onset of SLE.

Methods: This was a retrospective study. The electronic medical records of all SLE patients seen in the rheumatology clinic Hospital Sultan Ismail, Malaysia from 1/1/2007 to 30/4/2021 were reviewed. Patients who had LN were identified and selected. Data on demography, serology, duration of development of LN from SLE onset were obtained and analysed using SPSS Pearson Chi square and binary logistic regression.

Results: There were a total of 197 patients and 183 were females. The majority were Malays (96/197) followed by the non-Malay (101/197) which included Chinese (88/197) and others (15/197). The mean age group for the studied subjects was 34 (14-80). Of the 197 (100%) patients, 23 (11.7%) patients had the triple combination of Sm, Ro and RNP antibodies while 174 (88.3%) patients did not have the triple combination. For patient with the triple combination, regardless ethnicity, 20/23 (87%) developed LN within 5 years from the SLE onset while the remaining 3/23 (13%) developed LN after 5 years. For patients without this combination, regardless ethnicity, 142/174 (81.6%) of them developed LN within 5 years and 32/174 (18.4%) of them more than 5 years. This showed combination autoantibody does not significantly accelerated development of LN amongst Asian ancestry patients, P = 0.092. There was also no association between the positivity of triple antibody with the duration of development LN from SLE onset, P =0.772. Further stratification was based on ethnicity showed compare to Non-Malay ethnicity, the Malay patients is 3.966 higher odds of developing LN within the 5 years from SLE onset, P = 0.002.

Conclusion: Patient with triple serology combination did not showed significant in accelerating development of LN. Our data showed Malay patients are 4 higher odds of developing LN within the first 5 years after SLE onset compare to Non-Malay patients.

DRUGS, AUTOANTIBODIES AND GENES CONTRIBUTE TO THE DEVELOPMENT OF CHRONIC DAMAGE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

G. Oliveri1, F. Ceccarelli1, C. Pironi1, L. Picciariello1, F. Natalucci1, C. Ciccacci2, C. Perricone3, F.R. Spinelli1, C. Alessandri1, P. Borgiani4, C. Ceccarelli1, F. Conti1, 1Rheumatology, Dipartimento di Scienze Cliniche Internistiche, Anestesieologiche e Cardiovascolari, Sapienza University of Rome, Roma, Italy; 2Genetica Medica, UniCamillus, Saint Camillus International University of Health and Medical Sciences, Rome, Rome, Italy; 3Rheumatology, Dipartimento di Medicina e Chirurgia, University of Perugia, Perugia, Italy; 4Genetica Medica, Department of Biomedicine and Prevention, Genetics Section, University of Rome Tor Vergata, Roma, Italy.

Background: Genetic contribution to development of chronic damage have been scarcely investigated in systemic lupus erythematosus (SLE). In fact, whereas most studies have looked for an association between genetic variants and SLE susceptibility or disease phenotypes, only few have focused on the relationship between these biomarkers and damage development.
Objectives: Moving from these premises, we firstly analyzed the distribution of organ damage in a cohort of SLE patients and secondly we evaluate the role of clinical and genetic factors in determining the development of chronic disease. Methods: Caucasian SLE patients, diagnosed according with 1997 ACR criteria, were enrolled, and clinical and laboratory data were collected. Based on literature data, we selected a panel of 17 SNPs of following genes STAT4, IL10, IRAK1, HCP5, MIR146a, ATG16L1, IRGM, ATG5, MIR124, MIR1279, TNFSF4, CD40. Genotyping was performed by allelic discrimination assays. A phenotype-genotype correlation analysis was performed by evaluating specific domains of SLICC Damage Index (SDI).

Results: Among 175 Caucasian SLE patients, 105 (60%) exhibited damage (SDI ≥ 1) with a median of 1.0 (IQR 3.0). The musculoskeletal (26.2%), neuropyschiatric (24.6%) and ocular domains (20.6%) were involved most frequently. The presence of damage was associated with higher age, longer disease duration, neuropsychiatric (NP) manifestations, anti-phospholipid syndrome and the positivity of anti-dsDNA antibodies. Concerning therapies cyclophosphamide, mycophenolate fentyll and glucocorticoids resulted associated with the development of damage. The genotype/phenotype correlation analysis showed an association between renal damage, identified in 6.9% of patients, and rs2205960 of TNFSF4 (p=0.001; OR 1.70). This SNP resulted significantly associated with end-stage renal damage (p=0.018, OR 9.68) and estimated GFR<50% (p=0.025, OR 1.06, Figure 1). The rs1463335 of MIR1279 gene was associated with the development of NP damage (p=0.029; OR 2.783). The multivariate logistic regression analysis confirmed the associations between TNFSF4 rs2205960 SNP and renal damage (p=0.020, r=2.53) and between NP damage and rs1463335 of MIR1279 gene (p=0.013, r=1.26).

Conclusion: We showed the role of age, drugs, and autoantibody profile in determining chronic damage. Our data suggest a possible role of genetic background in determining the development of renal and neuropsychiatric damage, as demonstrated by the association with polymorphisms of TNFSF4 and MIR1279, respectively. These results agree with previous studies suggesting the involvement of TNFSF4 in Lupus nephritis and microRNA in neuroinflammation.

DISEASE FLARE OF SYSTEMIC LUPUS ERYTHEMATOSUS IN PATIENTS WITH END-STAGE RENAL DISEASE ON DIALYSIS

Y. E. King1, S. J. Choi2, D. H. Lim3, S. M. Ahn1, J. S. Oh1, Y. G. Kim1, C. K. Lee1, B. Yoo1, S. Hong1.

1Asan Medical Center, University of Ulsan College of Medicine, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Ulsan University Hospital, Department of Rheumatology, Ulsan, Korea, Rep. of (South Korea)

Background: The systemic lupus erythematosus (SLE) disease activity in patients with lupus nephritis (LN) generally declines after the initiation of renal replacement therapy (RRT); this is known as the "burn out" phenomenon that possibly occurs due to the suppression of cellular and humoral immunity in the end-stage renal disease (ESRD) state and elimination of disease pathogenic factor by dialysis [1-4]. However, several studies showed that SLE flares could occur even during RRT [5-8]. Nevertheless, the details of disease flares of SLE in patients under dialysis have not been studied yet.

Objectives: This study aimed to investigate the clinical features, risk factors, and treatment details of SLE patients experiencing disease flare under RRT.

Methods: The medical records of SLE patients who received dialysis at two tertiary referral hospitals in Seoul and Ulsan, South Korea were reviewed. All patients in this study were either clinically or histologically diagnosed with LN

Results: Of a total of 121 patients with SLE on dialysis, 96 (79.3%) were on hemodialysis (HD) and 25 (20.6%) were on peritoneal dialysis (PD). During a median follow-up of 45 months (IQR, 23–120) after the initiation of dialysis, 32 (26.4%) patients experienced SLE flare (HD, n = 25, PD, n = 7). The most common flares of SLE flare were hematologic (40.6%) and constitutional manifestations (40.6%). Treatments for disease flares were based on corticosteroids, and 11 (34.3%) patients required additional immunosuppressants including cyclophosphamide and mycophenolate fentyll. There was no case of severe adverse events related to medication. non-renal SLE Disease Activity Index (SLEDAI) score before dialysis initiation (HR 1.235, 95% CI, 1.122–1.359; P = 0.001) was a significant risk factor for disease flare during dialysis.

Conclusion: More than one-quarter of SLE patients experienced disease flare during dialysis, which most commonly had hematologic manifestations. Continued follow-up and appropriate treatments including immunosuppressants should be considered for patients with SLE under dialysis.

IMPROVED PREGNANCY OUTCOMES IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE STUDY OF PREGNANCIES FROM A single CENTER IN DENMARK FROM 2010-2020 COMPARED WITH THE PERIOD 1990-2010

1Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; 2Aalborg University Hospital, Department of Rheumatology, Aarhus, Denmark; 3Aarhus University Hospital, Department of Gynecology and Obstetrics, Aarhus, Denmark; 4Aarhus University, Department of Clinical Medicine, Aarhus, Denmark

Background: Over the past decades, the approach to follow and treat pregnant SLE patients has changed. Today it is recommended that pregnant patients are monitored closely in a multi-professional team throughout pregnancy (1). The importance of low disease activity before pregnancy and continued treatment...
during pregnancy has been established (2). Even though many improvements in the management of SLE pregnancies has been made, there is still a high risk of adverse pregnancy outcome (APO).

Objectives: We aimed to evaluate APO in a Danish SLE cohort followed from 2010-2020 and compare the results with a previous study cohort from the same referral area followed from 1990-2010 (3).

Methods: This retrospective cohort study used the local patient registry to identify pregnancies in SLE patients followed at the Department of Rheumatology, Aarhus University Hospital, Denmark from January 2010 to October 2020. All patients were followed regularly and fulfilled at least four of the 1997 American College of Rheumatology (ACR) criteria for SLE classification. Data included demographic, clinical, and laboratory data. Demographics included ethnicity, smoking habits, body mass index (BMI), and comorbid APS (recognized before pregnancy). Data were compared with data from a previous study (1990-2010) from the same department.

Results: In total, 66 pregnancies were registered in 41 women. APO occurred in 65 % of pregnancies. Forty-seven pregnancies resulted in a live birth, while 19 ended in miscarriage. Compared to the 1990-2010 cohort, a reduction in preterm deliveries (7.58 % vs. 17.9 %), acute caesarean (6.1 % vs. 15.5 %), and higher average birth weight (3045 g vs. 2870 g) were found (Table 1). Further, we observed more pregnancies and live births per year (Figure 1). A change in the approach to treatment was found, i.e., significantly more patients were treated with hydroxychloroquine (73 %) compared to the 1990-2010 cohort (8 %).

**Conclusion:** Improvements in the frequency of APO were found in 2010-2020 compared with 1990-2010. However, even though a specialized multi-professional team closely follows pregnant women with SLE, pregnancy in SLE still carries a high risk of APO.

**Background:** Systemic lupus erythematosus (SLE) often affects women in their childbearing years, and pregnancy may affect SLE disease activity during pregnancy and post-partum (1,2). Limited data assessing the likelihood and characteristics of SLE activity in an extended time period post-partum which may be relevant as patients may wish to have subsequent pregnancies.

**Objectives:** To assess predicting factors that might influence SLE disease activity in women in an extended follow-up period of 2 years after giving birth and clinical assessment every three months.

**Methods:** The study was designed as an international retrospective, data-driven case collection study, enrolling 119 women with a first birth and with a strictly monitored follow-up period of 2 years.

**Results:** Table 1 shows pregnancy outcomes of all pregnancies. When considering disease manifestations, joint involvement was present in 80% of patients, acute cutaneous in 64%, haematological in 54% and renal in 41%; 75% of patients were positive for anti-dsDNA, 49% for anti-ENA and 37% for anti-Ro/SSA positive. The mean SLE disease activity index 2000 (SLEDAI-2k) at diagnosis was 13.5±6.8 and at first birth was 28.4±4.4.

*Percentages are calculated considering viable babies (total= 169) **Percentages are calculated considering first birth (total= 119) ***Exclusive breastfeeding was defined as feeding infants only breast milk

At follow-up, 51.3% of patients had at least one flare after a mean time after birth of 9±6.3 months (mean flare per patient 0.94±1.1). The most frequent flare manifestations were joint involvement (48%), followed by renal (33%), cutaneous (28%)
and haematologic (20%). Patients with remission of disease (SLEDAI-2K = 0; no clinical or laboratory manifestations of SLE) at conception had significantly lower rates of flares than those not in remission (18 ± 49–57% vs. 43 ± 70–61%; p = 0.008) (Figure 1).

Figure 1. Flare proportion: Survival Curve based on remission status at conception of the patients included in the study.

Patients who experienced a flare during pregnancy (17 patients), when compared to those who did not, had higher rates of flares during follow-up (76% vs. 47%, respectively, p = 0.019), lower time for first flare (4.4 ± 2.3 months vs. 10.3 ± 6.5 months, respectively, p < 0.001), lower rate of remission of disease at conception (12% vs. 46%, respectively, p < 0.001), lower rates of SLEDAI-2K at conception (5.9 ± 5.6 vs. 2.3 ± 4, respectively, p = 0.001) and lower rates of exclusive breastfeeding (24% vs. 57%, respectively, p = 0.009). Remission of disease and flares during pregnancy remained significantly associated with the development of flares during follow-up after multivariate analysis.

Conclusion: Remission at conception can influence SLE disease positively, even at long-term. Planned pregnancy counseling is fundamental when managing SLE patients.

NATIONAL TEMPORAL TRENDS IN ALL-CAUSE MORTALITY IN PATIENTS WITH SYSTEMIC SCLEROSIS IN MEXICO BETWEEN 1998-2017

P. Munguía-Realpozo1, M. García Carrasco1, I. Etchegaray-Morales1, J. Ayón-Aguilar1, O. Navarro-Milán1, C. Mendoza Pinto2, M. A. Escamilla-Márquez2, M. García Carrasco2, I. Facultad de Medicina BUAP Rheumatology Department, Heroica Puebla de Zaragoza, Mexico; IMSS Specialty Hospital, Systemic Autoimmune Diseases Research, Heroica Puebla de Zaragoza, Mexico; IMSS Specialty Hospital, Systemic Autoimmune Diseases Research, Heroica Puebla de Zaragoza, Mexico

Background: Systemic sclerosis (SSc) is a rare chronic connective tissue disease characterized by vascular injury, immune dysregulation, and extensive fibrosis of several organs. Due to its rarity, epidemiological data for SSc are sparse.

