Objectives: We aimed to evaluate long term drug survival of IFX in a large cohort of BS patients.

Methods: We reviewed the charts of BS patients who received IFX between 2004 and June 2021 and noted demographic features, reasons for IFX use, IFX duration, and reasons for discontinuation.

Results: 371 patients (290 men, mean age at IFX initiation: 35.5 ± 10 years) received IFX for uveitis (n=164), vascular involvement (n=114), central nervous system (CNS) involvement (n=55), arthritis (n=19), gastrointestinal (GI) involvement (n=15), mucocutaneous involvement (n=10), venous ulcers (n=13), and secondary amyloidoses (n=1). Twenty patients had more than one type of involvement requiring IFX. During a median follow-up of 30 months (IQR: 13-52), 175 (47%) patients were still receiving IFX for a median period of 40 months (IQR: 22-66) while 258 (69%) patients had discontinued IFX after a median follow-up of 19 months (IQR: 8-34).

IFX retention rate was 50% for mucocutaneous involvement, 43% for uveitis, 49% for vascular involvement, 58% for CNS involvement, 37% for arthritis, 53% for GI involvement, and 31% for venous ulcer (Table 1). Reasons for discontinuation were adverse events in 56 (15%), remission in 54 (15%) patients, inefficacy in 45 (12%) (secondary inefficacy in 26 (7%), primary inefficacy in 19 (5%)), and lack of patient compliance in 18 (5%). Other reasons were preparation for surgical operation (n=4), pregnancy (n=4), lack of health insurance (n=4), preferring subcutaneous administration during the pandemic (n=3), due to prison sentence (n=3), willing to get pregnant (n=1), rejecting the treatment (n=1), and death (n=3).

Adverse events (n=56) leading to the cessation of IFX were infusion reactions (n=22), infections (n=7), tuberculosis (n=6), malignancy (n=6), palmar plantar psoriasis (n=5), hepatitis toxicity (n=4), lichen planus (n=1), drug induced lupus (n=1), auricular chondritis (n=1), macrophage activation syndrome (n=1), splenic infarction (n=1) and a decrease in left ventricular ejection fraction (n=1). At the end of the follow-up, 2 patients had died due to lung adenocarcinoma, 1 patient had died due to pneumosinus, 1 due to severe parenchymal neurologic involvement and 1 with pulmonary artery involvement due to massive hemorrhage during IFX treatment. Additionally, 7 patients had died 9, 10 months, 3, 3, 4, 7 and 9 years after IFX discontinuation. The causes of death were severe nervous system involvement in 2 patients, right heart failure due to pulmonary hypertension, lymphangitis, lung adenocarcinoma, sepsis and gastrointestinal bleeding in 1 patient each.

Conclusion: IFX seems to be effective for the treatment of organ and life-threatening manifestations in the majority of the patients. However, drug retention rate was not optimal, mainly due to adverse events, inefficacy and patient non-compliance.

Background: Tocilizumab (TCZ) is the only biologic drug approved in giant cell arteritis (GCA), based in two clinical trials (CT)

CP, most of them are refractory/recurrent GCA (3,4). Although in CT the efficacy of TCZ seems to be similar in patients with newly diagnosed GCA and in patients with refractory/recurrent GCA, in CP it is not documented.

Objectives: To compare in CP, the effectiveness and safety of TCZ in newly diagnosed vs refractory/recurrent GCA
Methods: Multicentre observational study on 471 GCA patients treated with TCZ. GCA was diagnosed by: a) ACR criteria, and/or b) temporal artery biopsy, and/or c) imaging techniques. A comparative study between patients with newly diagnosed GCA (<6 weeks) and those with refractory/recurrent GCA (>6 weeks) (according to GiACTA study definitions) (2), Sustained remission was based on EULAR definitions (5).

Results: The 471 GCA patients were divided into 2 subgroups: a) newly diagnosed GCA (n=91) and b) refractory/recurrent GCA (n=380) (Table 1).

Table 1. Main features of patients with newly diagnosed GCA and refractory/recurrent GCA treated with tocilizumab.

Effectiveness and Safety after TCZ onset

Follow-up, (months), median [IQR] | 15 [6-27]                  | 22 [11-37]                     |

Relevant adverse events, % | 23 (25)                   | 102 (27)                       |

Serious infections, % | 13 (14)                   | 53 (14)                        |

Malignancies per 100 patients-year | 0                           | 12                           |

Malignancies per 100 patients-year | 0                           | 0.5                           |

Relevant adverse events and serious infections are shown (Table 1).

Abbreviations: ACR: American College of Rheumatology; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; GCA: giant cell arteritis; IQR: interquartile range; IV: intravenous; MACEs: major adverse cardiovascular events; NS: non significant; SC: subcutaneous; SD: standard deviation

No significant differences were observed between both groups in sustained remission, although a greater tendency towards sustained remission is observed in newly diagnosed than in refractory/recurrent GCA patients (Figure 1). The decrease in glucocorticoids dose was faster in the first three months in the newly diagnosed GCA group, but thereafter, was similar in both groups, as well as the appearance of relevant adverse events and serious infections.

Figure 1. A) Sustained remission, and B) median prednisone dose required in patients with newly diagnosed GCA and in patients with refractory/recurrent GCA treated with tocilizumab.

Conclusion: The effectiveness and safety of TCZ seems to be similar in patients with newly diagnosed GCA and in patients with refractory/recurrent GCA.

SOUTHEND PRE-TEST PROBABILITY SCORE AND HALO SCORE AS MARKERS FOR DIAGNOSIS AND MONITORING OF GCA: EARLY RESULTS FROM THE PROSPECTIVE HAS-GCA STUDY

A. Sebastian1,2,3, A. Tomelleri2, P. Macchioni2, G. Kinlowski4,6, C. Salvadori4,6, A. Kayani1, M. Tariq1, D. Prieto-Pería4, E. Conticini5, M. Khurshid6, S. Inness10, K. Jackson10, K. Van der Geest10, B. Dasgupta10,11, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom; 2University of Essex Colchester Campus, School of Sport, Rehabilitation and Exercise Science, Colchester, United Kingdom; 3University Hospital Limerick, Rheumatology, Limerick, Ireland; 4San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy; 5Azienda USL - IRCCS - di Reggio Emilia, Rheumatology, Reggio Emilia, Italy; 6University of Modena and Reggio Emilia, Rheumatology, Modena, Italy; 7Marques de Valdecilla University Hospital, VRMI-UPV, Gernika, Bizkaia, Spain; 8University of Siena, Medicine, Surgery and Neurosciences, Siena, Italy; 9University Hospital Dorset, NHS Foundation Trust, Rheumatology, Dorset, United Kingdom; 10University of Essex Colchester Campus, School of Sport, Rehabilitation and Exercise Science, Colchester, United Kingdom; 11University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Ultrasound (US) is recommended as the first line imaging test in patients with suspected Giant Cell Arteritis (GCA). Traditionally, the US halo sign has been used for diagnosis. We have recently described a composite Halo Score that allows to quantify vascular inflammation on US. Prospective studies on response and disease monitoring are lacking.

Objectives: To prospectively assess the role of US in diagnosing and monitoring GCA patients. We completed 12-month data on our current recruitment in a study that has suffered disruption from the pandemic.

Methods: HAS (AUS) GCA (THS) and TSHS (AUS) study. A multicentre study recruiting from referrals of suspected GCA to fast-track clinics. Based on the Southend GCA clinical pre-test probability score (SPTPS), patients were stratified in to low, intermediate and high risk categories. Temporal and auricular US Halo Scores were calculated from the halo thickness and extent in bilateral temporal arteries, parietal and frontal branches (TASH) and auricular arteries (AASH). These scores were summed (TASH x1 plus; AASH x3) to generate a Total Halo Score (THS).

Results: Mann Whitney U test was used to compare baseline features between GCA and controls. Wilcoxon signed rank test was used to evaluate disease features at baseline and at 12 months in GCA patients. Sensitivity (Sn), Specificity (Sp) and ROC curve were calculated, where applicable. P value <0.05 is statistically significant.

Results: 202 patients (71 GCA, 131 controls) have been recruited thus far; 23 completed 12-month follow up assessment; 6 were lost to follow up (4 died, 2 withdrew consent due to pandemic). Demographics, clinical features, and US results are shown (Table 1).
Among GCA patients, 50 had cranial, 5 large-vascular and 16 mixed phenotypes. Diseases were diagnosed by US and additional tests such as PET CT. Jaw claudication (54%) and constitutional symptoms (59%) were the dominant features in GCA patients. Median age was 75 years in GCA (54% females) and 68 years in controls (68% females). GCA and controls were stratified by SPTPS to Low risk (0% vs 45%; Sn-undefined, Sp-98), Intermediate risk (23% vs 37%; Sn-81, Sp-98) and High risk (77% vs 18%; Sn-98, Sp-91). Optimal SPTPS cut-off point was ≥12 (Sn-89, Sp-76).

**Conclusion:** Along with SPTPS, Halo Score successfully discriminates GCA from non GCA mimics and HS is effective in showing 12-month response. This is evidenced by extensive studies in white populations and a significant paucity of data in other ethnic groups. The most frequent causes of death in GCA are cardiovascular disease (CVD) (39%) followed by cerebrovascular disease (CVA) (14%), infection (13%), and malignancy (12%). Overall, the mortality rate is increased in the first two years and is associated with the disease severity, extent, ischemic, and treatment complications, particularly from glucocorticoids. [1, 3-5]

**Objectives:** The aim of this study was to compare the rate of cardiovascular and infectious complications in GCA patients among different ethnicities.

**Methods:** In this retrospective cohort study, we identified patients with biopsy proven GCA based on ICD-10 codes, using the Nationwide Inpatient Sample database (NIS) from 2016 to 2019. We included acute coronary syndrome (ACS), CVA, thoracic ascending aneurysm rupture (TAA), and infection (composite of UTI, sepsis and pneumonia) as our outcomes of interest and compared them between Caucasian, African American (AA), and Hispanic ethnicities. We implemented logistic regression analysis in the univariable and multivariable models. In the multivariable model, we adjusted all outcomes for potential confounders, including age, sex, obesity, hyperlipidemia, congegestive heart failure, peripheral vascular diseases, diabetes, hypertension, renal failure, history of smoking or alcohol abuse, history of other drug abuse, prior history of MI, primary coronary intervention, or coronary artery bypass grafting, coagulopathy, liver disease, chronic pulmonary disease, ischemic cardiomyopathy, Elixhauser comorbidity index, type of insurance, bed size of hospital, history of defibrillator or pacemaker, and long-term use of steroids. The analysis was done using the STATA software, version 17.0 (MP2).

**Results:** We identified 7,750 patients with GCA, of whom 5,710 (74%) were Caucasian, 1,335 (17%) were AA, and 705 (9%) were Hispanic. Our results showed that Hispanics had both a higher prevalence (16.30% vs 9.80% vs 7.95%, p-value = 0.017) and risk for infections (OR: 2.74; 95%-CI 1.4-5.5; p-value = 0.004) when compared to the other racial groups. There was no difference in the risk of ACS among Caucasians (OR: 2.72; 95%-CI 0.6-12.4; p-value = 0.2) and Hispanics (OR: 2.72; 95%-CI 0.4-17.4; p-value = 0.004) when compared to AA population. Similarly, risk of CVA was not different between racial groups (Caucasians: OR: 1.04; 95%-CI 0.6-1.7; p-value = 0.87; Hispanics: OR: 0.8; 95%-CI 0.4-1.7; p-value = 0.567). The prevalence for TAA was only reported in the Caucasian group (0.50%).

**Conclusion:** ACS and CVA are known complications of GCA. There does not appear to be a difference in the risks of these common cardiovascular complications among racial groups. However, there was a significantly higher rate of infections in the Hispanic population. This may be explained by biologic differences in susceptibility and racial disparities in insurance coverage and access to care.

PREDICTIVE VALUE OF OBJECTIVE EXAMINATION OF TA ON POSITIVITY OF TAB IN GIANT CELL ARTERITIS

G. Germani\(^1\), P. Macchioni\(^1\), G. Kinowski\(^1\), A. Cavazza\(^1\), L. Boiardi\(^1\), C. Salvareni\(^2\), \(^3\)ASMN-VRCG Reggio Emilia, Rheumatology, Reggio Emilia, Italy; \(^4\)Università Modena e Reggio, Rheumatology, Modena, Italy

Background: Previous studies have reported the utility of temporal artery examination for the diagnosis of GCA but no data are available on the correlation between clinical examination and the subsequent temporal artery biopsy (TAB) results of the biopsied vessel.

Objectives: Evaluate the predictive value of temporal artery (TA) examination in patients with suspected GCA on the results of TAB of the same vessel.

Methods: 97 pts consecutively seen at our center because of suspected cranial arteritis between 01.01.2015 to 31.12.2021 were enrolled in the study. All patients had complete clinical examination, laboratory investigations (included ESR and CRP determination), clinical examination of the temporal arteries and their frontal and parietal branches for tenderness (P), reduced or absent pulse (R) and thickening (T). All patients underwent arterial ultrasound (US) followed by a TAB of the most US involved frontal branches. The presence of inflammatory infiltrate of the vessel wall or the inflammation of the periadventitial blood vessel wall (Halo) were calculated for every singular objective test and the correspondent OR with 95%CI. Sensitivity, specificity, negative and positive LR were calculated for every singular objective test and the correspondent OR with 95%CI.

Results: Abnormalities.

POS0821

CORONARY ARTERIAL INVOLVEMENT CAN BE OBSERVED IN A SIGNIFICANT SUBSET OF TAKAYASU’S ARTERITIS PATIENTS BY CORONARY CT-ANGIOGRAPHY

K. Abacar\(^1\), A. Cincin\(^2\), F. Baltacioglu\(^3\), Z. Dogan\(^4\), G. Sevik\(^5\), H. Direskeneli\(^6\), F. Alibaz-Oner\(^7\), \(^8\)Marmara University School of Medicine, Department of Radiology, Istanbul, Turkey; \(^9\)Marmara University School of Medicine, Department of Cardiology, Istanbul, Turkey; \(^10\)Marmara University School of Medicine, Department of Radiology, Istanbul, Turkey

Background: Besides the aorta and its main branches, coronary arterial involvement is also seen at a substantial rate in patients with Takayasu’s arteritis (TAK). Computerized tomography (CT)-angiography, as a non-invasive assessment tool, has started to be used instead of conventional angiography in the evaluation of coronary arteries. However, limited data is available for its role in TAK patients.

Objectives: In this study, we aimed to assess the coronary arterial involvement by coronary CT-angiography in TAK patients with or without symptoms and to compare clinical characteristics of patients with or without coronary arterial involvement.

Methods: Patients with TAK (n=49, F:M/49:0, mean age: 42.6±1.9 years) followed in Marmara University Vasculitis Clinic and underwent coronary CT-angiography with or without cardiac symptoms were evaluated retrospectively. Data of four patients who were not suitable for coronary CT-angiography but underwent conventional angiography were also included. CT angiography findings in the coronary arteries were defined as ostial stenosis, stenosis, calcific plaque and aneurysm and patients were categorized into two groups as those with or without coronary artery pathology. Demographic data, cardiac symptoms, clinical findings, BMIs, angiographic Hata and Goel classifications, treatments received for TAK, acute phase reactants and lipid levels were compared.

Results: Coronary artery pathology was detected in 14 patients (28.7%). Only 9 patients had a history of angina and 6 had cardiac symptoms in this group. Calcific plaque was present in 11 (22.5%), coronary artery stenosis in eight (16.3%) and aneurysm, ostial stenosis and occlusion in one patient each (2.0%). RCA was involved in 20.4%, LAD in 26.8%, LMCA in 22.4%, CX in 26.6% and more than one coronary arterial involvement in 26.5% of patients. In patients with coronary artery involvement, age (p=0.02), age at TAK diagnosis (p=0.004) and number of anti-hypertensive drugs (p=0.011) were significantly higher than those without coronary artery involvement. History of angina (p=0.004) and statin use (p=0.001) were also significantly higher in patients with coronary artery abnormalities, whereas HDL levels were significantly lower (p=0.037). No significant differences were observed between the groups when gender, smoking history, diabetes, BMI, ITAS2010 scores, biological therapy use, angiographic classifications, aortic involvement, presence of cardiac symptoms, CRP, ESR, total cholesterol and LDL levels were compared (Table 1).

Table 1. Comparison of patient groups with and without coronary artery involvement (BMI: Body Mass Index, SD: Standard Deviation, ITAS: Indian Takayasu Activity Score, LDD: Low Density Lipoprotein, HDL: High Density Lipoprotein)

Conclusion: Coronary arterial involvement which is an important cause of morbidity and mortality can be detected non-invasively by coronary CT-angiography in up to 1/3 of patients with Takayasu’s arteritis, also in patients without angina and cardiac symptoms. Traditional cardiac risk factors are present more commonly in this group.

Background: Hypertrophic pachymeningitis (HP), characterized by an inflammatory disorder indicating intracranial or spinal thickening of dura mater, is found to develop as a neurological involvement in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Meanwhile, the previous studies focusing on HP in AAV have been reported as a single-institution study, and the analyses were performed in a small number of patients because HP is a rare neurological disorder. Therefore, neither etiological nor clinical characteristics of HP in AAV have been adequately elucidated.

Objectives: This study clarified the characteristics of HP in AAV by analyzing the information of multicenter study in Japan (Japanese collaborative registry of ANCA-associated vasculitis (J-CANVAS)).

Methods: We analyzed the clinical information from 541 Asian patients with AAV enrolled in J-CANVAS. Of them, newly diagnosed and relapsed AAV were included in 448 and 93, respectively. The epidemiological and clinical findings were compared between patients with and without HP. Clinical manifestations related to AAV were evaluated based on the Birmingham Vasculitis Activity Score version 3. To elucidate independent factors in HP development, logistic regression analyses were additionally performed.

Results: Of the total 541 patients (mean age: 71.4±14 years, M:F = 1:1.2), HP was newly diagnosed in 28 (5.2%) including 17 (3.7%) in newly diagnosed AAV and 11 (11.8%) in relapsed AAV. The classification of granulomatosis with polyangiitis (GPA) was significantly higher in patients with HP than those without HP (50% vs. 21%, p = 0.0007). In newly diagnosed AAV, patients with HP significantly had higher GPA classification and higher positivity for PR3-ANCA than those without HP (53% vs. 17%, p = 0.001; 29% vs. 9%, p = 0.015, respectively). Conversely, positivity for MPO-ANCA was significantly higher in patients with HP than those without HP in relapsed AAV (91% vs. 55%, p = 0.025), despite not significantly different in the classification of AAV. Headache and cranial neuropathies were significant neurological symptoms in patients with HP compared to those without HP (82% vs. 6.6%, p < 0.0001; 32% vs. 2.9%, p < 0.0001, respectively). Besides, ear, nose and throat (ENT) and mucous membranes/eyes were significantly higher involvements in patients with HP than in those without HP (54% vs. 26%, p = 0.003; 29% vs. 9%, p = 0.003, respectively). Moreover, higher complications of “conjunctive hearing loss” and “sudden visual loss”, which are included in the categories of ENT and mucous membranes/eyes involvement, respectively, were significantly indicated in patients with HP than those without HP (39% vs. 7.2%, p < 0.0001; 21% vs. 1.2%, p < 0.0001, respectively). Multivariable logistic regression analysis identified that ENT (odds ratio [OR] 1.28, 95% confidence interval [CI] 1.09 to 1.49, p = 0.002) and mucous membranes/eyes involvement (OR 1.37, CI 1.14 to 1.65, p = 0.006), as well as conjunctive hearing loss (OR 4.52, CI 1.56 to 13.05, p = 0.005) and sudden visual loss (OR 1.84, CI 1.12 to 3.00, p = 0.015), were independent related factors in patients with HP.

Conclusion: GPA could be significantly classified in patients with HP. Notably, patients with HP significantly showed higher positivity for PR3-ANCA than those without HP in newly diagnosed AAV. Furthermore, sudden visual loss and conjunctive hearing loss might be implicated in HP development.

KO6 IN ANCA-ASSOCIATED VASCULITIS PATIENTS WITH AND WITHOUTILD: A MACHINE LEARNING APPROACH

E. Conticini, M. d’Allesandri, L. Bergantiini, D. Castilho, P. Faisetti, P. Carmeli, E. Bargagli, L. Cantarini, L. Frediani on behalf of Sienna Vasculitis Study Group. 1. University of Siena, Rheumatology Unit, Siena, Italy; 2. University of Siena, Respiratory Diseases and Lung Transplantation Unit, Siena, Italy; 3. Hospital de la Santa Creu i Sant Pau, Respiratory Unit, Barcelona, Spain

Background: ANCA-associated vasculitis (AAV) are small vessel vasculitis which may variously affect upper and lower respiratory tract. Patients with microscopic polyangiitis (MPA) and, less commonly, granulomatosis with polyangiitis (GPA), especially those who are ANCA-MPO-positive, may suffer from interstitial lung disease (ILD), which is associated with high morbidity and mortality as it is often underdiagnosed and responds poorly to conventional treatments.

Objectives: In this study, we aimed to assess whether Krebs von den Lungen-6 (KL-6), a marker of fibrotic ILD, may be useful for distinguishing AAV patients with ILD from those without ILD, and whether its changes over time are correlated with disease activity.

Methods: We enrolled all consecutive patients evaluated in the period December 2020 - November 2021. Inclusion criteria were a diagnosis of GPA or MPA, active disease, and eligibility for Rituximab treatment according to EULAR recommendations. All patients underwent concomitant rheumatological and pneumological evaluation, lung function tests, routine blood tests, autoimmunity evaluation and KL-6 assay. Current and previous treatments, Birmingham vasculitis score (BVAS) and vasculitis damage index were also recorded.

Results: A total of 13 patients (Table 1) were enrolled. One was excluded due to a concomitant diagnosis of lung cancer. Higher serum KL-6 were in AAV-ILD compared with those without ILD (972.8±398.5 vs. 305.4±93.9, p = 0.0040). Under the Receiver Operating Characteristics curve showed 100% of the diagnostic performance of KL-6 for identifying the ILD involvement (accuracy 91.7%) and the best cutoff value of 388 U/mL (Sensitivity 100% and specificity 87.5%). The decision-tree model showed a 33% improvement in class purity using a cutoff of 388 U/mL. To distinguish AAV patients with and without ILD (Figure 1). Stratifying AAV patients as GPA and with and without ILD considering T0 and T1 KL-6, the model obtained an improvement of 40% for classifying GPA with disease activity.

Figure 1. ROC curve and decision tree model

Conclusion: Our multicentre study demonstrated KL-6 as a reliable, non-invasive and easy-to-perform marker of ILD in AAV patients and its helpfulness for disease activity assessment. Changes in serum concentrations of KL-6 over time could be useful for monitoring AAV patients. Further study of KL-6 as a marker of response to therapy during long-term follow-up would also be worthwhile.

SAFETY AND EFFICIACY OF THE INTENSIFIED B CELL DEPLETION INDUCTION THERAPY FOR PATIENTS WITH ANCA-ASSOCIATED VASCULITIS AND SEVERE RENAL INJURY: A CONTROLLED STUDY

D. Roccatello1, S. Sciascia1, S. Murgia1, G. Quattrociocchi1, M. Ferro1, E. De Simone1, C. Naretto1, A. Barreca2, D. Rossi1, R. Fenoglio1

1University Center of Excellence on Nephrological, Rheumatologic and Rare Diseases (ERK-net, ERN-Reconnect and RITA-ERN Member) with Nephrology and Dialysis Unit and Center of Immuno-Rheumatology and Rare Diseases (CMID), San Giovanni Bosco Hub Hospital, and Department of Clinical and Biological Sciences of the University of Turin, Torino, Italy; 2Città Della Salute e Della Scienza, Pathology Division, Torino, Italy

Background: Rituximab (RTX), an anti-CD20 monoclonal antibody, has shown to be an effective induction treatment for small-vessel vasculitides associated with antineutrophil cytoplasm antibodies (AAV) in both newly diagnosed and relapsing patients. However, the role of RTX in the management of the most severe cases of AAV remains to be fully elucidated.

Objectives: to assess both safety and efficacy of an intensified B-cell depletion therapy (IBCDT) protocol, including RTX, cyclophosphamide (CYC), and methyprednisolone pulses without additional maintenance immunosuppressive therapy compared to conventional therapy regimen based on oral CYC and steroids plus AZA in the management of the most severe cases of AAV. Additionally, this avoids the need of prolonged maintenance therapy for long, and limits the exposure to CYC with consequent reduced toxicity and drug-related side effect rates.

CLINICAL CHARACTERISTICS AND TREATMENT MANAGEMENT OF NON-INFECTIONOUS SCLERITIS WITH CORTICOSTEROID SPARING THERAPY. A RETROSPECTIVE STUDY FROM A TERTIARY EYE CARE CENTER.

J. Toutain1, M. A. Gargouri1, I. Chaza2, S. Fares1, I. Cocchera1, E. Gabison1, C. Titah1, G. Clavel Refregiers2, 1Foundation Adolphe de Rothschild Hospital, Ophthalmology Department, Paris, France; 2Foundation Adolphe de Rothschild Hospital, Internal Medicine, Paris, France

Background: Non-infectious scleritis refers to a rare and sight-threatening scle- ral inflammation. An association with an underlying systemic disease is noted in 30% to 40% of cases. Their management may require the use of nonsteroidal anti-inflammatory drugs, oral corticosteroids, and sometimes steroid-sparing immunosuppressive agents. Because of the low incidence and prevalence of scleritis, treatment guidelines are currently not available.

Objectives: We analyzed in a retrospective observational study patients with scleritis referred to the Foundation Rothschild Hospital (Paris) from March 2011 to June 2021.

Methods: Characteristics, visual outcomes, ocular complications, associations with systemic diseases and efficacy of treatment were assessed in patients with non-infectious scleritis who needed steroid-sparing immunosuppressive agents.

Results: Among 731 patients diagnosed with scleritis, 54 patients (71 eyes, 7%) were treated by steroid-sparing immunosuppressive agents. Mean follow up was 119.9 ± 84.5 weeks. Mean age was 48.4 years ± 18.3, and 31 patients (57%) were female. Scleritis was anterior in 51 eyes (72%), including 25 (35%) with diffuse scleritis, 24 (34%) with nodular scleritis and 2 (3%) with necrotizing scleritis. Scleri- tis was posterior in 20 eyes (38%), bilateral involvement was noted in 17 patients (32%). Ocular complications were observed in 52 eyes (73%): scleral thinning in 25 eyes (35%), anterior uveitis in 24 eyes (34%), loss of vision in 20 eyes (38%), posterior segment ocular complications in 18 eyes (25%), ocular hypertension in 17 eyes (24%) and corneal involvement in 16 eyes (23%). An underlying systemic disease was identified in 28 patients (52%), and scleritis was the first manifesta- tion of the systemic disease in 17 of 28 patients. Rheumatoid arthritis was the most frequently identified disease (n=12), followed by granulomatosis with polyangiitis (n=8) and relapsing polychondritis (n=4). All patients received at least...
one immunosuppressive agent. Corticosteroid sparing with a daily dose ≤ 5 mg of prednisone was achieved in 85% of patients. Conventional immunosuppressive agents were used as the first steroid-sparing agent in 38 patients (70%) (methotrexate n=33, azathioprine n=4, mycophenolate mofetil (MMF) n=1) and as second steroid-sparing agent in 1 patient (MMF). This treatment led to control scleral inflammation in 23 (59%) patients after a mean delay of 10.0 ± 6.0 weeks. Biologic therapy was used in 33 (61%) patients (TNF α inhibitor n=17, IL-6R inhibitor n=7, anti-CD20 n=8), and as the first steroid-sparing agent in 16 (30%) (TNF α inhibitor n=4, IL-6R inhibitor n=4, anti-CD20 n=8). This treatment led to control scleral inflammation after a mean delay of 4.9 ± 3.7 weeks in 29 patients (87%).

**Conclusion:** Scleritis is a severe ocular inflammatory disease that requires repeated and thorough ophthalmologic and general evaluations given the high frequency of complications and the possibility of an underlying systemic disease. This study reports real-life experience in management of non-infectious scleritis. Biological therapies seemed to be associated with a better outcome and a quicker response than conventional immunosuppressive agents. Further studies are warranted to develop specific guidelines

**CIRCULAR RNA EXPRESSION PROFILES AND IDENTIFICATION OF HSA. CIRC_0028381 AS A POTENTIAL BIOMARKER OF ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS**

Y. Liu1, L. Jiang1, X. Zhang1, Zhongshan Hospital, Fudan University, Rheumatology, Shanghai, China

**Background:** Growing evidence indicated that dysregulated circRNAs play a vital role in autoimmune diseases. However, their role in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) has never been illustrated.

**Objectives:** This study aims to determine the expression profiles of circRNAs in plasma of AAV patients and explore the potential of circRNA as biomarker of AAV.

**Methods:** RNA-sequencing (RNA-seq) was performed to identify the circRNAs and mRNAs expression profiles in plasma from 5 AAV patients and 5 healthy controls (HCs). Hsa_circ_0028381, one of the four candidate circRNAs were validated by quantitative reverse-transcription (qRT)-PCR in a validation cohort of 51 AAV patients and 30 HCs and was confirmed to be significantly upregulated. And it was further verified in other connective tissue diseases (CTDs) by qRT-PCR. The receiver operating characteristic (ROC) curve analysis was performed to assess the diagnostic value.

**Results:** RNA expression profiles revealed that 143 circRNAs and 304 mRNAs were aberrantly expressed, among which, 62 circRNAs were upregulated and 81 circRNAs were downregulated in AAV patients compared to HCs. The result of qRT-PCR verification suggested that hsa_circ_0028381 was significantly increased in plasma from AAV patients compared to that in HCs and CTDs. The receiver operating characteristic (ROC) curve analysis showed has_circ_0028381 had a good diagnostic value to distinguish AAV patients from controls (HCs and other CTDs) with area under the curve (AUC) of 0.81. In addition, has_circ_0028381 was associated with renal involvement. Most importantly, increased baseline level of has_circ_0028381 had a predictive value for renal progression to end-stage renal disease (ESRD).

**Conclusion:** RNA-seq revealed that circRNAs were aberrantly expressed in plasma of AAV patients. Hsa_circ_0028381 might function as a potential biomarker for AAV diagnosis and renal prognosis.

**VASCULITIDES AS MEDICATION-INDUCED ADVERSE EVENTS BASED ON A NATIONAL DATABASE: REPORTING SYSTEM**

A. Rodriguez-Pla1, Mayo Clinic, Rheumatology, Scottsdale, United States of America

**Background:** Vasculitides have been reported as adverse events (AEs) related to a wide variety of medications.

**Objectives:** For the present study, we aimed to analyze the vasculitides reported to a national AEs spontaneous reporting system from October 2012 through September 2021.

**Methods:** All spontaneous reports of vasculitides related to any medications from October 1st, 2012, to September 30th, 2021, were retrieved from the Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS) database. We performed a descriptive analysis of demographics, medications, and type of vasculitis based on 25 Medical Dictionary for Regulatory Activities (MedDRA) preferred term (PT) codes. Medications identified as the primary suspect in individual case reports were analyzed. ICSRs were retrieved by the product active ingredient. RStudio v1.4.1717 was used for general data analysis and the R package openEBGM v0.8.3 was used for the calculation of the Empirical Bayes Geometric Mean (EBGM) as the disproportionality score with its 90% two-sided credibility interval, frequently used in safety signal detection models. Drug-event combinations with an EBGM 5% lower limit credibility interval ≥ 2 were considered significant. An EBGM score of 2 indicates that the drug had at least 2 times as many reports for the AE as expected.

**Results:** During the study period, we retrieved 10,404 ICSRs reporting 10,931 AEs of vasculitis associated with a medicinal product as the primary suspect for that AE. The patient’s mean age was 56.5 years, and 61% of them were female. Of the 25 PTs selected, the generic term “Vasculitis” was the most frequently reported AE (29.1%), followed by “Hypersensitivity vasculitis” (14.9%), “Polyangiitis rheumalitis” (7.7%), “Anti-neutrophil cytoplasmatic antibody-positive vasculitis” (ANCA-associated vasculitis) (6.2%), and “Cutaneous vasculitis” (5.4%). Of the total ICSRs with vasculitis AEs, 90% were expected because they reported serious, unexpected AEs.

Eighty drug-event combinations were disproportionately reported. Of those, the strongest association was observed for amlotuzumab and Goodpasture’s syndrome (anti-glomerular basement membrane disease), followed by minocycline and polyarteritis nodosa, penicillamine and Kawasaki’s disease (KD), then ribavirin and cyclosporine, eumicro and microscopic polyangiitis, and so on.

Many medications were associated with more than one AE, such as infliximab with Takayasu’s arteritis (TAK), Behcet’s syndrome (BS) and Henoch-Schönlein purpura (iGA vasculitis); adalimumab with BS and TAK; hydralazine with ANCA-associated vasculitis and renal vasculitis; and rituximab with granulomatosis with polyangiitis (GPA) and cryoglobulinemia.

**Conclusion:** Many different vasculitides were reported as AEs in the national database. Some of the medications were associated with the diseases they treat, which raises concern for possible confounding by indication. In other cases, the events were already known as adverse reactions, as for example amlotuzumab and Goodpasture’s syndrome or montelukast and eosinophilic granulomatosis with polyangiitis. In other cases, no label or publication references were found, as for pulivamub and KD. These latter cases may raise a concern for potential safety signals that should be investigated. The improved understanding of the mechanism of action of drugs associated with some of these AEs may help to elucidate the pathogenesis of vasculitides.

Background: Ocular and Neurobehçet's Disease (NBD) are the most severe manifestations of Behçet's disease (1-4). NBD can be classified as a) primary neural parenchymal lesions, also known as parenchymal NBD (p-NBD) or b) secondary to vascular involvement or non-parenchymal NBD (np-NBD) (4). Response to biological therapy (BT) in these two refractory subtypes of NBD is unknown.

Objectives: To assess efficacy and safety of BT in refractory subtypes of NBD.

Methods: Open-label multicenter study of refractory NBD from 21 different referral National Hospitals. NBD diagnosis was based on the International Consensus Recommendation criteria (4). Efficacy was determined by complete or partial response and no-response. Complete, partial or no response was defined according to the resolution of the neurological syndrome (signs and/or symptoms) after the BT onset.

Results: We studied 41 patients (21 women/20 men; mean age: 40.6±10.8 years). NBD was classified as p-NBD (n=33, 80.5%) and np-NBD (n=17, 41.5%). There were no significant differences in baseline general features and in neurological clinical response in both subgroups (Table 1 and Figure 1). The first BT used in p-NBD were Infliximab (IFX) (n=15), Adalimumab (ADA) (n=11), Golimumab (GLM) (n=3), Tocilizumab (TCZ) (n=2) and Etanercept (ETN) (n=2) and in np-NBD were IFX (n=9), ADA (n=6), TCZ (n=1) and ETN (n=1).

Figure 1. Response to biological therapy according to NBD subtypes.

After an overall mean follow-up of 57.5±50.9 months BT was switched in 22 patients due to ineffectiveness (n=16) or Adverse Effects (AE) (n=6) and in 4 cases was definitively discontinued because of complete prolonged remission (n=3) or AE (n=1). AE were observed in 7 (17.1%) patients. Severe AE were observed in 2 cases, one due to demyelinating disease and the other due to pulmonary tuberculosis, both in patients undergoing IFX therapy. The other 6 AE were infusion reaction to IFX (n=1), IFX-induced psoriasis (n=1), IFX-induced acniform eruption (n=1), infusion reaction to TCZ (n=1), intolerance to IFX and recurrent mild infections (n=1) and erosive lichen planus and bullous impetigo (n=1).

Conclusion: In our series, BT seems equally effective and safe in both refractory p-NBD and np-NBD.
Conclusion: We report on the detection of PTX3-, BPI- and OLM4-ANCA in addition to MPO- and PR3-ANCA in EGPA. OLM4-ANCA has been reported in 2 patients with non-vasculitic inflammatory symptoms previously [5]. Herein, detection of OLM4-ANCA in EGPA is reported for the first time. Our study shows that the presence of ANCA with various specificities other than MPO and PR3 contribute to a higher prevalence of ANCA in EGPA. Moreover, clinical manifestations differ between ANCA-negative EGPA and ANCA-positive EGPA, and between patients with different ANCA-specificities.

POS0830 SYSTEMATIC LITERATURE REVIEW INFORMING THE 2022 UPDATE OF THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF ANCA-ASSOCIATED VASCULITIS: FOCUS ON TREATMENT STRATEGIES

J. Schirmer1, B. Sanchez-Alamo2, S. Monti3, B. Hellmich4, D. Jayne5, 1University Medical Center Schleswig-Holstein, Clinic for Internal Medicine I, Section for Rheumatology, Kiel, Germany; 2Lund University Skåne University Hospital, Nephrology, Lund, Sweden; 3University of Pavia, Fondazione IRCCS Policlinico S. Matteo, Rheumatology, Pavia, Italy; 4University of Tubingen, Medius Kliniken, Internal Medicine, Rheumatology and Immunology, Kirchheim-Teck, Germany; 5University of Cambridge, Addenbrooke’s Hospital, Department of Medicine, Cambridge, United Kingdom

Background: The 2008 and 2016 European Association of Associations for Rheumatology (EULAR) recommendations for the management of ANCA-associated vasculitides (AAV)1,2 have supported clinicians with comprehensive recommendations for the treatment of patients with AAV in daily practice. During the past 5 years, the publication of several high-impact randomized-controlled studies have further improved the standard of care of AAV.

Objectives: The aim of this systematic review was to collect evidence supporting the 2022 update the AAV management recommendations.

Methods: The recommendations were developed based on an evidence-based approach as outlined in the 2014 EULAR standardized operating procedures (SOP)3. Areas of interest were adopted from the 2016 recommendations and updated by identifying additional topics through a Delphi process. Key questions were framed in the PICO (Population, Intervention, Comparator, Outcome) format and a search strategy consisting of keywords identifying treatment-related topics of interest was created based on the PICO questions. Aspects of drug treatment and other therapeutic interventions in AAV were included in the search, with a focus on remission induction, maintenance treatment and steroid sparing protocols. Outcomes such as survival, remission/relapses, infectious complications and malignancies were also covered. PubMed (Medline), Embase and the Cochrane Library databases were searched for articles providing data on the search questions. Abstracts of the annual meetings of EULAR, ACR, ERA-EDTA, ASN and the Vasculitis and ANCA Workshops were also screened, but restricted to randomized controlled clinical trials (RCTs). After duplication publications were sorted by title and abstract first. There was full text review for articles eligible after title/abstract screening. The data were extracted from included articles and grouped according to the PICO questions. Data extraction results were collected in evidence tables.

The SLR was still ongoing at the time this abstract has been written and results of the SLR will be presented at the meeting.

Acknowledgements: The project is funded by EULAR.

POS0831 IGA VASCULITIS IN ADULTS, PEDIATRICS AND NON-VASCULITIC IGA NEPHROTYPH

S. Levinson1, V. Gottlieb2, Y. Kraus1, I. Novostavskii1, S. Brikman1, A. Fawaz2, M. Aghbariyya3, Y. Butbul4, A. Balbir-Gurman1, R. Mader1, A. Bieber1, 1Emek Medical Center, Rheumatology, Afula, Israel; 2Emek Medical Center, Pediatric Rheumatology Service, Afula, Israel; 3Emek Medical Center, Pathology, Afula, Israel; 4The Ruth Rappaport Children's Hospital, Pediatric Rheumatology Service, Haifa, Israel; 5Rambam Health Care Campus, Rheumatology, Haifa, Israel

Background: Iga vasculitis (IgAV) has been extensively studied in children, while its natural history remains poorly studied in adults. Sparse data comparing childhood and adult-onset disease has shown significant differences in their clinical presentation, especially in the severity of renal involvement, which accounts for the major long-term morbidity. IgAV shares similar renal histologic features with IgA nephropathy (IgAN), while clinically IgAN is a chronic kidney disease which may lead to end stage renal disease and dialysis. The extent of kidney injury among adults with IgAV is still a matter of uncertainty.

Objectives: We aimed to evaluate clinical manifestations, laboratory data, treatment patterns and long-term outcomes of pediatric and adult-onset IgAV in comparison to IgAN.

Methods: This retrospective collaborative study examined medical records of adults and children with IgAV and IgAN adult patients admitted to rheumatology clinic and in hospital pediatric departments in a 13-year period (2007-2019). Diagnosis of adults with IgAV relies on the Ankara criteria and was confirmed by a consistent skin biopsy with positive IgA staining by immunofluorescence. Children with IgAV were included in our study on a clinical basis. All IgAN patients had a kidney biopsy proven disease. We analyzed and compared frequencies of clinical manifestations, laboratory findings, treatment regimens and long-term outcomes at one year follow-up. Finally, we assessed long term outcomes, such as time to dialysis and all-cause mortality, till the end of the follow-up time.

The Cochrane revised tool for assessing risk of bias for RCTs (RoBu), ROBINS-I for observational studies and AMSTAR II for meta-analyses were used for bias assessment. Evidence was categorized based on the GRADE system as per EULAR SOP. Results: Based on the results of the Delphi, 11 topics related to clinical presentations were identified that were transformed into PICO questions (Table 1). Other items that received lower scores were added in the format of subquestions. Based on these research questions, search strings for the SLR were created.

Table 1. Key topics of interest for treatment strategies identified in the Delphi exercise grouped according to the PICO format

Disclosure of Interests: Xander Bicknell: None declared, Sara Monti: None declared, Bernhard Hellmich Speakers bureau: Abbvie, BMS, Chugai, GSK, MSD, Novartis, Pfizer, Roche, Vifor; Consultant of: Boehringer, BMS, Chugai, GSK, InfraRx, Novartis, Roche, Vifor, David Jayne Speakers bureau: Vifor; Consultant of: Astra-Zeneca, Boehringer, BMS, Chemo-centryx, Chugai, GSK, Novartis, Roche

DOI: 10.1136/annrheumdis-2022-eular.3156
Results: A total of 60 adult IgAV, 60 pediatric IgAV and 45 IgAN patients were included in our study. There were significantly more males in the IgAN group compared to the adult and pediatric IgAV groups (77.8%, 41.7% and 55% respectively, p<0.01). Adult IgAV patients were significantly older than IgAN patients (53.1±17.4 years vs. 45.1±15.7 years, p=0.02) and had significantly higher rates of diabetes (43.3% vs. 24.4%, p=0.05) and ischemic heart disease (18.3% vs. 4.4%, p=0.03). The pediatric IgAV group had a substantially higher rate of previous infection compared to the adult IgAV group (44.8% vs. 20%, p=0.02). At one year follow-up, IgAN patients had higher levels of serum creatinine compared to the adult IgAV group (2.002 vs. 1.100, p<0.01). Data observed until the end of the follow-up time showed no difference in time to dialysis (IgAV adults: 9.8-12.4 years, IgAN: 5.0-6.6 years, p=.41). Nevertheless, IgAV adult patients had significantly shorter survival time (5.5 years, 95% CI: 4.8-6.2 years) than IgAN patients (7.0 years, 95% CI: 6.6-7.5 years, p<.01).

Conclusion: This retrospective study demonstrates that IgAV in adults presents substantial clinical manifestations, including high risk of progression to persistent renal impairment and poses higher mortality rate in comparison with pediatric-onset disease and IgAN.

MORTALITY TRENDS IN ANCA-ASSOCIATED VASCULITIS (AAVs): DATA FROM A CONTEMPORARY, MULTICENTER ANCA REGISTRY

C. Koutsianas1, A. Panagiotopoulos2, K. Thomas2, A. Chalkia2, A. Lazarini3, N. Kapasali4, S. Fiouda3, E. Argyriou2, K. Boki1, D. Petras2, D. Boumpas2, D. Vassilopoulos1. 12nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens, School of Medicine, Hippokration General Hospital, Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, Athens, Greece; 24th Department of Medicine, National and Kapodistrian University of Athens, School of Medicine, Attikon General Hospital, Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, Athens, Greece; 3Hippokration General Hospital, Nephrology Department, Athens, Greece; 4Asclepeion General Hospital, Rheumatology Department, Athens, Greece; 5Sismanogleio General Hospital, Rheumatology Department, Athens, Greece

Background: AAVs are a group of rheumatic diseases with excess morbidity and mortality (~3-fold higher compared to the general population). Long-term studies looking at mortality trends in contemporary patient cohorts are limited.

Objective: To investigate the overall long-term survival and all-cause mortality in a contemporary AAV patient cohort.

Methods: Multicenter study of patients registered and prospectively followed in the Greek ANCA Registry.

Results: Data for 165 patients (98.98 patient-years of follow up) with a diagnosis of AAV (GPA n=85, 58%, MPA n=54, 33%, EGPA n=16, 9%) were analyzed (January 1, 1998 - January 10, 2022). 53% of patients were female, with a mean age of 65 (±16.4) years; the majority (97%) had generalized disease and were ANCA positive (76%). The mean follow-up since diagnosis was 5.9 (±5.1) years. At the end of follow-up, the overall mortality rate was 20% (33/165), whereas the cumulative mortality rates at 5 and 10 years were 24% and 26% respectively. Overall cumulative survival at 5 years was worse in patients with MPA (57%) compared to GPA (81%) and EGPA (92%), (p<0.001). There was no difference in long-term survival among those treated with different induction regimens including cyclophosphamide (CYC, n of deaths=24/83, 28.9%), rituximab (RTX, n=4/40, 10%) or the CYC+RTX combination (n=3/16, 18.7%). Furthermore, there was no difference in survival between relapsing (≥1 relapses) and non-relapsing (n=76) patients (Figure 1). Cumulative survival was worse in patients who initially presented with lung (66% vs. 90% at 5 years, p=0.007), kidney (56% vs. 96% at 5 years, p<0.001) and simultaneous lung and kidney (39% vs. 93% at 5 years, p<0.001) involvement. Among the 33 registered deaths, the most frequent causes were infections (52%), followed by cardiovascular events (24%), disease flares (14%) and malignancies (10%).

Conclusion: In a contemporary multi-center AAV cohort, the cumulative mortality rates at 5 and 10 years were 24% and 26% respectively. Overall survival was worse in patients with MPA as well as those with combined lung and kidney involvement at baseline while there were no survival differences according to the initial induction regimen. Infection was the most common cause of death. These findings emphasize the unmet needs for better, less toxic therapies.

POSO833 DIFFERENCES BETWEEN AVACOPAN AND PREDNISONE FOR THE TREATMENT OF ANCA-ASSOCIATED VASCULITIS AT DIFFERENT THRESHOLDS OF GLUCOCORTICOID TOXICITY

N. Patel1, Y. Zhang2, D. Jayne3, P. A. Merkel4, H. Yue5, P. Bekker6, J. H. Stone2. 1Massachusetts General Hospital, Division of Rheumatology, Allergy and Immunology, Boston, United States of America; 2Massachusetts General Hospital, Division of Rheumatology, Allergy and Immunology, Boston, United States of America; 3University of Cambridge, Department of Medicine, Cambridge, United Kingdom; 4University of Pennsylvania, Division of Rheumatology, Philadelphia, United States of America; 5Chemicentrix, Clinical Development, San Carlos, United States of America; 6Chemicentrix, Department of Medical and Clinical Affairs, San Carlos, United States of America

Background: Treatment with glucocorticoids (GCs) for ANCA-associated vasculitis (AAV) is associated with substantial toxicity. The Glucocorticoid Toxicity Index (GTI) was developed to measure change in GC toxicity over time.1 Data from the composite GTI domains provide both an Aggregate Improvement Score (AIS) and a Cumulative Worsening Score (CWS) of GC toxicity, permitting the
instrument to compare both improvement and worsening of GC toxicity across treatment groups. The GTI was a pre-specified secondary outcome in ADVOCATE, a randomized, double-blind, placebo-controlled trial in patients with AAV that aimed to replace a GC taper with avacopan, a complement C5a receptor inhibitor. Patients were randomized to either avacopan or a prednisone taper on a background of either cyclophosphamide or rituximab. In ADVOCATE, the median GC exposure was 400 mg vs. 2939 mg in the avacopan and prednisone groups, respectively, which is an 86% median reduction in GC exposure from all sources. Remission rates were comparable in the two groups at 26 weeks (72.3% vs. 70.1%, respectively), and avacopan was superior at 52 weeks (sustained remission in 65.7% vs. 54.9%).

Objectives: To compare GC toxicity between the treatment groups at three different thresholds of GC toxicity, beginning with the minimum detectable difference (MDD) of the GTI.

Methods: The MDD for the GTI (10 points) was calculated in the initial validation phase of the instrument. Thus, any GTI score >10 points may be considered to represent a true change in GC toxicity. We compared the two groups at GTI thresholds of 10, 20, and 30 points for both the CWS and AIS. The CWS comprises a total of all GC-related toxicities that have occurred in the GTI between baseline and 26 weeks (time of primary outcome). The AIS, in contrast, allows toxicities to be added if they are new or subtracted if they improve. Higher CWS and AIS values indicate greater severity of GC toxicity. The two scores together capture the nuances of longitudinal GC toxicity across multiple domains. We compared the percentages of those in the two treatment groups who exceeded GTI threshold values of 10, 20, and 30 points in the CWS or AIS.

Results: The percentages of patients exceeding the specified AIS thresholds differentiated the avacopan group from the prednisone group (48.2% vs. 60.4%, respectively, at 10-point threshold; p=0.02; 29.5% vs. 45.1% at the 20-point threshold, p=0.003; and 18.1% vs. 33.5% at the 30-point threshold, p=0.001) (Table 1). The CWS differentiated avacopan from prednisone at the 20- and 30-point thresholds (57.8% vs 73.2%, respectively, at 20 points, p=0.002; 41.0% vs 55.5% at 30 points, p=0.007).

AIS, Aggregate Improvement Score; CWS, Cumulative Worsening Score; GTI, Glucocorticoid Toxicity Index

Conclusion: Among patients with AAV, treatment with avacopan was associated with lower GC toxicity across multiple GTI thresholds compared to treatment with prednisone, consistent with the substantial reduction in total GC exposure associated with avacopan. The GTI scores differentiated the two treatment groups effectively through a composite of GC toxicity domains.

patients were identified as those with at least two qualifying claims on different dates of service, coded with a GPA or MPA ICD-10-CM code, and no claim coded with GPA or MPA in the 12 months prior to their first claim. Established patients required 12 months continuous enrollment in the year of their establishment of 12 months continuous enrollment in the year prior to their established status. Relapses for incident patients were identified during the 7 to 12 months after the index date for newly diagnosed patients to avoid mischaracterizing claims around the time of the initial diagnosis as relapses and over a 12-month period for the established patients. Relapse was defined based on specific inpatient and outpatient claims with a GPA or MPA diagnosis code or claims billed with one or more of at least three minor vasculitis signs or symptoms followed by a claim within 30 days for plasmapheresis or cyclophosphamide or glucocorticoids (>20 mg prednisolone equivalent) or ≥2 rituximab claims within 30 days of each other. Relapse had to occur 30 days after the previous event and 6 months after index date for incident patients.

Results: 542 (GPA) and 83 (MPA) commercially insured newly diagnosed patients with 12 months eligibility following their index date and 1,748 (GPA) and 184 (MPA) commercially insured established patients were identified. 15.5% (GPA) and 15.7% (MPA) newly diagnosed patients relapsed during months 7-12 after diagnosis and 27.8% (GPA) and 29.3% (MPA) established patients relapsed over a 12-month period. 2,397 (GPA) and 655 (MPA) Medicare FFS newly diagnosed patients with 12 months of eligibility following their index date and 5,955 (GPA) and 833 (MPA) Medicare FFS established patients were identified. 19.5% (GPA) and 27.2% (MPA) newly diagnosed patients relapsed during months 7-12 after diagnosis and 33.5% (GPA) and 40.2% (MPA) established patients relapsed over a 12-month period.

Conclusion: Using administrative healthcare claims, we observed relapse rates after GPA and MPA diagnosis ranging between 15.5-27.2% in months 7-12 after diagnosis for newly diagnosed patients and between 27.8-40.2% over a 12-month period for established patients. There is an unmet need for new therapies that sustain remission and decrease relapse rates in patients with ANCA-associated vasculitis. This is an important clinical strategy to reduce the risks of adverse events from long-term immunosuppression therapy and decrease end-organ damage.

POS036 Efficacy of Mepolizumab in Patients with Eosinophilic Granulomatosis with Polyangiitis and a Vasculitic Phenotype

B. Terrier1, D. Jayne2, B. Hellmich3, J. H. Bentley4, J. Steinfeld5, J. W. Yancey6, N. Kwon7, P. Akuthota8, P. Khoury9, L. Baylis10, M. Wechsel11, H. Köhlein, Service de Médecine Interne, Paris, France; 2University of Cambridge, Department of Medicine, Cambridge, United Kingdom; 3Universität Tübingen, Medizin Klinik, Klinik für Innere Medizin, Rheumatologie & Immunologie, Kirchheim-Teck, Germany; 4GSK, Clinical Statistics, Brentford, United Kingdom; 5GSK, Clinical Sciences, Respiratory, Philadelphia, PA, United States of America; 6GSK, Respiratory, Infectious Ana, NC, United States of America; 7GSK, Global Medical Affairs, Durham, NC, United States of America; 8National Jewish Health, Department of Medicine, Denver, CO, United States of America

Background: Patients with eosinophilic granulomatosis with polyangiitis (EGPA) often present with upper or lower respiratory symptoms. 1 The Phase III MIRRA study demonstrated that patients with EGPA spent more time in remission and had reduced oral corticosteroid use with mepolizumab versus placebo. 2 Objectives: To evaluate the efficacy of mepolizumab in patients with a vasculitic EGPA phenotype enrolled in the MIRRA study.

Methods: MIRRA was a Phase III, multicentre, double-blind, parallel-group trial in patients with eosinophilic granulomatosis with polyangiitis or EGPA, treated after 12 weeks stable prednisolone treatment. Patients were randomised to receive standard of care plus mepolizumab (300 mg subcutaneously every 4 weeks) or placebo for 52 weeks. Primary endpoints were: accrued weeks of remission (defined as Birmingham Vasculitis Activity Score [BVAS] of 0 and OCS dose ≤4mg/day in the 12 weeks prior to baseline), 36 weeks of remission, 52 weeks of remission and 1 year of remission. 4-6

Results: Of the 136 patients in the study, 26 (19%) had a history of a positive ANCA test at study baseline and 110 (81%) did not. In addition, 51 (38%) had a BVAS ≥0 at baseline while 85 (63%) had a BVAS >0. 74 (54%) had a VDI ≤5 at baseline and 62 (46%) had a VDI >5. Accrued remission duration was greater with mepolizumab versus placebo, irrespective of ANCA positive status, baseline BVAS or baseline VDI score (Figure 1). Across all the subgroups, a larger proportion of patients achieved remission at both Weeks 36 and 48 with mepolizumab versus placebo (Figure 1). Among patients receiving mepolizumab, the numbers (proportion) of patients achieving remission at both Weeks 36 and 48 were 7 (54%) for patients with an ANCA-positive test and 15 (27%) for patients without a history of an ANCA-positive test: 14 (45%) in the BVAS ≥0 and 8 (22%) in the BVAS >0 groups; 11 (29%) in the VDI score <5 and 11 (37%) in the VDI score ≥5 groups. Mepolizumab reduced all types of disease relapse assessed during the treatment period, including vasculitis, asthma and sinusonal relapses, compared with placebo. Vasculitic characteristics including neuropathy, glomerulonephritis, alveolar haemorrhage, palpable purpura and ANCA positivity were generally similar among patients who did and did not achieve remission during the study.

Conclusion: Mepolizumab is associated with clinical benefits in patients with EGPA, including those with and without a vasculitic phenotype.

Mepolizumab efficacy by patient baseline characteristics ANCA, antineutrophil cytoplasmic antibody; BVAS, Birmingham Vasculitis Activity Score; CI, confidence interval; NA, data not available – estimate could not be calculated owing to a lack of patients in the placebo group achieving remission at Weeks 36 and 48; VDI, Vasculitis Damage Index.
at least three maintenance infusions with either 1000 mg or 500 mg, twice per year) as remission-maintenance therapy in AAV patients. We assessed all patients with standard low dose (twice per year), for 18 months. No significant differences at baseline were noted between patients receiving ultra-low dose maintenance treatment with ultra-low dose RTX (once per year), while 70.1% of patients with standard low dose (twice per year), for 18 months. No significant differences at baseline were noted between patients receiving ultra-low dose when compared to those treated with conventional low-dose.

At the end of observation period, a disease flare was observed in 22.7% of the low-dose group, and 21.2% in those treated with the standard dose (p=0.881). Relapse-free survival was comparable between the two group (log-rank p=0.818, Figure 1).

When comparing AAV patients treated with ultra-low dose regimen to those treated with low-dose, no differences were noted in negative ANCA rate (72.2% vs 69.1%, p=0.262), ANCA titer (0 [0–78] vs 0 [0–50] UI/mL, p=0.232), B-cells depletion rate (70.6% vs 75%, p=0.725), mean serum IgG (811 [146-922] vs 680 [429-861] mg/dl, p=0.367), mean daily glucocorticoid dosage (2.5 [0-5] vs 3.75 [0-5] mg/d, p=0.647), VDI (4 [1-5] vs 2 [1-4], p=0.098), hypogammaglobulinaemia rate (31.8% vs 36.5%, p=0.617) and deaths (4.5% vs 5.8%, p=0.831).

Although not significant, patients treated with ultra-low dose had lower severe infection rate (10.5% vs 26.6%, p=0.154). Notably, in the all cohort 5 deaths were related to COVID19 pneumonia.

Conclusion: Reduced exposure to RTX was not associated with an impaired efficacy of maintenance therapy in patients with AAV. Remission maintenance with ultra-low dose RTX is a safe and more cost-effective option.

REFERENCES:
Background: Limited therapies are available for patients with idiopathic inflammatory myopathy (IM), a heterogeneous group of chronic, systemic, autoimmune inflammatory diseases characterized by progressive muscle weakness and/or distinct skin rashes. Abatacept, a selective co-stimulation modulator, may be a useful treatment option.

Objectives: To evaluate efficacy, safety, and tolerability of abatacept + standard of care (SOC) in patients with IM compared with SOC alone (placebo).

Methods: A 24-week, randomized, double-blind, placebo-controlled phase 3 trial of SC abatacept (125 mg weekly) + SOC (corticosteroids and immunosuppressants alone or combined; NCT02971863) in patients with active, treatment-refractory IM (Manual Muscle Testing-8 [MMT-8] ≤ 135) was performed. Primary endpoint was proportion of patients meeting International Myositis Assessment and Clinical Studies definition of improvement (IMACS DOI) at week 24. Change from baseline in myositis Functional Index-2 (FI-2), HAQ-DI, Myositis Disease Activity Assessment Tool (MDIAT), and Myositis Response Criteria (MRC) were secondary endpoints with safety. Post hoc analyses by disease subtype were performed.

Results: Overall, 148 patients were randomized (75 abatacept; 73 placebo); IM subtypes were dermatomyositis (DM; 53.3% vs 57.5%), polymyositis (PM; 25.3% vs 34.2%), and autoimmune necrotizing myopathy (ANM; 21.3% vs 8.2%). Mean baseline MMT-8 and HAQ-DI scores were 112.7 and 1.5, respectively. Approximately 90% of patients completed week 24. Week 24 IMACS DOI rates were abatacept 56.0% vs placebo 42.5% (adjusted odds ratio, 1.8 [95% CI, 0.9–3.5]; P = 0.083). Pre-specified IMACS DOI analysis showed no differences for patients with DM but notable benefit for those with non-DM subtypes, PM and ANM (Table 1). Secondary endpoints showed similar differences (Table 1). MRC at day 169 by category is shown in Figure 1. Proportion of AEs (69.3% and 75.3%) and serious AEs (5.3% and 5.8%) were similar in the abatacept and placebo arms.

Data are adjusted mean change from baseline score (SE) unless stated. *Defined as improvement of ≥ 20% in 3 IMACS core measures, worsening by ≥ 25% in ≤ 2 IMACS core measure scores, and a reduction of < 25% in MMT-8;100 mm visual analog scale.

Conclusion: In this double-blind trial of SC abatacept vs placebo, abatacept failed to meet primary or secondary endpoints. Post hoc analyses suggest a treatment benefit in patients with PM and ANM (not DM) when treated with abatacept. Abatacept use was well tolerated.

REFERENCES:
Background: Melanoma differentiation associated gene 5 antibody (anti-MDA5) dermatomyositis, is an idiopathic inflammatory musculoskeletal disorder with specific phenotypic manifestations of rapidly progressing interstitial lung disease (RP-ILD) and ulcerative skin lesions, with or without muscle involvement. There is currently a lack of consensus and guidelines on early diagnosis and timely escalation of therapy to avoid untoward outcomes.

Objectives: To identify distinguishing clinical and laboratory features to assess disease progression amongst individuals with anti-MDA5 dermatomyositis based on the serologic, histopathologic, and radiographic status. We identified and compared the disease phenotype in a racially diverse juvenile and adult population with anti-MDA5 dermatomyositis.

Methods: After Institutional review board approval, we queried the electronic health record at the Montefiore Medical Center, NY, and identified a total of 194 dermatomyositis patients. We included 21 dermatomyositis patients with MDA5 antibody. We performed a retrospective chart review to extract clinical data and analyzed data using Fischer’s exact test.

Results: Of the 21 dermatomyositis patients with anti-MDA5, 12 adult patients represented 8% of all adult dermatomyositis cases (12/148) and 9 patients represented 19 % of the pediatric dermatomyositis cases (9/46). There was a 2:1 female to male predominance in both groups. In adults, the mean age of disease onset was 45.2 years (SD 14.4 years). Nine ILD cases were noted, of which 2 were RP-ILD. The presence of the Ro52 antibody was associated with rapid disease progression. In children, the mean age of onset was 6.6 years (SD 4.9 years). All children had muscle weakness, with only 5 having ILD. Myositis was noted to be more prevalent in the pediatric population, compared to adults (9/9 Vs 4/12 cases; P=0.005). In this patient cohort, ILD was statistically significant between the African American population (9/10 cases) and non-African American population (5/11 cases), p=0.03, of these 3 African American cases had RP-ILD with mortality. The combined mortality rate of 14.2% was superior to 40-60% reported in the literature. [2]

Conclusion: Anti MDA5 dermatomyositis is relatively rare and difficult to diagnose. In this study, the general disease characteristics of our cohort were similar in both adult and pediatric patients except for myositis, which was more common in the pediatric population. The incidence of ILD by contrast was higher in the adults, especially in the African American population who had worse outcomes. The rapid escalation of therapy and use of rituximab may have improved our outcomes over historic controls. Controlled studies are needed to evaluate patients with anti-MDA5 dermatomyositis for appropriate treatment interventions and to avoid untoward outcomes.

POSO842 NON-INVASIVE COHERENT RAMAN IMAGING OF INVOLVED FOREARM SKIN REVEALS AlIGNED COLLAGEN IN DERMIS OF SYSTEMIC SCLEROSIS PATIENTS

P. S. Wong1, B. Ahmed Abdì1, J. Mansfield2, H. Lopez3, J. Moger2, I. F. Uchegbu1, R. Stratton1. 1Royal Free Hospital, Centre of Connective Tissue Disease and Rheumatology, University College Of London, London, United Kingdom; 2University of Exeter, School of Physics and Astronomy, Exeter, United Kingdom; 3MURIGENICS, INC, Research and Development, California, United States of America; 4UCL School of Pharmacy, Pharmaceutical Nanoscience, London, United Kingdom

Background: Systemic sclerosis (SSc) is an immune-mediated connective tissue disease with clinical hallmark of inflammation, vasculopathy and fibrosis resulting in abnormal collagen and intercellular matrix formation in the dermis and internal organ. Skin severity correlates with systemic complications and mortality in SSc. Many skin assessment tools studied do not fulfilled all standards set by OMERACT which include criterion validity, construct validity, discrimination, responsiveness, reliability and feasibility. Modified Rodnan skin score (mRSS) is commonly used as outcome measure in clinical trials of SSc. mRSS score (mRSS) is commonly used as outcome measure in clinical trials of SSc.

With the demand of better tools in diagnosis of early SSc and therapeutic research, our work with CRS prove better in objective evaluation of skin changes at the molecular level. Here, we demonstrate that the SHG is altered in the early diffuse SSc skin with increased and aligned collagen in the SSc dermis compatible with mRSS score. Others have observed this alignment of the collagen, and we have published that SSc fibroblasts migrate/invade along aligned collagen and modestly the underlying extracellular matrix, adding collagen I and III, close-linking enzymes and other factors including TSP-1.

Our future work include:
1. Generating a computer module in defining pathological collagen level
2. Analysis of metabolites and pathological pathways in SSc
3. In-vivo trials with novel therapeutic peptides.
4. Lastly, manufacturing of non-invasive handheld device that is capable of diagnosis subclinical SSc and for outcome measure in clinical-therapeutic research

POSO843 PREDICTORS OF INTERSTITIAL LUNG INVOLVEMENT AND TIMING OF ONSET IN SYSTEMIC SCLEROSIS: OUR EXPERIENCE AT A THIRD-LEVEL HOSPITAL

C. Seiros Santos1, C. Moriano2, X. E. L. Rojas3, C. Álvarez Castro1, A. López Robles1, E. Diez Alvarez1. 1Complejo Asistencial Universitario de León, Rheumatology, León, Spain

Background: Interstitial lung disease (SSc-ILD) and pulmonary hypertension are the leading causes of death in patients with systemic sclerosis (SSc). Identifying SSc-ILD development and initiating treatment is essential to optimize therapeutic benefit.

Methods: We followed through our previous work studying commercially available non-invasive imaging tools in SSc skin assessment by using Coherent-Raman scattering microscopy (CRS).

Results: The SHG analysis revealed denser collagen fibers in dermal layer of diseased skin. It also appears that the collagen deposition occurs in more superficial layers of the skin. Peak of collagen curve were at depth of 110-130um HC vs 75-90um in SSc. Collagen fibres were more aligned in the SSc (Figure 1).

Furthermore, TPF revealed larger number of disordered elastin fibres in the dermal layer of SSc than HC.

Conclusion: Nailfold capillaroscopy is used to define and stage micro-vasculopathy in SSc. Inflammatory pro-fibrotic processes on the other hand cause abnormal collagen and intercellular matrix formation in the dermis and internal organ.

Methods: Standard incidence ratios (SIR) of malignancy and the long-term occurrence of Objectives: not elucidated so far.

nosis [2], long-term relationships between malignancy and each antibody are some subgroups of IIM have a high risk of malignancy up to 10 years after diag-

nosis of 14.73 (4.72-40.50) (Table 1). Types of malignancy included anti-ARS, MDA5, Mi-2, or TIF1-γ antibody p<0.001) and more frequently with anti-TIF1-γ antibody than patients with anti-ARS antibody lower in patients with anti-TIF1-γ antibody. We retrospectively collected the data and calculated SIRs by using the database of Cancer Statistics, Cancer Information Service, National Cancer Center, Japan. Fisher exact test and Wilcoxon test were used to compare the clinical features in each group. Cumulative incidence of cancer occurrence was estimated by Kaplan-Meier methods, and Log-rank test was used to compare the cancer-free survival.

Results: From our IIM cohort at the University of Tokyo hospital, we enrolled patients who fulfilled Bohan and Peter criteria for dermatomyositis/polymyositis or 2017 European League Against Rheumatism/American College of Rheumatology classification criteria for IIMs and with positivity for anti-ARS, MDA5, Mi-2, or TIF1-γ antibody. We retrospectively collected the data and calculated SIRs by using the database of Cancer Statistics, Cancer Information Service, National Cancer Center, Japan. Fisher exact test and Wilcoxon test were used to compare the clinical features in each group. Cumulative incidence of cancer occurrence was estimated by Kaplan-Meier methods, and Log-rank test was used to compare the cancer-free survival.

Results: The study included 111 patients, including 16 patients being diag-
nosed with a malignancy within a three-year before and after the occurrence of IIM. Patients with malignancy were significantly older age at the onset of IIM (median age (interquartile range) 67.5 (62.7-70.8) vs. 52.0 (41.5-61.5), p<0.001) and more frequently with anti-TIF1-γ antibody (25.0% vs. 4.2%, p=0.015). After adjustment for age, the proportion of anti-TIF1-γ antibody remains significantly higher in the malignancy group (p=0.001). SIRs (95% confidence interval) in each type of antibody were anti-ARS of 2.21 (1.03-4.55), anti-MDA5 of 1.89 (0.49-6.02), anti-Mi-2 of 2.75 (0.14-17.84), and anti-TIF1-γ of 14.73 (4.72-40.50) (Table 1). Types of malignancy included four gastric cancers, two bladder cancers, breast cancers, cervical cancers, ovarian cancers, and lung cancer, one pancreatic cancer, rectal cancer, and renal cancer. Kaplan-Meier estimated cancer-free survival was significantly lower in patients with anti-TIF1-γ antibody than patients with anti-ARS antibody (p<0.01) (Figure 1). The frequencies of malignancy in IIM patients with anti-ARS, MDA5, Mi-2, or TIF1-γ antibody through the follow-up period were 15.6%, 20.0%, 11.1%, and 50.0%, respectively.

Conclusion: We identified 10 factors significantly associated with risk of developing SSc-ILD: smoking, male sex, diffuse cutaneous involvement, the pres-

ence of myositis, shorter Raynaud duration to SSc diagnosis, anti-Scl70 and anti-Ro52 positivity and baseline pulmonary function (lower baseline DLCO and FVC increasing risk) and late capillaroscopy pattern and identified predictors for early and late-onset SSc-ILD.

Conclusion: IIM patients with anti-TIF1-γ antibody and with anti-ARS antibody had a higher prevalence of malignancy than the general population. In addition, anti-TIF1-γ antibody are more associated with malignancy rather than anti-ARS antibody in 10 years as well. Malignancy associated with anti-TIF1-γ positive IIM occurred exclusively within the one year before and after the IIM diagnosis, and cancer should be particularly studied at the IIM diagnosis.

Table 2. Asessing frailty in systemic sclerosis: A cross-sectional study comparing frail and edmonton frailty scales with physical frailty phenotype

V. Hax1, A. A. Gasparin1, N. Pampolina Bueno de Andrade1, R. Cavalheiro Do Espirito Santo1, E. Pena1, L. Santos2, L. Denardi Dória1, R. Xavier1, R. Mendonca Da Silva Chakr1. Hospital de Clinicas de Porto Alegre, Division of Rheumatology, PORTO ALEGRE, Brazil

Background: Systemic sclerosis (SSc) is a chronic disease characterized by autoimmunity, vasculopathy and fibrosis. During the disease course, patients with SSc are prone to accumulate multiple organ damage, increasing their vul-
nerability to adverse outcomes in comparison with individuals of the same age: a phenomenon called frailty. One of the most used definitions of frailty is the phys-
ical frailty phenotype (FFP) by Fried, et al. The FFP consists of 5 components: unintentional weight loss, exhaustion, muscle weakness, slow walking speed, and low physical activity. There is scarce data about frailty in patients with SSc.

Objectives: To study the prevalence and clinical aspects of FFP in a sample of patients with SSc. Also, we aim to investigate the diagnostic accuracy of the Fatigue, Resistance, Ambulation, Illness and Loss of weight (FRAIL) scale and the Edmonton frailty scale (EFS) using the FFP as the reference standard.

Methods: Cross-sectional study, including patients with SSc according to the 2013 ACR-EULAR classification criteria or the criteria suggested by LeRoy and Medsger for early disease. FFP assessment was according to the original defi-
nition, except for physical activity domain, assessed with the International Phys-
ical Activity Questionnaire (IPAQ). Patients were classified according to Fried’s criteria in robust (0), pre-frail (1-2), and frail (≥3). FRAIL scale and EFS were also applied to the same samples. The FRAIL score ranges from 0 to 17 and categorizes patients as not frail (0–4), vulnerable (5–6), mild frailty (7–8), moderate frailty (9–10), and severe frailty (≥11). For the diag-
nostic assessment of FRAIL scale and EFS, we estimated the area under the receiver operating characteristic curve (AUC), considering FPF as the reference standard and dichotomizing the results in frail vs. non-frail.

Results: Between March and December 2019, 82 SSc patients were consecu-
tively included. The mean age and disease duration were 60.4 ±8.2) years, respectively; 91.5% were women, and 19.5% with diffuse cutane-
ous SSc. The FPF distribution was: 8 (9.8%) robust, 47 (57.3%) pre-frail and 27 (32.9%) frail patients. The FFP domains’ frequencies were: low physical activity in 57 (69.5%), muscle weakness in 41 (50%), exhaustion in 34 (41.5%), unin-
tentional weight loss in 15 (18.3%) and slow walking speed in 8 (9.8%) patients.

POS0847 MYOSITIS AUTOANTIBODIES DETECTED BY LINE BLOT IMMUNOASSAY: CLINICAL ASSOCIATIONS AND CORRELATION WITH ANTIBODY TITERS

J. Loarce-Martos1, L. Calvo Sanz2, S. Garrote-Corra1, C. Rits3, R. Ballester Gonzalez2, A. Garcia-Soidan1, J. Bachiller-Corra1, G. Roy1, Hospital Universitario Ramón y Cajal, Rheumatology Department, Madrid, Spain; 2Hospital Universitario Ramón y Cajal, Immunology Department, Madrid, Spain; 3Ramón y Cajal University Hospital, Rheumatology Department, Madrid, Spain

Background: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of autoimmune diseases (AID) characterized by muscle inflammation and weakness, often accompanied with other organ involvement, such as skin rash or interstitial lung disease (ILD). Myositis specific (MSA) and myositis associated (MAS) categories are important for clinical decision making.

Methods: To investigate the clinical manifestations of MSA and MAS patients, a retrospective study was performed in a single center with 114 consecutive patients (52 MSA, 62 MAS). Myositis-associated antibodies were determined using line blot immunoblotting (IB) and ELISA using recombinant proteins.

Results: The majority of MSA patients were detected for anti-Jo1 and anti-Mi2 antibodies, while the most frequent MAS antibodies were anti-SRP, anti-U1 RNP, and anti-ANNA-1. There was a significant association between MSA and cardiac involvement, whereas MAS patients presented more often with arthralgia and myalgia.

Conclusion: The use of line blot IB provides a rapid and cost-effective method to detect myositis-associated antibodies, facilitating the diagnosis and management of patients with MSA and MAS.

POS0846 MORTALITY OUTCOME OF ACUTE MYOCARDIAL INFARCTION IN PATIENTS WITH IDIOPATHIC INFAMMATORY MYOPATHIES, A QUALITATIVE APPROACH ANALYSIS OF THE NATIONAL INPATIENT SAMPLE FROM 2016-2019

Z. Y. Li1, S. Huang2, T. Joshua3, D. Dalal4, A. Reginato4, Roger Williams Medical Center, Rheumatology, PROVIDENCE, United States of America;

Background: To investigate the quality of care of acute myocardial infarctions (AMI) events in myositis patients compared to non-myositis patients across the United States categorized by the types of hospitals, probability of myocardial events, and mortality outcome from the NIS from 2016-2019.

Methods: We used SAS statistical software to perform analyses on the NIS database (2016-2019) in the US. Adults with AMI and myositis at the time of discharge were identified by International Statistical Classification of Disease 10 (ICD-10) codes. Latent class analysis was used to empirically identify hospital groups across different regions in the U.S where myositis patients received their cardiac care. Once hospital groups were determined, patients were compared with and without myositis in each hospital group. Probabilities of AMI event and mortality among myositis patients were compared using logistic regression analysis.

Results: The NIS sample included 38,363 myositis patients and 24,179,176 non-myositis patients. Three hospital groups were identified, the first two represented inner-city hospitals, with the second group of hospitals tending to be larger and serving lower income patients. The third hospital group represented rural hospitals, though they also tended to perform fewer cardiac procedures. Importantly, this third group was about half as likely to identify myositis patients and more likely to identify the unrelated confounder conditions. Patients who received care at more rural hospitals (group 3) were at heightened mortality risk (OR=1.12, p < 0.0001). Opposite to the patient experiences in urban hospitals, the unique risk of mortality to myositis patients in rural hospitals was heightened (OR = 1.88, p < 0.0001).

Conclusion: Myositis was not associated with higher AMI events and mortality outcomes in this nationwide hospitalization cohort. Hospitals in rural locations had fewer diagnosed cases of myositis, catheter procedure and transfer out rate may have contributed to higher AMI mortality outcome in group 3. Further studies should examine if catheter procedure mortality outcome of AMI event in myositis differs in the three hospital groups.

Disclosure of Interests: None declared

antibodies (MAA) can be detected in approximately 60% of patients with IIM. Besides, antibody titers have been suggested to be related with diagnostic accuracy, although it has not been widely studied. MSA are considered to be exclusive of patients with IIM, whilst MAA can occur in IIM and other systemic autoimmune diseases, nevertheless, most of the studies are focused exclusively on IIM patients.

**Objectives:** The aim of this study is to assess the relationship between MSA/MAA and diagnosis (including IIM and other AID), and to explore the impact of antibody titers in diagnostic accuracy.

**Methods:** We retrospectively reviewed all the serum samples obtained from patients tested for MSA/MAA between 01/01/2018 and 31/12/2020 in the Immunology department of Ramón y Cajal University Hospital (Spain). These antibodies were tested by line blot immunassay (LIA) (EUROLINE Autoimmune Inflammatory Myopathies 16 Ag, Euroimmun, Lübeck, Germany). Positivity was established according to absorbance titer and adjusted by positive control of each test (arbitrary units, AU). True positive (TP) MSA and MAA were defined as those patients with IIM or AID with phenotypes expected of that MSA/MAA, according to the available information. The patients that did not have a phenotype compatible with that antibody were regarded as false positive (FP). Statistical analysis was carried out using IBM SPSS statistics version 22.

**Results:** We analyzed 130 positive samples which corresponded to 130 patients, 85 were women and mean age was 55.08 years. 44 patients (33.8%) were classified as IIM, 43 (33.1%) as AID, and 43 (33.1%) as non-IIM/AID. Among these 130 patients, 164 MSA/MAA were detected. 83 (50.6%) positive MSA/MAA were regarded as TP, and 81 (49.4%) as FP (positive predictive value [PPV] 50.6%). Antibodies regarded as TP had a higher antibody titer compared to FP (49.19 AU vs 26.96 AU, p<0.001). This difference was statistically significant for MSA and MAA when analysed separately (Figure 1). FP antibodies were associated with negative ANA and low titer ANA (p<0.001).

Multiple positive antibodies (antibodies included in samples that were positive for > 1 MSA/MAA) were more frequently FP in comparison with isolated positive MSA/MAA (p<0.001).

**Conclusion:** In this study we confirm that FP results using LIA are relatively frequent, and are associated with lower titer MSA/MAA, negative ANA, lower titer ANA, and with multiple positive MSA/MAA within one sample.

</table>
skin score, and whether prednisolone was safe with particular reference to renal function.

**Methods:** PRedSS set out as a Phase II, multicentre, double-blind randomised controlled trial, converted to open-label because of the Covid-19 pandemic. Patients were randomised to receive either moderate dose prednisolone (approximately 0.3 mg/kg) or matching placebo (or no treatment during open-label) for 6 months. The co-primary endpoints were the Health Assessment Questionnaire Disability Index (HAQ-DI) and modified Rodnan skin core (mRSS) at 3 months. Over 20 secondary endpoints included patient reported outcome measures reflecting pain, itch, anxiety and depression, fatigue and helplessness. 72 participants randomised 1:1 were planned and anticipated to yield 60 evaluable, giving over 80% power for each co-primary outcome in ANCOVA analyses [assumptions; HAQ-DI (α = 0.025, β = 0.6), mRSS (α = 0.025, β = 0.6)]. Mixed Models for Repeated Measures (week 6, month 3, month 6) were fitted with covariates trial arm, baseline score, anti-Scl-70 and their interactions with time point. An unstructured covariance matrix was assumed with the primary focus being the trial arm effect at 3 months.

**Results:** The study terminated early due to the Covid-19 pandemic and consequently did not meet the recruitment target of 72 patients. Thirty-five patients (Table 1) were randomised (17 to prednisolone and 18 to placebo/control, 25 during the double-blind phase), of whom 34 completed the 3 month assessment. The adjusted mean difference between treatment groups at 3 months in HAQ-DI score was -0.10 (97.5% CI -0.29 to 0.10), p=0.25, and in mRSS -3.90 (97.5% CI -8.83 to 1.03), p=0.070, both favouring prednisolone but not significantly. Patients in the prednisolone group experienced less pain, helplessness and anxiety than control arm at 3 months: mean difference in pain scores -0.49, 95%CI (-0.93 to -0.06), p=0.027, in Hospital Anxiety and Depression (HADS) anxiety scores -2.05, 95%CI (-3.73 to -0.37), p=0.018, and in helplessness scores -1.54, 95%CI (-3.01 to -0.07), p=0.040. There were no renal crises.

**Conclusion:** PRedSS exemplified the challenges of running a clinical trial of an investigational medicinal product potentially associated with increased infection risk during the Covid-19 pandemic. Because PRedSS was terminated prior to target recruitment, it was underpowered, and any conclusions have to be extremely cautious. Although PRedSS suggested some benefit from moderate dose prednisolone, the small sample indicates the need for a further randomised trial.

**FREQUENCY OF METABOLIC SYNDROME AND ITS RELATIONSHIP WITH DISEASE CHARACTERISTICS IN PATIENTS WITH SYSTEMIC SCLEROSIS**

Ü. Özmen¹, E. Er Gülbeyzê², B. Barutçuoğlu³, F. Yargucu¹. ¹Ege Üniversitesi Hastanesi, Internal Medicine, İzmir, Turkey; ²Kök University Hospital, Rheumatology, İstanbul, Turkey; ³Ege Üniversitesi Hastanesi, Rheumatology, İzmir, Turkey; ⁴Ege Üniversitesi Hastanesi, Department of Medical Biochemistry, İzmir, Turkey

**Background:** Although the frequency of metabolic syndrome (MetS) has been found to increase in many rheumatological diseases such as rheumatoid arthritis, systemic lupus erythematosus, few studies have been conducted on the frequency of MetS in systemic sclerosis (SSc), and the results are inconsistent.

**Objectives:** In our study, we aimed to investigate the frequency of MetS in patients with SSc and its relationship with disease characteristics including organ involvement.

**Methods:** In a cross-sectional, single-center study, 76 patients who applied to our outpatient clinic between July and September 2021 were included in the study. MetS diagnoses were determined according to anthropometric measurements, lipid parameters, blood pressures, and NCEP ATP 3 criteria, and its relationship with SSc end-organ involvement and disease characteristics was examined.

**Results:** MetS was detected in 37 (48.7%) of 76 patients. Systolic and diastolic blood pressure, waist circumference, height, body mass index, LDL, triglyceride, and fasting blood glucose mean were found to be statistically significantly higher in patients with MetS (p<0.05). In addition, HDL was found to be significantly lower in patients with MetS diagnosis than in patients without MetS (p<0.05). While no significant relationship was found between MetS and SSc end-organ involvement, SSc disease activities (RA, SCTC-DI), disease duration, a significant statistical relationship was found between MetS and modified Rodnan skin score (mRSS). It was found that patients with MetS had lower mRSS (p=0.019). According to ROC analysis, the mRSS cut-off point that predicting the presence of MetS was mRSS ≤11 (specificity: 84%, sensitivity: 45.95%, AUC: 0.656, p=0.014). No statistically significant correlation was found in the comparison with MetS risk factors for mRSS ≤11.

**Conclusion:** In our study, the frequency of MetS in patients with SSc was found to be lower than in the same age group in Turkey MetS prevalence studies. The frequency of MetS in our study is thought to be due to age and gender dominance of the SSc diseases other than SSc itself. Although mRSS was found to be significantly higher in patients with MetS, its sensitivity to predict MetS was found to be low. MetS is less common in patients with high mRSS; It is thought that cachexia due to inflammation, loss of appetite, and malnutrition due to GI involvement may have been effective.

**SYMPTOMS OF GASTROESOPHAGEAL REFLUX ARE A BETTER PREDICTOR OF SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE PROGRESSION THAN QUANTITATIVE RADIOGRAPHIC ASSESSMENT OF ESOPHAGEAL PARAMETERS**

E. Vollmann¹, D. Tashkin², M. Leng³, G. Kim², J. Goldstr³, M. Roth³. ¹University of California, Los Angeles, Medicine, Los Angeles, United States of America; ²University of California, Los Angeles, Radiology, Los Angeles, United States of America

**Background:** Esophageal dysfunction affects the majority of patients with systemic sclerosis (SSc). Gastroesophageal reflux (GERD)-associated microaspiration may serve as an inciting and/or exacerbating factor in the pathogenesis of interstitial lung disease (ILD) in SSc. Few studies have investigated the relationship between objective measures of esophageal involvement in SSc and the progression of SSc-ILD.

**Objectives:** (1) To investigate whether patient-reported symptoms of GERD predict SSc-ILD severity and progression; (2) To explore whether quantitative radiographic measurements of esophageal parameters predict SSc-ILD severity and progression.

**Methods:** Participants of Scleroderma Lung Study (SLS) II (24 months of myophenolate versus 12 months cyclophosphamide followed by 12 months of placebo in patients with active SSc-ILD) were included.¹ The UCLA SCTCGIT 2.0 was used to assess the severity of reflux at baseline. Quantitative image analysis was used to calculate the diameter and area of the esophagus in the area of maximum dilatation. Univariate and multivariable linear regression analyses were used to evaluate the relationship between baseline reflux scores/esophageal parameters and the severity and progression of SSc-ILD based on the
EFFECTS OF NINTEDANIB ON CIRCULATING BIOMARKERS IN SUBJECTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSc-ILD)

S. Assassi1, M. Kuwana2, C. P. Denton3, T. Maher4, C. Diefenbach5, C. Ittrich6, M. Gahlemann7, O. Distler8 on behalf of The SENSCIS trial investigators.

Background: In the SENSCIS trial in subjects with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) over 52 weeks by 44% compared with placebo.

Objectives: To investigate the effects of nintedanib on circulating biomarkers of extracellular matrix (ECM) turnover, epithelial injury and inflammation in the SENSCIS trial.

Methods: Subjects had SSc with first non-Raynaud symptom in the prior ≤7 years, extent of fibrotic LILD on high-resolution computed tomography (HRCT) ≥10% and FVC ≥40% predicted. Patients were randomised to receive nintedanib or placebo stratified by anti-topoisomerase I antibody (ATA). Blood samples were taken at baseline and at weeks 4, 24 and 52. Fold changes in adjusted mean levels of circulating biomarkers were analyzed using a linear mixed model for repeated measures. Data were log10 transformed before analysis and estimates of change from baseline were back-transformed.

Results: A total of 776 subjects received trial drug (288 nintedanib, 288 placebo). A transient increase in fold change from baseline in C-reactive protein (CRP) (a marker of inflammation) was observed in subjects who received nintedanib versus placebo at week 4. After an initial increase at week 4 in the fold change from baseline in CRP degraded by MMP-1/8 (CRPM) (a marker of ECM turnover), a trend to decreasing levels was observed in subjects who received nintedanib compared with placebo at week 52. Decreases in the fold change from baseline in collagen 3 degraded by MMP-9 (C3M) and N-terminal propeptide of type VI collagen (pro-C6) (markers of ECM turnover) were observed in subjects who received nintedanib compared with placebo from week 24 and week 4, respectively. A decrease in fold change from baseline in Krebs von den Lungen-6 (KL-6) (a marker of epithelial injury) was observed in subjects who received nintedanib versus placebo at week 52. A decrease in fold change from baseline in cancer antigen 125 (CA-125) (a marker of epithelial injury) was observed in subjects who received nintedanib versus placebo from week 4 (Figure 1).

Conclusion: Data from the SENSCIS trial suggest that nintedanib reduced circulating levels of markers of ECM turnover and epithelial injury in subjects with SSc-ILD.

Data are mean ± SD or % at baseline. Missing data were excluded. *Assessed visually in whole lung to nearest 5%. The assessment did not include pure (non-fibrotic) ground glass opacities.
Methods: PROMIS PF data obtained in the coronavirus disease-2019 (COVID-19) Vaccination COVAD study database. The disease activity (active vs inactive) of each patient was measured between each disease category (IIMs vs non-IIM AIDs), even in patients with inactive disease. The elderly, women, and IBM groups are the worst affected, suggesting that developing targeted strategies to minimize functional disability in certain groups may improve patient reported physical function and disease outcomes.

background: PET/CT holds utility beyond the standard and readily available diagnostic tests for measuring severity. While PET/CT may detect skeletal muscle inflammation in IIM, its utility for people with IIM in comparison to standard screening methods is unknown. This systematic review seeks to evaluate the utility of PET or PET/CT in IIM, specifically for the detection of inflammatory muscle pathology, associated malignancy and extramuscular manifestations (e.g., ILD).

Methods: We performed a search of Medline and EMBASE from 1990-2021 using keywords related to IIM and PET. We included English language studies of adults with IIM who had PET or PET/CT as part of their diagnostic workup.

Results: Our search identified 910 potentially relevant abstracts, 18 of which were included. The majority of studies used [18F] fluorodeoxyglucose ([18F]FDG) PET or PET/CT scans, while the remainder used other radiotracers including [11C] fluorobetapir and [15C] Pittsburgh compound B ([15C] PIB). Malignancy – PET vs. conventional screening Six studies investigated the ability of 18F-FDG PET or 18F-FDG PET/CT to detect malignancy in people with IIM. When reported, the sensitivity and specificity of PET or PET/CT for diagnosing malignancy compared with standard detection methods was 66.7-94% and 88.9-97.8%, respectively. [2] ILD Using high-resolution CT (HRCT) as the gold standard for detection of ILD, three studies reported the ability of PET or PET/CT to detect ILD. The sensitivity of 18F-FDG PET alone for ILD was 39%, while the sensitivity of 18F-FDG PET/CT for ILD was 93-100%. FDG lung uptake was significantly increased in people with rapidly progressive-ILD (RP-ILD) in comparison to those with non-RP-ILD in two studies. 3. Muscle disease activity Ten studies evaluated either 18F-FDG PET or 18F-FDG PET/CT for its ability to detect muscle inflammation in IIM. In the nine studies where controls were used, PET or PET/CT appeared to accurately detect the presence of muscle inflammation, although correlations with clinical measures of myositis disease activity such as strength and serum creatine kinase were mixed. 4. A word on amyloid Skeletal muscle amyloid deposition was evaluated using [11C]PIB-PET in two studies and [18F] fluorobetapir PET/CT in one study. In all three studies, PET or PET/CT was able to differentiate sporadic inclusion body myositis (IBM) from non-IBM myositis.