Objectives: To investigate national temporal trends over time in all-cause mortality rates in patients with systemic sclerosis (SSc) in Mexico between 1998 and 2017.

Methods: All-cause deaths between 1998 to 2017 were extracted from the General Board of Health Information (DGIS) Open Access datasets. We identified all persons aged ≥18 years with a diagnosis of SSc (ICD-10 code M34). We calculated the age-standardized mortality rate (ASMR) for SSc and non-SSc (information provided by the National Institute of Statistics, Geography and Informatics). A Joinpoint regression model was used to determine mortality trends by sex and geographic regions. Annual percentage change (APC) and average APC (AAPC) were calculated using Joinpoint analysis.

Results: From 1998 to 2017, the overall ASMR of SSc increased (AAPC= 2.5%), whereas the ASMR for non-SSc remained stable. By subpopulations, females and males with Ssc had a significant uptrend in the ASMR (AAPC= 4.6% and 4.4%, respectively), between 1998 and 2008 for the former and between 1998 and 2010 for the latter. Males had a non-significant ASMR upturn and males a non-significant ASMR decline. Some variations among geographic regions were found. Women had a higher SSc ASMR to non-SSc ASMR ratio than males. The relative cumulative change between 1998 and 2017 differed between females (78.1%) and males (50.8%), and residents of the Southern region had the largest cumulative change (147.8%).

Conclusion: SSc mortality rate increased in Mexico between 1998 to 2017, with SSc mortality higher than non-SSc mortality with variations by sex and geographic regions.

METABOLOMIC PROFILE OF INSULIN RESISTANCE IN NON-DIABETIC WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

P. Munguía-Realpozo1, C. Mendoza Pinto2, I. Etchegaray-Morales1, S. K. Pérez-Pelcastre1, A. D. Osorio-Peña1, S. Méndez-Martínez1, M. A. Escamilla-Márquez2, M. García Carrasco2, I. Facultad de Medicina BUAP Rheumatology Department, Heroica Puebla de Zaragoza, Mexico; IMSS Specialty Hospital, Systemic Autoimmune Diseases Research, Heroica Puebla de Zaragoza, Mexico; Puebla State Delegation IMSS., Research in Health Coordination, Heroica Puebla de Zaragoza, Mexico; Facultad de Medicina BUAP Endocrinology Department, Heroica Puebla de Zaragoza, Mexico

Background: Systemic lupus erythematosus (SLE) is associated with an increased risk of insulin resistance (IR). Metabolomics offers an opportunity to examine markers of IR and their relationship with SLE.

Objectives: 1) to compare the metabolomic profile of IR in SLE patients and controls; 2) to correlate the metabolomic profile with other IR surrogates and 3) to evaluate the relationship between the metabolomic profile of IR and SLE disease variables, vitamin levels and subclinical atherosclerosis in patients with SLE.

Methods: In this cross-sectional analysis, serum samples were collected from patients with SLE (n = 64) and gender- and age-matched controls (n = 71). Serum metabolomic profiling was performed using ultra-high-performance liquid chromatography and tandem mass spectrometry (UPLC-MS-MS). Homeostasis model assessment (HOMA) and the quantitative insulin sensitivity check index (QUICKI) were also carried out. Serum 25(OH)D concentrations were assessed by chemiluminescent immunoassay. Carotid IMT was quantified by ultrasound.

Results: In non-diabetic patients with SLE, the metabolomic Quantose score significantly moderately correlated with HOMA-IR, HOMA2-IR and QUICKI. Although levels of IR metabolites did not differ between SLE patients and controls, fasting plasma insulin levels were higher and insulin sensitivity lower in SLE patients. The Quantose IR score was significantly correlated with complement C3 levels (r = 0.7; p = 0.001). Neither 25 (OH)D nor IMT was correlated with any metabolite or Quantose IR index.

Conclusion: This exploratory study found that Quantose IR may be a useful tool for IR assessment. There was a possible correlation between the metabolomic profile and complement C3 levels. The implementation of this metabolic strategy may help develop biochemical insight into metabolic disorders in SLE.

TRIPLE POSITIVE PROFILE IN ANTIPHOSPHOLIPID SYNDROME: PROGNOSIS, RELAPSE AND MANAGEMENT FROM A RETROSPECTIVE MULTICENTER STUDY.

L. Charlotte1, L. Ricard1, N. Yann1, O. Fain1, A. Mekinian1. 1Saint Antoine, Internal Medicine, Paris, France

Background: The antiphospholipid syndrome (APS) is defined by the development of vascular thrombosis, or pregnancy morbidity in the presence of persistent antiphospholipid antibodies (APL). Antinuclear antibodies (ANA) can be detected in primary APS patients without any clinical systemic autoimmune disease. The presence of ANA antibodies could confer a specific phenotype in primary APS.

Objectives: Antiphospholipid syndrome (APS) is defined by the association of thromboembolic and/or obstetrical clinical manifestations and the presence of antiphospholipid antibodies (APL). Patients with all three APL are referred to as triple positive (TP). The objective of our study was to evaluate the impact of the TP profile in a cohort of 204 patients.

Methods: Clinical and biologic data from 195 APS were retrospectively collected. ANA test was considered to be positive when titters were superior or equal to the 1/80 dilution. ANA-positive APS patients did not fulfilled SLE ACR/EULAR classification criteria

Results: 204 patients were included in our study, 68 were TP and 136 were single or double positive (NTP). 122 patients (59.8%) had primary APS. 67 patients (32.8%) had obstetrical APS, with a higher rate among TP patients (45.6% versus 26.5%, P=0.010), and 170 patients (83.3%) had thrombotic APS, without difference between TP and NTP patients. TP patients had more placentation complications than NTP patients (176% versus 2.9%, P=0.001) and more non-criteria events (48.5% versus 25.7%, P=0.002). 97 patients (47.3%) presented at least one relapse, and the relapse rate was significantly higher in TP patients than in NTP patients (63.2% versus 39.7%, P=0.002). Of the relapses, 30 were obstetric and 74 thrombotic, and the rate of obstetric relapses was significantly higher in TP patients. During follow-up, 21 patients (10.3%) died and this rate did not differ between the two groups.

In univariate analysis, TP patients (HR 1.77; 95% CI 1.17-2.68; P=0.007), venous APS (HR 1.74; 95% CI 1.13-2.69; P=0.013), a history of premature birth (HR 2.47; 95% CI 1.24-4.93; P=0.010), and curative anticoagulation (HR 4.91; 95% CI 1.55-15.5; P=0.007) are associated with the risk of relapse. The serological profile was also a factor in relapse: the presence of the anti-β2GP1 antibody (HR 1.70; 95% CI 1.09-2.64; P=0.018) and LA (HR 1.59; 95% CI 1.01-2.50; P=0.046). The non-criteria manifestations of APS are associated with a higher risk of relapse, although not statistically significant (HR 1.49; 95% CI 1.00-2.23; P=0.052).

In multivariate analysis, the TP profile remained associated with a risk of relapse (HR 1.63; 95% CI 1.04-2.55; P=0.031), as well as venous APS (HR 2.05; 95% CI 1.30-3.23; P=0.002), and the antecedent of premature delivery (HR 2.33; 95% CI 1.10-4.92; P=0.027). The risk factors associated with relapse in multivariate analysis are summarized in Figure 1.

AB0462

CORRELATION BETWEEN SAXON TEST AND UNSTIMULATED SALIVARY FLOW RATE IN PATIENTS WITH SUSPECTED SJJÖGREN’S SYNDROME

M. J. Santos Bómez1, M. Fernandez Castro1, J. Sanz1, J. Campos Esteban1, H. Godoy1, C. Merino Arguménez1, O. Rusinovich1, N. De la Torre Rubio1, M. F. Piazza Rascado1, M. C. Sánchez Fernández1, J. P. Garia-De la Magallón1, C. Barbadiello Mateos1, L. F. De Villa1, C. Issai Saragozza1, J. L. Andéu Sánchez1, A. Sánchez1. 1Hospital Universitario Puerta de Hierro Majadahonda, IDIHPISA. Madrid, Spain, Rheumatology; Majadahonda (Madrid), Spain

Background: Sjögren syndrome (SS) is a chronic systemic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands, which alters their function producing dryness of the mouth, eyes and other mucous membranes. The method used to quantify glandular hypofunction is by whole saliva flow stimulated and unstimulated (UWSF) [1], which takes between 5 and 15 minutes (min). The Saxon test [2], is another tool with the same objective but requires less time: 2 minutes. In the literature, we only have found one study that compares the Saxon test with other diagnostic methods although it is developed in patients without SS [3].

Objectives: To compare the Saxon test and UWSF in a cohort of patients with suspected SS.

Methods: In a consecutive cohort of patients who attended the rheumatology department for suspected SS, UWSF was measured (mL/5min) and the Saxon test (g/2min) was performed. The Index Reported by Patients with Sjögren’s Syndrome of the EULAR (ESSPRI) was collected too. This is a patient-reported index designed to assess the severity of patients’ symptoms (dryness, pain, somatic and mental fatigue) in SS through an average of 0–10 numerical scale for each domain. To measure the UWSF, patients were asked to swallow their saliva before the start of the test and then to spit into a container for 5 min. The Saxon test was performed by calculating the difference in weight between the weight of two pieces of sterile gauze that the patient chews for two minutes. An UWSF >0.25/mL/min, a Saxon test >2.75/g/2min and an ESSPRI<5 were considered normal. Spearman’s rank correlation coefficient (r) was used to determine the correlation between both quantitative variables. The Chi-square test and the Gamma test were used in the comparisons between the groups (altered and normal) and the Mann-Whitney U test in the comparisons of the quantitative variables based on the groups (altered and normal) previously defined. Values p≤0.05 were considered statistically significant.

Results: We enrolled 70 patients (63 women/7 men), with a mean age a standard deviation of 54±13 years. The medians (Me) and interquartile ranges (IQR) obtained were 1500 (0.6750 – 2.5000) mL/5min for the UWSF, 2.405 (16775-3.4925) g/2min for the Saxon test, 6.67 (3.67-7.67) for ESSPRI and 7.00 (4.00-8.00) for ESSPRI-dryness score. A direct and significant correlation between the Saxon test and the UWSF (r=0.325; P=0.006) was observed. Twenty-four patients (34.3%) presented an altered UWSF and forty-two patients (60%) had an altered Saxon test. When we analysed the intensity of the association between the different groups (altered/normal) of both variables, we observed a direct and significant association (Gamma value=0.583, P=0.010) between both tools. We also detected differences in the Saxon test between patients with altered UWSF (Me: 1.89 g/2min; IQR: 1.47-2.68) and those with normal UWSF (Me: 2.78 g/2min; IQR: 1.77-3.75) (P=0.029). Similarly, we observed significant differences in UWSF values between patients with altered Saxon test (Me: 1.30 mL/5min IQR: 0.50-2.13) and those with a normal Saxon test (Me: 2.00 mL/5min IQR: 1.5-2.88) (P=0.008).

Regarding the ESSPRI, 42 (62,7%) patients presented an altered ESSPRI and 49 (73,1%) had an altered ESSPRI-dryness score. The group patients with ESSPRI-dryness score≥5 obtained significantly worse scores on the Saxon test (Me: 2.10g/2min IQR: 1.58-3.07) and on the ESSPRI (Me: 7.33 IQR:8.3-8.00) than the normal ESSPRI-dryness score group: Me:3.02g/2min, IQR:2.20-3.84, on the Saxon test (P=0.026); Me: 2.66 IQR:1-0.4, on the ESSPRI (P=0.000).

Conclusion: In patients with suspected SS, there is a direct and significant correlation between the Saxon test and the UWSF. Therefore, the Saxon test could be useful in the initial assessment of oral gland dysfunction, to save time and/or to select patients who require performing the UWSF.

Suppressive drugs had no significant effect on development of CD in SLE patients. Kidney damage, age at diagnosis, use of glucocorticoids, hydroxychloroquine and immunosuppressants (% use) were associated with poor cognitive performance (OR=1.4, p=0.03; OR=1.2, p=0.03). GFR values and other parameters evaluated (end stage renal disease, SLEDAI 2.4) were found in 64.2% (n=45) patients (Figure 1). The proportion of patients with CD according to MoCA score was found in 62.8% vs 65.7%, p>0.05). SLE patients per- centage regarding the rest of the size measurements, the vascularization pattern, nor significant differences were found between pSS patients and non-Sjögren's sicca subjects (n=25), who exhibited sicca symptoms but did not fulfill the AECG pSS classification criteria. We considered SGUS score based on parenchymal homogeneity, presence of hypoechogenic areas, and clearness of posterior glandular border of SG. The score of the highest graded gland was considered and a score ≥2 was defined as a positive SGUS, according to OMER- ACT US-SG scoring [1]. The size measurements of the SG were the diameters in anterior-posterior, medio-lateral, and vertical directions during dental occlusion, and length and width of anterior prolongation of parotid glands. The vascularization was ranked according to the color doppler ultrasonography pattern without salivary stimulation. For the lymph nodes examination we considered the shape, number, and size of submandibular, superficial parotid (parotid), and infraparotid lymph nodes, and the jugulodigastric lymph node, considering also that lymph nodes may not be detected. Categorical variables were compared using the Chi-square test and continuous variables were compared using Student's t-test with Welch's correction. p-values <0.05 were considered significant.

**RESULTS:** SGUS was positive in a higher proportion of patients with pSS, in comparison to non-Sjögren's sicca subjects (80% vs 24%, p=0.003). The size measurements showed a smaller antero-posterior diameter of both the right (mean 31.3mm vs. 35.4mm, p=0.037) and left (mean 30.1mm vs. 34.2mm, p=0.004) submandibular glands in pSS patients. A smaller antero-posterior diameter of the left parotid gland was also observed (mean 30.2mm vs. 34.2mm, p=0.046) in pSS patients. The lymph nodes evaluation showed that superficial parotid lymph nodes were detected in a lower proportion in pSS patients (45% vs. 72%, p=0.027) to significant differences were found between pSS patients and non-Sjögren's sicca subjects regarding the rest of the size measurements, the vascularization pattern, nor the shape, number, nor size of lymph nodes when they were detected. In addition, positive SGUS in pSS patients was also associated with a smaller antero-posterior diameter of both the right (mean 29.9mm vs. 35.4mm, p=0.009) and left (mean 32.9mm vs. 34.2mm, p=0.008) submandibular glands, and a smaller antero-posterior diameter of the left parotid gland (mean 27.5mm vs. 34.2mm, p=0.044).

**Conclusion:** Ultrasonographic features are a valuable resource for the evaluation of pSS. The score of parenchymal inhomogeneity is associated with clinical diagnosis, and other indices such as the antero-posterior diameter of the submandibular glands and a lower detection of the superficial parotid lymph nodes may be used to assist the evaluation. However, no other macrostructural features of the parotid and submandibular SG, and the adjacent lymph nodes, seem to be different between pSS patients and non-Sjögren's sicca subjects.

**AB0465 COMPARISON OF ULTRASOUND STRUCTURE CHANGES OF SALIVARY GLANDS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME WITH POSITIVE AND NEGATIVE ANTICENTROMERE ANTIBODIES**

J. Khvans, A. Torgashina, E. Sokol, B. Chalcev. V.A. Nasonova Research Institute of Rheumatology, Laboratory of Rare Rheumatic Diseases and Primary Sjögren's Syndrome, Moscow, Russian Federation

**Background:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by the presence of "sicca syndrome", secondary to the involvement of the exocrine glands. Different studies have been published and have shown that salivary gland ultrasound (SGUS) could be used as a tool for the diagnosis of pSS, especially the score of parenchymal inhomogeneity of salivary glands (SG) [1].

**Objectives:** To identify relevant ultrasonographic features associated with glandular involvement in patients with pSS, such as size measurements, vascularization, and the characteristics of adjacent lymph nodes of parotid and submandibular SG, and their association with the score of parenchymal inhomogeneity.

**Methods:** We enrolled patients with pSS (n=45) based on the 2002 American-European Consensus Group (AECG) pSS classification criteria, and non-Sjögren's sicca subjects (n=25), who exhibited sicca symptoms but did not fulfill the AECG pSS classification criteria. We considered SGUS score based on parenchymal homogeneity, presence of hypoechogenic areas, and clearness of posterior glandular border of SG. The score of the highest graded gland was considered and a score ≥2 was defined as a positive SGUS, according to OMERACT US-SG scoring [1]. The size measurements of the SG were the diameters in anterior-posterior, medio-lateral, and vertical directions during dental occlusion, and length and width of anterior prolongation of parotid glands. The vascularization was ranked according to the color doppler ultrasonography pattern without salivary stimulation. For the lymph nodes examination we considered the shape, number, and size of submandibular, superficial parotid (parotid), and infraparotid lymph nodes, and the jugulodigastric lymph node, considering also that lymph nodes may not be detected.

**Results:** SGUS was positive in a higher proportion of patients with pSS, in comparison to non-Sjögren's sicca subjects (80% vs 24%, p=0.003). The size measurements showed a smaller antero-posterior diameter of both the right (mean 31.3mm vs. 35.4mm, p=0.037) and left (mean 30.1mm vs. 34.2mm, p=0.004) submandibular glands in pSS patients. A smaller antero-posterior diameter of the left parotid gland was also observed (mean 30.2mm vs. 34.2mm, p=0.046) in pSS patients. The lymph nodes evaluation showed that superficial parotid lymph nodes were detected in a lower proportion in pSS patients (45% vs. 72%, p=0.027). To significant differences were found between pSS patients and non-Sjögren's sicca subjects regarding the rest of the size measurements, the vascularization pattern, nor the shape, number, nor size of lymph nodes when they were detected. In addition, positive SGUS in pSS patients was also associated with a smaller antero-posterior diameter of both the right (mean 29.9mm vs. 35.4mm, p=0.009) and left (mean 32.9mm vs. 34.2mm, p=0.008) submandibular glands, and a smaller antero-posterior diameter of the left parotid gland (mean 27.5mm vs. 34.2mm, p=0.044).

**Conclusion:** Ultrasonographic features are a valuable resource for the evaluation of pSS. The score of parenchymal inhomogeneity is associated with clinical diagnosis, and other indices such as the antero-posterior diameter of the submandibular glands and a lower detection of the superficial parotid lymph nodes may be used to assist the evaluation. However, no other macrostructural features of the parotid and submandibular SG, and the adjacent lymph nodes, seem to be different between pSS patients and non-Sjögren's sicca subjects.
Background: Apart from anti-Ro and/or anti-La positive primary Sjögren’s syndrome (pSS), there is a unique subtype of pSS with anticitromere antibodies (ACA). At the present time salivary gland ultrasonography (SGUS) is widely used to assess the structure of the salivary glands in pSS, but there are few publications about SGUS changes in ACA-positive patients [1].

Objectives: To investigate SGUS changes in ACA (ACA+) positive pSS patients and compare with ACA-negative (ACA–).

Methods: We examined 141 patients with pSS, including 103 ACA– patients (pSS-ACA–) with the mean age 49.8 ± 14.1 years and 38 ACA+ positive (pSS-ACA+) with the mean age 59.1 ± 10.2 years. All patients underwent standard examination for the diagnosis of pSS (stomatological, ophthalmological, immunological), and SGUS performed using GE LOGIQ 9 of two parotid and two submandibular glands. Ultrasound images were evaluated with the OMERACT SGUS scoring system (SGUS SS) from grades 0 to 3 [2]. Statistical analyses (chi-squared test, p < 0.05) were performed using STATISTICA version 12.

Results: Characteristics of patients with pSS-ACA+ and pSS-ACA– are presented in Table 1.

Characteristics of SGUS SS in pSS-ACA+ and pSS-ACA– are shown in Figure 1.

Figure 1.

We did not find significant differences when comparing SGUS SS in patients with pSS-ACA+ and pSS-ACA–.

Conclusion: We did not find significant differences in SGUS and SGUS SS in patients with pSS-ACA+ and pSS-ACA–.

AB0466

DYSFUNCTION OF THE AUTONOMIC NERVOUS SYSTEM IS ASSOCIATED WITH LOW-GRADE INFLAMMATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS.

A. Hempel Zinglerson1, K. K. Iverson2, J. Eugen-Olsen2, J. Fleischer2, S. Jacobsen1, 1Copenhagen Lupus and Vasculitis Clinic, Copenhagen University Hospital Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; 2Department of Clinical Research, Copenhagen University Hospital Amager and Hvidovre, Hvidovre, Denmark; 3Steno Diabetes Center Aarhus, Aarhus University Hospital, Aarhus, Denmark

Background: Systemic lupus erythematosus (SLE) is characterized by chronic, systemic inflammation, organ damage and -dysfunction. Autonomic nervous system dysfunction is highly prevalent in SLE patients (up to 54%); compared to controls the prevalence may be up to 12 times increased. These numbers parallel findings in other chronic conditions such as diabetes.

Heart rate variability (HRV) reflects autonomic activity, and low variability indicates impaired activity, denoted as autonomic dysfunction (AD). AD is associated with low-grade inflammation in healthy subjects and patients with diabetes or cardiovascular disease. The causality hereof is not fully understood: AD may impair the vagally mediated anti-inflammatory reflex, thus leading to increased systemic inflammation, but inflammatory mediated microvascular and neuronal damage may also impair autonomic function.

Objectives: To determine if markers of low-grade inflammation are associated with AD in SLE patients.

Methods: SLE patients (n=111) from the Copenhagen based PLUSHeart (Prospective Lupus Study on Cardiovascular Risk Factors) cohort were included for this cross-sectional analysis. The cohort has previously been described with the following characteristics in 2018-2019: 89.2% women, mean age: 51.5 (SD ±12.7) years, mean BMI: 25.1 (±5.0), mean disease duration: 19.9 (±9.5) years, median SLEDAI 2K score: 3 (IQR 1-4), and median SLE Damage Index score: 2 (I-4).

Low-grade inflammation was evaluated by plasma levels of C-reactive protein (CRP) and soluble urbinike-type plasminogen activator receptor (suPAR). Autonomic function was assessed with 5-min resting lead-I electrocardiograms using the Vagus device. Subsequent HRV analyses comprised RMSSD (the root mean square of successive interval differences between normal heartbeats), reflecting parasympathetic function, and SDNN (standard deviation of normal-to-normal heartbeat intervals), reflecting mixed parasympathetic-sympathetic function.

Results: All HRV- and inflammatory markers were non-normally distributed. The median SDNN was 50 (IQR 24-1,40,4), the median RMSSD was 19.7 (12.6-31.7). The median CRP level was 1 (1-3) and suPAR level was 3.2 (2.5-4.8).

Univariate and multivariate linear regression analyses adjusted for age and disease activity correlation of betas log-transformed (β) low-grade inflammation markers (CRP and suPAR) and heart rate variability markers (RMSSD and SDNN). β=standardized coefficients. Statistically significance (P<0.05) is marked with bold.

Conclusion: In SLE, HRV impairments reflecting both decreased parasympathetic and mixed parasympathetic-sympathetic autonomic function were associated with markers of low-grade inflammation independently of SLE disease activity and age. Longitudinal prospective studies are needed to determine causality.

COMPARISON OF 2002 AECG AND 2016 ACR/EULAR CLASSIFICATION CRITERIA AND ROLE OF SALIVARY GLAND ULTRASONOGRAPHY IN A SICCA COHORT

R. Solans-Laqué1, A. Portella Alegre2, M. Planes-Conanga3, J. Mestre-Torres1, X. Serres-Créixams2, M. I. González-Nieto1, 1Hospital Universitari Vall d’Hebron, Internal Medicine, Barcelona, Spain; 2Hospital Universitari Vall d’Hebron, Radiology, Barcelona, Spain

Background: For the last 20 years, different classification criteria have been used in clinical practice to improve the diagnosis of primary Sjögren’s syndrome (pSS) and for research purposes. Several recent studies have assessed major salivary gland ultrasonography (SGUS) as a tool for diagnosing pSS and its inclusion in the classification criteria sets. In addition, some research suggests that it may be important to distinguish between monospecific antibody assays to Ro60 or Ro52.

Objectives: To compare the new 2016 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria to the revised 2002 American-European Consensus Group (AECG) criteria in a cohort of subjects with sicca symptoms and to assess the diagnostic accuracy of SGUS. We include monospecific antibody determination to Ro60 or Ro52.

Methods: Patients ≥ 18 years old with diagnosis of sicca syndrome without other associated collagen diseases were included. The initial cohort compromised 72 patients. We assessed features of salivary and lacrimal gland dysfunction and autoimmunity as defined by tests of both AECG and ACR/EULAR criteria. We included separate antiRo52 and antiRo60 antibodies determination, and considered only antiRo60 for the ACR/EULAR criteria as recommended [1]. All the patients underwent SGUS. Agreement between the criteria sets was assessed using Cohen’s κ coefficient, and categorical variables were compared using the Chi-square test.

Results: Application of the AECG criteria resulted in the classification of 50 (69%) subjects with pSS, among whom 48 (67%) subjects also met ACR/EULAR criteria. Of the 22 patients receiving a physician diagnosis of pSS, 10 patients met ACR/EULAR only, and 22 (31%) subjects met neither criteria set. The concordance between AECG and ACR/EULAR criteria was almost perfect (κ = 0.94). The concordance group presented 8% antiRo60+, 4% antiRo52+, and 75% antiRo60/ antiRo52+, among whom 56% had antiRo60+/antiRo52+/antiLa+. No patients presented antiLa+ in the absence of both antiRo60 and antiRo52 antibodies. SGUS was abnormal in 63% of these patients. The 2 patients fulfilling only AECG criteria had antiRo52+, and SGUS was abnormal in one of them. SGUS was abnormal in 27% of the 22 patients fulfilling no criteria sets. Thus, SGUS was abnormal in a significantly higher proportion of patients with pSS, in comparison to non-Sjögren’s sicca subjects (62% vs. 27%, p=0.007). Including SGUS among the ACR/EULAR criteria would increase the concordance from κ = 0.94 to κ = 0.97 between the criteria set. Conclusion: The two sets of classification criteria yielded concordant results with an almost perfect agreement in our sicca cohort. The presence of both antiRo60 and antiRo52 antibodies was the most characteristic autoimmune pattern, with no detection of antiLa in the absence of them. SGUS was positive in a higher proportion of patients with pSS and may improve the classification criteria.