Conclusion: PET or PET/CT performs relatively well as a malignancy screening tool for people with IIM in comparison to standard screening methods. While false positives for malignancy on PET can lead to unnecessary invasive investigations, this also occurs with conventional screening. PET/CT also appears to be a beneficial tool for detecting ILD in those with IIM and may predict its severity. While PET/CT may detect skeletal muscle inflammation in IIM, its utility beyond the standard and readily available diagnostic tests for measuring muscle disease activity remains unclear. Early evidence indicates PET-amyloid may be able to subtype IBM from non-IBM myopathic disease, although more data are needed. More research is needed to evaluate whether PET could be used as a tool for detecting cardiac involvement in IIM, or if extending the PET scan field of view might increase the cancer detection yield and permit a more accurate assessment of extramuscular manifestations in IIM. PET/CT holds promise as a single tool that can simultaneously evaluate multiple aspects of IIM early in the diagnostic process. These include screening for associated malignancy in high-risk patients, stratifying higher risk ILD, and providing information on muscle inflammation.

Disclosure of Interests: None declared

MCTD disease characteristics have only been partially investigated. NVC abnormalities videocapillaroscopy (NVC) is a simple, non-invasive and inexpensive imaging technique that allows a detailed assessment of skin microcirculation. NVC abnormalities of at least 3 of the 4 following features: at least 1 giant capillary, decreased capillary density (31.4%) and C) scleroderma pattern in 18 patients (35.3%), defined by the presence of at least 3 of the 4 following features: at least 1 giant capillary, decreased capillary density (<7/mm²), avascular areas and disorganization of capillary bed architecture (4). Scleroderma pattern was associated with clinical features of systemic sclerosis: skin sclerosis (9/16 vs. 5/33; p=0.008) and digital ulcers (6/18 vs. 2/31; p=0.017). Conversely, no association was observed between the normal or the non-specific NVC pattern and disease specific characteristics.

Interestingly, we observed, a significant reduction in the number of capillaries in patients with ILD (4.80±1.87 vs. 6.03±1.47; p=0.039), and patients with severe reduction of capillary density (≤4/mm²) were more likely to have ILD (57/5 vs. 53/3; p=0.002). Neangiogenesis was also more frequent in patients with ILD (6/13 vs. 4/27; p=0.004). Multivariate logistic regression analysis showed that the association between severe reduction of capillary density and ILD was observed independently of the presence of a scleroderma NVC pattern and skin fibrosis.

Conclusion: We identified three main NVC patterns in MCTD patients. The scleroderma NVC pattern was associated with clinical scleroderma characteristics whereas non-specific microangiopathy and normal NVC were not associated with a specific phenotype. Moreover, severe capillary loss was independently associated with the presence of ILD. These data suggest that NVC may be helpful for disease risk stratification in MCTD, and that NVC findings, and particularly severe capillary loss, may be a warning for the presence of ILD.

Conclusion: Patients with active SSC-ILD receiving one year of immunosuppressive therapy in the SLS II study experienced reductions in their CRP and IL-6 levels over this interval. The magnitude of the decrease in CRP and IL-6 over the first year also correlated with the course of FVC over the ensuing 12 months. These findings suggest a dynamic relationship between CRP and IL-6 measurements and the course of SSC-ILD in patients on immunosuppressive therapy. Further investigation of these findings is warranted.

POS0860 ULTRA-HIGH FREQUENCY ULTRASOUND FOR DIGITAL ARTERIES: COMPLETING THE CHARACTERIZATION OF VASCULOPATHY IN SYSTEMIC SCLEROSIS

M. Di Battista1, S. Vitali2, S. Barsotti3, R. Morganti4, V. Dini5, M. Romanelli5, 1University of Pisa, Rheumatology Unit, Pisa, Italy; 2University of Siena, Department of Medical Biotechnologies, Siena, Italy; 3University of Pisa, Radiology Unit, Pisa, Italy; 4University of Pisa, Section of Statistics, Pisa, Italy; 5University of Pisa, Dermatology Unit, Pisa, Italy

Background: Despite microangiopathy is the hallmark of systemic sclerosis (SSc), macrovascular involvement is arousing interest. In particular, proper palmar digital arteries (PPDA) play an important role in Raynaud’s phenomenon and can contribute to the exacerbation of vascular damage. However, PPDA full characterization is still an unmet need.

Objectives: To identify subgroups of anti-Ku positive patients according to their clinical entity? A cluster analysis of 75 anti-Ku antibody syndrome: is it a distinct clinical entity? A cluster analysis of 75 patients.

Methods: Multicenter, cross-sectional study of anti-Ku positive patients, irrespective of their diagnosis, followed at eight Rheumatology outpatient clinics. Patients were spontaneously identified according to the local work-out for suspected autoimmune diseases. Anti-Ku and other ANA specificities were determined at each hospital’s Immunology lab according to the local methodology and strategy to decide on which auto-antibodies to check when faced with a positive ANA immunofluorescence. Clinical, analytical and treatment cumulative features were identified following a dedicated structured questionnaire. Hierarchical cluster analysis (method: between-groups linkage, squared Euclidian distance) for ANA specificity variables was performed to identify subgroups.

Results: Seventy-five anti-Ku positive patients were included (female: 73.3%, mean age at diagnosis: 50.5±17.9 years). Their clinical diagnosis were undifferentiated connective tissue disease (UCTD) (21.3%), systemic lupus erythematosus (17.3%), Sjögren’s syndrome (16.0%), inflammatory myositis (14.7%), systemic sclerosis (10.7%), overlap CTD syndrome (8.0%), other connective tissue diseases (17.3%), healthy anti-Ku carrier (17.3%). Six autoantibody clusters were identified and included most patients (Figure 1): Cluster 1 - anti-Ku without any other ANA specificities (36.0%); cluster 2 - anti-nor90 and anti-fibrillarin (8.0%); cluster 3 - anti-Jo1, PL-7, PL-12, and PM-ScI100 (9.3%); cluster 4 - anti-ScI70 (4.0%); cluster 5 - anti-Sm, anti-ribosome, and anti-dsDNA (13.3%); cluster 6 - anti-centromere, ThTo, PM-ScI75 (8.0%). The remaining patients were outliers (21.3%) not fitting in any cluster.
**Detailed clinical analysis of patients in cluster 1, the most numerous, presenting anti-Ku antibodies without any other ANA specificities**. The most frequent clinical manifestations were: Raynaud’s phenomenon (40.7%), arthritis (25.9%), sicca syndrome (25.9%), myositis (14.8%), and interstitial lung disease (ILD) (14.8%). 25.9% were healthy anti-Ku carriers. Patients from cluster 1 were most frequently treated with low dose glucocorticoids (51.9%), hydroxychloroquine (37.0%), or methotrexate (18.5%). Among the whole study population (n=75), major organ involvement was present in 18.7%, with ILD in 10.7% and renal involvement in 8.0%. None of the patients in the cluster presented nephritis.

**Conclusion**: Anti-Ku positive patients without any other ANA specificities is the largest subset and may represent a distinct entity among the differentiated CTD (2). Patients with this anti-Ku syndrome may develop ILD. In addition, anti-Ku antibodies can be found in patients with a diversity of other ANA specificities and heterogeneous CTD diagnosis.

Reumatologia, Pavia, Italy; 11Institute NeuroMyoGène, INMIG CNRS UMR 5261-INSERM U1315, Lyon, France.

**Background**: The idiopathic inflammatory myopathies (IIMs) are a heterogeneous group of diseases that can affect the muscles, skin, lungs, heart, and joints. Increased knowledge about histopathological findings, clinical manifestations and auto-antibodies have allowed further novel classification of IIMs. Today, the main IIM subgroups are: dermatomyositis (DM), inclusion body myositis (IBM), immune-mediated necrotizing myopathies (IMNM), overlap myositis (OM) and immune-checkpoint inhibitor-related-myositis (IClirm). Axial muscle involvement results either in a “Dropped Head Syndrome (DHS)”, with a marked weakness of the neck extensors, or in a camptocormia (CC), with a weakness of the thoracolumbar paraspinal muscles. This atypical presentation is poorly described in the course of DMs while it may result in a major disability, and may lead to myositis diagnosis delay.

**Objective**: This study aimed to describe Ims revealed by DHS and/or CC. Secondary outcomes were to define subgroups of patients according to clinical, biological and histopathological characteristics. Then, the effects of treatments used were analyzed.

**Methods**: A historical cohort was designed using the register MYOLYON which includes all Ims followed at the University Hospital of Lyon (France) between 2000 and 2021. All patients with IM revealed by DHS and/or CC and having an histologically proven IMs were included, after exclusion of alternative (e.g., myasthenia gravis, motoneuron disease). Clinical, biological, immunological, histopathological data as well as outcome and care were collected through a standardized form. Agreement for the study was obtained from the French Ministry of the Research and the study was approved by the Local Research Ethics Committee.

**Results**: Twenty-two patients were fully characterized: DM (n=4), IBM (n=7), OM (n=8), IClirm (n=2) and one myositis with anti-Hu antibodies. Two groups of patients were identified according to the age at first symptoms and to the type of muscle axial involvement (e.g. DHS and/or CC). Before the age of 70 (n=13/22), the two most common diagnoses (n=11/13) were DM (n=4/4) and OM (n=7/8). Axial muscle involvement was diffuse (DHS and CC) in 10/13 patients. After 70 years old (n=9/22), there were a majority of IBM (n=6/9) and all cases of IClirm (n=2). Axial involvement was restricted to one group of muscles (DHS or CC) in 5/9 patients. Finally, 77% (17/22) of patients had refractory disease and required a second line treatment (e.g. immunoglobulins). All of these results are summarized in the Figure 1.

**ANTI-NOR90 ANTIBODIES IN THE SETTING OF CONNECTIVE TISSUE DISEASE: CLINICAL SIGNIFICANCE AND COMPARISON WITH A COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS**

A. Biglia1, E. Dourado2, B. Parderes3, P. Parrochi4, M. R. Pellicci1, G. Zannfrunno5, P. A. Rivera Matias1, P. Martins3, A. Miranda1, J. E. Cabral Da Fonseca6, E. Di Agostina7, D. Carmelli7, G. Emmi8, E. Ros9, R. Bixio8, E. Conticini10, E. Bellis5, C. Brunis3, C. Montecucco4, M. Matucci-Cerinici11, J. Rijos-Serrano12, L. Cavagna1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12.

**Background**: Anti-NOR90 antibodies (aNOR) are a recently described autoantibody with a strong association to dermatomyositis (DM). The test is commercially available in most laboratories.

**Methods**: We retrospectively analyzed 100 consecutive patients with systemic sclerosis (SSc) and 100 consecutive patients with idiopathic inflammatory myopathies (IIMs, DM or IClirm). aNOR was determined in all patients with SSc and in half of patients with IIMs.

**Results**: aNOR were present in 60% of DM patients and 80% of IClirm patients, whereas in SSc patients, aNOR were present in 15% of DM (n=9/60) and in 87.5% of OM (n=28/32).

**Conclusion**: While IM diagnosis is challenging in the presence of inaugural axial involvement, these results highlight the subset of IM to be considered according to the age at first symptoms and the type of axial involvement (e.g., DHS and/or CC). The presence of aNOR is associated with a specific disease pattern, but it remains to be seen if this antibody has clinical significance.

**Disclosure of Interests**: None declared

Background: Anti-NOR90 antibodies are directed against a 90-kD nucleolar protein located in the nucleolar organizing regions (NORs), mainly described in systemic sclerosis (SSc) [1, 2, 3] but reported also in other rheumatologic and oncologic diseases [4, 5, 6]. The clinical correlates of anti-NOR90 antibodies are still to be defined because the cohorts described thus far include a low number of patients.

Objectives: To describe the characteristics of a large cohort of anti-NOR90 antibodies positive patients and compare them with a matched cohort of SSc patients negative for anti-NOR90 antibodies.

Methods: A retrospective analysis was performed on patients positive for anti-NOR90 antibodies referring to participating centres. The concomitant positivity for anti-RNA polymerase III, Th/To, PM-Sc, Ku, and PDGFR antibodies was an exclusion criterion. In all cases the diagnoses, the different organ involvement and related clinical, instrumental and laboratory characteristics were evaluated. The EUROLINE SystemicSclerosisProfile kit from Euroimmun (Lübeck, Germany) was used to detect anti-NOR90 antibodies.

Results: We included 101 patients positive for anti-NOR90 (MF=13/88, mean age 52.5 years). They were mainly classified as SSc (n=38), undifferentiated connective tissue disease (UCTD) (n=21), interstitial pneumonia with autoimmune features (IPAF) (n=32), arthritis (n=30), and limited skin sclerosis (n=24). Anti-NOR90 antibodies were associated with anti-Ro52 antibodies in the 16% of cases, with anticentromere antibodies (n=32), arthritis (n=30), and limited skin sclerosis (n=24). Anti-NOR90 antibodies were associated with anti-Ro52 antibodies in the 16% of cases, with anticentromere antibodies in the 7% of cases, and with anti-Scl70 in the 5% of cases. After excluding patients, anti-NOR90 antibodies were associated with anti-Ro52 antibodies in the 16% of cases, with anticentromere antibodies in the 7% of cases, and with anti-Scl70 in the 5% of cases. After excluding those patients, and considering the isolated anti-NOR90 positivity, 12 patients had SSc, 35 UCTD, and 11 IPAF. The most frequent clinical manifestations were arthritis (n=40), RP (n=37), and sicca syndrome (n=21). Compared to 242 matched SSc without anti-NOR90 antibodies, patients with anti-NOR90 had more frequently joint manifestations and sicca syndrome and less frequently all vasculopathic manifestations (RP, telangiectasia, pitting scars, acral ulcers), dysphagia and fibromyalgia.

Conclusion: Our study shows that anti-NOR90 antibodies are more commonly observed in females, and clinically associated with the occurrence of arthritis/sialalgias, sicca syndrome and RP. In more than 50% of cases they may be found with other autoantibodies, such as the anti-Ro52, the anticientromere, and the anti-Scl70 antibodies. Anti-NOR90 seems to play an accompanying role in the context of CTDs, and has an antimicrobial effect. Despite its generalized use among SSc patients, this approach can be considered as a possible treatment for RP secondary to SSc.

POSO865

THE EFFECT OF SILVER FIBER GLOVES ON RAYNAUD’S PHENOMENON IN PATIENTS WITH SYSTEMIC SCLEROSIS: A DOUBLE-BLIND RANDOMIZED CROSS-OVER TRIAL.

1 Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2 Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 3 Maasstad Ziekenhuis, Rheumatology and Clinical Immunology, Rotterdam, Netherlands; 4 Zuyderland MC, Rheumatology, Heerlen, Netherlands; 5 Haga Teaching Hospital, Rheumatology, The Hague, Netherlands

Background: Over 90% of patients with systemic sclerosis (SSc) experience Raynaud’s phenomenon (RP), which strongly influences quality of life. Therapeutic options of RP include drug treatment and general lifestyle measures such as smoking cessation and avoiding cold by wearing warm clothes and gloves including electrically heated gloves or silver fiber gloves. Clinical observations suggest an additional benefit of silver fiber gloves compared to normal gloves. Silver is thought to help by reflecting heat back into the hands allowing less heat to escape and has an antimicrobial effect. Despite its generalized use among SSc patients, no objective evidence regarding its superiority for RP over normal gloves exists.

Objectives: To evaluate the added value of 8% silver fiber gloves compared to normal gloves in the treatment of patients with RP secondary to SSc.

Methods: This was a multicenter double-blind randomized cross-over trial in which 8% SSc-patients (RP) were randomized in two sequences: 8% silver fiber gloves in period 1 and normal gloves in period 2 or vice versa; each period lasted six weeks. To
reduce bias of interindividual differences and external factors (e.g. temperature), a cross-over design was performed in the Netherlands during the winter months. The primary outcome was the triweekly Raynaud Condition Score (RCS), a scale from 1 (no symptoms) to 10 (extreme symptoms). A linear mixed model was used with RCS as dependent and type of gloves as independent variable, adjusted for baseline RCS. Secondary outcome measures included number of RP attacks, RP attack duration, Health Assessment Questionnaire (HAQ-DI) and vascular complications. Secondary outcomes were also analyzed with linear mixed models. All analyses were performed and interpreted before unblinding.

Results: The BS included SSc patients who had a mean age of 60 (SD:12), 80% were female, 60% had limited cutaneous SSc and 67% used vasoactive medication. Ten patients prematurely ended the study due to various reasons, most notable: allergic reaction to gloves (n=2). At baseline, mean RCS was 6.43 (SD 1.6), with silver fiber gloves the mean RCS decreased to 3.91 (SD 2.3) and with normal gloves to 3.90 (SD 2.3) (Figure 1). No statistically significant difference in RCS during follow-up was observed between the silver fiber gloves and normal gloves (β 0.067, 95% CI -0.006 to 0.19), meaning that on the 1-10 scale, silver fibre gloves gave only a 0.067 higher RCS compared to normal gloves (Table 1). For all other secondary outcome measures, we did not find a statistically significant difference between silver fiber gloves and normal gloves, except for the HAQ (β 0.036, 95% CI 0.026 to 0.046; Table 1), which is not clinically relevant. One vascular complication occurred in the silver fiber gloves, compared to three vascular in the normal gloves, which was not statistically significant different (OR:3.2, 95% CI 0.32 to 31.1).

RCS: Raynaud Condition Score; BL: Baseline.

Figure 1. Raynaud Condition Score during the study period

Conclusion: This trial shows that wearing any type of glove decreases the RP burden in SSc patients, but no additional benefit from gloves containing 8% silver fibers compared to normal gloves could be demonstrated. Potentially, less vascular complications may arise in SSc patients wearing silver fiber gloves. Further confirmation of this potential benefit is necessary.

Acknowledgements: The authors would like to thank all participants of this study and Skafit for providing the gloves.

POS0867 COMORBIDITY AND COMPLICATIONS PRIOR TO SYSTEMIC SCLEROSIS DIAGNOSIS: A RETROSPECTIVE COHORT ANALYSIS

D. Khanna1, D. Funst, J. W. Li2, S. Shah1, T. Lesperance, F. A2, B. Lamoreaux1, S. Taylor1, University of Michigan Medical Center, Rheumatology, Department of Internal Medicine, Ann Arbor, United States of America; 2University of California in Los Angeles, Professor Emeritus, Medicine, Los Angeles, United States of America; 3Innity Life Sciences, Research, Deerfield, United States of America; 4Innity Life Sciences, Research, Waltham, United States of America; 5Horizon Therapeutics plc, Pharmacoeconomics & Risk Management, Deerfield, United States of America; 6Horizon Therapeutics plc, Clinical Development, Deerfield, United States of America; 7Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; 8Horizon Therapeutics plc, Health Economics & Outcomes Research, Deerfield, United States of America

Background: Systemic sclerosis (SSc) is a rare autoimmune disease characterized by progressive microvascular damage, collagen deposition and subsequent
fibrosis of the skin and internal organs which contributes to substantial morbidity and premature death.1,2

**Objectives:** The objective was to evaluate the disease burden of SSC patients and their SSC diagnosis.

**Methods:** Patients with SSC were identified in a claims dataset (IBM MarketScan Commercial Database, 2015-2019) using ICD 10 diagnosis codes for SSC. Eligible subjects were required to have > 1 inpatient or >2 outpatient/office claims with a scleroderma diagnosis code on separate days and > 24 months of continuous health plan enrollment without a SSC diagnosis before the first SSC claim (‘index date’) and > 12 months of enrollment after the index date. Overall comorbid disease burden was assessed via the Charlson Comorbidity Index (CCI) 13-24 and 12 months before and 12 months after index date. The prevalence of SSC-related complications for atherosclerosis, pulmonary arterial hypertension (PAH), pulmonary fibrosis (PF), Raynaud’s Phenomenon (RP), and gastrointestinal (GI) complications (e.g., GERD, dysphagia, etc.) were identified using ICD codes and reported as percentages for the aforementioned time intervals relative to patients’ index dates.

**Results:** 902 eligible SSC patients were identified for analysis. The mean age at index SSC diagnosis was 54.3 years and 84.7% of patients were female. Mean CCI scores 13-24 months before, 12 months before, and 12 months after index SSC diagnosis were 0.84, 1.13 and 1.30, respectively. From the time points 13-24 months before, 12 months before, and 12 months after index SSC diagnosis, increasing rates were also observed of atherosclerosis, PAH, PF, RP, and GI complications (Table 1).

**Conclusion:** Results from this analysis suggests that SSC-related sequelae are present at least two years prior to SSC diagnosis and rates of these complications increased markedly over time. Patients’ overall comorbid disease burden also worsened substantially over this period, likely because of these complications. The internal organ involvement is likely under reported due to requirements to link each diagnosis with an ICD-10 code. These data indicate the significant burden of SSC, prior to and after diagnosis, highlighting the need for awareness, prompt diagnosis, and effective therapies for SSC and its related complications.

THE DEVELOPMENT OF THE LINEAR CRISIS; A CLINICAL AND PATIENT MEANINGFUL ANCHOR TO THE ACR-CRISS IN SCLERODERMA.

L. A. Bissel 1,2, D. Furst 1, S. Johnson 1, P. Hansen 1, E. Recalde 1, D. Khanna 1, F. Del Galdo 1 on behalf of Linear Crisis. 1Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 2University of Leeds, Leeds Institute of Rheumatism and Musculoskeletal Medicine, Leeds, United Kingdom; 3University of California, Department of Rheumatology, Los Angeles, United States of America; 4University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; 5University Health Network & Sinai Health Systems, Toronto Scleroderma Program, Toronto, Canada; 6University of Otago, Department of Economics, Otago, New Zealand; 7World Scleroderma Foundation, Basel, Switzerland; 8University of Michigan, Division of Rheumatology/Department of Internal Medicine, Ann Arbor, United States of America

**Background:** The ACR Composite Response Index in Systemic Sclerosis (ACR-CRISS) is one of the first composite outcome measures in diffuse cutaneous Systemic sclerosis (dcSSc). It relies on validated clinical domains selected through a data-driven methodology; however, it only provides a probability of response and is unable to differentiate between patients who do not improve and who worsen respectively.

**Objectives:** To improve the clinical interpretation of the ACR-CRISS by creating a continuous ranked score of clinically and patient meaningful changes of its individual measures.

**Methods:** Following OmerACT guidelines for outcome measurement development, relevant stakeholders were identified from 5 continents, including 100 physicians with proven experience in managing patients with dcSSc and 100 patients with dcSSc who have participated in at least one clinical trial. An adaptive joint analysis survey based on the PARRIKLA method and implemented using 1000minds software was administered. Patients and doctors were asked to choose which of two hypothetical patients had a better or worse outcome according to Minimally Clinically Important Differences (MCID) in two domains at a time from FVC, HAQ-DI and mRSS and the presence of organ failure. These pairwise choices were analysed to rank and weight the MCIDs against each other. With patient and public involvement, utilising a ‘think aloud’ approach, a video tutorial was produced explaining the objectives and process of the adaptive survey to the participants.

**Results:** Eighty rheumatologists and 80 patients with dcSSc completed the survey, which ran from June 2020 to January 2021. From the survey, relative weights for the 4 domains, reflecting their relative importance with respect to improving and worsening outcomes, were determined. A continuous composite ranked score reflecting the relative weighting of the individual outcome measures (Ranked Composite Important Difference, RCID) was developed accordingly (Table 1). The score ranges from -1 (worst possible outcome) to 1 (best possible outcome), in patients who experience no organ failure and do not meet any MCID in any of the 3 domains scoring 0.

**Conclusion:** This collaborative process using a novel, robust methodology and involving both rheumatologists and patients has created a clinically and patient meaningful composite score that can be used as an anchor to the ACR-CRISS, or other clinical outcomes. Performance against the ACR-CRISS and revised CRISS in randomised controlled trials and in observational cohorts will determine the clinical value of the RCID.

Background: Immune pathways have been implicated in both systemic sclerosis (SSc)-related interstitial lung disease (ILD) and idiopathic pulmonary fibrosis (IPF). Determination of blood cytokine differences in these two disorders need to be elucidated to better understand potential biological processes and common pathogenic pathways.

Objectives: This study compared 87 circulating cytokine levels amongst healthy controls and both SSc-ILD and IPF. There was also exploration of the association between cytokine levels and disease progression based on the annualized rate of decline of forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO).

Methods: Levels of 87 plasma cytokines were measured using commercial panels for consecutive SSc-ILD, IPF, and healthy individuals recruited at a Canadian tertiary-care center. Pulmonary function tests were performed as clinically indicated every 3-12 months. Cytokine levels are compared using the Wilcoxon rank sum test for two samples pairwise. The association between differentially expressed cytokines with both percent predicted annualized FVC and DLCO change was assessed within each disease group using multiple linear models adjusted for age, sex, baseline FVC, and immunosuppressive or anti-fibrotic treatment at sampling. Correction for multiplicity of testing was by Holm's method.

Results: There were 19 healthy controls, 40 SSc-ILD, and 17 IPF participants with clinical features shown in Table 1. Eotaxin-1 and interleukin 6 (IL-6) were significantly elevated in both SSc-ILD and IPF compared to healthy controls (Figure 1). SSc-ILD had significantly lower soluble epidermal growth factor receptor (sEGFR) and higher levels of both soluble tumor necrosis factor receptor type II (sTNFRII) and soluble vascular endothelial growth factor receptor-1 (sVEGFR1) compared to healthy controls. IPF cases were distinguished from healthy controls by significantly higher monocyte chemotactic protein-1 (MCP-1) and monokine induced by gamma interferon (MIG) when compared to healthy controls (Table 1). Significant association was found for any of the cytokines with ILD progression based on annualized rates of either FVC or DLCO change.

Conclusion: Differences in seven circulating cytokines between healthy controls with both SSc-ILD and IPF show evidence of immune system activation. All seven cytokines have a role in immune cell extravasation and pro-fibrotic signalling, which provides further evidence of immune pathways involved in pulmonary fibrosis. Further studies will be pursued of longitudinal change of these biomarkers for halting or slowing disease progression and improving response to treatment.

DIAGNOSTIC ACCURACY OF POWER DOPPLER ULTRASONOGRAPHY FOR THE DIAGNOSIS OF IDIOPATHIC INFLAMMATORY MYOPATHIES.

E. Conticini1, P. Falsetti1, M. D’alessandro2, S. Grazzini1, C. Baldi1, M. Bardelli1, S. Gentileschi1, F. Bellissai1, G. Biasi1, R. D’alessandro1, E. Garcia Gonzales1, N. Volpi1, M. A. Mazzeli1, E. Bargagli2, L. Cantarini1, B. Fредiani1. 1University of Siena, Rheumatology Unit, Siena, Italy; 2University of Siena, Diagnostic Imaging Unit, Siena, Italy

Background: No clear-cut guidelines exist about the use of imaging procedures for the diagnosis of idiopathic inflammatory myopathies (IIM). Similarly, conflicting, and scanty data exist about Power Doppler Ultrasonography (PDUS) in this subset of patients. In this regard, we recently proposed (1) a 0-3 grey scale (GS) and Power Doppler (PD) score in a cohort of patients affected by IIM, evidencing a positive, statistically significant, correlation for PD and oedema and disease activity.

Objectives: The aim of this study was to assess the diagnostic accuracy of our score in IIM patients compared to a control group.

Methods: We prospectively collected, since July 2020 to December 2021, all patients evaluated in Vasculitis and Myositis clinic, Rheumatology Unit, University of Siena, with a recent diagnosis of IIM, as well as patients with a previous, definite diagnosis of IIM and evaluated during follow-up or referred from other centres for a second opinion. As control group, we collected all patients affected by amyopathic dermatomyositis (DM) or who underwent myositis immunoblot or muscle biopsy for proximal limbs weakness but eventually received a diagnosis other than IIM. All patients underwent US examination of both thighs in axial and longitudinal scans.

Results: Forty-five IIM patients (11 anti-synthetase syndrome, 20 DM, 12 PM, 2 scleromyositis) and twenty-six controls were included. During the observational period, 7, 8, 1 and 1 patients underwent PDUS twice, three, four and five times, respectively.

Assessing area under the receiver operating characteristic (AUROC) curve analysis, IIM patients and control group were distinguished according to PD sum. Oedema sum, atrophy sum and CRP values (Figure 1a). The best cut-off value for PD sum values was 0.5 (70.2% SE and 83.3% SP), for Oedema sum 1.5 (74.5% SE and 79.2% SP), atrophy sum 0.5 (63.4% SE and 65.4% SP) and CRP was 0.22 mg/dL (61.5% SE and 75% SP).

Figure 1.

Stratifying IIM population into two groups according to disease activity (PhGA≥2), AUROC curve analysis allow to distinguish these groups according to PD and oedema sum and CRP values (Figure 1b) and the best cut-off values was 1.5 (69.6% SE and 76.9% SP), 2.5 (52.2% SE and 92.3% SP) and 0.55 mg/dL (66.7% SE and 88.9% SP), respectively.

Testing the IIM group versus control as dependent variable by logistic regression, with PD sum, oedema sum, atrophy sum, CRP, CPK and myoglobin as independent variables, the AUROC was 0.976. From the probability associated with the Chi-square tests, the Type II analysis showed the variable that most influences the IIM diagnosis was PD sum and oedema sum (p=0.017 and p=0.013, respectively) (Figure 1c).

Conclusion: GS and PDUS have proven an overall good diagnostic accuracy in distinguishing between IIM and myositis mimicker. In particular, even low values of PD sum (1.5) display a good sensitivity and specificity and, together with oedema, elevated CRP values and myositis-specific and associated antibodies, may be considered a reliable tool for a definitive diagnosis of IIM.

Background: Systemic sclerosis (SSc) is characterized by chronic inflammation that leads to damage of the vascular endothelium and excessive collagen deposition in several target organs (1). The interaction of interleukin 2 (IL-2) with the corresponding receptor (IL-2R) is involved in the regulation of autoimmune processes (2). The shedding product of the IL-2R alpha chain, soluble IL-2 receptor (sIL-2R, CD25), is able to either reduce or enhance immune responses (2). Previously, elevated serum levels of sIL-2R were found in the bronchoalveolar lavage of SSc patients with interstitial lung disease (SSc-ILD) as well as serologically in patients with early SSc, and thus suggested to be a biomarker for clinical development of SSc (3,4).

Objectives: To examine concentrations of sIL-2R in patients with SSc and analyse their association with clinical and serological parameters.

Methods: To determine if serological levels of sIL-2R serve as predictor of clinical complications in SSc, sera were analysed (limited cutaneous SSc (lcSSc) n=160; diffuse cutaneous SSc (dcSSc), n=137) using a sandwich ELISA. Clinical data (pulmonary fibrosis, PAH, mRSS, therapy) and serological markers (hs-NT-proBNP, neutrophil counts, creatinine, hs-troponin T, creatinine kinase, beta2-microglobuline) were assessed at the time of serum sampling and up to 48 months after baseline. Clinical progress was defined by the need to change therapies.

Results: Patients with dSSc presented elevated levels of sIL-2R compared to SSc (dcSSc: 673±428 U/ml vs. 646±473 U/ml, p<0.0001). In SSc general, sIL-2R levels correlated with beta2-microglobuline (r=0.8161, p=0.0001, ROC-AUC:0.8428), hs-CP (r=0.4091, p<0.0001, ROC-AUC:0.7110, NT-proBNP (r=0.2610, p<0.0001, ROC-AUC:0.6793), neutrophil count (r=0.2749, p=0.0001) and hs-troponin T (r=0.4548, p<0.0001, ROC-AUC:0.8729). Further, sIL-2R levels discriminated normal from pathological levels of hs-troponin T (sensitivity 80.0%, specificity 80.1%). Using Log-rank test and Mantel-Cox proportional hazard modeling, sIL-2R levels above 745 U/ml were associated with early progress in SSc. 80.0% of SSc patients with a CRP ≥5 mg/l had a worse disease course with a hazard ratio (HR) 3.45 (95% CI 2.24 to 5.30) compared with patients with CRP <5 mg/l (HR 1.19, 95% CI 0.85 to 1.66, p=0.29).

Conclusion: In SSC, serum levels of sIL-2R could be of diagnostic value by identifying clinical progress. Its role in pathophysiology, especially with regard to disease manifestations such as cardiac involvement needs to be investigated in more detail.

Background: The use of glucocorticoids (GC) in systemic sclerosis (SSc) is controversial (1). Despite the lack of solid evidence about their efficacy in SSc, GC are prescribed to control musculoskeletal symptoms, or in combination with immunosuppressive drugs (1). The extent of GC use over the disease course has been poorly investigated in SSc. As long-term GC exposure is detrimental even at low doses, estimating the use of GC and identifying patients at high risk for long-term utilization is crucial to plan better management of SSc patients.

Objectives: To estimate the prevalence of GC use in a large sample of SSc patients, identify patient characteristics associated with time spent on GC, and describe the variations in GC utilization over time and across main recruiting countries.

Methods: We included SSc patients with at least one visit in the EUSTAR database from January 2013 (defined as baseline visit) to November 2019. We analyzed the prevalent (in the main feature of patients using GC at baseline, and the exposure to GC over time. Multivariable linear regression identified patient characteristics associated with the proportion of follow-up time spent on GC. Time trends and variations in GC utilization across main recruiting countries were explored. Missing data were imputed using multiple imputation with chained equations.

Results: The 9819 patients included were mostly females (86%), with limited cutaneous (lc) SSc (73%), and median age of 58 years. At baseline, 2769 (34%) patients diffuse cutaneous (dc) SSc vs. 29% lcSSc were on GC, at a median dose 7.5mg/day [IQR 5-9 mg]. Only 2% of patients (n = 162) received >15mg/day prednisone equivalent. GC were mostly used in combination with an immunosuppressive drug, mainly methotrexate (29%), cyclophosphamide (21%), and mycophenolate mofetil (21%). Compared to patients not receiving GC at baseline, GC users were more frequently males (18% vs. 14%), anti-Scl70 positive (42% vs. 27%), had more synovitis (21% vs. 8%), pericardial effusion (9% vs. 5%), C-reactive protein elevation (33% vs. 19%), increased CK (12% vs. 8%), and significantly lower respiratory volumes. In the subgroup of patients with an early disease duration (< 3 years from first non-Raynaud's onset) (n = 1896), the prevalence of GC users was similar to that observed in the entire sample, but more dcSSc patients were receiving GC in combination with immunosuppressors. On average, GC users spent 25% of their follow-up time (median 33.2 months) on GC, with no significant difference between lcSSc and dcSSc patients. Notably, 971 (33%) and 647 (22%) patients followed-up for >1 year received GC for >6 or >12 months, respectively. In multivariable analysis, patient characteristics poorly explained the variability of GC exposure (adjusted-R² = 0.062, P < 0.001). The yearly proportion of glucocorticoids users (2013 - 2018) gradually decreased from 45% to 35% in 2018). The rate of GC users and the median proportion of follow-up time spent on GC was highly heterogeneous within and across countries.

Conclusion: GC are widely and long-term used in SSc, mainly to patients with dcSSc, with significant between- and within-country differences. A gradual decrease in their utilization over time is observed.

REFERENCES:
Objectives: To visualize the patterns of PAP elevation in SSc and to identify the clinical characteristics of each trajectory, by applying latent trajectory modeling for PAP measured repeatedly by echocardiography.

Methods: This was a multicenter, retrospective cohort study conducted at four referral hospitals in Kyoto, Japan. Patients with SSc who visited the study site between April 2008 and March 2021 and had at least three echocardiographic measurements of systolic pulmonary arterial pressure (sPAP) were included in this study. Follow-up concluded in March 2021.

A group-based trajectory model was applied to the change in sPAP over time, and individual patients were classified into distinct subgroups that followed similar trajectories. The number and shape of the trajectories were estimated based on adequacy, goodness of fit, parsimony, and interpretability of the model. Clinical plausibility was assessed by comparing PH-free survival, i.e., time to either PH or death, for each trajectory. Multinomial logistic regression analysis was performed for baseline clinical characteristics associated with trajectory assignment.

Results: A total of 236 patients with a total of 1097 sPAP measurements were included. We identified five trajectories following the quadratic function as “rapid progression (n=9, 3.8%)”, “early elevation (n=30, 12.7%)”, “mid elevation (n=54, 22.9%)”, “late elevation (n=24, 10.2%)”, and “low stable (n=119, 50.4%)”.

Each trajectory, in this order, showed earlier elevation of sPAP and shorter PH-free survival (Figure 1). In the multinomial logistic regression, the “low stable” as reference, cardiac involvement was associated with the “rapid progression” (adjusted odds ratio [OR] 28.9, 95% CI 3.21–259.5), diffuse cutaneous SSc was associated with the “early elevation” (OR 4.08, 95% CI 1.27–13.1), anti-centromere antibody positive was associated with the “mid elevation” (OR 4.50, 95% CI 1.11–18.2), and older age of onset was associated with the above three trajectories.

Conclusion: The pattern of changes in pulmonary artery pressure over time in SSc can be classified into five distinct trajectories. Each trajectory differed in baseline clinical characteristics and outcomes.

OBJECTIVES:

However these autoantibodies may be found in up to 10% of SSc patients (2). Antibodies is primarily associated with mixed connective tissue disease (MCTD), mortality in systemic sclerosis (SSc) patients (1). The presence of anti-U1RNP antibodies in univariate analysis. Associations between anti-U1RNP status and disease features were compared between anti-U1RNP positive and anti-U1RNP negative patients. Upper-gastrointestinal involvement (GI) is associated with more severe interstitial lung disease in patients with systemic sclerosis (SSc-ILD).

RESULTS:

We included in our study 334 patients. The study outcome was the presence of SSc-ILD on high-resolution computed tomography. Two sets of predictors were identified based on their potential association with GI. The first set contains the following variables available in the EUSTAR registry: esophageal symptoms (dysphagia and reflux), stomach symptoms (early satiety, vomiting), intestinal symptoms (diarrhea, bloating and constipation), malabsorption syndrome, body-mass-index (BMI) and proton pump inhibitor therapy; calcium channel blocker therapy and immunosuppressive therapy. In the second set, we replaced the first three EUSTAR variables of the first set with the presence of the U1RNP antibody.

CONCLUSION:

Our results from the EUSTAR database show that SSc patients positive for anti-U1RNP antibodies have more impaired baseline lung function but similar rate of progression during follow-up. This suggests that early stages might be important in RNP+ SSc-ILD patients who may require specific management and follow-up.

LUNG ULTRASOUND FOR INTERSTITIAL LUNG DISEASE DETECTION IN A COHORT OF SYSTEMIC SCLEROSIS PATIENTS: ROLE OF B-LINE AND PLEURAL LINE MODIFICATIONS

D. M. Reza Beigi1, G. Pellegrino1, M. Loconte1, G. Paone2, F. R. DI Ciommo1, M. Cadar1, I. Bisconti1, K. Stefanantoni1, F. Conti1, V. Riccioli1, Sapienza University of Rome, Department of Internal Medicine, Anesthesiology and Cardiovascular Sciences, Rome, Italy; 2Sapienza University of Rome, Department of Cardiovascular and Respiratory Sciences, Rome, Italy

Background: Lung ultrasound (LUS) is a technique that showed a high diagnostic accuracy for interstitial lung disease (ILD) detection in systemic sclerosis (SSc) patients and currently in progress of standardization. Traditionally, B-lines represented the finding of ILD, with the ≥10 cut-off reported by Tardella et al. resulting to be closely related to moderate ILD detected on high resolution computed tomography (HRCT). Recently, Fairchild et al. proposed novel LUS criteria for the evaluation of pleural line, disclosing high accuracy and reproducibility.

Objectives: To compare B lines cut-off with novel pleural line criteria and the respective associated variables.

Methods: We enrolled 55 consecutive patients affected by SSc according to ACR/EULAR 2013 criteria who underwent respiratory functional tests (RFTs) during 2021, excluding smokers and those with arterial pulmonary hypertension. Twenty-four of them carried out a HRCT during a 6-months’ time. In the same day of RFTs, two certified blinded operators performed LUS for each patient applying the 14-areas technique proposed by Gutiérrez et al., looking for the presence of total ≥10 cumulative B lines and the fulfilling of Fairchild’s criteria for pleural line. A 3-13 MHz operating linear probe was used. Clinical-demographic data and ongoing therapies were collected.

Results: Among 55 total SSc patients, the agreement between the two operators for Fairchild’s criteria was almost perfect (Cohen’s kappa (κ) =0.81) and substantial for ≥10 cumulative B-lines count (κ=0.74). Fairchild’s criteria showed a higher diagnostic accuracy compared with ILD detected on HRCT, with an overall specificity (SP) and a positive predicted value (PPV) of 100% (Table 1). A negative correlation emerged between total lung capacity values (TLC%) and both B lines cut-off (first operator: (IO): p<0.04, r=-0.27; second operator (IO): p=0.042, r=-0.28) and pleural line criteria (IO: p=0.009, r=-0.35; IO: p=0.008, r<0.36), but only the latter negatively correlated also with forced vital capacity values (FVC%) (IO: p=0.04, r<0.27; IO: p=0.03, r<0.28). The ≥10 total B lines amount correlated positively with concurrent mycophenolate therapy (IO: p=0.09, r=0.28; IO: p=0.005, r<0.37) and negatively with anti-centromere antibodies (IO: p=0.002, r<-0.3; IO p=0.009, r<0.34). The presence of digital ulcers showed a positive correlation with pleural line criteria (IO: p=0.03, r=0.29; IO: p=0.005, r<0.37), with a significant association on multivariate analysis (IO: p<0.03, IO: p<0.01).

Table 1. Overall sensitivity, specificity, positive predictive value, negative predictive value of LUS compared to ILD detected on HRCT. CI 95% confidence interval.

Conclusion: We confirmed the feasibility and reliability of Fairchild’s recently proposed pleural line LUS criteria, that showed a higher diagnostic accuracy versus ≥10 cumulative B-lines count for ILD detected on HRCT, presenting SP and PPV values of 100% in SSc. Furthermore, these LUS features seem to differently associate with other aspects of the disease such as autoantibody specificity and vascular lesions, thus deserving future deeper evaluations. For the first time, we found that Fairchild’s criteria were associated with a clinical variable such as digital ulcers. Our results highlight the relevance of pleural line evaluation for ILD detection in SSc on LUS and its possible role towards a standardization of this diagnostic technique.

Disclosure of Interests: None declared

treatment. Longitudinal study included patients with at least one follow-up visit. Patients were classified as treated if they received a potential ILD modifying drug (immunosuppressant, biologic or nintedanib). Treated and untreated patients were compared at baseline. Progression in the untreated group was defined as (i) forced vital capacity (FVC) decline from baseline of ≥10% or (ii) an FVC decline of 5-9% in association with a decline in diffusing capacity for carbon monoxide (DLCO) of ≥15%, or (iii) start of a ILD modifying treatment during follow-up. In the untreated group, patients who progressed at any time were compared with patients with stable disease during follow-up. Multivariable logistic regression was performed to identify (i) factors associated with non-prescription of a treatment in ILD patients at baseline and (ii) factors associated with progression in the untreated patients. Covariates were selected according to clinical experience and literature evidence.

Results: Among 496 patients included in our cohort, 209 (42%) patients had ILD on baseline HRCT: 48/209 (23%) were males, median disease duration 8 [IQR: 4-12] years, 67/209 (32%) of diffuse cutaneous subset and 86/209 (41%) had anti-ScI70 antibodies. Among them, 142/209 (68%) did not receive any potentially ILD modifying treatments at baseline. Untreated patients were older (59 vs. 54 years), had a longer disease duration, were less frequently smokers, had more frequently anticentromere antibodies and lower levels of CRP. They had more frequently a limited extent (<20%) of lung fibrosis on HRCT, higher FVC (97.02 ±19.76 % vs. 78.29 ±19.23 %) and DLCO (72.10 ±18.97 % vs. 57.57 ±20.81 %), better performances in the 6 minute walking test and were less frequently treated with low dose of glucocorticoids. In multivariable logistic regression, older age (OR: 1.04 [1.01-1.08], p=0.021), a more extensive disease on HRCT (OR: 0.29 [0.09-0.90], p=0.037) and less frequent prescription of glucocorticoids (OR: 0.036 [0.12-0.92], p=0.037) were independently associated with absence of ILD modifying treatment prescription in our cohort. From the 142 untreated patients, 96 were followed-up for 64 [39-96] months. Of these, 56 (58%) patients showed progression of ILD, of whom 43 progressed by lung function parameters. Of these 56 patients, 31 (56%) progressed in the first 18 months. Diffuse cutaneous subtype (OR: 5.26 [1.26-27.62], p=0.031), shorter disease duration (OR: 0.95 [0.90-0.99], p=0.035) and osseopha-geal symptoms (reflux, dysphagia) (OR: 3.51 [1.12-12.18], p=0.036) at baseline were independent predictors of progression during follow-up in untreated patients.

Conclusion: A considerable number of SSc patients with ILD are not treated in clinical practice, in particular patients with limited cutaneous SSc, older age and an overall less extensive ILD. However, during a follow-up of 5 years, contrary to the common belief, about 60% of the untreated patients showed ILD-progres-sion. The diffuse cutaneous subtype, shorter disease duration and osseopha-gelogal symptoms at baseline characterized these patients. With the development of effective and safe therapies for SSc-ILD, our results support a change in practice for ILD patients for treatment.

The table presents secondary endpoints at week 24 for the comparison of Brodalumab and Placebo groups. The table includes the mean and standard deviation (SD) for different variables, as well as the difference between groups, 95% confidence interval (CI), and p-value. The variables include CRiSS score, FACIT-Fatigue subscale score, J-HAQ-DI*, CGA*, and POS0882.

**Background:** Systemic Sclerosis (SSc) is a rare disorder associated with hand radiological damage, typically acro-osteolysis (AO) and calcinosis, and increased risk of osteoporosis [1, 2]. Recently, high resolution peripheral quantitative computed tomography (HR-pQCT) has contributed to advances in noninvasive imaging in patients with osteoporosis, inflammatory arthritis, and osteoarthritis. Due to its three-dimensional, high resolution (82 μm³) imaging of calcified structures, HR-pQCT might be beneficial in detecting and describing early AO changes, and had significantly shortened DPs and soft tissue extending distally from the most distal part of DPs (ST) were measured in a three-dimensional multiplanar reconstruction. Volumetric BMD and bone microarchitecture were analyzed using HR-pQCT scanner specific software at the distal radius.

**Objectives:** To study the association between different types of hand radiological damage, typically acro-osteolysis (AO) and calcinosis, and increased risk of osteoporosis [1, 2].

**Methods:** This single-centre, cross-sectional study included patients with SSc according to ACR/EULAR 2013 criteria from the outpatient clinic at the Department of Rheumatology, Aarhus University Hospital, between 1st of October and 21st of December 2021. All patients underwent HR-pQCT (Xtreme CT, Scanco Medical AG) scan of the dominant hand’s distal radius and both hands’ distal phalanges (DP) on the 2nd to 4th finger. A semiquantitative scale of 0-3 was composed to quantify the degree of soft tissue calcifications identified in the 2nd to 4th finger (Figure 1).

**Results:** We included 40 patients with SSc of whom 13 had AO according to hand radiographs. The two groups had a similar distribution regarding age, sex, and BMI. Patients with AO had longer disease duration compared to patients without AO (med. 17 yrs. (IQR 7-20 yrs.) vs 3 yrs. (IQR 2-7 yrs.) (P<0.001)). One patient was excluded from the BMD analysis, and 21 (9%) DP and 20 (8%) soft tissue measurements were excluded due to motion-induced image degradation.

A higher prevalence of calcinosis was observed in patients with AO (n=11/13) compared to patients without AO (n=11/27) (P<0.05). Patients with AO had more or larger calcifications according to our grading system (med. 1-3) vs 0 (IQR 0-1) (P<0.001). Grade 3 changes were observed in patients with AO (n=6/13, 46%) but not in patients without AO. Furthermore, the patients with AO had shorter DPs on the 2nd finger on both hands (right P<0.001; left P<0.01) and less ST on the right 2nd, 3rd, and 4th (P<0.01; P<0.01) as well as the left 3rd (P<0.05). We observed no differences between bone volume ratio (med. 0.101 (IQR 0.069-0.143) vs 0.126 (IQR 0.104-0.141) (P=0.38)), cortical BMD (med. 828 (IQR 774-853) vs 842 (IQR 762-882) (P=0.50)), or trabecular BMD (med. 121 (IQR 82-172) vs 151.6 (IQR 125-170) (P=0.38)). Yet, the patients with AO had a lower number of trabeculae (P<0.05) and a lower homogeneity of spacing between trabeculae (P<0.05) at distal radius.

**Conclusion:** Patients with AO had a higher number of calcifications and had significantly shortened DPs and ST on several fingers assessed by HR-pQCT. A potential superiority compared with hand radiographs is yet to be established. Still, the modality could eventually prove useful in detecting and monitoring small hand lesions and facilitate earlier diagnosis and proper treatment among patients with SSc.

RT-FDC-based biophysical phenotyping of circulating immune cells in SSc, RA and healthy controls.

Methods: 63 SSc patients, 59 RA patients fulfilling the respective ACR/EULAR classification criteria and 18 age- and sex-matched healthy controls were included in the study between 05.2019 and 09.2021. Peripheral blood mononuclear cells (PBMC) were isolated and immunolabelled. PBMC subpopulations were identified in RT-FDC by standard gating strategies based on their marker expression and their deformation, Young’s modulus and area were determined.

Results: We identified SSc-specific changes (changes in SSc, but not in RA compared to healthy controls) in the biophysical properties of NK, NK-like cells and monocyte subpopulations in SSc. Monocytes subpopulations had a higher deformation and cross-sectional area and/or more compact intra-donor distributions of these parameters in patients with active disease and with extensive skin or lung fibrosis in comparison with patients with stable disease and limited skin or lung fibrosis, respectively. All monocytes subsets were stiffer in patients with progression of skin or lung fibrosis at the time of measurement in comparison with a previous visit. The deformation and area of intermediate monocytes could also identify patients at risk for future progression of lung fibrosis. Changes in biophysical properties of monocytes can indicate, beyond fibrotic burden, clinical manifestations of microvascular damage such as active digital ulcers and pulmonary arterial hypertension.

Conclusion: We demonstrated that changes in the biophysical properties of monocyte subsets are associated with multiple clinical outcomes in SSc such as disease activity, severity of fibrotic or microvascular manifestations and risk of progression and might thus directly reflect SSc-specific pathologic immune cell activation. Our results thus provide first evidence that RT-FDC-based biophysical phenotyping of circulating immune cells may be a useful tool for clinical evaluation of SSc patients.

POSO884 DESCRIPTIVE EPIDEMIOLOGY OF SEVERE CARDIAC INVOLVEMENT IN SYSTEMIC SCLEROSIS: A BICENTRIC RETROSPECTIVE STUDY ON 459 PATIENTS

E. Bories1, S. DE Almeida Chaves2, T. Portel3, L. Alric1, L. Astudillo1, F. Gaches2, M. Michaud3, F. Catros2, G. Prevot4, L. Sailler1, D. Adoue1, O. Lairez5, G. Pugnet1, P. Xanthouli1,2, O. Gordjani1, C. Eichstaedt1,3, N. Benjamin1, B. Egenlauf1, S. Harutyunova1, A. Marr1,4, V. Theobald1, N. Milde1, C. Nagel1, N. Blank2

Background: The prevalence of cardiac involvement in systemic sclerosis (SSc) varies in the literature between 3% and 44% and represents a leading cause of morbidity in this disease. The incidence and severe cardiac involvement and the factors associated with the occurrence of severe cardiac involvement are not known in the literature.

Objectives: The objective of this study was to evaluate the incidence, prognosis and factors associated with the occurrence of severe cardiac involvement during SSc course.

Methods: We conducted a retrospective, bi-centric study from January 1, 1966 to December 31, 2018. The patients included had a diagnosis of SS according to the ACR/EULAR 2013 criteria. The primary endpoint was the occurrence of severe cardiac involvement. Cardiac involvement was defined by the presence of at least one of the following elements: death of cardiovascular origin, left ventricular ejection fraction less than or equal to 50%, abnormality of at least 3 measurement parameters of diastolic function, global longitudinal strain less than or equal to 18 in absolute value, ventricular tachycardia, ventricular extrasystoles requiring intervention or elevated troponin. Patients with associated myositis and whose only criterion for cardiac involvement was elevated troponin were not included in the group with cardiac involvement. Severe cardiac involvement was defined by the occurrence of hospitalization for cardiovascular reasons or by death of cardiovascular origin. Unvariable and multivariable Cox-proportional hazards models were used to determine variables associated with severe cardiac involvement occurrence. Survival analysis was performed using the Kaplan-Meier method with comparisons performed using the log rank test.

Results: Four hundred and fifty-nine patients with SSc were included and were followed for a median of 71 years [3.1; 13.3]. The median age of our population was 54 years old. There were 81% of women. 77% of patients had limited cutaneous SSc, 15% diffuse cutaneous SSc and 8% SSc sine scleroderma. Of the 459 patients, 105 (23%) had cardiac involvement and 56 (12%) severe cardiac involvement. The incidence of severe cardiac involvement was 2.42 per 100 patient years. Ninety-six hospitalizations were recorded, including 40 (42%) for acute heart failure, 19 (20%) for arrhythmia, 5 (5%) for acute pericarditis, 6 (6%) for acute myocarditis and 14 (15%) for coronary artery disease (acute coronary syndrome, myocardial infarction or coronary revascularization). The independent factors associated with severe cardiac involvement in SSc were age over 54 years at SSc-diagnosis (OR = 3.21 95% CI [1.73; 5.95], p < 0.001), the presence of myositis (OR = 5.01 95% CI [1.89; 13.28], p = 0.001), pericardial involvement (OR = 3.79 95% CI [2.05; 7.03], p < 0.001) or scleroderma renal crisis (OR = 4.72 95% CI [2.05; 10.92], p < 0.001). The survival rate of patients with severe cardiac involvement was 70% at 5 years and 53% at 10 years. Patients with severe cardiac involvement had a mortality risk three times greater than patients without severe cardiac involvement, HR = 3.1 (95% CI [1.7; 5.7], p<0.0001) (Figure 1). Pericardial involvement was an independent risk factor for mortality, HR = 2.0 (95% CI [1.02; 4.0], p=0.04).

REFERENCES:

Figure 1. Survival of patients with severe cardiac involvement of systemic scleroderma. HR: Hazard ratio; 95% CI: 95% Confidence interval; Nb at risk: Number at risk

Conclusion: We need to focus our clinical attention on diagnosing and manage cardiac involvement in SSc, as severe cardiac involvement is not uncommon and is responsible for a poor prognosis.

Disclosure of Interests: None declared

POSO885 HYPOCHROMIC ERYTHROCYTES AS PROGNOSTIC INDICATOR OF SURVIVAL AMONG PATIENTS WITH SYSTEMIC SCLEROSIS SCREENED FOR PULMONARY HYPERTENSION

P. Xanthoulis1,2, O. Gordjani3, E. Fischlert1,4, N. Benjamin5, B. Egenlauf6, S. Harutyunova1, A. Marr1,4, V. Theobald1, N. Milde1, C. Nagel1, N. Blank2

Background: Scleroderma-related pulmonary hypertension (SR-PAH) is the leading cause of mortality in systemic sclerosis (SSc). Early diagnosis and treatment of SR-PAH is crucial for improving patient survival. Hypochromic erythrocytes (HE) are a well-known indicator of reduced oxygen saturation, but their role in the management of SR-PAH is not well established.

Objectives: To determine the prognostic value of HE as a marker of mortality in patients with SSc and SR-PAH.

Methods: We performed a retrospective analysis of patients with SSc and SR-PAH from a single tertiary care setting. HE were assessed as a dichotomous variable using a cutoff value of 30%. Kaplan-Meier survival analysis was performed to evaluate the association between HE and mortality.

Results: A total of 100 patients with SSc and SR-PAH were included in the analysis. The median age of the patients was 62 years (range: 26-85) and 70% were female. The median follow-up time was 36 months (range: 6-84). The overall mortality was 32% at 3 years. Patients with HE had a significantly lower survival rate compared to patients without HE (p = 0.03). The median survival time for patients with HE was 24 months compared to 58 months for patients without HE.

Conclusion: Hypochromic erythrocytes are a valuable indicator of mortality in patients with SSc and SR-PAH. Early recognition and intervention for patients with HE may improve survival outcomes.

Disclosure of Interests: None declared

Background: Iron deficiency is frequent among patients with systemic sclerosis (SSc), particularly among those with pulmonary hypertension (PH). First data indicate prognostic importance of hypocromic erythrocytes (HRC) >2% among patients with PH1. Hence, the aim of this study was to investigate the predictive value of HRC in SSC patients screened for PH.

Objectives: The objective of this study was to investigate the predictive value of HRC in SSC patients screened for PH.

Methods: In this retrospective, single-center cohort study SSC patients screened for PH were included. Clinical characteristics, laboratory and pulmonary functional parameters associated with the prognosis of SSC were analysed using uni- and multivariable analysis.

Results: A total of 280 SSc patients were screened, 171 were included in the analysis having complete iron metabolism (79% female, 61±12.9 years of age, 73.2% limited cutaneous SSc, 56% manifest PH and 112 pulmonary fibrosis). The patients were followed for 2.4±1.8 (median 2.4) years. HRC >2% at baseline was significantly associated with worse survival in the uni- (p=0.018) and multivariable analysis (p<0.0001). Overall 34.5% of the patients suffered from iron deficiency and 22% received iron substitution during follow-up. HRC >2% was identified as independent predictor of mortality, for patients with and without pulmonary manifestations of SSC.

Conclusion: This study detected for the first time that HRC >2% is an independent prognostic predictor and can possibly be used as a biomarker among SSC-patients. Further studies are needed to confirm these results.

Background: Interstitial lung disease (ILD) is a common condition in patients with connective tissue disease (CTD). It is associated with increased morbidity and mortality. Rituximab (RTX) has been approved for treatment of RA and some recent retrospective studies suggest that it could be an alternative treatment for patients with CTD-ILD, even in cases that prove refractory to conventional immunosuppressants.

Objectives: To analyze the efficacy and safety of RTX in connective tissue disease associated with interstitial lung disease (CTD-ILD).

Methods: We performed a multicenter, prospective, observational study of patients with CTD-ILD receiving RTX between 2015 and 2020. Patients who had worsening of respiratory symptoms or decline in the pulmonary function tests (PFT) compared to the time of ILD diagnosis were treated with rituximab. The patients were assessed using high-resolution computed tomography and PFT baseline, at 12 months, and at the end of follow-up. The main outcome measure at the end of follow-up was forced vital capacity (FVC)>10% or diffusing capacity of the lungs for carbon monoxide (DLCo)>15% and radiological progression or death. We recorded clinical characteristics, time to initiation of RTX, concomitant treatment, infections, and hospitalization. A Cox regression analysis was performed to identify factors associated with worsening of ILD.

Results: We included 37 patients with CTD-ILD treated with RTX for a median (IQR) of 38.2 (17.7-69.0) months (Table 1). At the end of the follow-up, disease had improved or stabilized in 23 patients (62.1%) and worsened in 7 (18.9%); 7 patients (18.9%) died. Mean PFT values decreased significantly at the start of RTX compared to the date of ILD diagnosis in FVC (72.2[21.3] vs 73.5 [16.9] mg/l;p=0.040) and DLCO-SD (55.2 [15.7] vs 58.3 [16.1] mg/l;p=0.041).

Table 1. Baseline demographic and clinical characteristics of 37 patients with CTD-ILD receiving rituximab.

</table>
significant decline was observed in median FVC (72.2 vs 70.8; $p=0.330$) or DLCO (55.9 vs 52.2; $p=0.100$). The multivariable analysis showed the independent predictors for worsening of CTD-ILD to be baseline DLCO (OR [95% CI], 0.904 [0.8-0.9]; $p=0.015$), time to initiation of RTX (1.01 [1.001-1.02]; $p=0.029$), and mycophenolate (0.202 [0.04-0.8]; $p=0.034$). The incidence rate ratio was 0.21 patient-years.

**Conclusion:** Lung function improved or stabilized in more than half of patients with CTD-ILD treated with RTX. No significant increase in infection rates was observed. Early treatment and combination with mycophenolate could reduce the risk of progression of ILD.

**Disclosure of Interests:** None declared.

**POSO887**

**CHORIORETINAL MICROVASCULAR INVOLVEMENT IN SYSTEMIC SCLEROSIS**

**Methods:** The study aims to evaluate retinal and choroid capillaris microvasculature in a group of SSc patients compared to matched controls (HC) and according to disease characteristics, capillaroscopy findings and pulmonary function tests. Method: WAS assessed through OCTA at the retinal superficial (SCP) and deep (DCP) capillary plexus, at the foveal avascular zone perimeter (FAZP) and at the choroid capillaris (CC) of 30 SSc patients compared to 30 sex- and age-matched subjects without any retinal disease.

**Results:** The SSc patients (age 57.3±10.0, female 86.7%) had diffuse cutaneous skin disease in 30.0% of the cases, an average disease duration of 10.4±7.2 y, and anti-centromere and anti-Scl70 antibody positivity in 40.0% and 30.0% of the cases, respectively. Compared to the HC, SSc showed an impaired VD at SCP (47.7±3.6 vs 59.1±3.5%; $p=0.009$), DCP (50.6±7.4 vs 54.3±5.5%; $p=0.015$), FAZP (48.7±4.55 vs 51.9±3.5%; $p=0.034$) and CC (67.1±2.2 vs 68.6±1.7%; $p=0.05$). Moreover, VD was inversely correlated with the presence of digital ulcers (46.7%), telangiectasia (43.3%) and interstitial lung disease (46.7%) was related to reduced VD at FAZP (46.8±4.1 vs 55.0±4.3%; $p=0.033$), CC (66.1±4 vs 67.9±2.4%; $p=0.004$), and DCP (47.2±6.5 vs 51.9±4.3%; $p=0.004$), respectively. Lastly, the average capillary density on capillaroscopy showed a positive correlation with VD at FAZP ($r=0.474, p=0.008$), DCP ($r=0.414, p=0.023$), and foveal CC ($r=0.482, p=0.007$) and there was also a correlation between CC and both DLco ($r=0.467, p=0.009$) and FVC/DLco ($r=0.436, p=0.004$).

**Conclusion:** The SSc patients in our cohort showed lower ocular vessel density at different levels compared to HC. Furthermore, impaired VD at different levels of the eye correlates with the organ involvement and the degree of digital and pulmonary microvascular impairment. According to those data, the OCTA could be proposed as a biomarker tool to investigate the microvascular abnormalities in SSc.

**POSO888**

**NON-SURGICAL LOCAL TREATMENTS FOR DIGITAL ULCERS IN SYSTEMIC SCLEROSIS: A SYSTEMATIC LITERATURE REVIEW**

**Methods:** A systematic literature review (SLR) of papers describing the use of ln-sT for DU in SSc was performed up to May 2021 according to the PICO framework. References were independently screened by two reviewers who independently assessed the full text of eligible articles and extracted data. Results: Among 790 retrieved references, 12 were included. Median (range) number of patients per study was 9 (7-84), mean age ranging from 37 to 62.5 years. In 541% studies a control group was included. Background systemic therapies are summarized in Table 1. The most studied treatment was botulinum toxin A (BTX). It was used as hand injection in 3 studies (median dose ranging from 90 to 150 U) and as 50 U single finger injection in 1 study. Healing rate after a median time of 8-49 weeks ranged from 71% to 100%. In 2 studies a reduction in VAS pain was observed from 20% to 100%. Transient muscle weakness was the most common side effect in 10% of patients. Amniotic (Am) and hyaluronic acid microparticles (HA) were used in 1 study each. They were associated with a good healing rate, statistically significant for the HyM. Tadalafil 2% cream was studied in 1 study and was associated with a reduction in the median DU number from 1.6 to 1 per patient after a median time of 4 weeks and a reduction by 1.4 point in the 10-mm VAS scale. Vitamin E gel was shown to be associated with a statistically significant reduction in the healing time compared to SoC alone in 1 RCT (13.2 ± 2.7 versus 20.9 ± 3.6 weeks, $p=0.001$). Low-level light therapy, hydrodissection and corticosteroid injection and extracorporeal shock wave (ESW) were evaluated in 1 study each. They were all associated with positive outcomes which was statistically significant only for the ESW. The only negative trial examined dimethyl sulfosilxide and was associated with local toxicity.

**Conclusion:** Our SLR supports interest to develop in-sTs for SSC-DUs. The number of studies is limited and mainly case reports and small single studies are present. Treatments were well tolerated and there was evidence of efficacy for BTA, vitamin E, ESW and HyM in refractory DU. The evidence is not robust and confounding factors (vasodilators background therapies) could impact on the findings. Future research is indicated to conduct larger, well-designed studies.

*Unless otherwise stated. **Statistically significant. ARB= angiotensin receptor antagonist. ACE= ACE inhibitors. APA= anti-platelet agents. CCB= calcium channel blockers. CH= contralateral hand. DRBR= double blind randomized-controlled trial. ETA = endothelin antagonist. IS= immunosuppression. PGE= prostaglandins. PDE-5i= Phosphodiesterase type-5 inhibitors. P = prospective. R = retrospective. SoC= standard of care (as per local protocol).

**Conclusion:** Although EF is a rare adverse effect of ICI treatment, individuals receiving these drugs should be monitored closely for symptoms of EF. Discontinuation of ICI and administration of immunosuppressants may prevent the progression of EF.

POS0889 CASE SERIES OF PATIENTS WITH EOSINOPHILIC FASCIITIS SECONDARY TO IMMUNE CHECKPOINT INHIBITORS THERAPY

Background: Eosinophilic fasciitis (EF), a fibrotic disease that causes inflammatory infiltration in the subcutaneous fascia is clinically characterized by edema and subsequent induration and tightening of the skin and subcutaneous tissue. EF is a rare immune-related adverse event of immune checkpoint inhibitors (ICI).

Objectives: This article aims to investigate the clinical features of ICI-related EF and to improve the understanding of the disease among rheumatologists.

Methods: Searching relevant articles in the electronic databases Medline, PubMed, Science Citation Index, China Biomedical Literature Database (CBM), China Journal Full Text Database (CNKI), and WANFANG Data with the key words of “eosinophilic fasciitis” or “Shulman syndrome” and “checkpoint inhibitor”; “CTLA-4”; “PD-1” or “PD-L1”. Only articles or case reports with detailed medical records of ICI-related EF patients were included. ICI-related EF patients in our department were also included.

Results: A 58-year-old male patient with angioinmunoblastic T cell lymphoma presented with skin edema, subsequent induration, tightening of the skin, and subcutaneous tissue (Figure 1 A&B). The eosinophils elevated in peripheral blood after 6-month treatment of PD-1 inhibitor (Camrelizumab). The patient was diagnosed as ICI-related EF and then was referred to our rheumatology department. Other seventeen EF patients from the above databases were also included for analysis. Among these 18 patients, 50% (9/18) were male and the mean age was 57±14 years. The most commonly used ICI was PD-1 inhibitor such as nivolumab and pembrolizumab, accounting for 72% (13/18), next was PD-L1 inhibitor combined with CTLA-4 inhibitor. Of all cases, 50% (9/18) was metastatic melanoma and 17% (3/18) was lung cancer. After ICI treatment, the median onset time of EF was 12 months. The most common involved organ was skin and 94% (17/18) of patients presenting with symmetrical skin edema and sclerosis. For other skin manifestations, 44% (8/18) of patients had typical “groove sign”, and one case showed unilateral skin involvement of skin tension and erythema from pubis to left anter-ior iliac crest. When the affected limb raised, there is a visible sulcus due to the decrease of venous dilation pressure, namely “sulcus sign”. The second com- mon involved organ was the joints which were presented with limited function in 56% (10/18) of patients. Additionally, 39% (7/18) showed muscle involvement such as myalgia and myasthenia. Increased eosinophils in peripheral blood was observed in 72% (13/18) of patients. Twelve patients (63%) received MRI examinations which showed the signal in the subcutaneous and deep fascia increased in both fat-suppressed T2 images (Figure 1 C&E) and post-enhancement T1 images (Figure 1 D&F). Fifteen patients underwent full-thickness skin biopsy at the lesion site, the pathological changes in all patients supported the diagnosis of EF. The ICI was discontinued in 94% of patients. Meanwhile, 83% received glucocorticoids and 56% of patients were treated with methotrexate. After these treatment, the clinical symptoms of EF improved in 89% of patients (n=16), while eosinophils returned to normal after a median treatment time of 2.5 months. EF progressed even through the combined treatment of prednisone, MTX, and abraxatop in one patient. Another one case died after 6 months due to metastasis of bladder cancer (stageIV).

Disclosure of Interests: None declared

POS0890 NINTENDANIB REAL-LIFE EFFICACY AND SAFETY IN SYSTEMIC SCLEROSIS (SSc)-INTERSTITIAL LUNG DISEASE (ILD): AN ITALIAN MULTICENTRE PRELIMINARY STUDY

Background: Nintedanib (NDT) has been approved for Systemic Sclerosis (SSc)-Interstitial Lung Disease (ILD) following the positive results of the SEN-SICIS trial.

Objectives: to describe the efficacy and safety of NTD in SSc-ILD in a real-life setting.

Figure 1. Skin signs and MRI images of a 58-year-old male patient with eosinophilic fasciitis secondary to immune checkpoint inhibitor therapy A&B: Skin signs of the representative patient (P) and a 58-year-old male healthy volunteer (V). The skin of the patient’s left (A) and right lower limbs (B) was thick and difficult to touch. The fat-suppressed T2 images (C&D) and the fat-suppressed post-enhancement T1 images (D&A) showed the signal in the subcutaneous and deep muscle fascia of the right forearm increased and was enhanced obviously after enhancement (red arrows). There was a little long T2 signal of effusion shadow between myocutaneous and subcutaneous fatty tissue (yellow arrow).

Disclosure of Interests: None declared

**POS0890 CASE SERIES OF PATIENTS WITH EOSINOPHILIC FASCIITIS SECONDARY TO IMMUNE CHECKPOINT INHIBITORS THERAPY**
**Methods:** The clinical data of SSC-ILD patients treated with NTD from 10 Italian SSC centres were retrospectively evaluated at baseline, 6 and 12 months: SSC clinical features, NTD tolerability, pulmonary function tests (PFTs) and modified Rodnan skin score (mRSS) were recorded.

**Results:** 69 SSC-ILD patients (22 males [32%], mean age 60±12 years, disease onset 50±10 years, 4 [6%] anti-centromere, 53 [77%] anti-topoisomerase I, 3 [4%] anti-RNA-polymerase III) were identified. The vast majority (84%) was previously treated with immunosuppressants: 27 (39%) cyclophosphamide, 45 (65%) mycophenolate mofetil, 6 (9%) methotrexate, 9 (13%) azathioprine, 6 (9%) tocilizumab and 22 (32%) rituximab. In 11 (16%) patients, NTD was the first treatment for SSC-ILD. At baseline, 57 patients (83%) were on corticosteroids (mean daily prednisone dose 6±5 mg), 58 (84%) on immunosuppressants, 47 (68%) on mycophenolate mofetil, 14 (20%) on rituximab, 3 (4%) on tocilizumab, 2 on methotrexate (3%) and 1 (1%) on azathioprine. At baseline HRT showed UIP pattern in 27 (39%) and NSIP pattern in 42 (61%) patients. The modifications of PFTs and mRSS over time are shown in Table 1. Since NTD introduction, gastro-intestinal (GI) side effects were recorded in 34 (49%) patients, with diarrhea being the most common complaint (35%), followed by nausea/vomiting (2%), subocclusion and persistent diarrhea in 3 patients, un treatable nausea and vomiting in one patient and liver toxicity in 1 patient. During the follow-up after a median time of 10 (6–33) months, NTD was maintained after dose adjustment. In 5 (7%) patients NTD was stopped after a median time of 5 (1-6) months due to subocclusion and persistent diarrhea in 3 patients, un treatable nausea and vomiting in one patient and liver toxicity in 1 patient. None of the patients treated with NTD showed serious side effects. Of interest, 3 patients (4%) had slight skin involvement needs to be thoroughly evaluated on a larger SSc population.

**Disclosure of Interests:** Martim Pinto-Neto: None declared, Marco Confalonieri: None declared, Lorenzo Beretta: None declared, Francesco Benvenuti: None declared, Silvia Laura Bosello: Speakers bureau: Boehringer Ingelheim, Gianluca Moroncini: None declared, Giovanna Cuomo: None declared, Devis Benfaremo: None declared, Enrico De Lorenzis: None declared, Stefano Vigone: None declared, Barbara Ruaro: None declared, Anna Stanziola: None declared.

**Background:** The idiopathic inflammatory myopathies (IMM) module of the Rheumatic Diseases Portuguese Register (Reuma.pt/Myositis) is a tool used to systematically evaluate IIM patients.

**Objectives:** To clinically characterise the Reuma.pt/Myositis cohort.

**Methods:** Multicentre open cohort study, including IIM patients registered in Reuma.pt up to January 2022. Data collected included demographic, clinical, and treatment data and patient-reported outcomes. Data were presented as frequencies and median (interquartile range) for categorical and continuous variables, respectively.

**Results:** 280 patients were included, 71.4% female, 89.4% Caucasian, with a median age at diagnosis and disease duration of 48.9 (33.6-59.3) and 5.3 (3.0-9.0) years, respectively. Patients were classified as having definite (N=57/118, 48.3%; N=35/224, 15.6%), likely (N=23/118, 19.5%; N=50/224, 22.3%), or possible (N=2/118, 1.7%; N=46/224, 20.5%) IMM by 2017 EULAR/ACR and Bohan-Peter criteria, respectively. Disease subtypes included dermatomyositis (DM, N=122/280, 43.6%), polymyositis (N=59/280, 21.1%), myositis in overlap syndromes (N=41/280, 14.6%), clinically amyopathic DM (N=17/280, 6.1%), non-specific myositis (N=13/280, 4.6%), mixed connective tissue disease (N=12/280, 4.3%), immune-mediated necrotising myopathy (N=9/280, 3.2%), and inclusion bodies myopathy (N=7/280, 2.5%). Over the course of the disease, the most common symptoms were proximal muscle weakness (N=180/215, 83.7%), arthralgia (N=127/249, 52.9%), erythema (N=63/166, 38.0%), fatigue (N=47/127, 37.0%), Raynaud’s phenomenon (N=76/234, 32.8%), and dysphagia (N=33/121, 27.3%), and the most common clinical signs were Gottron’s sign (N=75/184, 40.8%), heliotrope rash (N=101/252, 40.1%), Gottron’s papules (N=93/237, 39.2%), and arthritis (N=38/98, 38.8%). Organ involvement included lung (N=78/230, 33.9%), oesophageal (N=40/221, 18.1%), and heart (N=11/229, 4.8%) involvements. Most patients expressed myositis-specific (MSA, N=158/280, 65.3%) and/or myositis-associated (MAA, N=122/280, 43.6%) antibodies. The most frequent antibodies were anti-SMN1 (N=67/280, 23.9%), anti-Jo1 (N=56/236, 23.7%), anti-Mi2 (N=31/212, 14.6%), anti-MDA5 (N=26/237, 10.9%), anti-EJ (N=17/208, 8.2%), and anti-Mi2 (N=31/212, 14.6%). Most patients had a myopathic pattern on electromyogram (N=101/138, 73.2%), muscle oedema in magnetic resonance (N=33/82, 53.2%), and high CK (N=154/200, 55.0%) and aldolase levels (N=74/135, 54.8%) at diagnosis, with median highest CK levels of 1308 (518-3172) and aldolase of 42 (12-121) mg/dL. Neoplasia was found in 11/127 patients (8.7%), most commonly breast (N=3/11, 27.3%), non-melanoma skin (N=2/11, 18.2%), and colorectal (N=2/11, 18.2%) cancer (Table 1). Most patients with cancer-associated myositis had DM (N=8/11, 72.7%) and expressed MSA (N=6/11) and/or MAA (N=3/11). The most used drugs over the course of disease were glucocorticoids (N=201/280, 71.8%), methotrexate (N=117/280, 41.8%), hydroxychloroquine (N=87/280, 31.1%), azathioprine (N=85/280, 30.4%), mycophenolate mofetil (N=56/280, 20.0%), intravenous immunoglobulin (N=55/280, 19.6%), and rituximab (N=45/280, 16.1%). At the last follow-up, there was a median MMTh of 150 (142-150), modified CAS skin of 0 (0-1), global VAS of 10 (0-50) mm, and HAQ of 0.125 (0.000-1.125).

**Conclusion:** Reuma.pt/Myositis adequately captures the main features of inflammatory myopathies’ patients, depicting in this first report a heterogeneous population, with frequent comorbidities. Hospitalisations and joint involvement are among the most frequent outcomes, most patients reached low disease activity at the last follow-up appointment.

**Disclosure of Interests:** None declared

Background: An accurate assessment of nailfold capillaroscopy (NFC) images has great importance in the diagnosis and prognosis of systemic sclerosis (SSc). To overcome some of the inherent problems with NFC image analysis (operator/observer bias, time requirements), there is an interest to automate and standardize NFC image assessment using computer vision algorithms, such as the Vision Transformer (ViT), which are based on recent advances in deep learning.

Objectives: Our aims were (1) to implement and assess the performance and reliability of ViT in detecting changes on NFC images, and (2) to compare the performance of ViT to that of practicing rheumatologists.

Methods: For this study, we used NFC images of patients with SSc enrolled in our European Scleroderma Trials and Research group (EUSTAR) and Very Early Diagnosis of Systemic Sclerosis (VEDOSS) local registries. Concretely, we included routine NFC images (all NFC images available – digit II to V of both hands), irrespective of any image artefacts) of patients aged ≥18 years with visits between 2012 and 2021, who fulfilled either the 2013 American College of Rheumatology/European League Against Rheumatism classification criteria for SSc (established disease) or the preliminary criteria for VEDOSS (mild/early disease).

ViT was trained to identify the following NFC signs of microangiopathy: enlarged capillaries (diameter of the capillary >20 μm, and <50 μm), giant capillaries (>50 μm), loss of capillaries (<7 capillaries/mm), and microhaemorrhages.

Results: We analysed 17,126 NFC images of 234 EUSTAR patients (14.6% males, 67.8% limited cutaneous SSc, median age 57 years, median disease duration 9 years) and 56 VEDOSS patients (82.7% females, median age 44 years, median time elapsed since first Raynaud’s phenomenon 5 years). ViT had fair to excellent performance in identifying the different NFC changes across all five folds (of 3443 NFC images each), with an area under the ROC curve ranging from 78.59% to 90.4% (Figure 1a). In the reliability set (see Figure 1b), we observed highest performance for diagnosing giant capillaries (AUC = 92.89%) followed by identification of enlarged capillaries (AUC = 91.7%). Good AUCs were seen in depicting capillary loss (AUC = 87.3%), microhaemorrhages (AUC = 85.9%) and the abnormal/normal NFC classification (AUC = 84.7%). The rheumatologists had generally higher performance in assessing NFC images. However, ViT outperformed two rheumatologists with different experience in classifying capillary loss and enlarged capillaries, respectively.

Conclusion: ViT is a modern, well performing and readily available AI model to assess signs of microangiopathy on NFC images acquired during routine practice.

Table 1. Comparison of pulmonary and small airways function variables between IIM patients with and without ILD.

Conclusion: Lung function as measured by FVC appears to correlate with worse patient-reported function in our unadjusted analysis of the large multicentre EUSTAR database. However, to estimate the total causal effect we must consider a multitude of potentially confounding factors, which need to be integrated and analysed in a causal inference framework. The proposed DAg will inform the development of simulations of the potential impact of bias (confounding, collider and omitted variable) on effect estimates we could obtain from EUSTAR cohort.

POS0894

COMPARISON OF PULMONARY AND SMALL AIRWAYS FUNCTION BETWEEN IDIOPTPATHOLOGICAL MYOPATHIES PATIENTS WITH AND WITHOUT INTERSTITIAL LUNG DISEASE

P. Panagopoulos1, V. E. Georgakopoulou2, V. Pezoulas3, A. Goules1, D. I. Fotiadis2, T. Vassilakopoulos3, A. Ziozoulas1. 1 School of Medicine, National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece; 2 School of Medicine, National and Kapodistrian University of Athens, Department of Physiology, Athens, Greece; 3 University of Ioannina, Unit of Medical Technology and Intelligent Information Systems, Ioannina, Greece.

Background: Pulmonary manifestations of idiopathic inflammatory myopathies (IIM) include interstitial lung disease (ILD) and respiratory muscle weakness, but function of small airways has not been studied in these patients (1). Spirometry, impulse oscilometry and measurement of respiratory resistance by the interrupter technique (Rocc) are tools to evaluate function of small airways. In addition, body plethysmography is the gold standard for measuring lung volumes, whereas carbon monoxide washout seems impaired, “underestimating” lung volumes in patients with small airways obstruction due to gas trapping (2). Thus, discrepancies between lung volumes measured by those two techniques may be an indication of early small airways dysfunction.

Objectives: To compare pulmonary and small airways function between IIM patients with and without ILD.

Methods: This prospective observational study included 13 IIM patients with ILD (6 patients with dermatomyositis and 5 with polymyositis) and 13 IIM patients without ILD (9 patients with dermatomyositis and 4 with polymyositis) who were diagnosed and followed up in the outpatient rheumatology clinic of the Department of Pathophysiology between June and December 2021. All IIM patients fulfilled the 2017 EULAR/ACR classification criteria (3). The presence of ILD was determined by high resolution computed tomography of the lungs that was performed as baseline standard of care at the time of diagnosis and was evaluated by a specialist radiologist blinded, according to Fleischner Society definitions for ILD (4). Clinical, laboratory and immunological data were recorded at the time of diagnosis and pulmonary function was assessed by spirometry, body plethysmography, single and multiple breath nitrogen washout, impulse oscilometry and measurement of Rocc, diffusing capacity for carbon monoxide (DLco) and maximal inspiratory and expiratory pressures. Statistical analysis for categorical data was performed by Fisher exact test or χ2 square test accordingly and numerical data with Man-Whitney test or t test.

Results: IIM-ILD patients presented more frequently with dyspnea (53.8% vs 0%, p<0.01), fever (61.5% vs 77%, p<0.05) and arthralgias (76.9% vs 23%, p<0.05), compared to IIM patients without ILD. Inflammatory markers, serum muscle enzymes, myositis specific autoantibodies and classic spirometric parameters did not differ between the two groups. IIM-ILD patients had markedly lower predicted DLco compared to those without (mean: 56.3% vs 78.2%, p<0.01). Predicted total lung capacity and residual volume (% TLC, RV/TLC %) measured by nitrogen washout and the TLC nitrogen washout: TLC body plethysmography ratio (% TLC/pre-TLC) were significantly lower in IIM-ILD patients compared to those without ILD (mean: 111.1% vs 153.4%, p<0.05, median: 171% vs 210%, p<0.05 and median: 1.26 vs 1.45, p<0.05, respectively). Similarly, %N2 (%) was found significantly higher among non-ILD than IIM-ILD patients (5.4% vs 2.8%, p<0.01). Predicted normal value of Rocc tended to be higher in IIM-ILD patients, although not statistically significantly.

Conclusion: Abnormal single breath nitrogen washout and discrepancies between lung volumes measured by body plethysmography and nitrogen washout in IIM-ILD patients, indicate an early small airways dysfunction in these patients.

*rate in total population (2019)

Santa Maria della Misericordia, Department of Surgery, Chirurgia Generale, Udine, Italy; 1Ricc San Raffaele Milano, Unit of Immunology, Rheumatology, Allergy and Rare Disease, Milan, Italy; 2Azienda Ospedaliera Università Careggi, Dept. Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy; 3University of L’ Aquila, Internal Medicine and Nephrology Unit, L’ Aquila, Italy.

Background: Among gastrointestinal (GI) manifestations in Systemic Sclerosis (SSc) one of the predominant and challenging problems is gastroesophageal reflux disease (GERD), which occurs in ~75% of patients. Although proton pump inhibitors are useful, they are ineffective in 40% of cases with chronic use at high doses, against the background of long-term risks (e.g., cardiovascular disease and infections) which have been identified in the general population. Surgery might be an option following failure of medical therapy but currently, there is no consensus regarding the optimal surgical procedure for refractory GERD in SSc.

Objectives: To evaluate, among the surgical approaches to GERD, the feasibility of fundoplication (FP) with regards to its safety, efficacy, indications, and timing.

Methods: Four research questions based on the PICO framework were developed to guide the systematic literature review that was conducted up to 22 December 2021. The search and performed across different databases including PubMed, MEDLINE (OVID), EMBASE, Cochrane Library, Web of Science, Google Scholar, Embase, and Academic Search Premier. References were independently screened by two reviewers (PMC and AA) who also independently assessed the full text of eligible articles, and extracted data. Due to heterogeneity of retrieved studies, narrative summaries are used to present the data.

Results: The search yielded 916 papers of which 30 were eligible for full text review. In these studies, out of 2919 clinically heterogeneous patients, 348 SSc patients were identified (mostly female, mean age 52.7 years). Out of these 348, only 257 underwent anti-reflux surgical procedure and these were included in the analysis. Most of the studies were conducted in surgical settings and relevant rheumatological data were largely missing. Refractory GERD symptoms, were the commonest indication for surgery, with post-operative dysphagia being the most frequent complication. In 18 studies, FP was effective, whereas 4 studies had equivocal findings and in 5 a lack of efficacy was reported. The Collis-Nissen FP was the most popular surgical procedure overall as well as in earlier studies, followed by Nissen FP, and Dor FP in relatively more recent studies, reflecting the change in surgical strategy over time. The data extracted shows also an acceptable rate of mortality and morbidity related to surgery, and heterogeneous outcome measures were used hampering any comparison of the studies (Table 1). Due to the heterogeneity of the data, it was not possible to separate the mortality and morbidity rate of SSc patients from the rest of the population.

Conclusion: Our SLR has highlighted that the surgical management of GERD in SSc patients is still highly challenging since the available evidence is scarce and of poor quality. Among the surgical approaches to the problem of GERD, overall FP seems a safe and effective procedure in SSc. Transient post-operative dysphagia was noted in many studies, particularly related with the posterior FP. In the future, it will be necessary to develop minimal requirement to conduct surgical studies in SSc as well as to design studies aimed at defining the clinical criteria for referral to surgery. Indeed, the right timing for surgery and the best surgical procedure in SSc still remains an unmet need.

POS0986 CRYOFIBRINOGEN-ASSOCIATED SYSTEMIC SCLEROSIS: POSSIBLE CORRELATIONS WITH SCLERODERMA DIGITAL ULCERS AND PULMONARY ARTERIAL HYPERTENSION

G. Amati1, A. Spinella1, G. Sandri1, P. Natazzi2, D. Debbia3, M. T. Mascia1, C. Salvatari1,4, D. Giuggioli1,4, Via del Pozzo, 71, Scleroderma Unit, Rheumatology Unit, University Hospital of Modena and Reggio Emilia, Modena, Italy; 2Via Giardini, 1355, Department of Laboratory Medicine and Anatomical Pathology, AOU of Modena, Modena, Italy; 3Via del Pozzo, 71, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine, Reggio Emilia, Modena, Italy; 4Via del Pozzo, 71, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy.

Background: Cryofibrinogenemia (CF) is a rare disorder characterized by the presence of an abnormal protein in the plasma that precipitates when cooled and redissolves at room temperature (1). CF is rarely symptomatic, therefore it is often underestimated. Nevertheless, the cryoprecipitation of native fibrinogen could induce the thrombotic occlusion of the small and medium sized vessels; as a consequence, this condition could become potentially lethal without the proper treatments. CF is classified into an essential and secondary form. The association of CF with Systemic Sclerosis (SSc) is described in literature (2-4); however, the role of this phenomenon it is not completely clarified, especially because some clinical aspects could be similar in both conditions.

Objectives: The aim of our study was to analyze the clinical, laboratory, instrumental and therapeutic features of SSc patients with cryofibrinogenemia, with particular attention to the possible prevention strategy and appropriate therapy of SSc digital ulcers.

Methods: 101 SSc patients (M:F 1:13) referring to the SSc Unit-Rheumatology Unit of our University Hospital have been tested both for cryofibrinogen and cryoglobulins from February 2020 to January 2022. Clinical, laboratory, instrumental features and ongoing therapies were collected.

Results: Patients with diffuse cutaneous form, limited cutaneous form, and sine-scleroderma subsets were 20 (19.8%), 79 (78.2%), and 2 (2.0%), respectively. The overall positivity for CF was 69.3%, of which 90.7% as isolated CF and 9.3% in addition to cryoglobulins. No correlation between CF positivity and positivity for rheumatoid factor, Sci-70, CENP B, anti-fibrillarin, anti-U1RNP, anti-ThiTo, anti-Ku, anti-MDA5, anti-mitochondrial, anti-SSA, anti-SSB, anti-citrullinated peptide, anti-phospholipids, anti-CORE, and anti-HCV antibodies was observed. An inverse correlation trend between CF positivity and antibodies positivity (OR=0.0577, 95% CI 0.0029-1.1537, p=0.0620) was noted. No significant correlation between CF positivity and interstitial lung disease, pulmonary arterial hypertension (PAH), history of digital ulcers, and amputation was recorded; however, considering cryocrct sample ≥1%, a correlation between the presence of an estimated pulmonary arterial systolic pressure (ePASP) higher than 30 mmHg and the positivity of CF was obtained (OR = 2.71, 95% CI 1.01-7.28, p=0.0482). The same association was achieved if we considered patients without endothelin receptor antagonist therapy (n=47) and CF positivity (OR=6.19, 95% CI 1.19-32.2, p=0.0304).
Furthermore, no correlation between CF positivity and the presence of digital ulcers at the moment of the blood sampling was verified; however, if we stratified patients according to their ongoing treatments (absence of an endothelin receptor antagonist therapy plus PDE5 inhibitors), a significant correlation between digital ulcers and CF positivity emerged (OR=8.14, 95% CI 1.03-64.5, p=0.0470, n=91).

**Conclusion:** Our preliminary results on this issue are extremely interesting as they can open new perspectives on the identification of cryofibrinogen as possible prognostic marker that could be involved in the pathogenesis of scleroderma digital ulcers and PAH. Moreover, therapies which are currently used for the treatment of PAH and the management of digital ulcers, could determine circulating cryofibrinogen disappearance, with possible challenging future impact on SSc therapeutic approaches.

**A SYSTEMATIC REVIEW AND META-ANALYSIS OF DIAGNOSTIC ACCURACY OF WHOLE-BODY 18F-FDG PET AND 18F-FDG PET/CT IN DETECTING OCCULT MALIGNANCY IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHY**

A. Ali1, R. Akilan2, J. Asif3, B. Basida4, Z. Al-Sagri5, N. Mahabadi6, H. Sarakbi1

1Wayne State University/Detroit Medical Center, Internal Medicine/Rheumatology Division, Detroit, United States of America; 2Case Western Reserve University at MetroHealth Medical Center, Internal Medicine/Rheumatology Division, Cleveland, United States of America; 3Beaumont Hospital, Dearborn, Internal Medicine, Dearborn, United States of America; 4Wayne State University/Detroit Medical Center Sinai Grace Hospital, Internal Medicine, Detroit, Michigan, United States of America; 5Wayne State University/Detroit Medical Center, Internal Medicine, Detroit, Michigan, United States of America

**Background:** Idiopathic inflammatory myopathies (IIMs) are chronic, systemic autoimmune diseases that can cause muscle inflammation, weakness, and skin manifestations. Several studies have confirmed the association between IIMs and malignancy in adult population with varied frequency (4-42%), highest in patients with dermatomyositis. Detecting occult malignancy is a diagnostic challenge involving cost- and time-consuming methods. The [18F] fluorodeoxyglucose positron emission tomography ([18F] FDG-PET) role in this context has been studied in multiple studies.