COMPARISON OF THE DIAGNOSTIC PERFORMANCE OF SALIVARY GLAND SCINTIGRAPHY AND ULTRASOUND IN SJÖGREN’S SYNDROME

M. I. González-Nieto1, A. Portella Alegre2, A. García-Burillo3, S. Asadurian4, J. Mestre-Torres1, X. Serres-Créixams2, R. Solans-Laqué1, 1Hospital Universitari Vall d’Hebron, Internal Medicine, Barcelona, Spain; 2Hospital Universitari Vall d’Hebron, Radiology, Barcelona, Spain; 3Hospital Universitari Vall d’Hebron, Nuclear Medicine, Barcelona, Spain

Background: The 2002 American-European Consensus Group (AECG) criteria included salivary gland scintigraphy (SGS) as one of the possible objective methods for assessing salivary gland involvement in primary Sjögren’s syndrome (pSS). However, this test as well as the sialography were not included in the 2016 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria and considered obsolete. On the other hand, salivary gland ultrasound (SGUS) is a simple and non-invasive procedure that is readily available and provides important information on the major salivary glands. Several recent studies have assessed SGUS as a tool for diagnosing pSS and for research purposes.

Objectives: To compare the diagnostic performance of SGS and SGUS for the diagnosis of pSS.

Methods: Patients ≥ 18 years old with diagnosis of sicca syndrome without other associated collagen diseases were included. The initial cohort compromised 72 patients. We assessed features of salivary and lacrimal gland dysfunction and autoimmunity as defined by tests of both AECG and ACR/EULAR criteria. We included separate antiRo52 and antiRo60 antibodies determination, and considered only antiRo60 for the ACR/EULAR criteria as recommended [1]. All the patients underwent SGUS. Agreement between the criteria sets was assessed using Cohen’s κ coefficient, and categorical variables were compared using the Chi-square test.

Results: Application of the AECG criteria resulted in the classification of 50 (69%) subjects with pSS, among whom 48 (67%) subjects also met ACR/EULAR criteria. Of the 22 patients receiving a physician diagnosis of pSS, 10 patients met ACR/EULAR only, and 22 (31%) subjects met neither criteria set. The concordance between AECG and ACR/EULAR criteria was almost perfect (κ = 0.94). The concordance group presented 8% antiRo60+, 4% antiRo52+, and 75% antiRo60/ antiRo52+, among whom 56% had antiRo60+/antiRo52+/antiLa+. No patients presented antiLa+ in the absence of both antiRo60 and antiRo52 antibodies. SGUS was abnormal in 63% of these patients. The 2 patients fulfilling only AECG criteria had antiRo52+, and SGUS was abnormal in one of them. SGUS was abnormal in 27% of the 22 patients fulfilling no criteria sets. Thus, SGUS was abnormal in a significantly higher proportion of patients with pSS, in comparison to non-Sjögren’s sicca subjects (62% vs. 27%, p=0.007). Including SGUS among the ACR/EULAR criteria would increase the concordance from κ = 0.94 to κ = 0.97 between the criteria set. Conclusion: The two sets of classification criteria yielded concordant results with an almost perfect agreement in our sicca cohort. The presence of both antiRo60 and antiRo52 antibodies was the most characteristic autoimmune pattern, with no detection of antiLa in the absence of them. SGUS was positive in a higher proportion of patients with pSS and may improve the classification criteria.

Background: Since the goals of remission or low disease activity are becoming more realistic with advances in treatment for SLE, there is a need to examine the measurements for SLE especially in patients with low disease activity. It has been known that disease activities in SLE are correlated with anti-DNA antibodies (Abs). However, it was not clear which measurements of disease activities or patient reported outcomes correlate better with anti-DNA Abs.

Objectives: To examine the association between parameters for SLE and anti-DNA Abs measured with RIA in Kyoto Lupus Cohort, a SLE registry in Kyoto University Hospital from 2019 to 2021.

Methods: 1)Correlations between anti-DNA Abs with SLEDAI, M-SLEDAI (SLEDAI without anti-DNA Abs), VAS, LupusPRO, SF-36, and Systemic lupus erythematosus Symptom Checklist (SSC) were evaluated cross-sectionally (n = 310). 2) The alterations in SLE parameters and anti-DNA Abs between two visits were examined (n = 106). Further, the correlations within 3 months were examined in cases with flare-ups of SLE (the alteration in SLEDAI > 0 and anti-DNA Abs≥20, n = 39). The associations of the alterations of anti-DNA Abs with each item of SLEDAI classified by organs were also examined.

Results: 1) 313 percent of the cases in the entire registry was classified as remission or low disease activity (Table 1). SLEDAI (means±SD) was higher in patients positive for anti-DNA Abs (7.94±5.20) than in patients negative for anti-DNA Abs (4.56±4.65) (p < 0.0001). Anti-DNA Abs were weakly correlated with SLEDAI (R = 0.24 [p < 0.0001]), M-SLEDAI (R = 0.15 [p = 0.014]), and Physician-VAS (R = 0.19 [p = 0.0016]). On the other hand, there were no significant correlations between anti-DNA Abs and LupusPRO and SSC. Some dimensions in SF-36 had weak correlations with anti-DNA Abs, while no component summary scores had significant correlations with anti-DNA Abs.

AB0471 FIRST SYMPTOMS AT THE ONSET OF PRIMARY SJÖGREN’S SYNDROME – THE PATIENTS’ PERSPECTIVE OF A SNEAKY DISEASE

A. Lackner1, J. Fessler1, S. Zenz1, J. Hermann1, J. Thiel1, M. Stradner1. 1Medical University of Graz, Department of Rheumatology & Immunology, Graz, Austria

Background: Primary Sjögren Syndrome (PSS) is an autoimmune disorder with a diverse spectrum of clinical manifestations ranging from sicca symptoms to severe systemic organ involvement. Little is known about the symptoms at the onset of PSS, as these are often ignored by both, patients and physicians leading to a substantial delay of diagnosis.

Objectives: The aim of this study was to investigate patients’ recollection of the first symptoms before diagnosis of PSS in qualitative interviews. The second aim was to verify and quantify these aspects in a representative cohort.

Results: Twenty-three patients were included in the study (21 women, age: 62 years). At the time of the study, the ESSPRI averaged 47 points and the ESSDAI 8.5 points. The Schirmer test gave an average value of 6.4 mm/5 min, the unstimulated salivary flow (UWSF) 0.2 ml/5 min. The evaluation of the B-mode sonography showed predominantly hypoechoic lesions and less hyperechoic bands. In the evaluation of the tissue information obtained by means of MSOT, a correlation between increased lipid content and salivary flow measurement was shown as well as a significant difference between collagen proportion between parotid and submandibular glands.

Conclusion: With the help of MSOT, statements about the actual tissue changes within the salivary glands in SjS can be made for the first time. This project demonstrated for the first time a correlation between tissue composition and clinical parameter. The evaluation of other wavelengths in order to obtain further information on the tissue composition is planned.

Disclosure of Interests: None declared.

Methods: All PSS patients fulfilled the EULAR/ACR 2016 classification criteria. In the first part of the study, consecutive PSS patients were recruited for individual, semi-structured interviews. A discussion guide with five open-ended questions was developed to explore patients' experiences on the onset of PSS. All interviews were audio-recorded and transcribed verbatim, and an inductive thematic data analysis was performed using MAXQDA software (VERBI, Berlin, Germany). In the second part, the identified aspects of the qualitative analysis were grouped to a checklist with ten items. Patients were asked to complete the checklist before their routine clinical assessment.

Results: One-hundred and thirty-four patients participated in the study. The qualitative part was completed by 31 PSS patients; 90.3% (n=28) were female and patients had a mean disease duration of 6.9 years (±5.7(SD)) and a mean age of 58.1 years (±12.6).

Four different major aspects emerged of how patients experienced the beginning and first symptoms of PSS: (1) sicca symptoms started after initial swelling of parotids and/or lymph nodes (2) “Classic” PSS symptoms (fatigue, pain, dryness): patients reported wandering joint pain before diagnosis with a long time apart from first symptoms until diagnosis. Patients described joint pain, chronic malaise, and fatigue over months. (3) Hormonal changes (e.g., after birth, hysterec- tomy) or infections before the onset of PSS symptoms. (4) Slowly progressing discomfort due to sicca: patients reported a slow progression of symptoms with no initial recognition of sicca discomfort. In these patients recurrent dental problems and loss of teeth in the years prior to diagnosis was common.

In the second part of the study, the four themes were verified in an independent cohort of 103 PSS patients. Patients were 59.9 (±13.7) years old and six patients were male. The main symptom before diagnosis was dryness (n=77, 74.8%) with wandering joint pain (n=51, 49.5%) and fatigue (n=47, 45.6%). In 38.8% (n=40), patients reported a swelling/infarention of the parotid gland at the onset of disease.

Conclusion: We identified four themes describing the initial symptoms of PSS. Raising awareness of these symptoms among physicians and among the general public may allow earlier diagnosis of PSS.

AB0473  EFFECT OF THYROID LESIONS ON THE COURSE OF SYSTEMIC LUPUS ERYTHEMATOSUS

A. Trofimenko1, O. Emel'yanova1, O. Rusanova1,2. Federal State Budgetary Institution « Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Laboratory of Clinical Immunology, Volgograd, Russian Federation

Background: Thyroid disease is a common complication of systemic lupus erythematosus manifesting in 30% of cases due to a disturbance of autoimmune mechanisms. Objectives: evaluating the effect of thyroid lesions on the course of systemic lupus erythematosus based on clinical and laboratory parameters, and the level of antibodies to thyroid hormones.

Methods: Among 65 examined patients with SLE (63 women and 2 men aged 18-65) we revealed a thyroid disorder in a third of patients. Patients were diagnosed with autoimmune thyroid diseases in 16 cases, nodular goiter (degree I and II), and single diffuse toxic goiter in 5 cases. The duration of the disease was 5 years, that concomitant thyroid diseases — 3 years. The concentration of antibodies to thyroid hormones was determined by enzyme immunomassay using immobilized thyroxine and triiodothyronine.

Results: When the thyroid gland (TG) gets involved, there is a pronounced discordance in the parameters of immune and hormonal status in patients with SLE compared with patients without thyroid complications. It was found that 68% of patients had antibodies to nDNA, compared with 46% without concomitant thyroid lesion, CIC - 77% and 32%, respectively, IgG - 54% and 25%. The SLICC/ACR damage index in the SLE group with thyroid involvement was higher than in the second group: 4.55 and 3.6 points. This indicates an increase in the severity of SLE in patients with involvement of the thyroid gland. Joint involvement was seen in 79% with thyroid involvement, and 49% without thyroid involvement. A lesion of serous membranes in the form of pleurisy was in 39% and in 3% without involvement, that of the heart in 66/24%. Lupus erythematosus cell phenomenon in 44 / 31%. Immunological activity prevailed in the group of SLE patients with combined auto thyroid disease. Among these patients, 100% had an elevated level of antibodies to thyroid-stimulating hormones, versus 15% in the group without auto thyroid disease.

Conclusion: The involvement of the thyroid gland increases the severity of the course of SLE, antibodies to thyroid hormones are produced actively, which is indicative of thyrocyte destruction and of blocking the normal process of hormone synthesis by their antibodies.

Disclosure of Interests: None declared

AB0474  IMPACT OF HEALTH LITERACY ON TRUST IN PHYSICIANS AMONG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: THE TRUMP2-SLE PROJECT

N. Oguro1,2, N. Yajima1,3,4, Y. Miyawaki5, R. Yoshimi5, Y. Shinomjia6, K. E. Sada3,4, K. Hayashi1,2, K. Shidahara1,2, N. Sakurai1, C. Hidekawa1, D. Kishida2, T. Ichikawa1, Y. Ishikawa1, N. Kuri1,2, 1Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan; 2Kushikuma Medical University, Department of Clinical Epidemiology, Graduate School of Medicine, Fukushima, Japan; 3Kyoto University, Department of Healthcare Epidemiology, School of Public Health in the Graduate School of Medicine, Kyoto, Japan; 4Fukuoka University Graduate School of Medical Sciences, Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama, Japan; 5Okayama University Graduate School of Medical Sciences, Dentistry and Pharmaceutical Sciences, Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama, Japan; 6Yokohama City University Graduate School of Medicine, Department of Stem Cell and Immune Regulation, Yokohama, Japan; 7Shinshu University School of Medicine, Department of Medicine, School of Medicine, Nagano, Japan; 8Kochi University, Department of Clinical Epidemiology, Kochi Medical School, Kochi, Japan; 9University of Occupational and Environmental Health, The First Department of Internal Medicine, school of Medicine, Fukuoka, Japan; 10Fukushima Medical University, Department of Innovative Research and Education for Clinicians and Trainees (DiRECT), Fukushima, Japan

Conclusion: This study determined the AQLS and the minimal detectable change for HRQL. These results will help evaluating the HRQL of patients in clinical practice, as well as possible assistance designing future clinical trials. Patients in AQLS show lower dysne symptoms scores but higher immunological activity compared to non-AQLS patients. Longitudinal studies are needed to determine factors affecting patients' HRQL in PSS.

Disclosure of Interests: None declared

**Background:** Information technology has expanded the gap in patient health literacy (HL), and HL has various implications on the trust in patient-doctor relationship. Previously, only functional HL, the ability to interpret health information through reading and writing skills, has been studied in patients with SLE (1).

**Objectives:** We examined how trust in physicians is affected by the broader concept of HL, including communicative HL, the ability to extract health information from communication to use, and critical HL, the ability to discern and use such information (2).