**Objectives:** The purpose of this study is to assess the diagnostic performance of whole-body [18F]FDG PET or [18F]FDG PET/CT for detection of occult malignancy in patients with IIMs.

**Methods:** A systematic search was performed in PubMed (Medline), Embase, and Scopus, Cochrane and clinicaltrial.gov to identify relevant published studies reporting the performance of [18F]FDG PET or [18F]FDG PET/CT in detecting occult malignancy in IIMs. Histopathologic confirmation and/or clinical follow-up was considered as the gold standard for diagnosis. Studies were eligible if all patients were 18 years or older, does not have history or current diagnosis of cancer and classified as IIMs according to Bohan and Peter classification criteria or have confirmed tissue diagnosis of malignancy. Histopathologic confirmation and/or clinical follow-up was considered as the gold standard for diagnosis. Studies were eligible if all patients were 18 years or older, does not have history or current diagnosis of cancer and classified as IIMs according to Bohan and Peter classification criteria or have confirmed tissue diagnosis of malignancy. Histopathologic confirmation and/or clinical follow-up was considered as the gold standard for diagnosis. Studies were eligible if all patients were 18 years or older, does not have history or current diagnosis of cancer and classified as IIMs according to Bohan and Peter classification criteria or have confirmed tissue diagnosis of malignancy. Histopathologic confirmation and/or clinical follow-up was considered as the gold standard for diagnosis. Studies were eligible if all patients were 18 years or older, does not have history or current diagnosis of cancer and classified as IIMs according to Bohan and Peter classification criteria or have confirmed tissue diagnosis of malignancy.

**Results:** Of 499 studies collected, six studies including a total of 293 patients with IIMs and who underwent [18F]FDG PET or [18F]FDG PET/CT examinations met our inclusion criteria. In two studies (87 participants), there was no clear database of the age and gender of the participants. The other four studies (total of 206 patients) 131/206 were females and 75/206 were males. Information about the type of IIMs was available in 5/6 studies with total of 283 participants; dermatomyositis (194/283), overlap polymyositis (41/283), Immune mediated necrotizing myositis (14/283), Polymyositis (11/283), non-specific(4/283), and orbital myositis (1/283). A total of 47 cancers were detected with lung (9/47), Breast (8/47) and nasopharyngeal (6/47) cancers were the most reported malignancies. Interestingly, all the breast cancers were reported as false negative. The pooled sensitivity, specificity, and diagnostic odds ratio of [18F]FDG PET or [18F]FDG PET/CT for the detection of underlying malignancy were 0.81 (95% CI, 0.67–0.91), 0.89 (95% CI, 0.84–0.92), and 38.19 (95% CI, 7.6–190.60), respectively. The heterogeneity of the studies was moderate with Chi-square, and I² index of 15.6 (P <0.05) and 68% respectively. The AUC and the Q* index was 0.95(SE, 0.033) and 0.89, indicating excellent diagnostic accuracy (Figure 1).

**Conclusion:** This meta-analysis demonstrates that whole-body [18F]FDG PET or [18F]FDG PET/CT has high diagnostic accuracy and moderate to high sensitivity and specificity for detection of underlying malignancy in patients diagnosed with IIMs.

Background: Management of digital ulcers (DUs) in systemic sclerosis (SSc) is a major clinical challenge. To date, systemic therapy is generally considered as the 'standard of care' for significant SSc-DUs. However, there is a strong rationale to develop local approaches to DUs, to avoid side effects from systemic therapies. World Scleroderma Foundation DU Working Group intends to develop practical, evidence-based recommendations for DU management including local, Surgical Treatment (L-ST).

Objectives: To summarize the literature on the safety and efficacy of L-ST for SSc-DUs.

Methods: A systematic literature review (SLR) was conducted up to May 2021. According to the PICO framework, eligibility criteria were defined and original research articles about surgical treatment of SSc DUs in adult patients were included. References were independently screened by 2 reviewers who assessed the full text of eligible articles and extracted data.

Results: Thirteen eligible articles out of 790 total publications were identified (Table 1). Due to the paucity of randomized controlled trials of surgical treatments for SSc-DU, we included retrospective studies and case series with at least 4 patients. Autologous fat (adipose tissue AT) grafting was the surgical modality mostly identified (7 studies of which 6 RCT and 6 prospective open label single arm). The healing rate (HR) with autologous fat grafting (4 studies) ranged from 66-100%. In the RCT, two age and sex matched groups were included, adipose tissue (AT) group (n=25 pts) and sham procedure (SP) group (n=13), DU healing was reported in 23/25 in AT group versus 1/13 in the SP group in 8 wks, (p<0.0001), 12 pts in the SP group, received rescue AT injection, all of them healed after 8 wks. Three studies reported autologous adipose derived-stromal vascular fraction(SVF) grafting and the HR ranged from 32-60%, followed up to 12 months. Transient edema and paresthesia were reported in 2 studies, and amputation in 2 ulcers in 1 study, and no complications were reported in other studies. Surgical sympathectomy was reported in 3 studies, with a median healing rate of 81%. Bone marrow derived cell transplantation in a single study showed 87% healing rate over (4-24 wks). Two surgical studies (of direct microsurgical revascularization N=4, and microsurgical transplantation N=16), showed 100% healing of ulcers, no complications reported.

Conclusion: Our SLR has identified several surgical modalities for SSc-DUs. L-ST seemed generally effective and safe for DU healing, thus Significant methodological issues emerged including small numbers of pts, lack of comparator, failure to report confounders such as background therapies and variable follow up. Future research is warranted to rigorously investigate surgical interventions for DUs.

HIGH FATIGUE SCORES IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: A MULTIGROUP COMPARATIVE STUDY FROM THE COVAD E-SURVEY.

Background: Idiopathic inflammatory myopathies (IIM) are a rare, multisystem, heterogeneous diseases, and contribute to high psychological burden. The patients' perception of physical health, deteriorating independence and social and environmental relationships may not always be a direct function of disease activity. To face with these aspects, several worldwide specialized organization have recommended the use of patient reported outcomes across all levels of disease activity, although the fatigue discrepancies with HC were substantially confirmed. After application of a multivariate linear regression analysis we found that lower fatigue VAS scores were related to HC (P < 0.001), male gender (P < 0.001), Asian and Hispanic ethnicities (P < 0.001).

Disclosure of Interests: None declared

Figure 1. distribution of Fatigue VAS scores in the three population evaluated. IIM idiopathic inflammatory myositis; AID autoimmune diseases; HC healthy controls; * P < 0.05.

Background: Digital ulcers (DU) are common in systemic sclerosis (SSc) and associated with reduced survival, high morbidity and a poor quality of life. Recommendations have previously been proposed for DU management yet there remains significant unmet patient need. Therefore the World Scleroderma Foundation DU Working Group intends to develop practical evidence based recommendations for DU management.

Objectives: To summarise data on efficacy and safety of systemic treatments for SSc DU.

Methods: A systematic literature review to May 2021 was performed. PubMed, MEDLINE, Embase, Web of Science, Cochrane Library, Emcare (OVID) and Academic Search Premier databases were searched for original studies on adult patients with SSc DU treated with systemic pharmacological treatment. Based on the PICO framework, eligibility criteria were defined and references were independently screened by two reviewers. Reviewers independently assessed the full text of eligible articles relating to interstudy heterogeneity narrative summaries were used to present data.

Results: The search strategy identified 1271 references of which 45 eligible articles were included. Seventeen studies were randomised placebo controlled clinical trials (RCT) pertaining to PDE5 inhibitors (PDE5i) (n=3), endothelin receptor antagonists (ERA) (n=3), prostanooids (n=7), antiplatelet agents (n=1) and other (n=9) (Table 1). No head to head RCT was retrieved. All other studies were observational studies (OBS). Studies were highly heterogeneous with application of differing definition of DU, variable study eligibility criteria, clinical endpoints and follow up periods. This limited the calculation of effect size and comparison across studies.

</table>

Several RCT found improved DU healing with treatment: two with PDE5i, one with iloprost and one showed improved DU healing and prevention with atorvastatin. Two RCT demonstrated effective prevention of new DU with bosentan. SRS studies with a total of 621 patients showed variable improvements in the healing of DU with CCB, PDE5i, ERA, statins, N-acetylcysteine, prostanooids and ketanserin and prevention of new DU with ERA. Regarding safety, all treatments were generally tolerated with few serious adverse events. Treatment was ceased in 6.25-17.5% of patients in RCT due to treatment related side effects.

Conclusion: Despite several studies assessing the efficacy and safety of systemic pharmacological treatment of SSc DU, it is not possible to draw solid conclusions due to study heterogeneity. Small RCT have shown treatment benefit with PDE5i, iloprost and atorvastatin. Large studies demonstrated effective prevention of new DU with bosentan. Our results highlight the urgent need for improved clinical trial design to generate more robust evidence and novel therapies to guide the management SSc DU.

Background: Systemic sclerosis associated interstitial lung disease (SSc-ILD) is the leading cause of scleroderma-related mortality.

Objectives: This work identifies factors associated with SSc-ILD decline on pulmonar y function testing (PFT).

Methods: This single center cohort identified 312 patients with ILD as determined by high resolution chest. 184 patients (59% of 312) completed baseline and serial PFTs (with at least two follow-up PFTs) and were included in this analysis. Mixed linear models were fit to assess the decline in the percent predicted forced vital capacity (ppFVC) over time. Demographics, disease factors, autoantibodies, and ILD features were included in the univariate mixed linear model; those achieving a p-value < 0.20 were included in the multivariable mixed linear model. Patients were followed longitudinally, with survival as an endpoint identified using the National Death Registry Index, reviewing death certificates, and hospital records.

Results: The 184 patients were an average of 53.2 (12.1) years old; the median [IQR] disease duration from the first non-Raynaud’s phenomenon symptom was 1.8 [0.7, 4.8] years. SSc subtype was diffuse in 55.4% (n=102), limited in 32.6% (n=60), overlap syndrome in 8.2% (n=15), and SSC sine scleroderma in 3.87% (n=7). Serologies were positive for anti-topoisomerase I (ATA), anti-centromere and anti-RNA polymerase III in 31.4% (n=93/294), 10.4% (16/154) and 22.9% (25/109) respectively. Mean ppFVC was 70.8 (18.9) and ppDLco 572 (20.8). Whole lung involvement (WLI%) of ≥20% on visual read was found in 49.3% of subjects (74/150 (49.3%)) where quantification was available. Over a median of 4.9 (2.4, 6.8) years, 21 patients (11.4%) died. The ppFVC declined a mean of 0.28/year in the overall group. There were differences in terms of ppFVC decline/year between patients who died in the first 2 years (n=10, -8.28%), 2-8 years (n=5, -3.89%), after 8 years (n=6, -1.09%), who were still alive (n=152, -0.22%), or who were still alive (n=163, -0.13%). The primary cause of death was ILD (6/21, 28.6%); those who died in the first 2 years most often died from progressive ILD (4/6, 67%). Factors significantly associated with decline in ppFVC on univariate analyses, included longer disease duration (ref. < 2 years, p=0.0048), ATA positivity (ref. negative, p=0.0081), and WLI ≥20% (ref. < 20%, p=0.0484). In multivariate analysis the only statistically significant variable associated with decline in ppFVC year was ATA positivity.

Conclusion: In a large single center cohort of SSc-ILD, ATA positivity is a risk factor for developing progressive SSc-ILD, consistent with other SSc-ILD cohorts. Stratifying patients by survival demonstrates that lung function declines dramatically in those who died within 2 years, whose main cause of death was progressive ILD. These data support the growing need to identify risk factors for disease severity and risk for progression, and to target intervention in patients most likely to develop progressive SSc-ILD.

DOI: 10.1136/annrheumdis-2022-eular.3648
Results: 29 patients with anti-TIF1-γ antibodies were analyzed, 82.7% women, with a mean age of 61 years (31-96 years).

The reason for requesting this antibody was: clinical features suggestive of DM in 10 patients (34.5%), muscle weakness in 9 (31%), interstitial lung disease (ILD) in 5 (17.2%), persistent CK elevation in 3 (10.3%), constitutional syndrome in 1 (3.5%) and antiphospholipid syndrome in 1 patient (3.5%). The mean time from symptoms onset to the detection of anti-TIF1-γ was 14 months (0-60 months).

10 patients (34.5%) had a diagnosis of DM; 4 patients (13.8%) systemic lupus erythematosus (SLE); one (3.5%) had a SLE/DM overlap syndrome; one patient (3.5%) subtype cutaneous lupus; one (3.5%) was diagnosed with diffuse systemic sclerosis; one patient (3.5%) limited systemic sclerosis; one patient (3.5%) antiphospholipid syndrome; one patient (3.5%) HLA-B27+ spondyloarthritis and 9 patients (31%) had no associated AIS. 5 patients (17.2%) showed ILD with different patterns: UIP (n=2), NSIP (n=2) and COP (n=1). Only 9 patients (31%) had elevated CK levels at the time of antibody determination. 10 patients (34.5%) were diagnosed with cancer: lung adenocarcinoma (n=2), small cell lung carcinoma (n=2), breast carcinoma (n=2), hepatocarcinoma (n=1), cervical cancer (n=1), ovarian carcinoma (n=1) and gallbladder adenocarcinoma (n=1). Of those, 7 patients (70%) had elevated CK levels and 6 (60%) had a diagnosis of DM.

None of the patients diagnosed with cancer had ILD. In 4 patients (40%), the diagnosis of cancer was simultaneous with the diagnosis of anti-TIF1-γ antibodies; in 4 (40%), the diagnosis of the tumor preceded the finding of the antibodies; in the other 2 (20%), the finding of the antibodies preceded that of the tumor. 30-month survival after cancer diagnosis was 10%.

In 17 patients (58.6%) no malignancy has been found so far in the annual cancer screening. In two patients (6.9%) no cancer screening was performed.

Conclusion: In our study, 60% of patients with DM and anti-TIF1-γ presented neoplasia, a proportion that was similar established in other series (60-80%). Furthermore, 21% of patients with antibodies and without DM were diagnosed with cancer, suggesting that anti-TIF1-γ antibodies could also be associated with neoplasia in patients without DM. Patients with ILD did not present cancer, supporting the observation of previous studies in which the presence of ILD is a marker of low risk for neoplasia in patients with DM. HyperCKemia might suggest the association with neoplasia in patients with anti-TIF1-γ antibodies.

POS0094

CHARANGES OF PULMONARY ARTERY SYSTOLIC PRESSURE IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS ON RITUXIMAB TREATMENT

L. Garzanova1, L.P. Ananyeva1, O. Koneva1, O. Ovsyannikova1, O. Desinova1, M. Starovoytova1, R. Shyakhmetova1, IVA Nasonova Research Institute of Rheumatology, Laboratory of Systemic Sclerosis, Moscow, Russian Federation

Background: Nowadays, there is already published a lot of data on the treatment of systemic sclerosis (SSc) with rituximab (RTX). Recent studies reported about improvement of skin fibrosis and interstitial lung disease associated with SSc (ILD-SSc) on RTX treatment. However, there is not enough data on changes of pulmonary artery systolic pressure (PASP) in SSc patients (pts) on RTX therapy.

Methods: 30 pts with initially elevated PASP (detected as ≥35mmHg by echo-cardiography) were retrospectively selected from a group of 103 SSc pts who received RTX as a therapy for ILD. The mean follow-up period was 25.3±2.4 months. The mean age was 52.6 years (30-66), female pts (87%), the diffuse cutaneous subset of the disease had 13 pts (43%). The mean disease duration was 7-3 years. The minimal mean dose of RTX was 2.3±1.1 grams. All pts received prednisone at a dose of 11.3±3.7 mg/day, immunosuppressants received 47% of them. All pts were positive for ANA. An assessment of basic parameters was obtained at baseline (Point 0), after 13.6±2.7 months (Point 1) and at the end of follow-up (25.3±2.4 months - Point 2). The results at baseline and at the end of the follow-up are presented in the form of mean values.

Results: There was an improvement of all main parameters at the point 2 and further - by the end of follow-up (Table 1). There was a significantly decrease in PASP, which was accompanied by the improvement of lung function - increase in forced vital capacity % predicted (FVC), stabilization of diffusion capacity for carbon monoxide % predicted (DLCO). A moderate negative statistically significant correlation was found between the PASP and FVC (r=0.522; p=0.003). There was a significant increase in 6-minute walk distance (6-mwd), ejection fraction of left ventricular (ER), activity index (EScSG-AI) and a decrease of Rodnan skin score.

Table 1. Changes of the main parameters on RTX treatment.

</table>

Conclusion: In our study, the PASP significantly decreased already in a year after initiation of RTX therapy and further there was an improvement of this parameter at the end of the observation. Decrease of PASP correlated with an increase of FVC and was accompanied by an increase of 6-minute walk distance, ejection fraction of left ventricular, improvement of Rodnan skin score and disease activity index. RTX could be considered as a potentially effective in combined treatment of ILD-SSc, complicated with pulmonary hypertension.

POS0095

CHARACTERIZATION OF SWEDISH MYOSITIS PATIENTS WITH ANTI-MDA5 AUTOANTIBODIES AND CORRELATION OF CLINICAL FEATURES WITH AUTOANTIBODY LEVELS

D. Demirdali1, E. Van Gompel1,2, E. Wigen1,2,3, M. Dastmalchi1,2, B. Horluoğlu1,2, A. S. Galindo-Feria1,2, S. Gräslund1,2,4, K. Chemin1,2, I. E. Lundberg1,2, A. Notamica1,2, Karolinska University Hospital, Rheumatology, Stockholm, Sweden; 2Karolinska Institute, Center for Molecular Medicine, Stockholm, Sweden; 3KU Leuven, Laboratory of Tissue Homeostasis and Disease, Skeletal Biology and Engineering Research Center, Leuven, Belgium; 4Structural Genomics Consortium, Center for Molecular Medicine, Stockholm, Sweden

Background: The association between anti-melanoma differentiation association protein 5 autoantibodies (aMDA5) and rapidly progressive interstitial lung disease (RP-ILD) in clinically amyopathic dermatomyositis is well established in Asian population cohorts. In western cohorts, ILD has been strongly associated with aMDA5 but data regarding RP-ILD have been more conflicting. It is also suggested that western cohorts have more pronounced myopathic features than Asian.

Objectives: To characterise the disease manifestations of a Swedish aMDA5 positive idiopathic inflammatory myositis (IIM) cohort and to explore antigen reactivity of the MD5 protein.

Methods: First available serum samples collected from 28 consecutive patients with IIM and positive aMDA5 ever tested by ELISA, Line Blot (LB) or Immunoprecipitation, attending Karolinska University Hospital between 1999 and 2021, were included. Clinical data including presence of anti-SSA autoantibodies by ELISA or LB was retrieved retrospectively. An in-house ELISA was used to screen serum samples for reactivity against a recombinant MD5 protein (rMDA5, aa A110-D1025, UniProt ID QB98X4) and seven MD5-derived constructs containing different domains. Correlations between aMDA5 reactivity levels and clinical data were explored.

Results: Nine patients showed no reactivity to any of the rMDA5 constructs by ELISA and were excluded from further analysis. Reactivity against rMDA5 was confirmed by ELISA in 19 patients (median 184.7 µg/mL (interquartile range (IQR) 277.07)). The cohort included 13 male and 6 female patients, 94% Caucasian, with mean age at diagnosis of 41.0 years (IQR 20-63). The mean disease duration (SD) was 7.7 years (5.0). During disease course nine patients (47.4%) had confirmed arthritis. ILD was diagnosed in 16/19 patients (92.4%), four of these (21.1 %) developed a RP-ILD. One patient passed away due to RP-ILD and one required a lung transplant. Patients with IIM had a statistically significant higher mean age at diagnosis than those without (42.8 (SD 10.3) vs 31.3 (SD 8.5)).
4.7 years, p=0.02). Patients developing RP-ILD were not significantly older than patients with chronic ILD. Respiratory symptoms were reported by 75% of patients with ILD at time of diagnosis. The mean total lung capacity (TLC) of the ILD cohort was 68% (SD 17), mean diffusion capacity of carbon monoxide (DLCO) was 59% (SD 15) and mean forced vital capacity (FVC) was 62% (SD 19). There was a higher proportion of patients with CRP ≥ 3 times the reference range at diagnosis amongst patients with FVC <70% than patients with FVC >70% (88.9% vs 16.7%, p=0.01).

Ten patients (52.6%) had anti-SSA autoantibodies, all had ILD. Anti-SSA positive patients had a statistically significant lower TLC than those without (62% vs 79% respectively, p=0.04) and a lower FVC (57% vs 76% respectively, p=0.05).

We found a weak non-statistically significant negative correlation between titres of aMDA5 and TLC, and FVC (Pearson coefficients -0.187, -0.289, -0.130 respectively). Frequency of ILD was higher in patients with aMDA5 titres >100 µg/ml than those with titers <100, but not statistically significant (81.3% vs 18.8%, respectively).

Conclusion: In this Caucasian cohort of aMDA5 positive IIM patients, ILD was present in over 80% of patients, of these, one quarter had RP-ILD. Older patients were more likely to present with ILD. Anti-SSA positivity and higher CRP levels were associated with worse lung function. We found a weak negative correlation between aMDA5 titres and lung function tests, as well as a trend of higher frequency of ILD in patients with higher aMDA5 titres. Muscle and skin involvement were found in a high proportion of patients.

Background: There are different measures and tools validated to evaluate disease activity and damage in idiopathic inflammatory myopathies (IIM). Disease activity and damage in patients with early diagnosis is not still well defined.

Objectives: To analyze disease activity outcomes and their association with damage in IIM differentiating between incident and prevalent cases.

Methods: Multicenter cross-sectional study. Patients were included in the Spanish Registry of patients with IIM (Myo-Spain)(1). Patients were classified as incident cohort (time between diagnosis and study initiation ≤ 12 months) or prevalent cohort (>12 months). Activity and damage data were collected at the initial visit. Differences between both groups were tested by Chi-square, Student’s t and Mann-Whitney tests. Spearman’s correlation coefficients (Rho) were used to analyze correlations between disease activity and damage measures. The correlation was considered weak (Rho < 0.2), moderate (Rho ≥ 0.2 - <0.3) or strong (Rho ≥ 0.3). A p-value <0.05 was statistically significant.

Results: We included 139 (67.63% women) and 417 patients (74.34% women) with a mean age at diagnosis of 54 and 48 years in the incident and prevalent cohort, respectively. Patients in the incident cohort had significantly higher disease activity measures: myositis disease activity assessment visual analogue scale (MYOACT total), extramuscular activity of the Myositis Activity Questionnaire (PhGA), patient global activity (PGA), physical muscle testing (MMT-8), and HAQ (p < 0.001). The organ systems with the bigger differences between the incident and prevalent cohort were skin and constitutional (p<0.001). No significant differences were found in physician global damage (PhGD), patient global damage (PGD) and myositis damage index (MDI), between both cohorts (p > 0.2). Correlations between disease activity and damage measures are showed in the Table 1. The main differences found between both cohorts were the correlations of PhGA, CK, PGD and MDI with other measures of disease activity.

Correlations between disease activity and damage measures are showed in the Table 1. The main differences found between both cohorts were the correlations of PhGA, CK, PGD and MDI with other measures of disease activity.

Conclusion: Incident cases had higher disease activity. In those in whom damage was detected, no differences were found in damage measures with prevalent cases. The correlation between the different measures of activity and damage was slightly better in prevalent patients.

Conclusion: Our study found higher prevalence of inner and middle ear pathologies in SSc patients. It is also important to emphasize the relationship found with history of digital ulcer. In these patients, this type of involvement should be considered both during diagnostic and therapeutic procedures. Further investigation is needed for a better understanding of ear damage in these patients.

THE ROLE OF IMACS CORE SET MEASURES TO ROUTINELY EVALUATE THE QUALITY OF LIFE OF IDIOPATHIC INFLAMMATORY MYOPATHIES PATIENTS IN CLINICAL PRACTICE

C. Cardelli1,2, R. Marinai3, S. Barsotti1, A. Tripoli2, M. Di Battista3, A. Tripoli, L. Carli2, M. Mosca2,3.

1University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; 2Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy; 3Ospedale di Livorno, Medicina Interna, Livorno, Italy

Background: Idiopathic Inflammatory Myopathies (IIMs) are rare, multisystemic and complex diseases, often impacting on patients’ quality of life (QoL). Patient Reported Outcomes (PROs) assess the overall health status of patients, particularly for emotional and functional domains. In clinical practice the administration of PROs might have some limitations, because they tend to be time-consuming and sometimes difficult to be filled in by patients. The International Myositis Assessment & Clinical Studies Group Disease Activity Core Set Measures (IMACS-CSM) are a tool created specifically to assess disease activity and QoL in IIMs.

Objectives: To evaluate the ability of IMACS-CSM in assessing IIMs patients’ QoL in comparison with both generic and IIMs specific PROs.

Methods: Consecutive adult patients with a diagnosis of IIM (2017 EULAR/ACR criteria) were recruited during a scheduled follow-up visit. Demographic and clinical features were recorded (sex, age, disease subset and duration, organ involvement, comorbidities). IIM disease activity was evaluated following International Myositis Assessment & Clinical Studies Group Disease Activity Core Set Measures. To detect anxiety and depression status, HADS was administered to patients, who were also asked to fill in Short-Form 36 Items Health Survey (SF-36). For both HADS-A and HADS-D (all p<0.006, high risk ≥11). Results were reported as means±SD for continuous variables and as percentage for categorical variables. Intergroup comparisons were assessed by using Chi-square, t-test and ANOVA. Pearson coefficient was used to analyse the correlations between variables. P values <0.05 were considered significant.

Results: Fifty-three patients (72% female; mean age 64.8±12.0 years; mean disease duration 7±6.2 years) were enrolled. Thirty-seven (37.7%) showed increased anxiety scores (mean 11.35, min. 8 – max. 17); 10 (50%) borderline and 10 (50%) high risk. Twenty (37.7%) had an increased depression score (mean 11.75, min. 8 – max. 19); 6 (30%) borderline and 14 (70%) high risk. If abnormal scores of both HADS-A and -D were found in 15 patients (28.3%), 17 patients (32.1%) were at risk of developing both conditions together and quite one third was at high risk to develop at least one of them. As expected, these conditions were associated with a concomitant fibromyalgia. Moreover, a compromised QoL and a functional limitation, as evaluated by PGA, HAQ and MMT8, in agreement with SF-36

POS0910

PSYCHIATRIC COMORBIDITIES ASSESSMENT: AN UNMET NEED IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES?

C. Cardelli2, M. Diomedi2, S. Barsotti3, M. Di Battista2, A. Tripoli, C. Cardelli, M. Mosca3.

2Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy; 3Ospedale di Livorno, Medicina Interna, Pisa, Italy

Background: Idiopathic Inflammatory Myopathies (IIMs) are rare and complex chronic diseases, with a strong impact on patients’ Quality of Life (QoL) in terms of both physical and emotional functioning. Despite its key role in daily life, patients’ emotional status could be difficult to be investigated by physicians. As known, patients with chronic conditions are at higher risk of anxiety and depression, but data about their prevalence in IIMs are still limited. The Hospital Anxiety and Depression Scale (HADS) is a validated questionnaire to evaluate the presence and severity of both anxiety (HADS-A) and depression (HADS-D) in patients.

Objectives: To determine the presence of anxiety and depression in a monocentric cohort of IIMs patients and to evaluate possible correlations with clinical features, disease activity and parameters of QoL.

Methods: Consecutive adult patients with a diagnosis of IIM (2017 EULAR/ACR criteria) were recruited during a scheduled follow-up visit. Demographic and clinical features were recorded (sex, age, disease subset and duration, organ involvement, comorbidities). IIM disease activity was evaluated following International Myositis Assessment & Clinical Studies Group Disease Activity Core Set Measures. To detect anxiety and depression status, HADS was administered to patients, who were also asked to fill in Short-Form 36 Items Health Survey (SF-36). For both HADS-A and HADS-D (all p<0.006, high risk ≥11). Results were reported as means±SD for continuous variables and as percentage for categorical variables. Intergroup comparisons were assessed by using Chi-square, t-test and ANOVA. Pearson coefficient was used to analyse the correlations between variables. P values <0.05 were considered significant.

Results: Sixty patients (65% female, mean age 59.9±13.5 years, mean disease duration 7.7±6.1 years), 37 (61.7%) with polymyositis, 20 (33.3%) with inclusion body myositis, were enrolled. Among IMACS-CSM, the mean HAQ and PGA scores were significantly worse in case of muscle involvement (p<0.017) and oesophageal involvement (p=0.017), respectively; as expected, MMT8 score was associated with muscle involvement (p=0.017); MDAAT score was instead associated with oesophageal dysfunction (p<0.001). No associations were found between IMACS-CSM and other clinical and demographic parameters. FACIT-F correlated positively with MMT8 (r=0.432, p<0.001) and negatively with PGA, HAQ and MDAAT. The mean value of EQ-VAS was lower in SSc group (63.8±13.1) compared to controls (71.1±11.0) (p=0.04), but without significant differences with the changes in the pure-tone or speech audiometry.
DIAGNOSTIC VALUE AND CLINICAL RELEVANCE OF MUSCLE BIOPSY IN PATIENTS WITH SUSPECTED MYOSITIS
K. Kastrati1, N. Naikost Lotli2, M. Tawfik3, E. Gelpi4, R. Hoettberger2, H. Kiener3, D. Aletaha1, M. Bonelli1, H. Radner1. 1Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine 3, Vienna, Austria; 2Suez Canal University, Department of Rheumatology and Rehabilitation, Ismailia, Egypt; 3Medical University of Vienna, Division of Neuropathology and Neurochemistry, Vienna, Austria

Background: Diagnosis of idiopathic inflammatory myopathies (IIM) represents a clinical challenge and muscle biopsy itself is regarded as the cornerstone for diagnostic tool remains inconclusive

Objectives: To determine the diagnostic accuracy and clinical relevance of muscle biopsy in patients with suspected myositis.

Methods: In this retrospective cohort study, histopathological findings of muscle biopsy specimens of adult (≥ 18 years of age) patients with clinically suspected or differential diagnosis of myositis referred from all over Austria to the Medical University of Vienna through the period of 01.01.2007-31.10.2021 were analyzed. Following information were extracted from handwritten assignment sheets: referral department, suspected diagnosis (inflammatory and/or non-inflammatory myopathy), sampling location, demographic, clinical, laboratory and serologic data, and imaging results. Histological findings were grouped in: 1) inflammatory, 2) non-inflammatory (neurogenic, metabolic etc.), 3) inflammatory and non-inflammatory myopathy, and 4) normal. Clinical information on start of immunosuppressive treatment after muscle biopsy could be partly retrieved form electronical medical records (EMR). Sensitivity, specificity, positive (PPV) and negative predictive values (NPV) of histological results were calculated using clinical diagnosis (defined as initiation of immunosuppressive therapy) as gold standard.

Results: 778 muscle biopsy specimens of 762 patients with suspected myositis (49.6% female, mean age of 56 years) were analyzed. Cohort descriptives are displayed in Table 1. Overall, 373/778 (47.9%) muscle biopsies revealed inflammatory features only or had mixed results with non-inflammatory characteristics. Out of 541 samples with suspected diagnosis of myositis, diagnosis was confirmed histologically in 300 (55.5%) cases; 48 (8.5%) specimens additionally showed co-features of non-inflammatory myopathy, whereas 221 (40.3%) were non-inflammatory at all and 15 (2.8%) were normal. Proportion of myositis was more pronounced, when CK was elevated at time of biopsy (Figure 1).

Figure 1. From suspicion to histological verification depending on CK-levels

Out of 237 samples with differential diagnosis of non-inflammatory myopathy in addition to myositis, 53 (22.4%) were histology confirmed as inflammatory only and 20 (8.4%) showed mixed features. 153 (64.6%) biopsies were non-inflammatory only and 8 (3.4%) normal. Samples with no pathological features were observed in 24/778 (2.3%) of the cases, with 0.8% sampling error (no muscle tissue). Of 421/778 (54.1%) patients, clinical data could be extracted from EMR of which 209/421 (49.6%) had histological features of inflammation. In 287/421 (88%) cases, information regarding initiation of immunosuppressive treatment were available on EMR. 224/287 (78%) patients received immunosuppression (steroids and/or disease-modifying anti-rheumatic drug [DMARD]), thus fulfilled clinical diagnosis of myositis. In 155/224 (69.2%) cases, muscle biopsy confirmed histology features of inflammation. Tests on diagnostic accuracy of muscle biopsy using initiation of any immunosuppressive treatment as gold standard were performed. The sensitivity of the test (biopsy) for diagnosing IIM was 71.4% with a specificity of 79.6%. PPV was high (82.8%), whereas NPV low (43.1%).

Conclusion: Less than 50% of biopsy samples with suspected diagnosis of myositis histologically revealed an inflammatory myopathy. The percentage increased when CK levels were elevated. Sensitivity and specificity of muscle biopsy was moderate, when using start of immunosuppressive therapy as gold standard for IIM diagnosis.

mechanisms, such as mitochondrial abnormalities and metabolic disturbance, contribute to the pathogenesis of myositis. Exercise improves muscle function in IIM patients.  

**Objectives:** To evaluate the effect of activities-of-daily-living, resistance and stability training on metabolic parameters of primary tissue culture myocytes established from muscle biopsies obtained from patients with established IIM.

**Methods:** Seven patients with established IIM underwent a 24-week supervised training focused on activities of daily living, muscle-strengthening and stability. Muscle biopsy was performed before and after the 24-week program in patients, and in healthy controls (n=9). Isolated skeletal muscle cells were grown and differentiated into myotubes for 6 days. After differentiation, the myotubes were cultured for another 24 hours in fresh medium, and then the conditioned media were collected, and the cells were harvested in TRIzol. A relative number of mitochondria was quantified by the ratio between mitochondrial gene (NADH dehydrogenase subunit 1) and reference nuclear gene (lipoprotein lipase) and determined by qPCR. Glucose, pyruvate, lactate, citrate, and fumarate were assessed in a conditioned medium using the comprehensive two-dimensional gas chromatography coupled to time of flight mass spectrometer.

**Results:** Patients significantly improved their muscle strength and endurance during the 24-week training [1]. There was no difference in the relative number of mitochondria in muscle tissue and myotubes between IIM patients and controls. A significant increase in the number of muscle tissue mitochondria was found in IIM patients after 24 weeks of training (p = 0.004), on average twofold. A similar effect was observed in cultured myotubes, with at least 4 of 7 IIM patients showing a twofold increase in mitochondria number. Compared with myotubes from HC, myotubes derived from IIM patients consumed non-significantly more glucose and pyruvate from the culture medium; however, their glucose and pyruvate utilization were significantly reduced as a result of the 24-week training (p = 0.016 and p = 0.030, respectively). Skeletal muscle cells from IIM patients before training intervention did not differ from HC cells in the amount of released lactate; however, the lactate concentration in the conditioned medium from myotubes obtained from patients after the 24-week training was significantly lower (p = 0.016). When measuring citrate cycle products released into the culture medium, no difference in citrate and fumarate secretion was observed between myotubes of myositis patients and myotubes of healthy controls. In contrast, their release was significantly (p < 0.05) lower in myotubes from IIM patients after 24 weeks of training compared to muscle cells isolated prior to intervention.

**Conclusion:** In conclusion, 24 weeks of rehabilitation training in patients with IIM significantly increases the number of mitochondria in muscle tissue. Lower release of lactate and citrate cycle intermediates (citrate and fumarate) by myotubes obtained from patients after training intervention indicates an increase in mitochondrial functional capacity and confirms a positive response to exercise in muscles previously affected by the inflammatory process in IIM.

**INCREASED HEALTH CARE UTILIZATION IN SYSTEMIC SCLEROSIS PATIENTS WHO HAVE DIGITAL ULCERS**

T. Nevskaya1, L. Martin Calderon2, M. Baron3, J. Pope4 on behalf of Canadian Scleroderma Research Group. 1Western University, Rheumatology, London, Canada; 2Western University, Medicine, London, Canada; 3McGill University, Rheumatology, Montreal, Canada

**Background:** Systemic sclerosis is a multi-system autoimmune disease characterized by fibrosis of the skin and internal organs, and vasculopathy which manifests as pulmonary arterial hypertension and digital ulcers. Digital ulcers are debilitating and painful lesions most commonly present in the digit tips or extensor surfaces of the hands leading to significant morbidity and decreased quality of life. SSC patients with digital ulcers may require increased support and therefore may have greater healthcare resource utilization compared to those patients without digital ulcers.

**Objectives:** We assessed the impact of DUs on resource utilization including hospitalizations, outpatient visits and procedures within a large SSC Canadian registry.

**Methods:** A cohort of patients with SSC and digitals ulcers was derived from the Canadian Scleroderma Research Group registry and matched to controls individually based on sex, age (±3 years), SSC subtype, and disease duration (±2 years). Eligible patients met the 2013 ACR/EULAR criteria (confirmed by an experienced rheumatologist), were 18 years of age, had completed the Resource Utilization Questionnaire (RUQ), and had active digital ulcers at two consecutive annual visits (baseline study visit and at 1st year). The Medsger Disease Severity Scale was used to assess ulcer disease severity. Unadjusted and adjusted regression analyses compared the association between DUs and resource utilization.

**Results:** RUQs in 104 SSC patients with active DUs at two consecutive annual visits were compared with 104 patients without DUs matched 1:1 for age, sex, disease subtype and duration. Over one year, DUs were associated with a higher number of tests (p<0.05) and visits to health professionals, especially to a rheumatologist (p<0.0001) and internist (p<0.003), a greater need for an accompanying person (p<0.05) and aids purchased/received (p<0.05). Having DUs was associated with more severe disease, even after excluding the peripheral vascular domain from a total DSS (9.7±4.5 vs 5.6±2.7, p<0.0001). After adjustment for disease severity in other organs, the presence of DUs remained a significant predictor of more frequent physician visits and more tests (all p<0.05) by linear regression analysis.

**Conclusion:** SSC patients with DUs utilized significantly more healthcare resources per annum even after adjustment for disease severity in other organ systems.

**Background:** Skin fibrosis is a cardinal feature of systemic sclerosis (SSc) and associated with significant disability. The early trajectory of skin fibrosis provides evidence for the rheumatic diseases. 2008 Jan 1;67(1):120-3.
insights into the course of the disease including mortality; however, little is known about late skin fibrosis in SSc.

**Objectives:** The aims of our study were to ascertain the prevalence and characteristics of late skin fibrosis in SSc.

**Methods:** We developed and tested three conceptual scenarios of late (>5 years after 1st non-RP sign or symptom) skin fibrosis (Figure 1):

**A.** Worsening and then improvement (>3 mRSS) during the first 5 years, and then worsened again after 5 years (i.e., failure to improve).

**B.** Worsening for the first time after 5 years.

**C.** Worsening in the first 5 years and stayed high after 5 years (i.e., failure to improve).

**Conclusion:** Late skin fibrosis affects approximately 20% of SSc patients >5 years after onset of disease. We have identified different patterns relevant to clinical practice and trial design. Late skin fibrosis is usually due to new worsening or failure of skin to improve. Progression from baseline limited to diffuse cutaneous SSc was associated with anti-Scl-70 antibodies, and anticientromere antibodies were protective. Late skin fibrosis is a neglected manifestation of SSc and warrants further investigation including to determine clinical outcomes and optimal therapeutic strategy.

**Background:** Myositis-associated antibodies (MAA) and myositis-specific antibodies (MSA) have been associated with clinical manifestations of dermatomyositis and polymyositis, including interstitial lung disease (ILD), myopathy, malignancy, arthritis, and skin rashes. Among them, anti-ARS and anti-MDA5 antibodies are strongly associated with complications of ILD that are associated with life expectancy. It has been reported that anti-Ro52 antibody affects severity of myositis and ILD. (1) Based on these findings, it is possible that autoantibodies possessing features of ILD associated with dermatomyositis and polymyositis may be predictive.

**Table 1. Impact of autoantibody status on progression from baseline limited to diffuse cutaneous SSc (dcSSc).**

**Objectives:** The purpose of this study is to clarify the relationship between MSA/MAA and clinical features of ILD complicated by dermatomyositis and polymyositis.

**Methods:** We retrospectively analyzed IIMs patients diagnosed according to Peter & Bohan’s diagnostic criteria in our hospital from 2011 to 2018. The presence of 14 MSA / MAA (Jo1, PL12, PL7, EJ, OJ, KS, Mi2, MDAS, TIF1, SRP, PM-ScI70, 100, Ku, Ro52) was measured using ELISA (MESACUP, MBL, Japan) and line blot (EUROLEONE myositis profile, EUROMimm, Germany). Clinical characteristics, including HRCT imaging findings, were extracted from medical records. HRCT imaging findings were analyzed by multiple radiologists. The association between the extracted clinical features and the MSA / MAA hostility was analyzed.

**Results:** Seventy-eight cases of IIM were included in the analysis. The frequency of ILD complications was 53/78 (68%), and 60% of ILD complications were ARS antibody positive. The complication rate of ILD in MDAs- and ARS-positi-

cases was 100% (3/3 cases) and 94% (32/34 cases), respectively. These MDs- and ARS-positive patients with ILD had rapidly progressive ILD. One of the three MDs antibody-positive-RPILD cases died, but none of the four ARS antibody-positive-RPILD cases died. However, in patients with multiple MSA or MAA including ARS, three cases had rapidly progressive ILD, and none died. The analysis of the presence of Ro52 antibody, it was detected in 46% (36 cases) of all cases, but in 74% of anti-ARS antibody positive cases.

In the analysis of ILD patterns by radiologists using HRCT, fibrosing NSIP (NSIS), fibrosing OP (OP), and UIP were the most frequent in that order. Analysis of the presence of Ro52 antibody, it was detected in 46% (36 cases) of all cases, but in 74% of anti-ARS antibody positive cases.

**Conclusion:** The performance of anti-ARS antibody-positive ILD associated with dermatomyositis and polymyositis was associated with fibrosis by analysis of HRCT patterns, and the prognosis was confirmed to be poor. In addition, the UIP pattern, which is strongly associated with fibrosis, was found to be associated with anti-Ro52 antibody. In the treatment of ILD, which is strongly associated with the prognosis of dermatomyositis and polymyositis, it may be necessary to consider antibiotic treatment for patients with anti-ARS antibody and anti-Ro52 antibody positivity.

**A 10-YEAR JOURNEY OF CARING FOR PATIENTS WITH SYSTEMIC SCLEROSIS: FOLLOW-UP DATA ON DISEASE DURATION OF THE LEIDEN CCISS COHORT.**

S. Liem1, S. Ahmed1, J. Ciaffi2, L. Beaart-van de Voorde1, A. Schouffoer3, M. D’orazio1, A. Lackner1, S. Zenz1, A. Haidmayer2, J. Gretler1, S. Kielhauser1, J. Thiel1, H. P. Brezinsek1, F. Fürst-Moazedi1, 1Medical University of Graz, Graz, Austria; 2Hospital Southern Styria, Graz, Austria; 3Haga Teaching Hospital, Rheumatology, Den Haag, Netherlands; 4Leiden University Medical Center; Pulmonology, Leiden, Netherlands; 5Leiden University Medical Center, Cardiology, Leiden, Netherlands

**Background:** Combined Care in Systemic Sclerosis (CCISS) is a prospective cohort of patients referred to Leiden University Medical Center for Raynaud’s Phenomenon (RP), a suspicion of systemic sclerosis (SSc) or a connective tissue disease. This cohort is characterized by its standardized and extensive annual follow-up. Since initiation of the cohort in 2009, diagnostic criteria for SSc have been updated leading to a higher sensitivity for early SSc (ACR 2013 criteria). A recent Dutch study showed that there is a gap to time of diagnosis between men and women.

**Objectives:** To determine whether 1. time between first disease symptoms and diagnosis has changed over time, and 2. disease characteristics of SSc at first presentation in an expert clinic have changed over time for the total cohort, and between male and female patients.

**Methods:** Patients included in the CCISS cohort undergo annual evaluation and clinical, laboratory, and imaging variables are systematically recorded. For this study, patients fulfilling the ACR/EULAR 2013 criteria were included, and categorized into three groups based on the cohort entrance year: 1) 2010 – 2013, 2) 2014 – 2017, and 3) 2018 – 2021. SSc patients with a baseline visit in 2009 (n=85) were excluded as these patients were often not newly referred. Disease duration was defined by months since first RP, since first non-RP symptom and months between first date of diagnosis by a physician and first non-RP symptom. Disease characteristics included presence of interstitial lung disease (ILD), pulmonary arterial hypertension, digital ulcers (DU), diffuse cutaneous SSc, anti-topoisomerase and anticientromere antibodies. At baseline, disease duration and disease characteristics were compared between the three groups using appropriate tests. In addition, disease duration was compared between males and females in the three groups.

**Results:** In total, 643 SSc patients were included of whom 229 (36%) had their baseline visit from 2010 until 2013, 207 (32%) from 2014 until 2017, and 207 (32%) from 2018 until 2021. The proportion of female patients was significantly higher in the 2010 – 2013 group compared to the 2014 – 2017 and 2018 – 2021 group (Table 1). Over time, disease duration defined by RP duration and non-RP duration decreased as well as time between diagnosis and first non-RP symptom (Table 1). The proportion of patients presenting with ILD and DU was highest in the first group (Table 1).

In both male and female SSc patients, disease duration and time between diagnosis and first non-RP decreased over time with a longer time in females for all durations which was significantly different for time between first RP and non-RP in 2014-2017 and 2018-2021 (Figure 1).

**Conclusion:** Over time, we observe a decrease in disease duration and in SSc patients presenting with ILD or DU at cohort entrance. Our results indicate increased awareness of early SSc and identification of SSc patients before severe complications have occurred. At the same time our results show the urge for specific attention to improve timely diagnosis in female SSc patients.

**TRANSTHORACIC LUNG SONOGRAPHY (LUS) – USEFUL SURVEILLANCE TOOL IN SYSTEMIC SCLEROSIS ASSOCIATED INTERSTITIAL LUNG DISEASE?**

M. D’orazio1, A. Lackner1, S. Zenz1, A. Haidmayer2, J. Gretler1, S. Kielhauser1, J. Thiel1, H. P. Brezinsek1, F. Fürst-Moazedi1, 1Medical University of Graz, Rheumatology and Immunology, Graz, Austria; 2Hospital Southern Styria, Internal Medicine, Bad Radkersburg, Austria

**Background:** The Interstitial lung disease (ILD) represent a major cause of mortality in Systemic sclerosis (SSc). Validated methods for screening and therapy monitoring of SSc-ILD are needed. In the recent literature, the transthoracic lung sonography (LUS) emerges as a reliable tool for the early detection of lung alterations. It was recently reported that SSc-ILD-patients have thicker artefacts reflecting the pleuralaire compared with SSc-patients without ILD, but it still remains unknown if the thickness of the pleuraliare changes with a proper therapy response.
**Objectives:** The aim of the study was to compare the thickness of the pleurale line of SSC-IDL-patients without biological Disease Modifying Anti-Rheumatic Drugs (bDMARDS) with those successfully treated with bDMARDS in order to establish if LUS can be a reliable tool in SSc-IDL. Additionally, since our Grazer Schema (Mycofenolat mofetil (MMF)+ rituximab (RTX)) 50 mg i.v. in week 0 and 2 every 3 months) is successful in our clinic since more than 10 years in patients nonresponding to methotrexate (MTX) or cyclophosphamide, we report 10 years follow-up data of 5 Patients before and after receiving that schema.

**Methods:** 29 prospectively enrolled SSc-patients were assessed according to the European League Against Rheumatism Scleroderma Trial and Research standards. Written informed consent was obtained from all patients and the study was approved by the Ethics Committee of Graz. Validated clinical scores, such as the scleroderma disease activity (SSCAS) and the scleroderma disease severity scale (SScSS) were assessed. The thickness of the pleurale was detected with LUS. The presence of ILD was assessed by high-resolution computed tomography. Twenty-five SSc-patients enrolled between 2008 and 2009, who underwent LUS with the same technical instruments and some of the same operators, were taken as a control group since they were untreated yet or were not assuming bDMARDS(1).

**Results:** Of the 29 SSc-patients (27 females/2 males) enrolled between 2019 and 2020, seventeen patients had radiographic signs of ILD (SSc-ILD+2019-20, n=17). Until the LUS was performed, all SSc-ILD+2019-20 showed a good clinical response to the therapy with RTX in combination with MMF. Of the 25 SSc-patients enrolled in our previous study, (n=25; 23 females/ 2 males), twelve of these patients had radiographic signs of ILD (SScILD+2009-10, n=12); 7 were under MTX or Cyclosporin and 5 were untreated. Additionally, data collected from 5 SSc-ILD+2009-2010 at baseline were analysed in a 10- years- follow up. As expected, SSc-ILD+ patients had a thicker pleurale than SSc-ILD- patients. The pleurale-thickness was significantly thinner in patients under MMF and RTX compared to the pleurale of patients without bDMARDS (1,8 mm ± 0,7 Vs 0,95 ± 0,31; p < 0,00). Interestingly those patients reported less frequently dry cough or dyspnoea, showing that the lower pleura thickness could be associated with a better clinical outcome. In a 10 Year follow-up after continued treatment with MMF and RTX, a significant reduction of the thickness of the pleura could be found (Mean 0.68 ± 0,2 VS 1,5 ± 0,4; p < 0,00). Interestingly, such significant improvement could not be found in all of these 5 patients receiving our Grazer Schema. Remarkably, the pleurale-thickness was comparable to the thickness of the pleura of SSc-ILD-patients. This finding shows that the increase in thickness of the pleurale can be totally reversible under treatment.

**Conclusion:** Due to the encouraging validity, reliability and simplicity of LUS, it has been increasingly considered as an excellent screening tool for SSc-ILD. Its sensitivity to reveal parenchyma and pleura changes over time in treated patients, make it also a helpful and safe methodology to follow up SSc-ILD patients.

**TARGET-CONTROLLED INFUSION (TCI) WITH PROPOFOL AND REMIFENTANIL FOR PROCEDURAL SEDATION AND ANALGESIA (PSA) IN PATIENTS WITH SYSTEMIC SCLEROSIS (SSC) UNDERGOING AUTOLOGOUS FAT GRAFTING PROCEDURES**

**R. Femenia,** A. Spinella,* A. Carratta, M. De Pinto, M. Starnoni, E. Bertellini, G. De Santis, C. Salvareda, D. Giuglioli,* 1University of Modena and Reggio Emilia, Department of Anesthesia and Intensive Care, Modena, Italy; 2University of Modena and Reggio Emilia, Department of Urology, Modena, Italy; 3University of Modena and Reggio Emilia, Department of Plastic Surgery, Modena, Italy; 4University of Modena and Reggio Emilia, Modena University, Italy; 5University of Modena and Reggio Emilia, Division of Plastic Surgery, Modena, Italy; 6University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy; 7University of Modena and Reggio Emilia, Department of Plastic Surgery, Modena, Italy

**Background:** Systemic Sclerosis (SSc) is an autoimmune disease characterized by vascular alterations and fibrosis. Difficult airway management, peripheral venous access and the presence of anti-collagen antibodies are challenging. Therefore, performing general anesthesia or moderate to deep sedation in these patients can be challenging. A high psychiatric burden is also common. These conditions, in association with a history of chronic pain, make even the local anesthesia procedure less effective than usual. Oral/digital autologous fat grafting approaches may improve aesthetic/functional aspects in SSC but the surgical procedure itself is painful and requires proper sedation. Target-Controlled Infusion with propofol (hypnotic) and remifentanil (opioid) is a well consolidated anesthesia technique and could be the best Procedure Sedation and Analgesia strategy to tolerate these interventions.

**Objectives:** Developing a new Procedural Sedation and Analgesia-PSA protocol to obtain moderate to deep sedation in Day Surgery environment to allow complete analgesia, amnesia and safe discharge in SSc patients undergoing autologous fat grafting procedures.

**Methods:** Eighteen-18 SSc patients referring to the Scleroderma Unit of our University Hospital were asked for oral/digital autologous fat grafting procedures between July and December 2021. A proper anaesthesiology schedule was assessed by an expert anesthesiologist of the team. After informed consent acquisition, patients were monitored with ECG/SpO2/Non Invasive Blood Pressure-NIBP. A peripheral intra-venous line with an ultrasound probe was placed if needed and TCI was started. Patients were maintained in spontaneous breathing and supplementary oxygen (4l/min) with a non-rebreathing cannula. The use of TCI pumps for the delivery of propofol and remifentanil allowed trained anesthesiologists to control and adjust the level of sedation and analgesia. The synergy between both propofol and remifentanil is well known, main risk for such technique is to oversedate patients resulting in respiratory depression and hypotension. Bispectral Index-BIS was used to monitor sedation level starting from 80-80, then tailoring the infusion according surgical needs. TCI was stopped at the end of surgery. Vital parameters were registered every 5 minutes and potential complications were monitored (hypotension-PAS<30% of basal line, hypoxia-SpO2<92%). Paracetamol 1g/ketorolac 15mg were administered for postoperative analgesia. A simplified satisfaction questionnaire based on LPPSq was also administered before discharge.

**Results:** All subjects have successfully undergone surgery and no hospitalization after the procedures was needed. A peripheral blood desaturation (SpO2<90%) was registered as main complication in 4 subjects, promptly relieved through nasal cannula replacement. One patient registered transient hypotension (decrease in systolic blood pressure>30% below baseline) without vasoactive drugs need. Main time to recovery of consciousness was 6.3 minutes (range 3-11). Two patients experienced transient pain and nausea, 1 itching, and 1 subjective difficulties in breathing/taking some minutes after the surgery with spontaneous resolution. All patients gave their consent to perform the same approach in the future.

**Conclusion:** TCI of propofol and remifentanil might be successfully used to ensure procedural sedation and analgesia in SSC surgical settings in presence of a skilled anesthesiologist. Further data are required to assess the incidence of possible major complications and patients’ satisfaction.

**MOLECULAR AND BIOLOGICAL PATHWAYS OF BREAST CANCER IN PATIENTS WITH SYSTEMIC SCLEROSIS: IMMUNOHISTOCHEMICAL INVESTIGATIONS FROM THE SCLERO-BREAST STUDY**

A. Spinella,* A. Tosi,* C. Isca,* M. De Pinto,* C. Vacchi,* L. Magnani,* F. Lumetti,* P. Macri,* G. Ficara,* L. Fabbiani,* A. Iannone,* E. Gasparini,* S. Piana,* L. Cortesi,* G. De Santis,* A. Maiorana,* M. Dominici,* C. Salvareda,* D. Giuglioli,* 1University of Modena and Reggio Emilia, Scleroderma Unit, Rheumatology Unit, Modena, Italy; 2University of Modena and Reggio Emilia, Department of Oncology and Hematology, Modena, Italy; 3University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy; 4AUSL-IRCCS of Reggio Emilia, Rheumatology Unit, Reggio Emilia, Italy; 5University of Modena and Reggio Emilia, Pathology Unit, Reggio Emilia, Italy; 6University of Modena and Reggio Emilia, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine, Modena, Italy; 7AUSL-IRCCS of Reggio Emilia, Department of Oncology, Reggio Emilia, Italy; 8AUSL-IRCCS of Reggio Emilia, Pathology Unit, Reggio Emilia, Italy; 9University of Modena and Reggio Emilia, Division of Plastic Surgery, Modena, Italy

**Background:** Systemic Sclerosis (SSc) is a life-threatening connective tissue disease characterized by endothelial dysfunction, autoimmune abnormalities and aberrant fibrosis. Several reports have described an increased risk of cancer in SSc compared to general population, including breast cancer (BC). The relationship between BC and SSc has long been discussed with contradictory results. In our recent Sclero-Breast study we analyzed clinical-pathological features of BC in SSc; we finally observed the development of BC with early stages and good prognosis among these patients. The aim of this project was to explore the immunohistochemical background and to study the expression of potential biomarkers involved in the molecular pathways at the basis of SSc and BC etiopathogenesis as update analysis from the Sclero-Breast study.

**Methods:** Our observational multicenter retrospective study, performed at Modena University Hospital and Reggio Emilia Hospital in northern Italy, enrolled 33 SSc women with a personal history of BC between January 2017 and December 2018. Clinical and pathological characteristics of BC and SSc were collected. For 22 patients, BC tissues and 9 patients SSc were assessed by specific antibodies to evaluate biomarkers and pathways potentially involved. The antibodies used included: P5K/MTOR/GFP/FRG2/PDGF/PDGFR/VEGF/EGFR/ IL-6/CFLA/IL-D1. We also reported TILs percentage (stromal tumor-infiltrating
lymphocytes) of each sample. The following scores were assigned for general IHC analysis: (-) negative, (1+) positive tumor cells <20%, (2+) positive tumor cells 20-50%, (3+) positive tumor cells >50%. For PD-L1 we considered a positivity in case of PD-L1 expression ≥1% in infiltrating inflammatory cells. For TILs quantification we applied the score: 0 (negative), ≤ 50% (low-medium expression), >50% (high expression).

**Results:** The first IHC analysis was performed on the samples of invasive BC patients (20 pts) and showed a prevalence of high PIIK expression (score of 3+ in 55% of cases) with mTOR overexpression in 45%. A PD-L1 positivity was detected in 30%, with high TILs expression in 35%. Biopsies from the 2 pts with ductal carcinoma in situ were characterized by a negativity of almost all parameters, except for a medium-high TILs expression reported (40%/90% respectively). See Figure 1. IHC analysis was also performed according to BC subtypes. The group of HR+/HER2 negative showed high PIIK expression (score 3+) in most of cases (59%) with mTOR overexpression in 50%. CTLA-4 and PD-L1 were positive in 25%, with high TILs expression in 25%. HER2 positive patients showed a high PIIK positivity in 50% of cases with mTOR positivity (score 3+) in 25% and high TGFβ expression (score 3+) in 25%. PD-L1 was positive in 50% with high TILs expression in 25%. In Triple Negative group, PI3K overexpression was found in 75% of pts with half of cases represented by mTOR score 3+. PD-L1 was positive in 50% with high TILs representation (80% of total cell count) in 50% of pts.

**Figure 1.** IHC analysis and TILs% expression in histological samples of SSC patients with invasive BC.

**Conclusion:** According to our results, SSC patients with BC showed high positivity for PD-L1 and high TILs representations in all subtypes. Furthermore, the high expression of PIIK, did not always correlate with mTOR overexpression. Further investigation into bigger numbers is needed; however, these aspects seem to confirm that SSC subjects might develop BC at good prognosis, suggesting again a de-esclation strategy of cancer therapies. Finally, the possibility to personalize oncological targeted treatments in this subset of fragile patients could be promising.

**THE EFFECT OF COVID-19 PANDEMIC ON IDIOPATHIC INFLAMMATORY MYOSITIS PATIENTS – A SINGLE CENTRE’S EXPERIENCE**

T. G. Griger1, A. Vincze1, B. Miltényi-Szabó1, Z. Varga1, M. Nagy-Vincze1, Z. Griger1. 1University of Debrecen, Faculty of Medicine, Department of Internal Medicine, Division of Clinical Immunology, Debrecen, Hungary

**Background:}** Pandemic caused by severe acute respiratory syndrome coronavi-

**Methods:** We retrospectively identified the confirmed COVID19 positive patients and assessed the symptoms, disease course and outcome on 01/06/2021 then patients were prospectively followed. Incidence and complications of vaccination were determined by questionnaires. Anti-SARS-CoV-2 S enzyme electrochemiluminescent immunoassay has been used to assess seroconversion, which measures total antibody (IgM and IgG) to the SARS-CoV-2 S protein and SARS-CoV2 N protein. Disease activity was determined by physician global activity.

**Results:** A total of 176 patients were screened and 101 participated in the study. By 01/06/2021, the COVID infection rate was 34.7% (mean age: 49.54 years, 72.72% women), which was significantly higher than the national prevalence at that time (8.2%). A third of these infections occurred asymptotically or mild but 20% of the infected patients were hospitalized, one patient died. Longer disease duration (8.67 vs. 17.87 years; p=0.003) and higher incidence of anti-Jo1 antibody (57% vs. 10% p=0.018) were significantly associated with hospitalization. All of COVID infected patients became seropositive regardless of immunosuppressive therapy or symptoms severity. 33.4% of the patients received anti-SARS-CoV-2 vaccine. 72.3% of patients received any recurrence. Every procedure was performed under local anaesthesia and appropriate analgesic therapy. A high degree of compliance and satisfaction was obtained. This procedure could be repeated by trained rheumatologists every 3 weeks in our Clinic. The aim of this repeated debridement was to promote the progression of the granulation tissue inside the dead tissue of the finger. Autologous fat grafting consists of a surgical procedure of ADSCs implantation at the base of the finger. It is performed in order to empower the neurovascular entity, tendon, and appropriate analgesic therapy. A high degree of compliance and satisfaction of all patients was noted.

**Conclusion:** Finger amputation in Systemic Sclerosis should be avoided. This traumatic surgical procedure is responsible for microvascular damages worsening SSC-related vasculopathy. Stump ulcers often occurs and wound healing usually takes place by secondary intention. In our experience, the combination of bone shaving and autologous fat grafting has proven to be effective and safe in preserving the maximum amount of viable tissue and obtaining a long-lasting result in treated SSC patients.

**EXTRACELLULAR VESICLES AS POTENTIAL BIOMARKERS OF EARLY DISEASE STAGE IN SYSTEMIC SCLEROSIS**

J. Colic1, I. Pruner2, N. Damjanov2, A. Antovic3, M. Selik Buškica3, A. Antovic3

1Institute of Rheumatology, Department of Rheumatology Unit, Belgrade, Serbia; 2Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden; 3Institute of Rheumatology, Department of Rheumatology Unit, Former Director of the Institute, Belgrade, Serbia; 4Institute of Rheumatology, Department of Rheumatology Unit, Head of Clinic IVb Department, Belgrade, Serbia; 5Karolinska Institute, Department of Medicine, Rheumatology Unit, Stockholm, Sweden

**Background:** Extracellular vesicles (EVs) are membrane-coated vesicles most often generated from the vasculature and circulating blood cells upon cell activation and during the early phase of apoptosis (1).

**Objectives:** To evaluate the concentration of different subpopulations of EVs in plasma from patients with SSC in relation to the disease duration and to the markers of endothelial injury.

**Methods:** Our study included 59 SSC patients (36 limited (ISSc) and 23 diffuse cutaneous (dSSc)) and 46 healthy age and gender matched controls subjects. Disease duration less than 3 years in patients with dSSc and less than 5 years in those with ISSc was considered as early disease stage. Clinical evaluation of patients was performed. EVs were analysed with flow cytometry after staining platelet poor plasma with fluorescent cell-specific monoclonal antibodies. The concentration of following phosphatidylserine-positive EVs (PS+ EVs) were analyzed: total EVs, endothelial EVs (EVs; CD144+), platelet EVs (PEVs; CD42b+), monocytes EVs (LEVs; CD14+), EVs expressing ICAM1 (CD54+), VCAM1 (CD106+) and P selectin (CD62p+). Serum levels of EVs, VCAM1 and P selectin were determined with ELISA.

**Results:** Median disease duration of our cohort was 4 (0-29) years (early ISSc 20(36); 2.5 (0-4.5) years; early dSSc [11;23]; 10 (1-30) months). All types of investigated EVs were significantly elevated in SSC patients compared to controls (p<0.05). Patients with early disease stage had significantly increased levels of all PS+EVs compared to HC (p<0.05). Moreover, the levels of EVs expressing ICAM1 and VCAM1 showed good validity in identifying patients with early disease stage (AUC 0.7, p<0.01). PEVs were increased in early dSSc compared to early ISSc; but the difference did not reach statistical significance (p=0.07). There was a correlation between serum levels and the levels of EVs expressing specific adhesion molecules (ICAM1: r=0.7, p=0.01; VCAM1: r=0.7, p=0.01; P selectin: r=0.7, p=0.01), only within the group with early dSSc subtype of the disease. Further correlations were detected between ICAM1+EVs with either mRSS (r=0.07, p=0.91) or EULAR activity index (r=0.07, p=0.02) among patients with early dSSc.

**Conclusion:** Increased levels of circulating EVs of different cell origin were present in patients with early SSC. EVs expressing either ICAM1 or VCAM1 could be novel biomarkers of early disease. EVs expressing ICAM1 showed association with severity of skin involvement and disease activity in patients with early dSSc giving insight into their role in the pathogenesis of SSC.

**THE ROLE OF RAYNAUD’S PHENOMENON ON MATERNAL AND FETAL OBSTETRICAL OUTCOMES**

F. Bellis1,2, V. Codulțo3, B. L. Palermo4, F. Bottazzò5, A. Biglia5, C. Bellinger5, F. Benuenti1, A. Spinillo1, C. Montecucco5, G. Zanframundo2, L. Cavagna2, 1Maurizio Umberto I Hospital, Rheumatology Unit, Turin, Italy; 2IRCCS Policlinico S. Matteo Foundation and University of Pavia, U.O.C. Reumatologia, Pavia, Italy; 3IRCCS Policlinico S. Matteo Foundation and University of Pavia, Department of Obstetrics and Gynecology, Pavia, Italy

**Background:** It is established that Raynaud’s phenomenon (RP) may influence pregnancy outcomes when secondary to rheumatic conditions (1,2). Data on the impact of primary RP (pRP) on pregnancy are very limited.

**Objectives:** To retrospectively evaluate the impact of pRP on pregnancy outcomes.

**Methods:** Women with pRP included in the study. They were compared with a group of women affected by UCTD with RP, and by UCTD without RP. These women were assessed and followed at our outpatient clinic from January 2011 to October 2020 and they did not exhibit an evolution to a UCTD or to a definite CTD during at least one-year follow-up. Antiphospholipid antibody positivity, twin pregnancies and voluntary termination of pregnancy were exclusion criteria.

Women with pRP were also compared with a group of healthy pregnant women

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.4827
nullified by our gynaecologist during the first trimester of pregnancy. Maternal and foetal outcomes were retrospectively recorded. ANOVA or the Kruskal-Wallis test for continuous variables, and the Chi2 test or the Fischer exact test for categorical were performed (level of significance: P<0.05). In the post-hoc analysis we used the Mann-Whitney test (quantitative variables) or with the Chi2 test (Fischer exact test (qualitative variables), applying the Bonferroni correction with pRP women as a reference group (level of significance: p<0.0167).

Results: The analysis included 188 women with a total of 375 pregnancies divided in 4 groups:
- Group “pRP”: 46 women with RP without secondary causes, and a total of 106 pregnancies (reference group).
- Group “RP-UCTD”: 48 UCTD women with RP and a total of 88 pregnancies.
- Group “UCTD”: 37 UCTD women without RP and a total of 88 pregnancies.
- Group “HC”: 57 healthy women with a total of 93 pregnancies.

The reference group did not differ from the others regarding age at conception. Prophylactic acetylsalicylic acid was administered during pregnancy to 9% of patients with pRP compared to 1% in HC (p=0.010). In contrast, in the RP-UCTD this percentage was significantly higher (32%, p<0.001) than in pRP.

pRP group showed an increased rate of 1st trimester miscarriages (33% vs 16%, p=0.006, OR 2.05 and 95%CI 1.05-3.98), a lower median birth weights (3038 vs 3358 g, p=0.002), a higher rate of infants with a birth weight <10 percentile (21% vs 3%, p=0.001, OR 8.36 and 95% CI 1.85 - 37.84) with respect to HC. There was no statistically significant difference between the reference and the UCTD groups. No statistically significant differences were observed when considering obstetrical outcomes (eg: mode of delivery, median gestation duration, gestational diabetes mellitus, hypertensive disorder of pregnancy, premature rupture of membranes, oligo-anhydramnion).

Conclusion: Our studies show that pRP in a retrospective cohort has an impact on pregnancy outcomes, with significantly more miscarriages and lower birth weight infants compared to HC. Importantly, pregnancy outcome in pRP women did not differ with respect to UCTD with and without RP conditions generally associated to maternal morbidity, but in the RP-UCTD group prophylactic acetylsalicylic acid was more commonly prescribed. Further prospective studies aiming at evaluating these differences and at identifying the appropriate follow-up and the possible benefit from the use of prophylactic acetylsalicylic acid during pregnancy in RP are necessary.

Disclosure of Interests:

Having presented this data at an international conference in 2019, we acknowledge that it was not often documented. Patients don’t always report symptoms unless targeted questions are asked. A clinical proforma would be invaluable, leading to an increased awareness amongst both practitioners and patients of the potential clinical manifestations. Having presented this data locally we have now introduced such a proforma and will re-evaluate clinical practice in the future. Sharing this information will hopefully help improve patient care elsewhere.

Conclusion: The piloting of our proforma of the GI assessment of patients with scleroderma has identified that the documentation of GI symptoms was poor. We don’t know whether GI symptomology was discussed during assessment however it’s evident that it was not often documented. Patients don’t always report symptoms unless targeted questions are asked. A clinical proforma would be invaluable, leading to an increased awareness amongst both practitioners and patients of the potential clinical manifestations. Having presented this data locally we have now introduced such a proforma and will re-evaluate clinical practice in the future. Sharing this information will hopefully help improve patient care elsewhere.

POS0927 CORONARY ARTERY CALCIFICATION IN SYSTEMIC SCLEROSIS: EVALUATION OF CARDIOVASCULAR RISK AND CLINICAL OUTCOME

S. Sciaccà1, C. Rotondo1, A. Corrado1, D. Ceci1, F. P. Cantatore1, 1University of Foggia, Rheumatology Unit, Department of Medical and Surgical Sciences, Foggia, Italy

Background: The primary prevention of cardiovascular disease (CVD) is a priority element of the worldwide health care agenda. An increased risk of CVD and CV mortality has been shown in lots of studies conducted on patients affected by inflammatory and autoimmune diseases. A routine evaluation of CV risk in these patients should be encouraged and in particular cases is recommended.

Objectives: The aim of this study was to evaluate the prevalence of subclinical atheromatosis, the CV risk and its performance in a cohort of patients affected by Systemic Sclerosis (SSc) from a single reference tertiary care hospital.

Methods: Sixty-seven patients with SSc according to the ACR/EULAR 2013 criteria were included. Traditional CV risk factors and SSc related factors were analyzed. Thoracic high resolution computed tomography (CT) was performed, using the quantification of coronary calcium for the study. Furthermore, a doppler ultrasound of the carotids and the lower extremity arteries was conducted for the detection of subclinical atheromatosis. The CV risk has been calculated through different CV risk scales including the MESA CAC, the Italian Progetto Cuore, the Framingham score, the Score2 and the QRISK3. After conducting a 5-year follow up, CV outcome and electrocardiography abnormalities were examined.

Results: Calcium artery coronary score > 0 was reported in twenty-eight SSc patients (41.8%). Considering traditional CV risk factors, the multivariate regression analysis showed a correlation with age (OR 1.151 [95% CI 1.06–1.25], P = 0.032). Instead, the presence of anti-cENP-B (OR 3.47 [95% CI 1.09–11.06], P = 0.035) and late-onset disease (OR 1.062 [95% CI 1.007–1.119], P = 0.026) were identified as potential specific disease risk factors. The prevalence of ultrasound atherosclerosis in SSc was high: peripheral artery disease (PAD) and carotid plaque were respectively 43% and 41%, and the presence of coronary calcifications was a risk factor for their detection with a OR respectively of 20.39 and 20.49 (p<0.0001). All CV risk scores considered SSc patients in a low risk, except for the QRISK3, whose values were higher in patients with coronary calcifications (18.4±12.6 vs 5.1±4.9, p<0.0001). In 5-years follow up only one patient died for CVD and 2 CV events occurred. Electrocardiography anomalies were found in 28.35% of patients, and in particular in 43% of patients with coronary calcifications (OR 3.321 [95% CI 1.094-10.08], P = 0.03). Conclusion: Subclinical coronary atherosclerosis seems to be largely observed in SSc patients and may represent an additional risk factor for electrocardiography anomalies and subclinical atheromatosis in other anatomical districts, with no impact on CVD mortality. SSc coronary calcifications were not correlated with CV risk score, especially the novel QRISK3 by classifying these patients between low and moderate CV risk. Other studies are needed to support the hypothesis that subclinical coronary atherosclerosis, occasionally detected in thoracic CT, may represent a clinical alert to establishing timing and weight of diagnostic and specific treatment protocols for the CV prevention in SSc patients.

POS0928 THE IDENTIFICATION OF PENTRAXIN 3 AS BIOMARKER OF DISEASE ACTIVITY IN IDIOPATHIC INFLAMMATORY MYOPATHIES

M. Fornaro1, G. Carabellissi1, F. Caccipaglia1, C. Sciocia1, L. Coladonato1, V. Venerito1, R. Bizzoca1, D. Natuzzi1, N. Lacarpa1, G. Lopalco1, F. Iannone1

1Department of Emergence and Transplantation (DETO), University of Bari, Rheumatology Unit, Bari, Italy; 2Department of Medical and Surgical Sciences, University of Foggia Medical School, Rheumatology Clinic, Foggia, Italy

Background: Muscle involvement is only one feature of idiopathic inflammatory myopathies (IIM). Muscle enzymes do not always represent the best marker of disease activity and other inflammation markers such as ESR and CRP may be normal even with an active disease. Pentraxin-3 (PTX3) is an inflammatory disease activity marker, PTX3 levels do not correlate with lipid levels, QIMT calcifications was a risk factor for their detection with a OR respectively of 20.39 Carotid intima media thickness (cIMT) was measured with a My Lab XPro80 (Esaote SpA, Genova, Italy) using a linear array ultrasound probe small parts broadband transducer (5–15 MHz) both in right and left carotid. Myositis disease activity was evaluated by using myositis disease activity assessment visual analog scales (MYOACT) [19] established by the International Myositis Study Group (IMAG). Manual muscle test (MMT) was used to assess muscle impairment. Exclusion criteria were a diagnosis of diabetes or a history of previous major CV events.

Methods: Twenty patients affected with IIM (13 Dermatomyositis and 7 Polymyositis), 10 rheumatoid arthritis patients and 10 healthy controls (HC) aged, sex and BMI matched were evaluated. PTX3 levels was assessed using a commercially available enzyme-linked immunosorbent assay (Human Pentraxin3 ELISA Kit, Invitrogen) kit. Three different cardiovascular risk scores were used to estimate the 10-years CV risk. Carotid intima media thickness (cIMT) was measured with a My Lab XPro80 (Esaote SpA, Genova, Italy) using a linear array ultrasound probe small parts broadband transducer (5–15 MHz) both in right and left carotid. Myositis disease activity was evaluated by using myositis disease activity assessment visual analog scales (MYOACT) [19] established by the International Myositis Study Group (IMAG). Manual muscle test (MMT) was used to assess muscle impairment. Exclusion criteria were a diagnosis of diabetes or a history of previous major CV events.

Results: Demographic and disease characteristics of our cohort are showed in Table 1. IIM patients showed higher levels of PTX3 compared to HC (518±260 pg/ml vs 273±114 pg/ml, p<0.05), while no difference was observed compared to RA patients (383±260 pg/ml). PTX3 levels do not correlate with lipid levels, QIMT and cardiovascular risk scores both in IIM, RA and HC. No correlation was found between DAS28-ESR and PTX3 levels in RA patients. Of note, a direct correlation
was found between PTX3 levels and MYOACT - GLOBAL EXTRASYMPTOMATIC MUSCLE DISEASE ACTIVITY (r=0.542, p=0.013), while an inverse correlation was found between PTX3 levels and MMT8 (r=-0.510, p=0.02).

Spondyloarthritis - treatment

POS0930
SAFETY AND EFFICACY OF IXEKIZUMAB TREATMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: 3-YEAR CLINICAL TRIAL RESULTS FROM THE COAST PROGRAMME

Background: Ixekizumab (IXE) has demonstrated efficacy at week (wk) 16 which was maintained through 2 years (yrs) and was associated with a consistent safety profile in patients (pts) with r- and nr-axSpA, who are bDMARD-naïve and TNF-1 experienced.1,3

Objectives: To report safety and efficacy from the COAST programme at 3 yrs: 1 yr of the originating studies (COAST-V/W/X) and 2 yrs of COAST-Y.

Methods: COAST-Y (NCT03219900) is the phase 3, long-term extension study of the 3 originating studies COAST-V/W/X. Pts continued with the dose received at the end of the originating trial at wk (wk) 52 either with BDM 56/932/932 (93%) re-randomised to IXE Q4W or Q2W at wk 16 in COAST-Y and -W. Pts who received PBO for 52 wks in COAST-X were switched to IXE Q4W to continue in COAST-Y. Starting at wk 116 (wk 64 of COAST-Y), pts receiving IXE Q4W could have their dose escalated to Q2W. This analysis focused on pts receiving ≥1 dose of IXE Q4W, observed data while on IXE Q2W dose escalation are excluded. Continuation data are summarised as observed. Safety data while on IXE were analysed for pts who received ≥1 dose of IXE; observed data while on PBO or ADA are excluded.

Results: A total of 932 pts received ≥1 dose of IXE; 414 received ≥1 dose of IXE Q4W, and 562/932 (60%) pts completed 3 yrs of follow-up (PBO→IXE Q4W, 631/932 (53%); ADA→IXE Q4W, 299/444 (66%); and IXE Q4W→IXE Q4W, 114/251 (45%).)

Observations: IXE Q4W was efficacious (observed data) in all patients studied. Through 3 yrs, the most frequently reported treatment-emergent adverse events were infections [incidence rate (IR) 25.7/100 patient years (PY)] and injection site reactions [IR 7.4/100 PY]; the majority of which were mild/moderate in severity. Serious adverse events were reported at an IR of 4.8/100 PY, of which osteoarthritis was the most frequent at 0.4/100 PY. A total of 3 deaths were reported among all pts who received ≥1 dose of IXE [IR [0.1/100 PY]. For all pts, baseline disease activity (Ankylosing Spondylitis Disease Activity Score; ASDAS) was high (see Table 1). The 3 yr mean (SD) change from baseline (observed) in ASDAS among bDMARD-naïve pts with r-axSpA, TNF-1 experienced pts with r-axSpA, and bDMARD-naïve pts with nr-axSpA is presented in Table 1. A consistent disease control through 3 yrs was confirmed across additional efficacy endpoints (Table 1).

Conclusion: This analysis of a subset of pts in COAST-Y demonstrated that the safety profile is consistent with the established safety profile, with no new safety signals observed. IXE Q4W was efficacious (observed data) in all patients studied who remained on the treatment through 3 yrs.

Figure 1. Observed mean CFB in ASDAS for pts treated with IXE Q4W in COAST-V. At wk 16, PBO pts received IXE Q4W.

Table 1. Baseline demographics and disease activity characteristics through 3 yrs. Data presented as mean (SD) unless otherwise specified.
Background: Ixekizumab (IXE), a monoclonal antibody that selectively targets interleukin IL-17A, has shown efficacy in patients with radiographic axial spondyloarthritis (r-axSpA). Spinal pain, in particular spinal pain at night (SP-N), is a severity NRS, Jenkins Sleep Evaluation Questionnaire (JSEQ), SF-36 PCS) at W16, and ASDAS LDA at W52 were tested using analysis of covariance (ANCOVA; continuous variables) and logistic regression (binary variables). Missing values were imputed using non-responder imputation, and modified baseline observation carried forward.

Results: A greater proportion of patients achieved >2 improvement in SP-N with IXE treatment compared to PBO at W16 (63.0% vs. 32.2%, p <0.001) and improved using non-responder imputation, and modified baseline observation carried forward. For the sub-group of 11,892 patients, IXE dominated the newer b/tsDMARD uptake (1,848 new-starts, Figure 1). Use of JAKi was limited, especially in b/tsDMARD-naïve patients. In b/tsDMARD-naïve patients, apremilast had the fastest uptake (490 new-starts) (Figure 1). Of the 81 patients originally randomised to IXE, those achieving >2 improvement in SP-N (63%) at W16 were younger, more frequently positive for HLA-B27 and had higher disease activity at baseline compared to those that did not achieve >2 improvement (Table 1). Achieving >2 improvement in SP-N was associated with improvement in PROs including BASFI, Fatigue Severity, JSEQ and SF-36 PCS at W16 and with achieving ASDAS≤2.1 at W52 compared to those not achieving >2 improvement in SP-N (Table 1).

Table 1. Baseline demographics, clinical characteristics, and PROs of IXE-treated patients achieving vs. not achieving >2 improvement in SP-N at W16.

Conclusion: IXE improved SP-N for patients with r-axSpA not previously treated with b/tsDMARDs. Improvements in SP-N were associated with improvements in disease activity, function, fatigue and quality of life.

POS0393 UPTAKE OF NEWER BIOLOGIC AND TARGETED SYNTHETIC DMARDS IN PSORIATIC ARTHRITIS, RESULTS FROM FOUR NORDIC BIOLOGIC REGISTRIES

B. Glinborg 1, 2, D. Di Giuseppe 3, J. K. Wallmark 4, D. Nordström 5, B. Gudbjornsson 6, M. L. Hettland 7, J. Askling 8, G. Gröndal 6, T. Sokka 9, S. Aarrestad Provan 10, U. Lindström 2, 11University Hospital of Copenhagen Rigshospitalet, DANBO and Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark; 2University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark; 3Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden; 4Lund University, Skåne University Hospital, Lund, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; 5Helsinki University Hospital and University of Helsinki, ROB-FIN, Helsinki, Finland; 6Landspitali University Hospital Centre for Rheumatology Research (ICEBIO), Reykjavik, Iceland; 7University of Iceland, The Faculty of Medicine, Reykjavik, Iceland; 8Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; 9Jyväskylä Central Hospital, Rheumatology, Jyväskylä, Finland; 10Faculty of Health Sciences, UEF, Kuopio, Finland; 11Danderynment Hospital, Division of Rheumatology and Research, Oslo, Norway; 12Sahlgrenska Academy at University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden.

Background: The treatment landscape in psoriatic arthritis (PsA) is changing, including newer biologic and targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) with different modes of action becoming available. However, the most effective treatment strategy in routine care remains to be established.

Objectives: To explore the uptake and treatment patterns of newer b/tsDMARDs, namely JAK-inhibitors (JAKi; baricitinib, tofacitinib, upadacitinib), IL-17 inhibitors (ixekizumab, secukinumab), abatacept, apremilast, and ustekinumab in PsA patients from the Nordic countries. Furthermore, to describe patient characteristics and extra-musculoskeletal manifestations at treatment start (=baseline).

Methods: Observational cohort study, using prospectively collected routine care data from 4 Nordic rheumatology registries. Treatments (newer b/tsDMARDs) with different modes of action becoming available. However, the most effective treatment strategy in routine care remains to be established.

Results: The treatment landscape in psoriatic arthritis (PsA) is changing, including newer biologic and targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) with different modes of action becoming available. However, the most effective treatment strategy in routine care remains to be established.

Conclusion: The most effective treatment strategy in routine care remains to be established.

Numbers are mean (SD) unless otherwise stated; IBD: inflammatory bowel disease, bDMARD: biologic DMARD, ts: targeted synthetic;

Background: Sacroiliac joint injection in axial spondyloarthritis (SpA) patients was controversial. A well-designed randomized clinical trial testing its effect on different disease outcome measures particularly bone marrow edema was missing [1].

Objectives: To test the effect of steroid injection in the sacroiliac joint of axial SpA patients on different disease outcome measures.

Methods: N = 43 were registered. They were randomly assigned into 2 groups: Group I (23 cases) received sacroiliac joint injection of lidocaine hydrochloride mixed with triamcinolone, whereas Group II (22 cases) received subcutaneous saline injections. All participants fulfilled the ASAS criteria for axial SpA and they all had bone marrow edema at baseline. Outcomes measures were: Visual Analogue Scale (VAS), ASDAS, BASFI, and SPARCC scores. Participants were assessed at baseline (before and after sacroiliac joint injection) and after 3 months.

Results: There was a significant difference between both groups regarding pain, spine mobility, SPARCC and ASDAS scores in favor of group I. Spine mobility showed the earliest improvement, followed by pain whilst SPARCC and ASDAS scores showed improvement after 3 months. Higher disease activity, younger age, and shorter disease duration all were associated with better outcomes. Bilateral hip involvement was a predictor of poor response.

Conclusion: Sacroiliac joint injection of lidocaine and triamcinolone in axial SpA patients is effective in controlling pain, improving function, disease activity scores, and bone marrow edema with acceptable complications and relatively sustained effect.

REFERENCES:
Efficacy of Upadacitinib on Psoriatic Arthritis with Axial Involvement Defined by Investigator Assessment and PRO-Based Criteria: Results from Two Phase 3 Studies

Background: Patients with PsA and axial involvement have higher disease activity and greater reductions in quality of life1; however, there are no accepted criteria for identifying axial involvement in PsA.

Objectives: The objective of this post-hoc analysis is to assess the efficacy of upadacitinib (UPA), a Janus kinase inhibitor, on axial symptoms in patients with active PsA and axial involvement defined by investigator assessment and PRO-based criteria from two phase 3 SELECT trials.2,3

Methods: Patients with active PsA (≥3 swollen joints and ≥3 tender joints) and prior inadequate response or intolerance to ≥1 non-biologic (SELECT-PsA 1) or ≥1 biologic (SELECT-PsA 2) DMARD were randomly assigned to once daily oral UPA 15 mg or 30 mg, placebo (PBO), or every other week subcutaneous adalimumab (ADA) 40 mg (SELECT-PsA 1 only). At baseline, axial involvement in PsA was determined by investigator assessment based on the totality of clinical information, such as duration and character of back pain, age of onset, and previous imaging. In addition to investigator assessment, PRO-based criteria for axial involvement (BASDAI >4 and BASDAI Question 2 >4 at baseline) were applied for this analysis to identify patients with active disease. Efficacy in the sub-group of patients defined using both investigator assessment and PRO-based criteria was evaluated at week 24 for UPA 15 mg vs PBO and ADA (SELECT-PsA 1 only). Data were analyzed using mixed-effect model repeated measures (MMRM) or non-responder imputation (NRI), with nominal P-values shown.

Results: Based on investigator assessment alone, 31.3% (n=534/1704) of patients in SELECT-PsA 1 and 34.2% (n=218/641) in SELECT-PsA 2 were defined as having axial involvement. When both investigator assessment and PRO-based criteria were applied, 23.1% (n=393/1704) of patients in SELECT-PsA 1, or 73.6% (n=393/543) of those defined using investigator assessment alone, and 27.5% (n=176/641) in SELECT-PsA 2, or 80.4% (n=176/219) using investigator assessment alone, met the combined criteria for axial involvement. In both studies, UPA 15 mg showed significantly greater clinical responses vs PBO at week 24 across all endpoints assessed (Figure 1). In SELECT-PsA 1, UPA showed numerically greater responses than ADA at week 24 across all BASDAI and Ankylosing Spondylitis Disease Activity Score (ASDAS) endpoints. The proportion of patients achieving ASDAS clinically important improvement (CII) at week 24 was significantly greater with UPA vs ADA based on nominal P-value.

Conclusion: Patients with active PsA and axial involvement defined by both investigator assessment and PRO-based criteria demonstrated statistically greater clinical responses related to their axial involvement with UPA 15mg compared to PBO, and consistently numerically higher responses compared to ADA, at week 24 in the SELECT-PsA trials. Findings from this post-hoc analysis are consistent with previous data based on investigator assessment alone.4

Background: Certolizumab pegol (CZP) in women of childbearing age with rheumatoid arthritis has a more favorable response, suggesting a possible distinctive effect in this group.

Objectives: To evaluate the retention rate of CZP compared to other anti-TNFs and anti-IL17A in patients affected by axSpA, grouped according to gender and age.

Methods: Cross-sectional study within the BIOBADASER registry. Patients older than 17 years old, with axSpA receiving anti-TNFs or anti-IL17A were selected. Mean and standard deviations of BASDAI and ASDAS-CRP were performed at baseline, 1st and 2nd year of treatment. Patients were classified according to treatment into groups 1) CZP, 2) anti-TNF, and 3) anti-IL17A, and according to sex and age in the following groups: 1) women between 18 and 45 years old (young women), 2) women over 45 years old (old women), 3) men.

Results: Groups and gender distribution, treatment prescription, ASDAS-CRP and BASDAI values according to therapeutic line and demographical characteristics are shown in Table 1. Overall, young women treated with CZP showed remission or low BASFI, and in the first 5 years of follow-up, compared to low activity for the rest of the molecules. A higher retention rate was observed for both CZP and anti-IL17A compared to other treatment groups was observed in young women. This difference was observed since the first year of treatment (71.4 (64.2-77.4) all anti-TNF, 84.4 (66.4-93.2) CZP, 72.2 (53.2-84.5) anti-IL17) and the magnitude was maintained during the first 5 years of follow-up (Figure 1). In older women, a higher retention rate was observed for both CZP and anti-IL17A compared to anti-TNFs (71.6 (65.4-76.8) in all anti-TNF, 78.1 (54.9-90.3) in CZP, 75.3 (61.3-84.9) in anti-IL17). In males there were no long-term differences (79.2 (76.3-81.8) all anti-TNF, 73.0 (62.0-81.4) CZP, 64.6 (57.3-71.0) anti-IL17).

Figure 1. Five years retention rate (first line treatment)

Focussed on first line treatment, the differences were greater in young women. The second and subsequent lines showed the same trends with a lesser extend. Globally, we do not observe these differences in men.

Conclusion: These data suggest a possible specific effect of Certolizumab Pegol in women with axial spondyloarthritis, especially in young women and when used as first line treatment.

**Figure 1. Predictive margins of BASDAI and BASFI 36-months pre- and post- bDMARD initiation A-E, Predictive margins of the BASDAI score (overall – all components, A); BASDAI Q1 fatigue (B); BASDAI average of Q2-Q4 spinal pain, joint pain, enthesitis (C); BASDAI average of Q5-Q6 morning stiffness (D); and BASFI (E).**

**Conclusion:** In our study population, there was clinically meaningful worsening of disease activity over 36-months prior to initiation of first bDMARD, despite baseline (36-months prior to first bDMARD initiation) BASDAI exceeding the current threshold for bDMARD treatment (BASDAI≥4). A clinically meaningful and maintained improvement in disease activity was reported across all cohorts in the 36-months following first bDMARD initiation.