**Methods:** This cross-sectional study enrolled 362 SLE patients at 5 sites between June 2020 and August 2021. Three domains of HL (i.e., functional HL, communicative HL, and critical HL) were assessed using the 14-item FCCHL scale (range: 1-4 points for each domain). The outcomes were patients’ trust in physicians and physicians in general and were measured using the Japanese version of the 5-item Wake Forest Physician Trust scales (range: 0-100 points for each scale). General linear models adjusted for age, gender, education, income, SLEDAI, disease duration, depression, and hours of internet use were conducted. Subsequently, a series of general linear models were then fit to each of the three domains of HL to examine whether or not it was associated with the aforementioned covariates.

**Results:** The median age of the patients was 45 (interquartile range [IQR], 34-55), 88% were female. The median value of SLEDAI was 80 ([IQR], 70-95) and trust in physicians generally was 65 ([IQR], 50-80). Trust in one's physician increased with higher functional and communicative HL (per 1-pt increase, 3.2 [95% CI 0.7 to 5.9]; 5.4 [95% CI 1.6 to 9.3]). Trust in doctors generally increased with higher communicative HL and decreased with higher critical HL (per 1-pt increase, 6.8 [95% CI 2.0 to 12]; -6.7 [95% CI -12 to -1.9]). Lower functional HL was associated with older age and depression, while higher HL was associated with higher educational level. Higher communicative HL and critical HL were each associated with longer Internet use.

**Conclusion:** In patients with SLE, higher trust in one's physician was associated with both functional and communicative HL, while higher trust in physicians generally was associated with higher communicative HL and lower critical HL. Our findings suggest that trusting relationships may be fostered by the encouragement of rheumatologists to cultivate patients’ ability to share their health problems with their physicians and family members and to obtain useful health information (i.e., communicative HL), rather than to improve their ability to discern health information (i.e., critical HL).

**AVASCULAR NECROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF LONG-TERM FOLLOW-UP FROM A SINGLE CENTRE**

B. Bulut\(^1\), D. Sahin Eroglu\(^2\), T. M. Turgay\(^3\), G. Kimikli\(^4\), A. Ates\(^5\). \(^1\)Ankara University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey; \(^2\)Ankara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

**Background:** Avascular necrosis (AVN) is a major cause of morbidity and loss of quality of life in systemic lupus erythematosus (SLE) patients. AVN is often diagnosed at advanced stages and treatment options are limited.

**Objectives:** To identify the differences of demographic, clinical, and serological factors in SLE patients with and without AVN, and to investigate associated risk factors of AVN in patients with SLE.

**Methods:** In this single-centre retrospective cohort study, we included 533 SLE patients [86.6% female, mean (standard deviation), (SD)] age at diagnosis 34.6 (14.3) years who fulfilled SLICC 2012 classification criteria. AVN diagnosis was confirmed by radiological imaging techniques in symptomatic patients. To investigate the correlation between maximum daily steroid dose and AVN development, we divided our patients into four groups according to the highest dose of prednisolone used for a month or longer during their follow-up (Group 1: 0-19mg/day, Group 2: 20-39mg/day, Group 3: 40-59mg/day, Group 4:≥60mg/day). Pulse steroid administration was also recorded. Multivariable logistic regression analyses were performed to demonstrate the associated factors with AVN. Clinical parameters found to be related to AVN development in univariable analyses were analyzed both in the sex- and age-adjusted model, and the model including sex, age, time to AVN or last follow-up, immunosuppressive therapy, and steroid dosages (multivariable model). To determine the relation of different steroid groups and pulse steroids with AVN, odds ratios (OR) were calculated in the sex- and age-adjusted model and multivariable model.

**Results:** After a median disease duration of 9.1 years, AVN was detected in 46 (8.6%) patients. There were 85 AVN sites involved, the hips being the most commonly affected (71.7%) (Figure 1). The mean age at SLE diagnosis was significantly younger in the AVN group (mean [SD] 26.8 [11.7] vs. 35.3 [11.4], p<0.001). Fever (21.6% vs. 10.9%), malar rash (52.2% vs. 36.3%), serositis (26.1% vs. 14.6%), renal involvement (65.2% vs. 35.1%) and hemolytic anemia (32.6% vs. 19.3%) were found more frequently in the AVN group compared to non-AVN group, respectively (p<0.05). In the multivariable logistic regression analyses, malar rash was found to be the only clinical feature associated with AVN (OR 2.01, 95% confidence interval [CI] 1.02-3.97). The steroids had an association with AVN development in a dose-dependent manner (Table 1). Pulse steroids did not increase the risk of AVN (Table 1).

**Table 1. Factors associated with avascular necrosis.**

<table>
<thead>
<tr>
<th>Variable</th>
<th>OR Crude (95% CI)</th>
<th>OR Age-sex adjusted (95% CI)</th>
<th>OR fully adjusted* (95% CI)</th>

<td>1.00 (reference group)</td>
<td>1.00 (reference group)</td>
<td>1.00 (reference group)</td>
</tr>
<tr>
<td>Pulse steroids</td>
<td>6.29 (3.35-11.81)</td>
<td>4.86 (2.53-9.37)</td>
<td>1.51 (0.69-3.32)</td>
</tr>
</tbody>
</table>

*In addition to the age at SLE diagnosis and sex, immunosuppressant use, and follow-up duration were also added to the final model.

**Conclusion:** High-dose daily steroid use was associated with an increased risk of AVN in SLE patients. Therefore, to prevent AVN in patients with SLE, the aim should be minimizing the dosage and duration of steroid use as much as possible. Furthermore, we showed that malar rash independently increased the risk of AVN development. Further research is required to explain this finding.

**Figure 1.** Magnetic resonance imaging of avascular necrosis of bilateral femoral heads in a patient with SLE.
SLE development is needed for patients with ITP, particularly those with young age (<40 years), organ bleeding, and ANA positivity (>1:160).

Methods: Of 130 patients with primary ITP, 10 (7.7%) were later diagnosed with SLE during follow-up (median, 30 months [IQR, 15.5–105]). The presence of skin bleeding, organ bleeding, lymphopenia, anemia, and positive antinuclear antibody (ANA) titer (>1:160) were more common among patients who later developed SLE than did those who did not develop SLE. Multivariate analysis showed that young age (<40 years; odds ratio [OR], 8.359 [95% confidence interval (CI), 1.230–56.793]; p = 0.033), organ bleeding (OR, 18.349 [95% CI, 2.771–121.517]; p = 0.003), and ANA positivity (>1:160; OR, 7.692 [95% CI, 1.482–39.910]; p = 0.015) were significantly associated with the development of SLE in patients with primary ITP.

Results: Young age (<40 years), organ bleeding, and ANA positivity (>1:160) were risk factors for the development of SLE in patients with primary ITP. Multivariate analysis showed that young age (<40 years), organ bleeding, and ANA positivity (>1:160) were risk factors for the development of SLE in patients with primary ITP. Multivariate analysis showed that young age (<40 years), organ bleeding, and ANA positivity (>1:160) were risk factors for the development of SLE in patients with primary ITP.

Conclusion: These results suggest that continued follow-up for the detection of SLE development is needed for patients with ITP, particularly those with young age, ANA positivity, or organ bleeding.

LUPUS ANTICOAGULANT IS ASSOCIATED WITH PROSPECTIVE ECHOCARDIOGRAPHIC CHANGES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A FIVE-YEAR FOLLOW-UP STUDY

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with increased risk of cardiovascular complications such as coronary artery disease, myocarditis, pericarditis, and valvular dysfunction (1–3). The pathophysiological mechanisms are poorly understood and markers to identify high-risk patients are warranted.

Objectives: We aimed to identify SLE-characteristics that are associated with progressive cardiac dysfunction.

Methods: A total of 108 patients with SLE (90% female, mean age 46±13 years, median disease duration of 14 (7–21) years) were included from 2013 to 2014. Blood samples were collected with inclusion of biomarkers, and a standard echocardiography was performed at baseline and at a five-year follow-up. Multivariate regression analyses with five independent lupus-specific baseline variables of interest (disease activity, lupus nephritis, anti-cardiolipin and/or anti-beta-2 glycoprotein I antibodies, and lupus anticoagulant (LAC)) were performed for the association with baseline echocardiographic parameters as well as for changes during follow-up.

Results: During the five-year follow-up period, left ventricular (LV) end-diastolic volume index increased from 43.5±13.9 to 52.5±15.7 ml/m² (p <0.001) (Figure 1 A1), and LV diastolic parameters declined (E/A ratio 1.4±0.5 vs. 1.3±0.5, p=0.002; e’ velocity 12.8±3.8 vs. 12.0±3.7 cm/s, p=0.02; mitral valve deceleration time 227.9 vs. 200.8 ms, p<0.001), except for E/e’ (7.5±3.8 vs. 6.8±3.4, p=0.02) (Figure 1B1) in the entire SLE population. LV ejection fraction remained stationary (59.5±6.8 vs. 59.6±6.4 %, p=0.81). Presence of LAC was associated with progressive LV dilatation during the follow-up period (p=0.005) (Figure 1 A2) but not baseline LV volumes (p=0.35). LAC was associated with lower E/A ratio at baseline (p=0.006) but did not predict a decrease of E/A ratio during follow-up (p=0.09) (Figure 1 B2). Follow-up changes of other echocardiographic parameters were not associated with any of the lupus-specific variables.

Conclusion: Presence of LAC was associated with lower E/A ratio at baseline as well as progressive left ventricular dilatation during a five-year follow-up period. Hence, LAC might be a predictor of progressive cardiac dysfunction in SLE patients. LAC is known to have implications for the microvascular circulation, but the clinical significance of the present findings is yet to be elucidated.

Disclosure of Interests: None declared

Background: Assessment of organ damage has become the standard outcome measure for morbidity and mortality in patients with lupus over the world including the Russian Federation (RF), Kirgizstan and Kazakhstan.

Objectives: The aim of this study was to compare organ damage of patients with systemic lupus erythematosus in the Russian Federation, Kirgizstan and Kazakhstan in real clinical practice.

Methods: 1102 SLE pts who fulfilled SLICC 2012 criteria were enrolled into the study. Disease activity was evaluated by SLEDAI-2K, while chronic damage was assessed by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI).

Results: A total of 400 patients with lupus (F/M 363:37, mean age 34,2±11,5 years, mean disease duration 106,3±81,9 months) were included. All patients were divided into 4 groups: SLEDAI 2K <4 – 136 pts, SLEDAI-2K ≥4 – 264 pts, SDI =0 – 177 pts, SDI ≥1 – 223 pts.

QOL was assessed by SF-36 and LupusQol was low in all groups of patients with SLE. The mean scores for each of the domains of the LupusQol and SF-36 are shown in Table 1.

It was shown that the domain of pain of the LupusQol questionnaire (p<0.007) statistically significantly responds to disease activity in contrast to the comparable SF-36 scale. The domains MH (p<0.001) and VT (p<0.007) of the SF-36 are more sensitive to change of disease activity.

It was found that in patients with SLE with a high activity of the disease, the noncomparable domains such as Planning (p<0.0004), Intimate relationship (p<0.003), Burden to others (p<0.03), Body image (p<0.007) significantly change. The QOL in patients with SLE with SDI ≥1 was poor in the domain of Physical health of the LupusQol and in the comparable domain of the SF-36 PF. Higher QOL in these domains was in patients without damages. The domains Fatigue and VT are also significantly affected by the damage. So, in patients with SDI ≥1, there was a significant decrease of QOL in these domains up to 60.35±24.0 and 49.55±20.32, respectively, as compared with patients with SLE with SDI =0 – 177, SDI ≥1 – 223 pts.

Conclusion: LupusQol is more sensitive to changes in SLE activity. Both SF-36 and LupusQol are equally sensitive to changes in organ damage.

Disclosure of Interests: None declared

The aim of this study was to determine factors affecting quality of life (HRQoL) for patients with systemic lupus erythematosus (SLE). We conducted this study to compare the efficiency of LupusQoL and SF-36 in 400 Russian patients with systemic lupus erythematosus.

**Objectives:**

- To compare the efficiency of LupusQoL and SF-36 in assessing the health-related quality of life (HRQoL) of 400 Russian lupus patients.
- To investigate the differences in HRQoL between lupus patients in different regions of the Russian Federation.
- To identify factors associated with HRQoL in Russian lupus patients.

**Methods:**

- The study included 400 patients with systemic lupus erythematosus (SLE) from the Russian Federation.
- The SF-36 and LupusQoL questionnaires were administered to participants.
- Data analysis involved descriptive statistics and correlation analysis.

**Results:**

- The mean scores for the 8 domains of the SF-36 were below 50, indicating poor health status.
- The LupusQoL scores were lower than the SF-36 scores, indicating a worse impact on HRQoL.
- The most affected domains were physical functioning and role-physical.

**Conclusion:**

- LupusQoL and SF-36 are equivalent in assessing HRQoL in Russian lupus patients.
- Factors associated with HRQoL include disease activity, quality of life, and patient demographics.

**Disclosure of Interests:** None declared.

The worst HRQoL (Sum LupusQol<20) was associated with older age, duration of illness before verification of SLE diagnosis, unemployed status, high disease activity, organ damage, anxiety and depression (Table 1).

During the year after vaccination, a decrease in episodes of infections of the lower respiratory tract by more than 3 times was recorded compared with the year preceding immunization (43% and 12.5%, respectively), p=0.0001. Not a single case of recurrent pneumonia was noted (before vaccination - in 5 patients).

The number of infections of the upper respiratory tract has more than halved (19.4% and 8.3%, respectively). In 4 (6.6%) patients, non-severe pneumonia developed within a year after vaccination, all of these patients had risk factors for the development of respiratory infections: anti-B-cell therapy with the absence of an adequate vaccine response (3), intestinal lung damage (1), work activities and home environments associated with an increased risk of viral or bacterial infection (3). After a year of observation, 25 patients were followed up for another 4-5 years, the development of pneumonia was not registered in any case (2 out of 25 had pneumonia in the year prior to vaccination). At the same time, 5 years after vaccination, only 18% of patients had more than a 2-fold excess of the initial anti-pneumococcal antibodies.

Conclusion: Sufficient immunogenicity and clear clinical efficacy of PPV-23 have been demonstrated in SLE patients receiving combined immunosuppressive therapy.

INFLAMMATORY MUSCULOSKELETAL ABNORMALITIES BY CONTRAST ENHANCED MRI IN SLE PATIENTS

P. Corzo García1, I. García-Duitama2, A. Agustí Claramunt3, I. Carrón Barberà3, S. Marsicò4, J. Monfort5, T. C. Salaman Monte3, 1Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain; 2Hospital del Mar, Radiology, Barcelona, Spain; 3Hospital del Mar, Rheumatology, Barcelona, Spain

Background: Joint involvement in SLE is the most frequent manifestation and shows a wide heterogeneity1. It has not a valid classification and it is often under-estimated. Subclinical inflammatory musculoskeletal involvement is not well known2.

Objectives: We aim to describe the prevalence of joint and tendon involvement in hand and wrist of SLE patients, either with clinical arthritis, arthralgia or asymptomatic and compare it with healthy subjects using contrasted MRI.

Methods: SLE patients fulfilling SLICC criteria were recruited and classified as follows: group (G) 1: hand/wrist arthritis, G2: hand/wrist arthralgia, G3: no hand/wrist symptoms. Jaccoud arthropathy, CCPa and RF positivity, hand OA or surgery were excluded. Healthy subjects (HS) were recruited as controls: G4: Contrasted MRI of non-dominant hand/wrist was performed. Images were evaluated following RAMRIS criteria extended to PIP. Tenosynovitis score for RA and periarticular areas.

Results: 107 subjects were recruited (G1: 31, G231, G231, G244). Any lesion: SLE patients 74.7%, HS 41.67%; p < 0.002. Synovitis: G1: 64.82%, G2: 51.61%, G3: 45%, G4: 20.83%; p = 0.013. Erosions: G1: 29.03%, G2: 54.84%, G3: 47.62%; G4: 25%; p = 0.066. Bone marrow edema G1: 29.03%, G2: 22.58%, G3: 19.05%, G4: 0.0%; p = 0.046. Tenosynovitis: G1: 38.71%; G2: 25.81%, G3: 14.29%, G4: 0.0%; p = 0.005. Periarticular: G1: 12.90%; G2: 3.23%, G3: 0.0%, G4: 0.0%; p = 0.07.

Conclusion: SLE patients have a high prevalence of inflammatory musculoskeletal alterations by contrasted MRI, even if asymptomatic. Not only tenosynovitis but periarticular is also present.

SJÖGREN SYNDROME: DESCRIPTIVE AND COMPARATIVE STUDY OF PRIMITIVE AND ASSOCIATED FORMS

S. Skhiri1, A. Baya Chatti1, W. Ben Yahia1, A. Atig1, N. Ghannouchi1.

1Farhat Hached Hospital, Internal Medicine, Sousse, Tunisia

Background: Sjögren syndrome (SS) is an autoimmune disease (AID) characterized by a dysfunction of the exocrine glands (mainly salivary and tear glands). It is responsible for xerostomia and xerophthalmia as well as systemic manifestations that may affect multiple organs. This syndrome comes in two forms: primary when it is isolated (pSS) and associated (aSS) when it is in association with another AID whether it is specific of organs or not. These two entities have different particularities, requiring explorations and adapted treatments. Few studies have taken interest in determining them.

Objectives: The objective of this study was to compare the various clinical and evolutionary manifestations of these two forms.

Methods: We conducted a prospective analytical study over a period of 33 years. All patients with SS based on ACR 2012 and/or ACR/EULAR classification
criteria were included. Epidemiological, clinical, para-clinical, therapeutic and
disease course characteristics in both groups were described and compared.

Results: One hundred and forty-five patients were included. Sixty-three (43.4%)
had pSS and 82 (56.5%) had aSS. The pSS group consisted of 58 women (92%)
and five men (8%) with a mean age at diagnosis of 51.9 ±15.3 years.
Seventy-eight women (95%) and four men (5%) with a mean age at diagnosis
of 45.4±16.2 years had a SS. The most common AADs associated with the latter
were SLE (99%) and RA (18.3%). The comparison of the two groups concluded
that the mean age at the time of diagnosis was significantly higher in patients
with pSS (p < 0.01). Glandular involvement was almost constant in both groups.
Joint involvement, skin involvement and Raynaud’s syndrome were significantly
more common in the aSS group (p < 0.01; < 0.001 and 0.02 respectively).
Central neurological involvement was significantly more common in the pSS group
(p<0.04). The other clinical manifestations were comparable in both groups.
Comparison of biological parameters between pSS and aSS showed a statisti-
cally higher frequency of leukopenia (p<0.04), lymphopenia (p <0.001), Anti-
nuclear antibodies (p<0.001), anti SSA antibodies (p=0.003), rheumatoid factor
(p < 0.001) and anti CCP antibodies (p<0.001) in aSS. Synthetic antimalarial
drugs, corticosteroids and immunosuppressive treatment were significantly
more prescribed for aSS (p < 0.003, p < 0.001 and p=0.02 respectively). After a mean
of follow up of 3.4 ±5.5 years for the pSS and 4 ±4.5 years for the aSS. No cases of
lupusyma were observed in both groups.

Conclusion: Differentiating between pSS and aSS is crucial in order to establish
an early diagnosis and ensure adequate management and a better prognosis.

</tbody>
</table>

CRP had a pooled sensitivity of 0.75 (95%CI 0.57-0.94) and specificity of 0.72
(0.59-0.85). PCT had a pooled sensitivity of 0.68 (95% CI 0.59-0.77) and speci-
ficity of 0.75 (0.59-0.90), and for ESR pooled estimates were not calculated
due to insufficient data but sensitivity ranged from 50 to 69.8 and specificity from
38.8 to 55.6. Modifying cut-offs improved sensitivities and specificities (see Table 1).
The ESR, CRP, and PCT mean differences were all greater in infection groups
versus non-infection (10.1, 95% CI 3.2-17.0; 46.8, 95% CI 36.5-57.0; 0.53, 95% CI
0.26-0.80; respectively).

Conclusion: SDI in our SLE-cohort was correlated with age, vascular risk factors, severe organ involvement, aPLs and steroid use. Only antimalarials were associated with a lower mean SDI. SDI increases significantly with longer follow-up time, especially after the fifth year of follow-up. Prevention and early treatment of the aforementioned risk factors could avoid irreversible organ accrual damage in lupus.

AB0490
INFLAMMATORY MUSCULOSKELETAL ABNORMALITIES BY CONTRAST ENHANCED MRI SHOW A SPECIFIC PROFILE IN SLE PATIENTS
Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain; 2Hospital del Mar, Radiology, Barcelona, Spain; 3Hospital del Mar, Rheumatology, Barcelona, Spain.

Background: Joint involvement in SLE is the most frequent manifestation and often it is the first clinical symptom. Despite this, it is not well characterised and demographic, serological and clinicoterapeutic correlations have not been well established.

Objectives: We aim to determine if there is a demographic, clinic or serological profile related to inflammatory joint involvement of hand and/or wrist (sinovitis, bone marrow edema, erosions, tenosynovitis or peritendinitis) confirmed by contrasted MRI in SLE patients.

Methods: Consecutive SLE patients fulfilling SLICC criteria both symptomatic and asymptomatic for joint involvement were recruited. Contrast MRI of non-dominant hand/wrist was performed for joint and tendon evaluation. Socio-demographic, clinicoterapeutic and serological data were collected and statistically analysed along with each MRI abnormality.

Results: 83 subjects were recruited. Erosions and synovitis were more frequent at advanced age (55±12.61 vs 45.06±12.18 years, p=0.001 and 52.78±12.69 vs 44.95±12.49 years, p=0.011). Synovitis is less frequent in patients with renal involvement (6.7% vs 24.3%, p=0.031). No other SLE organ-specific involvement showed statistical correlation. Neither SLE related autoantibodies (ANA, DAnDs, Sm, RNP, Ro, La, antiphospholipid), complement fractions, ESR nor CRP correlated with MRI lesions, except for erosions which showed lower DNAds titers (15.94±49.56 vs 27.23±52.41, p=0.008). Patients with bone marrow edema received more methotrexate (25% vs 6.3%, p=0.033), and those with erosions and peritendinitis received less mycophenolate (5.6% vs 22.9%, p=0.034; 0% vs 12.8%, p=0.026). Patients with synovitis reported higher values in pain NE (6.03±2.57 vs 4.26±2.49, p=0.005; 6.56±1.95 vs 4.75±2.75, p=0.017; 8.60±1.30 vs 4.95±2.55, p=0.001; 8.47±2.72 vs 4.83±3.58, p=0.018) and on their collaboration in fatigue EN (3.22±0.82 vs 1.91±0.84, p=0.035) and patients with tenosynovitis showed worse FSS-9 (61.50±1.73 vs 45.70±16.80, p=0.015) versus patients who did not show these abnormalities by MRI. Patients with synovitis and peritendinitis had a worse HAQ (1.14±0.69 vs 0.75±0.65, p=0.031; 0.19±0.07 vs 0.90±0.69, p=0.018).

Conclusion: SLE patients with joint and/or tendon involvement confirmed by contrast enhanced MRI have a worse HRQoL measured by pain, fatigue and functional disability.

AB0492
INTESTINAL MICROBIOLOGICAL DISORDER CLOSELY ASSOCIATED WITH PERIPHERAL LYMPHOCYTE SUBSETS AND CYTOKINES IN SYSTEMIC LUPUS ERYTHEMATOSUS.
R. Zhai 1,2,3, S. X. Zhang 1,2,3, J. Qiao 1,2,3, S. Song 1,2,3, J. Chen 1,2,3, X. Li 1.
1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 3Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China.

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by widespread inflammation and tissue damage in multiple organs[1]. Microbiome is one of environmental factors that has been suggested to contribute to the occurrence and development of SLE[2].

Objectives: This study aims to the understanding of the pathogenesis of SLE from the perspective of intestinal microorganisms and investigate the associations between flora and peripheral lymphocyte subpopulations and cytokines in SLE patients.

Methods: Fecal samples were collected from 96 patients with SLE, and 96 sex- and age-matched healthy controls (HCs). The gut microbiota were investigated via 16s rRNA sequencing and the peripheral T lymphocyte subsets of these participants were assessed by flow cytometry. Indicators of disease activity such as erythrocyte sedimentation rate (ESR), C-reaction protein (CRP), complement C3 and C4 were recorded. Differential abundance analysis was carried out using the edgeR algorithm. The Wilcoxon rank-sum test was used to compare alpha diversity indices, bacterial abundances, and the F/B ratio between groups. R (version 4.0.1) was used for comparative statistics, and pearson’s correlation analysis was used to assess the correlations between the relative abundances of bacterial genera and serum levels of ESR, CRP, C3 and C4 in the samples; correlations with p < 0.05 were considered significant.

Results: The alpha estimators of richness (ACE and Chao 1) were significantly reduced in SLE feces samples compared with those of HCs (p < 0.001). Bacterial diversity estimators, including the Shannon (p < 0.001) and Simpson’s (p < 0.01) indices, were also significantly lower in SLE (Figure 1A-D). The microbial community structures of the SLE and HCs could be separated by unweighted UnFrac-based principal coordinates analysis (PCoA) (R = 0.186, and p = 0.011, Figure 1E). Significant differences in gut microbiota composition between SLE and HCs were found using the edgeR algorithm. Compared with HCs, 24 species of flora were discovered to be distinctly different(p < 0.05). Moreover, there was a significant positive correlation between Tregs and Cytobacterium.
Antiphospholipid syndrome (APS) patients are associated with stress related factors, and can lead to higher mortality rates. Suicidal ideations in SLE/APS patients are mainly caused by anxiety-depressive spectrum disorders provoked by stress factors, so associations with the duration, activity and manifestations of the rheumatic diseases were found. Timely identification and therapy of depressive and anxiety spectrum disorders can prevent suicidal ideations and possible poor outcomes.

**Objectives:** To describe the rates and potential causes of suicidal ideations in SLE and APS patients.

**Methods:** 159 patients (62 with SLE, 49 with SLE and secondary APS, 48 with primary APS (PAPS)), mostly women (120 (75.5%)), were consecutively enrolled in the study. The mean (±SD) age was 37.5 ± 12.2 years. SLE activity was measured by SLEDAI. Suicidal ideations and mental disorders were detected by psychiatrist in semi-structured interview. The severity of mental disorders was measured with MADRS, HADS, PHQ9, PSS10, and quality of life with EQ-5D, LupusQoL. The APS duration was significantly longer in patients with suicidal ideations; no differences in activity, severity and duration of SLE or steroid therapy were found. APS patients with current suicidal ideations compared to patients without them were 2 times more likely to receive rituximab (Table 1).