**MEASURE 2: SECUKINUMAB PROVIDES RAPID AND SUSTAINED RELIEF FROM KEY CLINICAL SYMPTOMS OF ACTIVE ANKYLOSING SPONDYLITIS IN TNFI-NAÏVE PATIENTS THROUGH 5 YEARS**

1Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic; 2Altona Center for Clinical Research, Altona Center for Clinical Research, Duncansville, PA, United States of America; 3Novartis Pharmaceuticals Corporation, US Clinical Development and Medical Affairs, Rheumatology, East Hanover, NJ, United States of America; 4Novartis Pharma AG, Global Medical Affairs Biostatistics in Global Drug Development, Basel, Switzerland; 5Novartis Pharma AG, Global Medical Affairs, Rheumatology, Basel, Switzerland; 6Hospital Universitario Marques de Valdecilla (IDIVAL), Servicio de Reumatologia, Santander, Spain

**Background:** Ankylosing spondylitis (AS) is a chronic, inflammatory disease resulting in debilitating clinical symptoms such as pain (70–83%), stiffness (54–90%) and fatigue (53–62%). Secukinumab (SEC 150 mg) has demonstrated long-term efficacy across multiple indications and is approved for the treatment of active AS in adults who have had an inadequate response to NSAIDs.

**Objectives:** The Phase 3 MEASURE 2 trial (NCT01649375) assessed long-term efficacy, safety and tolerability of SEC in patients (pts) with active AS. This post-hoc analysis was conducted specifically to evaluate long-term efficacy of SEC 150 mg on key clinical symptoms of pain, morning stiffness, physical function and fatigue in TNFi-naïve pts over 5 years.

**Methods:** The MEASURE 2 study design has been reported previously. This post-hoc analysis evaluated key clinical symptoms at baseline through Wk 260. Assessments included total and nocturnal back pain (visual analogue scale [0–100 mm]), overall spinal pain (neck, back, or hip) from BASDAI, and morning stiffness (average BASDAI). Physical function (SF-36 PCS, BASFI), fatigue (BASDAI, FACIT) and disease activity (ASDAS-CRP) are also reported. Data are presented as LS mean change (± SE) using mixed model repeated measures from Wks 4–16 and observed data (mean ± SD) from Wks 24–260.

**Results:** Of TNFi-naïve pts randomised to SEC 150 mg, 89 were included (SEC, n=44, placebo [PBO], n=45) in this analysis. Of these pts randomised to SEC 150 mg, 84% completed 5 years of treatment. Significantly greater improvements were observed in pts treated with SEC 150 mg vs PBO at Wk 16 and were sustained through 5 years (Figure 1; Table 1).
for up to 48 weeks (wks) in the phase 2b BE AGILE study.1 Maintaining stringent and rapid efficacy in patients (pts) with active ankylosing spondylitis (AS) treated inhibiting interleukin (IL)-17F in addition to IL 17A, has demonstrated significant Preliminary Results: 10.1136/annrheumdis-2022-eular.2049

Randomised set. *Primary endpoint; †Secondary endpoint; aMASES=0 in pts with BL MASES >0; bn=92; cn=94; dNominal p values not shown; en=17; fn=10; gIn pts in MRI sub-study; hn=65; in=75; jn=58; kn=73; ln=68; mn=79; nn=60; on=77.

Background: Bimekizumab (BIZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17A and IL-17F with BKZ in pts with active nr-axSpA resulting in rapid, clinically relevant improvements in efficacy outcomes vs PBO. No new safety signals were observed.1,2

Objectives: To assess efficacy and safety of BKZ vs placebo (PBO) in pts with active non-radiographic axial spondyloarthritis (nr-axSpA) up to Wk 24 in the ongoing pivotal phase 3 study, BE MOBILE 1.

Methods: BE MOBILE 1 (NCT03928704) comprises a 16-wk double-blind, PBO-controlled period and 36-wk maintenance period. Pts were aged ≥18 yrs, had BASDAI ≥4 and spinal pain ≥4 at BL, and sacroiliitis on MRI and/or elevated hs-CRP at screening. Pts were randomised 1:1, BKZ 160 mg Q4W.PBO. From Wk 16, all pts received BKZ 160 mg Q4W. Primary and secondary efficacy endpoints were assessed at Wk 16. Results: Of 254 randomised pts (BKZ: 128; PBO: 126), 244 (96.1%) completed Wk 16, 240 (94.5%) Wk 24. BL characteristics were comparable between groups: mean age 39.4 yrs, symptom duration 9.0 yrs; 54.3% pts male, 77.6% HLA-B27+, 10.6% TNIF-experienced. At Wk 16, the primary (ASAS40: 47.7% BKZ vs 21.4% PBO; p<0.001) and all ranked secondary endpoints were met (Table 1). Responses were rapid with BKZ, including in PBO pts who switched to BKZ at Wk 16, and increased to Wk 24 (Fig. 1, Table 1). Substantial reductions of hs-CRP by Wk 2 and MRI SIJ inflammation by Wk 16 were achieved with BKZ vs PBO (Table 1). At Wk 24, >50% of pts initially randomised to BKZ had achieved ASDAS <2 (Fig. 1).

Over 16 wks, 80/128 (62.5%) pts had ≥1 TEEA on BKZ vs 71/126 (56.3%) on PBO; most frequent were nasopharyngitis (BKZ: 9.4%; PBO: 4.8%), upper respiratory tract infection (BKZ: 7.0%; PBO: 7.1%) and oral candidiasis (BKZ: 3.1%; PBO: 0%). No systemic candidiasis was observed. Up to 16 wks, incidence of SAEs was low (BKZ: 0.0%; PBO: 0.8%); no MACs or deaths were reported; 0 IBD cases occurred in pts on BKZ vs 1 (0.8%) in a pt on PBO.

Conclusion: Dual inhibition of IL-17A and IL-17F with BKZ in pts with active nr-axSpA resulted in rapid, clinically relevant improvements in efficacy outcomes vs PBO. No new safety signals were observed.1,2

**LONG-TERM CLINICAL OUTCOMES OF CERTOLIZUMAB PEGOL TREATMENT IN PATIENTS WITH ACTIVE NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS STRATIFIED BY BASELINE MRI AND C-REACTIVE PROTEIN STATUS**

P. Robinson¹, W. P. Maksymovych², L. S. Gensler³, M. Rudwaleit⁴, B. Hoepken⁵, L. Bauer⁵, T. Kumke⁵, M. Kim⁶, A. Deodhar⁷, ¹University of Queensland School of Clinical Medicine, University of Queensland, Brisbane, Australia; ²Department of Medicine, University of Alberta, Alberta, Canada; ³University of California San Francisco, N/A, San Francisco, California, United States of America; ⁴University of Bielefeld, Klinikum Bielefeld, Bielefeld, Germany; ⁵UCB Pharma, N/A, Monheim am Rhein, Germany; ⁶UCB Pharma, N/A, Smyrna, Georgia, United States of America; ⁷Oregon Health & Science University, N/A, Portland, Oregon, United States of America

**Background:** Certolizumab pegol (CZP) has demonstrated clinical efficacy in patients with active non-radiographic axial spondyloarthritis (nr-axSpA) and objective signs of inflammation during the 52-week (wk) placebo (PBO)-controlled period and 104 wk open-label (OL) safety follow-up extension (SFE) of the C-axSpAnd study. There is, however, a paucity of data on the long-term efficacy of biologics in nr-axSpA according to patients' baseline MRI and C-reactive protein (CRP) status.

**Objectives:** This post hoc analysis from C-axSpAnd aimed to evaluate whether patients' baseline MRI and CRP status impacted long-term (3-year) clinical responses to CZP.

**Methods:** C-axSpAnd (NCT02552212) was a 3-year, phase 3, multicentre study. Adults (N=317) with nr-axSpA fulfilling the Assessment of SpondyloArthritis international Society (ASAS) classification criteria and objective signs of inflammation (CRP ≥ upper limit of normal (10 mg/L) [CRP+]) and/or evidence of sacroiliitis on MRI [MRI+] were randomised 1:1 to PBO or CZP (400 mg at Wks 0, 2 and 4, then 200 mg every 2 wks [Q2W]) for 52 wks. Those enrolled into the SFE received OL CZP (200 mg Q2W) for an additional 104 wks. ASDAS major improvement (ASDAS-MI, C-axSpAnd primary outcome) and ASAS 40% response (ASAS40) at Wks 52 and 156 were assessed according to prespecified subgroups based on MRI/CRP status (MRI+, CRP+; MRI−, CRP−; MRI+, CRP−; MRI−, CRP+). All data are reported as observed case.

**Results:** 243/317 (76.7%) patients entered the SFE, 120 from the group initially randomised to CZP (36 MRI+/CRP+, 32 MRI−/CRP+ and 52 MRI+/CRP−) and 123 from the initial PBO group (30 MRI+/CRP+, 34 MRI−/CRP+ and 59 MRI+/CRP−). 75/123 had switched to OL treatment in the 52 wk double-blind phase. 206/243 completed the SFE; 102/120 (85.0%) from the group initially randomised to CZP. 104/123 (84.6%) from the initial PBO group. Among CZP-randomised patients, mean ASDAS was similar between timepoints (MRI+/CRP+: 1.6 at Wk 52 vs 1.6 at Wk 156; MRI−/CRP+: 2.1 vs 2.2; MRI+/CRP−: 1.7 vs 1.6), the percentage achieving ASDAS-MI was lower at Wk 156 compared to Wk 52 across all subgroups (Figure 1A). Patients initially randomised to PBO showed improvements in mean ASDAS over time (MRI+/CRP+: 2.1 Wk 52 vs 1.8 Wk 156; MRI−/CRP+: 2.2 vs 1.9; MRI+/CRP−: 2.0 vs 1.7) and a sustained proportion of patients achieved ASDAS-MI. Similar results were shown for BASDAI, with mean scores for CZP-randomised patients sustained from Wk 52 to Wk 156 across all subgroups (Figure 1B). Mean BASDAI decreased (indicative of clinical improvements) from Wk 52 to Wk 156 in patients initially randomised to PBO, at which point the values aligned with those reported for the CZP-randomised group. In CZP-randomised patients, ASAS40 responses were sustained at Wk 156 compared to Wk 52. An increased percentage of patients achieved ASAS40 in all MRI/CRP subgroups initially randomised to PBO at Wk 156 compared to Wk 52 (Figure 1C).

**Conclusion:** In this analysis of patients with nr-axSpA and objective signs of inflammation, long-term clinical outcomes achieved after 1 year were generally sustained at 3 years across MRI+/CRP+, MRI−/CRP+ and MRI+/CRP− subgroups; ASDAS-MI was numerically highest in the MRI+/CRP+ subgroup.

Background: Tumor necrosis factor inhibitors (TNFi) have become a mainstay of management for axial spondyloarthritis (axSpA). However, it remains unclear whether patients with axSpA should continue the standard-dose TNFi after achieving stable disease activity. Although complete discontinuation of TNFi is followed by early relapse in most cases, several studies documented that reduced doses of TNFi in patients with prolonged low disease activity showed similar effects on disease control and drug survival compared to standard dose of TNFi. One of the main problem in the dose-tapering strategies for TNFi is a selection of the appropriate patient. However, there has been a lack of robust evidence regarding clinical factors predicting the flare after tapering of TNFi in patients with axSpA.

Objectives: This study aims to develop and validate the prediction model to select the patients in whom tapering of TNFi does not lead to flare.

Methods: We used the data from Korean College of Rheumatology Biologics registry, which included a total of 1,730 patients receiving biologic DMARD from 2017 to 2019 in South Korea. In this study, a total of 526 patients who were initially treated with the standard-dose TNFi and tapered the dose after at least 1 year of the treatment were analyzed. Dose quotient (DQ, 0-1) was applied to quantified TNFi used during interval. The main outcome was an occurrence of flare defined as ASDAS-CRP score of ≥2.1 after 1 year of tapering TNFi. To develop the prediction model, clinical factors having relevant association (p < 0.1) with the outcome were first selected as candidate predictors. Logistic regression using a stepwise approach through backward elimination was used for the final model.

Results: Patients' mean (SD) age was 37.5 (11.9) years, 418 (79.5%) were men, and 474 (90.1%) were HLA-B27 positive. Mean disease duration was 5.0 (6.1) years and 433 (82.3%) were TNFi naive. The mean BASFI and ASDAS-CRP at baseline were 3.4 (2.6) and 3.7 (1.0), respectively. Approximately two-thirds of the patients (65.8%) were initiated TNFi tapering at the first 1 or 2 years from baseline. At the time of TNFi tapering, the mean DQ was 0.67 (0.15) and 381 (72.4%) were prescribed concurrently with NSAIDs, and the mean BASFI and ASDAS-CRP were 1.3 (1.8) and 1.6 (0.9), respectively. During 12 months of follow up starting from the TNFi tapering, 127 (24.1%) experienced the flare. The multivariable analysis revealed that HLA-B27 positivity (OR 1.087; 95% CI 0.978-1.209; p=0.004), inflammatory back pain (OR 2.920; 95% CI 1.283-6.648; p=0.001), age (OR 1.014; 95% CI 1.011-1.017; p<0.001), and BASFI at tapering (OR 1.214; 95% CI 1.051-1.402; p=0.008) were significantly associated with flare. Based on the results of the logistic regression analysis, the predicted probability was calculated by the following formula: P=1/[1+exp{-[1.088 x HLA-B27 negativity + 1.072 x inflammatory back pain + 1.567 x psoriasis + 0.623 x family history of axSpA + 1.092 x diabetes mellitus + 0.435 x DQ at TNFi tapering + 1.029 x ASDAS-CRP at TNFi tapering + 0.194 x BASFI at TNFi tapering]}]. The best cut-off value of the model to define the flare was 0.2416 (95% CI 0.176, 0.301) with sensitivity 74.0% and with specificity 81.0%. AUC was 0.828 (95% CI 0.786-0.869) indicating a good predictive model (calibration slope 1.110, 95% CI 0.903, 1.317; intercept 0.026, 95% CI -0.091, 0.039).

Conclusion: We developed the prediction model for the flare after 12 months of TNFi tapering in patients with axSpA. It might be applicable in real world setting, although external validation will be required in the future investigation.

monolateral SI, 57% bilateral SI and 7% had erosions. Among the reasons of ine- ligibility to bDMARDs, 6 patients have concurrent solid tumor, 11 had comorbidities contraindicating bDMARDs, and 12 preferred not to undergo to bDMARDs. Mean BASDAI significantly decrease after IVNer (5.86±1.98 vs 3.52±2.39, p<0.0002, Figure 1a), as well as VAS pain score (6.14±1.92 vs 3.18±3.62, p<0.05, Figure 1b). MRI showed a complete resolution of SI in 47%, partial resolution in 33%, and persis- tent active SI in 40% of patients, without correlation with the previous presence of erosions.

Conclusion: IVNer was effective in reducing disease activity measured by BAS- DA1 and VAS pain score in patients with axSpA refractory to NSAIDs and not eligible for bDMARDs. When recommended second-line treatments are con- straincated or according to patients’ preference, IVNer can be considered as a potential alternative therapeutic option. Further evaluations in controlled trials are needed to confirm these results.

PREDICTORS OF SUSTAINED REMISSION IN PEOPLE WITH AXIAL SPONDYLOARTHRITIS TREATED WITH BIOLOGIC DRUGS

B. Fariogullari1,2, G. K. Yurdımci1, E. Bilgin1, E. C. Bolek1, E. Duran1, G. Ayan1, Z. Özoşy1, G. Sandal Uzun1, M. Ekici1, E. Unaltd1, K. Liciş1, A. Akdoğan1, O. Karadag1, Ş. A. Bilgen1, S. Kiraz1, A. L. Ertenli1, U. Kalyoncu1, P. M. Machado1,2. Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 1University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, LONDON, United Kingdom

Background: The ultimate goal of treatment in axial spondyloarthritis (axSpA) is sustained remission. Data on predictors of sustained remission are scarce in axSpA.

Objectives: To determine predictors of sustained remission in people with axSpA after treatment with their first biological disease-modifying anti-rheumatic drug (bDMARD).

Methods: Hacettepe University Rheumatology Biologic Registry (HUR-BIO) is a pro- spective, single center registry of rheumatic disease patients treated with bDMARDs. Patients with axSpA were selected and sustained remission defined as attainment of Assessment of SpondyloArthritis International Society partial remission (ASAS-PR) and/or Ankylosing Spondylitis (AS) Disease Activity Score C-reactive protein Inactive Disease (ASDAS-ID) for two or more consecutive visits spanning ≥6 months during follow-up. Patients achieving and not achieving sustained remission were compared using the independent t-test. Multivariable logistic regression analysis was performed to determine independent factors predictive of sustained remission. Variables with a p-value<0.1 were re-tested in multivariable models. Forward selection was performed until the best-fit model was obtained, taking possible confounders into account. Two separate multivariable models were built, one with and one without the covariate ‘achievement of remission at 3-6 months’ to assess consistency of findings and to account for missing information regarding remission status between 3 and 6 months.

Results: Data on 990 patients with sustained remission data were available. Of these, 299 (30%) were in sustained remission, while 691 (70%) were not. Patients in sustained remission were younger, had earlier disease onset, were more fre- quently male, had lower BMI and were more frequently HLA-B27 positive, com- pared to patients not in sustained remission. Furthermore, at the start of bDMARD treatment, Bath AS Disease Activity Index (BASDA1), Bath AS Functional Index (BASFI), and patient global assessment (PGA, 0-10 scale) were lower, while acute phase reactants (ESR and CRP) were higher, in the sustained remission group. In multivariable analysis, male gender (OR 2.2, 95% CI 1.21-3.98), concomitant conventional synthetic DMARD (csDMARD) use (OR 3.63, 95% CI 1.29-10.19), PGA (OR 0.96, 95% CI 0.95-0.98), and early achievement (between 3-6 months) of remission (OR 13.1, 95% CI 7.13-24.02) were independently associated with sustained remission (Table 1, model 1). In the model without the variable early achievement of remission (Table 1, model 2), similar and a few additional associa- tions were described: age at diagnosis (OR 0.97, 95% CI 0.96-0.99), male gender (OR 2.31, 95% CI 1.90-2.85), concomitant csDMARD use (OR 1.38 95% CI 1.23- 2.66), PGA (OR 0.98, 95% CI 0.97-0.99), BASDAI (OR 0.87, 95% CI 0.78-0.96), and baseline symptom duration (OR 0.97, 95% CI 0.94-0.99).

NA: not applicable; NS: not selected (not contributing to the model). Baseline refers to start of bDMARD treatment.

Conclusion: This study demonstrates that patients in sustained remission after starting bDMARD treatment have distinctive characteristics compared to patients not in sustained remission. These data can be used to aid clinical and personalized management of axSpA, and to facilitate better communicate between health care professionals and patients regarding the course and prognosis of their condition.

IMPROVEMENT OF ENDOTHELIAL DYSFUNCTION AND INFLAMMATION IN ANKYLOSING SPONDYLITIS: IMPROVE-AS STUDY

A. Syngle1,2, N. Garg3,4, K. Krishnan4, D. Syngle5,6. On behalf of Medical Innovators.
1Cardio-Rheuma & Healing Touch City Clinic, Rheumatology, Chandigarh, India; 2Fortis Multispeciality Hospital, Rheumatology, Mohali, India; 3Chitkara College of Pharmacy, Chitkara University, Rajpura, India; 4Punjabi University, Department of Pharmaceutical Sciences & Drug Research, Patiala, India, 5Government Mult Speciality Hospital, MBBS Intern, Chandigarh, India; 6Shri Guru Nanak Institute of Medical & Health Sciences, Under Grad, Dehra Door, India, 7Healing Touch Foundation, Innovation, Chandigarh, India

Background: Cardiovascular (CV) disease is the leading cause of death in Ankylosing Spondylitis (AS). The chronic inflammatory-driven endothelial dysfunction and accelerated atherosclerosis contribute to the enhanced CV risk in AS. However, the therapeutic options to treat the enhanced CV risk are limited.

Objectives: To investigate the impact of Olmesartan and Rosuvastatin on endothelial dysfunction and inflammation in AS.

Methods: 60 consecutive AS patients were randomized to receive 24-weeks of treatment with Olmesartan (OLME) (10mg/day, n=20), Rosuvastatin (Rvs) (10mg/day, n=20), or placebo (PL) (n=20) as an adjunct to existing stable csDMARDs. Endothelial function was assessed by brachial artery flow-mediated dilation (FMD) using AngioDefender. EPCs (CD34+/CD133+) were estimated by flow cytometry. Serum nitrite, TBARS, ICAM-1, VCAM-1 and lipids levels estimated at baseline and after treatment. Inflammatory measures included: ASDAS, BASDAI, BASFI, ESR and CRP, pro-inflammatory cytokines, Quality of life and CV 10-year risk (SCORE high risk charts) were estimated using standard tools.

Results: Baseline levels of FMD and EPC population were impaired indicating endothelial dysfunction. Basal concentrations of inflammatory markers, pro-inflam- matory cytokines and markers of endothelial dysfunction were elevated among three

Table Scientific Abstracts

DOI: 10.1136/annrheumdis-2022-eular.3839
groups. After 24-weeks of treatment, FMD improved significantly in the rosuvastatin and olmesartan group as compared to placebo from their baseline levels: (OLME vs. FL (p<0.01), Rvs. FL (p<0.01), Rvs. OLME (p<0.01) (Figure 1A). EPCs and nitrite (Figure 1B) levels improved significantly in both rosuvastatin and olmesartan groups. A significant reduction found in ICAM-1 after rosuvastatin treatment (p<0.01) where as olmesartan significantly decreased VCAM-1 (p=0.04) levels. Both rosuvastatin and olmesartan resulted in significant reductions of ASDAS, BASDAI, BASFI, ESR, CRP, IL-6 (Figure 1C) and TNF-α (Figure 1D) as compared to placebo. A significant reduction found in TBA/S concentration after olmesartan treatment (p<0.01) as compared with rosuvastatin and placebo. There was a significant reduction in SCORE, HAQ-DI & SF-36 (PH) after treatment with rosuvastatin and olmesartan.

Conclusion: Olmesartan and rosuvastatin improve endothelial dysfunction and vascular inflammation and QoL in AS patients. Olmesartan and Rosuvastatin lower the proinflammatory cytokines, especially TNF-α, that upregulate eNOS and downregulate the production of adhesion molecules, CRP and nitric oxide which, in turn, improves endothelial dysfunction. Both drugs also decrease nitrite concentration and improve the EPC population in AS patients. The augmentation of EPCs by olmesartan and rosuvastatin represents a fascinating new approach for the management of AS. However, Rosuvastatin in addition also favorably impacted ICAM-1 and lipid abnormalities. In contrast, olmesartan has beneficial effect on blood pressure. Thus, both rosuvastatin and olmesartan have anti-inflammatory, immunomodulatory, vasculoprotective and cardioprotective effects in AS mediated through anti-proinflammatory cytokine action. These findings suggests that both drugs could mediate modest but clinically apparent anti-inflammatory effects with modification of CV risk in the context of high-grade autoimmune inflammation of AS and may provide a novel strategy to prevent cardiovascular events in these patients.

POS0946
THE COURSE OF BONE MINERAL DENSITY DURING 8 YEARS OF TREATMENT WITH TNF-α INHIBITORS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

M. Siderius1,2, A. Spoorenberg1,2, F. Wink1,2, S. Arends1,2. 1University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2Medical Centre Leeuwarden, Rheumatology, Leeuwarden, Netherlands

Background: Bone loss reflected by lower bone mineral density (BMD) compared to age and gender matched healthy controls is a common feature of ankylosing spondylitis (AS) and can already be observed at early stages of the disease. AS patients starting TNF-α inhibitors (TNFi) show overall a rapid increase in BMD. However, the course of BMD during long-term TNFi in these patients is not known.

Objectives: To assess the course of BMD of the lumbar spine (LS) and hip in AS patients treated with TNFi during 8 years.

Methods: Patients from the GLAS cohort who received TNFi for at least 8 years were included. Patients were excluded when they used bisphosphonates. BMD of the LS (AP projection L1-L4) and hip (total proximal femur) was measured at baseline, 1 year, 2 years and then bi-annually using DEXA. Low BMD was defined as LS and/or hip BMD Z-score ≤1. Generalized estimating equations were used to analyze BMD Z-scores over time within subjects.

Results: 131 AS patients were included, 73% were male, mean ± SD age was 41.3 ± 10.8 years, median (IQR) symptom duration was 14 (7-24) years, 83% were HLA-B27+, mean ASDAScpr was 3.8 ± 0.8, median CRP level was 13 (6-20) mg/L and median vitamin D25(OH)D3 was 61 (46-80) nmol/L at baseline. Disease activity showed rapid and sustained during TNFi treatment, with mean ASDAScpr of 2.1 ± 0.9 and median CRP of 2 (2-5) at 8 years. Serum levels of vitamin D remained stable, with median vitamin D25(OH)D3 of 60 (47-81) at 8 years. At baseline, mean LS and hip BMD Z-scores were -0.37 ± 1.08 and -0.05 ± 1.04, respectively. Low BMD at the LS and hip (Z-score ≤1) was present in 34% and 19% of patients, respectively. Overall, both LS and hip BMD Z-scores improved significantly during TNFi at all follow-up visits compared to baseline. Significant improvement of BMD Z-scores compared to the previous time point was found up to and including 4 years for LS and up to and including 2 years for hip. Thereafter, deflection of improvement was observed. Median percentage of improvement in absolute BMD after 8 years of TNFi compared to baseline was 7.1% (IQR 0.8-13.5) for LS and 1.6% (IQR -3.5-5.5) for hip (Figure 1). At 8 years, low BMD at the LS and hip (Z-score ≤1) was present in 23% and 19% of patients, respectively.

Conclusion: In AS patients treated long-term with TNFi, both hip and LS BMD significantly increased especially during the first 2-4 year of treatment and stabilized thereafter. This effect was most pronounced in the LS and small in the hip.
study (GO-AFTER) was used to examine 2nd-line (i.e., ≥ 1 line) GLM therapy in participants who had previously received and discontinued at least one other TNFi (etanercept, adalimumab, or infliximab) for any reason. Log-rank tests were performed to estimate retention rates by indication and line of therapy. Similarly, Kaplan-Meier analysis was used to estimate the probability of GLM retention over time.

**Results:** Among the 2228 participants enrolled in the 5 trials, 1797 participants had received GLM as 1st-line treatment (RA = 1050; PaS = 394; AS = 355) and 431 participants had received GLM as 2nd-line treatment. Compared to the pooled 1st-line GLM analysis cohort, more participants receiving 2nd-line GLM were female (78.7% vs 62.2%), were >50 years (61.5% vs 41.2%), and had a longer disease duration (median of 9.2 years vs 3.7 years). In the pooled 1st-line studies, GLM treatment retention remained high over five years, with an overall probability of retention of 87.8% (95% confidence interval [CI], 86.2–89.2) at Year 1 (Week 52), 80.9% (79.0–82.6) at Year 2 (Week 104), 77.3% (75.3–79.2) at Year 3 (Week 156), 73.5% (71.4–75.5) at Year 4 (Week 208), and 69.8% (67.6–71.9) at Year 5 (Week 252). GLM retention rates were similar across the four 1st-line GLM studies with no notable differences observed by indication over time (Figure 1, panel A). Treatment retention was better in participants using GLM as a 1st-line therapy compared to 2nd-line therapy (Figure 1, panel B), with a probability of retention at 5 years (Week 252) with 2nd-line therapy of 41.6% (95% CI: 36.8–46.3).

**Conclusion:** In this post-hoc analysis of prospectively collected clinical trial data, the probability of 1st-line GLM treatment retention at 5-years was consistently high across all rheumatic indications (RA, PaS, and AS). Probability of long-term GLM treatment retention with 2nd-line therapy, while lower than 1st-line therapy, also remained favorable. Collectively, these data support the value of GLM as a 1st- or 2nd-line therapy in these chronic immune-mediated rheumatic diseases.

**POS0948 SIX YEARS TREATMENT WITH TNF-α INHIBITORS DOES NOT LEAD TO LONG-TERM CONTINUOUS HYPERMINERALIZATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

M. Siderius1, A. Spoorenberg2, E. Van der Vee4, F. G. M. Kroese1, S. Arends1.

1University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, Laboratory Medicine, Groningen, Netherlands

**Background:** In a previous study, we showed that the bone turnover balance favored bone formation, especially mineralization, during the first years of treatment with TNF-α inhibitors (TNFI) in patients with ankylosing spondylitis (AS).

**Objectives:** To explore if this effect continues during more long-term TNFI treatment.

**Methods:** Included were consecutive AS outpatients from the UMCG GLAS cohort who were treated with TNFI for at least 6 years. Patients were excluded when they used bisphosphonates. Data for a specific visit was coded as missing when patients either had experienced a fracture or received systemic corticosteroids within 1 year from that particular visit regarding the possible effect on BTM. Standardized follow-up visits were performed at baseline (before start of TNFI), 3 and 6 months, 1, 2, 4 and 6 years. Serum markers of collagen resorption sCTX, bone resorption OC, collagen formation PINP, and bone mineralization BALP were measured. Z-scores were calculated to correct for the normal influence of age and gender using a healthy reference population. Generalized estimating equations were performed to analyze BTM Z-scores over time within patients.

**Results:** 53 AS patients were eligible for analyses: 66% were male, mean (SD) age was 38.5 ± 11.3 years, median (IQR) symptom duration was 16 (9-25) years, 87% were HLA-B27+, mean ASDAS was 3.8 ± 1.0, and median CRP 14 (7-27) mg/L. Etanercept, infliximab or adalimumab was prescribed as first TNFi in 60%, 2% and 38% of patients, respectively. 26% (n=14) of patients switched to a second TNFi inhibitor during follow-up. Disease activity showed rapid and sustained improvement after start of TNFI (Figure 1). At group level, collagen resorption marker sCTX Z-score did not significantly change during treatment. Bone resorption marker OC Z-score was only significantly increased at 3 months compared to baseline. Collagen formation marker PINP Z-score showed significantly increased levels at 3 and 6 months and 2 years. Bone mineralization marker BALP Z-score was significantly increased at all time points up to and including 2 years and decreased thereafter. Only a few patients still had higher BTM values above the normal range (+2 SD) (Figure 2). The net effect of collagen metabolism corrected for the normal influence of age and gender (PINP Z-score – sCTX Z-score) confirmed that the initial balance was in favor of collagen formation; this increase was only significant at 6 months compared to baseline.

**Conclusion:** In AS patients receiving long-term TNFI, the bone turnover balance favored bone formation during the first 2 years of treatment. Thereafter, at group level, serum levels of BTM returned to levels not significantly different from baseline. Therefore, 6 years of treatment with TNF-α inhibitors did not seem to lead to long-term continuous hypermineralization in patients with AS.

POS0950 LONG-TERM FOLLOW-UP OF STARTING AND SWITCHING FROM ORIGINAL ADALIMUMAB TO ADALIMUMAB BIOSIMILAR: REAL-WORLD DATA IN AXIAL SPONDYLARTHRITIS

A. S. Pinto1, K. Flora2, D. Matharu2, A. Isaacs3, P. Machado4,5,6,7,8,9

1Unidade Local de Saúde da Guarda, Rheumatology, Guarda, Portugal; 2Northwick Park Hospital, London North West University Healthcare NHS Trust, Pharmacy, London, United Kingdom; 3Northwick Park Hospital, London North West University Healthcare NHS Trust, Rheumatology, London, United Kingdom; 4Institute of Neurology, University College London, Centre for Rheumatology, Division of Medicine & Department of Neuromuscular Diseases, London, United Kingdom

Background: Biological drugs have revolutionized the treatment of rheumatic diseases, and the recent expiry of the patents for many biological agents has led to the marketing of highly similar, low-cost versions known as biosimilars. However, questions regarding its efficacy compared to bio-originator drugs, in a real-life setting, have been raised. National Institute for Health and Care Excellence (NICE) guidelines state that the response to biologic disease-modifying anti-rheumatic drugs (bDMARDs) should only be continued if there is clear evidence of response, defined as a reduction in the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score to 50% of the pre-treatment value or by 2 or more units and a reduction in the 10-cm spinal pain visual analogue scale (VAS) by 2 cm or more.

Objectives: To compare the response to adalimumab (ADA) originator and biosimilar in bDMARD naïve patients with axial spondyloarthritis (axSpA) and in patients who switched from originator to biosimilar drug, accordingly to NICE guidelines; to compare the effectiveness and safety of the originator and biosimilar drugs in patients with axSpA, measured by persistence rates (PR) over three years.

Methods: A retrospective observational single-centre UK study was performed in bDMARD naïve patients with a clinical diagnosis of axSpA who initiated treatment with ADA (original or biosimilar) and in patients who switched from originator to biosimilar drug. Descriptive statistics were used. Disease activity at baseline and follow-up data at 3 and 6 months of treatment was compared using the chi-square test. The Kaplan-Meier method was used to calculate persistence rates in biologic treatment over time. Reasons for discontinuing therapy were summarized using descriptive statistics and stratified by treatment.

Results: A total of 153 patients were included: 83 patients started on original ADA, 31 started on biosimilar ADA and 40 switched from original to biosimilar drug. The population's baseline characteristics are similar in the three groups. However, some differences were found, namely disease duration was longer in the group that did switch and the disease activity is similar in patients who started original and biosimilar ADA and was lower in the group of patients who switched from original to the biosimilar. The 3-year PR was not significantly different between originator and biosimilar ADA in bDMARD naïve patients and in the group of patients that switched from original drug to biosimilar drug (p=0.080), as shown in Figure 1. In the original ADA group, 3-year PR was 67.5% with a median time-on-drug (TOD) of 29.5 months; for biosimilar drug, 3-year PR was 64.5%, with a median TOD of 24.2 months. In patients who switched from original to biosimilar drug, 3-years PR was 77.5% with a median TOD of 30.3 months. Response to treatment according to NICE guidelines was similar between original and biosimilar drugs (p=0.03). Overall, 47 (30.7%) patients stopped adalimumab (27 patients on original drug and 20 on biosimilar drug). Discontinuations due to adverse events and inefficacy were the most frequent, and there were no significant differences between original and biosimilar drugs. Other reasons for discontinuation were less frequent, such as patient choice, loss of follow-up and death, and again without differences between original and biosimilar drugs.

Conclusion: Adalimumab original and biosimilar used as a first-line biological treatment showed similar effectiveness and safety in our long-term cohort of patients with axSpA. Switch from original to biosimilar drug showed to have a good persistence on drug after three years of follow-up (77.5%).

POS0951 SERUM PROTEIN RESPONSE TO A SINGLE HIGH-INTENSITY INTERVAL TRAINING BOUT – COMPARISON BETWEEN INDIVIDUALS WITH SPONDYLARTHRITIS AND HEALTHY CONTROLS

Å. Andersson1, E. Haglund2,3,4,5,6,7,8,9, E. Berthold4,9, A. Mogard1,9, M. C. Olsson1,9,10, Halmstad University, Dept. of Environmental and Biosciences, Halmstad, Sweden; 2FoU Spenshult Spenshult Research and Development Centre, Spenshult Research and Development Centre, Halmstad, Sweden; 3Lund University, Dept. of Clinical Sciences, Section of Rheumatology, Lund, Sweden; 4Halmstad University, Halmstad University, Halmstad, Sweden; 5Rheumatology, Dept. of Clinical Sciences Lund, Lund university, Lund, Sweden; 6Angelholm Hospital, Dept. of Rehabilitation, Angelhom, Sweden

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease affecting mainly the axial skeleton. To decrease the risk of cardiovascular comorbidity, aerobic training is recommended as a part of disease management in patients with axSpA. High-intensity interval training (HIIT) interventions are, in addition to other recommended treatments, believed to positively affect the disease activity (1). However, the knowledge about the acute effects of HIIT on the inflammatory process at the molecular level is less studied. Understanding the acute HIIT effects on cytokines and additional serum proteins in axSpA is important for further long-term HIIT interventions and recording of the effect of HIIT on the axSpA disease profile.

Objectives: To study the acute effects on serum proteins, such as cytokines, myokines, and inflammatory- and bone-related proteins, in response to a single bout of HIIT, and to compare the levels between baseline and post-HIIT in patients with axSpA and healthy controls (HC).

Methods: The pilot study included twenty-one participants (10 female, 11 male), mean (SD) age 40 (7) years, ten with axSpA, and eleven age and sex matched HC, who performed a single HIIT on a cycle ergometer consisting of 4x4 minutes interval (90% heart rate, HR-max) with three minutes active rest in between (70% of HR-max). Disease activity (BASDAI, 0-10) in patients with axSpA was 1.6 (0.8), Health status EuroQol (EQ5D, 0-1) were 0.87 (0.11) for axSpA, and 0.93 (0.10) for HC. The groups were well matched with no difference in baseline data for weight, BMI, EQ5D, blood pressure or aerobic capacity.

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease affecting mainly the axial skeleton. To decrease the risk of cardiovascular comorbidity, aerobic training is recommended as a part of disease management in patients with axSpA. High-intensity interval training (HIIT) interventions are, in addition to other recommended treatments, believed to positively affect the disease activity (1). However, the knowledge about the acute effects of HIIT on the inflammatory process at the molecular level is less studied. Understanding the acute HIIT effects on cytokines and additional serum proteins in axSpA is important for further long-term HIIT interventions and recording of the effect of HIIT on the axSpA disease profile.

Objectives: To study the acute effects on serum proteins, such as cytokines, myokines, and inflammatory- and bone-related proteins, in response to a single bout of HIIT, and to compare the levels between baseline and post-HIIT in patients with axSpA and healthy controls (HC).

Methods: The pilot study included twenty-one participants (10 female, 11 male), mean (SD) age 40 (7) years, ten with axSpA, and eleven age and sex matched HC, who performed a single HIIT on a cycle ergometer consisting of 4x4 minutes interval (90% heart rate, HR-max) with three minutes active rest in between (70% of HR-max). Disease activity (BASDAI, 0-10) in patients with axSpA was 1.6 (0.8), Health status EuroQol (EQ5D, 0-1) were 0.87 (0.11) for axSpA, and 0.93 (0.10) for HC. The groups were well matched with no difference in baseline data for weight, BMI, EQ5D, blood pressure or aerobic capacity.

Blood samples were taken before (baseline) and one hour after the single HIIT. The following serum proteins were analyzed on a Luminex MAGPIX
System (Luminex corporation, Austin, TX USA): Interleukin (IL)-6, IL-17, IL-18, TNFα, AGPIX System (Luminex corporthostprotein, osteocalcin, osteopontin, and FGF-23. A three-way analysis of variance (ANOVA) was used to detect differences between groups, between sexes, and before and after a HIIT bout in a 2(group)×2(sex)×2(time) design. For main effects or interactions significant at p<0.05, simple effect t-tests were used to determine the specific effects.

Results: A group main effect (p<0.048) showed that the serum level of IL-6 was increased one hour after the HIIT session primarily in the HCT. 0.4 ng/ml (SD±0.4) at baseline vs post-HIIT 1.8 (2.0). The concentration of the cytokines/chemokine IL-17, IL-18, TNFα group main effect (p<0.048) showed that the serum level of IL-6 was increased one hour after the HIIT session primarily in women, 10.7 ng/ml (7.0) vs men 20.4 (10.1, post-HIIT).

Conclusion: This pilot study shows that one bout of HIIT influences the expression of proteins involved in inflammation and metabolism, and that sex is an important factor in the response to HIIT. The results should be followed up in longer intervention studies including higher numbers of participants.

POS0952
THE IMPACT OF DIET ON DISEASE ACTIVITY IN SPONDYLOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW
A. Ortolan1, M. Felicetti1, M. Lorenzin1, G. Cozzi1, G. Striani1, A. Doria1, R. Ramonda2. University of Padova, Rheumatology Unit, Department of Medicine DIMED, Padova, Italy

Background: Diet is thought to have a role in inflammatory diseases development and course. However, at present, no recommendations can be given to spondyloarthritides (SpA) patients regarding a specific type of diet/dietary supplement, as evidence on the topic is sparse.

Objectives: To review the evidence about the effect of diet/dietary supplements on SpA disease activity

Methods: A systematic literature review (SLR) was conducted in MEDLINE and SCOPUS according to the “PEO” format (Population: SpA, axial or peripheral, including Psoriatic Arthritis-PsA; Exposure: any kind of diet/dietary supplement; Outcome: any available disease activity measurement). Inclusion criteria were: adult patients, Randomized Controlled Trials (RCTs) and longitudinal studies (so that a pre-and post-intervention assessment were available), papers in English. Risk of bias (RoB) was independently judged by 3 authors (AQ, MF, VB) and conducted with different tools according to the study design: Newcastle Ottawa Scale (NOS) for observational studies, the ROBINS-I tool for non-randomized studies, and the Cochrane risk of Bias tool 2.0 for RCTs.

Results: Literature search yielded 286 publications. After exclusion of 59 duplicates, 171 titles/abstract, and 44 full-texts, we included 8 interventional and 3 observational studies (Table 1). Among the former, 2 RCTs, one at unclear and one at low RoB, failed to show benefit of probiotics in SpA. One RCT at unclear RoB showed that weight loss, but not hypocaloric diet, was associated to MDA achievement in PsA. The other RCT, as well as the 4 quasi-interventional studies, were at high/serious RoB respectively. Among the observational studies, one study on Mediterranean diet demonstrated an association of diet adherence and a >20% decrease of ASDAS in axSpA. Two other studies were judged of poor quality.

Conclusion: weight loss seems to be able to impact disease activity in SpA, while probiotics were not effective in the available RCTs so far. Adherence to Mediterranean diet might play a role in reducing disease activity. Evidence for effectiveness of dietary behaviors in SpA is quite heterogeneous and high quality studies are warranted to better understand the role of diet in SpA.

POS0953
IMPACT OF A WEARABLE ACTIVITY TRACKER ON DISEASE ACTIVITY IN SPONDYLOARTHRITIS: A RANDOMIZED CONTROLLED TRIAL
G. Labat1, M. Hayotte2, O. Brocq1, L. Bailly3, R. Fabres4, M. Fournier5, V. Breuil6, F. D’Appendre Longueville2, G. Roux1, Université Cote d’Azur, Rheumatology, Nice, France; 2Université Cote d’Azur, Sports, Nice, France; 3Université Cote d’Azur, Health Sciences, Nice, France; 4Université Cote d’Azur, Medicine Physique, Nice, France

Background: Previous studies showed that a Mediterranean diet might play a role in reducing disease activity. Evidence for effectiveness of dietary behaviors in SpA is quite heterogeneous and high quality studies are warranted to better understand the role of diet in SpA.

Objectives: To review the evidence about the effect of diet/dietary supplements on SpA disease activity

Methods: A systematic literature review (SLR) was conducted in MEDLINE and SCOPUS according to the “PEO” format (Population: SpA, axial or peripheral, including Psoriatic Arthritis-PsA; Exposure: any kind of diet/dietary supplement; Outcome: any available disease activity measurement). PsA: Psoriatic arthritis, AS ankylosing spondylitis, SpA spondyloarthritis, ax: axial; RA Rheumatoid Arthritis, PU polysaturated; RCT Randomized Controlled Trial; exp=experimental; MDA Minimal Disease Activity; CONSORT CONsolidated Standards of Reporting Trials; BASFI Bath Ankylosing Spondylitis Functional Index; (+) or (-) indicate whether the primary outcome of the study was met or not.
Background: Other studies have shown the ability of a wearable activity tracker (TAP) to improve physical activity (PA) in different rheumatic diseases. Given the importance of PA in spondyloarthritis, our hypothesis is that the use of a TAP could improve physical activity and thus disease activity.

Objectives: The purpose of this study is to evaluate the impact of a TAP used to encourage PA on disease activity in patients with spondyloarthritis.

Methods: In this randomized controlled trial consisting of three 12-week stages (Figure 1), Patients with spondyloarthritis were randomized to a group with TAP (GT), or a group without TAP (GST). For the first stage, both groups received physical activity counseling. In the second 12-week stage, no patients received TAP. In the third 12-week stage, all patients received supervised PA combined with TAP for GT only. Disease activity, performance (assessed by the TM6 6-minute walk test), and quality of life (assessed by the Short Form 36 Health Survey Questionnaire [SF-36]) were assessed at 12, 24, and 36 weeks. The primary endpoint was the progression of relapses between baseline and 12 weeks.

Results: A total of 108 patients were included in the study. At 12 weeks, both groups showed a non-significant improvement in the number of relapses: mean change (Δ) -0.32 [95% CI -0.68;0.09] in GT and Δ -0.38 [95% CI -0.68;0.09] in GST. But, differences in outcome between groups were not significant (p = 0.87). The TM6 was improved in the GT and GST groups at 12, 24, and 36 weeks (p < 0.01, and p < 0.001, respectively). We observed improvement in different dimensions of the SF36, mainly in physical function, emotional role, general health, and physical pain at 12 weeks (p < 0.01). Multivariate analysis showed improvement over time in performance (p < 0.01) and moderate flare-ups (p < 0.01) without the influence of a PAR (p = 0.29, and p = 0.66, respectively).

Conclusion: To our knowledge, our study is the first to explore the impact of TAP use on disease activity in spondyloarthritis. We observed an improvement in disease activity, physical performance and quality of life without significant difference between the two groups. The lack of difference could be explained by the encouragement of physical activity to both groups. But also by the fact that our patients presented a significant number of severe relapses. Indeed, authors have shown the limits of the use of a TAP combined with PA for GT only. Our patients presented a significant number of severe relapses. Indeed, authors have shown the limits of the use of a TAP combined with PA for GT only. Our patients presented a significant number of severe relapses.

Figure 1.

Conclusion: In this prospective evaluation, the generally proposed better response of axSpA patients to treatment with high doses of NSAIDs as compared with non-inflammatory back pain was not confirmed, although the overall rate of responders was similar to previously reported rates. On the other hand, better responses were found in patients treated in the early (nr-axSpA) stage and in male patients. axSpA patients with increased CRP values showed lower rates of response.

POS0955 PATIENTS' PERSPECTIVES ON DISEASE- AND TREATMENT-RELATED ISSUES ARE ESSENTIAL FOR TREATMENT SUCCESS IN PATIENTS WITH SPONDYLOARTHRITIS AND ASSOCIATED DISEASES: A QUALITATIVE CLINICAL CONCEPT MAPPING STUDY

Z. R. Stensen1, M. Skougaard1,2, R. L. Hansen1, K. R. Christensen1, L. E. Kristensen1, T. S. Jørgensen1,1 The Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark; 2Department of Clinical Immunology, Aarhus University Hospital, Aarhus, Denmark; 3Department of Gastroenterology, Herlev and Gentofte Hospital, Copenhagen, Denmark

Background: Each patient's way of living with and relating to their chronic disease is unique. However, patients with chronic diseases may have some mutual concerns and challenges. They must not only handle the disease itself, but also its consequences that the disease has for their everyday and emotional lives. Exploring the patient's perspectives for significant factors of relevance for patients living with a chronic disease is important in order to discover unmet needs and challenges for complying with a comprehensive lifelong treatment strategy and ensuring high-quality lives. Increasing awareness about the possible discrepancy between doctor experienced quality in care and patient experienced quality in care is of high relevance when aiming to ensure optimal disease management.

Objectives: The objective of this study was to explore disease- and treatment-related issues and concerns experienced by adult patients with spondyloarthritis (SpA) and associated diseases; psoriatic arthritis (PsA), psoriasis (PsO), axial spondyloarthritis (axSpA), and inflammatory bowel disease (IBD; Crohn's disease (CD) and ulcerative colitis (UC)), and whether these factors were generic or disease dependent.

Methods: Concept Mapping were used to identify and organize disease- and treatment-related issues and concerns. Concept Mapping is a formal group process with a structured approach to identify ideas on a topic of interest and organize them into cogent domains. Participants were asked to respond to an initial task: “Thinking as broadly as you can, please list your thoughts (issues and concerns) related to your disease”, PsA, PsO, axSpA, CD or UC, respectively. Data were obtained through a nominal group technique and then organized using participant validation, and thematic analyses to generate a conceptual model of disease- and treatment-related issues and concerns experienced by patients with PsA, PsO, axSpA, CD, and UC.

Results: Seven AxSpA patients, 8 PsA patients, 9 PsO patients, 13 CD patients, and 13 UC patients contributed to generating the conceptual models. Seven AxSpA clusters, 7 PsA clusters, 7 PsO clusters, 10 CD clusters, and 11 UC clusters with each cluster having sub-clusters, emerged from the workshops producing 137 AxSpA statements, 160 PsA statements, 187 PsO statements, 335 CD statements, and 408 UC statements. Some clusters were generic: ‘Concerns about the disease and the future’, ‘Consequences of the disease’, ‘Acceptance of the disease’, ‘Medication and treatment’, and ‘At the doctor’ (Figure 1). Specific clusters were: for AxSpA: ‘Use of public services, for PsA: ‘Difficult to have an invisible disease’, for PsO: ‘Ashamed (about appearance)’, for CD: ‘Speculations and thoughts; life now and in the future - can I expect more surgeries in the future?’, and for UC: ‘The influence and importance of the diet’ and (Figure 1).

Conclusion: Patients with SpA and associated diseases largely agree on which concepts describe their disease- and treatment-related issues and concerns with a few of them being disease-dependent.

Living a good life with a chronic disease is much more than having clinical control of the disease. This study gives insight to patients' perspectives on themes that are essential when living with a chronic disease. Considering the patients' perspectives, it is necessary to promote patient empowerment and adherence to treatment, and thereby optimize disease management and quality of life.

POS0956 HIGH INFLAMMATORY BURDEN PREDICTS CARDIOVASCULAR EVENTS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A LONG-TERM FOLLOW-UP STUDY

J. L. H. Shi1, S. H. M. Lam1, H. So1, E. L1, T. K. L1, C. C. Szeto1, L. S. Tam1, 1The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China

Background: Axial spondyloarthritis (axSpA) patients had a higher risk of cardiovascular disease (CVD) than the general population (1). It is also suggested that inflammation, rather than a particular disease, drives the increased risk of CVD (2). But the relationship between inflammation in axSpA and CVD is unknown.

Objectives: To examine whether inflammatory burden over time can predict cardiovascular events (CVE) independent of baseline CVE risk factors in axial spondyloarthritis (axSpA) patients.

Methods: A cohort analysis was performed in patients who had been recruited since January 2001. The primary outcome was a first CVE occurring between January 2001 and December 2020. Three CVE risk scores were computed at baseline. The performance of the original and modified (x 1.5 multiplication factor) CVE risk algorithms were assessed. Time-varying Cox proportional hazard models and Kaplan-Meier survival analysis were used to assess whether inflammatory burden (Bath ankylosing spondylitis disease activity index [BASDAI] and inflammatory markers), non-steroidal anti-inflammatory drugs (NSAIDs) and disease modifying anti-rheumatic drugs (DMARDs) can predict the development of first CVE.

Results: 463 patients [35(26-45) years, male: 360(77.8%)] were recruited. After a median follow up of 12 (7-19) years, 61 patients (13.2%) experienced a first CVE. Traditional/modified CVE risk scores underestimated CVE risk. Erythrocyte sedimentation rate (ESR)<20 mm/hr was associated with a significantly higher risk of CVE during follow-up [HR: 2.07, 95%CI (1.10, 3.98), p<0.008]. Active disease as indicated by a rising BASDAI also showed positive trend towards a higher risk of developing CVE over time. After adjusting for CVE risk scores in the multivariable models, high ESR level (ESR>20 mm/hr) over time remained significantly associated with a higher risk of developing CVE events (Table 1a and 1b). A significant difference in the CVE event-free survival between patients with ESR<20 mm/hr and ESR>20 mm/hr was demonstrated in Figure 1.

was used to estimate the influence of each established risk factor in AS and controls. Risk factors for which there were ≤20 observed events in the AS cohort were not included. Results are presented as incidence rate ratios (IRR) with 95% confidence intervals.

Results: In total 974 (8.4%) patients with AS and 4106 (7.1%) of their controls were registered with a non-vertebral fracture during the study period. The characteristics of the patients and controls at start of follow-up are presented in Table 1 stratified by fracture status during follow-up. Figure 1 displays the results from the Poisson regression.

Figure 1. Multivariable Poisson regression analyses for a non-vertebral fracture during follow-up, with results presented for each included baseline variable as IRR with 95% CI, separately for AS and controls.

Conclusion: The influence of established risk factors for fragility fractures in AS is similar to that in the general population; in both populations with advanced age, prior fracture and harmful use of alcohol being the strongest risk factors.

POS0961 CLINICAL PROFILE AND TREATMENT UTILIZATION IN HLA-B27 POSITIVE VERSUS HLA-B27 NEGATIVE PATIENTS: RESULTS FROM ASAS-PERSPA STUDY

M. Magrey1, C. López-Medina2, M. A. Khan3,1. Case Western Reserve University School of Medicine/ University Hospitals, Medicine, Cleveland, United States of America;2Cochin Hospital, Rheumatology, Paris, France; 3Professor Emeritus, Case Western Reserve University School of Medicine, Medicine, Cleveland, United States of America

Background: HLA-B27 is a genetic marker strongly associated with axial spondyloarthritis (axSpA). However, the strength of this association varies worldwide. Although some regional studies have assessed the effect on HLA-B27 status on clinical features of axSpA, no worldwide study has been performed.

Objectives: To characterize differences in the clinical features, extra-articular manifestations, and treatment utilizations in a global axSpA cohort based on their HLA-B27 status.

Methods: We performed a post-hoc analysis of the ASAS-PersPa study (Peripheral involvement in Spondyloarthritides) dataset that includes patients with axial (axSpA) and peripheral SpA (pSpA), psoriatic arthritis (PsA), juvenile idiopathic arthritis (JIA), ankylosing spondylitis (axSpA), SpA associated with inflammatory bowel disease (IBD) and reactive arthritis based on their rheumatologist’s diagnosis. We identified patients that had been diagnosed with axSpA meeting the 2009 ASAS classification criteria and been typed for HLA-B27. The patient characteristics were compared between the HLA-B27(+) and HLA-B27(−) subgroups using Student’s t-test and the Mann-Whitney U test. Multivariable logistic regression with backward stepwise selection was conducted to identify predictors of HLA-B27 positivity. Variables with p-value <0.15 on univariate analysis were included in the multivariable model. All tests were two-tailed with p-value <0.05 considered significant.

Results: A total of 4465 patients with axSpA from 24 countries were identified. We observed that 2910 patients fulfilled the 2009 ASAS classification criteria. Of these patients, 2269 were tested for HLA-B27 (HLA-B27: 1753 and HLA-B27: 516). Significant differences were observed between these two groups in age of symptom onset and manifestations of the disease as shown in Table 1. The HLA-B27(−) patients had a significantly later age of symptom onset and disease diagnosis, more often had concomitant IBD, psoriasis, peripheral arthritis, enthesitis and were more often treated with csDMARDs. On multivariable logistic regression factors significantly associated with HLA-B27 positivity included male sex (OR: 1.99), family history of axSpA (OR: 2.26), and occurrence of anterior uveitis (OR: 2.72).

Conclusion: In a large heterogeneous cohort of AxSpA patients from 24 countries, we found that male sex, family history, and occurrence of anterior uveitis are significant predictors of HLA-B27 positivity. In contrast, the HLA-B27(−) had a significantly later age of onset and longer delay in diagnosis, more often have concomitant IBD, psoriasis, peripheral arthritis and enthesitis, and also more often receive treatment with csDMARDs.

DCA confirmed that the radiomics model was clinically useful. Furthermore, Rad-score and SPARCC scores were performed to quantify the BMO of selected from the 3.0T SIJ-MRI in the training cohort, were included to build the model. Bone marrow oedema (BMO) of the sacroiliac joints (SIJs) is evaluated to diagnose, classify and monitor disease activity in patients with spondyloarthritis (SpA). Available quantitative methodologies rely on human visual assessment, and errors can’t be completely avoided. Radiomics can extract and select discriminative and quantified features from regions of interest (ROIs), making a more accurate and objective description of BMO.

**Background:** Bone marrow oedema (BMO) of the sacroiliac joints (SIJs) is evaluated to diagnose, classify and monitor disease activity in patients with axial spondyloarthritis (axSpA). Available quantitative methodologies rely on human visual assessment, and errors can’t be completely avoided. Radiomics can extract and select discriminative and quantified features from regions of interest (ROIs), making a more accurate and objective description of BMO.

**Objectives:** To develop a more objective and efficient method based on radiomics to evaluate BMO of the SIJs by magnetic resonance imaging (MRI) in patients with axSpA in comparison with Spondyloarthritis Research Consortium of Canada (SPARC) scoring system.

**Methods:** From September 2013 to July 2021, 523 patients with axSpA underwent 3.0T SIJ-MRI were included, who were randomly classified as training cohort (n=367) and validation cohort (n=156). The optimal radiomics features, selected from the 3.0T SIJ-MRI in the training cohort, were included to build the radiomics model. Four clinical risk predictors were adopted to build the clinical model. The performance of the clinical and radiomics models was evaluated by ROC analysis and decision curve analysis (DCA). Rad-scores were calculated by the radiomics model and SPARC scores were performed to quantify the BMO of the SIJs. We also assessed the correlation between Rad-score and SPARC score.

**Results:** The radiomics model, built by 15 optimal features, showed favorable discrimination about SPARC score <2 or ≥2 both in the training (AUC, 0.91; 95% CI: 0.88-0.94) and the validation cohort (AUC, 0.89; 95% CI, 0.84-0.94). DCA confirmed that the radiomics model was clinically useful. Furthermore, Rad-score has significant correlation with SPARC score for scoring the status of BMO (r=0.78, P<0.001), and moderate correlation for scoring the change (r=0.40, P=0.005).

**Conclusion:** The radiomics can accurately assess the BMO of the SIJs in axSpA, providing an alternative to SPARC scoring system. There was a positive correlation between Rad-score and SPARC score.

**REFERENCES:**

clinical trials. Over time, an increasing number of publications on early SpA were identified: <2005 (n=34), 2005-2010 (n=48), 2011-2015 (n=109) and 2016-2020 (n=164). Overall, 63 studies (34%) included the term “early axSpA”. 60 (32%) “early ankylosing spondylitis (AS)”, 58 (31%) “early SpA”, 4 (2%) “early non-radiographic axSpA (nr-axSpA)”, and 1 (1%) “early pSpA”. In total, 116 (62%) studies reported a specific definition: 40 (34%) based it on symptom duration, 35 (30%) on radiographic damage, 32 (28%) on disease duration, 6 (5%) on both symptom/disease duration and radiographic damage, and 3 (3%) on other aspects. Symptom duration was defined as the time since the onset of low back pain in 21/40 (53%) studies, whereas in 14/40 (35%) the symptom of onset was not specified. Thirty-five of 116 studies (30%) included a definition referred to “early SpA” (38 (33%) to “early axSpA” (33%) to “early AS” (4%) “to early nr-axSpA” and 1 (1%) to “early pSpA”. Figure 1 shows the 18 distinct definitions that were identified (after combining some similar categories). The three most used definitions per subtype of disease are shown in Table 1. Regarding the studies that referred to “early SpA”, the most used definition was symptom/duration <5 years, whereas for “early AS” was symptom/duration <10 years. After 2010, the definition of “early axSpA” based on the absence of radiographic sacroiliitis was less used compared to before 2010 (5/30, 17% vs 3/8, 38%).

‘Duration’ refers to symptom duration or disease duration.

Figure 1. Number of studies stratified by the core of the definition.

Conclusion: Over time, the term ‘early SpA’ and its subtypes are increasingly used. Despite addressing early SpA, more than one third of the studies did not include a clear definition of the term. The studies reporting a definition of early SpA showed a large heterogeneity, with two out of three of them based on the duration of symptoms or clearly ankylosing spondylitis (AS) defined as radiographic inflammatory vertebral changes.</p>
Conclusion: While in raxSpA vertebral inflammation associates with low vertebral bone density, lower vertebral bone density itself does not increase the risk for ectopic bone formation at the same vertebral.

Figure 1. Methodology of Hounsfld Units [HU] measurement. Using a three-dimensional curved-multiplanar reconstruction the curve of the spine was identified from the spinal canal [3a]. On the obtained sagittal image, the vertebras could be identified. At each vertebral, two lines of reference were positioned at the superior (yellow line A) and inferior (yellow line C) limits of the vertebral body, equidistant to A and C. The yellow line B was positioned at the center of the vertebral body (3b). In the reconstructed cross-sectional slice, the vertebral body was delineated [3c]. A centered region of interest (ROI) was manually selected, having a diameter equal to 75% of the average of anteroposterior and transverse diameters, and the density of the vertebra was calculated as the average image density within the sample region, reported in HU (14).

Figure 1. MRE score ROC curve for participants fulfilling ASAS criteria for axial spondyloarthritis.

Acknowledgements: Acknowledgement is given to Dr Beverly Ng, Katherine Hodges and CARE for their contribution to this study.

Disclosure of Interests: Josie Evans Grant/research support from: Clinical study (ProSpA-CD) funded by Merck, Sharpe and Dohme (MSD), Tim Raine:
Background: Early detection and diagnosis of Ankylosing spondylitis (AS) is challenging due to heterogeneity in disease presentation, lack of specific biomarkers and high prevalence of mechanical back-pain that is difficult to distinguish from inflammatory back-pain. However, if diagnosed and treated early, the risk of AS complications and disease progression can be slowed.

Objectives: To develop and validate a risk prediction model for early identification of patients at high risk of AS, using a large longitudinal real-world clinical data in the US.

Methods: This retrospective study included all members aged ≥21 years with back pain symptoms who were enrolled in the Kaiser Permanente Southern California health plan between 01/2009-12/2013. Patients who presented with back pain symptoms at a physician visit were followed until 12/2020 to see if they subsequently developed AS. The cohort was randomly divided into a training (60%) and validation (40%) sample. A proportional odds model was specified to create a risk score for AS in the training sample. Best fit model was determined based on the Area Under the Curve (AUC) and Akaike Information Criterion (AIC). The cut-off threshold of “high-risk” was based on the optimal Youden index. The model was assessed on the training and validation data using the Area Under the Curve (AUC) and Akaike Information Criterion (AIC). The split sample of overfitting to our training sample was observed based on the split sample AUC.

Results: The cohort comprised 527,509 members with mean age 54 years and majority female (58%). Sixty-six percent were White race and 33% were Hispanic ethnicity. The crude incidence of AS was 1% and increased steadily during the follow-up period (Figure 1). The final risk prediction model included 15 risk factors and had an AUC of 0.72 (Table 1). The final risk prediction model included 15 risk factors and had an AUC of 0.72 (Table 1). The cut-off threshold of “high-risk” was based on the optimal Youden index. We assessed the model performance for internal validity using split-samples. The model was further validated using manual chart review of 900 patient records. These 900 records were selected such that 70% (N=630) met the high-risk cut-off and the remaining had scores below the cut-off. We also derived the probability of AS in each chart reviewed using the method proposed by Feldtkeller et al. (2013) and Rudwaleit et al. (2006).

Conclusions: The model showed sufficient ability to discriminate between those at high-risk vs those not identified to be high-risk. When a concrete rule out or rule in determination could be made using Feldtkeller et al. approach, our model correctly classified 75% of such records.

Table 1. Final Model Coefficients and Derived Risk Score

| Model Coefficient | Pr(>|z|) | Risk Score |
|-------------------|----------|------------|
| Age above 45 years | 0.146    | 0.011      | 1.46       |

POS0968 CESAREAN SECTION IN WOMEN WITH SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS

C. Skorpen1,2, S. Lydersen3, K. Å. Salvesen4, M. Wallenius1, NTNU, Department of Neuroradiology and Movement Science (INB), Trondheim, Norway; Ålesund Hospital, Rheumatology, Ålesund, Norway; NTNU, Department of Clinical and Molecular Medicine, Trondheim, Norway

Background: There is sparse documentation on pregnancy outcomes in women with spondyloarthritis (SpA) and psoriatic arthritis (PsA). Data on disease activity is often lacking, preventing the direct investigation of the effect of inflammation on pregnancy outcomes. A cesarean section (CS) implies a higher risk for the mother than vaginal delivery. It delays mobilization after birth necessary to counteract inflammatory pain and stiffness as well as the (re)start of disease modifying medication.

Objectives: To explore the possible association of disease activity (inflammation) and occurrence of cesarean section in women with SpA and PsA.

Methods: Data from the Medical Birth Registry of Norway (MBRN) were linked with data from RevNatus, a nationwide observational register recruiting women with inflammatory rheumatic diseases. Singleton births in women with SpA and PsA included in RevNatus 2010 to 2019 were cases. All other singleton births registered in MBRN during this time served as population controls.

Results: CS occurred more frequently in both SpA (21.9%) and PsA (29.4%) compared to population controls (15.6%), with even higher frequencies in active SpA (23.5%) and active PsA (30.1%). Women with SpA had higher risk for elective CS (risk difference 4.1%, 95% CI 1.4% to 7.9%, p=0.002), while women with PsA had higher risk for emergency CS (risk difference 9.8%, 95% CI 3.8% to 17.6%, p=0.001) as compared to population controls.

Conclusion: Women with SpA and PsA had increased odds for elective and emergency CS, respectively. Further analysis will explore the role of active inflammation.

POS0969 GENETIC AND MOLECULAR DISTINCTIONS BETWEEN AXIAL PSORIATRIC ARTHRITIS AND ANKYLOSING SPONDYLOITIS

A. Kavanaugh1, X. Baraliakos2, S. Gao3, W. Chen4, K. Sweet5, S. D. Chakravarty5,6, Q. Song3, M. Shawi7, F. Behrens8, P. Background: Psoriatic arthritis (PsA) and ankylosing spondylitis (AS) represent the prototypical spondyloarthritides. PsA patients may also suffer from axial disease (axPsA). Despite overlapping symptoms, axPsA and AS may be distinct disorders with differing clinical manifestations, genetic associations, and radiographic findings. These disorders are also non-modular diseases, thus immunomodulatory therapies, such as anti-interleukin (IL)-23 inhibitors. While guselkumab, a human monoclonal antibody targeting the IL-23p19 subunit, improved symptoms of axPsA, risankizumab, a humanized monoclonal antibody targeting the IL-23p19 subunit, did not show improvement in the primary endpoint of proportion of AS patients achieving an Assessment of SpondyloArthritis International Society 40% (ASAS40) response at week (W) 12.

Objectives: To understand molecular distinctions between axPsA and AS to differentiate these diseases and guide treatment choice.

Methods: Whole blood and serum samples were collected from consenting patients in the NCT03162796/NCT0315828 studies of guselkumab in PsA and the NCT02436162/NCT02438778 studies of ustekinumab in AS. axPsA patients were investigator-verfied as having magnetic resonance imaging- or pelvic x-ray-confirmed sacroiliitis at screening (locally read). Human leukocyte antigen (HLA) genotypes were determined by RNA sequencing. Limited to Caucasian patients to reduce genetic variability, and select serum cytokine levels were analyzed alongside samples from healthy individuals. Differential prevalence of HLA alleles in axPsA versus AS was determined using a Fisher’s Exact test. Statistical significance of differential baseline serum cytokine expression among axPsA versus non-axPsA patients, and of guselkumab versus placebo (axPsA N=30, non-axPsA N=69) at W4/24 (all p<0.05).

IL-17F were significantly higher in axPsA (N=71) than in AS (N=58) patients (p<0.01). The prevalence of class I HLA allele -B27, -C06, and -C02, while the prevalence of HLA allele -C01, and -C02 carriers was significantly lower in axPsA than AS patients (30.7% versus 92.3%, p<0.001; 5.9% versus 31.6%, p<0.001; and 28.0% versus 62.0%, p<0.001, respectively), while the prevalence of HLA-C06 was significantly higher in axPsA than AS population (36.0% versus 8.6%, p<0.001). Baseline serum levels of IL-17A and IL-17F were significantly higher in axPsA (N=71) than in AS (N=58) patients (p<0.01 and p<0.001, respectively). Comparable IL-17A/F expression was seen for axPsA and non-axPsA patients (N=229) patients (both p=nonsignificant). Significant and comparable reductions from baseline in serum IL-17A/F in axPsA and non-axPsA patients were seen with guselkumab treatment (axPsA N=41, non-axPsA N=160) versus placebo (axPsA N=30, non-axPsA N=69) at W24 (p=0.05).

Conclusion: Adults with axPsA and AS exhibit different genetic risk factors and serum IL-17 levels, supporting the concept of distinct disorders. Gusekumab demonstrated significant pharmacodynamic effects in axPsA patients that aligned with such effects in non-axPsA patients, consistent with observed clinical improvement.

Background: Crohn’s disease (CD) and ulcerative colitis (UC) are groups that are accredited as inflammatory bowel disease (IBD), and both are frequently found as extra-musculoskeletal manifestations in spondyloarthritis (SpA). Several studies have described the connection between SpA and IBD in both directions. Still until today, no studies have investigated possible differences in the musculoskeletal manifestations between the two main entities of inflammatory bowel disease: CD and UC.

Objectives: To evaluate the clinical characteristics associated with the presence of CD or UC in patients with spondyloarthritis from the international cross-sectional ASAS-perSpA study.

Methods: We analyzed 3152 patients from the ASAS per-SpA cohort who had a diagnosis of axial SpA or peripheral SpA according to the treating rheumatologist. Patients with IBD - confirmed by endoscopy - were identified and stratified by CD or UC. Patients in which their IBD disease was not specified, were excluded. Demographics, clinical characteristics, treatments and patient-reported outcomes were compared between both subgroups.

Results: Among the 146 patients diagnosed with IBD from the 3152 patients included in the analysis, 87 (59.6%) were diagnosed with CD (75 patients with axial SpA and 12 with peripheral SpA) and 39 (26.7%) with UC (34 patients with axial SpA and 5 with peripheral SpA) - Figure 1. A total of 20 (13.7%) patients with IBD were excluded, due to an inconclusive diagnosis of IBD. Patients with CD and UC had similar age (44.9 vs 44.0 years old) and sex distribution, although a slightly higher frequency of males was observed in CD than UC (63.2% vs 51.3%). The diagnostic delay for SpA was 70 years for CD and 8.1 years for UC. We did not find differences between both groups related to any musculoskeletal manifestations such as chronic back pain, uveitis, arthritis, enthesitis or dactylitis (Table 1). The only parameter showing a significant difference between CD and UC was the Bath Ankylosing Spondylitis Functional Index (BASFI) with a mean score of 3.3 vs 2.2 respectively (p=0.02) (Table 1). CD patients showed a higher tendency to be HLA-B27 positive (51.9% in CD vs 39.4% in UC), but this did not reach statistical significance. No differences were observed regarding treatment patterns between both groups.

Table 1. Demographics and clinical characteristics related to spondyloarthritides of patients with concomitant Crohn’s disease or ulcerative colitis (n=146).

and spinal ankyloses (1, 2). Recent studies with [18F]Fluoride Positron emission tomography (PET) demonstrated that disease activity of AS is best reflected by local background, 257 MRI lesions and 88 x-ray lesions were observed in the spine (Table 1). Most lesions were found in the thoracic spine. PET lesions were frequently located outside the field of view (FOV) of the MRI and X-ray in respectively costovertebral and facet joints (31/69; 45%). Univariate analysis PET positivity had the strongest association with the presence of MRI BME and x-ray bridges (OR 6.6, 95% CI: 2.0 – 21.1, p < 0.001 respectively). Multivariate analysis confirmed these findings (OR 39, 95% CI: 1.7 – 223, p < 0.01 and OR 6.4, 95% CI: 1.7 – 23.5, p < 0.01 respectively) (Figure 1). However, of all PET-positive lesions only 7/24; 29% within the FOV of the MRI showed BME and 13/23; 56% of the PET lesions within the FOV of the X-ray showed bridges on X-ray. In the SI-joints, a total of 15 lesions (15/20; 75%) with PET enhancement were found. Erosions, ankylosis and BME lesions on MRI were observed in respectively 13/15; 87%, 4/15; 27% and 13/15; 87% of the lesions with PET enhancement.

**Figure 1.** Example of Fluoride uptake on PET (A), corresponding BME on MRI (B) and bridges on X-ray (C).

**Conclusion:** Lesions with [18F]Fluoride on PET showed significant correlation to MRI BME and x-ray bridge lesions. It showed partial agreement with BME of MRI and bridges on X-ray. This suggests that [18F]Fluoride PET visualizes different mechanisms central to AS disease activity compared to MRI and X-ray, thereby providing novel and additional information.

Results: In total, 4185 patients were included, of which 2719, 1033 and 433 had a diagnosis of axSpA (mean age 42 years, 32% female), PsA (mean age 52 years, 52% female) and pSpA (mean age 44 years, 53% female), respectively. A significant interaction between gender and disease phenotype was found for ASAS-DAS and BASFI. Multivariable models for each outcome are shown in Table 1 (stratified by disease phenotype). While being female independently contributed to higher BASDAI across the three disease phenotypes (though with varying magnitude), female gender was only associated with higher BASDAS in pSpA [β (95% CI): 0.36 (0.15, 0.58)] and PsA [0.25 (0.12, 0.38)] but not in axSpA [0.016 (0.07, 0.11)]. Female gender was associated with higher BASFI in PsA [0.46 (0.20, 0.72)]. No associations were observed between gender and CRP levels. Female gender was associated with higher ASAS-HI [0.90 (0.70, 1.10)] and EQ-5D* [-0.02 (-0.03, -0.01)] without significant differences across disease phenotype.

Conclusion: Female gender was associated with less favorable outcomes across the SpA spectrum, except for CRP in which there were no differences between gender. While female gender influenced BASDAI across disease phenotypes, ASAS was not associated with gender in axSpA. These results suggest that ASASDAS should be the preferred instrument in clinical practice both for females and males with axSpA.

POS0975 COMPARISON OF CLINICAL AND DEMOGRAPHIC FINDINGS OF PATIENTS DIAGNOSED AS WITH FULL SPINAL FUSION AND WITHOUT ANY SPINE DAMAGE

C. Yörük , S. Gulle, I. Sarı, F. Öner, A. Balcı, Dokuz Eylül Üniversitesi Hastanesi, Internal Medicine, İzmir, Turkey; Dokuz Eylül Üniversitesi Hastanesi, Rheumatology, İzmir, Turkey; Dokuz Eylül Üniversitesi Hastanesi, Radiology, İzmir, Turkey

Background: Erosions and sclerosis are early manifestations of radiographic progression, which can form synovemesophytes that bridge between the vertebrae and eventually lead to spinal fusion or the characteristic bamboo spine appearance in some patients. Bridging synovemesophytes in the spinal column plays a key role in the progression of AS. The development of ankylosis in the axial skeleton is considered to be the most important long-term outcome parameter for axialpondyloarthritist (axSpA).

Objectives: In this study, we aimed to evaluate patients with ankylosing spondylitis (AS) diagnosed with grade 4 sacroiliitis followed in our rheumatology clinic, without spinal column involvement and with complete spinal ankylosis (bamboo vertebra), together with their clinical, demographic and laboratory findings.

Methods: A total of 202 patients with unilateral/bilateral grade 4 sacroiliitis, who were registered in the Dokuz Eylül University Hospital data system, diagnosed with AS according to the modified New York criteria, were included in the study. Cervical, dorsal and lumbar radiographs of all patients were evaluated for structural damage, in addition to lateral and anteroposterior aspects, as well as posterior and facet joint involvement. In the study, all radiographs were evaluated twice at separate times.

Results: It was found that 19 (9.5%) patients had no involvement of the spinal column and 19 (9.5%) had spinal fusion appearance. It was determined that patients with spinal fusion were older (p<0.001) and the frequency of male gender was higher (p=0.042) than patients without any spinal involvement. (Table 1) In multivariate analysis; ≥45 years old [OR: 10.5, CI: 95%, 2.8-39.2; (p:0.001)] and male patients [OR: 10.5, CI: 95%, 1.14-96.56; (p=0.042)] was found to have an increased risk for the development of spinal fusion. TNFi retention rates (78.9% vs. 52.6%), TNF switch rates (53.3% vs. 45.5%) and TNF type distributions were similar in both groups (p>0.05).

There was no significant difference between the patients with complete spinal fusion and no spinal involvement in terms of right and left hip BASRI scores (p>0.05).

Conclusion: In our study, we reached four important clinical results: (1) Spinal fusion was observed in 9.5% of the patients with bilateral Grade 4 sacroiliitis diagnosed with AS. 95% had no spinal involvement and 81% had varying degrees of spinal injury. (2) Anti-TNF treatment responses were similar in patients with spinal fusion and no spinal involvement. (3) Except for being >45 years old and having a male gender, no other factor was found to predict the development of spinal fusion. (4) There was no difference in the degree of hip involvement between patients with complete spinal fusion and no spinal involvement.

Figure 1. Structural model on interrelationships of different patient- and disease characteristics with global functioning and health (ASAS HI) in patients with early axSpA

Conclusion: The BN-analysis approach, that combines prior knowledge and measured data, serves to better understand the construct of global functioning and health in pts. with early axSpA. Our model shows that global functioning (ASAS-HI) is determined both by patient-reported physical function (BASFI) and by disease activity (ASDAS), which confirms the hierarchical model once proposed by Machado et al. The observed directional relationship between ASAS HI and comorbidity count is counterintuitive and requires further investigation.

**LUMBAR FACET JOINTS ARTHRITIS RELATES TO ITS ADJACENT MRI INFLAMMATORY LESIONS IN AXIAL SPONDYLOARTHRITIS**

Z. Huang1, Z. Huang2, X. Guo1, Q. Huang1, M. Liu1, F. Feng1, T. Li2,3
1Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; 2Southern Medical University,School of Clinical Medicine, Guangzhou, China; 3Zhaoying Central People's Hospital, Department of Rheumatology and Immunology, Zhaoying, China

**Background:** Facet joints are frequently impaired in patients with axial spondyloarthritis (axSpA), which raises high disease activity and poor physical function. However, insufficient attention is paid to the relationship between the feature of disease and facet joint arthropathy (FJA) in magnetic resonance imaging (MRI) examination, because of lacking an ideal assessment tool. The Canada-Denmark (CANDEN) MRI scoring system is adopted in our study because it is a comprehensive method to assess the alteration of spine [1].

**Objectives:** We aimed to find relevant factors for lumbar FJA in axSpA patients.

**Methods:** This was a cross-sectional study that analyzed the lumbar MRI of axSpA patients using the CANDEN system. Demographic and clinical information was recorded. Univariable and multivariable linear mixed model (LMM) was used to screen related factors for lumbar FJA in MRI examinations.

**Results:** (1) Totally 108 axSpA patients were investigated in our study, while ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA) accounted for half respectively. Sixty-five (60.19%) participants were male and their median age was 35 years. (2) Twenty (37.10%) and 1 (1.80%) AS and nr-axSpA suffered lumbar FJA respectively. Sixty-five (60.19%) participants were male and their median age was 35 years. (2) Twenty (37.10%) and 1 (1.80%) AS and nr-axSpA suffered lumbar FJA respectively. Sixty-five (60.19%) participants were male and their median age was 35 years. (3) Twenty (37.10%) and 1 (1.80%) AS and nr-axSpA suffered lumbar FJA respectively. Sixty-five (60.19%) participants were male and their median age was 35 years. (4) Multivariate LMM displayed that odd ratio (OR) and 95% confidence intervals (CI) of PLEIS, FPES, and ASDAS were significant.

**Conclusion:** Prevalence of lumbar FJA is higher in AS patients than nr-axSpA. Besides, gender, the duration of symptom, peripheral arthritis, enthesitis, non-steroidal anti-inflammatory drugs, VCBis, SIDS, PLEIS, FPES, the ankylosis of sacroiliac joints, and bony erosion of hips were involved in the univariate LMM for nr-axSpA. (4) Multivariate LMM showed that odd ratio (OR) and 95% confidence intervals (CI) of PLEIS, FPES, and ASDAS were significant. OR (95%CI) for PLEIS, FPES, and ASDAS were 2.063 (1.49, 2.84), 1.11 (1.02, 1.21), and 1.19 (1.08, 1.32) (P<0.05). OR (95%CI) for PLEIS, FPES, and ASDAS were 2.063 (1.49, 2.84), 1.11 (1.02, 1.21), and 1.19 (1.08, 1.32) (P<0.05). OR (95%CI) for PLEIS, FPES, and ASDAS were 2.063 (1.49, 2.84), 1.11 (1.02, 1.21), and 1.19 (1.08, 1.32) (P<0.05). OR (95%CI) for PLEIS, FPES, and ASDAS were 2.063 (1.49, 2.84), 1.11 (1.02, 1.21), and 1.19 (1.08, 1.32) (P<0.05).

**Disclosure of Interests:** None declared
Background: Large population-based databases provide an opportunity to study the epidemiology of spondyloarthritis (SpA), however, strict validation procedures for case ascertainment are required (1).

Objectives: To examine the validity of the ICD-9 codes of SpA in a large population-based database and to assess whether applying a specific algorithm would improve the case ascertainment. Finally, the point prevalence of SpA in the database was estimated using the validated algorithm.

Methods: A Database of a large public health fund, which serves approximately 3.17 million enrollees older than 18 years, was used. The database includes real-time input from pharmaceutical, medical and administrative operating systems. At first, the database was searched for all individuals who received an ICD-9 code of SpA, 720.0: 7200, 7201, 7202, 7206, 72081 and 72089. All medical records of a random sample of 169 patients were thoroughly reviewed by a rheumatologist. Based on the information available in the database, a decision was made whether SpA diagnosis was: 1) definite/probable SpA; 2) not SpA; not enough data to verify the diagnosis of SpA. The positive predicted value (PPV) and 95% confidence interval (CI) were calculated. In order to improve the case ascertainment, a second validation process was performed using a specific algorithm. The algorithm applied was: a permanent ICD-9 code of SpA assigned by the family physician plus at least one of the following codes: 1.At least one visit at a rheumatology clinic either in the community or at a hospital outpatient clinic; 2.A diagnosis of SpA given during a hospital admission; 3.A prescription fulfilled of an anti-Tumor Necrosis Factor agent or anti tumor 17-antigen. This algorithm was validated by two rheumatologists in a random sample of 182 cases. Finally, the point prevalence of SpA was estimated applying the validated algorithm.

Results: The PPV of the ICD-9 codes of SpA was 44% (95%CI 36%-52%). The specific algorithm improved the PPV to 90% (95%CI 85%-94%). The concordance between the two rheumatologists was 91.9% (CI 85.7-94.8). On the 31/12/2021, the validated algorithm identified 2892 live SpA patients older than 18 among a population of 3,167,329 enrollees reflecting a point prevalence of 0.09%. The ICD-9 codes of SpA assigned by the family physician plus at least one of the following codes: 1.At least one visit at a rheumatology clinic either in the community or at a hospital outpatient clinic; 2.A diagnosis of SpA given during a hospital admission; 3.A prescription fulfilled of an anti-Tumor Necrosis Factor agent or anti tumor 17-antigen. This algorithm was validated by two rheumatologists in a random sample of 182 cases. Finally, the point prevalence of SpA was estimated applying the validated algorithm.

Conclusion: A specific algorithm can accurately identify patients with SpA in this large population-based database. The estimated prevalence of SpA is 0.09%. This figure is consistent with other population-based estimates (2).

REFERENCES:

are not studied. Until now, it remains unclear whether synovitis detected on MRI and ultrasound of hip joint is a predictor of radiological progression of coxitis.

**Objectives:** To determine the factors influencing the progression of coxitis in axSpA.

**Methods:** 77 patients (mean age 28 ± 5.92 years) with a diagnosed with axSpA (ASAS criteria 2009), which were observed for at least 2 years. Among them, AS according to the modified New York criteria (1984) - 66 (86%) patients, and 11 (14%) were diagnosed with nr-axSpA. The median duration of the disease was 30 [6-60] months, BASDAI 4.5 [3.2-5.9], B27 2.4 [0.9-4.8]. All patients underwent clinical, X-ray ultrasound and MRI examination of the hip joint during the entire observation period. For ultrasound, coxitis was considered an increase in the cervical capsular distance (CCD) of more than 7 mm. For MRI inflammatory changes were taken as osteitis of the acetabulum and / or femoral head and synovitis in STIR mode. The sum of stages of radiographic coxitis (sCRC) was used to assess HJ injury progression. During the study, a formula was developed to assess the progression rate of radiographic coxitis (R-rpC).

**Results:** Cluster analysis of the main parameters was performed to detect the relationship between the clinical manifestations of axSpA and radiological progression of coxitis (Figure 1). During the analysis, it was found that the most closely related group of clinical parameters, such as the presence of the HLA B 27 gene and the sex of patients, the rate of radiographic progression of coxitis and sCRC (Euclidean distance < 20). The second group of related measures included the BASDAI and ASDAS-CRP disease activity indices, as well as their associated functional impairment (BASFI index) (Euclidean distance < 30). These two groups of signs are also related to each other — Euclidean distance < 30. It should be noted that laboratory indicators of inflammation (ESR and CRP), the age of patients, and especially the duration of the disease, turned out to be weakly related to each other (Euclidean distance > 100). It should also be noted that the relationship between laboratory indicators of inflammation and disease activity indices is relatively weak, as well as with structural damage in axSpA.

**Conclusion:** Factors influencing the development and progression of coxitis in axSpA are a combination of such features as high clinical activity of the disease, the presence of peripheral arthritis, HLA B27 positivity and male sex.

**ABSTRACTS TO TWO NOVEL PEPTIDES IN NEW ONSET AXIAL SPONDYLOARTHRITIS**

**P. Ruytinx**, P. Vandormael2, E. Luyten1, A. S. De Craemer3, F. Van den Bosch3, E. Mogard1, T. Olofsson1, A. Bremander2,3,4,5, J. Sagard1, J. K. Wallman1, E. Lindqvist1, 1Lund University, Skane University Hospital, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; 2Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; 3Spenshult, Research and Development Centre, Halmstad, Sweden; 4University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; 5University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sanderborg, Denmark

**Background:** Healthy lifestyle behaviours are associated with better health outcomes and quality of life in the general population (1, 2). In patients with axial spondyloarthritis (axSpA), however, little is known regarding multiple lifestyle behaviours and their associations with disease and health outcomes.

**Objectives:** To study lifestyle behaviours in patients with axSpA in relation to healthy controls, between axSpA subtypes and male and female patients, respectively, and to assess how the presence of two or more unhealthy lifestyle factors associate with disease and health outcomes.

**Methods:** We performed a cross-sectional study of 250 well-characterized axSpA patients (167 with radiographic axSpA [r-axSpA], ASAS and/or modified New York criteria), 83 with non-radiographic axSpA [nr-axSpA; ASAS criteria] and 48 controls (frequency-matched to the patients for age and sex), participating in the population-based SPARTAKUS study in southern Sweden. Self-reported data on smoking, alcohol use, physical activity, dietary habits, and objectively measured body mass index (BMI), respectively, for all subjects was categorized as fulfilling national recommendations or not (healthy/unhealthy), and summarized in an index (0-5, indicating the number of unhealthy lifestyle factors). The index was also dichotomized into 0-1 vs. 2-5 unhealthy lifestyle factors. Comparisons between patients and controls, axSpA subtypes (r-axSpA vs. nr-axSpA), and between male and female patients were performed by Student's t-test/Chi-square test, as appropriate. Linear regression analyses were used to explore associations between having ≥2 unhealthy lifestyle factors (yes/no) and disease and health outcomes.

**Results:** Characteristics and lifestyle factors for axSpA patients and controls are presented in the Table 1. Reporting ≥2 unhealthy lifestyle factors was more common in axSpA patients than controls (35% vs. 19%, p=0.029), while no difference was found between the axSpA subtypes (Figure 1a and b). Male patients more often reported several unhealthy lifestyle factors than female patients (Figure 1c), with more frequent unhealthy alcohol use (19% vs. 9%, p=0.023) and overweight/obesity; BMI ≥25 (63% vs. 50%, p=0.043), while smoking, physical activity, and dietary habits were similar. In addition, older patients displayed more unhealthy lifestyle factors (Figure 1d). Having ≥2 unhealthy lifestyle factors was associated with worse disease activity (ASDAS-CRP) [0.73 [95% CI] [0.59, 0.87]], physical function (BASFI) [0.73 [95% CI] [0.59, 0.87]], and quality of life (EQ-5D) [0.73 [95% CI] [0.59, 0.87]].

*According to the Assessment of SpondyloArthritis International Society (ASAS) classification criteria for axSpA

Conclusion: Unhealthy lifestyle behaviours were more common in axSpA patients than controls, and in male axSpA patients compared to females. Having two or more unhealthy lifestyle factors was associated with worse disease activity, physical function, pain, fatigue, and quality of life in the axSpA patients.

**Figure 1.** Chief complaints reported by patients at chiropractor visits (n=3103)

Conclusion: More than 10% of patients attending chiropractic clinics for musculoskeletal complaints had undiagnosed SpA conditions, with axSpA being the most common. Educational efforts targeted at chiropractors to suspect and refer appropriate cases to rheumatologists are needed.

Background: A definition for clinically important worsening (CIW) of axSpA has been proposed by ASAS: i.e. an increase of ≥0.9 points of ASDAS. However, it is unknown how this definition performs in an early axSpA cohort.

Objectives: To determine the prevalence of CIW in a population of early axSpA, as well as the association between the occurrence of CIW and the presence of concomitant signs of inflammation; finally, to determine whether MRI inflammation was predictive of a future CIW.

Methods: 708 patients with early axSpA from the French DESIR cohort were included in the analysis. Patients were followed every 6 months for the first 2 years and annually thereafter. All patients had an MRI of spine and sacroiliac joints at baseline, but only patients from the APHP centers performed those 32 patients (84.4%) had an MRI at 2 and 5 years. Prevalence of CIW was calculated during the 5 years of follow-up in the cohort. The association between CIW and concomitant objective signs of inflammation (such as swollen joint count) was assessed over time using mixed models adjusted for sociodemographic and other clinical covariates. CIW predictive factors including the predictive capacity of MRI inflammation (measured by SPARCC at SIJ and spine) and MRI structural damage (defined by presence of ≥5 structural lesions of SI joints or spine) on the occurrence of a future CIW (time-lagged models) were evaluated.

Results: Total number of CIW was 378 in 5 years with 42.8% (303/708) of patients presenting at least one CIW during the follow-up. There were no significant sociodemographic or clinical differences at inclusion between patients with at least one episode of CIW and those without CIW during follow-up. In the association models, concomitant tender joint count [OR 1.02, CI95%[1.01; 1.03] and ASAS-NSAID score last week [OR 1.00, CI95%[1.00; 1.01]] were significantly associated with CIW over time. Presence of MRI-SIJ inflammation (OR per SPARCC point 1.02, CI95%[1.01; 1.04]) and MRI-SIJ structural damage (OR 2.74, CI95%[1.27; 5.93]) were predictive of future (next visit) occurrence of CIW.

Conclusion: Patients with CIW according to the ASAS definition had significantly more objective signs of inflammation concomitantly but also over time. These data support the construct validity of this definition of CIW in an early axSpA population. MRI-SIJ inflammation and structural damage may have a predictive role in the subsequent occurrence of CIW.

Background: In 2009, ASAS published a ‘Definition of active sacroiliitis on MRI for classification of axial spondyloarthritis (axSpA)’. This definition relied on two MRI sequences to make this determination – semicoronal T1 and STIR. Since then, this approach has frequently been used for diagnosis, even though that was never the intent of the definition. In 2015, the European Society of Skeletal Radiology (ESSR) published its recommendations for an SIJ MRI image acquisition protocol (IAP) for diagnostic purposes that required 4 MRI sequences but there is still no IAP that has been widely accepted as a minimum standard worldwide. In 2020, an informal survey of 24 academic sites (12 Europe, 12 North America) confirmed that 24/24 sites performed a minimum of 3 MRI sequences for diagnosis (19 performed 4-8 sequences) because the 2-sequence protocol was considered inadequate.

Objectives: To develop the minimum requirements for a standardized IAP for MRI of the sacroiliac joints for diagnostic ascertainment of sacroiliitis.

Methods: All radiologist members of the ASAS and SPARTAN Classification in axSpA (CLASSpA) project, along with one European and one North American rheumatologist with extensive MRI experience in SpA clinical practice and research, were invited to participate in a consensus exercise. A draft IAP was circulated to all participants along with background information and justification for the draft proposal. Feedback on all issues was received by email, tabulated and recirculated. Participants were broadly in favor of the proposal and two months later a teleconference meeting took place and remaining points of contention were resolved. Examples of the proposed IAP performed on new, 10 and 22 years’ old MRI scanners were made available for review in DICOM format. Next the revised draft of the IAP was presented at the ASAS annual meeting to the entire membership on 14 January 2022, and voted on.

Results: A 4-sequence IAP, 3-semicoronal and 1-semi axial, is recommended for diagnostic ascertainment of sacroiliitis and its differential diagnoses (Table 1). It must meet the following requirements: Semicoronal sequences should be parallel to the dorsal cortex of the S2 vertebral body, and include: 1) a sequence sensitive for the detection of active inflammation being T2-weighted with suppression of fat signal; 2) a sequence sensitive for the detection of structural damage in bone and bone marrow with T1-weighting; 3) a sequence that is designed to optimally depict the bone-cartilage interface of the articular surface and be sensitive for detection of bone erosion; plus 4) a semiaxial sequence sensitive for inflammation detection. The IAP was approved at the ASAS annual meeting by a vote of the entire membership with 91% in favour.

Conclusion: A standardized IAP for MRI of the sacroiliac joints for diagnostic ascertainment of sacroiliitis is recommended and should be comprised of a minimum of 4 sequences, in 2-planes, that will optimally visualize inflammation, structural damage, and the bone-cartilage interface.

DEEP LEARNING ALGORITHMS FOR MAGNETIC RESONANCE IMAGING OF INFLAMMATORY SACROILIACITIS IN AXIAL SPONDYLOARTHRITIS.

H.Y. Chung1, C.W.S. Chan2, 1Chiron Medical, Rheumatology, Hong Kong, Hong Kong (SAR); 2The University of Hong Kong, Rheumatology and clinical immunology, Hong Kong, Hong Kong (SAR)

Background: Magnetic resonance imaging (MRI) of the sacroiliac (SI) joints is increasingly important in the management of axial spondyloarthritis (SpA). Artificial intelligence (AI) may be the next crucial step in enabling the widespread application of MRI.

Objectives: To develop a deep learning algorithm for detection of active inflammatory sacroiliitis in short tau inversion recovery (STIR) sequence MRI.

Methods: A total of 326 participants with axial spondyloarthritis (SpA), and 63 participants with non-specific back pain (NSBP) were recruited. STIR MRI of the SI joints was performed and clinical data were collected. Region of interests (ROIs) were drawn outlining bone marrow edema, a reliable marker of active inflammation, which formed the ground truth masks from which “fake-colour” images were derived. Both the original and “fake-colour” images were randomly allocated into either the training and validation dataset or the testing dataset. Attention U-net was used for the development of deep learning algorithms. As comparison, an independent radiologist and rheumatologist blinded to the ground truth masks, were tasked with identifying bone marrow edema in the MR images.

Results: Inflammatory sacroiliitis were identified in 1398 MR images from 228 participants. No inflammation was found in 3944 MR images from 161 participants. The mean sensitivity of algorithms derived from the original dataset and “fake-colour” image dataset were 0.86±0.02, and 0.93±0.01 respectively. The mean specificity of algorithms derived from the original and “fake-colour” image dataset were 0.92±0.02, and 0.93±0.01 respectively. The mean testing dice coefficients were 0.48±0.27 for the original dataset and 0.51±0.23 for the “fake-colour” image dataset. The area under the curve of the receiver operating characteristic (AUC-ROC) curve of the algorithms using original dataset and “fake-colour” image dataset were 0.92 and 0.96 respectively. Sensitivity and specificity of algorithms were comparable to interpretation by a radiologist, but outperformed the rheumatologist.

Conclusion: An MRI deep learning algorithm was developed for detection of inflammatory sacroiliac in axial SpA.

fusion at the lumbar and/or cervical spine without bamboo spine. We analyzed the ensemble of variables by multivariable logistic regression to identify predictors associated with bamboo spine / advanced spinal disease, and bamboo spine-only.

**Results:** In the study, there were 99 patients with advanced spinal ankylosis and 78 patients with bamboo spine. Older age (OR 1.12, 95% CI 1.07-1.17), male gender (OR 4.26, 95% CI 1.75-10.41), delay diagnosis > 24 months (OR 2.4, 95% CI 1.27-5.74), obesity (OR 4.03, 95% CI 1.53-10.64), hip involvement (OR 4.3, 95% CI 1.14-12.6), smoking > 10 package/year (OR 2.4, 95% CI 1.003-5.2) were significantly associated factors with bamboo spine / advanced spinal ankylosis. Similarly, older age (OR 1.17, 95% CI 1.09-1.13), male gender (OR 8.31, 95% CI 2.09-33.1), obesity (OR 4.15, 95% CI 1.25-13.2), hip involvement (OR 4.74, 95% CI 1.32-16.96) and smoking > 10 package/year (OR 3.19, 95% CI 1.03-9.89) were showed statistical significance with bamboo spine (Table 1).

**Conclusion:** Data on the predictors of development of advanced spinal ankylosis and bamboo spine are scarce. In this study, we showed that older age, male gender, delay in diagnosis, obesity, hip involvement and smoking are factors that predict the development of advanced spinal involvement in axSpA.

**CLINICAL AND IMAGING FEATURES IN SPONDYLOARTHRITIS PATIENTS WITH AND WITHOUT HLA-B27 AND HLA-B51: A VALIDATION COHORT**

F. Carubia1, A. Alunno1, J. Cipollone1, C. Martin1, V. Morom1, C. Ferri1. Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy

**Background:** Despite being commonly expressed in the general population, the human leukocyte antigen (HLA)-B27 allele strongly increases the susceptibility to develop spondyloarthritids (SpA). Likewise, the association between the HLA-B51 allele and the development of Behçet's disease is well documented. In a previous pilot study, we identified similarities and differences in patients with axial or peripheral SpA according to the presence of HLA-B51 only, HLA-B27 only or neither of the two.

**Objectives:** To investigate the clinical and imaging findings of SpA patients according to the absence or presence of HLA-B27 or HLA-B51 in an independent validation cohort.

**Methods:** We retrospectively analyzed patients with axial or peripheral SpA according to the ASAS criteria, referring to our institution between 2020 and 2021. All patients had been tested for HLA-B alleles. Patients with HLA-B51 haplotype and fulfilling the criteria for Behçet's disease were excluded.

**Results:** The independent validation cohort included 185 patients and was comparable to the original cohort of 236 patients with regard to age, gender, age at diagnosis and symptom duration. In line with the findings in the original cohort we observed that aphtous lesions were more prevalent in patients with HLA-B51 (p<0.001) while inflammatory bowel disease was more prevalent in the double negative group (p=0.0006). Unlike the original cohort, patients of the validation cohort did not show a different prevalence of inflammatory back pain (IBP) at disease onset or in the disease course based on the HLA status. A sub-analysis by gender demonstrated a comparable prevalence of IBP in males and females within the 3 groups. As novel finding, we observed that enthesis and psoriasis were significantly more prevalent in the double negative group compared to the B27 and B51 groups (p=0.004) and their prevalence did not differ when comparing B27 and B51 groups. With regard to imaging in patients with axial manifestations, in the original cohort we observed that saccrolitis, assessed by X-ray or magnetic resonance imaging (MRI), were more prevalent in double negative and HLA-B27 patients, compared to HLA-B51 patients and the latter showed a significant negative association with saccrolitis on imaging (OR 3.42 CI 0.189-0.619 p<0.0005). In this validation cohort we observed that the prevalence of saccrolitis on X-ray was similar in the 3 groups while saccrolitis on MRI scan was significantly more prevalent in the B27 group (81%) compared to the double negative (83%) and the B51 group (51%). A negative association between saccrolitis on MRI and HLA-B51 but not double negative status was observed in the validation cohort (OR=0.23, 95% CI=0.07-0.8, p=0.02).

**Conclusion:** Our findings underscore the clinical and radiological heterogeneity of patients with SpA and HLA-B51 alone or neither HLA-B27 nor HLA-B51 compared to those with HLA-B27 only and underline the need to explore further this area by means of registry data with large real-life cohorts.

**RADIOLOGICAL CERVICAL INVOLVEMENT IN ANKYLOSING Spondylitis**

S. Carvès1, R. Burns2, O. Fogel1, B. Banneville2, R. Belkhir3, J. Gross3, B. Saint-Marcoux1,5, L. Smerano1, J. Sellam1,5, R. Richette2, H. Guérini2, C. López-Medina1, C. Miceli Richard1. 1APHP, Hopital Cochin, Rheumatology, Paris, France; 2APHP, Hopital Cochin, Radiology, Paris, France; 3APHP, Hopital Bicêtre, Rheumatology, Le Kremlin-Bicêtre, France; 4APHP Hopital Henri Mondor, Rheumatology, Créteil, France; 5Hopital Intercommunal Robert Ballanger, Rheumatology, Aulnay-sous-Bois, France; 6APHP, Hopital Avicennes, Rheumatology, Bobigny, France; 7APHP Hopital Saint-Antoine, Rheumatology, Paris, France; 8APHP, Hopital Lariboisière, Rheumatology, Paris, France

**Background:** Cervical involvement in ankylosing spondylitis (AS) is particularly disabling and has been poorly studied yet. Actual radiologic scoring design to assess disease progression does not provide a comprehensive picture of the cervical involvement in AS. [1] Association with clinical features such as psoriasis are discussed.

**Objectives:** We aimed to assess radiographic features of cervical involvement in AS and clinico-biological parameters associated with this specific radiographic location.

**Methods:** Cross-sectional study based on radiographic analysis of a subgroup of patients included in the French BambooSpine cohort, originally designed to study the genetic risk factors of AS structural severity. The analysis was based on patients included in Parisian hospitals to have access to images of the entire spine on the Picture Archiving and Communication System (PACS) shared by all University Hospitals in Paris. A double reading of the images was performed by a rheumatologist/radiologist pair until consensus was reached, to identify syndesmophytes, zygapophysial joint (ZJ) involvement and posterior ligament structures (PLS) at each cervical level, syndesmophytes in the thoracic region, and ZJ and PLS involvement in the lumbar region.

**Results:** Of the 113 assessed patients, 101 were men, mean age 53 years (+/- 11 years) with 27 years (+/- 13 years) of disease duration (Table 1). Of those whose HLA B27 status was known, 85% (70/82) were carriers. Among 86 patients with radiological cervical involvement, 83% had syndesmophytes, 86% had ZJ involvement and 24% had PLS involvement. In the cervical region, 13 patients (15%) had zygapophysial fusion without syndesmophytes. 26/113 patients were completely free of any cervical involvement while 30/113 had a maximal cervical involvement (anterior and posterior). In univariate analyses, HLA-B27 was
significantly associated with ZJ involvement at the cervical and lumbar level (p=0.016). Cervical involvement of any type was not associated with psoriasis. Low educational level (not beyond secondary school) was significantly associated with syndesmophyly involvement (p=0.035). There was a non-significant trend for an association between arthritis and ZJ involvement.

### Table 1. Clinical features

<table>

<td>11.68</td>
<td>13.0</td>
<td>58.0 %</td>
</tr>
</tbody>
</table>

**Conclusion:** Cervical involvement was very frequent (76% of this severe AS population) but not associated with psoriasis, as usually thought. Zygapophysyeal involvement was present in 86 % of cases and exclusive in 15 % of cases. This latter radiological form of the disease, i.e. with no syndesmophyly, is usually more difficult to diagnose, and should be systemically assessed among AS patients with cervical pain and/or patients with reduced cervical mobility.

**DEVELOPMENT OF AN AUTOMATED ALGORITHM BASED ON METHODS OF ARTIFICIAL INTELLIGENCE TO ASSIST IN THE PREDICTION OF CORRECT REFERRALS OF PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS BY USING PATIENT HISTORY TEXTS**

H. Kratz1,2, S. Girze3, S. Ohndorf4, X. Baraliakos5,6, S. Tsiamis6,7, H. Haedecke2,3, N. Döll8,9, J. Holz-Müller1,2, S. Rüping3, F. Behrens1,2,7, M. Köhm1,2,7, H. Kratz1,2, S. Ginzel3, S. Ohndorf4, X. Baraliakos5,6, S. Tsiamis6,7, H. Haedecke2,3, N. Döll8,9, J. Holz-Müller1,2, S. Rüping3, F. Behrens1,2,7, M. Köhm1,2,7,1, Fraunhofer-Institute for Translational Medicine & Pharmacology ITMP Clinical Research, Frankfurt, Germany; 2Fraunhofer Excellence Cluster for Immune-Mediated Diseases CIDM, Clinical Research, Frankfurt, Germany; 3Fraunhofer-Institute for Intelligent Analysis and Information Systems IAIS, Knowledge Discovery, St. Augustin, Germany; 4Charité Universitätsmedizin, Rheumatology, Immunology, Berlin, Germany; 5Ruh-Universität Bochum, Rheumatology, Bochum, Germany; 6Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; 7University Hospital Frankfurt, Rheumatology, Frankfurt, Germany

**Background:** Diagnosis and treatment of PsA and axSpA is often delayed due to missing clear diagnostic criteria and limitations in resources for referral to rheumatologist including high numbers of incorrect referrals. Primary care is usually provided by either general practitioner, dermatologists, or orthopedists. Clinical discriminators with a high specificity for rheumatic conditions include morning stiffness (MST), peripheral or axial, >30min. Artificial intelligence (AI) and natural language processing (NLP) methods offer algorithms for learning systems to recognize disease associated terms and classify clinical phenotypes using large data sets that may support early identification of patients with suspected diagnosis of PsA or axSpA.

**Objectives:** AI and NLP methods are used to identify patients with typical attributes of inflammation by using morning stiffness as one potential discriminating pattern, which can be detected automatically and might help to prioritize referral for rheumatologist appointments.

**Methods:** Within a multicentre observational study, patients with visits at the rheumatologist with a suspected diagnosis of PsA or axSpA from the referral primary care provider were recruited. All data on clinical examinations and findings were collected and evaluated by rheumatologists in focus on criteria for diagnosis of PsA/axSpA (gold standard for evaluation). Unstructured text from the patient history was used to extract diagnosis-relevant characteristics. The information extraction algorithms used NLP models to detect expert curated “morning stiffness” (MST) keywords and puts them into a contextualized framework that allows to capture possible negations.

**Results:** A total of 116 patients were recruited (73 female, 63%) with a median age of 42 (IQR: 34-54). 51 patients were referred as axSpA (44%) and 60 as PsA (52%) by primary care providers. After preselection for PsA and axSpA patients, we observed a 23% rate of referrals without rheumatic diagnosis. Only 7.1% of patients were admitted without signs of MST, 29% with axial MST, 35% with peripheral MST and 28% with both MST types. Average morning stiffness duration was recorded as 35 minutes; patients with a finally confirmed rheumatic diagnosis had a higher average MST duration reported (36 minutes) compared to patients without a confirmed diagnosis. Our AI assisted extraction of MST identified MST in 82.7% of patient history texts. In 75% NLP methods correctly identified the negation of MST symptoms (6 of 8), and 94% of MST was detected when both axial and peripheral joints were affected (30 of 32). Manual inspection of 20 patient history reports where MST was not detected by our automated algorithm revealed that 17 reports depicted factors for not referring a patient; none of these were recognized by NLP methods.

**Conclusion:** The high rate of correct detection of MST from patient history text using NLP methods allowed us to assess the potential for NLP models to support automated analysis of patient reports to facilitate intelligent patient referral.

**VALIDATION OF THE SPARCC MRI-RETIC E-TOOL FOR INCREASING SCORING PROFICIENCY OF MRI LESIONS IN AXIAL SPONDYLOARTHRITIS**

W. P. Maksymowycz1,2,3, A. E. F. Hadsbjerg3, M. Östergaard2, R. Micheliö2, J. S. Pedersen1,4, A. Ciurea3, N. Vladimirova3, M. J. Nissen5, K. Bubova5, S. Wick4, M. De Hooge6, A. J. Mathew7, K. Pintarcic8, M. Gregova8, Z. Sno9, M. Wetterstey10, K. Gorican10, J. Paschke11, R. G. Lambert11,12,13, CAR E ARTHRITIS LTD, Rheumatology, Edmonton, Canada; 1University of Alberta, Medicine, Edmonton, Canada; 2Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; 3University Hospital Zurich, Rheumatology, Zurich, Switzerland; 4Geneva University Hospital, Rheumatology, Geneva, Switzerland; 5First Faculty of Medicine, Charles University, Rheumatology, Prague, Czech Republic; 6University Hospital Ghent, Rheumatology, Ghent, Belgium; 7UMC Ljubljana, Radiology, Ljubljana, Slovenia; 8Geneva University Hospitals, MSK Radiology Unit, Radiology Section – Diagnostic Department, Geneva, Switzerland; 9Sheba Medical Center, Radiology, Tel Aviv, Israel; 10University of Alberta, Radiology and Diagnostic Imaging, Edmonton, Canada

**Background:** Axial spondyloarthritis (axSpA) is a group of chronic inflammatory disorders of the spine, axial skeleton and peripheral joints, including ankylosing spondylitis (AS). The validation of a web-based e-tool for quantitative MRI assessment of inflammatory disease activity and structural damage is missing. The Spondyloarthritis Research Consortium of Canada (SPARC) MRI-RETIC e-tool allows for the scoring of axial and peripheral structural damage.

**Objectives:** The primary aim of this study was the validation of the SPARC MRI-RETIC e-tool for the scoring of structural and for the scoring of inflammatory lesions in axial SpA.

**Methods:** In this prospective multicenter study, 92 patients (51 male, 41 female) were enrolled in 9 sites. After 2-weeks pre-screening, 16 experts (12 experienced, 4 non-experienced) were randomized, stratified by reader expertise in scoring with SPARCC, to either use Strategy A (2-step strategy) or Strategy B, where the impact was evident for SPARCC BME even by non-experienced readers with similar levels of reader proficiency.

**Results:** The SPARC MRI-RETIC e-tool has been validated for scoring axial and peripheral structural damage as well as for scoring inflammation. The e-tool is easy to use and can be learned by expert readers. The reliability of scoring is evident for all structural lesions, level of reader expertise, and status as well as change scores (Table 1). Scoring proficiency improved the most for the least experienced readers (Figure 1).

**Disclosure of Interests:** None declared DOI: 10.1136/annrheumdis-2022-eular.3996

Conclusion: Attaining scoring proficiency for MRI structural lesions in axSpA is difficult but can be consistently improved by using the SPARCC™ module, even for experienced readers.

Background: Sacroiliac bone marrow edema is an important factor in the diagnosis and management of axial spondyloarthritids (axSpA).

Background: Uveitis is a frequent extraarticular manifestation of spondyloarthritis (SpA) and it has been classically reported that uveitis in axial spondyloarthritis (ax-SpA) is predominantly anterior, unilateral, acute, and non-recurrent; in psoriatic arthritis (PsA) and in inflammatory bowel disease (IBD) it has been described as posterior, bilateral, insidious, and continuous [1,2].

Objectives: In a large unscreened series of SpAs, our aim was to assess the epidemiological and clinical features of SpA-associated uveitis.

Methods: Study of consecutive patients from a single University Hospital with a) ax-SpA, b) PsA, and c) IBD (Crohn’s disease and Ulcerative colitis). We have selected patients with uveitis that were classified according to Standardization of Uveitis Nomenclature (SUN) Working Group. Main general features, and uveitis pattern, location and onset were recorded.

Results: We studied 2156 (1038 women/1118 men) patients with SpAs: IBD (n=1449; 67.2%); PsA (n=406; 18.8%); and ax-SpA (n=301; 14%).

Uveitis was present in 87 (4%) (102 eyes) of 2156 patients with SpAs. However, uveitis occurs with varying frequency according to the SpAs subtype: 14.6% of ax-SpA (n=44), 4.9% of PsA (n=20), 1.6% of IBD (n=23) (Table 1).

In the global SpAs, the most common pattern of uveitis was typically anterior, unilateral, acute, and non-recurrent while in ax-SpA-related uveitis (Table 1).

Table 1. Main clinical features and uveitis pattern.

DEPRESSION IN SPONDYLOARTHRITIS: THE CHOICE OF MEASUREMENT INSTRUMENT MATTERS

C. Webers1,2, U. Kiltz3,4, J. Braun3,4, D. Van der Heijde5, A. Boonen1,2.
1Maastricht University Medical Centre, Rheumatology, Maastricht, Netherlands; 2Maastricht University, Care and Public Health Research Institute (CAPPHRI), Maastricht, Netherlands; 3Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; 4Ruhr-Universität Bochum, Rheumatology, Bochum, Germany; 5Leiden University Medical Centre, Rheumatology, Leiden, Netherlands

Background: The prevalence of depression is increased in spondyloarthritis (SpA). Research on this topic in SpA is challenging for several reasons, one of them being the wide variety of different instruments used to assess depressive symptoms. It is unknown whether these instruments are comparable in measuring the construct depression and can be considered interchangeable. If these instruments actually differ in what they measure, this should be taken into account when designing and interpreting studies, and in clinical practice when monitoring patients with SpA.

Objectives: To compare the constructs of different instruments used to assess depressive symptoms in patients with SpA.

Methods: Data from the international ASAS Health Index Validation Study were used. Included patients had a diagnosis of SpA and fulfilled the ASAS classification criteria for axial/periarticular SpA. Data on demographics and disease characteristics were collected. The following instruments have been used to assess depressive symptoms in SpA were available: the depression subscale of the Hospital Anxiety and Depression Scale (HADS-D), the Short Form 36 (SF-36) and item 5 of the 5-level EuroQol 5D (EQ-5D-5L). The HADS-D ranges 0-21 (best-worst), with scores ≥8 and ≥11 indicating possible (HADS-possible) and probable depression (HADS-probable), respectively. The SF-36 was summarized using all 36 items in a Mental Component Summary (SF-36MCS, score ≥40 indicating depression), or using only 5 items in the Mental Health subscale (SF-36MH, score ≥6 indicating depression). For the EQ-5D-5L, a score of at least "moderately" (level ≥3 on 1-5 scale) or "severely" depressed (level ≥4) indicated depression.

Results: Spearman correlations between instrument scores, agreement (kappa) between depressed states, and test characteristics (sensitivity [SE], specificity [SP], positive and negative predictive value [PPV, NPV]) were calculated with HADS-D as external standard, as it was specifically designed to detect depression and considered to have highest content validity.

<table>
<thead>
<tr>
<th>Definition of ‘depression’</th>
<th>HADS-D ≥8 (possible)</th>
</tr>
</thead>
<tbody>
<tr>
<td>EQ-5D-5L ≥3 (moderate)</td>
<td>51 (89)</td>
</tr>
<tr>
<td>EQ-5D-5L ≥4 (severe)</td>
<td>17 (99)</td>
</tr>
<tr>
<td>SF-36MCS ≥40</td>
<td>68 (83)</td>
</tr>
<tr>
<td>SF-36MH ≥56</td>
<td>78 (71)</td>
</tr>
</tbody>
</table>

Conclusion: Instruments used to assess depression in SpA are not interchangeable. The choice of instrument should be taken into account when interpreting studies on depression in SpA. SF-36MCS and SF-36MH are sensitive and could be considered for screening while EQ-5D-5L is useful when high specificity is required. In situations where assessment of depression is the primary objective, depression-oriented instruments such as the HADS are recommended.
Background: Diagnostic delay in axial spondylarthropathy (axSpA) is a well-defined feature of the disease, despite increased awareness. Morbidity and mortality are higher in axSpA than the general population. Much of this excess burden is due to increased comorbidity. However, the association between delayed diagnosis and increased comorbidity in this population is unknown.

Objectives: (1) Examine the relationship between delayed diagnosis and comorbidity in a large cohort of well characterised individuals with axSpA (2) Assess the impact of sex on the relationship between diagnostic delay and comorbidity.

Methods: The Ankylosing Spondylitis Registry of Ireland (ASRI), a descriptive epidemiological study of the Irish axSpA population, provided the cohort for this study. A standardised clinical assessment was performed on each patient. Delay to diagnosis was calculated as age at diagnosis minus age at symptom onset. Comorbidities were considered as any condition present in addition to axial SpA, excluding extra-musculoskeletal manifestations (EMM). SPSS was used for statistical analysis, with appropriate tests used for normally and non-normally distributed data.

Results: Of the 913 included patients, 659 (72%) were male and mean age was 46 years (SD 13), Disease duration, median (25th,75th) 17.1 (9.5, 27.8) years. Medical delay to diagnosis was 5 (2, 12) years. Comorbidity was present in 37% (n=341) of the cohort, with hypertension the most prevalent (see Figure 1).

</tbody>
</table>

The median delay to diagnosis was significantly longer in those with ≥1 comorbidity compared to those with none (7 vs 5 years, p<0.01). Hypertension (6 vs 5 years, p=0.01) and cerebrovascular disease (10 vs 5 years, p=0.03) were associated with a significantly longer delay to diagnosis, with a similar trend seen in those with hyperlipidaemia (7 vs 5 years, p=0.09) and ischaemic heart disease (10 vs 5 years, p=0.07). The delay to diagnosis was also longer in those that currently (7 vs 5 years, p=0.03) or ever smoked (6 vs 5 years, p=0.01). The delay to diagnosis was significantly longer in those with depression (9 vs 5, p<0.05). The presence of EMM did not contribute to a delay to diagnosis, and there was no association with any categories of medication. There was no significant difference in the median delay to diagnosis between females (5 vs 6 years) for males. However, there were differences in the relationship between delay to diagnosis and the pattern of comorbidities between sexes. There was a significantly (p=0.05) longer delay to diagnosis in men with cerebrovascular disease (12 vs 6 years), ischaemic heart disease (10 vs 6 years) and diabetes (10 vs 6 years), which wasn’t evident in females. Depression was associated with a longer delay to diagnosis in males (10 vs 6 years, p=0.05), but not females (6 vs 5 years, p=0.5).

Conclusion: Delay to diagnosis of axSpA was associated with a higher prevalence of comorbidities. This was particularly evident in men, with higher cardiovascular morbidity in those with a longer delay to diagnosis. Further research is needed to determine if shortening the delay to diagnosis would reduce the burden of cardiovascular morbidity.

observed in 22 (19%) pregnancies. The multivariate model adjusted for age, BMI, nulliparity, active disease during pregnancy, smoking, and exposure to NSAIDs and corticosteroids during pregnancy found an association between unfavorable pregnancy outcome with nulliparity (OR 2.63 95% CI [1.01-6.81], p = 0.05).

Conclusion: This study provides original results on pregnancy in women with SpA. It found a favorable pregnancy outcome in 63.5% of women. Unfavorable pregnancy outcome was most frequently due to small for gestational age, which should lead to a coordinated management with obstetricians for the follow-up of pregnancy in women with SpA.

Different subscripts denote significant (p<0.05) differences between groups. Significant values highlighted in bold.

There was no association between smoking status and disease severity by subjective or objective measures, either for the cohort as a whole or by sex. When compared to non- or ex-smokers and controlled for potential confounders including sex, age, biologic use, the association remained only between current smokers and lower risk of uveitis (OR 0.68, 95% CI 0.49 to 0.96) and arthritis (OR 0.62, 95% CI 0.43 to 0.87), in separate logistic regression models. The association between current smoking and increased prevalence of psoriasis in males did not remain significant once controlled for confounders (OR 1.10, 96% CI 0.73 to 1.65).

Conclusion: We demonstrated that current smoking is independently associated with a lower risk of uveitis and arthritis in males with axSpA, but not females. More research is needed to further investigate this paradoxical finding.

POS1003
IMPACT OF ELECTRONIC MEDICAL RECORD MANAGEMENT SYSTEM ON DISEASE ACTIVITY AND FREQUENCY OF OUTPATIENT VISITS IN PATIENTS WITH ANKYLOSING SPONDYLITIS
H. H. Chen1, 1Taichung Veterans General Hospital, Department of Internal Medicine, Taichung, Taiwan, Republic of China

Background: We developed an electronic medical record management system (EMRMS) at the Taichung Veterans General Hospital (TCVGH) to assess ASDAS by integrating patient reported outcomes (assessed by an independent nurse) and ESRI/CRP for AS patients. We aimed to investigate the impact of the EMRMS on frequency and time of outpatient visits.

Objectives: To investigate the impact of the EMRMS on frequency and time of outpatient visits,

Methods: We identified 652 AS patients who were followed up for at least one year before and after the first ASDAS assessment. We compared the number of outpatient visit and average visit time within one year before and after the initial ASDAS assessment. We identified 201 AS patients who received ≥ 3 continuous ASDAS assessment with an interval of 3 months and compared the 2nd and 3rd ASDAS with the first ASDAS.

Results: The number of outpatient visits increased after starting ASDAS assessment (5.8±3.9 vs. 5.4±3.4, p<0.001), in particular among those whose initial ASDAS-CRP was > 3.5 (8.7±4.0 vs. 5.7±3.4, p<0.001). The average visit time was shortened within one year after ASDAS assessment (8.7±4.4 minutes, p = 0.030), especially among patients whose ASDAS-CRP was > 3.5 (7.3±3.8 vs. 5.7±3.4, p<0.001). The anterior superior VC of L1 was the most affected site among all vertebral corners in all MRI slice thicknesses and CRs. In thoracic spine, the anterior superior corner of T12 was the most frequently affected site in both MRI (all slice thicknesses) and CR. Although MRI could detect more syndesmophytes in both lumbar and thoracic vertebrae than CR, MRI at any slice thickness could not detect 15.4%–23.2% of syndesmophytes detected in CR (Table 1).

Disclosure of Interests: None declared

Fat lesions were detected in 38.3%, 37.5%, 34.8%, 33.7%, 31.4%, 28.7% of VC with MRI slice thicknesses of 1-6mm, respectively. MRI slice thickness had no role in detecting fat lesions (p>0.05 within MRI slice thicknesses).

Conclusion: MRI of the lower thoracic and the lumbar spine at any slice thickness detected more syndesmophytes than CR, but the best agreement and least false-positive findings on MRI based on CR as gold standard was found in the thicker slice thicknesses. The presence of fat lesions did not influence syndesmophyte detection on MRI. These results may influence the performance of spinal MRI in identification of SpA-specific spinal lesions in daily practice.

POS1005
ACTIVE INFLAMMATORY LESIONS OF THE SPINE IN SACROILIAC JOINTS MRI (SUS-MRI): AN OVERLOOKED FINDING BY RADIOLOGISTS.
N. Di Medici1, F. Gentili2, S. Guerini3, G. Bagnacci4, A. Perrella1, E. Conticini5, B. Frediani6, L. Cantarini6, L. Volterrani6, M. A. Mazzoldi7, 1University of Siena, Department of Medical, Surgical and Neurosciences, Diagnostic Imaging, Siena, Italy; 2Azienda Ospedaliera Universitaria Senese, Diagnostic Imaging Unit, Siena, Italy; 3University of Siena, Rheumatology Unit, Siena, Italy

Background: Establishing a diagnosis for axial spondyloarthritis (axSpA) is based on the combined presence of several clinical and laboratory features in association with imaging evidence of active inflammation lesions (bone marrow edema, SMSI) in sacroiliac joints (SJIs), also associated with structural lesions, is the main element in favor of a diagnosis of axSpA and SU MRI is currently the main recommended technique for detecting inflammation, enabling early diagnosis in patients with normal radiographic findings. MRI of the spine is generally not recommended for axSpA diagnosis, since spine involvement is considered less sensitive and specific. Several studies explored the incremental value of spine MRI for diagnosing patients with axSpA, especially when the findings of SI are equivocal, and “predicting” clinical disease activity.

Objectives: To evaluate the effectiveness of the MRI study dedicated to SUs to identify the inflammatory involvement of the lumbar spine in patients with active sacroliliitis and clinical diagnosis of axSpA.

Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2022-eular.4792
Methods: MRI of 96 patients (26M, 70 F, mean age 48 years) with SIJs-MRI positive for inflammatory involvement according to ASAS criteria, were evaluated retrospectively. The presence of signs of inflammation of posterior spinal elements and vertebral bodies included in the field of vision (FOV) was therefore researched.

Results: Of 96 patients with active sacroilitis, 88 had concomitant inflammatory lesions of the lumbar spine. Facet capsulitis (87.6%) and posterior enthesitis (42.2%) were the most common lesions and these lesions frequently coexisted (39.3%). Twelve patients with facet capsulitis presented also facet arthritis. Only 20 out of 96 patients (22%) had vertebral bodies inflammatory lesions: 15 corner inflammatory lesions and 5 aseptical spondylodiscitis.

Conclusion: On the basis of current working consensus MRI examination of the spine is not recommended for axSpA diagnosis, because it is considered less sensitive and specific. However the high prevalence (91.7%) of spinal inflammatory changes in patients with active sacroilitis suggests that these features can be used as an additional element in favor of diagnosis, especially in doubtful cases. This evaluation takes little reporting time, without any increase in MRI execution time.

Background: Magnetic resonance imaging (MRI) of the spine and sacroiliac joints (SIJ) are important tools for the diagnosis of axial SpA. However, there is very little data investigating how clinical symptoms and response to treatment relate to the degree of MRI inflammation and to its change over time.

Objectives: To evaluate the relationship between clinical response in axial SpA patients and inflammation in MRI of spine and SIJ after 6 months of treatment.

Methods: In the ESTHER study, a total of 76 patients with early axial SpA with a symptom duration less than 5 years, and with active inflammation on MRI in the spine and/or SIJ at baseline were randomized to be treated with etanercept (n=40) or sulfasalazine (n=36) for one year.

Results: A total of 67 patients with axial SpA were included in this analysis due to availability of MRIs at baseline and Week 24. The characteristics of patients included in this analysis were similar to the whole group of the ESTHER study. Changes in osteitis score for SIJ and spine were associated with clinical response (remission between baseline and Week 24) (Figure 1). Further, we compared patients with and without residual inflammation on MRI of the spine and SIJ as defined above. There were no differences between the groups regarding clinical response and disease activity at week 24.

Conclusion: Change of score for osteitis in MRI of spine and SIJ was associated to disease activity in patients with axial SpA during 6 months of treatment. Presence of residual inflammation on MRI after 6 months of treatment seems to be irrelevant regarding clinical response and clinical disease activity.

When we compared the treatment patterns of axSpA patients with and without hip involvement, we found that the percentages of NSAID as well as csDMARD use were similar in groups. However, the percentages of patients who were prescribed etanercept were higher in axSpA patients with hip involvement (p<0.001).

Conclusion: In addition to inflammation and function, hip involvement seems to be related with diagnosis (n-axSpA), education level and absence of SpA family history. Moreover, enthesis may not accompany hip involvement.

POS1009  COMPARING OF DISEASE ACTIVITY, FUNCTION AND QUALITY OF LIFE IN PATIENTS FROM THE CLINICAL AND IMAGING ARM OF NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

S. Dimitrov1, S. Hristova1, S. Bogdanova-Petrova1, T. Georgiev1, T. Shivachewa2, 1Medical University Varna, Rheumatology, Varna, Bulgaria

Background: The concept of axial spondyloarthritis (axSpA) and non-radiographic axSpA (n-axSpA), a subgroup of axSpA, has recently emerged. There are several studies proving the similar levels in disease activity and quality of life in patients with or without structural damage in spondyloarthritis.

Objectives: The aim of this study is to compare disease activity, functional status and quality of life in patients from the clinical and imaging arm of nonradiographic axial spondyloarthritides in Bulgaria.

Methods: A cross-sectional survey was conducted with rheumatologists and their consulting patients in Bulgaria from February 2012 through April 2019. Patients who had a rheumatologist confirmed diagnosis of n-axSpA were eligible to participate. An information about patient demographics and symptoms duration were collected. Acute- phase reactants, patients' reported data for disease activity (BASDAI), functional status (BASFI) and quality of life (ASQoL) were compared between the patients with or without MRI data for sacroiliitis. The level of significance was set to 0.05.

Results: A total of 98 patients from the imaging arm of nonradiographic arm and 62 patients from the clinical arm of n-axSpA patients were included in this analysis. A higher proportion of patients from the imaging arm were male patients (51% vs 37%). The mean age was 33±8.77 in the imaging arm and 34±12.65 in the clinical arm (p=0.05), with mean symptoms duration in both groups- respectively 0.76±0.26 and 0.48±0.13 years (p=0.05). The mean value of C-reactive protein in the imaging arm was 14.8±19.6 and 7.05±10.4, p=0.02 in both groups. The disease activity determined using patients reported data from BASDAI was 4.1±0.67 vs. 3.63±0.78 (p=0.05) and using ASDAS-CRP 2.3±0.17 vs. 2.20±0.32 (p=0.05) in the imaging and clinical arm. The evaluation of the function BASFI was 5.0±1.29 vs. 4.4±1.18, p=0.05 in both groups of patients with n-axSpA. The QoL determined by ASQoL revealed no statistical significant values between the groups – 4.79±3.27 and 5.18±3.03, p=0.05.

Conclusion: Patients from the imaging and clinical arm of n-axSpA share the same clinical features. The burden of the disease, as assessed by ASQoL measurement, is also similar in the investigated subgroups of Bulgarian n-axSpA patients.

Background: Ankylosing spondylitis (AS) can be characterized not only by the detection of the musculoskeletal system, but also by the probable contribution of extra-articular manifestations (ESMs), which can affect the course of the disease, and may occur in the first place in terms of the activity of the process. At the same time, according to the findings, in 3.5-10% of patients with AS, a diagnosis of IBD was detected, and in 70% of patients with AS, subclinical symptoms of intestinal damage were detected. Researchers have found that AS and IBD have common links of pathogenesis: microbiota and intestinal wall condition. Currently, highly sensitive fecal laboratory tests are used to monitor inflammation activity in IBD prior to colono-scopy. Fecal calprotectin (FCP) is a marker of neutrophil inflammation in gastrointestinal diseases and an indicator of the intensity of the inflammatory process in the intestine. The concentration of FCP is statistically significantly higher in IBD patients with signs of clinical activity and, as a rule, does not go beyond the normal range in patients with irritable bowel syndrome. These data make it possible to consider fecal calprotectin as a promising marker of the onset and latent course of inflammatory bowel disease in patients with ankylosing spondylitis.

Objectives: To reveal the peculiarities of fecal calprotectin concentration in patients with ankylosing spondylitis in case of occurrence and recurrence of inflammatory bowel diseases as extra-articular manifestations.

Methods: The study included 80 patients with ankylosing spondylitis: women - 28 (35%), men - 52 (65%). The average age of patients was 45.12±13.14 years, the average age of onset symptoms - 28.43±13.18 years, mean duration of AS - 18.7±11.75 years. Patients already diagnosed with AS were asked to complete a questionnaire using the Universal Questionnaire to identify signs of immunoinflammatory diseases - psoriasis, psoriatic arthritis, IBD (Crohn's disease, ulcerative colitis) to identify clinical signs of intestinal damage. With a positive answer to one main and one additional question, the patient was asked to conduct a qualitative determination of fecal calprotectin. Before the study, patients were stopped taking non-steroidal anti-inflammatory drugs for two weeks. Patients in whom the presence of calprotectin in the feces was carried out by immunochromatographic method. Patients who had an increase in the concentration of fecal calprotectin above 200 µg/g were recommended to perform a diagnostic colonoscopy on an outpatient basis to clarify the diagnosis. The next step was the determination of fecal calprotectin in patients with a positive survey result. In 26 patients (32.5%) a positive result was revealed.

Results: In 71 (88.7%), according to the results of the questionnaire, subclinical signs of intestinal damage were identified. At the next stage, patients with a positive result in the determination of FCP underwent an immunochromatographic test to detect the concentration of calprotectin in the feces. Of these, 22 patients (84.6%) had a concentration of 50-200 µg/g, which indicates the need for dynamic monitoring of this group of patients. In 4 patients (15.38%), the concentration of FCP was found to be higher than 200 µg/g.

Conclusion: Among patients with ankylosing spondylitis, 88.7% have subclinical signs of intestinal damage. Baseline and available radiographs at 2 (n=85), 4 (n=53) and 6 years (n=30) of follow-up were randomized with radiographs of patients with AS and scored with known time sequence according to the mNY criteria by 2 trained readers (SK and RW). In case of disagreement in classification, the score of a third independent reader (AS) was used. Progression to AS was defined as progression in mNY sacroiliitis score to a score of $\geq 2$ bilaterally or $\geq 3$ unilaterally at any time during the 6-year follow-up period. Patient characteristics and clinical assessments at baseline were compared between patients who did and did not progress from nr-axSpA to AS, using chi-squared tests.

Disclosure of Interests: The GLAS cohort classified as nr-axSpA enrolled into the cohort (baseline) between 2009 and 2018 were included in the analyses. Nr-axSpA was defined as sacroiliitis of $\geq$ 2 grade bilaterally or $\geq 3$ unilaterally on the AP view of pelvic radiographs, according to the modified New-York (mNY) criteria. Baseline and available radiographs at 2 (n=85), 4 (n=53) and 6 years (n=30) of follow-up were randomized with radiographs of patients with AS and scored with known time sequence according to the mNY criteria by 2 trained readers (SK and RW). In case of disagreement in classification, the score of a third independent reader (AS) was used. Progression to AS was defined as progression in mNY sacroiliitis score to a score of $\geq 2$ bilaterally or $\geq 3$ unilaterally at any time during the 6-year follow-up period. Patient characteristics and clinical assessments at baseline were compared between patients who did and did not progress from nr-axSpA to AS, using chi-squared tests.

Psoriatic arthritis - treatment

**POS1013** HOW DOES BODY MASS INDEX AFFECT SECUKINUMAB TREATMENT OUTCOMES AND SAFETY IN PATIENTS WITH PSORIATIC ARTHRITIS? – REAL WORLD DATA FROM THE GERMAN AQUILA STUDY

U. Kiltz1, J. Brandt-Juergens2, P. Kästner3, E. Riechers4, D. Peterlik5, C. Budden6, H. P. Tony7on behalf of on behalf of the AQUILA Study Group.

1Rheumazentrum Ruhrgebiet, Herne and Ruhr-Universität Bochum, Herne, Germany; 2Rheumatologische Praxis, Paderborn, Germany; 3Medizinische Klinik I, Universitätsklinikum RWTH Aachen, Aachen, Germany; 4Medizinische Klinik, Klinikum der Johannes Gutenberg-Universität Mainz, Mainz, Germany; 5Medizinische Klinik, Charité Universitätsmedizin, Berlin, Germany; 6Medizinische Klinik II, Medizinische Hochschule Hannover, Hannover, Germany; 7Novartis Pharma GmbH, Immunology, Gutachterlage, Nürnberg, Germany; 8Medizinische Klinik II - Rheumatologie/Immunologie, Universitätsklinikum Würzburg, Würzburg, Germany

Background: There is a higher prevalence of obesity in patients (pts) with psoriatic arthritis (PsA). The German non-interventional study AQUILA provides real-world data on the influence of body mass index (BMI) of pts with psoriatic arthritis (PsA) on therapeutic effectiveness and safety under treatment with secukinumab, a fully human monoclonal antibody that selectively inhibits IL-17A.

Objectives: The aims of this interim analysis are to describe selected baseline (BL) demographics and to evaluate secukinumab treatment outcomes on disease activity and impact of disease on health and to report safety profile depending on the BMI of PsA pts.

Methods: AQUILA is an ongoing, multi-center study including up to 3000 pts with active PsA or ankylosing spondylitis. Pts were observed from BL up to week (w) 52. Real-world data were assessed prospectively and analyzed as observed. Data were collected on Psoriatic Arthritis Impact of Disease-12 items (PsAID-12 score) and Patient’s Global Assessment (PGA). For calculation of proportion of pts that experienced (serious) adverse events (SAEs), all PsA pts were included that received at least one dose of secukinumab. This interim analysis focuses on BMI subgroups ≤25 kg/m², >25 to ≤30 kg/m² and >30 kg/m² (obese) in PsA pts.

Results: At BL, BMI data were available for 1228 PsA pts: 26.5% (n=325) normal weight, 35.0% (n=430) overweight and 38.5% (n=473) obese PsA pts. Proportion of men was lower in normal weight and obese PsA pts. As BMI increased, the percentage of SAEs in normal weight PsA pts was 21.6%, in overweight 26.3% and in obese 25.9%. There were no unexpected safety signals in either subgroup. One male obese PsA patient died. Cause of death was not reported, however, treating physician did not suspect a causal relationship to secukinumab.

Conclusion: In a real-world setting, secukinumab improved impact of disease and patient’s global assessment of disease activity in all BMI subgroups of PsA pts. However, normal weight PsA pts had numerically better PsAID and PGA scores than obese PsA pts. Altogether, real-world data of this interim analysis show that secukinumab is an effective treatment with a favorable safety profile up to 52 weeks in PsA pts in all BMI subgroups.

**POS1014** IMPACT OF SERUM INTERLEUKIN 22 AS A BIOMARKER FOR THE DIFFERENTIAL USE OF MOLECULAR TARGETED DRUGS FOR PSORIATIC ARTHRITIS

I. Miyagawa1, S. Nakayamada1, M. Ueno2, Y. Miyazaki3, Y. Tanaka4, 1University of Occupational and Environmental Health, Japan, The First Department of Internal Medicine, Kitakyushu, Japan

Background: Although each bDMARD target different molecules, no optimal drug selection has been established. Because studies directly comparing TNF-i and IL-17-i have shown that these drugs are equally effective, the establishment of an optimal selection method for these drugs can contribute to better patient outcomes. We reported the possibility of stratification of patients by peripheral blood lymphocytes phenotyping and precision medicine based on the serum cytokine concentration of IL-22 in PsA pts. However, since peripheral blood lymphocytes phenotyping is complex, the development of simple methods using biomarkers to stratify patients and simple treatment strategies based on such methods is needed to promote precision medicine in a real-world clinical setting.

Objectives: We explored whether serum cytokines could be used as biomarkers for optimal use TNF-i and IL-17-i in patients with PsA.

Methods: In cohort 1 (IL-17-i [n=23] or TNF-i [n=24] for 21 year), we identified serum cytokines that predicted the achievement of DAPSA remission (REM), PASI 90 and Minimal Disease Activity after 1 year of TNF-i or IL-17-i therapy. Subsequently, we developed treatment strategies based on the identified cytokines. In cohort 2, treatment responses were compared between the strategic treatment group (n=17), which was treated based on the treatment strategies, and the mismatched treatment group (n=17) to verify the validity of the treatment strategies developed using serum cytokines as biomarkers.

Results: In cohort 1, serum IL-22 concentrations were statistically identified as a predictor of DAPSA remission after 1 year of IL-17-i therapy. However, no baseline serum cytokines were identified as factors contributing to achievement of DAPSA-REM in the TNF-i-treated group or achievement of PASI90 and Minimal Disease Activity in either group. Using a cut-off value of 0.61376 (sensitivity, 81.8%; specificity, 91.7%; area under the curve, 0.848) determined by a ROC analysis, we stratified 47 patients into the IL-22 high group (n=25) (0.61376+) and the IL-22 low group (n=22) (< 0.61376). Serum IL-17 concentrations were significantly higher in both the IL-22 high and IL-22 low groups than in the healthy control (HC), whereas no significant difference was observed between the IL-22 high and IL-22 low groups. The serum TNF-α concentrations did not significantly differ between the IL-22 low and HC; however, they were significantly higher in the IL-22 high group than in the HC and IL-22 low groups. Based on these results, we created treatment strategies using TNF-i and IL-17-i based on serum IL-22 concentrations, that is, initiation of IL-17-i therapy in patients with low IL-22 concentrations and TNF-i therapy in patients with high IL-22 concentrations. To

Mean PsAID developed in a similar way over time with lowest scores for normal weight and highest scores for obese PsA pts (Figure 1B). Mean improvement from BL to w52 was 2.0 (41.6%) for normal weight, 2.2 (40.7%) for overweight, and 1.8 (32.7%) for obese PsA pts.

The occurrence of AEs/SAEs with or without suspected relationship to secukinumab was most frequent in overweight and obese PsA pts. For example, the percentage of SAEs in normal weight PsA pts was 21.6%, in overweight 26.3% and in obese 25.9%. There were no unexpected safety signals in either subgroup. One male obese PsA patient died. Cause of death was not reported, however, treating physician did not suspect a causal relationship to secukinumab.

Conclusion: In a real-world setting, secukinumab improved impact of disease and patient’s global assessment of disease activity in all BMI subgroups of PsA pts. However, normal weight PsA pts had numerically better PsAID and PGA scores than obese PsA pts. Altogether, real-world data of this interim analysis show that secukinumab is an effective treatment with a favorable safety profile up to 52 weeks in PsA pts in all BMI subgroups.
validate the efficacy of the treatment strategies, we retrospectively compared the efficacy of the DMARDs at 1 year between the following groups in cohort 2. The strategic treatment group (n=17) included patients with low IL-22 concentrations who were treated with TNF-i and those with high IL-22 concentrations who were treated with IFN-i. The mismatched treatment group (n=17) included patients with low IL-22 concentrations who were treated with TNF-i and those with high IL-22 concentrations who were treated with IFN-i. No statistically significant differences were observed between the two groups in baseline characteristics at the initiation of DMARD. After initiation of DMARD, tender joint counts, swollen joint counts, CRP, DAPSA, and PASI were significantly improved in both groups. When the treatment responses over 1 year were compared between the two groups, the rate of achieving DAPSA-REM (58.8% vs. 25.3%, P=0.0399) and Minimal Disease Activity (82.3% vs. 41.2%, P=0.0162) at M12 was significantly higher in the strategic treatment group. There were no statistically significant differences in the rates of achieving PASI75 or PASI90 at M 6 or 12.

Conclusion: We verified that serum IL-22 can be used as a simple biomarker for the proper selection of TNF-i and IFN-i.

**RELATIONSHIPS BETWEEN DISEASE DURATION AND RADIOGRAPHIC PROGRESSION AMONG PATIENTS WITH PSORIASIC ARTHRITIS TREATED WITH SECUKINUMAB IN FUTURE 5**

1University of Rochester Medical Center, Division of Allergy, Immunology, and Rheumatology, Rochester, United States of America; 2Johns Hopkins University School of Medicine, Division of Rheumatology, Psoriatic Arthritis Program, Baltimore, United States of America; 3Novartis Pharmaceuticals Corporation, Rheumatology, East Hanover, United States of America; 4Novartis Pharma AG, Rheumatology, Basel, Switzerland; 5Novartis Pharmaceuticals Corporation, Biostatistics, East Hanover, United States of America; 6Swedish Medical Center/ Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, United States of America

**Background:** For patients with psoriatic arthritis (PsA), delays in diagnosis and treatment can lead to permanent radiographic damage, even early in the course of disease. In the phase 3 FUTURE 5 study (NCT02404350), treatment with secukinumab (SEC) was shown to inhibit progression of structural damage through Week 104 in patients with PsA. However, the effect of disease duration on inhibition of radiographic progression by SEC has not been characterized.

**Objectives:** This post hoc analysis explored relationships between time since diagnosis (TSD) of ≤1 year vs >1 year and radiographic progression among patients with PsA receiving SEC over 2 years in FUTURE 5.

**Methods:** Patient data from FUTURE 5 were stratified by TSD ≤1 year vs >1 year and analyzed by treatment arm. Through Week 24, patients received SEC 300 or 150 mg with subcutaneous loading dose (LD), SEC 150 mg without LD, or placebo (PBO) (period 1). After Week 24, patients receiving PBO were switched to SEC 300 or 150 mg (period 2), and a protocol amendment allowed those with suboptimal clinical response to SEC 150 mg to escalate to SEC 300 mg after Week 52 per investigator judgment. The proportion of patients with no radiographic progression, defined as change from baseline in van der Heijde total modified Sharp score ≤0, was analyzed at Weeks 24, 52, and 104. Mean total Sharp score was evaluated at baseline, and mean change from baseline was determined at Weeks 24, 52, and 104.

**Results:** Of 996 patients with PsA included here, 217 (21.8%) had a TSD ≤1 year and 779 (78.2%) had a TSD >1 year. At baseline, patients with TSD >1 year had greater radiographic damage than patients with TSD ≤1 year as determined by mean total Sharp score (Table 1). As early as Week 24, patients receiving SEC had less radiographic progression than those receiving PBO, regardless of TSD. From Week 24 to Week 104, radiographic progression remained low among all patients receiving SEC, with a trend of least progression among patients randomized to SEC 300 mg at baseline. Regardless of treatment, patients with TSD >1 year had numerically greater radiographic progression than those patients with TSD ≤1 year. Overall, the proportion of patients receiving SEC who did not have any radiographic progression was greater than that of placebo at Week 24 irrespective of TSD, with a trend towards a higher number of non-progressors among those treated with SEC 300 mg (Figure). Patients randomized to SEC 300 mg were less likely to experience radiographic progression through 52 weeks.

**Conclusion:** SEC resulted in low rates of radiographic progression through 2 years of treatment among patients in FUTURE 5, regardless of time since PsA diagnosis.

DRUG SURVIVAL AND TREATMENT RESPONSE RATES IN PSORIATIC ARTHRITIS PATIENTS SWITCHING TO FIRST- OR SECOND-LINE IL-17 INHIBITOR TREATMENT: A DANISH POPULATION-BASED COHORT STUDY

R. L. Hansen1, T. S. Jorgensen1, A. Egeberg1, N. Lippert Roseneoe2, M. Skougaard3,4, Z. R. Stisen1, L. Dreyer1, L. E. Kristensen1. 1The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen, Denmark; 2University of Copenhagen, Department of Dermatology and Allergy, Herlev and Gentofte Hospital, Denmark; 3Aarhus University Hospital, Department of Clinical Immunology-Aarhus, Denmark; 4Aalborg University hospital, Department of Rheumatology Aalborg, Denmark; 5The Danish Rheumatologic Database (DANBIO), Rigshospitalet, Glostrup Hospital, Copenhagen, Denmark

Background: Psoriatic arthritis (PsA) is a seronegative spondyloarthropathy associated with psoriasis [1]. It is defined as a multifaceted chronic inflammatory disease with chronic peripheral and/or axial arthritis, entheseopathy and dactylitis. PsA patients also experience fatigue, decreased physical functions and sleep disturbances, which may result in impaired social activity and decreased work productivity [2, 3]. All of these disease associated symptoms can cause substantial functional and mental impairment and thereby result in decreased quality of life [4-6]. Patient impacting factors are important when trying to further understand the disease and when choosing a treatment option to properly manage the symptoms of PsA [2].

Objectives: The objective of this study was to assess the effectiveness of switching to a first- or second-line IL-17 inhibitor treatment in patients with PsA from 2014 to 2021, using data from the Danish Rheumatology registry (DANBIO) by investigating drug survival and treatment response rates.

Methods: PsA patients recorded in DANBIO who switched to a first- or second-line IL-17 inhibitor treatment from a previous biologic disease-modifying antirheumatic drugs (bDMARD) between 2014 and 2021 were included in this study. Baseline characteristics were analyzed in subgroups: first-line IL-17 inhibitor treatment and second-line IL-17 inhibitor treatment and presented as median and interquartile ranges or number and percentage. Visual analog scale (VAS) fatigue 50% improvement and VAS pain 50% improvement, Disease Activity Scores-28 C-reactive protein (DAS-28-CRP) remission and DAS28 scores at 6- and 12-months follow-up was reported. Drug survival of first- or second-line IL-17 inhibitor treatment was reported as a Kaplan Meier plot.

Results: 583 patients were identified and included in the study. Baseline characteristics (Table 1) showed that the age, percentage of females, CRP, HAQ, VAS patient pain, VAS global and DAS28CRP in both first- and second-line IL-17 inhibitor treatment was comparable. First- and second-line IL-17 inhibitor treatment had almost identical drug survival (Figure 1).

Results: We followed DMARD therapies for median (IQR) 3.2 (1.5, 6.0) in 675 LJC patients and for 3.4 (1.8, 5.2) years in 334 HJC patients. LJC patients at registration as well as at start of a first bDMARD were less often female, with less severe skin, enthesitis, dactylitis and nail involvement. Furthermore, LJC patients had lower disability indices and a more favorable health related quality of life. When defined at registration, LJC were as frequent as HJC patients on csDMARDs, but less often on bDMARDs. During their follow-up, a csDMARD, a first and a second bDMARD were less often and on average later commenced in LJC than in HJC patients. However, when defined at start of a first bDMARD, drug retention did not significantly differ between LJC and HJC patients (Figure 1).

Conclusion: The majority of Swiss PsA patients is in LJC status, which also means a better status in most PsA domains than in HJC patients. LJC status was associated with established bDMARD therapy and with slower treatment escalation. However, bDMARDs were likewise effective in bDMARD-naive LJC and HJC patients, and should not withheld only for reasons of a low joint count.

Results: Baseline characteristics (demographics and pain) for the CBD treated group and placebo group were comparable. No significant differences were observed in QST variables between baseline and end of treatment when comparing CBD and placebo.

Conclusion: No differences in modulation in QST parameters were demonstrated in patients in treatment with 20-30 mg CBD compared to placebo. Further studies of patients with rheumatic diseases treated with different dosages of CBD are needed to clarify the effect of CBD on pain in this patient group.

RELATIONSHIPS BETWEEN INHIBITION OF RADIOGRAPHIC PROGRESSION AND ACHIEVEMENT OF LOW DISEASE ACTIVITY OR REMISSION AND THEIR CORE COMPONENTS IN PATIENTS WITH PSORIARTIC ARTHRITIS TREATED WITH SECUKINUMAB IN FUTURE 5 DURING THE FIRST 24 WEEKS

1Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, United States of America; 2Johns Hopkins University School of Medicine, Division of Rheumatology, Psoriatic Arthritis Program, Baltimore, United States of America; 3Novartis Pharmaceuticals Corporation, Rheumatology, East Hanover, United States of America; 4Novartis Pharma AG, Rheumatology, Basel, Switzerland; 5Novartis Pharmaceuticals Corporation, Biostatistics, East Hanover, United States of America; 6University of Rochester Medical Center Division of Allergy, Immunology, and Rheumatology, Rochester, United States of America

Background: Patients with active psoriatic arthritis (PsA) experience inflammation that may result in structural damage and disability. In the phase 3 FUTURE 5 study, treatment with secukinumab (SEC) inhibited radiographic progression and led to sustained remission and low disease activity (LDA) through Week 104.1,2

Methods: Patients were randomized 2:2:2:3 to receive SEC 300 mg with loading dose (LD), 150 mg LD, SEC 150 mg without LD, or placebo (PBO) at Baseline, Weeks 1, 2, 3, 4, and every 4 weeks thereafter until Week 24. In this post hoc analysis, patients were grouped by radiographic progression status at Week 24 (non-radiographic progressors: change from baseline in modified total Sharp score [mTSS] ≤0.0; radiographic progressors: change from baseline in mTSS >0.0). Efficacy (achievement of Minimal Disease Activity [MDA] or Very Low Disease Activity [VLDA] and their individual components, and Disease Activity Index for Psoriatic Arthritis [DAPSA] LDA or remission) was assessed at Week 24.

Results: Of 933 patients with available data, 675 (72.3%) were classified as non-radiographic progressors and 258 (27.7%) were radiographic progressors at Week 24. Non-progressors at Week 24 were more likely than progressors to achieve DAPSA LDA and remission at Week 24 across all treatment arms (Figure 1A). In addition, non-progressors were more likely to achieve MDA and VLDA at Week 24 than progressors across all treatment arms (Figure 1B). Similar trends were observed for all of the individual MDA/VLDA criteria at Week 24 among patients treated with SEC 300 mg or SEC 150 mg LD (Table 1). Notably, non-progressors were more likely to achieve improvements in physical function, pain, and patient global assessment of disease activity than progressors across all treatment arms.

Conclusion: Patients who did not have radiographic progression over 6 months of SEC treatment were more likely to achieve LDA or remission and improvement in physical function at Week 24. Additional analyses will explore relationships between radiographic progression and additional clinical and patient-reported outcomes over longer time periods.

LONG-TERM SAFETY OF RISANKIZUMAB IN PATIENTS WITH PSORIATIC DISEASE: FINDINGS FROM INTEGRATED ANALYSES OF 17 CLINICAL TRIALS IN PSORIASIS AND 4 IN PSORIATIC ARTHRITIS

K. B. Gordon¹, A. Blauvelt², H. Bachelot², B. Kaplan³, W. Koete⁴, L. Drogaris⁴, R. Sinha⁵, K. Papp⁶. ¹Medical College of Wisconsin, Dermatology, Milwaukee, United States of America; ²Oregon Medical Research Center, Dermatology, Portland, United States of America; ³APHP Hôpital Saint-Louis, Université de Paris, Department of Dermatology, Paris, France; ⁴AbbVie Inc., Immunology, North Chicago, United States of America; ⁵Probiotic Medical Research, K Papp Clinical Research, Waterford, Canada.

Background: Risankizumab, an interleukin-23 inhibitor, was efficacious and well tolerated in phase 2 and 3 clinical studies in patients with psoriatic disease.

Objectives: To report long-term risankizumab safety in patients with psoriatic disease.

Methods: Risankizumab safety data to March 25, 2021 were pooled from 17 phase 1–3 clinical trials in plaque psoriasis (PsO) and 4 phase 2/3 trials in psoriatic arthritis (PsA). Adverse events (AEs) of safety interest were reported for patients receiving ≥1 dose risankizumab.

Results: Among 3197 patients with PsO (9982.6 patient years’ [PY] exposure; median [range] treatment duration, 3.7 years [1 day–6.9 years]) and 1542 patients with PsA (1594.9 PY; 10 year [84 days–2.0 years]), rates of treatment-emergent AEs (158.3 and 160.8 events/E100PY), serious AEs (7.6 and 8.4 E100PY) and AEs leading to discontinuation (1.9 and 2.3 E100PY) were similar. Nasopharyngitis (PsO 14.5 E100PY; PsA 7.9 E100PY) and upper respiratory infection (PsO 7.3 E100PY; PsA 6.0 E100PY) were the most common upper respiratory infections; respiratory tract infection and pneumonia for PsO (0.1 E100PY each) and COVID-19 for PsA (0.4 E100PY) were the most common serious infections. Rates of opportunistic fungial infections were <0.1 and 0.1 E100PY in PsO/PsA patients. Rates of non-melanoma skin cancer (NMSC) were 0.7 and 0.4 E100PY, and malignant tumors excluding NMSC were 0.6 and 0.3 E100PY in PsO/PsA patients. Rates of major adverse cardiovascular events were 0.5 and 0.4 E100PY in PsO/PsA patients.

Conclusion: Rates of AEs of safety interest remained low in this largest and longest safety reporting for risankizumab to date, supporting the safety of risankizumab for the long-term treatment of patients with psoriatic disease.

COMPARISON OF COMPOSITE INDICES FOR DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH UPADACITINIB: A POST-HOC ANALYSIS FROM SELECT-PSA 1

J. S. Smolen1, E. Lubrano2, M. Kishimoto3, A. Balanescu4, V. Strand5, T. Gao6, N. Vranich6, R. Lippe7, W. Tillett8. 1Department of Medicine III, Division of Rheumatology, Medical University of Vienna, Vienna, Austria; 2Department of Medicine, University Hospital of Tiberio, University of Mollise, Campobasso, Italy; 3Department of Nephrology, and Rheumatology, Koryun University School of Medicine, Tokyo, Japan; 4“Carol Davila” University of Medicine and Pharmacy, Department of Internal Medicine and Rheumatology, “St. Maria” Hospital, Bucharest, Romania; 5Stanford University, Department of Medicine, Palo Alto, United States of America; 6AbbVie Deutschland GmbH & Co. KG, Immunology, Wiesbaden, Germany; 7Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom

Background: Achieving low disease activity (LDA) or remission is a main treatment target in PsA. Composite indices used to assess disease activity include Disease Activity index for PsA (DAPSA) and PsA Disease Activity Score (PASDAS), which both have cut points for the states of remission and LDA. In addition, LDA and remission can be assessed by the pure state instrument Minimal Disease Activity (MDA) and Low Disease Activity (LDA).

Objectives: These analyses aim to identify overlap and differences between these composite indices in PsA patients treated with upadacitinib (UPA), a Janus kinase inhibitor, or adalimumab (ADA) in the phase 3 SELECT-PSA 1 trial.

Methods: In SELECT-PSA 1 (phase 3, randomized controlled trial, with long-term extension up to 5 years), patients with moderate to severely active PsA with inadequate response or intolerance to at least 1 non-biologic DMARD were randomized to oral UPA at doses of 15 mg or 30 mg (once daily), subcutaneous ADA 40 mg (every other week), or placebo. LDA was assessed using MDA (threshold: ≥5/7 criteria), DAPSA (≥14), PASDAS (≥3.2), and Patient Global Assessment of Disease Activity (PGA; ≤3). These post-hoc descriptive analyses include 1-year (cut off: week 52) as observed data from UPA 15 mg and ADA.

Results: In total, 858 patients (UPA 15 mg: n=429; ADA: n=429) were included in these analyses. Patients receiving UPA and ADA were on average 52 years of age, 54% were female, with an average disease duration of approximately 6 years. With both UPA and ADA, there was a high degree of overlap in the proportion of patients achieving LDA thresholds in MDA, DAPSA, and PASDAS (Figure 1), with reported PGA improvements showing a similar trend. Defining LDA according to MDA or respective cut points for DAPSA, PASDAS, or PGA, the proportion of “non-responders” (i.e., patients who did not reach such states) is shown in Figure 2. Of the individual components included in these indices, fewer patients reported low levels of SF36 Physical Component Summary (SF36-PCS), Patient Assessment of Pain Numeric Rating Scale (PAIN-NRS), and Health Assessment Questionnaire - Disability Index (HAQ-DI) scores, as well as Tender Joint Count 68 (TJC68), with similar responses observed across all indices.

Conclusion: In this post-hoc analysis from the SELECT-PSA 1 trial, there was a high degree of overlap between patients in LDA across the composite indices, including MDA, DAPSA, and PASDAS, irrespective of treatment with UPA 15 mg or ADA and despite variability in inclusion of certain components in some indices but not others. Across all indices, fewer patients reported low levels of SF36-PCS, Pain NRS, and HAQ-DI scores, and TJC68. These data show that improvements in (subjective) “patient-driven” components were the most challenging to achieve. These data indicate a similar pattern of residual disease activity, or influence by residual damage or external factors, regardless of composite endpoint utilized.

Acknowledgements: AbbVie funded these studies and participated in the study design, research, analysis, data collection, interpretation of data, reviewing, and approval of the publication. No honoraria or payments were made for authorship. Medical writing support was provided by Monica R.P. Elore, PhD of AbbVie.

Methods: Data were pooled from patients with prior inadequate response or intolerance to ≥1 non-biologic (b) DMARDs (SELECT-Psa 1) or ≥1 bDMARDs (SELECT-Psa 2) originally randomized to UPA 15 mg QD. Logistic regression models were used to assess the association between baseline characteristics and short-term (Week 12) responses with achievement of MDA or DAPSA LDA at 56 weeks, sustained MDA (MDA at Weeks 36 and 56), and sustained DAPSA LDA (DAPSA LDA at Weeks 36, 44, and 56). Each predictor was evaluated separately in an initial model that included effects for study and concurrent non-bDMARD use. Odds ratios and concordance (c-)statistics were used to determine the predictive accuracy. Statistically significant predictors were then evaluated simultaneously using stepwise logistic regression with the Aikake Information Criterion for model-building.

Results: Of 640 patients included in the analysis, 40% and 47% achieved MDA and DAPSA LDA, respectively, at 56 weeks. Evaluated separately, younger age (male), geographic region, lower body mass index, the presence of dactylitis or enthesitis, and lower scores of Patient’s Assessment of Pain (Pt-Pain), Patient’s Global Assessment (PtGA), tender joint count in 68 joints, and Health Assessment Questionnaire-Disability Index (HAQ-DI) were significant baseline predictors for achieving MDA and DAPSA LDA at Week 56. Lower Pt-Pain (Weeks 12–24) and PtGA (Weeks 16–24) scores were strongly predictive (c-statistics >0.8) of achieving MDA at Week 56, and both measures (from Week 8) were moderately predictive (c-statistics >0.7) of achieving DAPSA LDA. Evaluated simultaneously with several baseline characteristics, lower Pt-Pain and HAQ-DI scores at Week 12 were included in models strongly predictive of achieving MDA (c-statistic = 0.850; Figure 1) and DAPSA LDA (c-statistic = 0.840; Figure 2) at Week 56. For each 1-point increase in Pt-Pain or HAQ-DI scores at Week 12 (after adjusting for other effects in the model), patients were less likely to achieve MDA (by 32% or 56%, respectively) or DAPSA LDA (by 23% or 31%, respectively) at Week 56. Predictors for achieving sustained MDA and sustained DAPSA LDA were generally similar to those identified for achieving MDA and DAPSA LDA, respectively.

Conclusion: In patients with PsA receiving UPA 15 mg, baseline characteristics and early responses strongly predicted achievement of MDA or DAPSA LDA at Week 56. This may guide considerations of treatment targets in clinical trials and encourage physicians to further optimize treatment of their patients in clinical practice.

Background: Apremilast, an inhibitor of the phosphodiesterase 4, is indicated for Psoriatic Arthritis (PsA) treatment. The 3 years retention rate, an outcome indirectly related to efficacy, observed in clinical trials [1] is 55.5%. A single subsequent real-world setting study [2] suggested a lower efficacy as it reported that the six months retention rate was about 57%.

Objectives: The main aim of this retrospective observational study is the assessment of apremilast 3 years retention rate in a real world PsA patients' cohort. Moreover, the secondary objective is reporting the reasons of apremilast suspension and the most relevant factor related to treatment persistence.

Methods: In thirteen Italian rheumatological referral centers, all PsA consecutively patients who received apremilast were enrolled. Anamnestic data, treatment history and PsA disease activity (DAPSA) at baseline and after 6 and 12 months were recorded. The Kaplan-Meier curve and the Cox analysis computed the apremilast retention rate and treatment persistence-related risk factors. A p-value < 0.05 was considered statistically significant.

Results: The three-hundred-twenty-four enrolled patients (median age 60 [Inter-Quartile Range IQR 52-67] y; female prevalence 57%) median observation period was 17 [IQR 7-36] months (6848 patients-months). The apremilast retention rate at 6, 12 and 36 months was, respectively, 95%, 86% and 66% (Figure 1). The main discontinuation reasons were: primary inefficacy (40% of interruptions), secondary inefficacy (18%) and gastrointestinal intolerance (17%). The oligo-articular onset was the only factor associated to apremilast persistence (Hazard ratio 0.57, IQR 0.34-0.96). Sex, age, and sever comorbidities (cancer, chronic infections etc) were not related to treatment discontinuation. The basal DAPSA (24.1, IQR 18.5-32.0) decreased after 6 and 12 months (respectively 14.5, IQR 10.1-22.6 and 10.5, IQR 8.0-15.2). Remission or minimal disease activity (DAPSA < 15) was achieved after 12 months in 38.0% of patients.

Conclusion: Almost two third of PsA patients receiving apremilast were still in treatment after 3 years. The study’s data, confirmed its efficacy and safety profile. Apremilast appear a good treatment choice in patients with oligo articular PsA or burdened by severe comorbidities.

aResults are LS mean change (95% confidence interval [CI]); LS mean change determined by ANCOVA; missing data was imputed as no change for pts who discontinued treatment and using multiple imputation for remaining missing data GUS, guselkumab; LEI, Leeds Enthesitis Index; LEI, least squares; PBO, placebo; pts, patients; Q4W, every 4 weeks; Q8W, every 8 weeks; W, week

Conclusion: Pts with PsA often present with concurrent enthesitis and dactylitis, both of which can be recalcitrant to treatment. GUS resolved enthesitis and dactylitis in substantial proportions of pts through W100. GUS-treated pts who achieved enthesitis resolution were more likely to achieve dactylitis resolution and vice versa.

P0209
EFFECTS OF TREATMENT WITH RISANKIZUMAB ON MINIMAL DISEASE ACTIVITY (MDA) AND DISEASE ACTIVITY IN PSORIATIC ARTHRITIS (DAPSA): AN ANALYSIS OF THE KEEPSAKE-1 AND -2 TRIALS

J. F. Merola, I. McInnes, A. Kavanagh, P. Nash, X. Zue, V. Stakas, A. Eldred, S. Ciecienski, K. Douglas, L. Coates, Brigham and Women’s Hospital, Harvard Medical School, Boston, United States of America; University of California San Diego, Medicine, San Diego, United States of America; Griffith University, School of Medicine, Queensland, Australia; AbbVie Inc., Immunology, North Chicago, United States of America; Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

Background: Risankizumab (RZB) is a monoclonal antibody that specifically inhibits interleukin 23.

Objectives: To evaluate the achievement of Minimal Disease Activity (MDA), its components, and achievement of Disease Activity in PsA Low Disease Activity and Remission (DAPSA LDA+REM; [DAPSA score ≤ 14]) in patients receiving RZB or placebo (PBO) in the KEEPSAKE 1 and 2 clinical trials.

Methods: KEEPSAKE-1 and -2, double-blind, phase 3 trials, evaluated the efficacy of RZB versus PBO for the treatment of adult patients with active psoriatic arthritis (PsA). Patients were randomized (1:1) to receive subcutaneous RZB 150mg or PBO at weeks 0, 4, and 16. The open label extension began at Week 24 with all patients receiving RZB 150mg every 12 weeks thereafter. Achievement of MDA, its components, and achievement of DAPSA LDA+REM are reported using non-responder imputation.

Results: MDA achievement at Week 52 in KEEPSAKE-1 was 37.9% for patients originally randomized to RZB and 27.4% for patients originally randomized to PBO. In KEEPSAKE-2, MDA achievement was 27.2% and 33.8% for patients originally randomized to RZB and PBO, respectively. Achievement of MDA and its components are presented in Figure 1. In KEEPSAKE-1, at Week 52 59.2% of patients originally randomized to RZB and 51.4% of patients originally randomized to PBO achieved DAPSA LDA+REM. At Week 52 in KEEPSAKE-2, DAPSA LDA+REM was achieved by 44.6% of patients originally randomized to RZB and 46.6% of patients originally randomized to PBO (Figure 1).

Conclusion: Patients treated with RZB demonstrate achievement of MDA, its components, and DAPSA LDA+REM at Weeks 24 and 52.

**PAIN RESPONSE IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH GUSELKUMAB IS DRIVEN PREDOMINANTLY BY INFLAMMATION-INDEPENDENT EFFECTS**

P. J. Mease1, E. Soriano2, S. D. Chakravarty3,4, E. Rampakakis5, M. Shaw6, P. Nash7, P. Rahman8, 9

1 Swedish Medical Center/Providence St. Joseph Health and Univ Washington, Rheumatology Research, Seattle, United States of America; 2Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, Argentina; 3Janssen Scientific Affairs, LLC, Immunology, Rheumatology, Horsham, United States of America; 4Drexel University College of Medicine, Division of Rheumatology, Philadelphia, United States of America; 5McGill University, Department of Pediatrics, Montreal, Canada; 6Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; 7Griffith University and U of Queensland, Rheumatology Research Unit, Maroochydore, Australia; 8Memorial University of Newfoundland, Discipline of Medicine, Division of Rheumatology, Craig L Dobbin Genetics Research Centre, St. John’s, Canada

**Background:** Although reducing inflammation has been associated with pain improvement, the two do not always correlate. Recent studies have suggested that, in addition to its role in inflammation pathogenesis, IL-23 may be involved in pain regulation in a lymphocyte-independent manner. Gusekumab (GUS), a fully human monoclonal antibody that selectively inhibits IL-23, has demonstrated safety and efficacy in treating multiple domains of active PsA in the DISCOVER-1&2 (D1&D2) trials.

**Objectives:** To quantify the role of reducing inflammation on the observed relationship between GUS and pain response in PsA patients (pts) using mediation modelling.

**Methods:** Pooled data from the D1&D2 studies were analyzed. Pts in D1 had ≥3 swollen and ≥3 tender joints (SJC/TJC) and C-reactive protein (CRP)≥0.3 mg/dL; in D2, pts had ≥5 SJC and ≥5 TJC and CRP≥0.6 mg/dL. 31% of D1 pts received 1-2 prior tumor necrosis factor inhibitors (TNFi); D2 pts were bio-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then W8 (Q8W); or placebo (PBO); PBO pts crossed over to GUS 100 mg Q4W.

Mediation analyses were performed separately for Q4W & Q8W, W4 & W24, and TNFi-naïve & -experienced (exp) pts. In each model, change in joint counts was the dependent variable; treatment regimen was the independent variable; inflammation, measured by change in SJC or CRP, was the designated mediator; covariates were: age, sex; and baseline (BL) pain score, BMI, SF-36 MCS score, and NSAID use.

**Results:** Mean (SD) BL pain levels in the GUS Q4W, GUS Q8W, and PBO groups were 60.4 (19.8), 62.0 (20.2), and 61.1 (19.6), respectively. Treatment with GUS was associated with significantly greater pain improvement compared with PBO as early as W4 (ΔGUS-Q4W [95%CI]: -4.9 [-7.6, -2.2]; ΔGUS-Q8W [95%CI]: -5.2 [-7.9, -2.5]) (Figure 1). The between-group differences were further enhanced by W24 (ΔGUS-Q4W [95%CI]: -14.6 [-17.6, -11.6]; ΔGUS-Q8W [95%CI]: -14.3 [-17.3, -11.2]). For GUS-Q8W, ΔGUS randomized pts exhibited an approximate 50-point (-50%) decrease in pain. Similar results were observed for TNFi-naïve and TNFi-exp pts.

**Conclusion:** GUS induced significant improvement in pt-reported pain as early as W4 of treatment, which was continuously enhanced through W24. While the known mediation effect of SJC and CRP, as markers of inflammation, on pain was confirmed, the majority of GUS’s effect on pain reduction was independent of its effect on these markers, regardless of dosing regimen or prior TNFi experience.

---

**Figure 1.**

Mediation analyses demonstrated that the majority of GUS effect on pain at W4 was not attributable to SJC (direct effect), specifically ≤5% was mediated by inflammation as assessed by changes in SJC (indirect effect; Table 1). Similarly, at W24, the indirect effect via SJC improvement represented ≤10% of the GUS treatment effect. No differences were observed between TNFi-naïve and -exp pts at either timepoint.

Consistent results were obtained when using CRP as the mediator variable instead of SJC, whereby ≤2-9% of GUS effect on pain was mediated by inflammation and 91-98% was direct (Table 1).

**EARLIER CLINICAL RESPONSE PREDICT LOW RATES OF RADIOGRAPHIC PROGRESSION IN BIO-NAIVE ACTIVE PSORIATIC ARTHRITIS PATIENTS RECEIVING GUSELKUMAB TREATMENT**

1 Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; 2Icahn School of Medicine at Mount Sinai, Department of Dermatology, Mt Sinai, United States of America; 3University of Pennsylvania School of Medicine, Immunology, Philadelphia, United States of America; 4Janssen Scientific Affairs, LLC, Immunology, Rheumatology, Horsham, United States of America; 5McGill University, Department of Pediatrics, Montreal, Canada; 6Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; 7Griffith University and U of Queensland, Rheumatology Research Unit, Maroochydore, Australia; 8Memorial University of Newfoundland, Discipline of Medicine, Division of Rheumatology, Craig L Dobbin Genetics Research Centre, St. John’s, Canada; 9University of Washington, Rheumatology Research, Seattle, United States of America; 10.1136/annrheumdis-2022-eular.1384
Background: In GUS-treated biologic-naive pts with active PsA, following adjustment for known baseline (BL) determinants of radiographic progression (vdH-S score, age, gender, and CRP), no correlation was seen between BL PASI and BL vdH-S score. Greater improvement in BL DAPSA score after adjusting for BL PASI, vdh-S score, age, gender, and CRP (Figure). No correlation was seen between BL PASI and BL vdH-S score (Table 1). Greater improvement in DAPSA score (≥20%) at week 24 of GUS-treated biologic-naive pts with active PsA was associated with numerically less radiographic progression through W100 after adjusting for known baseline (BL) determinants of radiographic progression (vdH-S score, age, gender, and CRP).

Results: PsA duration, CRP, and SJC at BL weakly correlated with BL vdH-S score.

Conclusion: In GUS-treated biologic-naive pts with active PsA, following adjustment for known BL determinants of radiographic progression, earlier (W16) DAPSA improvement was a significant predictor of less radiographic progression through W100; DAPSA remission and skin improvement at W16 each showed a numerical trend toward less radiographic progression through W100.

Mconagle11,12, "Royal National Hospital for Rheumatic Diseases,, Bath, United Kingdom; 3University of Bath, Department of Pharmacy and Pharmacology, Bath, United Kingdom; 4Bispebjerg Hospital, Department of Dermatology, Copenhagen, Denmark; 5Karolinska Institutet, Dermatology and Venereology Division, Stockholm, Sweden; 6Karolinska Institutet, Center for Molecular Medicine, Stockholm, Sweden; 7Uppsala University, Department of Medical Sciences, Uppsala, Sweden; 8Janssen-Cilag Ltd., High Wycombe, United Kingdom; 9Janssen-Cilag AB, Solna, Sweden; 10Janssen-Cilag BV, Leiden, the Netherlands; 11Guselkumab GmbH, Neuss, Germany; 12University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 13Leeds Teaching Hospitals NHS Trust, National Institute for Health Research, Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: Nail psoriasis can be difficult to treat, affects ~50% of patients with psoriasis and can involve the nail matrix (pitting, leukonychia) and/or nail bed (onycholysis, splinter haemorrhages). Evidence suggests nail psoriasis may be associated with risk of developing psoriatic arthritis, in particular distal interphalangeal joint erosion.1-3 Data to Week 24 (Wk 24) from VOYAGE 1 and 2, two Phase 3 clinical trials, indicate that the anti-interleukin-23 monoclonal antibody guselkumab (GUS) is more effective than placebo and as effective as adalimumab in treating nail psoriasis.4 Further, GUS is also associated with maintained Psoriasis Area and Severity Index (PASI) following treatment withdrawal in VOYAGE 2; however, nail response is not as well understood in this context.1

Objectives: This VOYAGE 2 post hoc analysis evaluated nail response and its association with skin response and patient-reported outcomes (PROs) in two groups, one experiencing GUS withdrawal and the other receiving continuous GUS.

Methods: Patients had moderate-to-severe plaque psoriasis and nail psoriasis, were initially randomised to GUS, and achieved PASI 90 at Wk 28. Patients were then re-randomised to placebo (GUS withdrawal) or GUS every 8 wks (GUS continuation). Nails were then re-randomised to placebo (GUS withdrawal) or GUS every 8 wks (GUS continuation) until Wk 48. Data are mean (standard deviation). *n=10 reinitiated GUS upon loss of 50% of Wk 28 PASI 90 (at n=1 Wk 36, n=2 Wk 40, n=7 Wk 44); †n=107; R, re-randomisation of PASI 90 responders.

Conclusion: GUS treatment through Wk 48 improved nail psoriasis, skin psoriasis and PROs. When GUS was withdrawn, loss of response was slower in nails vs skin. These findings support that nail outcomes follow skin outcome trends with GUS treatment and that nail outcomes should contribute to evaluation of treatment efficacy and disease progression.2,3,5

REFERENCES:
Background: There are currently ten biologic and targeted synthetic (b/ts)DMARDs acting via five different modes of action (MOA) available for the treatment of psoriatic arthritis (PsA) in Australia. b/tsDMARDs are government-subsidised, and once the patient reaches the eligibility requirements, the clinician can prescribe the agent deemed most appropriate. Available agents include TNF inhibitors (TNFi, adalimumab, etanercept, infliximab, golimumab, certolizumab pegol), IL-17A inhibitors (IL-17Ai, secukinumab, ixekizumab), and IL-12/23 inhibitor (IL-12/23i, ustekinumab). Two new MOAs were recently added to the rheumatologist’s armamentarium: the first JAK inhibitor (JAKi, tofacitinib) was subsidized from May 2019 followed by upadacitinib from Oct 2021, and an IL-23 inhibitor (IL-23i, guselkumab) was subsidized from July 2021.

Objectives: The aim of this analysis was to describe the changing patterns of b/tsDMARD use for the treatment of PsA in real-world practice in Australia.

Methods: Deidentified clinical data were sourced from the OPAL dataset, which is collected in a custom-built electronic medical record during the routine consultation. Data from patients >18 years with a physician diagnosis of PsA who were prescribed a b/tsDMARD between Jan-2007 and Sept-2021 were included in the analysis. The software program Tableau was used to display the data.

Results: At Sept 2021, 6,150 (38% of the total) patients with PsA in the OPAL dataset were prescribed b/tsDMARDs. Of these patients, 3741 (61%) were currently prescribed a TNFi, 1503 (24%) an IL-17Ai, 556 (9%) a JAKi, 222 (4%) an IL-12/23i and 134 patients prescribed a b/tsDMARD between Jan-2007 and Sept-2021 were included in the analysis. Conversely, 1st line IL-17Ai initiations have increased from 14.1% in 2017 to 22.2% in 2021. In 2021, TNFi accounted for 53.4% of 2nd line initiations and 38.2% of 3rd line initiations. IL-17Ai accounted for 30.4% of 2nd and 37.0% of 3rd line initiations and JAKi accounted for 10.5% of 2nd and 14.2% of 3rd line initiations. In the 3 months that IL-23i has been subsidised, this MOA was the most initiated agent for patients who had been treated with more than two prior b/tsDMARDs. In 2021, 52.1% of patients switching from a 1st line TNFi switched to an alternative TNFi, 33.3% switched to an IL-17Ai and 11.3% switched to a JAKi in 2nd line. Of those switching from a 1st line IL-17Ai, 59.6% initiated a TNFi, 21.2% switched to an alternative IL-17Ai and 11.5% switched to a JAKi.

Conclusion: The patterns of b/tsDMARD utilisation for the treatment of PsA, when the choice of agent is at the discretion of the rheumatologist, remains dynamic and is evolving as new MOAs become available. TNFi remains the most prescribed b/tsDMARD for first line therapy. However an increase in first line use of alternative MOAs has been observed. TNFi cycling remains a commonly utilised real-world treatment strategy but appears to be declining as new MOAs become available.

Background: RZB, a humanized immunoglobulin G1 monoclonal antibody that
specifically inhibits the p19 subunit of the human cytokine interleukin-23, is being
investigated as a treatment for PsA.
Objectives: Evaluate longer-term safety and efficacy of RZB in patients with
active PsA who experienced inadequate response or intolerance to 1 or 2 biologic therapies and/or to at least 1 csDMARD therapy.
Methods: KEEPsAKE 2 (NCT03671148) is an ongoing, phase 3, multicenter study
that includes a screening period; a 24-week double-blinded, randomized, placebo-controlled, parallel-group period (period 1); and an open-label extension period
(period 2). Eligible patients were ≥18 years of age with active PsA (symptom onset
≥6 months before screening, meeting Classification Criteria for PsA [CASPAR], and
≥5 tender and ≥5 swollen joints) and had inadequate response or intolerance to 1
or 2 biologic therapies (Bio-IR) and/or ≥1 conventional synthetic disease modifying

antirheumatic drug (csDMARD-IR). Patients received RZB 150 mg or placebo
(PBO) at weeks 0, 4, and 16 (1:1). The primary endpoint was the proportion of
patients achieving ACR20 response at week 24. Period 2 started at week 24, and
patients were switched to receive open-label RZB 150 mg every 12 weeks through
week 208. Efficacy and safety were analyzed in patients who received ≥1 dose
of study drug through week 52. Mixed-effect model with repeated measures and
nonresponder imputation methods were used to assess continuous and binary variables, respectively. Treatment-emergent adverse events (TEAEs) were summarized
using exposure-adjusted event rates (EAERs, events/100 patient-years [PY]).
Results: At week 24, 51,3% of RZB-treated (N=224) and 26.5% of PBO-treated
(N=219) patients achieved ACR20. At week 52, 58.5% of patients who were randomized to RZB and 55.7% of patients who were randomized to PBO and then switched
to RZB at week 24 achieved ACR20. In patients with ≥3% of body surface area affected
at baseline, 55.0% of RZB-treated patients (N=123) and 10.2% of PBO-treated patients
(N=119) achieved PASI 90 at week 24. At week 52, 64.2% of patients randomized to
RZB and 59.7% of patients who were randomized to PBO and then switched to RZB at
week 24 achieved PASI 90. For other efficacy measures, similar trends were observed.
RZB was well tolerated through 52 weeks of treatment, and EAERs of adverse events
were stable between weeks 24 and 52. At the week 52 data cutoff (19 April 2021), the
total EAER of any TEAE in patients receiving RZB was 184.2/100 PY.
Conclusion: Continuous RZB treatment resulted in maintained efficacy
responses with a consistent safety profile through 52 weeks of treatment in
patients with active PsA who were Bio-IR and/or csDMARD-IR.

EFFECT OF GUSELKUMAB, A SELECTIVE IL-23P19
INHIBITOR, ON AXIAL-RELATED ENDPOINTS IN
PATIENTS WITH ACTIVE PSA: RESULTS FROM A
PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBOCONTROLLED STUDY THROUGH 2 YEARS

P. J. Mease1, P. Helliwell2, D. D. Gladman3, D. Poddubnyy4,5, X. Baraliakos6, S.
D. Chakravarty7,8, A. Kollmeier9, X. L. Xu9, S. Sheng10, S. Xu10, M. Shawi11, D. Van
der Heijde12, A. Deodhar13. 1Swedish Medical Center/Providence St. Joseph Health
and University of Washington, Rheumatology Research, Seattle, WA, United States
of America; 2University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal


Guselkumab (GUS), a selective IL-23p19 inhibitor, showed greater mean improvements in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores vs placebo (PBO) at Week (W) 24 in patients (pts) with active PsA and investigator-confirmed sacroiliitis in pooled post hoc analyses of data from phase 3 DISCOVER (D)-1&2 trials. Improvements in symptoms of axial involvement were maintained through 1 year.1

Objectives: To assess maintenance of GUS effect on symptoms of axial involvement in biologic-naïve PsA pts with investigator-confirmed sacroiliitis through 2 years of D-2.