**AB0494 COMPARISON OF CUTANEOUS SILENT PERIOD PARAMETERS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME WITH THE HEALTHY POPULATION**

Q. Yolcu1, K. Abacar2, O. Kenis-Coskun1, N. Inanc2, E. Karadag-Saygi1, O. H. Gunduz1, 2, *Marmara University, Physical Medicine and Rehabilitation, Istanbul, Turkey; 3Marmara University, Internal Medicine, Division of Rheumatology, Istanbul, Turkey; Marmara University, Physical Medicine and Rehabilitation, Division of Pain Medicine, Istanbul, Turkey*

**Background:** Neurological involvement has a great importance in the clinical spectrum of primary Sjögren’s syndrome (pSS) (1). The presence of small fiber neuropathy (SFN), which cannot be detected in routine electrophysiological examinations, causes the peripheral nervous system involvement to be underestimated in the course of the disease and causes pain-related symptoms in patients that cannot be explained by routine examinations (2). Various methods can be used in the detection of SFN, and cutaneous silent period (CSP) measurement is gaining popularity recently due to its non-invasiveness and practical application (3).

**Objectives:** Evaluating SFN involvement in patients with pSS using CSP and evaluating its relationship with clinical parameters.

**Methods:** A total of 161 patients (96 pSS, 65 healthy controls) were included in the study. CSP duration was measured in semi-structured interview. The severity of mental disorders was measured by MADRS, HADS, PHQ9, PSS10, and quality of life with EQ-5D, LupusQoL. The APS duration was significantly longer in patients with suicidal ideations; no differences in activity, severity and duration of SLE or steroid therapy were found. APS patients with current suicidal ideations compared to patients without them were 2 times more likely to receive rituximab (Table 1).

### Table 1. Description of patients with versus without suicidal ideations.

Conclusion: Suicidal ideations in SLE/APS patients are mainly caused by anxiety-depressive spectrum disorders provoked by stress factors, so associations with the duration, activity and manifestations of the rheumatic diseases were found. Timely identification and therapy of depressive and anxiety spectrum disorders can prevent suicidal ideations and possible poor outcomes.

**Disclosure of Interests:** None declared

Methods: Patients with a diagnosis of pSS followed in the rheumatology outpatient clinic and healthy volunteers demographically homogeneous with the patient group were included in the study. The CSP responses were recorded over the abductor pollicis brevis muscle in the upper extremity of all participants. The latency and duration values of the responses were obtained. In patient group, EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), Hospital Anxiety and Depression Scale (HADS), Short Form-36 (SF-36) questionnaire, Leeds Assessment of Neuropathic Symptoms and Signs (LANSSS) and Central Sensitization Inventory (CSI) were applied for the evaluation of symptom severity, mood, quality of life, presence of neuromyalgia and central sensitization, respectively. Comparison of CSP parameters between patients with pSS and healthy volunteers was determined as the primary outcome measure. The secondary outcome measure was the relationship between CSP parameters and ESSPRI, HADS, SF-36, LANSSS and CSI scores.

Results: A total of 36 patients and 36 healthy controls were included in the final analyses. There was no significant difference between the two groups in terms of demographic data. The mean CSP latency was significantly longer in patients with a mean of 78.18 (±5.71) when compared to a control of mean 67.91 (±6.41) (95% CI: 6.89 - 13.55, p<0.001). Mean CSP duration was also significantly shorter in patients with a mean of 33.40 (±6.93) (95% CI: 9.57 - 15.31, p<0.001). There were no significant differences in CSP parameters (latency and duration, respectively) according to patients neuropathic pain or central sensitization profile (p>0.05 for all analyses). There were significant correlations of CSP parameters with ESSPRI dryness (r=0.469, p<0.004; r=0.553, p<0.001; fatique (r=0.42, p=0.011; r=0.505, p=0.002), pain (r=0.428, p=0.009; r=0.57, p<0.001) subscores and mean ESSPRI score (r=0.631, p<0.001; r=0.749, p<0.001). Significant correlations were not found between CSP parameters and SF-36 scores, other than CSP duration and “pain” subscore (r=-0.395, p=0.017). When the other correlations were investigated there were no significant correlations other than CSP duration and the HADS anxiety score (r=0.27, p=0.02).

Conclusion: As an indicator of CSP measurement, SFN is more common in patients with pSS than in the healthy population. The association with important clinical symptoms of the disease course such as dryness, fatigue, pain and anxiety highlights the importance of detecting small fiber neuropathy.

References:
[2] Birnbaum J, Lalji A, Saed A, Baer AN. Biopsy-Proven Small-Fiber Neuropathy highlights the importance of detecting small fiber neuropathy. Figure 2. Clinical symptoms of the disease course such as dryness, fatigue, pain and anxiety. Figure 1. Levels of uGalectin-9 and uSIGLEC-1 between the groups (uGalectin-9 p=0.180 and uSIGLEC-1 p=0.699) (Table 1). Serum and urine levels of all biomarkers were re-tested in 41 of 63 patients (65%) with active SLE after a median treatment of 8 (5-22.5) months. At the time of the second tests, there was a significant decrease in disease activity as measured by SLEDAI [2 (0-4)] compared to the time of the first tests [10 (6-15.5)]. Comparison of uGalectin-9 levels between the serum at the time of active disease and remission showed a very significant decline (p<0.001) as shown in Figure 1. uGalectin-9, sip-10 and uSIGLEC-1 also decreased after treatment; however, the difference was not statistically significant.

Conclusion: sip-10, uIP-10, uGalectin-9 and uSIGLEC-1 are associated with disease activity in SLE. None is able to discriminate active renal from active extrarenal disease. S. Glukhova et al. in 2020. Two glycocalyx markers were elevated in the active disease group; however, the difference was not statistically significant.

2-glycoprotein 1 (IgG-α2-glycoprotein 1) is a protein associated with interferon signature, and considered as potential biomarkers reflecting disease activity in patients with systemic lupus erythematosus (SLE). The role of antiphospholipid antibodies (aPL) not included in the International Classification Criteria for the verification of APS continues to be discussed. Objectives: To determine the clinical significance of IgG antibody for domain 1 (β2-glycoprotein 1 (IgG-α2-glycoprotein 1)) in patients with APS and SLE.

Methods: The study included 187 patients: 52 - with primary APS (PAPS), 12 with probable APS (proAPS), 59 - with SLE-APS, and 64 - with SLE without APS. The comparison group included 49 patients with various rheumatic diseases (rheumatoid arthritis (RA) (n=10), Behcet's disease (BD) (n=15), systemic sclerosis (SSD) (n=12), pregnant women (n=2), with no previous treatment for SLE or APS.

Disclosure of Interests: None declared

polyomaviruses (n=2) and Buergers’ endarteritis (n=1)) and a control group of 100 relatively healthy people. IgG/IgM-antibodies to cardiolipin (aCL) and IgG/IgM-α2-GP1 were determined by ELISA, and IgG-α2-GP1-D1 - by chemiluminescence assay (CMA) in all patients and controls.

**Results:** IgG-α2-GP1-D1 was detected in 37 (71%) of 52 patients with primary APS (PAPS), in 6 (50%) of 12 patients with probable APS (proAPS), in 42 (71%) of 59 patients with SLE+APS, in 17 (26%) of 64 patients with SLE, in 1 (2%) of comparison group and in none of control group. IgG-α2-GP1-D1 was significantly associated with PAPS and SLE+APS compared with patients with SLE (P=0.0002 and P=0.0001, respectively). IgG-α2-GP1-D1 levels were significantly higher in patients with PAPS, proAPS, SLE+APS, and SLE compared to control group (P < 0.00001, 0.03, < 0.000001, and 0.02, respectively). IgG-α2-GP1-D1 levels were significantly higher in patients with PAPS and SLE+APS compared to patients with SLE (P = 0.001 and P = 0.000005, respectively) and patients from the comparison group (P < 0.05). The frequency of IgG-α2-GP1-D1 positivity was associated with both thrombosis and obstetric pathology - the risk of developing clinical manifestations of APS was 9.69 and 4.19 times higher, respectively. A reliable correlation between antibodies to IgG-α2-GP1-D1 and arterial thrombosis can be traced. Obstetric pathology was detected in 32 of 37 women with a history of pregnancy and all were with IgG-α2-GP1-D1, versus 21 of 32 with negative IgG-α2-GP1-D1 (y2=4,49; P=0.04). Eclampsia/preeclampsia and fetopelvic insufficiency in history was in 19 of 37 women with IgG-α2-GP1-D1, versus 7 of 32 with obstetric pathology but no IgG-α2-GP1-D1 (y2=6,35; P=0.01). The incidence of obstetric pathology was significantly associated with the presence of IgG-α2-GP1-D1 compared to women without these antibodies. Isolated IgG-α2-GP1-D1 positivity was reported in 13 (19%) of 70 aPL-negative patients. Obstetric pathology was present in all 6 (100%) women who had pregnancy in their disease course, and thrombosis in 7 (53%) of 13 patients. Sensitivity and specificity of IgG-α2-GP1-D1 depending on APS and its clinical manifestations are presented in the Table 1.

**Table 1. Sensitivity and specificity of IgG-α2-GP1-D1**

</tbody>
</table>

**Conclusion:** The frequency of IgG-α2-GP1-D1 positivity was higher in patients with APS compared to patients with SLE without aPL, comparison group and controls (P < 0.05). In 19% of cases, isolated IgG-α2-GP1-D1 positivity was observed. Positive IgG-α2-GP1-D1 levels were significantly associated with thrombotic complications and with obstetric pathology (y2=8.84; P=0.002 and 2=6.35; P=0.01), Specificity of IgG-α2-GP1-D1 for APS and its clinical manifestations (thrombosis and obstetric pathology) was higher than sensitivity.

**AB0497 IMMUNOLOGICAL DISEASE ACTIVITY PARAMETERS AT CONCEPTION ARE RISK FACTORS FOR PRETERM BIRTH AND LOW BIRTH WEIGHT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

H. Shimada1, R. Wakaiia, S. Nakashimaa, M. Kato1, T. Miyagi1, K. Sughiraa, R. Mino1, M. Mizusakia, T. Kamedaa, H. Dobashi1. 1Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa, Japan

**Background:** Women with systemic lupus erythematosus (SLE) are known to have congenital abnormalities and have a high risk for adverse pregnancy outcomes (APOs) including preterm birth (PB), low birth weight (LBW) (1,2). Many reports revealed that these APOs are strongly associated with negative pregnancy outcomes; PB and LBW. These include low serum C3 and CH50 levels and high anti-dsDNA antibody.

**Objectives:** The purpose of this study was to determine whether disease activity parameters at conception could be a risk factor for PB or LBW among APOs in patients with SLE.

**Methods:** Disease activity parameters including SLEDAI score, LLSDA achievement rate, serum complement levels (C3, C4, CH50), and anti-dsDNA antibody titer were retrospectively collected from medical records. We then collected information related to each APOs (PB and LBW), and analyzed the association with disease activity parameters.

**Results:** The subjects were 60 pregnancies of 45 patients. As for a comprehensive disease activity index at conception, SLEDAI score or the rate of LLSDA achievement became risk factors for PB (both of p<0.01, Table 1), and SLEDAI score was also a risk factor for LBW (P=0.04, Table 1). Analysis of immunological disease activity parameters showed that low C3 or high titer of anti-dsDNA antibody were risk factors for PB (P=0.03 and 0.01, respectively, Table 1). In the logistic regression analysis of PB, the cut-off levels of C3 and anti-dsDNA antibody were 62mg/dl and 5.4 IU/ml, respectively (Figure 1 [1]-A, [1]-D). The risk of PB was significantly higher in the cases with low serum C3 and high anti-dsDNA antibody titer at conception (P=0.02). Similarly, low C3 or CH50 were risk factors for LBW (P=0.02 and 0.03, respectively, Table 1). Logistic regression analysis for LBW showed the cut-off level of C3 as 87 mg/dl, and CH50 as 4.18 IU/ml (Figure 1 [2]-A, [2]-C). Cases with low C3 and low CH50 were at higher risk for LBW (P=0.03).

AB0498

CONCENTRATIONS OF ADVANCED GLYcation END PRODUCTS (AGES) CORRELATE WITH INDEXES OF ACTIVITY AND DAMAGE ACCRUAL IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE).

I. Carrón Barbera1, L. Trigüer2, L. Tio2, C. Pérez2, L. Poliño1, J. Llorente Onaindia2, A. Ribes2, E. Beltrán1, A. Pros2, M. Ciria Recasens1, J. Monfort1, T. C. Salmon Monte1, Hospital del Mar, Rheumatology, Barcelona, Spain; IMIM, Rheumatology, Barcelona, Spain

Background: It has been postulated that AGES could have a relevant role as inducers in the chronic inflammatory pathway present in various diseases; among them, in immune-mediated diseases such as SLE, as well as that its concentration could be related to some parameters of the disease such as activity or accumulated damage, showing studies discrepant results to date.

Objectives: To describe correlations between the concentrations of AGES measured by cutaneous autofluorescence and various parameters related to the disease in a population of SLE patients.

Methods: AGE concentrations were measured by skin autofluorescence (Age Reader Mu Connect from Diagnoptics Technologies BV) in 66 SLE Caucasian patients and correlations with demographic and clinical data were analyzed, after adjusting for age, smoking and corticosteroids as possible confounding factors, according to previous data. Previous validation studies have shown that skin autofluorescence is strongly related to AGE levels in skin biopsies. The indices were analyzed both as quantitative and categorized variables according to previously established categories or to medians/tertiles/quantiles depending on the distribution of the variable in our population.