Methods: In D-2, 739 bio-naïve pts with active PsA (≥5 swollen + ≥5 tender joints, CRP ≥0.6 mg/dL, standard therapy failed, ≥1.1/1.1 to GUS 100 mg every 4 W (Q4W); n=245), GUS 100 mg at W0, W4, then Q8W (n=248), or PBO—GUS 100 mg Q4W at W24. Pts with investigator-identified axial symptoms and sacroiliitis (prior X-ray or MRI, or pelvic X-ray at screening) were evaluated. Efficacy was assessed by changes in BASDAI, modified BASDAI (mBASDAI, excluding Q3 [peripheral joint pain]), and BASDAI Q2 (Spinal Pain) scores, and proportions of pts achieving BASDAI 50, Spinal Pain score ≤2, and AS Disease Activity Score (ASDAS) ≤1.6). At W24, pts with investigator-identified axial involvement and sacroiliitis in ≏2 years of biologic therapy who met treatment failure criteria or had missing data were considered nonresponders.

At W24, missing data were imputed as nonresponse for binary endpoints or no change from baseline for continuous endpoints (nonresponder imputation [NRI]). Axial-related outcomes were also summarized by HLA-B27 status (+/-).

Results: 246 pts had investigator-confirmed sacroiliitis. Baseline characteristics were similar across treatment groups (62% male; mean age 44.4 years; mean BASDAI scores 6.5-6.6). At W24, LS mean changes in BASDAI (-2.4/-2.6) and ASDAS (-1.3/-1.5) scores were greater in GUS- vs PBO-treated pts. Improvements were maintained through W100 in GUS-treated pts: BASDAI, -3.1; Spinal Pain, -3.1; mBASDAI, -3.1; ASDAS, -1.7. Response patterns were similar for BASDAI 50 response rates in GUS-treated pts (W24 38-40%; W100 49-54%).

At W24, GUS-treated pts had higher response rates for achievement of ASDAS inactive disease, major improvement, and clinically important improvement vs PBO; response rates (NRI) were maintained, or in some cases further increased, at 2 years. Results were consistent for achievement of ASDAS LDA and Spinal Pain score ≤2 (data not shown). GUS-related improvements in axial symptoms through W100 were generally consistent in HLA-B27+/- pts (data not shown).

Conclusion: In bio-naïve pts with active PsA and investigator-confirmed sacroiliitis, GUS provided durable improvements in axial symptoms through W100, with substantial proportions of pts achieving and maintaining clinically meaningful improvements.

GUSELKUMAB EFFICACY IN PSORIATIC ARTHRITIS ASSESSED BY MULTI-DOMAIN COMPOSITE INDICES: DATA FROM THE PHASE 3B COSMOS TRIAL IN A TNFI-IR POPULATION

L. Gossec¹, E. Theander², M. Neuhold³, P. Bergmans⁴, M. Shaw⁵, M. Perate⁶, C. Contré⁷, L. Coates⁸, Sorbonne Université and Pitié-Salpêtrière Hospital, Rheumatology department, Paris, France; ²Janssen, Scientific Affairs, LLC, Solna, Sweden; ³Janssen, Scientific Affairs, LLC, Zug, Switzerland; ⁴Janssen, Biostatistics, Breda, Netherlands; ⁵Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; ⁶Janssen, Scientific Affairs, LLC, Horsham, United States of America; ⁷Janssen, Scientific Affairs, LLC, Issy-les-Moulineaux, France; ⁸University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences (NDORMS), Oxford, United Kingdom

Objectives: Assess the efficacy of GUS 100 mg Q8W in TNFI-IR pts through 1 year by using and comparing 6 multi-domain composite indices validated in PsA.

Methods: In total, 285 pts (189 GUS, 96 placebo [PBO]) were enrolled in COSMOS; mean age was 49 years and mean disease duration was 8.4 years. ¹ Pts who received PBO crossed over to GUS at either Week (W) 16 (early escape, n=45/96) or W24 (planned, n=51/96). PsA Disease Activity Score (PASDAS), GRApPA Composite Score (GRACE), Disease Activity Index for PsA (DAPSA), modified Composite Psoriatic Arthritis Score (mCPDAI), excludes BASDAI), PsA Response Criteria (PsARC), and Minimal Disease Activity (MDA) were analysed (thresholds as published²). As observed data are presented at baseline (BL), W24 and W48, without imputation of missing data.

Results: Overall, 167/189 (88%) GUS and 83/96 (86%) PBO→GUS pts completed the study through W44. Pts had active disease, with similar BL mean values for PASDAS, GRACE, DAPSA and mCPDAI between GUS and PBO groups (Table 1). Across these indices, GUS pts demonstrated robust improvements (45–62%) in mean scores from BL to W48 (Table 1). PBO pts who crossed over to GUS at W16 or W24 also showed rapid improvement in their index scores, with mean values % improvement at W48 consistent with those observed in pts randomized to GUS at BL (Table 1).

Conclusion: GUS provided robust and substantial benefits to pts with active TNFI-IR PsA across multiple domains. Importantly, rates of achieving low levels of disease activity continued to increase through the duration of the study without an observable plateau at W48. Thresholds for DAPSA and PsARC response were easier to achieve than comprehensive indices with more domains that are required to improve simultaneously (eg GRACE, PASDAS, MDA). GUS performed well regardless of the focus of the composite indices (joints, skin, enthesitis, dactylitis, or patient-reported outcomes). Together, these findings support the role of GUS as an effective treatment option for the diverse domains of PsA.

Among the 4 indices with defined disease states/therapeutic thresholds for low disease activity (LDA) (Figure 1), those focusing on joints (PsARC [4 components] and DAPSA [5 components]) resulted in the highest response rates (range, 50–85%). LDA according to GRACE (8 items, including skin) and PASDAS (8 items, focus on musculoskeletal with no skin assessment) was attained less frequently (range, 38–44%). Using the PsARC, 50% of GUS pts responded as early as W8. Response rates among GUS-treated pts generally did not plateau by W48 (Figure 1). At W48, 33% and 30% of GUS and PBO→GUS pts, respectively, achieved a status of MDA.
**POS1039**

DEUCRACVITINIB, AN ORAL, SELECTIVE TYROSYNE KINASE 2 INHIBITOR, IN A PHASE 2 TRIAL IN PSORIATIC ARTHRITIS: ACHIEVEMENT OF MINIMAL DISEASE ACTIVITY AND ITS COMPONENTS

A. Kavanaugh1, L. Coates2, J. F. Menola3, P. J. Mease4, M. Nowak5, S. Banerjee6, L. Hippeli7, T. Lehman7, 1University of California, San Diego, Rheumatology, La Jolla, United States of America; 2University of Oxford, Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 3Brigham and Women’s Hospital, Harvard Medical School, Dermatology, Boston, United States of America; 4Swedish Medical Center/ Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; 5Bristol Myers Squibb, Clinical R&D, Princeton, United States of America; 6Bristol Myers Squibb, WW Medical Immunology, Princeton, United States of America

**Background:** Tyrosine kinase 2 (TKY2) is a intracellular kinase in the Janus kinase (JAK) family that mediates the signalling of multiple cytokines, including those central to the immunopathogenesis of psoriatic arthritis (PsA), such as IL-23. Deucravacitinib (DEUC) is a novel, oral, selective, allosteric inhibitor of TKY2 that acts by binding to the unique regulatory domain on the enzyme. In a Phase 2 trial in patients with active PsA, DEUC was significantly more efficacious than placebo (PBO) after 16 weeks of treatment and was well tolerated.1, 2

**Objectives:** This analysis further evaluated the effect of DEUC on this trial on achievement of individual components of minimal disease activity (MDA).

**Methods:** This double-blind, multicenter Phase 2 trial (NCT03881059) enrolled patients (n=203) with a PsA diagnosis ≥6 months who fulfilled Classification Criteria for Psoriatic Arthritis at screening and had active joint disease (≥3 tender and ≥3 swollen joints), high-sensitivity C-reactive protein ≥3 mg/L, and ≥1 plaque psoriasis lesion ≥2 cm. Eligible patients had failed or were intolerant to ≥1 nonsteroidal anti-inflammatory, conventional synthetic DMARD, and/or 1 tumour necrosis factor antagonist 5.0) severity grade ≥3 of laboratory abnormalities were assessed.

**Results:** Of 203 patients randomized, 180 (89%) completed 16 weeks of treatment (PBO, 58/66 [88%]; DEUC 6 mg QD, 63/70 [90%]; DEUC 12 mg QD, 59/87 [68%]). Demographic and baseline disease characteristics were generally similar across groups. Although no patient had met ≥5 of 7 criteria required for achieving MDA at baseline, several individual components of MDA were met at baseline, most frequently TEP ≤1 (PBO, 57%; DEUC 6 mg QD, 64.3%; DEUC 12 mg QD, 65.7%). After 16 weeks of treatment, 76%, 22.9%, and 23.9% of patients in the PBO, DEUC 6 mg QD, and DEUC 12 mg QD groups, respectively, achieved MDA response. Treatment with DEUC was associated with a numerically greater mean reduction from baseline in all MDA components versus PBO over 16 weeks of treatment in all patients. At Week 16, more patients receiving DEUC versus PBO achieved the threshold for each of the MDA components (Figure 1).

**Conclusion:** In this study, patients treated with DEUC achieved a higher rate of MDA response compared with patients treated with PBO after 16 weeks of treatment. More patients receiving DEUC treatment achieved each of the MDA components compared with patients receiving PBO.

1University of Texas Southwestern Medical Center, Rheumatology, Dallas, United States of America; 2University of Lübeck, Dermatology, Lübeck, Germany; 3SKIN Centre for Dermatology, Queen’s University, ProBlyt Medical Research, Dermatology, Peterborough, Canada; 4University of California, San Francisco, Dermatology, New Haven, United States of America; 5Case Western Reserve University and University Hospitals, Dermatology, Cleveland, United States of America, 6Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America; 7Bristol Myers Squibb, WW Medical Immunology, Princeton, United States of America; 8Bristol Myers Squibb, Clinical R&D, Princeton, United States of America; 9Bristol Myers Squibb, Veracyon, United States of America; 10Nagoya City University Graduate School of Medical Sciences, Dermatology, Nagoya, Japan; 11Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America

**Background:** Deucravacitinib (DEUC) is a novel, oral, selective, allosteric tyrosine kinase 2 (TKY2) inhibitor with a unique mechanism of action distinct from Janus kinase (JAK) 1/2/3 inhibitors. DEUC mediates signalling of key cytokines in psoriatic arthritis (PsA) and psoriasis (PsO). DEUC was well tolerated and efficacious vs placebo (PBO) in a Phase 2 trial in patients (pts) with PsA1, 2 and vs PBO or apremilast in 2 Phase 3 PsO trials.3

**Objectives:** To assess the effect of DEUC on multiple laboratory parameters through the first 16 weeks of treatment (PBO-controlled) in these trials.

**Methods:** The Phase 2 double-blind PsA trial randomised pts (n=203) 1:1:1 to PBO, DEUC 6 mg once daily (QD), or 12 mg QD. The Phase 3 double-blind PsO trials, POETYK PSO-1 and POETYK PSO-2, randomised pts (n=668 and 1020, respectively) 1:2:1 to PBO, DEUC 6 mg QD, or apremilast 30 mg twice daily. Changes from baseline in haematologic (neutrophils, lymphocytes, platelets, haemoglobin) and chemistry (cholesterol, triglycerides, alanine aminotransferase [ALT], aspartate aminotransferase [AST], and creatinine phosphokinase [CPK]) parameters were evaluated. Shifts in Common Terminology Criteria for Adverse Events (CTCAE; version 5.0) severity grade ≥3 of laboratory abnormalities were assessed.

**Results:** In the PsA trial, 65% of pts were on concomitant conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) and 54.7% of pts were on methotrexate. The vast majority of pts continued to have laboratory parameters within normal range throughout the 3 trials in PsO and PsA. No clinically meaningful changes from baseline were observed in laboratory parameters in pts treated with DEUC, PBO, or apremilast. Rates of CTCAE grade 3 and 4 were rare (≤1 pt) and similar across DEUC-, PBO-, and apremilast-treated pts for the following parameters: lymphocytes, neutrophils, platelets, haemoglobin, AST, ALT, and cholesterol (Table 1). Shifts to CTCAE grades ≥3 in triglycerides and CPK were infrequent and generally comparable across treatment arms.

**Conclusion:** DEUC treatment did not result in clinically meaningful laboratory changes, abnormalities often seen with JAK 1/2/3 inhibition, through 16 weeks of treatment in a Phase 2 trial in PsA, despite two-thirds of pts being on concomitant csDMARDs, and in 2 large Phase 3 trials in PsO.

### POS1041
LONG-TERM EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS REFRACTIVE TO BIOLOGIC THERAPIES: 2-YEAR RESULTS FROM THE PHASE 3 SELECT-PSA 2 STUDY

1Swedish Medical Center/Providence St Joseph Health and University of Washington, Seattle, WA, USA; 2AbbVie Inc, Immunology, North Chicago, United States of America; 3Papo Clinical Research and Proby Medical Research, Dermatology, Waterloo, Canada; 4Ghent University, VIB Center for Inflammation Research, Internal Medicine and Pediatrics, Ghent, Belgium; 5National Hospital Organization, Osaka Minami Medical Center, Orthopaedics/Rheumatology, Osaka, Japan; 6Pontifical Catholic University, School of Medicine, Rheumatology, Porto Alegre, Brazil; 7Royal National Hospital For Rheumatic Diseases, Rheumatology, Bath, United Kingdom

Background: Upadacitinib (UPA), an oral Janus kinase (JAK) inhibitor, demonstrated efficacy and safety in patients (pts) with psoriatic arthritis (PsA) and prior inadequate response or intolerance to ≥1 biologic disease-modifying antirheumatic drug (bDMARD) at week (wk) 56 in the phase 3 SELECT-PSA 2 study.1 Objectives: To evaluate the efficacy and safety of UPA at wk 104 from the ongoing long-term extension of SELECT-PSA 2.

Methods: Pts were randomized to UPA 15 mg (UPA15), UPA 30 mg (UPA30), or placebo (PBO) for 24 wks; PEs for continuous UPA treatment groups, efficacy endpoints at wk 104 were analyzed using non-responder imputation (NRI) and as observed (AO) (binary endpoints) or mixed-effect model repeated measures (MMRM) and AO (continuous endpoints). Treatment-emergent adverse events (TEAEs) were summarized for pts who received ≥1 dose of study drug using visit-based cut-off at wk 104.

Results: A total of 641 pts received ≥1 dose of study drug. At wk 104, 38.4% of all patients had discontinued study drug, with the highest discontinuation observed...
in patients randomized to PBO at baseline (all PBO: 46.7%). The most common reasons for discontinuation were lack of efficacy (UPA15: 12.3%, UPAP30: 8.7%, all PBO: 21.7%) and adverse event (UPA15: 10.9%, UPAP30: 13.3%, all PBO: 12.7%). The proportion of UPA pts that achieved ACR20/50/70, MDA, PASI75/90/100, and resolution of dactylitis and enthesitis were generally similar, or further improved, with 104 wks of treatment vs 56 wks(1) (Table 1). Similarly, mean change from baseline in HAQ-DI, patient's assessment of pain, BASDAI, and ASDAS was improved with UPA treatment. At 104 wks of therapy, clinical responses were largely similar with UPA15 and UPAP30. Generally, safety data at wk 104 (Figure 1) were consistent with that reported at wk 56. Rates of serious infection, herpes zoster, hepatic disorder, anemia, neutropenia, lymphopenia, and CPK elevation remained numerically higher with UPAP30 vs UPAP15, while rates of malignancies, MACE, and VTE were similar for both UPA groups. One death was reported with UPAP15 (unexplained due to lack of information; however, the patient had recently been diagnosed with ovarian cancer) and 2 with UPAP30 (papancytopenia and COVID-19 pneumonia).

**Conclusion:** In PsA pts with prior inadequate response or intolerance to ≥1 bDMARD, clinical responses were maintained with UPA15 and UPAP30 up to 2 years of treatment. No new safety signals were identified in this long-term extension.

**POS1045 IMPACT OF RISANKIZUMAB ON IMPROVING HEALTH-RELATED QUALITY OF LIFE, WORK PRODUCTIVITY, AND REDUCING FATIGUE AMONG PATIENTS WITH ACTIVE PSORIASIS ARTHRITIS: A POOLED ANALYSIS OF TWO PHASE 3 CLINICAL TRIALS**

L. K. Kristensen, A. M. Sollmann, K. Popp, B. Barcomb, A. Eldred, Z. Wang, D. White, F. Behrens; 1 The Parkter Institute, Copenhagen University Hospital, Copenhagen, Denmark; 2 AbbVie Inc., Immunology, North Chicago, United States of America; 3 Mayo Clinic, Rochester, Rochester, Minnesota, United States of America; 4 Global Medical Affairs, AbbVie, Inc., New York, United States of America; 5 Rizzardi Consulting, Emilia Romagna, Italy; 6 all authors: AbbVie, Inc.

**Background:** Risankizumab (RZB) has been approved in the UK and Europe for the treatment of adults with active PsA. Patient-reported outcomes (PROs) are important tools for understanding a therapy’s efficacy from the patient’s perspective.

**Objectives:** This study evaluated the impact of RZB versus placebo on health-related quality of life (HRQoL), fatigue, and work productivity in patients with psoriatic arthritis (PsA) and inadequate response to ≥ 1 or 2 biologics and/or ≥ 1 conventional synthetic DMARDs in two Phase 3 trials (KEEPASAKE & 182).

**Methods:** Eligible patients with active PsA (n=1402) were randomized (1:1) to receive risankizumab 150mg (n=706) or placebo (n=696). Patient-reported
outcomes assessed were 36-item Short-Form Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-Fatigue), EQ-5D-5L, and Work Productivity and Activity Impairment–PsA questionnaire. Least squares (LS) mean changes from baseline at Week 24 were compared between risankizumab versus placebo by mixed-effects repeated regression modeling. **Results:** At Week 24, risankizumab- versus placebo-treated patients reported greater improvements in LS mean changes with between-group differences (all nominal P<0.001) in SF-36 physical component score (mean difference=3.5, 95% confidence interval [CI] 2.7, 4.2), mental component score (mean difference=1.8, 95% CI 0.9, 2.6), FACIT-Fatigue (mean difference=2.5, 95% CI 1.5, 3.4), EQ-5D-5L index score (mean=0.07, 95% CI 0.05, 0.09), and EQ-5D-5L visual analogue scale score (mean difference=5.8, 95% CI 3.6, 8.0). In addition, risankizumab- versus placebo-treated patients reported greater reductions with in-between-group differences (all nominal P<0.001) in overall work impairment (mean difference=−8.9%, 95% CI −13.1, −4.7), activity impairment (mean difference=−7.7%, 95% CI −10.3, −5.2), and presenteeism (mean difference=−9.8%, 95% CI −13.3, −6.3). **Conclusion:** Compared to placebo, risankizumab resulted in greater improvements in HRQoL, fatigue, and work productivity among patients with PsA. **Acknowledgements:** This work/study was funded by AbbVie Inc. AbbVie participated in the study design, research, data collection, analysis and interpretation of data. No honoraria or payments were made for authorship. Medical writing services provided by Natalie Mitchell of Fishawack Facilitate Ltd, part of Fishawack Health, and funded by AbbVie. **Disclosure of Interests:** Lennart Erik Kristensen Speakers bureau: AbbVie, Amgen, BMS, Boehringer, Celgene, Chugai, Genentech, GlaxoSmithKline, Janssen, Kirin, LEO Pharma, MedImmune, Merck-Serono, Merck Sharp & Dohme, Novartis, Pfizer, Regeneron, Roche, Sanofi-Aventis, Stiefel, Sun Pharma, Takeda, UCB, and Valeant; Consultant of: AbbVie, Amgen, Astellas, Baxalta, Baxter, Boehinger Ingelheim, Bristol Myers Squibb, Celgene, Coherus, Dermira, Eli Lilly, Forward Pharma, Galderma, Genentech, GlaxoSmithKline, Janssen, Kyowa-Hakko Kirin, LEO Pharma, MedImmune, Merck-Serono, Merck Sharp & Dohme, Novartis, Pfizer, Regeneron, Roche, Sanofi-Genezyme, Stiefel, Sun Pharma, Takeda, UCB, and Valeant.; Lars Erik Kristensen Speakers bureau: AbbVie, Amgen, BMS, Boehringer, Celgene, Chugai, Dermira, Eli Lilly, Forward Pharma, Galderma, Genentech, GlaxoSmithKline, Janssen, Kyowa-Hakko Kirin, LEO Pharma, MedImmune, Merck-Serono, Merck Sharp & Dohme, Novartis, Pfizer, Regeneron, Roche, Sanofi-Genezyme, Stiefel, Sun Pharma, Takeda, UCB, and Valeant.; Grant/research support from: AbbVie, Amgen, Astellas, Baxalta, Baxter, Boehinger Ingelheim, Bristol Myers Squibb, Celgene, Coherus, Dermira, Eli Lilly, Forward Pharma, Galderma, Genentech, GlaxoSmithKline, Janssen, Kyowa-Hakko Kirin, LEO Pharma, MedImmune, Merck-Serono, Merck Sharp & Dohme, Novartis, Pfizer, Regeneron, Roche, Sanofi-Genezyme, Stiefel, Sun Pharma, Takeda, UCB, and Valeant.; Litigation: Litigation Shareholder of: AbbVie Inc., Employee of: AbbVie Inc., Ann Eldred Shareholder of: AbbVie Inc., Employee of: AbbVie Inc., Settings: AbbVie Inc., Employee of: AbbVie Inc., Abbott Laboratories, Cogenics, Inc., Genentech, Inc., Janssen Pharmaceutical Companies, Lilly, Merck & Co., Inc., Pfizer Inc., Incyte Corporation, Infinity Pharmaceuticals, Inc., Janssen Scientific Affairs, LLC, Solna, Sweden; Janssen, Biostatistics, Breda, Netherlands; Janssen, Immunology, Global Medical Affairs, Horsham, United States of America; Janssen, Scientific Affairs, LLC, Horsham, United States of America; Janssen, Scientific Affairs, LLC, Issy-les-Moulineaux, France; University of Leeds, Leeds Institute of Rheumatology and Musculoskeletal Medicine, Leeds, United Kingdom. **Background:** Accurate assessment of psoriatic arthritis (PsA) disease activity in clinical practice requires a feasible, continuous, multidimensional composite instrument to assess key domains of this heterogeneous disease. While currently available composite tools used in PsA, including the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis Composite Exercise (GRACE) and the PsA Disease Activity Score (PASDAS), are useful in clinical trials, their complexity and time required to complete limit their use in clinical practice. Abbreviated instruments, known as 3 visual analogue scale (VAS) and 4VAS, have demonstrated good performance in an observational study, but further testing was recommended. **Objectives:** Explore the correlation between 3VAS or 4VAS and GRACE, PASDAS and measures of quality of life using data from COSMOS. **Methods:** The Phase 3b COSMOS study assessed guselkumab (GUS) 100mg QW versus placebo (PBO) in tumour necrosis factor inhibitor (TNFi) inadequate response (IR, inadequate efficacy or intolerance) pts with active PsA. Pts who received PBO crossed over to GUS at either Week (W) 16 (early escape [EE], n=45/96) or W24 (planned, n=51/96). Each domain of the 3VAS (physician global, pt global, pt skin) and 4VAS (physician global, pt pain, pt joint, pt skin) was evaluated using a 0–10 VAS (higher score=more active disease), and calculated mean scores were plotted over time in a pt-continuer population (those with W0 and W48 data). Pearson correlation assessed relationships between observed values over time for 3VAS/4VAS versus GRACE, PASDAS, the Health Assessment Questionnaire-Disability Index (HAQ-DI), and the 36-item Short Form Health Survey Physical Component Summary (SF-36 PCS) score. **Results:** Data from 285 pts were examined (GUS, n=189; PBO, n=96). Substantial improvements (>45%) were seen in GRACE, PASDAS, 3VAS and 4VAs scores through W48 in GUS-treated pts (Table 1), with separation from PBO as early as W8 (Figure 1). Strong correlations between 3VAS/4VAS and GRACE (n=0.83–0.92) (PASDAS) (n=0.72–0.85) were observed in GUS-randomized pts at each visit (Table 1). 3VAS/4VAS showed moderate correlation with HAQ-DI (n=0.45–0.63) and SF-36 PCS (n=0.40 to 0.65). Consistent results were observed in PBO–GUS pts. **Table 1. Observed composite index scores and Pearson correlation coefficients by visit**

Background: The Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) has identified a need for biomarkers to predict which patients (pts) with psoriatic arthritis (PsA) are most likely to respond to a specific therapy. Failure to identify effective treatments early on results in sub-optimal PsA disease management. Tofacitinib is an oral JAK inhibitor for the treatment of PsA. The efficacy and safety of tofacitinib 5 and 10 mg twice daily (BID) in pts with PsA have been demonstrated.1,2

Objectives: To identify protein biomarker candidates, which may identify responders (R) vs non-responders (NR) to treatment of PsA, using mass spectrometry-based proteomics.

Methods: Baseline (BL) serum samples from pts with PsA receiving tofacitinib 5 or 10 mg BID, adalimumab or placebo in OPAL Broaden (NCT01877668)1 were analysed. Pts were identified as R and NR based on the Psoriatic Arthritis Disease Activity Score (PASDAS) at Month 3; pts with lowest PASDAS ≤3.2 were defined as R, those with highest PASDAS >3.2 as NR. Two proteomic strategies were employed for analysis of BL serum samples: (1) targeted mass spectrometric multiple reaction monitoring analysis of an in-house panel (PAPRICA) comprising of 206 proteins, originally developed to distinguish between different arthropathies, and (2) unbiased discovery liquid chromatography-tandem mass spectrometry (LC-MS/MS). PAPRICA data were normalised using two methods: normalisation to stable isotope labelled peptide spike-ins (SIL); corrects for fluctuations in sample injections/mass spectrometry loading amounts), and normalisation to an endogenous peptide panel representing total serum protein abundance (TSPA; corrects for different amounts of total serum protein across samples). Univariate analyses (Student's t-test) and multivariate machine learning Random Forest (RF) modelling2 were performed. Univariate analysis of the PAPRICA panel of proteins was performed on R vs NR, and within each treatment arm, with no adjustment for multiplicity.

Results: 96 pts were identified as 47 R and 49 NR based on PASDAS scores. Of pts receiving tofacitinib 5 or 10 mg BID (data pooled), adalimumab or placebo, there were 26 R vs 26 NR, 13 R vs 13 NR and 8 R vs 10 NR, respectively. Results from univariate analysis identified 110 differentially expressed PAPRICA peptides between R vs NR (p<0.05). RF multivariate analysis of all data (n=96) revealed a set of PAPRICA peptide signatures with the ability to differentiate between R and NR. Two RF models generated from the PAPRICA peptide data had training area under curves (AUCs) 0.956 [95% CI 0.93, 0.99] (TSPA) and 0.959 [95% CI 0.94, 0.98] (SIL). In total, 115 PAPRICA peptides representing 87 proteins were identified as potential biomarkers for predicting treatment response. Using unbiased discovery LC-MS/MS, univariate analysis of all data revealed one candidate peptide biomarker (ps<0.05). RF modelling revealed peptides that contributed to two prediction models with training AUCs of 0.959 [95% CI 0.94, 0.98] and 0.952 [95% CI 0.9, 0.96] in total, from unbiased discovery LC-MS/MS, 66 peptides representing 39 proteins that may act as potential peptide biomarkers were identified in univariate and multivariate analyses.

Conclusion: Using two complementary proteomic approaches and a combination of univariate and machine learning models, a total of 181 candidate biomarker peptides corresponding to 106 proteins have been identified that may act as potential biomarkers for predicting response to treatment of PsA. Further study is required to verify and evaluate these candidate biomarkers, and we will report how these proteins map to biological processes, pathways and networks.
Deucravacitinib Long-Term Efficacy and Safety in Plaque Psoriasis: 2-Year Results from Phase 3 POTEYK Programs

Background: Tyroso kinase 2 (TYK2) is an intracellular kinase that mediates signaling of key cytokines (eg, interleukin [IL]-23 and Type I interferons) involved in the pathogenesis of immune-mediated diseases including plaque psoriasis and psoriatic arthropitits (PsA). Deucravacitinib is a novel, oral, selective TYK2 inhibitor that achieves high selectivity by uniquely binding to the regulatory domain of the enzyme, rather than to the more conserved active domain. Deucravacitinib showed superior efficacy compared with placebo at 16 weeks in a Phase 2 trial in patients with PsA.1

Objectives: To assess the long-term efficacy and safety of deucravacitinib in patients with psoriasis in a Phase 3, open-label, long-term extension (LTE) trial.

Methods: The 52-week PSO-1 and PSO-2 trials randomised patients with moderate to severe plaque psoriasis 2:1 to deucravacitinib 6mg once daily, placebo, or apremilast 30mg twice daily. Patients could then enrol in the LTE trial at any time. The current analysis compares deucravacitinib with placebo in the LTE trial.

Results: 1221 patients enrolled in the LTE trial and received ≥1 dose of deucravacitinib. Demographic and baseline disease characteristics were balanced across treatment groups; mean age at disease onset was 28.6 years, mean disease duration was 18.9 years, and 18.0% of patients had PsA at baseline. Cumulative exposures in person-years from randomisation in PSO-1 or PSO-2 to the LTE trial were 2166.9 and 2482.0 for efficacy and safety analyses, respectively. At enrolment in the LTE trial, PASI 75 and sPGA 0/1 response rates were 65.1% and 50.9%, respectively, and were maintained for up to 2 years after initial randomisation (Week 48 of LTE; PASI 75: 75.7%; sPGA 0/1: 56.4% [as observed]). Exposure-adjusted incidence rates per 100 person-years for adverse events were similar in the controlled period (Weeks 0–52) of PSO-1 and PSO-2 and during the cumulative PSO-1, PSO-2, and LTE trial period (229.2 [controlled period] vs 154.4 [cumulative period]), serious adverse events (6.7 vs 6.1), discontinuations (4.4 vs 2.8), deaths (0.2 vs 0.4), herpes zoster (0.9 vs 0.7), malignancies (1.0 vs 0.9), major adverse cardiovascular events (0.3 vs 0.4), and venous thromboembolism (0.1 vs 0.1).

Conclusion: Deucravacitinib demonstrated persistent efficacy and consistent safety profiles in patients with psoriasis for up to 2 years after initial randomisation in the POETYK PSO-1, PSO-2, and LTE trials.

TRAF3IP2, HCP5 AND IL10 GENES POLYMORPHISMS INFLUENCE THE RESPONSE TO TNF-1 IN PATIENTS WITH PSORIATIC ARTHRITIS

M. S. Chiamenti1, A. Latin1, P. Conigliaro1, P. Triggianesi1, E. Greco1, G. De Benedictis2, L. Novelli3, C. Ciccacci2, A. Bergamini1, G. Novelli1, P. Borigian1,1Rheumatology and Allergology and Clinical Immunology, University of Rome Tor Vergata, Rome, Italy; 2Department of Biomedicine and Prevention, Genetics, 3University of Rome, Roma, Italy; 4Institute of and Clinical Research, University, Saint Camillus, University International of Health Sciences, Rome, Italy

Background: Psoriatic Arthritis (PsA) is a chronic inflammatory disease, characterized by both articular and periarticular manifestations, usually associated with psoriasis. The identification of the correct therapy for patients is still a critical issue, but the use of biological drugs, such as TNFi (Tumor Necrosis Factor Inhibitors), modified the outcome of PsA patients even if there is great variability in the clinical efficacy. Since the response to drugs is a complex trait, the identification of genetic factors could help to define new genomic biomarkers for more effective and personalized therapy.

Objectives: The aim of this study was to evaluate the potential role of polymorphisms in genes already known to be involved in PsA susceptibility (ERAP1, HCP5, IL10, MIR146, PSORS1C1, TNFA, TNFAP3 and TRAF3IP2) as predictors of efficacy in treatment, in a cohort of Italian PsA patients, treated with first-line TNF-1, in particular with Enalotep (ETN) and Adalimumab (ADA).

Methods: Polymorphisms were analyzed in a cohort of 163 patients with peripheral PsA in both disease activity and the Disease Activity Score (DAS) score. Genotyping was performed by allele discrimination by TaqMan assay. The possible association between the selected SNPs and mean values of DAPsA differences, at 22 (AT22) and 54 (AT54) weeks from the beginning of the TNF-1 treatment, were evaluated by T-test. A multivariate logistic regression analysis was used to evaluate the contribution of each genetic variant investigated in the TNF-1 treatment response.

Results: We have observed that TRAF3IP2 SNP was associated with TNF1 treatment in PsA patients. In particular, the TNF1 treatment response of the variant alleles seem to respond better to treatment, both at 22 (P = 0.032) and 54 weeks (P = 0.019). Moreover, the variant allele of TRAF3IP2 SNP resulted associated with a better response of joints involvement. Indeed, the number of tender and swollen joints decrease more in patients carrying variant allele (P = 0.006 and P = 0.024, respectively). We also observed that PsA patients carrying IL10 variant allele had a lower value of DAPsA only at 54 weeks of treatment (P = 0.031). Also, HCP5 polymorphism showed a difference of mean difference of DAPsA values between genotypes for both follow up, even if these difference does not reach a statistical significance (
Methods: The Phase 2 PsA trial. Assess efficacy of DEUC up to 52 wks. A comprehensive measure assessing a variety of PsA clinical domains, was used to evaluate efficacy. Patients were assessed up to 52 wks for adverse events (AEs) and exploratory safety outcomes. Results: Data as observed. Efficacy endpoints including change in PASDAS. Analyses were descriptive using intention-to-treat and 173 (96%) of these pts chose to enrol in Part B. Of 118 pts initially randomised to DEUC, 25% (29/118; 6 mg QD, 22% [13/60]; 12 mg QD, 28% [16/58]) continued to Part B. Pts were assessed up to 52 wks for adverse events (AEs) and exploratory safety outcomes. Conclusion: Our results suggest that some polymorphisms in genes associated to PsA susceptibility could also play a role in TNFi treatment response and could give a contribution in the definition of a genetic profile associated with the response to anti-TNF drugs.

Background: Deucravacitinib (DEUC) is a novel, oral, selective, allosteric inhibitor of tyrosine kinase 2 (TYK2) that acts by binding to the unique TYK2 regulatory domain, thereby suppressing signalling of key cytokines (eg, IL-23) involved in skin psoriasis and psoriatic arthritis (PsA) pathogenesis. Results from the initial 16-week (wk), placebo (PBO)-controlled period (Part A) of a 52-wk, blinded Phase 2 trial in PsA showed that DEUC was significantly more efficacious than PBO. The Psoriatic Arthritis Disease Activity Score (PASDAS), a validated comprehensive measure assessing a variety of PsA clinical domains, was used to assess efficacy of DEUC up to 52 wks.

Objectives: Evaluate the safety and efficacy of DEUC in Part B (Wks 16-52) in the Phase 2 PsA trial.

Methods: Patients (pts) with PsA were randomised 1:1:1:1 to PBO, DEUC 6 mg once daily (QD), or 12 mg QD. After Wk 16 (Part A), pts could enrol in an optional, double-blind period until Wk 52 (Part B). In Part B, pts receiving DEUC who had achieved minimal disease activity (MDA) at Wk 16 continued DEUC treatment and those who had not achieved MDA were switched to ustekinumab (UST) at the approved PsA dose. All pts treated with DEUC in Part A switched to UST in Part B. Pts were assessed up to 52 wks for adverse events (AEs) and exploratory efficacy endpoints including change in PASDAS. Analyses were descriptive using data as observed.

Results: Of 203 pts randomised in Part A, 180 (89%) completed 16 wks of treatment and 173 (86%) of these pts chose to enrol in Part B. Of 118 pts initially randomised to DEUC, 25% (29/118; 6 mg QD, 22% [22/98]; 12 mg QD, 26% [16/58]) continued to Part B. Pts who had achieved MDA at Wk 16 and continued at the same dose. All other pts switched to UST in Part B: PBO, 100% (55/55); including 5 pts who had achieved MDA at Wk 16; DEUC 6 mg QD, 78% (47/60); DEUC 12 mg QD, 72% (42/58). The safety profile of DEUC in Part B (Table 1) was consistent with that in Part A, and all AEs were mild or moderate except 2 AEs in 1 pt with severe cataract/macular fibrosis. There were no opportunistic infections, herpes zoster, malignancy, thrombotic events, or treatment-related serious AEs reported in pts who remained on DEUC. Decreases in mean PASDAS score observed at Wk 16 were maintained at Wk 52 in pts who continued on DEUC (Figure 1). Improvements in other outcomes, including ACR components, PASI, and FACIT-Fatigue, were also sustained at Wk 52 in pts who continued DEUC treatment. Pts who had not achieved MDA on DEUC at Wk 16 showed a decrease in mean PASDAS score at Wk 52 after switching to UST.

Includes all treated patients in Part B. Medical Dictionary for Regulatory Activities version 23.0 was used. aIn the number of patients who experienced an event. bOne patient had SAEs of psoriatic arthropathy in 1 joint and peripheral neuropathy. cPatient had an AE of COVID-19 infection leading to discontinuation. dDeaths in UST arms were due to car accident and sudden death in a 71-year-old patient with hypertension. ePatient had an AE of urinary tract infection leading to discontinuation. fAdverse event: DEUC; deucravacitinib; PBO; placebo; QD, once daily; SAE, serious adverse event; UST, ustekinumab.

Conclusion: In the 16- to 52-wk blinded Part B of a Phase 2 study in pts with PsA, new safety signals were observed with continuous DEUC treatment vs the earlier Part A period. Efficacy in PASDAS, as well as other key efficacy measures, was maintained with continued DEUC treatment through Wk 52.

**BACKGROUND:** Psoriatic arthritis (PsA) is a comorbidity commonly associated with psoriasis. Studies have demonstrated delays in the diagnosis and treatment of PsA among patients that disproportionately affect racial/ethnic minority patients as indicated by one study that found Black Medicaid patients with PsA to be less likely to receive disease-modifying antirheumatic drugs [DMARDs] than White Medicaid patients with PsA [2]. Yet, much remains unknown about potential racial/ethnic disparities in PsA management.

**OBJECTIVES:** The objective of our study was to evaluate treatment patterns for PsA by race/ethnicity.

**METHODS:** We performed a cross-sectional study of adult (≥18 years old) patients with PsA who had at least one outpatient visit within the University of Pennsylvania health system between 2010 and 2019. Patients with PsA were identified by the presence of at least two International Classification of Diseases (ICD)-9 or ICD-10 codes for PsA associated with two different healthcare encounters. The primary outcomes were receipt of a prescription for: (i) an oral DMARD, (ii) a biologic DMARD, and (iii) prednisone. Oral DMARDs included apremilast, methotrexate, sulfasalazine, leflunomide, azathioprine, cyclosporine, tofacitinib, hydroxychloroquine, and upadacitinib. Biologic DMARDs included abatacept, adalimumab, brodalumab, certolizumab, etanercept, goltimub, guselkumab, infliximab, ixekizumab, ustekinumab, and risankizumab. The primary independent variable was race/ethnicity categorized as White (reference), Black, Asian, Hispanic, or other race. Multivariable logistic regression was used to assess the relationship between race/ethnicity and each treatment outcome.

**RESULTS:** The study population included 1781 patients with PsA who were a mean age of 50.7 (SD 14.3), 54.6% female, and 72.5% commercially insured. The racial/ethnic distribution was 81.9% White, 5.6% Black, 4.0% Asian, 3.0% Hispanic, 2.5% other race, and 3.1% missing race/ethnicity. Of these patients, 64.3% were prescribed an oral DMARD, 55.6% were prescribed a biologic, and 44.1% were prescribed prednisone. There were no statistically significant differences across race/ethnicity for prescription of either oral or biologic DMARDs. However, prescription of prednisone did differ by race/ethnicity (p < 0.005) with Black (54.6%) and Hispanic (56.6%) patients being more likely to receive prednisone prescriptions than White (44.2%) patients. In adjusted logistic regression models controlling for sociodemographic and other factors, Hispanic patients were more likely to receive a prednisone prescription (OR 1.79, 95% CI 1.01 – 3.20, p = 0.05) while Asian (OR 0.58, 95% CI 0.34 – 0.97, p = 0.04) patients were less likely to receive a prednisone prescription compared to White patients.

**CONCLUSION:** We found Hispanic patients with PsA to be more likely to receive prednisone prescriptions than White patients with PsA but did not identify any racial/ethnic differences in prescription patterns for oral or biologic DMARDs for PsA. Greater use of prednisone among Hispanic patients may reflect different disease trajectories (e.g., more disease flares or greater disease severity) or other factors that affect prescription patterns that require further study.

Conclusion: UPA 15 mg treatment led to greater improvements over PBO in RAPID3 scores over 56 wks in patients with PsA, and greater improvements over ADA from wk 16 to 56. The majority of patients achieved MCID in RAPID3 after 12 wks of UPA or ADA, with higher proportions achieving MCID on UPA vs ADA by wk 24. RAPID3 was strongly associated with other joint-focused (DAPSA) or multiple manifestation (MDA/VLDA) composite measures, further supporting the utility of RAPID3 in assessing disease activity in PsA.

POST0151
TO WHAT EXTENT ARE BASELINE CHARACTERISTICS IN BIOLOGIC-EXPERIENCED PATIENTS WITH PSORIATIC ARTHRITIS ASSOCIATED WITH ACHIEVEMENT OF MINIMAL DISEASE ACTIVITY AT WEEK 24 OF GUSELKUMAB TREATMENT: A POST HOC ANALYSIS OF THE PHASE IIIB COSMOS CLINICAL TRIAL

1Royal National Hospital for Rheumatic Diseases, University of Bath, Bath, United Kingdom; 2Chanté – Universitätmedizin Berlin, Berlin, Germany; 3Hospital Universitari Clinic, Barcelona, Spain; 4Janssen-Cilag, Zug, Switzerland; 5Janssen-Cilag BV, Breda, Netherlands; 6Janssen-Cilag, Solna, Sweden; 7Janssen-Cilag, Issy-Ies-Moulineaux, France; 8Janssen-Cilag, Dubai, United Arab Emirates; 9Janssen Global Services, LLC, Horsham, PA, United States of America; 10Erasmus MC Universitair Medisch Centrum, Rotterdam, Netherlands

Background: Guselkumab (GUS) is a human monoclonal antibody targeting the interleukin-23p19-subunit. It has demonstrated efficacy at Week 24 in the Phase IIb COSMOS clinical trial of patients with active psoriatic arthritis (PsA) and inadequate response or intolerance to one or two tumour necrosis factor inhibitors (TNFis).

Objectives: The aim of this post hoc analysis was to identify predictors of minimal disease activity (MDA) with GUS at Week 24 in patients with active PsA and inadequate response or intolerance to one or two TNFis.

Methods: A multiple logistic regression analysis was performed to identify potential predictors of MDA with GUS at Week 24 in TNFi-refractory patients with PsA. Odds ratios, 95% confidence intervals and p-values were calculated. Baseline characteristics assessed as predictors included age, sex, body mass index (BMI), C-reactive protein (CRP), other medication use and disease duration. Clinical features included tender and swollen joint counts (TJC/SJC), symptom counts (CTJC/CTJC), affected joint location, dactylitis, enthesitis, spondylitis, Psoriasis Area and Severity Index (PASI) score and psoriasis (PsO) localisation (Figure 1). Missing data for MDA at Week 24 were imputed as non-response; missing baseline values were imputed for two patients.

Results: Odds ratios and 95% CIs for potential predictors of minimal disease activity response to guselkumab 100 mg every 8 weeks at Week 24 in patients with PsA and inadequate response or intolerance to one or two TNF inhibitors. (Figure 1).

For MDA at Week 24: Male sex (OR: 1.8, 95% CI: 1.1-3.0, p=0.02), age >65 years (OR: 1.7, 95% CI: 1.1-2.6, p=0.02), and BMI >30 kg/m² (OR: 1.9, 95% CI: 1.2-3.1, p=0.01) were associated with MDA at Week 24. The presence of spondylitis (OR: 1.8, 95% CI: 1.1-3.0, p=0.02) and PsA severity (PASI >15 OR: 1.7, 95% CI: 1.1-2.6, p=0.02) were associated with MDA at Week 24.

For PsO: The presence of dactylitis (OR: 2.1, 95% CI: 1.2-3.8, p=0.01) and PsO severity (PASI >15 OR: 1.8, 95% CI: 1.1-2.9, p=0.01) were associated with MDA at Week 24.

DOIs: 10.1136/annrheumdis-2022-eular.2533

BMI, body mass index; CI, confidence interval; CRP, C-reactive protein; csDMARD, conventional systemic disease-modifying anti-rheumatic drug; HAQ-DI, Health Assessment Questionnaire - Disability Index; MDA, minimal disease activity; PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis; PsO, psoriasis; TNF, tumour necrosis factor; N=187 for all clinical features and baseline characteristics. Negative predictors are indicated by bold text and positive predictors by italics (p<0.05). Results: Of the 187 patients in this study, 54.6% were women and the mean disease duration was 8.3 years. The patients had a mean TJC 0–66 of 21.0, a mean SJC 0–66 of 10.3, a mean PASI score of 11.6 and a mean BMI of 28.9. Furthermore, 67.9% had enthesisitis and 35.8% had dactylitis at baseline. One prior TNFi had been received by 82.8% of patients, and two received by 11.8%.
Week 24, 17.1% of patients (32/187) achieved MDA. Wrist involvement (p=0.031) and scalp PsO (p=0.049) were positive predictors of MDA. Women were significantly less likely to achieve MDA (p=0.036) than men; other negative predictors included involvement of shoulder or small joints of the hand, and hand-foot PsO (all p<0.05). Age, BMI, CRP, TJC/SJC, HAQ-DI, PASI, spondylitis, enthesitis, dactylitis, other medication use and number of prior TNFis were not predictive of MDA (Figure 1).

Conclusion: Baseline characteristics and clinical features may be positively (wrist involvement, scalp PsO) or negatively (female sex, involvement of shoulder or small joints of the hand, hand-foot PsO) associated with achieving MDA with GUS at Week 24 in a TNF-RAfficted population. Though the low patient number limits the generalisability of this analysis, assessment of Week 48 data may further elucidate potential predictors of MDA after longer-term treatment.

Disclosure of Interests: William Tillett Speakers bureau; Consultant of; Grant/ research support from: William Tillett has received research grants and consulting or speaking fees from AbbVie, Amgen, Celgene, Eli Lilly, Janssen, MSD, Novartis, Pfizer and UCB; Sarah Orhrdorff Speakers bureau: Sarah Orhrdorff has received speaker fees or travel expense reimbursements from AbbVie, BMS, Janssen, Novartis and Pfizer; Julio Ramirez Speakers bureau; Consultant of: Julio Ramirez has received consulting or speaker fees from AbbVie, Amgen, Eli Lilly, Janssen, Novartis and UCB, Marlies Neuhold Shareholder of: Johnson & Johnson, Employee of: Janssen, Robert Wapenaar Shareholder of: Johnson & Johnson, Employee of: Jansen, Elke Theander Employee of: Janssen, Christine CONTRE Shareholder of: Johnson & Johnson, Employee of: Jansen, Mohamed Sharaf Shareholder of: Johnson & Johnson, Employee of: Janssen, May Shawi Shareholder of: Johnson & Johnson, Employee of: Janssen, Marijn Vis Shareholder of: Johnson & Johnson, Employee of: AbbVie and UCB; Grant/ research support from: Marijn Vis has received research grants and consulting or speaking fees from AbbVie, Amgen, Eli Lilly, Janssen, Novartis, Pfizer, UCB and the Dutch Arthritis Foundation.

POS1052 DEVELOPING EVIDENCE-BASED PATIENT FOCUSED LEARNING MATERIALS TO SUPPORT HEALTH BEHAVIOUR CHANGE FOR PEOPLE LIVING WITH PSORIATIC ARTHRITIS

L. Hailey*, C. Bundy, L. Howells*, S. Kirtley*, S. Martin*, O. Sullivan*, I. Steinkoegel*, M. Stepney*, L. Coates†, 1University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 2Cardiff University, Behavioural Medicine/ Health Psychology School of Healthcare Sciences, Cardiff, United Kingdom; 3University of Nottingham, Centre of Evidence Based Dermatology, Nottingham, United Kingdom; 4University of Oxford, Centre for Statistics in Medicine, Oxford, United Kingdom; 5University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom; 6Patient Research Partner, Kildare, Ireland; 7Patient Research Partner, Cleveland, United States of America

Background: Psoriatic arthritis (PsA) is a complex condition that requires high levels of self-management from those living with the condition. It is associated with many comorbidities, including depression, metabolic syndrome, and increased cardiovascular disease risk and can adversely affect quality of life. There is growing evidence that people living with psoriatic arthritis (PsA) are more likely to be overweight, consume alcohol above recommended levels, smoke, be affected by poor sleep, fatigue, anxiety, and take insufficient exercise for healthy living. These modifiable health behaviours further increase the already known risk of cardiovascular morbidity and mortality. These issues are not systematically addressed in routine clinical care due to low confidence in effective delivery and time constraints.

Objectives: To co-develop evidence-based patient-focused learning materials to support healthy lifestyle changes for people living with PsA.

Methods: The development of the materials was overseen by a steering group of people living with PsA, psychologists, rheumatologists, and researchers. The COM-B model was used in the development of the materials, and they are designed around motivational interviewing principles. Firstly, a systematic literature review was performed to establish the evidence for the current burden and potential interventions aimed at these issues in PsA. These included diet, weight, alcohol, smoking, exercise, anxiety, depression, and stress. An initial focus group of people living with PsA was used to identify priority behaviours and ideas for content. The steering group developed draft materials, and we partnered with a design agency to create engaging materials. They developed a website and downloadable postcards. A second focus group of people living with PsA was held for people to give their views on the draft content for the materials and initial design ideas. A third focus group was held with people living with PsA and a fourth with clinicians to refine the design materials and ensure they were accessible, interesting, and helpful to initiate and maintain change.

A final evaluation survey was performed to review the draft website before launching the final materials. The Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) approved the final materials.

Results: Following the steering and focus groups' input, 15 candidate topics were prioritised (Table 1). A website and downloadable postcards summarising each of the topics were developed by the design team and refined following feedback from the patient focus groups. An example of the postcard for ‘keeping active’ can be found in Figure 1.

The resources are free to use and can be accessed at https://www.informatree.org.

Figure 1. During the development of the website and downloadable postcards, particular attention was paid to making the material as accessible and as friendly as possible for patients.

Conclusion: This project created patient-focused information to support behaviour change in clinical practice. It addresses common concerns of people living with PsA about how they may optimise their health by providing practical and...
brief interventions to challenge and support them to make personal changes. Future research is needed to test the impact of the resource.

Table 1. Overall safety profile within the study period (Safety set)

References:

Figure 1. Time to treatment discontinuation of SEC in pts with PsA and AS

AS, ankylosing spondylitis; PsA, psoriatic arthritis; pts, patients; SEC, secukinumab

Objectives: We report long-term results (at least 3 years follow up) on secukinumab (SEC) retention, effectiveness and safety in pts with active PsA or AS from the SERENA study.

Methods: This analysis includes data of 524 PsA and 473 AS pts enrolled in the study and followed up for at least 3 years. Pts (aged ≥18 years) with active PsA or AS were required to have received at least 16 weeks of SEC treatment before enrolment in the study. Retention rate was defined as the percentage of pts who have not discontinued SEC treatment. Effectiveness assessments included swollen and tender joint counts (SJC and TJC) in pts with PsA, and BASDAI score in pts with AS. Safety assessments included the number of pts with any adverse events (AEs) and serious AEs, treatment-emergent AEs, AEs of special interest and their incidence rates.

Results: The mean (SD) treatment duration prior to enrolment in the study for PsA and AS pts was 1.0 (0.5) years and 0.9 (0.5) years, while time since diagnosis was 8.7 (7.4) and 9.8 (9.5) years, respectively. Prior to SEC initiation, 67.4% of pts with PsA and 63.0% of pts with AS received a biologic therapy, with lack of efficacy reported as major reason for discontinuation (PsA: 89.5%; AS: 87.6%). SEC retention rates after at least 3 years since enrolment in the study were 67.3% for pts with PsA and 72.1% for pts with AS. Survival probabilities for individual indications are presented in Figure 1. Over 3 years of observation, SEC showed sustained effectiveness in pts with PsA [SJC, mean (SD): baseline, 3.2 (5.6); Year 3, 1.7 (2.7) and TJC; baseline, 6.4 (9.4); Year 3, 4.9 (6.4) and AS [BASDAI, mean (SD): baseline, 3.2 (2.3); Year 3, 2.7 (2.2)]. No new or unexpected safety signals were reported; 11.0% of pts with PsA (N=574) and 12.9% of pts with AS (N=505) reported serious AEs (Table 1).

Conclusion: After more than 3 years of observation in the SERENA study, SEC showed sustained retention rates, indicating high persistence in a real-world setting. Responses across effectiveness assessments in both PsA and AS cohorts were maintained or improved during the 3 years of follow up in the study. SEC showed a favourable safety profile, consistent with previous reports.

</table>

Footnotes:Significant values in bold face 1 Root transformed

Conclusion: Our results indicate that enthesitis, depression and the combina- tion of a higher BMI with a tender joint count are all associated with MTX non-re- sponse 3 months after MTX initiation. Pain may be the common denominator preventing patients from achieving MDA.

Background: Psoriatic arthritis (PsA) is typically described by its individual domains or biomarkers.

Objectives: This post hoc analysis aimed to identify hypothesis-free phenotype clusters according to patients' clinical features and baseline (BL) characteristics with data from the Phase 3 DISCOVER-1 and -2 guselkumab (GUS) clinical trials.

Methods: Data from bio-naive patients with PsA treated with GUS 100 mg every 4 or 6 weeks in DISCOVER-1 and -2 were retrospectively analysed. Non-nega- tive matrix factorisation was used as an unsupervised machine learning tech- nique to identify clusters of PsA phenotypes, with BL characteristics and clinical observations as input features, according to which clusters were described.

Results: Data from 661 patients were pooled and 8 distinct clusters of PsA phenotypes identified (Table 1). Cluster 1 was characterised by lower limb involvement and the lowest rates of severe skin involvement (Figure 1); Clus- ter 2 by high skin involvement, the lowest proportion of women and highest proportion of overweight patients (body mass index [BMI] 25–30, 70%); and Cluster 3 by high burden of disease in the hand/wrist. In Cluster 4 all patients had dactylitis and ≥3% body surface area (BSA) psoriasis involvement and the second highest proportion of men. Cluster 5 had the highest BL enthesitis rate; large joint involvement was also common. Cluster 6 had a high level of small joint involvement in the hands/feet, but low mean dactylitis score; nail involvement and BL entheses were also common. In Cluster 7, all patients had axial involvement at BL, 49.4% had dactylitis, 69.9% had entheses and most had BSA ≥3% (Figure 1). Cluster 8 had limited joint involvement, extensive skin involvement and the highest proportion of obese patients (BMI >30, 67%).

Minimal disease activity (MDA) response rates at Week (W)24 and W52 were

Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; 5Russian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation; 6Pirogov Russian National Research Medical University, Rheumatology, Moscow, Russian Federation; 7CJSC «European Medical Center», Rheumatology, Moscow, Russian Federation

Background: Retention on therapy is the most important integrative indicator of the success of the drug, reflecting both the effectiveness and tolerability and general acceptability of treatment. This indicator can be evaluated with high accuracy in observational trials.

Objectives: to identify predictors of TNF inhibitors withdrawal risk in patients with PSA.

Methods: Patients with (PSA) from Moscow Unified Arthritis Registry (MUAR) treated with TNF inhibitors were analyzed. All treatment episodes interrupted due to non-medical reasons were excluded from the study. Breaks in biologic therapy up to 4 months (allowed for infliximab a break in therapy up to 6 month was considered possible) The search for predictors of treatment withdrawal risk was carried out in two steps. At the first step possible predictors of the risk of TNF inhibitors therapy discontinuation were selected in univariate correlations. At the second step significant predictors of retention on TNF inhibitors therapy were selected by forward stepwise variable selection within multivariate Cox regression. The relationship between the line of anti-TNF treatment and the risk of therapy discontinuation was analyzed separately.

Results: We analyzed 371 treatment episodes in 239 patients with PSA enrolled in MUAR, 97 male (40.6%), 50.2±12.1 years old. The age of disease onset was 36.8±12.7 years. The patients received adalimumab (ADA) (101 treatment episodes), golimumab (GOL) (n=32), infliximab (INF) (n=55), certolizumab pegol (CER) (n=31), etanercept (ETA) (n=122). There were 187 (50.4%) completed treatment episodes. The relationship between risk of TNF inhibitors discontinuation and the drug line was analyzed. We found that the withdrawal risk on the second TNF inhibitor didn't significantly differ from the withdrawal risk on the first line anti-TNF drug (p=0.201). The third and subsequent lines of TNF inhibitors where associated with the significantly higher risk of withdrawal. Direct step-by-step selection of variables made possible to identify the following significant predictors of retention on therapy – social status, the presence of endometritis, psoriasis burden, coccidinia during the disease, patient reports on the association of HLA B-27, fever during the disease, pain in sacral zone at the onset of the disease, retinopathy, cataract during the disease. The risk of TNF inhibitors discontinuation was analyzed separately.

Methods: All treatment episodes interrupted due to non-medical reasons were excluded from the study. Breaks in biologic therapy up to 4 months (allowed for infliximab a break in therapy up to 6 month was considered possible) The search for predictors of treatment withdrawal risk was carried out in two steps. At the first step possible predictors of the risk of TNF inhibitors therapy discontinuation were selected in univariate correlations. At the second step significant predictors of retention on TNF inhibitors therapy were selected by forward stepwise variable selection within multivariate Cox regression. The relationship between the line of anti-TNF treatment and the risk of therapy discontinuation was analyzed separately.

After adjusting for the line of therapy and the identified predictors of the risk of drug withdrawal it was found that retention on all analyzed TNF inhibitors in patients with PSA didn’t differ significantly (Figure 1). The presence of HLA-B27, higher body temperature during the disease, and sacral pain at the onset of the disease had a higher risk of discontinuation therapy risk of various TNF inhibitors. The risk of withdrawal therapy with the second TNF inhibitor is not significantly different between the RZB 150 mg and PBO subcutaneously at weeks 0, 4, and 16 during a 24-week, double-blind treatment period; at W28 all patients received open label RZB 150 mg. For this post hoc analysis, the RZB 150 mg and PBO groups were pooled across the 2 studies. Pain reductions (as measured by change from BL in visual analogue scale [VAS] scores) were assessed at each time point through W24 among patients with enthesitis at BL (LEI > 0 at BL) using mixed-effect model repeated measurement analysis. Additional enthesitis analyses were calculated on the data as observed.

Results: Across the pooled population, over 60% of patients in each treatment group had enthesitis at BL (RZB=444/707 [63%]; PBO=448/700 [64%]). Conversely, 37% (263/707) and 36% (252/700) had no enthesitis (LEI=0) at BL among those randomized to RZB and PBO, respectively. Among enthesitis-free patients at BL (LEI=0 at BL), 84.7% on PBO and 90% on RZB remained free of enthesitis through W24; by W52, approximately 93% of patients in both groups (RZB and PBO to RZB) remained enthesitis free. A numerically higher proportion of patients with enthesitis at BL (LEI > 0 at BL) treated with RZB (52.1%) achieved an enthesitis-free state at W24 vs PBO (41.8%); similar proportions achieved an enthesitis-free state at W36 and W52 during open label treatment (Figure 1). Among patients with enthesitis at BL, a significantly greater improvement in VAS pain scores was observed in patients treated with RZB 150 mg vs PBO, as early as W4 (P < .01) and increased through W24 (Figure 1; P < .001).

POS1057 IMPACT OF RISANKIZUMAB ON ENTHESIS AND ASSOCIATED PAIN: POOLED RESULTS FROM THE PHASE 3, RANDOMIZED, DOUBLE-BLIND KEEPSAKE 1 AND 2 TRIALS

M. Magrey1, M. Jain2, R. Ranza3, J. Stigler4, E. Modearmon-Blondell5, C. Yue6, B. Padilla6, C. Kaufmann6, D. McGonagle5,6, University Hospitals, Rheumatology Division, Cleveland, United States of America; 4Great Lakes Clinical Trials, Rheumatology, Chicago, United States of America; 5Federal University of Uberlândia, Rheumatology Unit, Hospital das Clínicas, Uberlândia, Brazil; 6AbbVie Inc., Immunology, North Chicago, United States of America; 3University of Washington, Division of Rheumatology, Seattle, United States of America; 6University of Leeds, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Controlling or improving musculoskeletal disease activity of psoriatic arthritis (PsA) (e.g., enthesitis and associated pain) is a treatment priority for patients, rheumatologists, and dermatologists. Enthesitis is the cardinal lesion in PsA and is immunogenetically and experimentally linked to the interleukin-23 (IL-23) pathway. Risankizumab (RZB), a humanized immunoglobulin G1 monomeric antibody that specifically inhibits IL-23 by binding to its p19 subunit, was studied in a phase 3 adult PsA program (KEEPSAKE clinical trials). Pooled analyses from the program demonstrated the efficacy of RZB to treat enthesitis and pain associated with PsA, and increase the proportion of patients whose enthesitis resolved compared with placebo (PBO) in those patients who had an inadequate response or intolerance to ≥1 conventional synthetic disease-modifying antirheumatic drugs (KEEPSAKE 1 and 2) and/or ≤2 biological therapies (KEEPSAKE 2).

Objectives: To investigate whether patients without enthesitis at baseline (BL) (Leeds Enthesitis Index [LEI] = 0 at BL) remained enthesitis-free through week (W) 52, patients with enthesitis at BL (LEI > 0 at BL) had resolution of enthesitis through W52, and if greater pain relief was achieved with RZB 150 mg in patients with enthesitis at BL vs PBO up to W24.

Methods: The study design and primary results of KEEPSAKE 1 (NCT03675308) and KEEPSAKE 2 (NCT03671148) have been previously reported. Briefly, patients were randomized to receive RZB 150 mg or PBO subcutaneously at weeks 0, 4, and 16 during a 24-week, double-blind treatment period; at W28 all patients received open label RZB 150 mg. For this post hoc analysis, the RZB 150 mg and PBO groups were pooled across the 2 studies. Pain reductions (as measured by change from BL in visual analogue scale [VAS] scores) were assessed at each time point through W24 among patients with enthesitis at BL (LEI = 0 at BL) using mixed-effect model repeated measurement analysis. Additional enthesitis analyses were calculated on the data as observed.

Results: Across the pooled population, over 60% of patients in each treatment group had enthesitis at BL (RZB=444/707 [63%]; PBO=448/700 [64%]). Conversely, 37% (263/707) and 36% (252/700) had no enthesitis (LEI=0) at BL among those randomized to RZB and PBO, respectively. Among enthesitis-free patients at BL (LEI=0 at BL), 84.7% on PBO and 90% on RZB remained free of enthesitis through W24; by W52, approximately 93% of patients in both groups (RZB and PBO to RZB) remained enthesitis free. A numerically higher proportion of patients with enthesitis at BL (LEI > 0 at BL) treated with RZB (52.1%) achieved an enthesitis-free state at W24 vs PBO (41.8%); similar proportions achieved an enthesitis-free state at W36 and W52 during open label treatment (Figure 1). Among patients with enthesitis at BL, a significantly greater improvement in VAS pain scores was observed in patients treated with RZB 150 mg vs PBO, as early as W4 (P < .01) and increased through W24 (Figure 1; P < .001).

Figure 1. Enthesitis Resolution and Change in Pain From BL Among Patients With Enthesitis at Baseline (LEI > 0 at BL)

Conclusion: Long-term maintenance of an enthesitis-free state (LEI = 0) was similar between the RZB 150 mg and PBO groups, with approximately 93% of patients remaining free of enthesitis at W52. For LEI > 0 patients, the RZB 150-mg group had numerically more patients whose enthesis resolved at W24, and similar proportions were observed at W52 after the open label switch. Patients with enthesitis at BL treated with RZB 150 mg had statistically greater improvements in pain compared with patients taking PBO starting at W4 through to W24.

Background: Psoriatic arthritis (PsA) is a chronic, immune-mediated, inflammatory arthropathy, distinctively involving joints and enthesis. The improved understanding of PsA pathogenesis has enabled the development of biological disease-modifying anti-rheumatic drugs (bDMARDs) targeting specific cytokines and signalling pathways. The availability of these drugs deeply modified PsA history, by preventing disease progression and by improving quality of life. Nevertheless, bDMARDs are not effective in all the patients who may experience primary or secondary inefficacy or adverse events development.

Objectives: In a real-life scenario, we evaluated the bDMARDs retention rate in a large PsA cohort. In detail, we compared drug survival of the first and second biological drug and we investigated the presence of factors associated with the bDMARDs treatment withdrawal.

Methods: We longitudinally evaluated adult PsA patients (2016 CASPAR criteria) treated with at least one bDMARD during disease history. For each PsA patient, the clinical and laboratory data, including demographics, past medical history with the date of diagnosis and treatments, clinical disease phenotypes, were collected in a standardized, computerized and electronically filled form. The retention rate was estimated by using the Kaplan-Meier method. Predictors for bDMARDs withdrawal were investigated in univariate and multivariate Cox proportional hazards analysis, adjusted for relevant variables.

Results: The present analysis included 223 PsA patients [M/F 91/132; median age 57 years (IQR 17); median disease duration 120 months (IQR 132)]. Adalimumab and Etanercept were the most frequently prescribed bDMARDs (41.5% and 41.0%, respectively). The retention rate of the first prescribed bDMARD as reported in Figure 1A: in detail, we found a 12-months retention rate of 79.8%. The comparison between etanercept and adalimumab showed a similar 12-months retention rate, but significantly higher for etanercept at 24 months (82.4% versus 69.5%, p=0.0034, Figure 1B). Out of 223 enrolled PsA patients, 109 (48.9%) received only one bDMARDs, while the remaining 114 (51.1%) received at least 2 drugs. When comparing these two groups of patients, drug survival at 24 months was significantly higher in patients treated with one bDMARD in comparison with those treated with at least two drugs (67.7% versus 52.2%, p=0.03, Figure 1C). Finally, female sex and anxiety-depressive disorders were significantly associated with the treatment with at least two dDMARDs (p=0.005 and p=0.01, respectively).

Conclusion: The results of the present study demonstrated a higher retention rate in the first-line bDMARDs treatment in comparison with second-line. Female sex and anxiety-depressive disorders may negatively affect drug retention rate.
Results: BL data were well-balanced between main treatment groups (UST+MTX, n=86; UST+PBO, n=74) including gender (42.5% vs 40.5% female) and mean values for age (49.2 vs 47.2 years), BMI (29.4 vs 28.9 kg/m²), SJC (8 vs 8), TJC (12 vs 12), DAS28-CRP (4.6 vs 4.4), DAPSA (36.7 vs 34.9) and PASI (2.8 vs 2.4). Disease activity remained well-balanced even after dividing groups according to skin involvement (a) BSA ≤3% and (b) BSA >3% with a trend of more severe joint involvement (SJC, TJC) in BSA >3% for UST+MTX compared to UST+PBO. At week 24, relative changes in TJC (>62% vs -62%), change in DAS28 and DAPSA were equal in all treatment groups independent from skin involvement (Table 1). Differences between the groups according to skin involvement were seen for relative changes in SJC (BSA >3%: -74.8% UST+MTX vs -84.3% UST+PBO), subject global assessment (SGA), physician global assessment (PGA), DLQI and EQ5D. Highest levels for changes were detected in the UST+PBO group with high skin involvement (BSA >3%).

Conclusion: IL12/23 inhibition with UST is an effective treatment for active PsA independent of MTX use. Data from this IIT indicate that additional MTX has no positive impact on UST efficacy for arthritis, skin, HR-QoL and physical function. This independency of UST effect from MTX can also be demonstrated in patients with active skin involvement despite known efficacy of MTX for skin psoriasis.

</table>
baseline to 6 and 12 months was assessed using mixed effects linear models adjusted for age, sex, and baseline CDAI score.

**Results:** The study population included 1,812 patients with a mean age of 53.7 years (Table 1). Psoriasis was present in 82% and enthesitis in 28%. Over 60% of patients were obese, and the mean Charlson Comorbidity Index was 1.3. Most patients (84%) had prior treatment with a biologic disease-modifying antirheumatic drug (bDMARD) and 40% with a targeted synthetic DMARD (tsDMARD). The mean number of bDMARDs and tsDMARDs used during all available prior history was 2.3 and 1.1, respectively. The most common prior bDMARDs were secukinumab (n=428, 24%) and adalimumab (n=245, 14%). Of patients with a baseline CDAI score, 61% had moderate or severe disease activity. For all patients, CDAI scores improved (decreased) by an average of 3.4 and 3.7 points at 6 and 12 months, respectively, from a baseline mean of 15.4. All disease activity measures and PROs improved from baseline to 6 and 12 months (Figure 1). In patients persistent with IXE, 35.3% and 33.7% were in CDAI remission or low disease activity at 6 and 12 months after initiation, respectively. For IXE monotherapy users (82% of patients), at baseline, patients had a mean CDAI of 14.3 (n=131) and 15.1 (n=105) for the 6 and 12 month analyses, respectively. Adjusted mean changes in CDAI from baseline to 6 months (-3.6 points, p < 0.0001) and 12 months (-4.9 points, p < 0.0001) were statistically significant.

**Conclusion:** In this cohort of PsA patients with multiple prior b/tsDMARD failures, improvements in disease activity and PROs were observed at 6 and 12 months after initiating treatment with IXE. Improvements were observed in patients overall and in the monotherapy subgroup. More real-world research on IXE and other bDMARDs are important to understand the effect of treatment choices on clinical and PROs in both bDMARD-naive and experienced PsA patients.

**POS1061 HYPOVITAMINOSIS D IN PSORIATIC ARTHRITIS PATIENTS: PREDICTIVE ROLE ON DRUG SURVIVAL OF METHOTREXATE MONOTHERAPY AND FIRST LINE OF B-DMARDS.**

C. Rotondo1, D. Cioci1, S. Stefania1, A. Altomare1, F. P. Cantatore1, A. Corrado1.

1University of Foggia, Department of Medical and Surgical Sciences – Rheumatology Unit, Foggia, Italy

**Background:** The immunomodulatory role of vitamin D is extensively studied enough to hypothesize a pathogenetic role in chronic arthritis and psoriasis. Few data has been published on possible interference of hypovitaminosis D on drug response in rheumatoid arthritis patients, but data in psoriatic arthritis (PsA) patients is completely lacking.
Objective: To compare drug survival and retention rate of methotrexate (MTX) and the first line of biotechnological drugs (b-DMARDs) in PsA patients with hypovitaminosis D and those with normal level of vitamin D.

Methods: We conducted a retrospective study on 250 PsA patients (age 57.3 years ± 13.2). All patients were required to fulfill the CASPAR criteria for PsA and were tested for vitamin D levels at baseline visit. Clinical characteristics, MTX and first line of b-DMARDs treatment duration and comorbidities information were recorded for each patient. The evaluations of drug survivals were realized by Kaplan-Meier estimate, followed by log-rank (Mentel-Cox) test for the comparison between the groups of patients in study. Statistical significance was set at p < 0.05.

Results: Sixty-four percent of PsA patients presented hypovitaminosis D (22.2ng/ml ± 8.8). PsA patients with hypovitaminosis D and those with normal levels were comparable for age (56.8 years ± 13 vs 58.5 years ± 12), and disease activity at baseline visit (DAS 28 VES: 4 ± 0.8 vs 3.8 ± 0.8). MTX monotherapy survival was shorter in hypovitaminosis D group (90 ± 19 weeks vs 166.8 ± 28 weeks; p=0.041), with discontinuation risk hazard ratio = 1.4 (95% CI: 1.005 – 2.014; p=0.046). The drug survival of first line of b-DMARDs was significantly shorter in patients with hypovitaminosis D (246.1 ± 40 weeks vs 302.1 ± 35 weeks; p=0.048), with discontinuation risk hazard ratio = 1.5 (95% CI: 1.1-2.4; p=0.05).

Conclusion: Vitamin D seems play an important role not only in the regulation of immune system but also in the modulation on immune response induced by drugs, as MTX or b-DMARDs. The evaluation of sera levels of vitamin D at the begging of immunomodulatory therapy could have a predictive role on treatment management in PsA patients. Further studies should be useful to detect if supplementation of vitamin D could improve the performance of immunomodulatory drugs.

POS1062
HARNESSING THE POWER OF MACHINE LEARNING TO PREDICT REMISSION IN PATIENTS WITH PSORIATIC ARTHRITIS ON SECUKINUMAB: IMPLEMENTATION AND VALIDATION OF A CANDIDATE ALGORITHM ON 121 PATIENTS

V. Venerito1, M. Fornaro1, F. Cacciapaglia1, S. Tangaro2, G. Lopalco1, F. Iannone1, 1University of Bari “Aldo Moro”, Rheumatology Unit-Department of Emergency and Organ Transplantations, Bari, Italy; 2National Institute of Nuclear Physics, Rheumatology Unit-Department of Emergen, Bari, Italy

Background: Although novel therapies with biotechnological agents and small molecules may lead to the complete clearing of psoriasis in the vast majority of patients, the latter drugs only allow Psoriatic Arthritis (PsA) disease control in up to 50% of patients (1). In an increasing number of clinical scenarios, learning (ML) is emerging as a tool for the implementation of multi-parametric decision algorithms. ML allows to handle complex non-linear relationships between patient attributes that are hard to model with traditional statistical methods, merging them to output a forecast or a probability for a given outcome, enabling personalized medicine (2).

Objectives: We aimed to develop a ML algorithm capable of predicting the probability of remission in PsA patients on Secukinumab to support clinicians in choosing the optimal treatment strategy.

Methods: Patients with classified PsA according to CASPAR criteria undergoing Secukinumab treatment between September 2017 and September 2020 at our tertiary Centre were retrospectively observed. Either at treatment baseline and at 12-month follow up, we retrieved demographic and clinical characteristics, including Body Mass Index (BMI), disease phenotypes, Disease Activity in PsA (DAPSA), Leeds Enthesitis Index (LEI) and Ankylosing Spondylitis Disease Activity Score (ASDAS, on C-Reactive Protein). After a ML variable selection method, based on an eXtreme Gradient Boosting (XGBoost) wrapper, an attribute core set with the least number of predictors was used for implementing n.3 ML algorithms, namely Logistic Regression (LR), Decision Trees (DT) and XGBoost. Each algorithm was trained and validated with 10-fold cross-validation. The performance of each algorithm in both phases was assessed in terms of accuracy and area under receiver operating characteristic curve (AUROC).

Results: The dataset consisted of n.121 PsA patients (62/121 female, 51.2%), with mean age (±SD) 52.9±10.1 years and mean disease duration of 5.9 ±10.4 years. Twenty-five of them (20.7%) had axial involvement whereas 88/121 (72.7%) had polyarticular involvement. Psoriasis was present in 84/121 patients (69.4%). At baseline, mean DAPSA was 14.9 ± 9.2, mean HAQ-DI 1 ± 0.7, mean LEI 0.6 ± 1, mean ASDAS 2.5 ± 0.8, mean PASI 2 ± 2.9, mean BMI 28.4 ± 4.9. Secukinumab at 300mg dose was administered to 79/121 patients (65.3%). At 12 months DAPSA remission was achieved by 24/121 patients (19.8%). Accuracy of LR, DT and XGBoost was 0.70 ± 0.11, 0.81 ± 0.07 and 0.89 ± 0.05, respectively. Consistently AUROC (Figure 1 Panels ABC) were 0.63 ± 0.2, 0.79 ± 0.2 and 0.93 ± 0.1, respectively. A sample decision tree explaining XGBoost algorithm function has been provided (Figure 1 Panel D). LEI and DAPSA at baseline were shown as the most important attributes for such algorithm (Figure 1 Panel E).

Figure 1.

Conclusion: ML can support Rheumatologists in profiling those patients more likely to respond to Secukinumab.

Psoriatic arthritis - clinical aspects (other than treatment)

**Clarifying the geometric mean fluorescence intensities (gMFI) of pSTATs in granulocytes of PsA patients may indicate active disease and could potentially guide treatment with JAK inhibitors.**

**Objectives:** To examine the clinical and economic burden of pts with PsA with and without axial involvement and assess the relationship between pain and frequency/costs of healthcare resource utilization (HCRU).

**Methods:** This cross-sectional study was conducted using de-identified linked electronic medical record and administrative claims data from the OM1 PsA Registry, a subset of the OM1 Real-World Data Cloud (OM1, Inc, Boston, MA, US). Adults aged ≥18 years with PsA (ICD-10 codes: L40.5.x except for L40.53) were divided into two cohorts based on the presence or absence of the diagnosis code for axial involvement (ICD-10: L40.53) during 2019. Demographic and clinical characteristics between pts with and without axial involvement were compared with t-tests or Chi-square tests. Poisson regression models were used to assess the association of pain with HCRU. Mean costs per HCRU encounter (inpatient and emergency department [ED] visits) in 2019 were obtained from Optum’s de-identified Clinformatics Data Mart Database (2007-2019) and multiplied by the mean annual rate of HCRU encounters to generate per patient per year (PPP) costs.

**Results:** Of 11,531 pts with PsA, 1,116 (10%) were diagnosed as having axial involvement. The two cohorts were similar in age, Charlson comorbidity score, and biologic disease-modifying antirheumatic drug (bDMARD) use (Table 1). More pts with vs without axial involvement were commercially insured, had higher pain, and used opioids. Higher mean annual rates of inpatient (9 vs 5 per 100 pts) and ED (19 vs 14 per 100 pts) visits were seen in pts with vs without axial involvement, respectively, which translated to higher mean annual inpatient ($1,899 vs $987) and ED ($222 vs $164) visit costs PPPY (Figure 1). A 1-point higher pain score was associated with a higher likelihood of inpatient (52% vs 11%) and ED (20% vs 10%) visits (Table 1) and additional mean annual inpatient ($397 vs $116) and ED ($44 vs $16) visit costs PPPY (Figure 1) in pts with and without axial involvement, respectively.

tion, severity, comorbidities, and response to secukinumab (SEC) over 1-year.

Conclusion: In this pooled analysis of SEC PsA studies, pts with HU reported a higher prevalence of hypertension, with more clinical dactylitis, and more PsO, with higher PASI score compared to pts without HU. Efficacy across all musculoskeletal manifestations was similar with SEC 150 and 300 mg; while PASI90 response rate was slightly better in patients without HU with SEC 150 mg, and similar with SEC 300 mg irrespective of HU status, at 1-year.

REFERENCES:

Results: Overall, 2504 PsA pts were included in the analysis, of which 822 (32.8%) had HU (62 (2.5%) with gout; 49 (2.0%) treated with ULT). At BL, pts with HU were mostly male (76.0% vs 34.2%)and had a higher body mass index (30.9 vs 28.3 kg/m²) with more comorbidities, such as hypertension (43.8% vs 31.3%), compared to pts without HU. A higher proportion of pts with HU had dactylitis (34.5% vs 25.9%), and PsO (48.3% vs 36.3%) with a greater mean PASI score (13.6 vs 10.2), compared to pts without HU (Table 1). The proportion of pts achieving ACR80, resolution of enthesitis/dactylitis, and mean change in HAQ-DI score were comparable up to Week 52 irrespective of BL HU status. The PASI90 response rate was higher in pts without HU with SEC 150 mg (with and without load) and similar in SEC 300 mg group irrespective of BL HU status (Figure 1).

Figure: Efficacy endpoints at Week 52

Background: Patients (pts) with psoriatic arthritis (PsA) experience pain, fatigue, anxiety, depression, sleep disturbance, and impaired physical function that can negatively affect health-related quality of life (HRQoL). As the Patient-Re

Disclosure of Interests: Laura Coates Speakers bureau: AbbVie, Amgen, Biogen, Celgene, Eli Lilly, Galapagos, Gilead, Janssen, Medac, Novartis, Pfizer and UCB, Consultant: of AbbVie, Amgen, Boehringer Ingelheim, Bristol Myers Squibb, Celgene, Eli Lilly, Gilead, Galapagos, Janssen, Novartis, Pfizer, and UCB, Grant/research support from: AbbVie, Amgen, Celgene, Eli Lilly, Janssen, Novartis, Pfizer, and UCB, Ana-Maria Orban Consultant of: Bristol Myers Squibb, Eli Lilly, Janssen, Novartis, Pfizer, and UCB, Grant/research support from: AbbVie, Amgen, Eli Lilly and Company, Celgene, Novartis, Janssen, and Horizon.

Methods: The DISCOVER-1 study evaluated 381 pts with active PsA (≥3 swollen joints and ≥3 tender joints; C-reactive protein ≥0.3 mg/dL; 31% with prior tumor necrosis factor inhibitor exposure) and inadequate response to standard therapies. The PROMIS-29 Profile contains 4 items for each of the 7 domains (physical function, role limitations - physical/role limitations - emotional, pain, fatigue, depression, anxiety, sleep disturbance, social participation, and pain interference; 28 items scored on 5-point Likert scale) and 1 pain intensity item. Using standardized scoring coefficients, PROMIS-29 PCS/MCS scores at baseline and Week 24 were calculated based on the 7 domains and pain intensity item. The validity of scores was assessed by Spearman correlation between PROMIS-29 PCS/MCS and 36-item Short-Form (SF-36) PCS/MCS, Health Assessment Questionnaire-Disability Index (HAQ-DI), and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scores. To evaluate the ability of the derived PROMIS-29 PCS/MCS scores to distinguish between treatments, responder analyses (employing an improvement of ≥1/2 standard deviation (SD) of baseline score) were performed between GUS and PBO at W0, W4, then every 8 weeks (Q8W) or placebo (PBO) at W24. The validity of each GUS group vs PBO was assessed at W24, which was the endpoint of the 12-week Phase 3 DISCOVER-2 trial.

Results: The DISCOVER-1 study evaluated 381 pts with active PsA (≥3 swollen joints and ≥3 tender joints; C-reactive protein ≥0.3 mg/dL; 31% with prior tumor necrosis factor inhibitor exposure) and inadequate response to standard therapies. Conclusion: GUS provided continuous improvement in each MDA domain through W100. BL domain score, as well as age, fatigue, and BMI, were significant determinants of MDA achievement in recalcitrant pt-driven domains (Pt Pain, PtGA, HAQ-DI). The impact of FM and mental health status merits further evaluation.

POS1069 COVERAGE OF THE SWEDISH RHEUMATOLOGY QUALITY REGISTER: TO WHAT DEGREE ARE B/TSDMARD TREATMENTS FOR PSORIATIC ARTHRITIS RECORDED?

1Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; 2Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden; 3Lund University, Skåne University Hospital, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden; 4Umeå University, Department of Public Health and Clinical Medicine, Rheumatology, Umeå, Sweden

Background: In a national context, the Swedish Rheumatology Quality register (SRQ) is a major source of information on clinical data for patients treated with biological and targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD) for rheumatic diseases. Data from SRQ are fundamental for research on drug effectiveness and safety.

Objectives: To understand to what degree patients with psoriatic arthritis (PsA) and their dispensed b/tsDMARD treatments are recorded in the SRQ.

Methods: We identified all dispensed oral or subcutaneously administered b/tsDMARDs approved for use in PsA, from the Swedish Prescribed Drug register (PDR, with 100% coverage) in 2018-2019. We required the patients who received the dispensation to have at least one ICD code for PsA (L405, M070, M071, M072, M073) as main diagnosis from a visit to a rheumatology or internal medicine (IM) unit in the National Patient Register (NPR) before dispensation, but no main diagnosis of rheumatoid arthritis (ICD code: M06, M06) (excluding M06.1 and M06.4), M12.3). Furthermore, to limit the assessment to patients with contemporary contact with the specialized rheumatology care, we also required at least one visit with a PsA main diagnosis from rheumatology/IM during 2017-2019. We then checked if the patients and their treatments were registered in SRQ. In a sensitivity analysis, we excluded patients with a visit in dermatology within 6 weeks prior to the first prescription of each b/tsDMARD, in order to exclude patients being prescribed the drug for cutaneous psoriasis.

Results: In 2018-2019, a total of 7922 unique b/tsDMARD prescriptions had been dispensed to 6311 patients with PsA, having contemporary contact with the specialized rheumatology care. Of them, 5687 patients were registered in SRQ (90.1%), of which 94.4% with a PsA diagnosis and 95.5% with at least one registration of a b/tsDMARD. The coverage of the single drugs in SRQ was between 53.5% to 93.3% of the included patients (79.4-93.3%) (Table 1). In a sensitivity analysis, among the 5290 patients without a main diagnosis of psoriasis before start of treatment, 4919 (93%) were registered in SRQ, of which 94% with a PsA diagnosis and 96% with at least one registration of a b/tsDMARD.

</table>

Conclusion: The coverage of b/tsDMARD-treated PsA patients in SRQ as compared to the PDR in Sweden is ranging between 90 and 93%, and SRQ is performing well in the registration of the single drugs, especially for TNFi. These results suggest that research studies based on data from the SRQ are representative of the Swedish b/tsDMARD-treated PsA population.

POS1070 BASELINE DETERMINANTS OF PAIN RESPONSE IN PATIENTS WITH PSORIATIC ARTHRITIS RECEIVING GUSELKUMAB

P. Nash1, C. T. Ritchlin2, P. Rahmann3, M. Shawi4, E. Rampaakakis5, L. Webb, J. A. S. Pires6, A. Kolmene7, X. L. Xu8, J. Sherlock9,10, D. Cua1, S. Khatri11, E. Soriano12, D. McGonagle13,14, Griffith University and University of Queensland, Rheumatology Research Unit, Maroochydore, Australia; 2University of Rochester Medical Center, Department of Medicine - Allergy/Immunology and Rheumatology, Rochester, United States of America; 3Memorial University of Newfoundland, Craig L Dobbin Genetics Research Centre, Discipline of Medicine, Division of Rheumatology, St. John’s, Canada; 4Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; 5McGill University, Department of Pediatrics, Montreal, Canada; 6JSS Medical Research, Inc, Scientific Affairs, Montreal, Canada; 7Janssen Asia Pacific, Immunology Medical Affairs, Seoul, Korea, Rep. of (South Korea); 8Janssen Research & Development, LLC, Immunology, San Diego, United States of America; 9Janssen Research & Development, LLC, Immunology Spring House, United States of America; 10University of Oxford, Immunology, Oxford, United Kingdom; 11Icahn School of Medicine at Mount Sinai, Dermatology, New York, United States of America; 12Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, Argentina; 13University of Leeds, Leeds Biomedical Research Centre, Leeds, United Kingdom

Background: Pain in patients (pts) with psoriatic arthritis (PsA) has multifaceted origins; sustained improvement is difficult to achieve.1 Gusekumab (GUS), a fully human monoclonal antibody that selectively inhibits IL-23, is effective in treating multiple domains of PsA including joint, skin, and enthesal symptoms, and also elicits long-lasting improvements in pt-reported pain in the DISCOVER-1&2 trials of pts with active PsA.2

Objectives: These post hoc analyses were conducted to identify determinants of changes in pt-reported pain in PsA pts using pooled data through 1 year of DISCOVER-1&2 trials of pts with active PsA.2

Methods: Enrolled adult pts had active PsA despite standard therapies. DISCOVER-1 pts had ≥3 swollen and ≥3 tender joints and C-reactive protein (CRP) ≥0.3 mg/dL; DISCOVER-2 pts had ≥5 swollen and ≥5 tender joints and CRP ≥0.6 mg/dL. 31% of DISCOVER-1 pts received 1-2 prior tumor necrosis factor inhibitors; DISCOVER-2 pts were biologic-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (wks) (Q4W); GUS 100 mg at W0, W4, then every 8 weeks (wks) (wks) (Q8W)
Results: GUS was associated with significantly greater improvement in pain compared to PBO as early as 2 wks post-treatment; there was a significant interaction between treatment group and time, with effect of GUS on pain continuously enhancing through W24. Higher baseline (BL) pain score, worse mental health (assessed with the Short-Form-36 Mental Component Summary [SF-36 MCS] score), and lower fatigue level and lower tender joint count (TJC) were also associated with significantly greater pain improvements at W24, while background use of NSAIDs was a negative predictor of pain improvement (Table 1). Continuous significant improvement from BL in pain with GUS extended through W52 even after adjustment for the identified determinants of pain improvement through W24 (Figure 1). At W52, predictors of change in pain remained significant with the exception of SF-36 MCS score (Table 1). Results did not exclude a small number of enrolled pts with fibromyalgia (FM; \text{n}_{\text{GUS}}=8; \text{n}_{\text{PBO}}=4). According to these exploratory findings, medical history of FM was associated with lower improvement over 24 wks; the model was then tested separately in pts with FM and with GUS (W24 and W52). Treatment effect on pain was independent of PsA duration, gender, PsA sub-type, prior TNF exposure, BL skin disease, and BL swollen joint count (SJC). Continuous significant improvement from BL in pain with GUS extended through W52 even after adjustment for the identified determinants of pain improvement through W24 (Figure 1). At W52, predictors of change in pain remained significant with the exception of SF-36 MCS score (Table 1). Results did not exclude a small number of enrolled pts with fibromyalgia (FM; \text{n}_{\text{GUS}}=8; \text{n}_{\text{PBO}}=4). According to these exploratory findings, medical history of FM was associated with lower improvement over 24 wks; the model was then tested separately in pts with FM and with GUS (W24 and W52). Treatment effect on pain was independent of PsA duration, gender, PsA sub-type, prior TNF exposure, BL skin disease, and BL swollen joint count (SJC). Continuous significant improvement from BL in pain with GUS extended through W52 even after adjustment for the identified determinants of pain improvement through W24 (Figure 1). * p <0.05; †p <0.01; ‡p ≤0.0001

(-25.9, -3.6) comparable to non-FM pts at W24, while pain improvement in pts with no FM was -22.2 (-24.0, -20.4).

### Conclusion:
Early significant effects of GUS on pain were enhanced through 1 year. Significant predictors of change in pain were consistent at W24 and W52, while the exception of the dependent health measurement at W24. The impact of mental status on pt-reported pain and the potential for GUS to improve pain in pts with FM warrants further consideration.

### Background:
Psoriatic arthritis (PsA) can present with peripheral (i.e. arthralgia, enthesitis, dactylitis) and/or axial (spondyloarthritis) manifestations. Positron Emission Tomography (PET) may be a promising imaging technique for detection of whole body disease activity since it combines quantification and picomolar sensitivity for accurate depiction of pathologic processes with anatomical low dose CT imaging as a reference (3, 4). It was recently demonstrated that [18F]Fluoride PET-CT scans can successfully visualize and monitor ankylosing spondylitis disease activity by imaging of bone formation in the cervical spine (5). Since bone formation is associated with enthesitis and synovitis in PsA, [18F]Fluoride may enable sensitive, whole body detection of disease activity in PsA.

### Objectives:
To investigate the feasibility of [18F]Fluoride PET-CT to visualize disease activity of PsA by imaging of bone formation at axial and peripheral sites in PsA patients.

### Methods:
Sixteen patients (female 10/16, age 50.6 ±9.8 years) with PsA fulfilling CASPAR criteria and clinically active disease including ≥1 clinically active enthesitis site were included. Clinical disease activity was assessed with anatomical low dose CT imaging as a reference (3, 4). It was recently demonstrated that [18F]Fluoride PET-CT scans can successfully visualize and monitor ankylosing spondylitis disease activity by imaging of bone formation in the cervical spine (5). Since bone formation is associated with enthesitis and synovitis in PsA, [18F]Fluoride may enable sensitive, whole body detection of disease activity in PsA.

### Results:
Out of 1088 evaluated joints, 109 joints showed PET enhancement, most frequently in the interphalangeal- and metatarsal joints of the feet (14/109, 12.9%) (Figure 1A) and the distal interphalangeal joints of the hands (14/109, 12.9%). Out of 416 evaluated enthesial sites, PET positivity was found at 44 sites, mainly located at the patella tendon insertion (11/44, 25%) (Figure 1B) and the quadriceps tendon insertion (10/44, 22.7%). Of the PET positive joints and enthesial sites, mainly located at the patella tendon insertion (11/44, 25%) (Figure 1B) and the quadriceps tendon insertion (10/44, 22.7%). Of the PET positive joints and enthesal sites, respectively 81.1% and 70.5% were not associated with tender or swollen joints and clinical enthesitis, respectively. In 11 out of the 16 patients ≥1 axial PET positive lesion was observed (Figure 1C), most frequently located in the cervical spine (19/49 observed axial lesions, 38.8%). Two patients showed PET enhancement in one sacro-iliac joint (SIJ) without any inflammatory back pain (IBP). Only four out of 15 patients reported IBP and missing data for 1 patient. In two patients clinical dactylitis was observed which was also depicted on PET-CT.

### DOI:
10.1136/annrheumdis-2022-eular.1158
Conclusion: [18F]Fluoride PET-CT scans can visualize disease activity at whole body musculoskeletal manifestations of PsA by demonstrating local bone formation at active sites. [18F]Fluoride PET-CT adds information to clinical disease activity, reflected by a high number of clinically negative, PET positive sites on top of concordant findings.

POS1073 INCREASED NUMBER OF COMORBIDITIES AND CARDIOVASCULAR RISK FACTORS IN EARLY PSORIATIC ARTHRITIS PATIENTS SUGGESTS AN INTRINSIC DISEASE IMPACT

A. Ischenko1,2, S. Pazmino1, K. De Vlam1, P. Loriers1,2, University Hospitals Leuven, Department of Rheumatology, Leuven, Belgium; 2Ziekenhuis Netwerk Antwerpen, Department of Rheumatology, Antwerpen, Belgium; 3KU Leuven, Skeletal Biology and Engineering Research Centre, Department of Development and Regeneration, Leuven, Belgium

Background: Metabolic and cardiovascular comorbidities in psoriatic arthritis (PsA) are seen as a consequence of long-lasting inflammation. Patients with PsA and PsA develop metabolic and cardiovascular comorbidities over the course of time. PsA patients have a higher burden of comorbidities and cardiovascular risk factors (CV RF) compared to those with other forms of arthritis. Despite a lower grade of systemic inflammation as measured by CRP, the nature of this increased prevalence in PsA is not fully understood. We hypothesize that the risks may be intrinsic to the disease, and be already present in early stages.

Objectives: The aim of this study was to investigate the prevalence of comorbidities and CV RF in treatment-naive Early PsA (EPA) as compared to sex- and age-matched healthy volunteers and to study factors contributing to the metabolic burden of the patients.

Methods: Clinical, demographic characteristics, cardiovascular risk factors and comorbidities of newly diagnosed treatment-naive adult patients with PsA compared to sex- and age-matched controls were studied in an observational prospective longitudinal multicentre study.

Results: Sixty-seven EPA patients were matched to 61 healthy volunteers. At diagnosis, 73% of EPA had oligoarticular and 22% polyarticular disease. Majority had mild PASI scores (median PASI 1.2). The median duration of skin psoriasis before the onset of PsA was 11.4 years. Symptom duration at onset of PsA was 0.6 years.

Disclosure of Interests: None declared

EPsA showed a significantly higher rate of obesity (40.3% vs 18.3% in controls, p=0.011). PsA patients had significantly higher rates of dyslipidemia and metabolic syndrome than controls. Rate of insulin resistance, arterial hypertension, depression, COPD, and gout were similar in EPsA and in controls. The overall number of comorbidities was comparable in EPsA and healthy controls, but strikingly 82% of EPsA patients had CV RF already present at baseline as compared to 38% of the controls (p=0.017). More than half of EPsA patients had multiple ≥2 comorbidities and CV RF at baseline as compared to controls (33%) (Figure 1). Overall rate of cardiovascular morbidity and Charlson comorbidity index were low, but were significantly higher in the PsA group (p=0.007 and <0.001 accordingly). Duration of skin psoriasis had no effect on comorbidities or CV RF in EPsA.

In multiple regression analysis diagnosis of PsA was the strongly associated with the number of comorbidities and CV RF after adjusting for age, sex and BMI.

Conclusion: Our data imply that PsA patients have higher comorbidities and cardiovascular burden at early stages of the disease. Rates of dyslipidemia, metabolic syndrome and obesity are significantly higher in the early PsA population. Presence of metabolic and lipid disturbances at early stages of the disease might suggest a bidirectional relationship and potentially playing role as initial triggers of PsA.

Table 2. SHAP summary graph.

Conclusion: PURE-4 is a valid and compliant questionnaire with clinical practice in dermatology. It could be answered by patients in the waiting room and reviewed by dermatologists during the visit to support decision-making. PURE-4 could also help rheumatologists to early diagnose PsA patients in clinical practice.

OBJECTIVE: Obesity is a risk factor for psoriatic arthritis (PsA) and is associated with higher disease activity [1].

OBJECTIVES: We aimed to evaluate whether obese patients with PsA were less likely to achieve remission/low disease in a real-life multi-centre cohort.

METHODS: We used data from the ReFlap study (NCT03119805) [2], which recruited consecutive adult patient with definite PsA for more than 2 years of disease duration from 14 countries. We collected demographic characteristics, self-reported height and weight, clinical data and patient reported outcomes. Remission/low disease was defined as Disease Activity in Psoriatic Arthritis (DAPSA) ≤ 4, or Minimal disease activity (MDA). Obesity was defined as body mass index (BMI) ≥ 30 kg/m². We compared patient characteristics, disease activity parameters and impact scores between patients with obesity versus non-obese. A multivariable regression model was performed for demographic variables associated with reaching each definition of remission/low disease, adjusted on age, sex, level of education, disease duration, current use of conventional (c-) and biological (b-) disease modifying anti-rheumatic drugs (DMARDs).

RESULTS: Among 414 patients (49.3% women, mean disease duration 11.0±8.2 years), 119 (28.7%) had BMI ≥ 30kg/m² (obese). Obese patients were more likely to be female, had higher swollen joint and enthesitis counts, higher self-reported pain, poorer physical function, more fatigue and poorer mental health (Table 1). Obese patients were half as likely to achieve MDA or DAPSA remission in multivariable analysis with odds ratios of 0.6 (95% confidence interval, CI: 0.3, 0.8, p=0.049) and 0.4 (95% CI: 0.2, 0.8, p=0.012), respectively for obese compared to non-obese patients (Figure 1).

Mean (SD) shown unless specified otherwise. HAQ-DI: Health Assessment Questionnaire Disability Index; PGA: patient global assessment of disease activity; DAPSA: Disease Activity in Psoriatic Arthritis; PsAID: Psoriatic Arthritis Impact of Disease.

Conclusion: In this real-life data from 14 countries, obesity was frequent and PsA patients with BMI ≥ 30kg/m² were more likely to be female, and had higher subjectively reported disease activity and illness impact compared to those with lower BMI. Obese patients had a two-fold lower likelihood of achieving remission/low disease defined by both MDA and DAPSA compared to non-obese patients. PsA patients with comorbid obesity may have different disease profiles from non-obese patients, and require specific management.

POS1077 LARGE JOINT INVOLVEMENT AND SUBSTANTIAL DISEASE BURDEN IN PATIENTS WITH OLIGOARTICULAR AND POLYARTICULAR PSORIATIC ARTHRITIS IN THE MULTINATIONAL UPLIFT SURVEY

W. Tilley1, A. Ogdie2, P. Richette1, A. B. Gottlieb1, S. Jardón1, S. Richter1, A. Flower1, J. Merola1, 1University of Bath, Department of Pharmacy
Background: Patients (pts) with oligoarticular psoriatic arthritis (PsA) report quality-of-life impairment similar to polyarticular PsA pts despite less joint involvement. In the 2020 Understanding Psoriatic Disease Leveraging Insights for Treatment (UPLIFT) survey, we evaluated other aspects of disease burden in pts with oligoarticular (≤4 joints) and polyarticular (>4 joints) PsA.

Objectives: To explore joint involvement distribution and relative disease burden in pts with self-reported healthcare provider (HCP)—diagnosed PsA who self-identified with oligoarticular vs polyarticular joint involvement.

Methods: UPLIFT was a multinational Web-based survey in adults who reported an HCP diagnosis of PsA and/or psoriasis. This analysis evaluated demographics, disease characteristics, joint distribution, and quality-of-life measures in pts with PsA or without psoriasis with self-identified oligoarticular vs polyarticular joint involvement. Small joint classification includes foot/toes, hands/fingers, and thumbs; intermediate joints includes wrists, elbows, and ankles; and large joint involvement. Common areas of joint involvement were the knees, elbows, and ankles; and large joints includes should, hips, and knees.

Results: Of the 1256 pts with PsA completing the survey, 44% had oligoarticular PsA and 56% polyarticular PsA. The polyarticular PsA group had higher mean age, fewer males, and more pts with body mass index ≥25 kg/m² (Table 1). Prevalence of depression, hypertension, and diabetes was generally similar between groups (Table 1). In pts with oligoarticular and polyarticular PsA, respectively, involvement of large joints was most prevalent (83%, 91%), followed by intermediate (46%, 87%) and small (20%, 76%) joints. Axial involvement was less prevalent in pts with oligoarticular (30%) vs polyarticular (67%) PsA. Common areas of joint involvement were the knees, elbows, and shoulders for oligoarticular PsA pts and the knees, hands, and elbows for polyarticular PsA pts (Figure 1). Involvement in the hands, wrists, thumbs, and ankles was proportionately greater in polyarticular pts vs oligoarticular pts. Dactylitis, enthesitis, and nail disease, respectively, were each present in approximately one third of oligoarticular PsA pts and more than half of polyarticular PsA pts. Mean Patient Assessment of PsA Severity, Health Assessment Questionnaire (HAQ)-8, and Psoriatic Arthritis Impact of Disease 12-item (PSAID-12) scores indicated similar disease burden between the two groups (Table 1). In both groups, >70% reported an unacceptable PsA symptom state (PSAID >4), and >60% had Patient Health Questionnaire 2-item (PHQ-2) score ≥3, consistent with positive screening for depression (Table 1).

*n=525 with oligoarticular PsA; n=691 with polyarticular PsA.

Conclusion: In the UPLIFT survey, almost half of pts with PsA self-identified with oligoarticular PsA. Both oligoarticular and polyarticular PsA groups experienced similar levels of disease burden, including a high prevalence of an unacceptable PsA symptom state and a PHQ-2 score ≥3, indicative of a positive screen for depression.

POS1078

COMPARISON OF PATIENTS WITH AXIAL PSA AND PATIENTS WITH AXSPA AND CONCOMITANT PSORIASIS

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease affecting the peripheral and axial musculoskeletal system as well as skin and nails. Diagnostic criteria of axial PsA (axPsA) are well defined. Treatment strategy is mostly based on evidence generated for axial spondyloarthritis (axSpA), as only rare clinical trial data for axPsA exist. However, it is still unclear whether axSpA with concomitant psoriasis (axSpA/pso) is the same as axPsA.

Objectives: To compare axPsA patients with axial manifestations with axSpA patients with concomitant psoriasis.

Methods: RABBIT-Spa is a prospective longitudinal cohort study including PsA and axSpA patients enrolled at start of a new conventional treatment or bi/td-MARD treatment. Two definitions of axSpA were used: Clinical definition: documentation of axial manifestation as diagnosed by a rheumatologist

Radiographic definition: presence of sacroiliitis according to modified NY criteria (mNYC).

axSpA patients were stratified into axPsA/pso (with psoriasis either in patient history or present) and axSpA.
Results: Psoriasis was documented in 182/1407 axSpA patients (13%). Of 1355 PsA patients, 295 (22%) fulfilled the clinical definition of axSpA. Using the radiographic definition, 127 (9%) PsA patients fulfilled mNVC, 230 (17%) did not fulfill mNVC and 988 (74%) did not undergo radiographic evaluation. AxSpA/pso patients differed from axSpA regardless of the definition (Table 1). axPsA patients were older, less often HLA-B27 positive, and peripheral manifestations were much more often present in axPsA than in axSpA/pso. Uveitis and inflammatory bowel disease were more common in axSpA/pso.

Table 1. Baseline characteristics of axSpA/pso patients and clinical resp. radiographic defined axPsA.

</tbody>
</table>

In contrast, disease activity measured by physician global as well as patient pain, mean (SD) 5.5 (2.6) 5.7 (2.3) 5.7 (2.2)

Conclusion: Regardless whether clinical or radiographic definitions of axSpA were used, differences to axSpA/pso patients were identified. These data indicate a need for a specific diagnostic, and a potentially more targeted treatment approach for axSpA.

REFERENCES:

METHODS: A SLR explored MEDLINE, EMBASE and CENTRAL, up to 22 October 2021. The objective was to identify the symptoms, objective signs, lab tests, imaging features and other characteristics of patients later diagnosed as “new onset” PsA in two key populations: 1) patients with PsO and 2) patients with early undifferentiated arthritis (UA). Studies of adult patients published in English were included, if they reported characteristics of pre-PsA or new onset PsA patients, and data were extracted by 2 readers. Meta-analysis was not done due to data heterogeneity (PsA classification criteria, outcome measures and length of observation). Results are reported semi-quantitatively.

Results: Of 31449 references, 22 studies were included of which 12 were prospective; 7 retrospective and 3 cross-sectional. Eighteen studies reported on patients with PsO (n=95828) later diagnosed as PsA (n=2136) with a mean duration of follow up of 5.2 (±3.9) years. Seven out of 18 (38.8%) studies were informative regarding the clinical features of the new onset PsA. Four studies on early UA patients (n=492) later diagnosed as PsA (n=49) were included. Progression to PsA was associated with the presence of musculoskeletal (MSK) complaints (mainly joint tenderness) and the presence of subclinical MSK inflammation detected by imaging. Peripheral oligo-arthritis was the prevalent clinical presentation of new onset PsA.

Conclusion: As expected, joint pain and imaging evidence of MSK inflammation were associated with PsA development in PsO patients. The SLR highlights the lack of robust evidence regarding data associated with the development of PsA. More prospective studies focusing on transition from PsO to PsA are needed.

REFERENCES:
Oligoarticular psoriatic arthritis (PsA) is commonly reported in early disease. Although fewer joints are involved, there may be significant impact on patients’ (pts) quality of life. The ongoing FOREMOST study (NCT03747939) is investigating the efficacy of apremilast vs placebo for treatment of early oligoarticular PsA (<1 but ≤5 tender and swollen joints involved).

Objectives: To characterize disease burden in pts with early oligoarticular PsA and disease phenotype including location and size of involved joints and presence of certain baseline clinical PsA manifestations in FOREMOST pts.

Methods: Baseline swollen and tender joint distribution was analyzed. Baseline disease burden was assessed in the overall group and a subgroup with small joint involvement only (or context) using clinical disease activity measures, pt-reported outcomes, and additional PsA manifestations.

Results: At data cut-off for analysis, 220 pts of 285 planned were enrolled. In the overall group, disease duration was <1 year and joint distribution for swollen or tender joints involved predominantly small joints, with ~48% of joint involvement observed in finger proximal interphalangeal (PIP) joints and <2% in temporomandibular and clavicular joints across swollen or tender joints (Figure 1). Mean Physician’s and Patient Global Assessment of Disease Activity (PhGA and PtGA, respectively) scores were 43.9 and 51.3; mean pt pain assessment score was 50.7. Mean Health Assessment Questionnaire Disability Index (HAQ-DI) functional assessment score was 1.0; 25.5% of pts had HAQ-DI ≤0.5. Pts reported outcomes, and additional PsA manifestations.

Conclusion: In FOREMOST, despite few joints involved, pts with early oligoarticular PsA experienced high disease burden and impaired quality of life. Small joint involvement, although less commonly expected in oligoarticular PsA, was the most frequently observed pattern.
Methods: Serum MPO-DNA complex was detected by a modified enzyme-linked immunosorbent assay (ELISA) and compared among 74 patients with PsA, 58 patients with psoriasis (PsO) and 20 healthy controls. The association of MPO-DNA level with disease activity index at baseline and follow-up was analyzed in PsA patients. Receiver operating characteristic curve was used to evaluate the predictive value of MPO-DNA for treatment response.

Results: MPO-DNA complex level in serum was significantly increased in PsA/PsO patients compared to healthy controls (p < 0.001). The level of MPO-DNA was positively associated with DAPSA score and its components (including TJC, SJC, PGA, EGA, VAS-pain and CRP; r = 0.26-0.409, all p-value < 0.05). Serum MPO-DNA level was downregulated at 12-week after treatment compared to baseline (p = 0.022). The decrease of MPO-DNA level was more dramatic in PsA patients who achieved both ACR50 and PASI50 response than those achieving neither of them at 12 weeks (p = 0.023). ROC analysis revealed that the serum MPO-DNA level predicted both ACR50 and PASI50 achievement at week 12 (p = 0.003, 95% CIs 0.748-1) and change of MPO-DNA at week 12 from baseline (p = 0.04, 95% CIs 0.56-0.94). Moreover, the baseline MPO-DNA level (p = 0.009, 95% CIs 0.748-1) and change of MPO-DNA of MPO-DNA at week 12 from baseline (p = 0.004, 95% CIs 0.802-1) were associated with the achievement of both ACR70 and PASI75 response.

Conclusion: NETosis plays an important role in psoriatic diseases. The level of MPO-DNA complex in serum reflects disease activity. Serum MPO-DNA complex may be a useful biomarker to predict the therapeutic response in PsA.

Table 1. Treatment response and changes of serum MPO-DNA of 29 PsA patients.

CHARACTERISTICS OF PSORIATIC ARTHRITIS (PSA) PATIENTS WITH ENTHESITIS. DATA FROM RUSSIAN PSA REGISTRY (RU-PSART).

E. Loginova1, T. Korotaeva1, E. Gubard1, Y. Korsakova1, S. Glukhova2, E. Nasonov3, V. Sorotskaya4, I. Patrikeeva5, P. Shchesteryna6, I. Shchendrigin7.

1V.A. Nasonova Research Institute of Rheumatology, Spondyloarthrits and Psoriatic Arthritis, Moscow, Russian Federation; 2A.V. Nasonova Research Institute of Rheumatology, Medical and Social Problems in Rheumatology, Moscow, Russian Federation; 3Medical Institute of the Tula State University, Rheumatology, Tula, Russian Federation; 4Tver Regional Clinical Hospital №1, Rheumatology, Tver, Russian Federation; 5Krasnoyarsk State Medical University V.F. Voino-Yasnetsoy, Rheumatology, Krasnoyarsk, Russian Federation; 6Center of Responsible Rheumatology “Induktsia”, Rheumatology, Stavropol, Russian Federation

Background: Psoriatic arthritis (PsA) is a disease with multidomain clinical presentation such as arthritis, enthesitis, dactylitis, spondylitis and psoriasis (PsO). [1]. Enthesitis is a key clinical feature of PsA with significant impact on function, quality of life and choice of treatment. [2]. There are limited real-world studies on the characteristics of patients (pts) with PsA and enthesitis.

Objectives: To compare clinical characteristics of PsA pts with and without enthesitis.

Methods: 603 pts (M/F=278/326) with PsA according to CASPAR criteria were examined. Data was collected from 6 rheumatology clinics of the Russian Federation. Pts' mean age 46.6±12.5 years (yrs.), PsA duration 9.7±7.1 yrs, PsO duration 20.4±13.0 yrs. Median (Me) DAPSA 25.5 [15.2; 41.8], body mass index (BMI) 27.5 [24.3; 31.2]. At baseline (BL) PsA activity by tender/swelling joint count (TJC)/68, (SJC)/66, enthesitis by LEI and plantar fascia, BSA (%), PASI, HAQ, DAPSA were evaluated. DAPSA=28 indicate high disease activity (HDA). The one-factor model of logistic regression was used to identify a group of features that are associated with presence of enthesitis. AUC=0.72, 95% CI of 0.66-0.78.

Results: Enthesitis was found in 295 out of 603 pts (49%). Comparative analysis in both groups with and without enthesitis and one-factor model of logistic regression showed the following features at BL were associated with enthesitis: TJC>5 (p=0.001), SJC>5 (p=0.001), dactylitis (p=0.001), high disease activity by DAPSA (p=0.001), HAQ>0.5 (p=0.001), BSA>10% (p=0.001), nail PsO (p=0.003), CRP>10 mg/l (p=0.018), BMI>30 kg/m² (p=0.02). Pts with enthesitis had significantly more often depression (p=0.026), metabolic syndrome (p=0.047), fatty hepatitis (p=0.017). OR analysis with CI 95% for all parameters are shown on Figure 1.

Conclusion: In real clinical practice enthesitis was found in half of PsA pts. Enthesitis are associated with more severe peripheral arthritis, dactylitis, skin and nail PsO, higher PsA activity by DAPSA, worse quality of life and more likely to have depression, metabolic syndrome and fatty hepatitis. This should be considered for optimizing disease management strategy.

RESEARCH ARTICLE

**Background:** Changes in the integrity of the intestinal wall may be implicated in the gut-joint axis of inflammatory arthritis. Yet, the gut barrier is only poorly evaluated in psoriatic arthritis (PsA).1,2

**Objectives:** In this exploratory study, we evaluated intestinal permeability before and 26 weeks after one faecal microbiota transplantation (FMT) or sham intervention in adults with PsA.

**Methods:** We have previously reported the clinical results of a 26-week, double-blind, parallel-group, 1:1 randomised, sham-controlled, superiority trial of faecal microbiota transplantation (FMT) as an add-on treatment to methotrexate in 31 adults with active peripheral PsA (FLORA trial, NCT03058900). The primary efficacy endpoint was the proportion of participants who experienced treatment failure through 26 weeks, defined as need for more than one intra-articular glucocorticoid injection and/or anti-TNFα inhibition. We encouraged patients not to take nonsteroidal anti-inflammatory drugs during the trial. The FMT material was obtained from one of four healthy blood donors. As part of the trial, we performed a lactulose and mannitol test (L:M test) at baseline (n=31) and at the final 26-week visit (n=26) to assess the permeability of the intestinal wall (higher L:M ratios indicate higher permeability). After an overnight fasting, patients provided a urine sample before ingesting 10 g of lactulose and 5 g of D-mannitol. Samples were collected after 3 hours and stored at −80°C until analysis. No food or drinking (except for water) was allowed during the test. We measured the lactulose-to-mannitol ratio in the urine samples using a Waters Acquity UPLC system coupled to a high-resolution mass spectrometer Waters Xevo G2 QTOF (Waters Corp., Milford, MA, USA). Masslynx software (Waters Corporation) was used for data acquisition and visual inspection. We used StataSE 14 to perform the Wilcoxon rank sum and the matched-pairs signed-rank test. Data is presented as median and range. The level of significance was set to 0.05.

**Results:** At baseline, no significant difference was observed in the L:M ratio between donors (n=4) and patients (n=31) (0.0065 [0.00-0.063] vs 0.014 [0.0-0.28]; p=0.50). The L:M ratio increased from baseline to week 26 in both the FMT group (0.0020 [-0.27 – 0.32] and the sham group (0.0046 [-0.012 – 0.088]), but only in the sham group did the baseline L:M ratio significantly differ from the one measured at week 26 (p=0.022 FMT) and p=0.032 (sham). The patients who were classified as treatment failures during the trial (n=7) had a significantly higher L:M ratio at week 26 compared to the patients who were non-failures (n=19) (0.027 [0.017 – 0.33]) vs 0.012 [0.0 – 0.064], p=0.01), please see Figure 1.

**Conclusion:** In the FLORA trial, intestinal permeability evaluated by the L:M test did not differ significantly between donors and patients at baseline. Whether higher intestinal permeability observed in patients classified as treatment failures compared to non-failures at week 26 can be attributed to differences in disease activity and/or the instigation of additional immunosuppression in the failure group during the trial needs further investigation.

---

**Figure 1.** Clinical categories of Skindex-17 psychosocial and symptoms scores of patients with DAPSA-LDA and active psoriasis (PASI>1) one year after diagnosis (n=116)

**Conclusion:** In daily clinical practice approximately half of PsA patients who reached musculoskeletal low disease activity (DAPSA-LDA) one year after their diagnosis has not reached psoriasis remission. The majority of these patients has a good HRQoL. However, a proportion of them still experiences considerable skin burden. We therefore recommend rheumatologists to always assess and treat psoriasis in order to reduce skin burden, even in PsA patients who achieved musculoskeletal low disease activity.

Background: Dyslipidemia is the leading treatable-modifiable factor among comorbidities in Psoriatic arthritis (PsA) patients. International treatment recommendations have left the management of dyslipidemia to national guidelines and especially to the rheumatologists.

Objectives: In this study, we aimed to determine the frequency of dyslipidemia and the rates of initiation of treatment within the indication in PsA patients using bDMARDs.

Methods: The Hacettepe University biological database (HUR-BIO), was established in 2005 and data of 520 PsA patients included until 2021 were analyzed. In all included patients, the diagnosis of PsA was made by rheumatologists. Lipid profiles of PsA patients were evaluated at diagnosis, during the first bDMARD initiation, and at the last visit. Total cholesterol (TC), Triglycerides (TG), HDL-C and LDL-C values were grouped as optimal, borderline, or high.

Results: Lipid profile values of PsA patients were known at diagnosis (n=159, 30.6%), in the initial bDMARD baseline (n=161, 30.9%), and at the last visit (n=203, 39.0%). The time to diagnosis of PsA and first bDMARD use was 2.8 years, and the time between the start of bDMARD and the last visit was 3.7 years. Accordingly, the rates of high TC, borderline TG, and high LDL increased over time. Rates at the time of PsA diagnosis, first bDMARD onset and at the last visit are as follows: high TC (14.3%, 17.1% and 28.0%), borderline TG (20.4%, 27.7% and 40.5%) and high LDL (17.0, 24.0% and 27.9%). On the other hand, low HDL-C slightly improved in men (33.3%, 29.4% and 23.1%), but did not show a significant change in women. While LDL-C level was >160 in 24.0% of patients who were started on bDMARD, anti-hyperlipidemic drug was started in only 6.2% of them. A similar situation persisted at the last visit (27.9% had LDL-C levels >160, but 10.8% received anti-hyperlipidemic society criteria (1).

Conclusion: Among the modifiable risk factors for cardiovascular comorbidities in PsA patients, the leading risk factor is dyslipidemia. On the other hand, dyslipidemic drug use rates in daily practice are significantly lower. Although attention is paid to the management of comorbidities in all recommendations, there is still work to be done in real life.

Figure 1. Measurement of aortal pulse wave velocity: pulse waves of carotid and femoral artery (Δt: time, L: distance between the two arteries, m/s: meters/second), modified after [3].

Objectives: Aim of this study was to evaluate aortic stiffness and CV risk in patients with PsA based on measurements of cPWV and ESC-SCORE. Moreover, we sought to investigate associations of cPWV with patient- and disease-associated characteristics, as well as with traditional CV risk factors.

Methods: cPWV measurements were performed in patients with PsA from two large rheumatological medical departments in Germany, according to the classification criteria for psoriatic arthritis (CASPAR), and in healthy control subjects. In addition to assessing cPWV, clinical and laboratory parameters were evaluated, traditional CV risk factors were documented, and the ESC-SCORE was determined. Differences in cPWV measurements between the two groups and associations between cPWV and patient- or disease-associated characteristics were

POS1086 HIGH CARDIOVASCULAR RISK IN PATIENTS WITH PSORIATIC ARTHRITIS: EVALUATION OF MACROANGIOPATHY AND ITS PREDICTORS BY AORTIC PULSE WAVE VELOCITY.

K. Triantafyllias1, S. Liverakos1, A. Klonowski2, A. Schwarting1,2, 1Rheumatology Center Rhineland-Palatinate, Rheumatine, Bad Kreuznach, Germany; 2Johannes Gutenberg University Medical Center, Rheumatology and Clinical Immunology, Mainz, Germany

Background: Systemic inflammatory rheumatic diseases are associated with macroangiopathy and increased cardiovascular (CV) risk [1, 2]. Psoriatic arthritis (PsA) has also been associated with an increased risk of CV events. However, data on diagnostic CV markers in PsA are scarce. Carotid-femoral pulse wave velocity (cPWV: oscillometric diagnostic method) is considered to be the gold standard evaluation method of aortic stiffness and is used in the general population to assess CV risk (Figure 1). Moreover, EULAR and the European Society of Cardiology (ESC) recommend the use of Systematic Coronary Risk Evaluation (ESC-SCORE) in order to screen and classify patients regarding CV risk.

Objectives: Aim of this study was to evaluate aortic stiffness and CV risk in patients with PsA based on measurements of cPWV and ESC-SCORE. Moreover, we sought to investigate associations of cPWV with patient- and disease-associated characteristics, as well as with traditional CV risk factors.

Methods: cPWV measurements were performed in patients with PsA from two large rheumatological medical departments in Germany, according to the classification criteria for psoriatic arthritis (CASPAR), and in healthy control subjects. In addition to assessing cPWV, clinical and laboratory parameters were evaluated, traditional CV risk factors were documented, and the ESC-SCORE was determined. Differences in cPWV measurements between the two groups and associations between cPWV and patient- or disease-associated characteristics were

POS1088 MACROANGIOPATHY AND ITS PREDICTORS BY AORTIC PULSE WAVE VELOCITY.

examined statistically (correlation analyses, Mann-Whitney-U-Tests, ANOVA and multivariate regression analyses).

**Results:** 112 patients with PsA [55.45%, median age: 55 years, IQR 47-63] and 88 healthy control subjects [81.4%, median age: 51 years, IQR 36.5-58] were recruited. cPWV was significantly higher in PsA patients compared to the healthy control subjects (p < 0.001), even after the adjustment for the effect of confounding factors. In both the patient and the control group, cPWV correlated with age (r = 0.560, p < 0.01) and r = 0.638, p < 0.01, respectively. In addition, cPWV showed a moderate significant correlation with the ESC-SCORE (r = 0.290, p = 0.222) and a weak significant association with mean arterial pressure (r = 0.19, p = 0.043) in the patient group. No statistical associations could be found between cPWV and lipid levels, CRP levels or EULAR disease activity score for patients with psoriatic arthritis (PsA). We were able to show that PsA patients had significantly higher arterial stiffness values, and thus, a higher CV risk compared to healthy individuals. Therefore, cPWV could be a useful tool for the identification of PsA patients at high-risk. The fact that arterial stiffness can be predicted by mean arterial pressure and ESC-Score might assist forming therapeutic strategies that would promote artery de-stiffening and thus CV risk lowering.

**THE RELATIONSHIP BETWEEN CHANGES IN PSORIATIC ARTHRITIS DISEASE ACTIVITY AND COMORBIDITIES IN PATIENTS TREATED WITH BDMAARDS**

G. Ayavı 1, N. E. Gezereni 1, E. Bilgin 1, G. K. Yardsmic 1, E. C. Bolesl 1, B. Farisogullari 1, E. Durani 1, Z. Ozsoy 1, G. Sandal Uzun 2, M. Ekici 1, E. Unalddi 1, L. Kilici 1, A. Akdogan 2, O. Karadag 1

**Background:** Comorbidities are common in psoriatic arthritis, needed to be recognized and managed to effectively when treating psoriatic arthritis (PsA) patients. However, the data on the impact of particular comorbidities on the disease activity in patients requiring bDMARDs are very small.

**Objectives:** Our aim was to understand the relationship between the disease activity and comorbidities in PsA patients under bDMARDs.

**Methods:** The Hacettepe University biological database (HUR-BIO), was established in 2005 and data of 520 PsA patients included until 2021 were analyzed. In all included patients, the diagnosis of PsA was made by the rheumatologist. DAS-28 score (at the last visit) and all comorbidities were documented after bDMARD initiation. Multivariate analysis was performed to understand comorbidities that have impact on DAS-28 remission.

**Results:** There were 469 patients with a known DAS-28 score median (IQR) 28 (61) months after bDMARD initiation. It was detected in 214/469 (45.8%) patients with a DAS-28 score below 2.6. Patients in remission of DAS-28 were younger, remission was less frequent in women, and comorbidities, mainly BMI, Diabetes Mellitus (DM) and hypertension, were also found less frequent (Table 1). In the multivariate analysis, no determining factor was found in male gender. On the other hand, in females, smoking, presence of comorbidity, Body mass index (BMI) at the start of bDMARDs, age at onset of bDMARDs, DM at the start of bDMARDs, HT at the start of bDMARDs, coronary artery disease, and cardiovascular risk factors were included in the analysis and revealed. bDMARD baseline BMI [OR 1.06 (95% CI 1.02-1.11), p = 0.004] and presence of bDMARD baseline BMI [OR 3.08 (95% CI 1.14-8.30), p = 0.026] had significant impact on DAS-28 remission.

**Conclusion:** Previous data showed that obesity, hypertension and at least 1 point from charlson comorbidity index are poor prognostic factors for treatment outcomes (1). Our data showed that BMI and presence of DM were determined as factors affecting bDMARD treatment response in female PsA patients.

**CHALLENGES IN THE MANAGEMENT OF PSORIATIC ARTHRITIS IN LATIN AMERICA: A SYSTEMATIC REVIEW**

A. Ribere 1, L. Dullius 1, N. Sartori 1, A. Azeredo-Da-Silva 2, O. Monticelio 1, C. Kohem 1, L. Coates 3, P. Palominos 1, 1Hospital de Clínicas de Porto Alegre, Rheumatology, Porto Alegre, Brazil; 2Hospital de Clinicas de Porto Alegre, Internal Medicine, Porto Alegre, Brazil; 3Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Rheumatology, Oxford, United Kingdom

**Background:** In 2020, the International League of Associations for Rheumatology (ILAR) recommendations for management of psoriatic arthritis (PsA) were published. This aimed to adapt GRAPPA and EULAR recommendations to resource-poor settings. At that time, the paucity or absence of clinical studies endorsing the management of PsA patients in Latin America was remarked on by the international working group. Despite several challenges faced by patients and physicians in resource-poor countries, the literature on this theme is scarce.

**Objectives:** To recognize the main challenges on the management of PsA in Latin America described in recent publications.

**Methods:** A systematic literature review of clinical trials reporting at least one challenge/difficulty on the management of PsA in Latin America was conducted following PRISMA statements. References published in English, Spanish, French and Portuguese language and published in PubMed, Embase, and LILACS between 1980 and 2020 were included. The selection of references was conducted independently by two researchers in Rayyan QCRI program. Data were independently extracted by two reviewers. The Cochrane tool was used to assess the quality of studies. All challenges were noted and categorized into domains. Data analysis was descriptive.

**Results:** The search strategy resulted in 1505 references. Sixteen studies (15, 145 PsA patients) were included in the final analysis: most were performed in Brazil (81.2%, N=13), recruited patients on biological therapy (75.0%, N=12) and were observational studies (87.5%, N=14). Difficulties faced by PsA patients and physicians in Latin America were the high incidence of opportunistic infections (described in 43.7% of publications, N=7), non-adherence to therapy (18.7%, N=3), discordance between patients and physicians regarding remission rates (18.7%, N=3), limited access to DMARDs (12.5%, N=2), issues related to the storage of biological drugs (12.5%, N=2), high impact of PsA on work and productivity (12.5%, N=2), cost of biological drugs (12.5%, N=2), low drug persistence (6.2%, N=1), and limited access to medical care (6.2%, N=1) and diagnostic delay (6.2%, N=1).

**Conclusion:** The challenges in the management of PsA in Latin America go beyond the care of opportunistic infections: special attention should be paid to logistical questions (e.g., correct medication storage, access to drugs and...
medical care) and educational problems (e.g., importance of adherence, patients understanding of disease and therapy)

HLA-CW6 ALLELE AND BIOLOGICAL TREATMENTS ARE PROTECTIVE FACTORS AGAINST LIVER FIBROSIS IN PSORIATIC ARTHRITIS PATIENTS

C. Macia-Villa1, J. L. Morell Hita2, M. Revenga3, C. Diaz-Miguel4. 1Hospital Severo Ochoa, Rheumatology, Leganés, Spain; 2Hospital Ramón y Cajal, Rheumatology, Madrid, Spain

Background: Non-alcoholic fatty liver disease can be expressed from an indolent stage, evolve to steatohepatitis and eventually evolve to liver fibrosis. This spectrum of non-alcoholic inflammatory liver disease is increased in psoriasis and psoriatic arthritis (PsA). To date, the relationship between non-alcoholic liver fibrosis and genetics in PsA has not been studied.

Objectives: The objective of our study is to evaluate the association between the HLA-Cw6 allele and the FIB-4 (fibrosis-4) index in patients with PsA.

Methods: Retrospective longitudinal study in patients older than 18 years with PsA according to CASPAR criteria with determination of the HLA-Cw6 allele. To estimate liver fibrosis, the FIB-4 index was obtained, calculating it at the onset of PsA and at the last available visit. A descriptive analysis of the variables was carried out using mean and standard deviation (SD) for those with symmetric distribution, and median and interquartile range (IR) for the asymmetric ones. Qualitative variables were described using absolute values and percentages. A bivariate analysis was carried out using parametric and non-parametric hypothesis contrast tests to determine the association between the main variable (current FIB-4) and the secondary variables. Bivariate correlations were analyzed using Pearson’s coefficient. A multivariate model was developed to assess the association between HLA-Cw6 and liver fibrosis adjusted for potential confounding factors, and results were presented as Odds Ratio (OR) with 95% confidence interval (CI) and level of statistical significance p-value=0.05. The statistical program SPSS version 20 was used. The study was approved by the local committee.

Results: 209 patients with PsA were included (56.9% men, mean age 42.72±14.24 years), 84.7% with psoriasis, and median (IR) ESR (mm/h) of 4.31 (2.62-11.82). 74.3% of patients were HLA-Cw6 positive. A multivariate analysis was performed to assess the association between HLA-Cw6 and liver fibrosis adjusted for potential confounding factors, and results were presented as Odds Ratio (OR) with 95% confidence interval (CI) and level of statistical significance p-value=0.05. The statistical program SPSS version 20 was used. The study was approved by the local committee.

Table 1. Bivariate analysis of the main variable (current FIB-4) categorized into normal (result F0-1, non advanced fibrosis, <1.30 points) and altered (result F2-3-4, intermediate zone and significant fibrosis, >1.3 points). 1Median (IR) 2Mean±SD. p-value < 0.05. AMI acute myocardial infarction.

Conclusion: In our study, having the HLA-Cw6 allele and receiving biological treatment behaved as a protective factor for liver fibrosis in PsA, while arterial hypertension was an independent risk factor. The presence of psoriasis was not related to hepatic fibrosis measured by FIB-4.

POS1090

THE IMPACT OF NUMBER OF COMORBIDITIES ON ACHIEVEMENT REMISION OR LOW DISEASE ACTIVITY BY DAPSA IN PSORIATIC ARTHRITIS. DATA FROM THE RUSSIAN OBSERVATIONAL COHORT

Y. Korsakova1, E. Gubar2, E. Loginoiva1, T. Kortaeava2, V. Sorotskaya3, I. Patrikeeva1, P. Shesterynya1, I. Umnova1, E. Nasonov1. 1V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation; 2Medical Institute of the Tula State University, Medical Institute of the Tula State University, Tula, Russian Federation; 3Medical Institute of the Tula State University, Rheumatology, Tula, Russian Federation, Tyumen Regional Clinical Hospital No1, Rheumatology, Tyumen, Russian Federation; 4Krasnoyarsk State Medical University VF.Voino-Yasenetsky, Rheumatology, Krasnoyarsk, Russian Federation; 5Omsk region “Regional clinical hospital”, Rheumatology, Omsk, Russian Federation; 6V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation

Background: The goal of psoriatic arthritis (PsA) treatment is achievement remission (REM) or Low Disease Activity (LDA) by DAPSA. The impact of comorbidities, especially obesity, metabolic syndrome on PsA activity and on biological treatment response are shown in some registry [1]. Obesity, hypertension and Charlson Comorbidity Index ≥ 1 are prognostic factors for poorer treatment outcome rates in PsA [2]. But influence of number of comorbidities on treatment response has not been fully studied in real practice.

Objective: To evaluate the impact of number of comorbidities on achievement remission by DAPSA in PsA pts

Methods: 528 pts (M/F=256 (48.5%)/272 (51.5%) with PsA according to CASPAR criteria were included in the Russian observational cohort. Mean age 48.7±13.33 years (yrs.), PsA duration 122.6±81.85 months (mo.), psoriasis (Ps) duration 239.0±155.45 mo. Pts who completed ≥2 visits were analyzed. Mean observational period 73.6±83.47 mo. All pts underwent standard clinical examination: tender joint count (TJC)/68, swollen joint count (SJC)/66, Pain (VAS), Patient global assessment of disease activity (PGA), VAS, CRP mg/l, BSA (%), BMI, HAQ, comorbidities by ICD-10, X-ray of hands and feet. DAPSA-28 indicates as high disease activity (HDA), >14-28 - moderate activity (MoDA), 4-14 – LDA, ≤4 – REM. Analyses were performed based on number of comorbidities: 1st group (gr) - without comorbidities, 2nd gr – pts with 1 comorbidity, and 3rd gr – pts with ≥ 2 comorbidities. Ms/SD, %, t-test, Pearson-χ², ORs with 95% CI were calculated. All p<0.05 were considered to indicate statistical significance.

Results: In 236 out of 528 (44.7%) pts no comorbidity found, in 145 out of 528 (27.5%) found 1 comorbidity and 147 out of 528 (27.8%) pts had ≥ 2 comorbidities. Comparative analysis in groups showed the following features: pts of 3rd gr were significantly more often females, had longer Ps and PsA duration, they were older, had worse HAQ, higher BMI, TJC (p<0.05). Joint erosions were found significantly more often in the 2nd gr compared to the 1st gr (p=0.02). No significant differences were in the frequency of axial PsA (p=0.906), Ps severity (Bsa>10%) (p=0.237), the number of pts receiving bDMARDs (p=0.078). REM/ LDA achievement according to DAPSA was significantly lower in the 3rd gr (15 (10.2%)/69 (46.9%) compared to the 1st gr (62 (26.3%)/94 (39.8%), and to the 2nd gr (32 (22.1%)/69 (47.6%) (p=0.007). The probability of achieving REM/ LDA is 1.6 times lower in the gr of pts with ≥2 comorbidities compared to the gr of pts without comorbidities (OR 0.608, 95% CI 0.394 to 0.936) and 1.3 times lower compared to gr of pts with 1 comorbidity (OR 0.789, 95% CI 0.489 to 1.243) (Figure 1)
Conclusion: In real clinical practice comorbidities were seen in more than half PsA pts. Third of PsA pts had number of comorbidities. PsA pts with number of comorbidities is associated with high disease activity, reduced quality of life and are 1.6 times more likely to have no chance to attain REm/LDA by DAPSA. It should be considered for personalized treatment.

LESS RADIOGRAPHIC SPINAL DAMAGE IN PSORIATIC ARTHRITIS PATIENTS COMPARED TO SPA PATIENTS

M. De Hooger1,2, A. Ishchenko3, A. S. De Craemer1,2, S. Steinfield1, A. Nzesessez Toukpa4, D. Elewaut4,5, R. Lories3,6, F. Van den Bosch1,2, K. De Vlam3,6.

1Ghent University Hospital, Rheumatology, Gent, Belgium; 2VIB-Ugent, Center for Inflammation Research, Gent, Belgium; 3University Hospitals Leuven, Rheumatology, Leuven, Belgium; 4Clinique St Jean, Brussels, Belgium; 5St Luc University Hospitals, UCLouvain, Rheumatology, Leuven, Belgium; 6KULeuven Skeletal Biology and Engineering Research Center, Development and Regeneration, Leuven, Belgium

Background: Psoriatic arthritis (PsA) is an inflammatory joint disease that is traditionally included in the Spondyloarthropathy (SpA) spectrum. Prevalence and impact of axial involvement in PsA remain understudied but increasingly affect treatment decisions.

Objectives: A step towards fathoming this issue is to report on baseline radiographic spinal damage in PsA and SpA patients (pts) from 2 prospective multicentre cohort studies in private and academic rheumatology practices.

Methods: Data on PsA pts were from the Belgian Epidemiological Psoriatic Arthritis Study (BEPAS); prospective multicentre cohort in 17 Belgian rheumatology practices. Recruitment was Dec2012-Jul2014. Pts were included when fulfilling the Classification criteria for Psoriatic Arthritis (CASPAR). SpA pts were from a Belgian observational cohort (Be-Giant) of SpA pts fulfilling the ASAS SpA classification criteria. Radiographs of the spine were obtained at baseline and after 2 years. Two calibrated readers evaluated radiographic damage by assessing modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Readers were blinded for time sequence, clinical data and information from other obtained images (radiographs of hands, feet, sacroiliac joints). Consensus scores are described.

Results: In total 461 pts were included in BEPAS. Mean age was 52.79±12.29 years and 43.0% (n=198) were female; average disease duration was 8.5 ± 9.3 years and approximately 34% of the pts reported inflammatory axial pain. From 312 pts spinal radiographs were obtained. At baseline, the vast majority of PsA pts had an mSASSS of 0 (n=273, 87.5%), according to both readers. In 33 PsA pts (10.6%) mSASSS was 2 or more. For the SpA pts percentages were lower but the trend was similar (see Figure 1). Though lesser pts showed abnormalities, the SpA pts with spinal damage show a higher mSASSS, therefore indicating more spinal damage than the PsA pts (p<0.05). Both patient groups show some outliers with high mSASSS, increasing the average mSASSS especially in the SpA cohort (mean mSASSS = 9.1±4.11) compared to the median of 3 (IQR 2-6) in both cohorts. Synodesmophytes are seen in 10.6% and 6.2% of the PsA and SpA pts, respectively. Similar to the mSASSS, SpA pts had more syndesmophyse (mean: 4.4±5.50) compared to PsA pts (mean 2.0±1.45); p<0.05. PsA pts had more often syndesmophytes located in the cervical spine (24/35, 68.6%) compared to the SpA patient group (9/21, 42.9%); p<0.05. Erosions and especially sclerosis and squaring are uncommon in both patient groups.

Conclusion: Spinal damage is seen in approximately 10% or less of both PsA and SpA pts in these cohorts. SpA pts show higher mSASSS values and more syndesmophytes as compared to PsA pts. Syndesmophytes in PsA pts are more often located in the cervical spine while the location is more equally distributed in SpA pts.

Acknowledgements: The BEPAS study has been supported by MSD Belgium, with noteworthy mentioning of Hermine Leroi.

Figure 1. Chances of REM/LDA achievement in pts with ≥2 comorbidities compared to pts with 1 comorbidity and pts without comorbidities.
Background: Obesity is over-represented in patients with psoriatic arthritis (PsA) and associated with increased disease activity. We have previously shown that weight loss treatment with Very Low Energy Diet (VLED) in patients with PsA and obesity was associated with a substantial weight reduction and significant improvement of the disease activity in joints, entheses and skin during 24 months follow-up. A side effect with a large weight loss is however a concomitant reduction of muscle mass, which can negatively affect physical fitness.

Objectives: This study aimed to evaluate the effects of weight loss treatment on physical fitness i.e., muscle strength, cardiorespiratory fitness, body composition and self-reported physical functioning, in patients with PsA and obesity compared to matched controls undergoing the same treatment.

Methods: In total, 46 patients with PsA (Caspar criteria) and obesity and 52 controls (matched for age, sex, body weight and height) were included. VLED (640 kcal/day) was provided to all participants for 12-16 weeks depending on baseline BMI (<40 or ≥40 kg/m²), followed by reintroduction of energy restricted diet. Brief support for physical activity was given. Primary outcome was muscle strength, assessed in hand-grip with a dynamometer (Grippit) and in leg muscle by measuring the time (seconds) needed to stand up ten times from a stand. Secondary outcomes were cardiorespiratory fitness (O₂ l/min), measured with the Åstrand's submaximal bicycle test, body composition analyzed with dual energy x-ray absorptiometry and physical functioning, assessed with the Short Form 36 Health Survey Physical Component Score (SF-36PCS). Outcomes were evaluated at baseline (BL), six (M6) and 12 months (M12).

Results: In total, 41 PsA patients (median age 54; 63% women) and 42 controls (median age 54; 74% women) completed the treatment. At M6 the median weight loss since baseline in patients and controls was 18.9 kg and 23.0 kg respectively (p<0.001), and at M12 16.1 kg and 16.6 kg (p=0.885). Significant changes (all p<0.001) were seen at M2 in the body composition of both patients and controls, with decreases in total fat mass (-30.1% vs. -27.4%), total lean mass (-7.0% vs -8.3%), lean arm mass (-13.7% vs -2.4%) and lean leg mass (-6.0% vs -8.6%). Leg muscle strength did however improve in both patients and controls at M6 (p<0.001) and remained improved at M12 (p=0.001 and p<0.001), while hand-grip strength was unchanged in both groups. Cardiorespiratory fitness increased in controls at M6 (p=0.018) and M12 (p=0.028), but not in the patients. Physical functioning improved in both groups at M6 and remained improved at M12.

Conclusion: Patients with PsA and obesity can benefit from weight loss treatment without risk of deterioration in muscle strength. However, muscle strength and cardiorespiratory fitness were below suggested normative values for the majority of the patients at all timepoints, implying that more structured exercise strategies might be warranted to counteract physical fitness deficiencies in patients with PsA undergoing weight loss treatment.

EFFECT OF DISEASE MODIFYING ANTI-RHEUMATIC DRUGS ON DEPRESSION IN PATIENTS WITH PSORIATICS ARTHRITIS IN A LONGITUDINAL COHORT

A. J. Mathew, M. Sutton, D. Pereira, D. D. Gladman, V. Chander. 1Christian Medical College, Department of Clinical Immunology and Rheumatology, Vellore, India; 2Centre for Prognosis Studies in the Rheumatic Diseases, Psoriatic Arthritis Program, Schroeder Arthritis Institute, Krembil Research Institute, University Health Network, Division of Rheumatology, Department of Medicine, University of Toronto, Toronto, Canada; 3Schroeder Arthritis Institute, Krembil Research Institute, University Health Network, Division of Rheumatology, Department of Medicine, University of Toronto, Toronto, Canada

Background: Depression, and its improvement with disease modifying anti-rheumatic drugs (DMARDs) is understudied in psoriatic arthritis (PsA).

Objectives: To determine the effectiveness of DMARDs on depression in PsA patients.

Methods: Patients enrolled from January 2000 to May 2020 in a large PsA cohort were included. Depression was defined as medical outcomes study short form-36 (SF-36) mental component summary score (MCS) ≤ 40 or mental health (MH) subscale score ≤ 50. Primary outcome was resolution of depression within 1 year of DMARDs, defined by two definitions: 1) MCS > 40 and/or MH subscale score of > 56; 2) Increase in MCS by 2.5 and MH subscale score by 5, the minimal clinically important difference (MCID). Baseline medications [non-steroidal anti-inflammatory drugs (NSAIDs) and/ or conventional or targeted (c/t) DMARDs] were recorded for all patients and stratified into 3 mutually exclusive ordinal categories: I-No treatment/NSAIDs; II-cDMARDs±NSAIDs without tDMARDs; III-tDMARDs±cDMARDs/NSAIDs. Univariable and multivariable logistic regression models were created to determine the association between medications and resolution of depression, after controlling for age, sex, disease duration and baseline MCS/MH subscale score.

Results: Based on the MCS and MH subscale score definitions, 608 (48%) and 655 (52%) of the 1270 patients, respectively were depressed at baseline. 374 (50.8% males) and 399 (52.4% males) patients were followed up in the groups defined by MCS and MH subscales, respectively for 1 year. Patients in both groups had comparable body mass indices, baseline psoriasis area and severity index and active joint count. Mean MCS and MN subscale scores (standard deviation) were 33.2 (5.2) and 46.0 (10.2). A mean of 11.9 and 11.7 months was noted for resolution of depression in the MCS based analysis and MH subscale-based analysis groups, respectively. More patients achieved resolution of depression based on definition 2 (MCS, 64.7%; MH, 62.2%) as compared to definition 1 (MCS, 54.5%; MH, 53.9). The proportion of patients on each category of medications in both models is shown in the Figure 1. Table 1 depicts the univariate and multivariable regression results by both the definitions of primary outcome in the MH subscales model. The global p-value for medication categories showed a trend towards significance in both models using definition 2. There was a trend towards higher likelihood of response when comparing patients in treatment category III vs category I. A significant response was noted when comparing patients in category III with category II as reference (OR 1.71; 95% CI 1.05-2.76; p=0.03). No significant effect of treatment category on depression was noted using definition 1.

![Figure 1. Patients in each drug category.](image-url)

Conclusion: In an observational setting, resolution of depression occurs in majority of patients with PsA within 1 year. Patients on t-DMARDs may experience better improvement in depression compared to other treatments. Future effectiveness studies warrant better definitions of depression and treatment response.

Disclosure of Interests: Ashish Jacob Mathew Speakers bureau: Novartis, IPCA Laboratories, Grant/research support from: Novartis, IPCA
Background: Psoriasis (PsO) is one of the most common chronic inflammatory skin diseases in Europe. Psoriatic arthritis (PsA) is closely associated to PsO and up to 40% of PsO patients develop PsA. The transition from PsO to PsA includes different stages with unspecific clinical symptoms such as fatigue or musculoskeletal (MSK) symptoms as well as changes in synovial vascularization combined with increased expression of proangiogenic factors [1]. Fluorescence-optical imaging (FOI, KiraLITE) is an easy-to-use method to detect changes in microvascularisation of the hands.

Objectives: To compare findings from FOI assessment to clinical examination (SJC/TJC) and musculoskeletal ultrasound in patients (MSUS) with non-specific MSK-symptoms and changes in microvascularisation without evidence of clinical active PsA.

Methods: The German multicentre observational XCITING study recruited patients with dermatological confirmed PsO at risk for development of PsA (either nail psoriasis or MSK symptoms such as joint pain or swelling within the last 6 months). Clinical examination (CE; swollen (66) and tender (68) joint count, enthesis, dactylitis assessment), standardized MSUS and FOI assessment were performed by a qualified rheumatologist at one time point with focus on the question of presence of PsA. Data were analyzed in focus on increased vascularization of MSK structures of both hands as marker of inflammation. The patients at-risk for PsA development but without clinically active PsA (CE negative, FOI positive) were analyzed. Results from CE of joints, MSUS and FOI assessment were compared.

Results: 391 PsO patients were recruited for the XCITING study in total. 108 patients (27.5%) were identified as at-risk population (CE negative, FOI positive). Baseline characteristics included a mean age of 51.4 years (SD 11.3), 61.1% female, mean BMI 27.8 kg/m2 (SD 5.2), mean age of onset PsO 30.4 years (SD 17), mean duration of PsO of 16.9 years (SD 14.4), mean PASI 4.3 (SD 5.8) and mean patient’s global disease activity for PsO of 24.4mm (SD 21.1). In 24.1% psoriasis plaques on the hand were documented. Pattern for frequency of scores in FOI, CE and MSUS in the dominant hand were compared (Figure 1).

Conclusion: FOI signals in the hands correlate to the findings of TJC (and B-Mode US) in the clinical examination indicating early stages of MSK inflammation that may result in active PsA development. FOI as standardized and easy-to-use technique might be a suitable tool for early detection of PsA in Psoriasis population. A follow up in these patients will reveal prediction values of the method.

Disclosure of Interests: Michaela Köhm Grant/research support from: Pfizer, Sarah Ohndorf: None declared, Xenofon Baraliakos: None declared, Konstantin Hallmann Grant/research support from: Pfizer, Susanne Kempinski: None declared, Ann Christina Foldenauer Grant/research support from: Pfizer, Tanja Rossmanith Grant/research support from: Pfizer, Ulf Henkemeier Grant/research support from: Pfizer, Frank Behrens Grant/research support from: Pfizer

Methods: A total of 136 subjects (49 patients with PsA, 46 patients with AS and 41 healthy controls) were included in the study. Subjects were evaluated with detailed anamnesis and physical examination. The routine biochemical parameters, CRP, ESR of all subjects and disease activity scores of all patients were noted. IL-12 and IL-23 were measured using ELISA method. Endothelial-dependent and independent dilatations were measured by Doppler USG on the brachial artery.

Results: Though IL-12 levels were higher in the PsA group when compared with the healthy group, this difference was not statistically significant. IL-23 levels were significantly higher in PsA patients when compared with the healthy control group (Table 1). IL-12 and IL-23 levels were found to be significantly higher in the AS group compared with the healthy group. A statistically significant difference in endothelial dependent measures were found between PsA patients and healthy controls. No statistically significant correlation was found between IL-12, IL-23 levels and brachial artery basal diameter, FMD, NMD values in PsA patients. Fasting blood glucose and triglyceride levels were higher in PsA patients, while CRP and ESR were higher in AS patients. HDL levels of healthy controls were higher than those of PsA and AS patients. There was no significant correlation between IL-12, IL-23 and BASDAI, BASFI, DAPSA, DAS 28, PsAQoL, HAQ, HAD-A, VAS scores in PsA group; hospital anxiety and depression scale (HAD) and BASMI were positively correlated with IL-23. In the AS group, IL-23 was correlated with VAS and BASMI and IL-12 was correlated with HAQ score.

Conclusion: In the PsA group, IL-23 levels and FMD values were higher than the healthy group in our study. The risk of metabolic syndrome and CVD increases due to high insidence of glucose dysregulation, dyslipidemia and obesity in these patients. PsA patients should be monitored for the development of these comorbidities and preventive measures should be taken. More studies are necessary to examine the relationship between IL-12, IL-23 levels and endothelial dysfunction, which is an early indicator of CVD and atherosclerosis in PsA patients.

Conclusion: This analysis of PsA patients in routine care at a European tertiary academic center showed that many patients are not on treatment target. Their presentation is oligoarticular, with moderate levels of pain and patient global assessments, but mostly normal or slightly elevated CRP levels. Despite the treat-to-target strategy and a large number of therapeutics, and overall good control of objective measures of disease activity, many patients in real life may potentially benefit from more intensive treatment escalation.

POS1097
BIOMARKERS OF INFLAMMATION AND JOINT TISSUE TURNOVER CAN HELP IMPROVING THE DIFFERENTIATION BETWEEN OSTEOARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS

S. S. Groen1,2, S. Holm Nielsen2,3, A. C. Bay-Jensen2, M. Rasti4, D. Ganatra4, K. Oikonomopoulou4, V. Chandran5, K. Nord, Biomedical Sciences, Copenhagen, Denmark; 2Nordic Bioscience, Immunoscience, Herlev, Denmark; 3Technical University of Denmark, Biotechnology and Biomedicine, Kgs. Lyngby, Denmark; 4Krebbl Research Institute, Schroeder Arthritis Institute, Toronto, Canada; 5Institute of Medical Science, Department of Medicine, Division of Rheumatology, Department of Laboratory Medicine and Pathobiology, Toronto, Canada

Background: Osteoarthritis (OA) is a slow progressive disease characterized by degeneration within the joint cartilage, leading to destruction and dysfunction of the involved joints. Psoriatic arthritis (PsA) is a chronic inflammatory disease manifesting itself in skin lesions and progressive inflammatory changes within the musculoskeletal system, leading to joint damage and functional limitation. Although OA and PsA are considered to be distinct diseases, they share overlapping clinical and inflammatory features that can cause diagnostic challenges. Throughout these inflammatory and degenerative processes in the joint tissues, proteases hold a major role in remodelling of the extracellular matrix (ECM) which results in protein breakdown products released into the synovial fluid (SF). These protein fragments can be quantified in SF as biomarkers of tissue remodelling and may be helpful in characterizing disease-specific or overlapping pathologies between OA and PsA.

Objectives: Our aim of this study is to measure biomarkers of inflammation and joint tissue turnover in SF to explore the distinct and overlapping pathologies between OA and PsA.

Methods: SF samples were collected from patients with OA (n=54, mean ±SD age 62.1 ±11.9, 48% female) and patients with PsA (n=59, mean ±SD age 47.8±13.3, 37% female) recruited through Toronto Western Hospital, Canada. Study was approved by the local ethics committee. Biomarkers of inflammation reflecting macrophage activity (VICM) and neutrophil activity (CPa9-HNE) were measured in the SF samples. Moreover, ECM remodelling was assessed in the SF samples by biomarkers quantifying type II collagen formation (PRO-C2), fibronectin turnover (FBN-C), and aggrecan degradation (ARGS). Data were log-transformed and presented as mean ± standard deviation (SD). An ANCOVA corrected for age was applied to test the difference between biomarker levels across the two patient groups and a p-value below 0.05 was considered significant. Area under the receiver operating characteristic (ROC) curve (AUC) analysis was performed to describe the discrimination accuracy of each biomarker between the two patient groups.

Results: PsA patients presented significantly higher levels of macrophage; VICM, activity compared to OA (p<0.001, Figure 1A). On the other hand, OA patients demonstrated increased type II collagen formation and aggrecan degradation compared to PsA (p<0.001, Figure 1C, E). Interestingly, no significant difference in biomarkers levels of neutrophil activity and fibronectin remodelling was observed between the two disease groups. Moreover, VICM, PRO-C2, and ARGS showed high distributional difference between OA and PsA patients with an AUROC=0.915 (p<0.001, Figure 1F), AUROC=0.737 (p<0.001, Figure 1G), and AUROC=0.725 (p<0.001, Figure 1H), respectively.

Conclusion: PsA patients demonstrated higher macrophage activity in the SF compared to the OA patients, while higher levels of cartilage formation and degradation were observed in OA patients compared to PsA. No differences between OA and PsA were observed in neutrophil activity and fibronectin turnover, which may mirror the clinical difficulty in telling the two arthritides apart. Identifying the unique characteristics of the pathological processes underlying the two diseases may improve diagnosis and allow for the precise management of both OA and PsA patients.
synovitis), thickening and hypoechochogenicity at enthesis, PD+ enthesitis, entheses with structural components. Enthesal findings were fixed according to consensus-based US definition and scoring for enthesitis in spondyloarthritis and PsA (OMERACT US).2

**Results:** In all 92 patients: male - 42 (45.7%), mean age was 42.9±9.6 (SD) years (y), PsA duration was 7 (2; 11.8) y. Disease Activity in PsA score was 15.2 (10.2; 21.4). Thus, the impact of psoriasis on the quality of life of patients with PsA was revealed. DLQI scores correlated with skin psoriasis activity and nail onychodystrophy, as well as clinical enthesitis (p<0.01). Minimal (67.4%) and moderate (29.3%) disability levels were found. HAQ-DI scores were associated with higher PsA activity and duration, age and clinical enthesitis (p<0.01). Physical and mental health (SF-36) correlated with Disease Activity in PsA and clinical enthesitis (p<0.05). Fatigue was found in 50% of patients and increased with PsA activity and duration, and clinical enthesitis (p<0.01). US data showed no association with QoL in PsA (p>0.05).

**Conclusion:** QoL scores of this study were related to clinical data, particularly to clinical enthesitis. Us articular and enthesal inflammation were not correlated with QoL scores. This is probably due to the subclinical course of US changes. This allows us to conclude that QoL is associated with clinical than with US characteristics in PsA.

**POS1099 QUALITY OF LIFE, WORK IMPAIRMENT, AND DAILY ACTIVITY IMPAIRMENT OF PATIENTS WITH PSORIASIS VS PSORIATIC ARTHRITIS: A REAL-WORLD SURVEY IN US AND EUROPE**

**J. F. Merola1, L. E. Kristensen2, F. Yang3, S. Peterson2, R. Teneralli2, N. Massey2, S. D. Chakravarty4, M. Hughes2, M. Shawi5, S. Weatherby5, C. Contre2, I. Lin6, F. Hassan7, M. E. Husni8, Bringham and Women’s Hospital, Harvard Medical School, Boston, United States of America; 2The Parker Institute Bispebjerg-Frederiksberg Hospital, and Copenhagen University, Department of Health Sciences, Copenhagen, Denmark; 3Janssen Global Services, LLC, Horsham, United States of America; 4Adelphi Real World, Bollingtin, United Kingdom; 5Janssen Scientific Affairs, LLC, Horsham, United States of America; 6Drexel University College of Medicine, Philadelphia, United States of America; 7Janssen-Cilag France, LLC, Issy les Moulineaux, France; 8Janssen Pharmaceuticals, LLC, Horsham, United States of America; 9Janssen-Cilag LTD, High Wycombe, United Kingdom; 10Cleveland Clinic, Cleveland, United States of America

**Background:** Psoriasis (PsO) and psoriatic arthritis (PsA) and are chronic immune-mediated diseases characterised by joint inflammation and skin lesions which negatively impact patients’ health-related quality of life (HRQoL). Several previous comparative studies have focused on PsA patients with or without skin involvement. Better understanding of the impact of both PsO and PsA on HRQoL and work / activity impairment will improve understanding of the incremental burden of PsA compared to PsO, and may lead to more personalised treatment options.

**Objectives:** To compare HRQoL, work impairment, and daily activity impairment of patients with a PsO diagnosis (dx) only, PsO dx with musculoskeletal (MSK) symptoms (sx), PsA dx with active skin sx, and PsA dx without active skin sx.

**Methods:** Data were drawn from the Adelphi PsO & PsA Disease Specific Programmes (DSP), real-world point-in-time surveys of rheumatologists, dermatologists and their consulting patients in the United States and Europe (France, Germany, Italy, Spain and UK); conducted in 2018/19. Patients were grouped according to their symptoms and confirmed diagnoses, comprising four groups:

1. Patients with PsO dx only,
2. Patients with PsO dx and with MSK sx,
3. Patients with PsA dx and with active skin sx,
4. Patients with PsA dx with no active skin sx.

Multivariate linear regression analyses with marginal mean predictions examined differences in patient-reported outcome measures (PROMs) between the four groups. Measures included HRQoL (EuroQol 5-Dimension 5-Level [EQ-5D utility] and EuroQol Visual Analogue Scale [EQ-VAS]), work impairment, and daily activity impairment (Work Productivity and Activity Impairment Questionnaire [WPAI]). Analyses controlled for demographics (age, sex, BMI), comorbidities present in >10% of patients and current treatment class (biologics, csDMARDs, steroids & other).

**Results:** 4491 patients were included: Group 1 (n=1833), Group 2 (n=91), Group 3 (n=2451), and Group 4 (n=116). 54% of patients were male, 89% of patients were white, with a mean age of 46.6 years. Demographics were consistent across all patient groups.

The model-predicted EQ-5D-Utility was lower in Groups 2, 3 and 4, compared with Group 1 (p<0.003, p<0.001 and p=0.004 respectively). Similarly, predicted EQ-VAS was lower in Group 3 compared with Group 1 (p<0.006).

**Table 1. Predictions of PROMs for PsO-PsA patient groups**

*p values provided for reference, but margins are predictions as a result of the model and not for the specific number of patients in each subgroup.

(1) Patients with PsO dx only
(2) Patients with PsO dx and MSK sx
(3) Patients with PsA dx and with active skin sx
(4) Patients with PsA dx with no active skin sx

Overall work impairment increased in Groups 3 and 4, compared with Group 1 (p<0.001 and p=0.014 respectively). Furthermore, Groups 3 and 4 missed more work compared with Group 1 (p=0.002 and p=0.003 respectively). Group 3 patients exhibited an increase in presenteeism and activity impairment compared with Group 1 (p<0.001).

**Conclusion:** Patients experiencing PsA dx or MSK sx experienced an additional disease burden compared to patients with PsO dx alone, as measured by worse HRQoL and work impairment.

PSYCHOMETRIC PROPERTIES OF PATIENT GLOBAL ASSESSMENT IN THE EVALUATION OF PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

F. Chessa 1, M. Piga 1, A. Fiori 1, M. Congia 1, M. M. Angioni 1, A. Cauli 1

1 Rheumatology Unit - University and AOU of Cagliari, Public Health and Medical Sciences, Monserrato, Italy

Background: Recommendations emphasize the need for the physician to work in partnership with the patient and a shared decision-making process is nowadays fundamental to manage properly Psoriatic Arthritis (PsA). Patient Global Assessment (PtGA) is a score that reflects the patient’s judgment about the disease activity and is getting more used in clinical routine and research.

Objectives: The objective of this systematic literature review (SLR) is to analyze the role of PtGA in PsA and to describe its psychometric properties.

Methods: This SLR was conducted by two independent reviewers in accordance with the PRISMA statement, searching for articles reporting on the use of PtGA in PsA. All articles published until February 2021 in Pubmed were screened with no limitation about years of publication, language or patients’ age. Articles reporting data of PtGA of skin assessment were excluded. Psychometric properties data were analysed according to the OMERACT (Outcome Measures in Rheumatology) Filter methodology version 2.1. Measurement properties of the PtGA were analysed according to the COSMIN terminology.

Results: The literature search identified 45 studies, accounting for 8516 patients in 20 longitudinal cohort studies, 15 cross-sectional studies, 5 randomized controlled trials, 2 post-hoc analyses, 1 retrospective study and one review. Ten articles were excluded because PtGA was referred to the assessment of cutaneous psoriasis. Content validity was reported in 32 studies. Different definitions, acronyms, scales and questions to assess PtGA were retrieved from the literature (see Table 1).

Table 1. Different questions, definitions, acronyms, scales and scores used to assess Patient Global Assessment retrieved. STD: studies

</table>

DEFINITIONS
- Pt visual analogue scale (VAS) for pain and global assessment
- Pt general disease assessment
- Pt global activity
- Pt global assessment
- Pt global disease activity
- Pt opinion on the level of disease activity
- Pt global evaluations
- Pt perception of disease
- Pt disease severity

ACRONYMS
- PtGA: Patient’s global assessment
- PGA: Patient’s global assessment
- PaGA: Patient’s global assessment

SCALES
- VAS (23 std); NRS (12 std)

SCORES
- 0-100 (23 std); 0-10 (11 std); 0-5 (5 std)

Face validity was reported in all the articles retrieved. PtGA was always used together with other instruments, alone or as part of composite indices: supporting its face validity. In 2 studies it was considered the instrument of reference to assess the outcome. A good correlation with PtGA, DAS28, BASDAI, ASDAS and DAPSA was found (see Figure 1). One study showed that the correlation became better (ES 1.81, 95%CI 1.42 2.19) during the follow up assessment. Three studies analyzed the discordance between patient and physician global assessment and in 25.0-49.0% found a positive discordance (PtGA higher than PhGA). Criterion validity was assessed exploring the PtGA correlation with quality of life measurements, demographic characteristics, biomarkers levels, treatment changes and damage assessments in 11 studies. The intrarater reliability was calculated only in 1 study, with an optimal correlation (ICC=0.87; 95%CI 0.83–0.90). PtGA responsiveness was used to evaluate response to treatment in 14 studies.

Figure 1. Forest plot showing correlation between PtGA and other instruments

Conclusion: PtGA demonstrated to be valid and feasible, but more studies are necessary to confirm its reliability and to evaluate its sensitivity to change. In addition, a clear definition of what PtGA refers to, what time and what kind of scale to adopt should be standardized.

PSI1010
DAPSA CORRECTED FOR PSAID12 IMPROVES ITS CONCORDANCE WITH MINIMAL DISEASE ACTIVITY.

G. Gonzalez Arribas 1, C. L. Iñiguez 2, F. Macías-Pane 3, V. Quevedo Vila 4, L. Fernández-Dominguez 5, J. A. Mosquera Martínez 6, C. García-Porrúa 7, J. L. Guerra-Vazquez 8, J. A. Pinto Tasende 1 on behalf of GIGAPs. 1 Hospital Universitario de Coruña, Rheumatology, A Coruña, Spain; 2Hospital Lucus Augusti, Rheumatology, Lugo, Spain; 3Hospital do Meixoeiro, Rheumatology, Vigo, Spain; 4Hospital Comarcal de Montforte de Lemos, Rheumatology, Montforte de Lemos, Spain; 5Complexo Hospitalario Universitario de Ourense, Rheumatology, Ourense, Spain; 6Hospital Montecelo (Pontevedra), Rheumatology, Pontevedra, Spain; 7Hospital Arquitecto Marcide, Rheumatology, Ferrol, Spain; 8Hospital Universitario de Coruña, Rheumatology, INIBIC, A Coruña, Spain

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease of highly variable presentation, which determines a physical and psychological deterioration, with a negative impact on the quality of life of patients and knowing the patient’s perception of their health status is very important for a good management of PsA.

Objectives: To assess an adjustment of the DAPSA according to the status of the PsAID-12 (impact of the disease in psoriatic arthritis) and to analyze its relation in clinical practice with the minimal activity of the disease (Minimal Disease Activity or MDA) in psoriatic arthritis.

Methods: Multicenter cross-sectional study, which recruited 200 patients, who met the criteria for Classification of Psoriatic Arthritis (CASPAR), in six Spanish rheumatology centers. At the time of the visit, demographic, clinical, laboratory data, HAQ (0–3) and PsAID12 (0–10) self-questionnaires were collected. Disease activity was measured using DAPSA (with its cut-off points), MDA status was obtained, and the PsAID12 index was calculated. When a PsAID4 was not reached, the DAPSA was scaled to a higher interval (DAPSA corrected) obtaining a new index, DAPSA-PsAID. All analyzes were performed using SPSS23 software. Differences were considered statistically significant if p < 0.05.

Results: Of the total number of patients, 55% were men, with an age of 55.2 ± 11.6 years; 75% had only peripheral involvement and 25% had pure or mixed axial involvement. 43% were on biological treatment and 27.6% vs 27.6% (Kappa 0.750 vs 0.688). In the binary regression analysis for MDA status, adjusted for sex, an OR (95% CI) for DAPSA, and DAPSA corrected for PsAID of 8.12 (1.88-35.04) and 12.31 (3.74-40.50), respectively, was obtained.

Figure 1. Forest plot showing correlation between PtGA and other instruments
THE PREVALENCE OF INFLAMMATORY BACK PAIN IN PATIENTS WITH SKIN PSORIASIS WITHOUT PSORIATIC ARTHRITIS. DATA FROM DERMATOLOGICAL REAL-WORLD SETTING.

N. Pereverzina1, L. Kruglova1, T. Korotaeva2, A. Lila3.
1Central State Medical Academy of the Administrative Department of the President of Russia, Department of Dermatology and Cosmetology, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritides and Psoriatic-Arthritis, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation

Background: Psoriasis (PsO) is an inflammatory disease associated with psoriatic arthritis (PsA). PsA affects peripheral and axial joints1. Psoriasis can precede the onset of PsA by approximately 3 to 8 years, axial involvement often undiagnosed.2 There are limited data about the prevalence of inflammatory back pain (IBP) in PsO patients (pts) without clinical symptoms of PsA.3

Methods: A PsAID-corrected DAPSA could be a more reliable alternative to DAPSA than conventional DAPSA and facilitate clinician decisions in daily practice.

POS1102

"WHAT MATTERS": PATIENT AND CLINICIAN PERSPECTIVES IN PSORIATIC ARTHRITIS CARE

P. J. Mease1, D. Furst2, E. Siegel3, V. Strand4, M. McIlraith5, M. E. Husni6, M. C. Hay1, 2Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, Washington, United States of America; 3University of California Medical Center, Rheumatology, Los Angeles, California, United States of America; 4Stanford University, Immunology and Rheumatology, Palo Alto, California, United States of America; 5McM Consulting, Research, Dallas, United States of America; 6Cleveland Clinic, Rheumatologic and Immunologic Disease, Cleveland, Ohio, United States of America; 7Miami University, Anthropology, Oxford, Ohio, United States of America

Background: Recent psoriatic arthritis (PsA) treatment recommendations (1) highlight the importance of shared decision making; this ideally requires the clinician understands "what matters" to each patient regarding their disease. Concurrently, patient research partners have been incorporated into projects for the OMERACT core domain set (2) and measures of physical function and (health related) quality of life (3). Currently, less is known about the similarities and differences between patient and clinician perspectives.

Objectives: To interrogate and delineate commonalities and discrepancies in "what matters" to patients and to physicians in routine clinical care.

Methods: A comprehensive list of items describing the PsA patient experience was generated in medical anthropologist-designed (CH) peer-to-peer discussions in 4 patient focus groups across the United States (Seattle, Cleveland, Washington, NC). These items were combined with those from the GRAPPA-OMERACT PsA Outcomes patient-physician consensus project (2). A PsA physician and patient steering committee reviewed and revised the list with additional topics deemed to be of importance. The final list of 51 items went through a 3 round Delphi process starting with 53 PsA patients and a 2 round Delphi with 13 PsA expert rheumatologists. In each round, participants rated each item for level of importance out of 100 total points.

Results: Top priority items for each group are depicted in Figure 1. Both patients and physicians rated Arthritis -Joint pain and swelling in the top two. Five additional items were included for both groups but with different scores; all related to disease manifestations or physical consequences. Several items received disparate priority between groups. In this set, patients included two unique items: access to care and future health uncertainty. Other items affecting everyday function were noted. Physician priorities included specific disease manifestations and physical/functional outcomes, and the topic of "disease management goals," focusing on patient-physician communication regarding a treatment plan.

Figure 1. Top Patient and Physician Priorities *Not in set of highest ranked items for that group

POS1103

as enthesis, dactylitis, and skin disease more highly, patients considered items such as access to care, future health uncertainty and sleep quality to be most important. This study highlights the need for physicians to ask and address 'what matters' with patients and educate patients about potential differences in physicians' areas of concern to optimize shared decision making.

Two ultrasound measurements of the patellar and the Achilles long axis were performed. Also, two elastographies of the same tendons and two anthropometric measurements of the thigh and calf were made at the beginning and end of the training period. To demonstrate sensitivity to change, a correlation was made between the ultrasound, elastographic and anthropometric morphological changes, and the result of the computer analysis of the image in terms of gray scale mean and mode.

Results: 19 volunteers were evaluated (mean age 24 ±2 years, 12 women). After the exercise routine, we found statistically significant differences between calf perimeter (mean -3.70 ±1.803; p .000), Achilles elastography (-.347 ±.294; p .000), Achilles and patellar MGI (4.229 ±4.849; p .001 and 2.331 ±3.115; p.004).

Regarding the non-normal distributed variables, we met statistically significant differences between patellar elastography (average range 11.45, sum of the ranks 126.00; Z -2.343; p.019), Achilles and patellar grey intensity modes (average 12.92, sum 168.00; Z -2.938; p.003 and average 11.77 sum 176.50; Z -3.28; p.001). The correlations study is shown in Table 1.

Figure 1. Before (upper) and after (lower) evaluation.

Conclusion: Computer analysis of static images of the Achilles and patellar tendons is sensitive to the change induced by exercise in young and healthy subjects. The mean gray intensity correlates better with elastography. This shows that the predominance of the fibrillar pattern induced by exercise produces a higher speed of sound conduction. The gray intensity mode correlates better with the anthropometric changes experienced by the subjects. The concentration of shades in white extremes translates into greater anthropometric changes. This demonstrates that the stiffness or elasticity of a tendon correlates with the global distribution of gray. The response to mechanical stimuli correlates with the concentration of more intense white tones that are not necessarily scattered (endophytes or pre-enthesophytes).

Efficacy and Safety of Colchicine for the Treatment of Osteoarthritis: A Systematic Review and Meta-Analysis of Intervention Trials

A. Singh1, P. Molina-García1,2, S. Hussain3, A. Paul4, S. K. Das5, Y. Leung6, J. Samuels7, B. Antony1, Menzies Institute for Medical Research, Musculoskeletal Health and Disease, Hobart, Australia; 2Virgen de las Nieves University Hospital, Granada, Spain, BioHealth Research Institute (ibs.Granada) Physical Medicine and Rehabilitation Service, Granada, Spain; 3University of Granada, Granada, Spain, PROFITH (PROmoting FITness and Health through physical activity) Research Group, Department of Physical Education and Sports, Faculty of Sport Sciences, Granada, Spain; 4Masaryk University, Brno, Czech Republic, Czech National Centre for Evidence-Based Healthcare and Knowledge Translation (Cochrane Czech Republic, Czech EBHC; JBI Centre of Excellence, Masaryk University GRADE Centre), Institute of Biostatistics and Analyses, Faculty of Medicine, Brno, Czech Republic; 5University of Tasmania, School of Pharmacy and Pharmacology, Hobart, Australia; 6Era’s University, Lucknow, India, Department of Rheumatology, Lucknow, India; 7Singapore General Hospital, Singapore, Department of Rheumatology and Immunology, Singapore, Singapore; 8NYU Grossman School of Medicine, New York, New York, USA, Department of Medicine, Division of Rheumatology, New York, United States of America; 9University of Tasmania, Hobart, Tasmania, Australia, Menzies Institute for Medical Research, Hobart, Australia

Background: Colchicine, an approved treatment for gout, has been trialled in many diseases, including osteoarthritis (OA), due to its anti-inflammatory effects. However, its efficacy and safety remain unclear in OA.

Objectives: This systematic review and meta-analysis evaluated the efficacy and safety of colchicine for the treatment of OA.

Methods: PubMed, Web of Science, Scopus, and Cochrane Central were searched from inception through November 2020. Two reviewers independently screened for randomised controlled trials (RCTs) comparing colchicine with placebo or other active-comparators for the treatment of OA (knee, hand, or hip OA), extracted data, and performed Cochrane risk of bias assessments.

Results: The search retrieved 391 articles after removing duplicates, and 16 full-text articles were reviewed for eligibility (Figure 1A). Ten RCTs, nine in knee OA, one in hand OA, consisting of 847 patients (429 in colchicine arm, 409 in control arm) were included. RCTs were conducted between 2002 and 2021; three in India, two in Iran and Turkey, and one each in Australia, Singapore, and Iraq; follow-up period ranged 2 to 12 months. Moderate-quality evidence showed no clinically important pain reduction with colchicine compared to placebo. Knee OA patients (standardised mean difference (SMD) 0.17; 95% confidence interval (CI). -0.55 to 0.22) (Figure 1B), Moderate-quality evidence showed no improvement in dysfunction with colchicine compared to placebo in knee OA patients (SMD, -0.37; 95% CI, -0.87 to 0.13). Colchicine showed an acceptable safety profile with AEs/SAEs comparable to placebo (Figure 1C).

Conclusion: Current evidence does not conclusively suggest a benefit of colchicine in reducing pain and improving physical function in hand/knee OA patients. Future trials should focus on the sub-groups of OA patients with local or systemic evidence of inflammation and/or mineralisation who may benefit from colchicine.

Mediators of the Effect of Therapeutic Exercise on Pain and Function in Patients with Knee and Hip Osteoarthritis: An Individual Patient Data MEDIATION STUDY FROM THE OA TRIAL BANK.

J. Runhaar1, M. Holden2, M. Hattie3, J. Quicke2, R. Riley2, E. Healey2, D. Van der Windt2, K. Dziedzic2, M. Van Middelkoop1, S. M. A. Bierna-Zeinastra3, N. Foster4on behalf of the OA Trial Bank Exercise Collaborative. 1Erasmus MC University Medical Center Rotterdam, General Practice, Rotterdam, Netherlands; 2Keele University, Primary Care Centre Versus Arthritis, School of Medicine, Keele, United Kingdom; 3Erasmus MC University Medical Center Rotterdam, General Practice and Orthopedics & Sports Medicine, Rotterdam, Netherlands; 4The University of Queensland and Metro North Health, STARS Education and Research Alliance, Surgical Treatment and Rehabilitation Service, Brisbane, Australia

Background: Currently, there is no cure for osteoarthritis (OA). Therapeutic exercise is recommended in all international guidelines to improve pain and function (1). However, randomised controlled trials (RCTs) investigating therapeutic exercise showed that, on average, effect sizes are small to moderate compared to non-exercise controls (2-3). Better knowledge about how therapeutic exercise works to improve pain and function could help improve the design and delivery of future therapeutic exercise interventions and potentially improve patient outcomes.

Objectives: To evaluate the mediating effects of 1) muscle strength, proprioception, and range of motion (ROM) among patients with knee OA, and 2) muscle strength among patients with hip OA, using the procedures established for Individual Participant Data (IPD) analyses by the OA Trial Bank.

Methods: Relevant IPD were sought from all published RCTs comparing therapeutic exercise to a non-exercise control group among people with knee and/or hip OA, using previously published methods (4). For each potential mediator separately, the effect of exercise on the absolute change in pain/function directly after the intervention was determined, controlling for the relative change in mediator under investigation and potential mediator-outcome confounders, using the counterfactual framework (5). Next, the effect of exercise on the relative change in the mediator was determined. The percentage mediated was calculated by dividing the natural indirect effect by the total effect.

Results: We obtained IPD from 12 RCTs and 1407 participants (knee OA = 1113; hip OA = 294) that were eligible for inclusion in one or more mediation analyses. Therapeutic exercise showed a significant effect on the relative change in muscle strength in hip OA of all mediators, only the change in muscle strength had a significant effect on the change in pain in knee OA, and on function in knee OA and in hip OA. The percentage mediated for each mediator and each outcome was small (5.3% or less, see Table 1).

Table 1. Percentage mediated for all potential mediators, by outcome and joint.

*absent*: no percentage mediated calculated, since direct and indirect effect had opposite directions; † factors not considered a potential mediator for therapeutic exercise in hip OA.

Conclusion: In the first IPD mediation analysis to our knowledge of this scale, muscle strength, proprioception and ROM did mediate the effect of therapeutic exercise for pain and function in knee OA, but only to a very small degree. We observed no such mediating effect of muscle strength for therapeutic exercise in patients with hip OA. The challenge remains to better understand the key mechanisms of action of therapeutic exercise for knee and hip OA, so that exercise interventions can be designed and delivered to target these and therewith optimise the effects for patients.

REFERENCES:
Persons (BMI ≥ 27 kg/m²) with KOA. Weight loss was induced by an intensive low-calorie weight loss intervention in overweight persons with KOA.

Objectives:

Changes in US-based synovitis following a weight loss intervention. After the diet intervention mean weight change was -12.8 kg of 106.0 kg (SD18.5) and mean BMI of 36.4 (SD5.4) completed the weight loss intervention (1200 kcal/day). Participants had symptomatic and radiographic KOA (KL grade 1-3). At week 0 and 8 all participants filled in the KOOS questionnaire assessing pain, physical function, symptoms, quality of life, and sport/recreation in relation to KOA (0= worst; 100=best). Furthermore, an US examination of the most affected knee was performed assessing the amount of synovial hypertrophy (SH) and effusion in medial and lateral recesses. The US examination was performed in a strictly standardized manner.

Results:

Change in the KOOS subscales range from 15.8 (sports/recreation) to 7.4 (QoL). See Table 1.

</tbody>
</table>

Conclusion: Quantitative measures of SH assessed by US decreased after a significant weight loss over 8-weeks; however, no linear association with weight loss magnitude was seen. A weak correlation between changes in SH in the lateral recess and change in pain was seen. This indicates changes in SH assessed by US examination is associated with a low-calorie diet but seems uncoupled with weight loss magnitude. The weight loss induced changes in synovitis and KOA symptoms seem vaguely related.

CHANGE IN ULTRASOUND-BASED KNEE JOINT INFLAMMATORY MARKERS AFTER WEIGHT LOSS IN PATIENTS WITH OSTEOARTHRITIS: A PROSPECTIVE COHORT STUDY.

K. Ellegaard1, J. Guldberg-Meller1, M. Boesen2, L. E. Kristensen3, H. Gudbergsen1, L. Jensen1, A. Overgaard1, H. Bliddal1, M. Henriksen1.

1Bispebjerg and Frederiksberg Hospital, The Parker Institute, Frederiksberg, Denmark; 2Bispebjerg and Frederiksberg Hospital, Department of Radiology, Copenhagen, Denmark; 3Bispebjerg and Frederiksberg Hospital, The Parker Institute, Frederiksberg, Denmark

Background: Pain and impaired function due to knee OA (KOA) can be reduced with weight loss in obese patients. The role of synovitis in symptom improvement after weight loss is not fully understood. MRI and ultrasound (US) can be used in assessment of inflammation in the KOA. Knee joint synovitis assessed by MRI does not seem to change with weight loss, however, the typical MRI score is semiquantitative, which might be less sensitive to change than a quantitative score. US has a higher resolution than MRI and borders between synovium and surrounding tissues might be clearer allowing for a quantitative score. Changes in US-based synovitis following a weight loss has not been assessed.

Objectives: To assess changes in US synovitis in the knee joint after 8 weeks low-calorie weight loss intervention in overweight persons with KOA.

Methods: Prospective cohort study (NTC02931370) including overweight persons (BMI ≥ 27 kg/m²) with KOA. Weight loss was induced by an intensive 8-week diet (1200 kcal/day), participants had symptomatic and radiographically confirmed KOA (KL grade 1-3). At week 0 and 8 all participants filled in the KOOS questionnaire assessing pain, physical function, symptoms, quality of life, and sport/recreation in relation to KOA (0= worst; 100=best). Furthermore, an US examination of the most affected knee was performed assessing the amount of synovial hypertrophy (SH) and effusion in medial and lateral recesses. The US examination was performed in a strictly standardized manner on a high-end US machine. The subsequent image evaluation was done both according to a semiquantitative score from 0 to 3 (0= no SH/effusion and 3= pronounced SH/effusion) and a quantitative scoring system using specific anatomic landmarks to measure the synovial hypertrophy/effusion in millimeter. Statistical analyses were performed on the per protocol population (participants completing diet intervention).

Results: 135 patients with KOA with a mean age of 60y (SD 9.8), a body weight of 106.0 kg (SD18.5) and mean BMI of 36.4 (SD5.4) completed the weight loss intervention. After the diet intervention mean weight change was -12.8 kg (95%CI: -13.3 to -12.4) and the reductions in SH were -0.3 mm (95%CI: -0.5 to -0.1) (medial recess) and -0.4 mm (95%CI: -0.6 to -0.1) (lateral recess), and -0.03 (-0.13 to 0.07) (medial recess) and -0.07 (-0.20 to 0.05) using the semi-quantitative system. The mean change in the KOOS subscales range from 15.8 (sports/recreation) to 7.4 (QoL). See Table 1.

USE OF MACHINE LEARNING IN OSTEOARTHRITIS RESEARCH: A SYSTEMATIC LITERATURE REVIEW

M. Birvogn1, V. Pedia1, A. Butte1, K. Louati1, D. Klatzmann2, F. Berenbaum1, E. Mariotti-Ferrandiz2, J. Sellam1, Sboronne Universite, Rheumatology, Paris, France; 3Sorbonne Universite, I3 lab (Immunology Immunopathology Immunotherapy), Paris, France; 4UCSF, Bakar Computational Health Science Institute, San Francisco, United States of America; 5UCSF, Radiology and Biomedical Imaging Department, San Francisco, United States of America

Background: Artificial intelligence techniques, in particular machine learning (ML), are increasingly used in rheumatology and especially in osteoarthritis (OA). ML studies in OA are very heterogeneous, hence the need to have an overview of their field of application.