Results: Table 1 shows some descriptive characteristics of our cohort. There were clinically and statistically significant differences in the values of AGES according to the patient’s SLEDAI and SLICC. Specifically, it was observed that AGES’ values in the population with severe activity according to SLEDAI was 0.61 (95% CI 0.85-2.046; p=0.045) points > than in those in remission (p=0.045); as well as AGES’ values in patients with SLICC ≥1 was 1.23 (95% CI 0.49-1.98; p=0.030) points > than in the group without cumulative damage. In all the models, the values of AGES increased significantly with age, smoking and current treatment with corticosteroids, except for the model including the SLICC variable. Interactions in said model were explored, and it was observed that the concentration of AGES depended on the interaction between the value of SLICC and the intake of corticosteroids, so that differences were only observed between SLICC groups in those who took corticosteroids.

Conclusion: A correlation with elevated values of AGES was observed in those SLE patients with higher scores in the indexes of activity (SLEDAI) and damage accrual (SLICC). The fact that the differences in SLICC are only observed in those patients treated with corticosteroids suggests that, maybe, only the accumulated damage related to taking corticosteroids could be mediated by AGES.

LYMPHOID ORGANIZATION IN LUPUS NEPHRITIS: EVALUATING POSSIBLE AUTO ANTIGENS

V. A. Pacucci1, F. R. Spinelli1, C. Garufi1, F. Cuccarelli1, S. Colafraancesco2, M. Leopizzo1, C. Alessandri1, F. Conti1 on behalf of Lupus Clinic, Sapienza University of Roma, 1 Sapienza University of Roma, Rheumatology Unit; Department of Clinical, Internal, Anaesthesiologic and Cardiovascular Sciences, Roma, Italy; 2 Sapienza University of Roma, Pathology Unit, Department of Radiological, Oncological, Pathological Sciences, Roma, Italy

Background: Lupus nephritis (LN) represent one of the most frequent organ manifestations and one the major cause of morbidity in Systemic Lupus Erythematosus (SLE) patients. Tubulointerstitial infiltrate (TII) represents an independent prognostic factors of renal outcome.

Objectives: The aim of the study was to evaluate the inflammatory infiltrates organization in kidney biopsies obtained from LN patients and to investigate possible autoantigens for in situ immune response.

Methods: Paraffin embedded kidney specimens collected since 2017 from SLE patients who underwent a renal biopsy for diagnostic purpose were re-evaluated. Clinical, laboratory and histological data were collected in a standardized, computerized and electronically filled form, including demographics and past medical history. Disease activity was assessed by using SLEDAI-2K and in remission in therapy was defined as a score 0 of renal item of the SLEDAI. The cellular infiltrate were assessed by hematoxylin-eosin and by immunohistochemistry with a staining of sequential sections for monoclonal antibodies to CD3, CD20, CD21. Staining for detection of LL37, vimentin and citrulline was made. Serological levels of CXCL13 and anti-vimentin antibodies (AVAs) were evaluated in a subgroup of patients.

Results: Eighteen paraffin embedded renal specimens with TII, from LN patients were re-evaluated (F:M = 17:1, median age at biopsy-SD years 37±23; median disease duration at date of biopsy-IQR 3-4 years). A histo-morphologic grading score was performed based on the total count of TI lymphocytes and the presence of ectopic lymphoid structures-ELSs (grade 3-G3) (Figure 1). A correlation was found between G3 structures and the absence of renal remission with conventional immunosuppressive therapy (P=0.0026). Samples with G3 foci showed significantly higher intensity of LL37 (P=0.013) and LL37 co-localization with vimentin (P=0.006) compared to the other lymphocytic infiltrates. No correlation was found among the intensity of vimentin and citrulline and the grade of lymphoid aggregations. A statistically significant inverse correlation between AVAs serum levels and response to therapy was found (P=0.0048). Moreover, the presence of AVAs and CXCL13 were found in patients with G3 structures. To note, two patients underwent anti-CD20 therapy but renal remission was achieved only in the patients displaying G3 structure.

REFERENCES:
CONCLUSION: The study demonstrated that tubule-interstitium involvement is associated with the presence of lymphoid aggregation and poor renal outcome. For the first time we demonstrated that patients with G3 structures had a significant decreased response to immunosuppressant conventional therapies compared to those without ELSs. These results suggest a possible photogenic, prognostic and therapeutic role of lymphocytic aggregates. In addition, LL37, thus NEToSis, could have a possible role in inducing the formation of lymphocytic structures. Moreover, patients with a G3 foci showed high serological levels of AVAs and CXCL13, thus, promoting their possible role as circulating biomarkers of the presence of ELSs.

THE LEVEL OF PERIPHERAL BLOOD LYMPHOCYTE SUBSETS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS WITH RESPIRATORY TRACT INFECTION AND ITS CLINICAL SIGNIFICANCE

J. Q. Zhang1, S. X. Zhang1, J. Qiao1, M. T. Qiu1, X. Li1. The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China

Background: Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disorder. Infections are a common cause of morbidity and mortality in this patient population[1] and at least 50% of patients with SLE are suffered with infections during the course of their disease[2]. Lymphocytes and Natural killer (NK) cells play an important role in the occurrence and development of SLE[3]. In this study, peripheral blood lymphocyte subsets were detected in these patients, providing reference for early diagnosis and treatment of SLE patients with respiratory tract infection.

Objectives: To analyze the detection level and clinical significance of peripheral blood lymphocyte subsets in patients with SLE with respiratory tract infection.

Methods: A total of 333 SLE patients with no recent infection, 95 SLE patients with respiratory tract infection, and 132 healthy individuals matched in age and sex were enrolled in the second Hospital of Shanxi Medical University from July 2014 to December 2016. The characteristics of lymphocyte subsets in the three groups were compared and receiver operating characteristic (ROC) curves were drawn to analyze the predictive value of lymphocyte subsets in SLE patients with respiratory tract infection.

Results: The counts of T, B, CD4+ T, CD8+ T, NK, Th1, Th2, Th17 and Tregs in SLE non-infection group and SLE infection group were [(1094.235 ± 574.495) / (702.781 ± 432.152), t = -7.169, P < 0.001], [(208.338 ± 210.448) / (177.55 ± 170.256), t = -1.306, P = 0.192], [(523.382 ± 303.498) / (304.075 ± 215.497), t = -5.802, P < 0.001]. The absolute number of these subsets in infected SLE patients is significantly lower than that in uninfected patients, which indicates that the low absolute number of these cells can be used as an indicator of high infection risk in SLE patients. CD4 + T lymphocytes and NK cells in patients with respiratory tract infection are significantly lower, and can play a certain predictive value for SLE respiratory tract infection to a certain extent.

Conclusion: The absolute number of these subsets in infected SLE patients is significantly lower than that in uninfected patients, which indicates that the low absolute number of these cells can be used as an indicator of high infection risk in SLE patients. CD4 + T lymphocytes and NK cells in patients with respiratory tract infection are significantly lower, and can play a certain predictive value for SLE respiratory tract infection to a certain extent.

Disclosure of Interests: None declared

Background: Primary Sjögren's syndrome (pSS) is a systemic rheumatic disease that affects several organ systems, most frequently the ocular, oral and musculoskeletal domains. Multidisciplinary care is thus crucial in the optimal management of SS patients.

Objectives: To report the clinical impact of a Multidisciplinary SS Clinic (MSSC) over a 5-year period.

Methods: We prospectively included patients assessed in the MSSC from September 2015 to October 2020. All patients had a full clinical evaluation, including disease-related questionnaires, specialized oral/ocular assessment, salivary gland biopsy (SGB) and ultrasound (SGUS), tear and salivary flow and ocular staining scores. We compared the results of patient-reported outcomes, comprehensive clinical assessments and specialized complementary exams in patients with pSS and other diagnoses.

Results: 445 patients (96% women, mean age 57±14 years) with sicca symptoms underwent complete multidisciplinary evaluation. Patients were most frequently referred from Rheumatology (91%), but also from Stomatology (5%), Ophthalmology (2%), Internal Medicine (1%) and other medical specialties (1%). Most patients were diagnosed with pSS (n=221; 50%), followed by non-Sjögren sicca syndrome (nSSS, n=134; 30%), secondary SS (sSS, n=60; 13%) and other diagnoses (1%).

Conclusion: Multidisciplinary evaluation was crucial in the assessment of patients with similar sicca complaints and in the management of ocular/oral/systemic involvement. Objective measurements and specialized complementary exams greatly contribute to establishing or confirming the diagnosis of pSS.

STRESS AS POTENTIAL PATHOGENIC FACTOR IN PRIMARY SJÖGREN'S SYNDROME.

M. Jaskólska, D. Jaskólski, M. Zichiewicz, A. Višč, Z. Zdrojewski, M. University of Gdańsk, Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Gdańsk, Poland; ³Medical University of Gdańsk, II Department of Orthopedics and Traumatology, Gdańsk, Poland; ²University of Naples Federico II, Medical Faculty, Naples, Italy

Background: Sjögren's Syndrome (SS) is a common autoimmune disorder characterized by infiltration of exocrine glands by autoreactive immune cells that lead to the disease's two most common symptoms — dry eyes and a dry mouth, also known as sicca syndrome. The etiopathogenesis considers the coexistence of genetic predisposition and environmental factors, such as viral infections or sex hormones imbalance.

Objectives: The aim of the study was to determine whether major stressful life events are also risk factors for developing SS.

Methods: We performed a matched case-control study. Cases were patients with an established diagnosis of primary SS (pSS) within the previous five years. Controls were patients with osteoarthritis in whom systemic connective tissue disease has been ruled out. Data on major stressful life events were collected using the modified Holmes-Rahe stress scale. Data were collected for the period of the year before the disease onset.

Results: 100 patients were enrolled in the study (pSS group = 50, control group = 50), mean age was 55.8±10.4 years for pSS and 61.3±9.5 years for control group, in both groups 96% of patients were female. pSS patients had significantly higher on higher Holmes-Rahe stress scale within the preceding 1 year before the onset of disease symptoms than control group (pSS group = 152±63.6 vs control group = 50±54.6; p<0.001). In pSS group 50% of patients reported the subjective impression that the symptoms were caused by stress, while in control group it was 12% (p=0.001). The most frequently mentioned life events in the pSS group were divorce or marital separation, death or change in health of family member and stress related to work.

Conclusion: Patients with pSS are significantly more likely to have had a major stressful life event within the preceding 1 year before the disease onset. The relationship between stress and the occurrence of many diseases and their exacerbations is well documented, especially within autoimmune diseases. Stress is a ubiquitous problem these days, therefore it is of fundamental importance to understand the biological mechanisms underlying its influence on the development of diseases. It is crucial to properly recognize the stressful situation in the patient's life and undertake appropriate interventions in order to prevent health consequences.

CLINICAL AND SEROLOGICAL DIFFERENCES BETWEEN CAUCASIAN AND LATINO AMERICAN SLE PATIENTS IN A MULTIELIETHNIC SPANISH SINGLE-CENTER COHORT

J. Álvarez Troncoso, A. Robles Marhuenda, R. Sorriguieta Torre, C. Soto Añaldead, A. Noblejas Mozó, E. Martínez Robles, C. Sánchez Díaz, J. J. Rios, Hospital Universitario La Paz, Autoimmune Diseases Unit. Internal Medicine Department, Madrid, Spain

Background: Systemic lupus erythematosus (SLE) is a highly heterogeneous systemic autoimmune disease with multifaceted manifestations. There are differences in the clinical manifestations and response to treatment among different ethnic groups.

Objectives: To compare clinical and serological characteristics between Caucasian and Latino American SLE patients in a single-center cohort.

Methods: We performed a retrospective cohort study. We included patients with a confirmed diagnosis of SLE according to the American College of Rheumatology classification criteria. We compared demographic data, clinical manifestations, and laboratory results between Caucasian and Latino American patients.

Results: The study included 100 patients: 50 Caucasian and 50 Latino American. The mean age was 35.2±10.4 years for Caucasian and 34.5±10.2 years for Latino American patients. The most common clinical manifestations were arthritis (72% vs. 64%), mucocutaneous lesions (60% vs. 52%), and musculoskeletal pain (54% vs. 48%). The most common laboratory results were elevated antinuclear antibodies (98% vs. 96%), low complement levels (C3 54% vs. 48%, C4 50% vs. 42%), and hypergammaglobulinemia (76% vs. 72%). The prevalence of specific antibodies (anti-dsDNA, anti-Sm, anti-Ro, anti-La) was similar between groups.

Conclusion: There were no significant differences in clinical and serological characteristics between Caucasian and Latino American SLE patients in this single-center cohort. Further research is needed to fully understand the epidemiological and clinical differences among different ethnic groups.

Disclosure of Interests: None declared

disparities in its manifestations conditioned by sex, age of onset, and serological characteristics. The ethnic origin of the patients may be a conditioning factor for different organic manifestations, immunological markers, and outcomes.

Objectives: Our objective was to evaluate the clinical and serological differences in Caucasian vs. Latin American patients in a multiethnic Spanish single-center SLE cohort.

Methods: Single-centre retrospective observational study from a Spanish Lupus Cohort of adult SLE patients fulfilling the 2019 EULAR/ACR Classification Criteria. Only patients of Caucasian or Latin American origin were included.

Results: The study included 205 patients: 186 (90.7%) Caucasian and 19 (9.3%) Latin American. The mean age at diagnosis was 35.5 years. The female/male ratio was 9:1 in the Caucasian group and 19:1 in the Latin American group (ns).