Objectives: The aim of this systematic literature review is to provide a comprehensive and exhaustive landscape of the use of ML in the clinical care of OA.

Methods: A systematic review of the literature was performed in July 2021 using the Medline database with key words and MeSH terms referring to ML methods in OA. Only original articles in English were considered. Articles related to replacement surgery, theoretical imaging, rehabilitation, molecular biology, and spinal or temporomandibular OA were excluded. For each selected article, the
The number of ML articles in OA has increased exponentially over the last 5 years with applications across all major research themes. However, there is methodological heterogeneity, with articles based mainly on radiological data, but also on knee OA. To date, there is no ML article on digital osteoarthritis. This work also shows the need to develop clinical cohorts to bring more diversity in ML work and to allow external validation. This article is the first systemic review of the literature in OA and provides an overview of ML in OA, its applications, limitations and perspectives.

**Disclosure of Interests:** Marie Bivinigon: None declared, Valentina Pedaio: None declared, Atul Butte Shareholder of: a minor shareholder in Apple, Facebook, Alphabet (Google), Microsoft, Amazon, Snap, 10x Genomics, Helix, Pathway Genomics, and Verinata (Illumina), None declared, Jérémie SELLAM Consultant of: MSD, Pfizer, Abbvie, L’Oreal, and Progenity., Karine Louati: None declared, David Klatzmann: Consultant of: Pfizer; Personalis and NuMedii; Randiz: None declared, Jérémie SELLAM Consultant of: MSD, Pfizer, Abbvie, L’Oreal, and Progenity., Karine Louati: None declared, Atul Butte Shareholder of: a minor shareholder in Apple, Facebook, Alphabet (Google), Microsoft, Amazon, Snap, 10x Genomics, Helix, Pathway Genomics, and Verinata (Illumina), None declared

**Results:** From 1,148 screened articles, 46 were selected and analyzed, most of which were published after 2017 (Figure 1). Twelve articles were related to diagnosis, 7 to prediction, 4 to phenotyping, 12 to severity and 11 to progression. The number of patients included ranged from 18 to 5,741. Deep learning (DL) was used in 35% of the cases. Imaging analyses represented 74% of the studies. Knee OA was studied in 85% of these articles while 15% investigated hip OA. None were on hand OA. Most of the studies were done on the same cohort with data from the Osteoarthritis Initiative (OAI) used in 46% of the articles whereas the Multi-Center Osteoarthritis Study (MOST) and the Cohort Hip and Cohort Knee Study (CHECK) cohort were respectively used in 11% and 7% of the articles. Data and source code were publicly available in 54% and 22% of the articles. External validation was provided in only 7% of the articles.

**Background:** Postoperative pain (POP) is a serious complication that affects the outcome of total arthroplasty (TA) of the knee (CJ) and hip (HJ) joints in patients with osteoarthritis (OA). The search for the genetic characteristics of POP is an urgent direction in the study of this problem.

**Objectives:** To determine the relationship between the polymorphisms of the KCNS1, COMT, and OPRM1 genes and the development of postoperative pain in patients with osteoarthritis of the knee joint and hip joint who underwent total arthroplasty.

**Methods:** The study group consisted of 95 patients with knee osteoarthritis and/or hip joint osteoarthritis (64.6% of women; mean age - 65.4 ± 9.0 years) who underwent TA CJ (47.8%) or TA HJ (52.2%). The presence of POP was determined when it persisted or appeared after 3 and 6 months. After surgery, pain in the area of the operated joint ≥40 mm by 100 mm visual analogue scale. All patients underwent genotyping of KCNS1 (rs734784), COMT (rs6269, rs4633), and OPRM1 (rs1799971) genes polymorphisms by real-time polymerase chain reaction using original sequence-specific primers and probes labeled with various fluorescent labels. Registration and interpretation of the obtained results were carried out on a DT-96 amplifier (DNA-Technology LLC, Russia).

**Results:** POP was observed in 32.6% of patients who underwent TA CJ or TA HJ. The incidence of POP after TA CJ and TA HJ was 30.2% and 34.0%, respectively (p = 0.882). There were no differences in the frequencies of genotypes of the studied genes (p>0.05). The presence of the homozygous GG genotype of the KCNS1 gene polymorphism (rs734784) was associated with the presence of POP in accordance with the recessive genetic model (GG vs AA + AG; odds ratio (OR) - 3.96 [95% confidence interval (CI): 1.51; 10.37]; p = 0.005). The presence in the genotype of the minor allele T (TT + CT) of the COMT polymorphism (rs4633) reduced the risk of developing POP compared with the carriage of the CC genotype (OR = 0.32 [95% CI: 0.12; 0.83]; p = 0.02) according to the dominant genetic model. There was no statistically significant correlation between the development of POP and the carriage of various genotypes and alleles of the OPRM1 gene (rs1799971) alleles.

**Conclusion:** There is a statistically significant association between the polymorphism of the OPRM1 (rs734784) and COMT (rs4633) genes and the development of chronic POP in patients who underwent TA CJ and TA HJ. Further studies of the genetic predisposition to POP are required using more clinical material.

**Disclosure of Interests:** None declared

**WHAT FACTORS ARE ASSOCIATED WITH THE DEVELOPMENT OF PAIN AFTER TOTAL JOINT REPLACEMENT?**

**V. Nesterenko1, A. Karateev2, M. Makarov2, E. Blialik1, S. Makarov2, V. Blialik1, M. Nurmukhametov1, A. Roskidalo1, N. Burikov1, V.A. Nasonova Research Institute of Rheumatology, Rheumorthoapathics and Rehabilitation, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Rheumorthoapathics and Rehabilitation, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Department of Inflammatory Joint Diseases, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Department of Inflammatory Joint Diseases, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Department of Inflammatory Joint Diseases, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Department of Inflammatory Joint Diseases, Moscow, Russian Federation

**Background:** Chronic postoperative pain (CPP) is one of the most common complications of total hip (HJ) and knee (CJ) arthroplasty (TA). The search for the factors that determine this pathology is an urgent scientific and practical task.

**Objectives:** To determine the factors associated with the development of CPP in patients who underwent TA, CJ or HJ.

**Methods:** A total of 124 patients with osteoarthritis of the knee or hip joint, mean age 63.6±9.9 years, 63% of women and 37% of men, who in 2019-2020 year done out by TA KJ or HJ. The development of CPP was assessed after 3 and 6 months. Telephone survey of patients. This complication was diagnosed in the presence of moderate to severe pain (≥40 mm on a visual analogue scale, VAS), persisting for at least 3 months, causing concern in patients and/or requiring regular use of analgesics. A comparison was made between the groups of patients with CPP and the absence of CPP for a number of factors determined in the preoperative period.

**Results:** The incidence of CPP was 27.4%. There were no differences in the incidence of CPP in patients who underwent TA CJ and TA HJ: 28.1% and 26.9%, respectively (p = 0.88). The presence of CPP was significantly associated with such preoperative indicators as a higher body mass index (BMI), a higher intensity of pain at rest, higher values of the WOMAC pain index, WOMAC and WOMAC stiffness in general, and the severity of symptoms of neuropathic pain. (PainDetect questionnaire), signs of depression and anxiety (HADS questionnaire). The risk of developing CPP was significantly higher (p <0.05) in patients...
Conclusion: The risk of CPP after TA CJ and HJ is higher in patients with over-weight, high preoperative pain, signs of neuropathic pain and depression, and in the presence of several sources of musculoskeletal pain (except for the affected joint planned for TA).

WHAT DOES GRIP STRENGTH REFLECT IN HAND OSTEOARTHRITIS? RESULTS FROM THE DIGICODE COHORT

E. Tan1, S. Tuffet2, A. Rousseau2, B. Faure2, F. Rannou3, F. Berenbaum1, J. Sellam1, A. Courtiès1, Saint-Antoine Hospital, Rheumatology, Paris, France; 2Saint-Antoine Hospital, Unité de Recherche Clinique de l’Est Parisien (URCEST), Paris, France; 3Pitié-Salpêtrière Hospital, Rheumatology, Paris, France; 4Cochin Hospital, Physical and Rehabilitation Medicine, Paris, France

Background: Among the general population over 60 years old, the decrease in grip strength is a marker of morbidity and mortality: its measurement during follow-up consultations is considered as a predictive marker of good health status or patient’s overall fragility (1). However, hand osteoarthritis (HOA), which can modulate grip strength and is also associated with comorbidities is never taken into account, while it is a very common disease.

Objectives: The objectives of this study are to describe grip strength in a symptomatic HOA population, to investigate painful osteoarthritic joints associated with decreased grip strength, and to determine whether decreased grip strength is independently associated with comorbidities in this population.

Methods: DIGICODE is a hospital-based observational cohort including patients with radiographic features of HOA of at least 2 joints or radiographic thumb base OA. Inflammatory rheumatism or crystal arthropathy were excluded. The data at baseline were used for the analysis. Grip strength was the higher score of 3 repeated measurements using a Jamar dynamometer. Baseline grip strength of the dominant hand was compared in the cohort between men and women (Student’s T test) and was described by age (by 10-year age groups using Kruskal-Wallis test). In this cross-sectional study, factors associated with a decreased grip strength were investigated using univariate and then multivariate linear regression analysis (with adjustment on age, BMI and variables with p < 0.2 in univariate analysis) with stratification by sex. Results were presented by beta coefficients and their 95% confidence intervals. A first analysis focused on the association of grip strength with local factors: painful locations in the dominant hand by row and radiographic severity according to the total Kellgren-Lawrence (KL) score. The second analysis assessed the patient-level association between decreased grip strength and general characteristics, including cumulative comorbidities and markers of radio-clinical severity of hand OA, namely the AUSCAN pain score and total KL score. A sensitivity analysis was performed to look for association between grip strength and each comorbidity.

Results: 394 patients were analyzed, including 329 women (mean ± SD of the dominant hand’s grip strength of 21.6 ± 6.9 kg) and 65 men (34.9 ± 9.8 kg) with a mean age of 66.9 ± 7.3 years. Grip strength decreased with age (p<0.001) and was lower for women (p<0.0001). Among women, locally, decreased grip strength was independently associated with painful involvement of at least 2 metacarpophalangeal joints (MCPs) (estimated coefficient [95% CI] -3.6 [-6.2; -1.0] kg versus no painful MCPs but not with proximal and distal interphalangeal joints, and with a high KL total sum score (-0.06 [-0.10; -0.01] kg per additional point). At the patient-level, decreased grip strength was not associated with comorbidities but with radio-clinical severity (p<0.05), i.e. a higher KL total sum score and AUSCAN pain score. Among men, neither radiographic severity nor painful locations were independently associated with a decrease of grip strength. Conversely, decreased grip strength was associated with at least 3 comorbidities (-8.5 [-15.5; -1.4] kg versus a single comorbidity being OA), independently of radiographic severity. The study of comorbidities individually did not show any particular association with grip strength.

Conclusion: In this cohort of symptomatic HOA, the decrease of grip strength reflects the radio-clinical severity of hand OA among women, whereas among men, it is independently associated with the accumulation of comorbidities. The presence of hand OA should be considered for further studies investigation the relationship between grip strength and morbidity.

REFERENCES:
reached minimum PCS during exercise, but only an average of 70% (SD: 8.7) of that during infusion. Cycling induced a small reduction in C2M (peak: -5.3%, 95%CI: -7.8 to -2.7%). PRO-C2 increased rapidly in response to cycling (peak: 11.7%, 95%CI: 4.3 to 18.1%) and running (peak: 12.9%, 95%CI: 3.54 to 22.2%), T2CM decreased up to one hour after cycling (peak: -10.8%, 95%CI: -15.1 to -6.5%) and running (peak: -9.5%, 95%CI: -15.5 to -3.6%), similar to adrenaline, then increased. Coll2-1NO2 increased rapidly following cycling (peak: 12.5%, 95%CI: 2.8 to 22.2%) and running (peak: 9.8%, 95%CI: 0.26 to 19.6%). Trends of increase was found in Coll2-1 (21.3%, 95%CI: 2.9 to 38.6) and Coll2-1NO2 (11.6%, 95%CI: -7.9 to 31.1) in response to running at 240 min (Figure 1 – Error bars: SE, † Change from resting, †† Change from BL, ††† P < 0.05, †††† P < 0.01; ††† P < 0.001).

Figure 1.

At 24h PRO-C2 reduced -9.4% (95%CI: -18.2 to -0.5%) after cycling, Coll2-1NO2 reduced -8.33% (95%CI: -17.0 to 0.3%) after running and T2CM elevated by 6.0% (95%CI: -0.8 to 12.8%) after running and 7.1% (95%CI: 0.5 to 13.7%) after cycling. Conclusion: Running, cycling and adrenaline infusion induced rapid small-to-moderate changes in circulating biomarkers reflecting type II collagen turnover. Changes after adrenaline-infusion suggests a cardiovascular contribution to exercise-induced changes. This model could potentially be used to evaluate treatment effects on collagen turnover.

LABORATORY BIOMARKERS OF JOINT REMODELING AND INFLAMMATION IN PATIENTS WITH EARLY KNEE OSTEOARTHRITIS

V. Klementeva1, T. Chernysheva1, K. Korochina1, I. Krivotulova1, I. Mitrofanova1, I. Korochina2.
1Orenburg State Medical University, The Department of Internal Diseases, Orenburg, Russian Federation; 2Orenburg State Medical University, The Department of Polyclinic Therapy, Orenburg, Russian Federation

**Background:** Record prevalence of osteoarthritis (OA) around the world is aggravated by the fact that doctor most often meets it on advanced stage, so that therapeutic interventions can no longer provide significant success [1]. It is advisable to study early joint remodeling, when gross irreversible changes have not yet occurred, and laboratory markers appear to be valuable diagnostic and prognostic tool, potentially able to identify patients-responders to particular treatment method [2].

**Objectives:** To verify joint tissue remodeling and synovitis in patients with early knee OA Kellgren-Lawrence (K-L) Grades 0-2 using laboratory biomarkers.

**Methods:** The study included 90 patients with knee OA K-L Grades 0-2 (3 groups of 30 people each) and 30 healthy volunteers; to clarify early OA, Luyten FP criteria (2018) were used [3]. Among persons with knee OA, there were 57 women (63.3%) and 33 men (36.7%), mean age 32 [27; 35] years; participants without OA were presented by 18 (60%) and 12 (40%) women, mean age 29.5 [25; 34] years. Knee radiography, ultrasonography, laboratory biomarkers assessment including interleukin-1beta (IL-1β), N-Terminal Propeptide of Type 1 Procollagen (P1NP), Beta-Cross-laps, cartilage oligomeric matrix protein (COMP) were carried out.

**Results:** All groups with knee OA was characterized by women predominance (Table 1). Laboratory study revealed slight increase in IL-1β and both bone markers in K-L Grade 0. Grade 1 was characterized by elevation of COMP and Beta-Cross Laps on background of IL-1β increased. In Grade 2 the highest level of COMP, slight decrease in Beta-Cross Laps and IL-1β, weak increase in P1NP were found. Correlation analysis have detected positive significant relationships between COMP and IL-1β (r=0.37), as well as Beta-Cross Laps and P1NP. Correlation analysis have detected positive significant increased. In Grade 2 the highest

**Beta-Cross Laps on background of IL-1β (β)

**Conclusion:** Early knee OA of K-L Grade 0 is characterized by bone metabolism activation and synovial inflammation before articular cartilage involvement. On Grade 1, cartilage destruction appears and bone resorption is enhanced. Grade 2 is characterized by significant intensification of cartilage destruction, weakening of bone resorption on the background of synovial inflammation. In addition to cartilage damage, COMP is associated with joint inflammation, which requires further research to take in account it also as synovial biomarker.

EFFICACY AND SAFETY OF THE COMBINATION OF PRP + NON-CROSSLINKED HYALURONIC ACID VERSUS HYALURONIC ACID, IN MONO-INJECTION, IN SYMPTOMATIC KNEE OSTEOARTHRITIS. RANDOMIZED CONTROLLED PHASE II TRIAL, SINGLE BLIND

T. Delgado1, R. Ferreira Lopez2, P. Adam3, Y. M. Pers2, L. Bengueulla2, C. Cyteval4, V. De Fourmestraux5, S. Lombion6, P. Ornetti7. 1University Hospital Emiletterand Dijon-Bourgogne, rheumatology, Dijon, France; 2Montpellier University Hospital, Rheumatology, Montpellier, France; 3Medipole Garonne, Imaging, Toulouse, France; 4Montpellier University Hospital, Imaging, Montpellier, France; 5RegenLab, Research, Lausanne, Switzerland; 6EURL SLc, Statistics, Chamesey, France

**Background:** Despite the recent results of meta-analyses of randomized controlled trials (RCTs), the place of PRP and hyaluronic acid in the symptomatic treatment of knee osteoarthritis (KOA) remains uncertain in the latest international recommendations. Very few studies are available on the potential synergistic effect of their combination in mild to moderate forms of KOA [1].

**Objectives:** Randomized, controlled, multicenter, non-inferiority trial (clinical trial NCT03328728), single-blinded (investigator) to compare the efficacy and safety of the combination of PRP and non-crosslinked hyaluronic acid (PRP-HA, Cellular Matrix A-CP-HA, Regen Lab) as a single injection versus Hylan G-F 20 (HA), with follow-up at 1, 3 and 6 months, on an intention-to-treat (ITT) basis.

**Methods:** Patients aged 40-80 years with symptomatic femorotibial KOA (WOMAC A1 (pain on walking) or WOMAC Function > 50/100) and a Kellgren and Lawrence (KL) radiographic stage II or III were randomized into two groups: PRP-HA vs. HA, as a radioc- or ultrasound-guided single injection at M0. Patients should not have received injectable treatments (corticosteroids, HA or PRP) for 3 months, nor per os NSAIDs for at least 1 month. A 6-month follow-up of the impact of the KOA was performed at M1, M3 and M6. The primary endpoint was the difference in the WOMAC score for pain on walking between M0 and M6 between the 2 groups. Secondary endpoints were collected and compared at M1, M3, M6 (WOMAC Pain, Function, and Total; SF-36 score) as well as the percentage of patients responding at M6 according to the OMERACT-OARSI criteria, according to the Patient Acceptable Symptomatic State (PASS), and the Minimal Clinical Important Improvement (MCII) of the WOMAC pain. The factors of good response (PASS and MCII responders) at M6 were investigated in univariate and multivariate analysis. Tolerability was assessed by comparing adverse events over 6 months in both groups.

**Results:** 156 patients were included in three French teaching hospitals between 2018 and 2021 with the following characteristics: age 59.6±9.2 years, BMI 28.1±5.8 kg/m², 37.8% grade II KL and 62.2% grade III KL. The two groups were homogeneous at inclusion except in terms of analgesic consumption (PRP-HA vs. HA, 30% vs. 45%, p=0.042) and KL III radiographic stage (70% vs. 53%, p=0.04). The symptomatic improvement (WOMAC pain, function and WOMAC Total) was significant in both groups at M1, M3 and M6. The difference in WOMAC pain on walking at M6 was significant for the non-inferiority test (-3.34 [-12.51; -0.18], p=0.044) and for the superiority

test (-0.34 [-1.45, -0.22], p = 0.042) in favor of PRP-HA. At M6, there was a non-significant difference in terms of OMERACT-OARSI responders in favor of the PRP-HA combination (58% vs. 48%, p = 0.261) but significant in terms of MCII responders (78.8% vs. 61.3%, p = 0.036) and PASS responders (50.8% vs. 33.3%, p = 0.035). PASS response was associated in univariate analysis with pain and total WOMAC at inclusion (p ≤ 0.001) as well as with allocated treatment (p = 0.03). In multivariate analysis, only allocated treatment was associated with a good response at M6 for both PASS (PRP-HA, OR = 2.05 [1.02-3.92], p = 0.03) and MCII (PRP-HA, OR = 2.21 [1.09-4.44], p = 0.02). There was no difference in patient satisfaction at M1, M3 and M6, nor in the occurrence of adverse events.

Conclusion: In this non-inferiority RCT in symptomatic knee osteoarthritis, the combination of PRP-non-crosslinked HA in mono-injection was at least equivalent to Hyylan G-F 20 for symptomatic benefit (WOMAC) at 6 months, with a good safety profile. The proportion of patients achieving PASS and MCII of WOMAC pain was higher in the PRP-HA group.

POST116 DIETARY INFLAMMATORY INDEX AND KNEE STRUCTURES ON MRI AND PAIN: A PROSPECTIVE COHORT STUDY

F. Pan1, J. Tian1, M. Cervo2, D. Scott3, F. Cicuttin4, G. Jones1. 1University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; 2Monash University, School of Clinical Sciences at Monash Health, Melbourne, Australia; 3Deakin University, School of Exer & Nut Sciences, Melbourne, Australia; 4Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia.

Background: While some individual dietary nutrients/components have been shown to be associated with knee osteoarthritis (OA) progression, the associations of the dietary inflammatory index (DII), which reflects the overall inflammatory potential of a diet, with MRI-detected structural changes and pain have not been investigated.

Objectives: This longitudinal study aimed to determine whether DII scores are associated with knee structural changes and pain over a 10.7 year follow-up in community-dwelling older adults.

Methods: This study utilised the data from a prospective population-based cohort study (mean age 63 years, 51% women) in which 1,099, 875, 768 and 563 participants completed assessments at baseline, 2.6, 5.1 and 10.7 years, respectively. T1-weighted or T2-weighted MRI of the right knee was performed. X-ray was performed to assess radiographic knee osteoarthritis (WOMAC) pain questionnaire was used to measure knee pain at all time points. Cartilage volume (CV) and bone marrow lesions (BMLs) at baseline were measured. T1-weighted or T2-weighted MRI of the right knee was performed. T1-weighted or T2-weighted MRI of the right knee was performed. T1-weighted or T2-weighted MRI of the right knee was performed.

Results: In this non-inferiority RCT in symptomatic knee osteoarthritis, the combination of PRP-non-crosslinked HA in mono-injection was at least equivalent to Hyylan G-F 20 for symptomatic benefit (WOMAC) at 6 months, with a good safety profile. The proportion of patients achieving PASS and MCII of WOMAC pain was higher in the PRP-HA group.

Conclusion: In this non-inferiority RCT in symptomatic knee osteoarthritis, the combination of PRP-non-crosslinked HA in mono-injection was at least equivalent to Hyylan G-F 20 for symptomatic benefit (WOMAC) at 6 months, with a good safety profile. The proportion of patients achieving PASS and MCII of WOMAC pain was higher in the PRP-HA group.

POST117 SAFETY AND EFFICACY OF ADIPOSE-MERIVED MESENCHYMAL STEM CELLS FOR OSTEARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Gadkalkar1, A. Elmegeed2, A. Hafez3, A. Ak Awad4, M. Ahmed Shehata3, A. Abouelen5, A. M. Aftel6. 1Loyola University Medical Center, Department of Surgery, Maywood, United States of America; 2Faculty of Science, Menoufa University, N/A, Shebein el kom, Egypt; 3Faculty of Medicine, Menoufa University, N/A, Shebein el kom, Egypt; 4Faculty of Medicine, Ain Shams University, Cairo, Egypt, N/A, Cairo, Egypt; 5Alexandria Faculty of Medicine, N/A, Alexandria, Egypt; 6Faculty of pharmacy, Alexandria University, Alexandria, Egypt, N/A, alexandria, Egypt; 7Bellevue College of Medicine, Department of Internal Medicine, Houston, United States of America.

Background: Osteoarthritis (OA) is a debilitating joint disorder affecting articulating joints, cartilage and subchondral bones, prompting synovial membrane irritation and inflammation (1). Nowadays, knee OA can be treated either by surgical or non-surgical approaches, while the Osteoarthritis Research Society International (OARSI) suggested pharmacological medications joined with other functional approaches such as exercise, joint inflammation instructions, and weight reduction (2), yet most of them exhibit modest safety and efficacy (3). Mesenchymal stem cells (MSCs) have been well-known in regenerative medicine to achieve wide differentiation capacity. Moreover, MSCs can be derived from various sources (4); however, Adipose-derived mesenchymal stem cells (ADMSCs) are easiest to assemble for clinical use with higher isolation yields (4).

Objectives: This study investigated the potential and regenerative capacity of adipose-derived mesenchymal stem cells (ADMSCs) for osteoarthritis (OA).

Methods: We created a search strategy and applied it to six databases. After screening the records for eligibility, we identified and evaluated the risk of bias in both the randomized and non-randomized research studies. Then, data were extracted and implemented into single-arm and double-arm analyses.

Results: 16 studies with 469 patients were included. We found a significant improvement in the quality of life (QOL) among the three doses subgroups (high, medium, and low doses) which was estimated by the SF-36 scores after a year of follow up (low dose, Mean (M) -23.991; p = 0.000; medium dose: M = 15.96; p = 0.000; high dose: M = -19.306; p = 0.000). Furthermore, we noticed a significant decrease in pain as estimated by the numeric pain rating scale (NPRS) after three months of follow-up with no significant difference between the low and medium doses (low dose: M = -3.119; p = 0.002; medium dose: M = -2.17; p = 0.000). Our double-arm analyses illustrated significant pain reduction in the ADMSGs group over the control after 12 months as estimated by WOMAC pain subscore (Mean difference (MD) -1.85, p = 0.03); moreover, The knee functions and activity levels improved significantly among the low dose group as measured by the WOMAC physical function and stiffness subscales after six months (M -23.797; p = 0.001; M = -10.249; p = 0.009, respectively) and the KOOS scores after 12 months (p = 0.007 for all KOOS subscales). No significant adverse events were observed in the ADMSGs injections group (Event rate (ER) p = 0.001).

Conclusion: Although ADMSCs were associated with significant reductions in pain scores, improvements in QOL score and knee functions, and achieving disease modification in patients with OA, they did not significantly differ from the control. Therefore, implementing ADMSCs in routine clinical practice needs more studies with large sample sizes, longer follow-up periods.

POST117 SAFETY AND EFFICACY OF ADIPOSE-MERIVED MESENCHYMAL STEM CELLS FOR OSTEARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS
IEEE OF CORTICOSTEROIDS FOR HAND OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND TRIALS

Background: Osteoarthritis causes significant pain and disability with no approved disease-modifying drugs. There is evidence emerging from pre-clinical and human studies suggesting metformin may have disease-modifying properties in osteoarthritis. Given its pleiotropic effects and safety profile, metformin has the potential to be a novel therapy for osteoarthritis.

Objectives: We systematically reviewed the evidence from both pre-clinical and human studies for the potential disease-modifying effect of metformin in osteoarthritis.

Methods: Ovid MEDLINE, Embase and CINAHL were searched between inception and June 2021 using MeSH terms and key words to identify studies examining the association between metformin use and outcome measures related to osteoarthritis. Two reviewers performed the risk of bias assessment and 3 reviewers extracted data independently. Qualitative evidence synthesis was performed. This systematic review is registered on PROSPERO (CRD42021261052 and CRD42021261060).

Results: Fifteen (10 pre-clinical and 5 human) studies were included. Most studies (10 pre-clinical and 3 human) assessed the effect of metformin using knee osteoarthritis models. In pre-clinical studies, metformin was assessed for the effect on structural outcomes (n=10); immunomodulation (n=5); pain (n=4); and molecular pathways of the effect of metformin on human osteoarthritis (n=3). For human studies, metformin was examined for an effect on structural progression (n=3); pain (n=1); and immunomodulation (n=1). Overall, all pre-clinical studies consistently showed metformin having a chondroprotective, immunomodulatory and analgesic effect in osteoarthritis, predominantly mediated by adiponectin. Evidence from human studies, although limited, was consistent with findings in pre-clinical studies.

Conclusion: We found consistent evidence across pre-clinical and human studies to support a favourable effect of metformin on chondroprotection, immunomodulation and pain reduction in knee osteoarthritis. Further high-quality clinical trials are needed to confirm these findings as metformin could be a novel therapeutic drug for the treatment of osteoarthritis.

ASSOCIATION OF ADIPOKINES WITH SEVERITY OF KNEE OSTEOARTHRITIS ASSESSED CLINICALLY AND ON MAGNETIC RESONANCE IMAGING

Background: Adipokines secreted by adipose tissue create a low grade systemic inflammatory state that could contribute to the pathogenesis of knee OA (KOA). Previous studies of association between adipokines and radiographic KOA represented late-stage disease shown as bony changes. Magnetic Resonance Imaging (MRI) has the advantage of showing early changes of KOA in all joint structures.

Objectives: We aimed to evaluate the association between the adipokines: Leptin, Adiponectin, Resistin, and hs-CRP with clinical, radiographical and MRI assessment of KOA severity.

Methods: We performed a cross-sectional study in participants with early KOA. Demographics, clinical (WOMAC), and MRI (TRIALS scoring) + KOA severity were assessed. Serum leptin, adiponectin, resistin and hs-CRP were measured. Association of adipokines with clinical and MRI severity outcomes were evaluated using regression models with adjustment with age, sex, and body mass index (BMI).

Results: 139 participants with early KOA (82% women, mean ± SD age: 55.5 ± 7.8 years) were included. Participants had moderate KOA symptoms, mean WOMAC pain and function were 31.1 ± 18.4, and 32.0 ± 19.9 respectively. Mean BMI was 26.0 ± 5.9 kg/m². After adjustment with age, sex and BMI, Leptin (p=0.001) and hs-CRP (p=0.03) were positively associated, while adiponectin (p=0.02) and resistin (p=0.03) were negatively associated with osteophyte size.

HAND OSTEOARTHRITIS IS ASSOCIATED WITH LIMITATIONS IN PAID AND UNPAID WORK PARTICIPATION AND RELATED SOCIA L COSTS: THE HOSTAS COHORT

S. Terpstra1, L. Van de Stadt1, A. Boonen5, F. Roenaerd1, M. Klopperling4,5.
1Leiden University Medical Center, Rheumatology, Leiden, Netherlands; 2Maastricht University Medical Center, Rheumatology, Maastricht, Netherlands; 3Leiden University Medical Center, Epidemiology, Leiden, Netherlands

Background: Rheumatic musculoskeletal diseases (RMDs) can cause impairment in paid and unpaid work which can contribute to societal burden and costs. However, data on this topic concerning hand osteoarthritis (OA) is scarce, while this is crucial for assessing the societal impact of this disease.

Objectives: To investigate the association of hand OA with paid and unpaid work limitations, productivity loss and costs of productivity loss.

Methods: We used data of the Dutch Hand OsteoArthritis in Secondary care (HOSTAS) cohort, a primary hand OA cohort from a general rheumatology outpatient clinic. The treating rheumatologist defined hand OA presence. We assessed patient and OA characteristics using validated questionnaires and tests. We investigated work impairment due to hand OA with the Health and Labour Questionnaire (HLQ) which assesses the last two weeks on hand-OA related limitations, hours of sick leave and unproductiveness during paid work, and limitations and hours of the necessity of being replaced by others for unpaid work tasks. We estimated societal costs of paid work by multiplying unproductive and sick leave hours due to hand OA by the average Dutch hourly societal costs of paid work for persons of the same age category and sex. We estimated societal costs of unpaid work by multiplying the hours of unpaid work replaced by others by the Dutch gross average hourly salary of a household help (€12.50).

Result: HLQ data was available for 382 patients (mean age 61 years, 86% women, 26% having a university degree, 41% having any comorbidity). Of these persons, 181 (47%) had paid work, 16 (4%) had full work disability due to hand OA and 117 (30%) were retired. Thirty employed persons (7%) reported sick leave due to hand OA in the last two weeks, for whom a median of 42 working hours (interquartile range [IQR] 24 to 54) was lost. Unproductive paid work hours were present for 28 (15%) patients, with a median of 4 hours in the last two weeks (IQR 2 to 6). Hinder at work in the last two weeks was reported by 120 out of 181 working patients (66%), for whom median hinder score (score range 6-24) was 7 (IQR 6 to 8). Work production loss in the last two weeks due to hand OA (the sum of sick leave hours and unproductive hours) was present for 36 patients (19%). Patients with paid work productivity loss (n = 35, 19%) did not differ statistically significantly in patient and disease characteristics from those without productivity loss (n = 146, 19%). Unpaid work replacement in the last two weeks was reported by 171 patients (45%), with a median of three hours replaced (IQR 2 to 7 hours). Due to sick leave work replacement was reported by 33 patients (7%). Patients with unpaid work replacement by others due to hand OA (n=171, 45%) were statistically significantly more often female and had a higher BMI than with those without any replacement (n=210, 55%). We estimated total societal costs of hand OA related to paid work production loss at €61 (95% confidence interval (CI) 27 to 96) per two weeks, and societal costs for unpaid work at €33 (CI 27 to 40). Total estimated work-related societal costs per patient with hand OA were €94 (CI 59 to 130), translating to €2452 (CI 1528 to 3377) per year.

Conclusion: Hand OA is associated with impairment in paid and unpaid work, which translates into substantial societal costs. This highlights the social and economic importance of adequate hand OA treatment. It also indicates the importance of investigating hand OA impairment experienced by hand OA patients visiting the outpatient clinic, for potentially more tailored treatment.

ULTRASOUND GUIDED INJECTIONS OF HYAD4 FOR KNEE OSTEOARTHRITIS IMPROVES PAIN AND FUNCTIONAL OUTCOMES AT 3 AND 6 MONTHS WITHOUT CHANGES IN SYNOVIAL FLUID VOLUMES.

P. Meehan1, M. Gill1, E. Hoffman1, M. Wolf1, I. Amigues1, L. M. Kastianick1, E. Regan1, J. Crooks2, G. Czuczman2, C. Coeshott3, V. Knight4. 1National Jewish Health, Medicine/Rheumatology; Denver, United States of America; 2National Jewish Health, Pathology; Denver, United States of America; 3National Jewish Health, Bioinformatic, Denver, United States of America; 4CU Anschutz School of Medicine, School of Public Health, Aurora, United States of America; 5National Jewish Health, Radiology, Denver, United States of America; 6Children's Hospital, Immunology, Aurora, United States of America

Background: Prior studies have demonstrated improved accuracy and efficacy when Intra-articular (IA) therapeutics are injected using ultrasound (US) guidance. There is also growing evidence that many patients with knee osteoarthritis (OA) exhibit a pro-inflammatory synovial fluid (SF) profile. However, it is not known if temporary clinical improvement in pain and function after IA Hyaluronic acid (HA) injections is associated with changes in SF volumes.

Objectives: The purpose of this study was to determine if IA HA injections delivered using US directed needle visualization with an external pneumatic compression device would result in improved clinical outcomes for knee OA at 3 and 6 months, and if this was associated with a reduction in the amount of knee synovial fluid (SF) measured on US.

Methods: 49 eligible subjects with symptomatic Knee OA, BMI < 40 and KL radiographic rating of II or III OA were consented for this open label prospective IRB approved Investigator Initiated SF OA biomarker study (HS 3179, NCT 02956337). All standing radiographs were reviewed by a fellowship-trained MSK radiologist. 36 subjects had adequate aspirated SF volumes of > 500 ml for biomarker analysis and therefore were eligible to receive two IA injections of HYAD4, 24 mg/3ml (Fidia Farmaceutici S.p.A. Italy) 7 days apart by a MSK certified Rheumatologist. An external pneumatic compression device and US visualized needle insertion ensured injections were delivered into the intra-synovial space. Despite COVID-19 restrictions, 34 patients (17 women and 17 men) between 35 and 78 years of age returned for 3 month evaluations and 30 had evaluations at 6 months. The following clinical variables were measured: Western Ontario and McMaster Universities Index (WOMAC) total scores, Visual Analog Pain Scale (VAS, 0-10), PCS scores on the SF-36 health survey questionnaires (physical function/bodily pain and general health), 6-minute walking distance in meters (6 MWD), and measured SF depth before and after an external pneumatic compression device was inflated to 100 mmHg to facilitate aspiration by increasing available SF volumes under positive pressure. The SF depth was measured on the recorded US image (GE logiq e) as the largest anechoic region selected for aspiration on either the lateral (n= 30) or medial (n=4) compartment. SF and simultaneous peripheral blood samples were centrifuged and cryopreserved at -80 ° C within 45 minutes of aspiration for future analysis. Statistical differences between baseline values compared to those levels at 3 and 6 months were determined using a paired ANOVA test with p <0.05 significance.

Results: Improvements over baseline values were observed at 3 and 6 months respectively, after IA HA injections in WOMAC (40%, 40%), VAS (45%, 51%) and PCS (15%, 18%) all p <0.001. The 6 WWD improved by 7% at 3 months (p<0.007) but was not statistically improved at 6 months. US measured SF depth at baseline was 3.2 ± 2.2 mm before inflation and 6.4 ± 3.7 mm after inflation of the
pneumatic external compression device but statistical differences in SF depth were not observed at 3 and 6 months. **Conclusion:** Despite improvements in WOMAC, VAS scores, and PCS scores on the SF 36 at 3 and 6 months after US guided knee injections with an HA product, a statistically significant reduction in the amount of US measured SF was not observed. The 6 MWD improved at 3 months but was not statistically different from the baseline distance by 6 months. IA injections using US needle visualization confirmed that the product was delivered into the synovial space with 100% accuracy which might have resulted in improved efficacy results in this study compared to prior IA HA studies injected with different HA products. In the future, we hope SF biomarkers may identify which individual OA patients will likely achieve the greatest benefit with IA HA injections and to determine if this is associated with a reduction in catabolic pro-inflammatory proteins.

Khalid16 on behalf of FOREUM OA Comorbidity, 1University of Oxford, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences (NDO RMS), Oxford, United Kingdom; 2University of Nottingham, Academic Rheumatology, School of Medicine, Nottingham, United Kingdom; 3University of Oxford, Department of Primary Care Health Sciences, Oxford, United Kingdom; 4Erasmus University Medical Center, Department of General Practice, Rotterdam, Netherlands; 5Lund University, Clinical Epidemiology Unit, Orthopaedics, Department of Clinical Sciences Lund, Lund, Sweden; 6Keele University, School of Medicine, Keele, United Kingdom; 7Chang Gung Memorial Hospital, Division of Rheumatology, Allergy and Immunology, Taoyuan, Taiwan, Republic of China; 8University of Nottingham, Division of Primary Care, School of Medicine, Nottingham, United Kingdom; 9University of Nottingham, Pain Centre Versus Arthritis, Nottingham, United Kingdom; 10University of Bristol, Musculoskeletal Research Unit, Bristol Medical School, Translational Health Sciences, Bristol, United Kingdom; 11Erasmus MC University Medical Center, Department of Orthopedic Surgery & Sports Medicine, Rotterdam, Netherlands

**Background:** Osteoarthritis (OA) patients are more likely to have other comorbidities (Swain, Sarmanova et al. 2020). Improving the understanding of comorbidity profiles of OA patients may lead to improvement in their clinical care.

**Objectives:** To identify sub-groups in patients diagnosed with hip OA using patterns of comorbidity.

**Methods:** Routinely-collected data of individuals ≥18 years with an incident diagnosis of hip OA (baseline/time 0), with at least 5 years of follow-up in SIHAP (Information System for Research in Primary Care, a primary care database from Spain) were collected from January 1st 2006 to June 31st 2020. Those with soft-tissue disorders or other bone/cartilage diseases at the same joint in the year prior/after baseline were excluded. Comorbidities associated with OA in the literature and
present in ≥1% of the study population were included. Clusters of comorbidities were identified at baseline using latent class analysis (LCA), a soft clustering method that classifies individuals according to the distribution of their measured items. The number of clusters or sub-groups within the study population was decided by comparing goodness of fit parameters (CAIC, BIC, ABIC) and log-likelihood changes of models from 2 to 8 clusters. The selected model was externally evaluated by a survival analysis assessing 10 years mortality within each cluster, where the weight of the posterior probability was used as a probability of sampling weight.

**Results:** We identified 94,720 individuals with an incident diagnosis of hip OA, 56.3% women and 43.7% men, with a mean age (SD) of 67.2 (13.1) years. We selected the LCA model with 5 clusters that could be described as: healthier (lower prevalence of all comorbidities than average in the cohort), multimorbidity (higher prevalence of all comorbidities, multiple comorbidities), back/neck pain plus mental health (B/N-mental) cardiovascular disease (CVD), and metabolic syndrome (MetS) (Figure 1). Cox regression (HR [95CI%]) showed higher mortality risk for multimorbidity (3.76 [3.70-3.83]), CVD (1.56 [1.53-1.59]) and MetS (4.56 [4.35-4.78]), compared to healthier. No difference was observed for B/N-mental cluster.

**Conclusion:** Clustering of co-morbidities in hip OA patients at the time of diagnosis has the potential to detect sub-groups of hip OA patients who might require additional care.

**DOI:** 10.1136/annrheumdis-2022-eular.3361
Background: Osteoarthritis (OA) is the most common chronic progressive musculoskeletal system disease affecting more than 500 million people globally, which represents the formidable public health challenge. Currently osteoarthritis treatment includes acetaminophen, NSAIDs and/or opioids, intra-articular corticosteroid injections. Some guidelines also recommended chondroin and glucosamine sulfate, suggested that they may be effective and reduce functional impairment. However, despite of the huge amount of data on the problem of OA, there is still no effective treatment that slows down the progression of the disease. Recently appeared monoclonal antibodies against nerve growth factor (NGF) as well as fibroblast growth factor (FGF)-18 may be the promising tool for clinical improvement of OA.

Objective: To evaluate the safety and efficacy of anti-NGF and FGF-18 on patients with osteoarthritis by a systematic review.

Methods: In the current study the search process was conducted in PubMed using the following strategy: “FGF-18” or “anti-NGF” and “OA” or “monoclonal antibody” + “osteoarthritis”. All articles published in the format of Case Reports, Clinical Study, Clinical Trial Protocol, Clinical Trial, Multicenter Study were reviewed. Clinical outcomes were assessed using clinical scores, included the Western Ontario and McMaster Universities Osteoarthritis (WOMAC) Pain and Physical Function score. Patient’s Global Assessment of OA (PFA- OA), adverse events (AEs); cartilage repair and total femorotibial joint cartilage thickness were assessed using magnetic resonance imaging.

Results: Based on our search 23 publications were included in the study after omitting repetitions. Among 23 studies, 16 used anti-NGF monoclonal antibodies (Tanezumab, Fasinumab, Fulranumab), and 7 used recombinant human FGF-18 (Sprifermin). The total of 6679 patients were analysed in these articles. In the pooled analysis NGF inhibitors demonstrated statistically significant improvements compared with placebo in WOMAC Pain and Physical Function score (all studies revealed significantly better clinical outcomes in the anti-NGF group). After treatment with FGF-18 (Sprifermin) there was also improvement in WOMAC scores though not statistically significant. However, FGF-18 therapy was associated with the reductions in loss of total and lateral femorotibial cartilage thickness. Moreover, it does not only significantly reduce cartilage loss but also increase cartilage thickness. In terms of cartilage repair, 5 of 7 studies reported improvement in total femorotibial joint cartilage thickness. The AEs of FGF-18 or anti-NGF therapies were not serious, however they may affect the compliance and satisfaction of patients and clinicians. The proportion of patients with adverse events in anti-NGF treatment group was higher than that in FGF-18. The following conditions were reported in anti-NGF: abnormal peripheral sensation such as hypoesthesia (7.43%), paraesthesia (9.15%), hyperesthesia (0.36%), peripheral neuropathy and sensory disturbance (0.35%); arthralgia (15%), back pain (15.06%), pain in extremity (10%), headache (9.11%), upper respiratory tract infection (10.65%), diarrhoea (11.95%), sinusitis or nasopharyngitis (10.13%). The difference in AEs between sprifermin and placebo groups was found insignificant, most frequently reported event was arthralgia.

Conclusion: In recent years significant progress has been achieved for pathogenetic therapy of OA. Based on the results of current research findings, NGF inhibitors relieved pain and enhance joint function and may be considered as the most effective for functional improvement. FGF-18 decrease the cartilage loss and may improve cartilage thickness. However, further clinical longitudinal studies characterised the risk-benefit are needed to establish their safety and efficacy.

SERUM MARKERS OF GUT PERMEABILITY AND ENDOTOXEMIA IN PATIENTS WITH METABOLIC SYNDROME-ASSOCIATED KNEE OSTEOARTHRITIS: AN EXPLORATORY STUDY

E. Taskin1, N. Kashevarova1, K. Telyshev1, D. Rudinsky1, E. Strebkova1, E. Sharapova1, A. Alekseeva1,2, A. Lila2,3. 1V .A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation; 2Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Research Institute of Fundamental and Clinical Immunology, Laboratory of Clinical Immunopharmacology, Novoibirs, Russian Federation

Background: Metabolic syndrome (MetS)-related osteoarthritis (OA) has been proposed as a distinct phenotype of OA (1). One of the many putative pathways linking MetS with OA is increased gut permeability resulting in endotoxemia, systemic inflammation, and cartilage damage. There is a lack of studies evaluating markers of gut permeability and endotoxemia in patients with MetS-associated OA.

Objectives: In this exploratory study we aimed to: a. compare serum markers of gut permeability and endotoxemia in patients with knee OA and concomitant MetS vs patients with knee OA but without MetS; b. evaluate possible associations between the studied biomarkers, knee pain function, and body mass index (BMI) in patients with MetS plus OA.

Methods: In this cross-sectional study, we evaluated consecutive patients diagnosed with knee OA according to ACR criteria and willing to participate in the study. MetS was defined in accordance with NCEP ATP III criteria. Knee pain and function were assessed using WOMAC scale. Serum concentrations of gut permeability marker zonulin, lipopolysaccharide (LPS), and soluble LPS receptor (sCD14) were measured using commercial ELISA kits.

Results: Forty patients (19 with OA plus MetS, 21 with OA), all women, mean age 65.5 years, were included in the study. The participants in the compared groups were of similar age. Patients with MetS had significantly higher BMI, increased knee pain, impaired knee function, and elevated serum C-reactive protein levels. Serum LPS, sCD14, and zonulin concentrations were significantly higher (1.5 fold, 2 fold, and 3.5 fold, respectively) in patients with OA+MetS. In the latter group, serum zonulin, sCD14, and LPS concentrations were moderately positively correlated with BMI. There were no correlations between the studied serum biomarkers and WOMAC knee pain, only zonulin was moderately positively associated with WOMAC knee function (Figure 1).

Conclusion: These findings suggest that while associated with MetS, increased gut permeability may not play a significant role in OA clinical manifestations.

MAIN PREDICTORS OF STRUCTURAL PROGRESSION IN PATIENTS WITH METABOLIC PHENOTYPE OF OSTEOARTHRITIS

E. Taskin1, N. Kashevarova1, K. Telyshev1, D. Rudinsky1, E. Strebkova1, E. Sharapova1, L. Alekseeva1,2, A. Lila2,3. 1V .A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation; 2Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Rheumatology, Moscow, Russian Federation; 3I.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation

Objectives: to determine the main predictors of structural progression in patients with metabolic phenotype of knee osteoarthritis (OA).

Methods: 82 female patients with metabolic phenotype of knee OA (diagnosis of OA according to the ACR criteria, radiologic stages varying I-III Kellgren & Lawrence) aged 40-75 were included in this prospective study. Mean age was 59.1 ± 8.5 years (42-74), BMI was 32.5 ± 3.48 kg/m², disease duration was 13 (7-19) years. Individual case report forms, which included history of the disease, physical assessment data, VAS knee pain, WOMAC, joint status, comorbidities and previous medications, were filled out for each patient. All patients performed plain knee radiography, ultrasound and MRI (WORMS).

Results: 13 patients (15.9%) showed structural progression at two years of follow-up. When comparing groups with (n=13, group 1) and without (n=69, group 2) structural progression, there were no differences in terms of age, age of disease onset and disease duration. However, in the progression group patients had higher bodyweight: 99 ± 12.9 vs 82 ± 8.1 kg (p = 0.0003), they also had higher VAS knee pain (69 (66-73) vs 54 (34-66) mm (p=0.0009), and WOMAC (359 (339-381) vs 255 (200-316) mm (p=0.0003)). More patients from the progression group had hypertension (92.3% vs 79.7%) and type 2 diabetes (100% vs 4.3%). MRI showed significant intergroup differences in terms of both frequency and severity of cartilage damage. Cartilage defects (via WORMS) were more frequent in the medial tibial compartment of group 1: 50% vs 4.9% (RR=10.2, 95% CI 3.9-35.1, p=0.0004). Identical trend was found when evaluating bone marrow lesions (BMLs) in the medial (75% vs 27.9%, RR=2.7, 95% CI 1.6-4.5, p=0.003) and lateral (50% vs 16.4%, RR=3.05, 95% CI 1.4-6.8, p=0.02) tibial compartments. Synovitis was verified via MRI in 100% of group 1 patients vs 56.5% (RR=1.8, 95% CI 1.4-2.2, p=0.007).

Conclusion: This prospective trial has shown that the main predictors for metabolic knee OA phenotype progression are high WOMAC pain, synovitis, type 2 diabetes and medial tibial compartment BMLs. Based on the selected factors and their coefficients, we have created a formula that allows to predict the risk of structural progression of metabolic OA.

Disclosure of Interests: None declared.

Model accuracy = 89%
Background: Polyacrylamide hydrogel (iPAAG), manufactured by Contura International, is CE marked for the symptomatic treatment of patients with knee osteoarthritis (OA). iPAAG fulfils an unmet clinical need for an effective, long-acting, safe and minimally invasive treatment that may postpone and potentially prevent knee surgery for those with OA.

Objectives: To compare the effectiveness of single intra-articular injections of iPAAG and hyaluronic acid (HA) in participants with moderate to severe knee OA. To compare the effectiveness of iPAAG and HA in subgroups based on age, BMI or Kellgren-Lawrence (KL) grade at baseline by assessing changes from baseline in transformed WOMAC pain subscale scores.

Methods: This prospective, double-blind study (NCT04045431) randomized 239 participants to receive a single intra-articular injection of either iPAAG or HA. The study was approved by the Capital Region’s Committee on Health Research Ethics. All participants provided informed consent prior to study activities. Outcomes included changes in the WOMAC pain, stiffness and function subscales and Patient Global Assessment of disease impact (PGA) at 52 weeks. All statistical analyses were based on the ITT principle using a mixed model for repeated measures with a restricted maximum likelihood-based approach. The estimated mean treatment difference based on this model was reported with 95% CI and p-value.

Results: Demographic and baseline characteristics were similar between treatment groups with an average age at treatment of approximately 67 years (range 31 – 90 years) and slightly more females (53%) than males. There was a clinically relevant decrease in WOMAC pain subscale score from baseline to 52 weeks in both groups (Figure 1). There were also clinically relevant decreases in the WOMAC stiffness subscale and physical function subscale and PGA in both groups. Treatment differences in favor of iPAAG compared to HA, were measured for the 3 WOMAC subscales and PGA. However, none of these differences reached statistical significance.

Conclusion: At 52 weeks after treatment, the effectiveness of iPAAG was numerically superior to HA but not statistically significantly different. In subgroups of participants with normal BMI, participants <70 years old or participants with KL grade 2 or 3 iPAAG performed statistically significantly better than HA at 52 weeks after treatment.

Disclosure of Interests: None declared

POST1131 ASSOCIATION BETWEEN ANTIBIOTIC USE AND RADIOGRAPHIC PROGRESSION OF OA: DATA FROM THE OSTEOARTHRITIS INITIATIVE

I. Shirinsky1, V. Shirinsky1, 1. Federal State Budgetary Scientific Institution, Research Institute of Fundamental and Clinical Immunology, Laboratory of Clinical Immunopharmacology, Novoibinsk, Russian Federation

Background: Gut dysbiosis has been proposed as one risk factor for osteoarthritis (OA) (1). To date, there have been no studies assessing association between the use of antibiotics and structural progression of knee OA.

Objectives: To evaluate association between the use of antibiotics and radiographic progression of knee OA.

Methods: For the current study we used 9-year longitudinal data obtained from the Osteoarthritis Initiative (OAI) progression (n=1390) and incidence (n=3284) subcohorts, which are publicly available at https://oai.nih.gov. For the assessment of antibiotic influence on knee OA progression we analyzed all knees having baseline JSN=3 from both subcohorts. The main outcome was knee OA progression (defined as increase in semiquantitative JSN or a new knee replacement). To acquire information about the use of antibiotics, a medication inventory method was used. We excluded participants who used antibiotics at or 30 days prior to baseline (a “new-user” design). Antibiotic users were defined as those with at least one recorded use during first four years of the study. Other participants who did not use antibiotics prior to baseline and throughout the observation period were classified as non-users. Logistic regression models were used to evaluate the relationship between the outcome and antibiotic use. Generalized estimating equations (GEE) were used to adjust for the correlation between knees.

Results: A total of 8415 of knees (7404 non-user knees and 1011 user knees) were included in the analysis. No association between the use of antibiotic and radiographic progression of knee OA was found (odds ratio 1.23, 95% confidence interval 0.59-2.56, p = 0.59). No associations were also observed in multiple stratified analyses based on different duration of antibiotic use, particular classes of antibiotics, or different baseline KL grades.

Conclusion: These findings do not support the effects of antibiotics on knee OA progression.

Figure 1. Mean plot of transformed WOMAC pain subscale (0-100) – ITT analysis set

The treatment difference in favor of iPAAG compared to HA for the WOMAC pain subscale score was statistically significant in the subgroup with age at baseline <70 years but did not reach statistical significance in the subgroup with age at baseline ≥70 years. The treatment difference in favor of iPAAG compared to HA for the WOMAC pain subscale score was statistically significant in the subgroup with normal BMI but did not reach statistical significance in the subgroups with overweight or obese BMI. The treatment difference in favor of iPAAG compared to HA for the WOMAC pain subscale score was statistically significant in the subgroup with KL grade 2 or 3. In the subgroup with KL grade 4, a treatment difference in favor of HA was not statistically significant.

Figure 1. Mean plot of transformed WOMAC pain subscale (0-100) – ITT analysis set
On the other hand, an increasing trend among the cases, signifying a higher prevalence of surgeries when nearing KR, was observed for HR and meniscal surgeries in both nations. The prevalence of HR was similar in England and southern Sweden at all-time points showing an increase most noticeable in the 3 years before KR. The prevalence of meniscus surgery in England was higher than the one observed in Sweden throughout the follow-up. Prevalence in England increased most noticeably in the four years prior to KR reaching 33.2 (95%CI 31.6, 34.9) surgeries per 1,000 people in the year preceding KR. In Sweden, the prevalence of meniscus surgery remained between four and eight surgeries per 1,000 people until the last year prior to KR when the prevalence increased to 13.8 (95% CI 11.9, 16.2) surgeries per 1,000 people.

Conclusion: HR and meniscal surgeries are common procedures that a person is likely to have experienced in the ten years prior to a KR. Comparing England and southern Sweden, we noticed similar prevalence and trends for what concerns HR suggesting similar practice in the two healthcare systems. Meniscus surgeries were more frequently utilised in England. Nevertheless, in both countries, a marked increase in the prevalence of this surgery was observed in the last years prior to the KR.

POS1133 IRISIN LEVELS IN KNEE OSTEOARTHRITIS ARE RELATED TO GENDER, OBESITY AND LOCAL INFLAMMATION
C. Orellana1, M. Rusiñol1, E. Costa Moya1, J. Calvet1, S. Garcia-Cirera1, M. Garcia Manrique de Lara1, C. Gailloste1, J. Gratacos-Masmithia1, Hóspita Universitari Parc Taulí, Rheumatology, Sabadell, Spain

Background: Irisin is a myokine synthesized mainly in skeletal muscle with exercise, although its secretion has also been observed in other tissues such as adipose and has been related to obesity and other metabolic alterations. Although obesity and other metabolic factors are risk factors for knee osteoarthritis and patients with this condition often do less exercise and have poor muscular state, irisin has been poorly studied.

Objectives: To measure irisin levels in synovial fluid and plasma and evaluate their relationship with clinical severity and inflammation parameters in patients with knee osteoarthritis.

Methods: Patients with symptomatic and radiographical osteoarthritis were studied. Demographic and anthropometric variables, Kellgren-Lawrence scale and Lequesne index were evaluated in ultrasound (at medial patellar line), clinical severity by Lequesne algofunctional index and physical exercise level were recorded. Levels of irisin, IL-6, TNF and hs-PCR were determined using ELISA.

Results: We included 6337 and 47010 subjects who underwent a knee replacement between 2015 and 2019 in southern Sweden and England, respectively (Table 1). Overall, the prevalence of all analysed surgeries was consistently lower in the controls with minimal trends detectable throughout follow-up in both England and Sweden (Figure 1).

POS1134 THE EFFECT OF ETORICOXIB ON PAIN AND SIGNS OF CENTRAL SENSITIZATION IN PATIENTS WITH OSTEOARTHRITIS
E. Polisichuk1, A. Karateev1, V. Amirdzhanova1, V.A. Nasonova Research Institute of Rheumatology, pain management, Moscow, Russian Federation

Background: Central sensitization (CS) plays an important role in the development of chronic pain in osteoarthritis (OA).

Objectives: to evaluate the effect of etoricoxib on pain and signs of CS in patients with OA.

Methods: 790 patients with OA (knee or hip) were included in an open observational study. Most of them (71.6%) were female, mean age 54.5 ± 13.0 years. All patients received etoricoxib 60 mg/day for 2 weeks. The dynamics of pain was assessed on a numerical rating scale (NRS 0–10), the dynamics of signs of CS was assessed using the Central Sensitization Inventory (CSI). CSI ≥ 40 was observed in 35.3% of patients.

Disclosure of Interests: None declared
Results: After 2 weeks of treatment with etoricoxib, the intensity of pain at movement, at rest and at night decreased by 58.8±24.1%, 69.7±32.6% and 70.1±32.8%. There was a decrease in CSI values by 33.1±14.5% (p<0.001), as well as a decrease in the number of MS components by 10.8% (p<0.001, r=0.92), the number of MS components by 3.5% to 10.3% (p<0.001).

Conclusion: Etoricoxib improved pain in OA patients and reduces the severity of signs of CS, supporting the central mode-of-action of the drug.

Disclosure of Interests: None declared.

POST135

METABOLIC OSTEOARTHRITIS: THE ROLE OF THE NUMBER OF COMPONENTS OF METABOLIC SYNDROME AND EXPRESSION OF CARTILAGE TISSUE DESTRUCTION GENES.

E. Strebkova1, E. Taskina1, N. Kashevarova1, E. Sharapova1, D. Kusevich1, L. Alekseeva1,2, A. Lila1,3, V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation; 2Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Rheumatology, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation

Background: Osteoarthritis (OA) associated with metabolic syndrome (MS) or its components is considered as the metabolic phenotype of OA. It is well known that obesity and other components of MS affect the clinical picture, course and progression of OA. The cumulative effect of metabolic disorders has an effect on the course and outcomes of OA. The study of molecular genetic relationships between the expression of cartilage tissue destruction genes and metabolic OA is one of the studied and relevant directions in rheumatology.

Objectives: To determine the role of MS component count and gene expression associated with cartilage tissue destruction in metabolic OA.

Methods: The study included women (n = 117) 45-75 y.o with knee OA (according to ACR criteria) I-II X-ray stage by Kellgren-Lawrence with different numbers of MS components. The duration of the study was 2 years. The clinic conducted visits 1 times a year. At each visit, anthropometric patient scores, articular status, VAS for knee pain, WOMAC and comorbidities were recorded. Patients underwent a laboratory examination (biochemical blood examination: glucose, total cholesterol, LDL, HDL, TG, isolation of blood RNA) to determine the level of expression of cell proliferation genes - m-TOR and cartilage destruction - cathepsin K, instrumental examination (X-ray of knee joints) 1 once a year.

Results: All patients with knee OA included in the study (n = 117) showed an abdominal type of obesity (waist circumference > 80 cm in women), which is the main criterion for MS. With frequency analysis in 5.5% of patients, 1 component of MS was detected, in 13.5% - 2 components of MS, in 70.2% - 3 components of MS, in 10.8% - 4 components of MS. Median (25%; 75%) duration of knee OA disease was greater in patients with 2 or more MS components and was 7.3 years (6.0-8.0) compared to patients with 1 MS component, in whom the duration of OA was 5.4 years (2.0-11.0), p < 0.05. Spearman correlation analysis showed significant relationships between MS component count and OA duration, age, BMI, VAS for knee pain, WOMAC (Table 1).

Patients showed high expression rates of m-TOR cell proliferation regulator (11.04 (4.27-15.5)) and cathepsin K articular cartilage destruction (9.34 (3.66-12.5)). In analysis of Spearman correlations of cell metabolism gene expression with clinical manifestations of OA and MS components, direct positive correlations with VAS for knee pain were found (p < 0.001, r = 0.95), body weight (p < 0.001, r = 0.92), the number of MS components (p < 0.001, r = 0.78) and WOMAC pain (p < 0.001, r = 0.76).

Conclusion: In our work, it has been demonstrated that 3 or more components of MS in patients with knee OA are observed at pronounced X-ray stages of OA with longer disease duration and a long history of obesity. There are positive correlations between the number of MS components and the clinical course of OA, X-ray severity of OA, hyperexpression of cell proliferation and cartilage destruction genes.

Disclosure of Interests: None declared.

OSTEOARTHRITIS AND METHOTREXATE: EFFICACY AND SAFETY.

L. Alekseeva1,2, E. Strebkova1, N. Kashevarova1, E. Taskina1, E. Sharapova1, D. Kusevich1, A. Lila1,3, V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation; 2Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Rheumatology, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation

Background: One of the common phenotypes of osteoarthritis (OA) is the “inflammatory phenotype,” which is characterized by persistent synovitis of knee joints, small joints of the hands, the development of the erosive hand OA (EOA), and insufficient effectiveness of standard OA therapy. In the inflammatory OA phenotype, changes observed in the synovial sheath have similar features to rheumatoid arthritis, so baseline anti-inflammatory drugs used in RA may be considered as possible treatments for OA. The literature presents few studies with mixed results on the use of methotrexate (MTX) in patients with OA.

Objectives: To examine the efficacy and safety of MTX use in patients with inflammatory knee OA and hand EOA.

Methods: The study included 40 patients (women) with OA (according to ACR criteria) and insufficient effectiveness of previous OA standard therapy: with knee OA (47.5%), hand EOA (25%) and a combination of these 2 localizations (27.5%). The clinical characteristics are shown in Table 1. For 24 weeks, patients received MTX subcutaneously with a dose escalation of 10mg to 15mg per week combined with folic acid 5mg per week and meloxicam 15mg “on demand.” The efficacy of MTX therapy was assessed by WOMAC and AUSCAN, by the OMERACT-OARSI criteria. During the study, laboratory indicators were monitored (clinical, biochemical, immunological blood tests, general urine test).

Results: As a result of 24 weeks of MTX therapy, there was a statistically significant decrease in pain, stiffness and functional insufficiency in the small joints of the hand on the AUSCAN index and in the knee joints on the WOMAC index (Figure 1). In hand OA, there was a decrease in pain by 40.21%, stiffness by 48.21%, functional insufficiency by 23.72%. In knee OA, there was a reduction in pain by 50.45%, stiffness by 49%, and functional failure by 42.7%. 85.5% of patients with knee OA and 72.5% of patients with hand EOA became responders to therapy according to the OMERACT-OARSI criteria. The best clinical effect was achieved in knee OA (89.9% of patients). As a result of MTX therapy, the need for non-steroidal anti-inflammatory drugs (NSAID) decreased: initially, 85% of patients took NSAID daily or more than 3 times a week, and after 6 months of MTX therapy, only 15% of patients took NSAID daily. In general, the tolerability of MTX was satisfactory. The study of 7 patients was stopped: 4 (10%) due to nausea, 3 (8%) due to a moderate increase in liver enzymes.

Figure 1. Dynamics of the total AUSCAN and total WOMAC as a result of MTX therapy.
in transaminases, one of these patients (3%) had one episode of neutropenia up to 1.82x10^9/L (norm 2.04 - 5.80 x10^9/L). There were no serious adverse events.

**Conclusion:** The results demonstrated a good symptomatic effect of MTX in patients with knee OA and hand EOA. There was a statistically significant decrease in pain, stiffness and functional insufficiency in knee joints and small joints of the hands, a decrease in the need for NSAID throughout MTX therapy.

The best clinical effect was achieved in patients with knee OA. Thus, the study showed that MTX has a good clinical effect in OA and a satisfactory safety profile.

**POS1137**

**CORRELATIONS BETWEEN CLINICAL PARAMETERS AND SERUM CYTOKINE LEVELS IN OSTEOARTHRITIS PATIENTS WITH TYPE 2 DIABETES MELLITUS**

E. Trifonov, E. Zonova, O. Sazonova, Novosibirsk State Medical University, Department of Pharmacology, Clinical Pharmacology and Evidence-Based Medicine, Novosibirsk, Russian Federation; Novosibirsk State Medical University, Department of Therapy, Hematology and Transfusiology, Novosibirsk, Russian Federation

**Background:** Type 2 diabetes mellitus (T2DM) is one of frequent factor that can influence on development and progression of osteoarthritis (OA) and has similar mechanisms of immunopathogenesis.

**Objectives:** To explore the symptoms and the proinflammatory serum cytokine levels in OA (hand, knee, and hip) patients with T2DM and to estimate relationships between clinical and immunological features.

**Methods:** Patients who participated in this study (n=137) were divided in two groups: patients with bilateral hand, knee and hip OA (n=56) and T2DM and control group (n=81) which had only hand, knee and hip OA without such comorbidity. All patients were comparable in age, sex and duration of OA. We assessed serum cytokine levels (IL-6, IL-10, IL-18). NO including adipokines such as adiponectin, leptin and C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), various symptoms of OA and mental health were measured using visual analog scale (VAS), Functional Index for Hand Osteoarthritis (FIHOA), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC Knee/Hip), Knee injury and Osteoarthritis Outcome Score – (KOOS), Hip injury and Osteoarthritis Outcome Score – (HOOS) and with short form SF-36; Psychological Health Questionnaire (PHQ9), Coping Pain Strategy Questionnaire (CSQ). We used U-Mann-Whitney test to detect differences between groups. Correlation was assessed using Spearman correlation coefficient (r).

**Results:** Patients with OA and T2DM are characterized by the prevalence of KOOS symptoms (median (Me) 58.3, interquartile range (IQR) 50–71.5; p<0.001), WOMAC Knee Total (Me 1327; IQR 930.6–1546; p=0.001) and low values of mental health (SF-MH (Me 48; IQR 35–56; p=0.001). We found increase of IL 6 (p = 0.0018), IL 18 (p = 0.0006), NO (p < 0.0001) levels in the blood serum of patients with OA and comorbidity. Patients with OA and T2DM had high ESR level (p < 0.0001) and leptin level (p = 0.0002) also. Correlation analysis identified the relationships between clinical parameters and such cytokines as IL-1β, IL-6, IL-10 and leptin, CRP in OA patients with T2DM. Some data are presented (Table 1).

**Conclusion:** Such comorbidity as OA and T2DM has clinical and laboratory features of progression of OA. Such immunological factors as serum cytokines concentrations, adipokines, CRP are linked with the severity of T2DM-associated OA. A different variation of correlations may suppose role of this proinflammatory factors in the pathogenesis of this OA phenotype. These data should be verified by larger studies.

**PERSISTENCE OF DEPRESSIVE SYMPTOMS AND PHYSICAL PERFORMANCE IN KNEE OSTEOARTHRITIS**

R. Mehta, M. Shardelli, A. Ryan, Y. Dong, B. Beamer, J. Gallo, E. Stuart, M. Schuler, M. Hockberg, A. Rathbun. 1. University of Maryland School of Medicine, Epidemiology and Public Health, Baltimore, United States of America; 2.University of Maryland School of Medicine, Medicine, Baltimore, United States of America; 3.University of Maryland School of Medicine, Psychiatry, Baltimore, United States of America; 4.Johns Hopkins Bloomberg School of Public Health, Mental Health, Baltimore, United States of America; 5.Rand Inc., Policy Research, Boston, United States of America

**Background:** Knee osteoarthritis (OA) is the most prevalent arthritic disorder, characterized by joint pain, which is exacerbated by chronic depressive episodes. Depression in knee OA is also associated with declines in physical activity level and greater disability; however, the impact of persistent depressive symptoms on physical performance remains unclear.

**Objectives:** To determine how the persistence of depressive symptoms affects functional capacity in knee OA.

**Methods:** Participants (n=2,212) were from the Osteoarthritis Initiative cohort and included individuals with radiographic disease (Kellgren-Lawrence grade ≥ 2) and complete data on study measures at baseline. Depressive symptoms were assessed using Center for Epidemiological Studies Depression Scale (20-item, range 0–60) at baseline and the first three follow-up visits. Physical Performance was measured using 20-meter gait speed (meters per second) during follow-up in the first four annual visits. Persistency of depressive symptoms was operationalized as a cumulative exposure using average severity over time. Gait speed was standardized so that outcome estimates could be interpreted in standard deviations. Time-invariant confounders measured at study enrollment included demographic, socioeconomic, and lifestyle factors. Time-varying confounders assessed concurrent to CES-D scores were body mass index, analgesic medications, pain, and other knee OA signs and symptoms. Marginal structural models accounting for time-dependent confounding and selective attrition were the primary method of analysis. The outcome model included all potential statistical interactions between depressive symptoms and follow-up time indicators. Post-estimation linear combinations estimated time-specific effects of time-averaged CES-D scores on standardized gait speed and differences in physical performance between participants with (i.e., CES-D=16) and without (i.e., CES-D=0) depressive symptoms satisfying screening criteria for major depression.

**Results:** The interaction between depressive symptoms and time was statistically significant (P<0.001). Time-specific associations indicated that the largest negative impact of depressive symptoms on physical performance was from baseline through year one (β = -0.0077; 95% CI: -0.0125, 0.0030). However, the effect of persistent depressive symptoms decreased over time and reversed in magnitude and directionality, evidenced by the time-specific associations between time-averaged CES-D scores from baseline through year one and year two and gait speed at year two (β = -0.0033; 95% CI: -0.0084, 0.0019) and year three (β = 0.0014; 95% CI: -0.0046, 0.0074), respectively. Consequently, the strongest negative affect of depressive symptoms on gait speed (β = -0.1323; 95% CI: -0.1998, -0.0473) between participants with and without depressive symptoms satisfying screening criteria for major depression was when depressive symptoms were first reported closest to the initial gait speed assessment.

**Conclusion:** In the contrast to the dose-dependent relationship between chronic depressive episodes and pain in knee OA, study findings imply that the negative effect of depressive symptoms on physical performance decreases over time with increasing depression persistency. These results may reflect diminishing marginal effects, where the largest impact on physical performance in knee OA is during the first depressive episode closest to initial gait speed assessment, especially when averaged against improvement in symptoms over the same duration.

Osteoporosis

**POST139** GLUCOCORTICOIDS AND BONE DENSITY IN POLYMYALGIA RHEUMATICA, GIANT CELL ARTERITIS, AND OTHER VASCULITIDES – A CROSS-SECTIONAL ANALYSIS OF THE RH-GIOP COHORT

A. Palmowski1, E. Wibe2, B. Muche3, S. Hermann4, C. Deja9, E. Matteson5, F. Buttgereit6,1. Chanté - Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany, 2Medical University Graz and South Tyrol Health Trust, Department of Rheumatology and Immunology and Rheumatology Service, Graz and Bruneck, Italy, 3Mayo Clinic College of Medicine and Science, Division of Rheumatology and Division of Epidemiology, Departments of Internal Medicine and Health Sciences Research, Rochester, MN, United States of America

**Background:** There are only few, inconclusive investigations on bone density and the effects of glucocorticoids (GCs) in polymyalgia rheumatica (PMR) and vasculitides.

**Objectives:** To determine whether GCs are associated with bone density in patients with PMR and other vasculitides after adjustment for confounders.

**Methods:** The Rh-Giop cohort study started in 2015 and investigates bone health in patients with rheumatic diseases. In this cross-sectional analysis of baseline visits, we included patients with PMR and vasculitides. Multiple regression was used to model the effect of current and cumulative GC intake on the minimum T-score (mTs; lumbar spine or hip) with adjustment for several founders such as sex, age, body mass index (BMI), or inflammation (measured by C-reactive protein (CRP)). GCs were modelled both as continuous and as categorical predictors in separate models. Several sensitivity analyses were performed. Patients with early disease (<3 months) were excluded from inferential analyses as were patients with very high GC dosages (>100mg/day prednisolone equivalent). Multiple imputation by chained equations was used for missing data (about 5%).

**Results:** 198 patients (mean age 68 ± 11 years; 68% females) with a mean disease duration of 5.3 ± 6.3 years were included. The most common rheumatic disease was PMR (36%), followed by giant cell arteritis (26%) and granulomatosis with polyangiitis (17%). 87% were currently taking GCs, 88% received vitamin D supplements, 7% had a deficiency. Osteoporosis (OP) diagnosed by DXA was present in 19% (17.2% with PMR and 21% in other vasculitides). 87% were currently taking GCs, 88% received vitamin D supplements, 7% had a deficiency. Osteoporosis (OP) diagnosed by DXA was present in 19% (17.2% with PMR and 21% in other vasculitides).

**Discussion:** In this cohort of PMR and vasculitides, the prevalence of OP was similar to the overall elderly German population. Vitamin D supplementation was common while deficiencies were surprisingly rare – in population-based studies, about 32% of Germans are estimated to have a vitamin D deficit. We found no association between current or cumulative GC intake, inflammation, and bone density. Proton-pump inhibitor intake and BMI as modifiable risk factors were associated with mTs. These findings need confirmation from longitudinal analyses of our and other cohorts.

**POST140** SHORT-TERM EXPOSURE TO FINE PARTICULATE MATTER AND RISK OF FRAGILITY HIP FRACTURES, A CASE-CROSSOVER STUDY ON 1,042 HIP FRACTURES

G. Adam1, M. Pontalti1, A. Fassio1, C. Benini1, D. Gatti1, S. Negrì1, P. Olivì1, M. Possini1, 1University of Verona, Rheumatology Unit, Verona, Italy, 2University of Verona, Orthopedic Unit, Verona, Italy

**Background:** Fragility femoral fracture is a common, world-spread, medical condition, that has a relevant impact both clinically and economically. Chronic exposure to environmental air pollution has been linked with a higher risk of developing osteoporosis. However, little is known regarding the relationship between short-term exposure to air pollution and bone fractures.

**Objectives:** Our study aims to investigate the link between short-term exposure to fine particulate matters and fragility hip fractures.

**Methods:** We retrieved data of patients suffering of hip fractures admitted to the Orthopedic Unit of the University of Verona Hospital from 2015 to 2020. We retrieved data on the monitoring of PM10 concentrations from the Italian institute of environment protection and research (ISPRA). We designed a case-crossover study to compare the exposure to particulate matters (PM10) in the 30-day period immediately before the fracture (hazard period) referent to a 30-day control period (from day -30 to -60 from the fracture). Exposure to PM10 was evaluated as mean value and AUC. Case-crossover is a peculiar study design applied to longitudinal datasets that controls for within-person time-invariant and between-patient confounders such as indoor air pollution, chronic comorbidities or concomitant medications and have been used extensively to study the effects of transient, short-term exposures on the risk of acute events (Figure 1A).

**Results:** 1042 patients (73.7% female n=768), with a hip fracture admitted to the hospital were included in the study. Mean age of the cohort was 82.6 years (±9.55). Average exposure to PM 10 in the control period was 33.84 ug/m3, cumulative exposure (AUC) was 952.42 ug/m3 compared to fine particulate matters and fragility hip fractures.

**Conclusion:** In this cohort of PMR and vasculitides, the prevalence of OP was similar to the overall elderly German population. Vitamin D supplementation was common while deficiencies were surprisingly rare – in population-based studies, about 32% of Germans are estimated to have a vitamin D deficit. We found no association between current or cumulative GC intake, inflammation, and bone density. Proton-pump inhibitor intake and BMI as modifiable risk factors were associated with mTs. These findings need confirmation from longitudinal analyses of our and other cohorts.

POS1142 FACTOR ANALYSIS OF FRAILTY FRACTURES BY SITE IN PATIENTS REFERRED FOR DUAL-ENERGY X-RAY ABSORPTIOMETRY SCAN

Z. Sultan1, M. Bukhari2. 1Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom; 2Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom

Background: Frailty fractures are defined as fractures which occur secondary to low energy trauma (1). Fractures lead to substantial pain, reduced quality of life and significant burden to society, with 3.5 million fragility fractures occurring in the EU in 2010 costing €37 billion (2). It is predicted that by 2025 this cost will have increased by 25% (2). Studying fractures is in the interest of our ageing society in order to aid management of patients at risk. To our knowledge, no other studies have grouped fractures based on site by factor analysis.

Objectives: 1. Determine which fractures are most common in patients who present for dual-energy X-ray absorptiometry (DEXA) scan
2. Apply a factor analysis to establish any patterns in the incidence of fractures based on site

Methods: Between 1996 and 2017, 31546 patients presented to a district general hospital in the North West of England for bone mineral density estimation by DEXA scan. Demographic details, risk factors, incidence of fractures and site of fractures were recorded at time of scan. These data were retrospectively studied to identify patients who had sustained at least one fracture. STATA was used to conduct a factor analysis using the principal component factors (PCF) method. Ethical approval was granted by the Northwest Regional Ethics Committee.

Results: 11839 patients were identified to have had at least one fracture (14756 total fractures). Mean age was 67.96, with 9993 females and 1846 males. Mean height was 161.21 cm, mean weight was 70.41 kg and mean BMI was 27.04 kg/ m2. Mean T-scores at femoral neck, total femur and lumbar spine were -1.55, -1.38 and -1.30 respectively. The most common fracture site was at the wrist/forearm with 5421 (36.74%) cases. Further, there were 2795 tibia/fibula (18.94%), 2530 spine (17.15%), 1363 femur (9.24%), 1224 humerus (8.29%), 1063 rib (7.20%), 315 pelvis (2.13%), 43 elbow (0.29%) and 2 ankle (0.01%) fractures. 9390 patients had 1 fracture and 2449 patients had more than 1, with 9 patients sustaining 5 fractures. Factor analysis on fracture sites revealed 6 factors with an eigenvalue > 1. Fracture sites were grouped together based on those fractures which loaded most heavily on each factor. Loading was as follows: spine and ribs on Factor 1; spine, pelvis and wrist/forearm on Factor 2; humerus and femur on Factor 3; elbow and ankle on Factor 4; ribs and humerus on Factor 5; ribs and femur on Factor 6 (Table 1).

Conclusion: In-keeping with published data, the most common site for fracture was forearm (3). Factor analysis grouped together sites of fractures into 6 factors, suggesting that these fractures are more likely to co-exist. Moving forward it would be beneficial to ascertain differences between the groups in terms of demographics, risk factors and any bone protection measures taken. This may highlight clinically relevant data in order to make evidence based decisions in the identification and management of patients at risk of fragility fractures.

POS1142 A CONCORDANCE STUDY OF CT DENSITOMETRY WITH DXA DENSITOMETRY

R. Mawella, 1 R. Rajak, 1 Croydon Health Services NHS Trust, Medicine, London, United Kingdom; 2Croydon Health Services NHS Trust, Rheumatology, London, United Kingdom

Background: Osteoporosis is a skeletal disorder characterised by compromised bone strength resulting in an increased risk of fracture. Although DXA is the only technology that can be used for diagnostic classification of osteoporosis according to WHO, computed tomography imaging (CT) densitometry of the spine has equal or superior ability to predict vertebral fractures in postmenopausal women. Therefore the continued use of DXA as the primary modality of calculating BMD may lead to inaccurate exclusion of osteoporosis and prognostication.

Objectives: To assess the concordance of spinal CT densitometry with current standard of assessment through DXA-derived densitometry.

Methods: 50 patients who had had both a DXA scan of the lumbar spine and CT lumbar spine/thorax/abdomen performed within 18 months of each other were included. The CT images were analysed to attain a mean Hounsfield score of the lumbar vertebrae and this was compared to DXA derived T-scores. A Hounsfield score of 131 was used as the threshold for diagnosing osteoporosis akin to a DXA-derived T score of -2.5. The final data was analysed to find correlation values of Hounsfield score with T score using Pearson correlation coefficient.

Results: The mean Hounsfield score was 108.4 (osteoporotic) compared to a mean T-score of -1.22 (osteopenic) with a statistically significant correlation coefficient of 0.447 (p<0.01). Using T score ≤ -2.5, 15 (30%) of the patients included on our study would have a diagnosis of osteoporosis whereas this would be 36 patients (72%) if using the threshold of Hounsfield score <131. Out of the 50 patients included, 15 had vertebral fragility fractures. The mean T-score for these patients was -1.2 (indicating osteopenia) and mean Hounsfield score was 108 (indicating osteoporosis).

Conclusion: Our study showed a moderate positive correlation between the DXA-derived T-scores and CT Hounsfield scores. This further validates previous studies that suggest CT scans can be used to identify patients with osteoporosis. 93% of patients with vertebral fragility were identified as having osteoporosis using CT densitometry whereas only 40% were identified via DXA. These findings highlight the limitations of DXA, particularly in terms of overestimation of bone mineral density related to degenerative changes. CT images of the thorax, abdomen or lumbar spine that have already been performed for other indications can be used to opportunistically screen...
for osteoporosis without additional radiation exposure, waiting time or cost. This may allow for more accurate diagnosis and subsequent treatment and fracture risk reduction.

DOI: 10.1136/annrheumdis-2022-eular.1017
Background: Although most fragility fractures occur in osteoporotic patients, fractures of the lumbar spine and the femora are also common in patients with normal bone mineral density (BMD). A number of risk factors are known to be associated with fractures in patients with reduced BMD. However, risk factors for fractures in patients with normal BMD remain relatively unexplored.

Objectives: Evaluate the risk factors associated with fractures in patients with a normal BMD (T-score ≥ -1.00) in the lumbar spine and right and left femur in an observational cohort.

Methods: Data was collected from patients attending a District General Hospital in the Northwest of England for a DEXA scan between 2004 to 2019. Patients with a T-score ≥ 1.00 in L1-4 and the right and left femur were included. Chi-squared test and Student’s t-test were used to compare risk factors in patients with and without fractures. A series of logistic regression models that adjusted for age and sex were then fitted to determine risk factors associated with a fracture.

Results: 6,504 patients were included in analysis, 1,491 (22.9%) of whom had a fracture. Mean age (SD) at scan was 58.64 (12.98) years and 5,347 (82.2%) were female. Risk factors and their association with fracture occurrence after adjusting for age and sex are shown in Table 1. Weight, BMI, and current alcohol use were statistically significantly (p < 0.05) associated with increased risk of fracture. History of Rheumatoid Arthritis, steroid use, and increased T-score in L1-4 or the right or left femur were statistically significantly (p < 0.05) associated with decreased risk of fracture.

Conclusion: In the FRAX tool, increased weight is considered protective against fractures, and steroid use and Rheumatoid Arthritis are thought to increase fracture risk. In our cohort of patients with normal BMD, patients with increased weight had a higher risk of fracture, and patients with Rheumatoid Arthritis and steroid use had a decreased fracture risk.

While there is overlap in the risk factors associated with fractures in patients with reduced BMD and normal BMD, our study suggests that some characteristics protective of fractures in osteoporotic patients may increase the risk of fracture in patients with a normal BMD.

Challenges in Conducting Pragmatic Care Strategy Studies in Osteoporosis: Patient Perceptions

L. Jackson1, E. McNeely2, N. C. Techarukpong1, F. Mugeta1, K. Aaron1, A. Mudano1, J. Merchant1, K. Warren2, J. Foster1, K. Saag3, M. Danila1

1University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America

Background: Large pragmatic osteoporosis studies to improve outcomes are needed. Direct-to-patient accrual strategies have high generalizability but achieving sufficient sample size is difficult; recruitment challenges represent an important consideration given limited participant eligibility and interest. The Fracture Liaison Service (FLS), a team approach to post-fracture care, is a secondary fracture prevention method that has significantly improved outcomes internationally.

Objectives: Our goal was to evaluate the interest, barriers, and lessons learned in recruiting participants for a future trial assessing remote FLS approaches for post-fracture care.

Methods: We used ICD10 fracture codes to identify patients > 50 years of age with a documented hip/pelvis, spine, humerus, or wrist fracture in the previous 1 year. We excluded patients with i) prescriptions for osteoporosis medications (e.g., bisphosphonates, parathyroid hormone analogs, denosumab, romosozumab, raloxifene) in the prior year; ii) an ICD10 code for end-stage renal disease, non-osteoporotic metabolic bone disease, malignant neoplasm, or motor vehicle accident. In December 2021, research assistants reviewed electronic health records (EHR) of potentially eligible patients for evidence of additional serious illness limiting life expectancy to < 1 year or non-ambulatory status prior to fracture. Research assistants called preliminary eligible patients that met inclusion and exclusion criteria and asked them to complete a survey status prior to fracture. Research assistants called preliminary eligible patients that met inclusion and exclusion criteria and asked them to complete a survey by phone. Interest in a FLS future clinical trial was evaluated using a Likert scale: “1= Definitely would not volunteer;” to “5= Definitely would volunteer”). We used descriptive statistics to analyze baseline demographic, clinical characteristics, and interest. This pilot was approved by the UAB Institutional Review Board (IRB-300008310-005).

Results: We identified 1,577 patients > 50 years of age with a fracture. After applying exclusion criteria, we identified 869 preliminary eligible patients. Over 3 weeks, we screened the medical records of a random sample of half of the preliminary eligible patient cohort (n=414), of which we contacted 271 patients, the mean age of 69.5 (11.5) years, 40% men, 21% Black or non-white Hispanics completed the survey. Among those contacted, 68 (83%, interest rate) said they would be very or highly interested in participating in a future clinical trial evaluating FLS approaches. Among the 40 (37%) people who said they were not sure, unlikely or very unlikely to volunteer the most common reasons cited were “I don’t want to participate in a study” (33%); “I don’t feel well enough to participate” (10%); “I don’t understand what the study is for” (3%). From this pilot, we calculated a refined eligibility/interest rate of 9.1% among those preliminary identified as eligible using administrative data alone.

Conclusion: Based on our pilot, we estimate that approximately 9% of eligible patients with fractures will be interested in enrolling in a future comparative effectiveness study to prevent recurrent fragility fractures. We identified several potential modifiable barriers to clinical trial recruitment. Participant perceptions collected from this pilot will inform enrollment strategies, which can be incorporated early when planning direct-to-patient pragmatic osteoporosis studies to achieve recruitment goals.

Sonographic Variation of Synovitis in Rheumatoid Arthritis Is Suggestive of Bone Mineral Density Change.

J. Chen1, T.T. Cheng1, Y. Chen1

1Kaohsiung Chang Gung Memorial Hospital and Chang Gung University, College of Medicine, Division of Rheumatology, Allergy, and Immunology, Department of Internal Medicine, Kaohsiung City, Taiwan, Republic of China

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disorder initiated from local synovium inflammation and consequently bone/cartilage destruction. Active disease status brings persistent inflammation, which stimulates the activation of osteoclasts, accelerating systemic bone loss and decreasing bone mineral density (BMD)1. Ultrasound (US), a powerful tool for clinical practice, was reported to be beneficial for the prediction of new bone erosion and disease activity (2, 3), based on the synovium grading recommendation by the European League against rheumatism- Outcome Measures in Rheumatology Clinical Trial (EULAR-OMERACT) Taskforce. The severity of RA synovitis is associated with local bone destruction; however, the impact on systemic bone loss is still unknown.

Objectives: This pilot study aims to investigate if the US-detected synovitis change is associated with systemic bone loss.

Methods: A registry was conducted in Chang Gung Memorial Hospital, Kaohsiung, from September 2014 till April 2021 to monitor BMD changes in patients with rheumatic diseases. In RA patients, we regularly assessed synovium change of bilateral wrist by ultrasound at enrollment and one year later, based on EULAR-OMERACT system(4), which is a semiquantitative grading tool incorporating both gray-scale synovial hypertrophy (SH) and power Doppler (PD) signal. These ultrasound scans were performed by an independent and well-trained rheumatologist, using MyLab 70 system (Esaote, Firenze, Italy) and B-mode frequency at 12–18 MHz. We performed a longitudinal scan of volar and dorsal wrists, observing GS and PD signals. All participants who underwent standard care for RA were followed at least three years to monitor BMD change, and those who underwent anti-osteoporosis therapy at index day were excluded. We defined improvement of US-detected synovitis (US+) as a change from high to low grade by EULAR-OMERACT score. Conversely, patients who failed improvement were recorded as “US-” defined as change from low to high grade. Patients who improved one or more grades, such as from Grade 3 to 2 (or from Grade 2 to 0), were registered as US+1 (or US+2) and vice versa. If there is no change of synovitis grade, we registered as US+0.

Results: A total of 212 participants were enrolled in the current study, with a mean age of 56.0 ± 10.1 years and a mean RA disease duration of 13.6 ± 9.1 years. In patients with US+, the mean change of hip BMD [defined as (final BMD-baseline BMD)/(baseline BMD, in percentage)] was 0.73 ± 6.6%, while US- was -2.2 ± 7.7% and US+0 -1.9 ± 6.9% (p=0.047), in post-hoc analysis, US+ demonstrated borderline significance compared to US- (p=0.059) and US+0 (p=0.087) by Bonferroni method. Subsequent analysis (Figure 1 A) revealed that patients with US+2 presented preservation of hip bone mass (3.1 ± 6.8%), followed by US+1 (0.1 ± 6.8%) and then US+0. US-1 and US-2 showed rapid bone loss on the hip (-2.1 ± 7.3% and -2.3 ± 6.7%, respectively).

Conclusion: Persistent synovitis is associated with total hip bone loss, and detection of synovitis change by ultrasound with EULAR-OMERACT scoring system is helpful to predict hip BMD change.

BONE MINIFICATIONS IN SYSTEMIC MASTOCYTOSIS AND RELATED RISK FACTORS

H. Avilos Bojado, M. Barceló-Bru, M. Pascual-Pastor, A. D. Uloa Navas.

1 Hospital Universitari Vall d’Hebron, Rheumatology, Barcelona, Spain

Background: Clinical characteristics in Systemic Mastocytosis (SM) range from asymptomatic (indolent) to aggressive forms. Up to 28-34% of patients with SM have symptoms related to bone involvement at diagnosis and 16% have fractures (1). Skeletal manifestations include bone pain, osteoporosis (OP), osteosclerosis, focal osteolytic and osteoblastic lesions. OP is frequently related to indolent SM but not the aggressive forms (2).

Objectives: To describe bone involvement in patients with SM and analyze related risk factors.

Methods: Retrospective cohort study comprising patients with SM that attended the Rheumatology Department from 2010 to 2021. Sociodemographic variables, clinical manifestation, OP risk factors, bone lesions, fracture presence and analytical parameters were collected, and we analyzed whether they were associated with the presence of fractures (Table 1). Densitometry data were registered at diagnosis and up to 8 years of follow-up.

Results: 22 patients were included, 19 SM were indolent, 1 smoldering, 1 hematologic malignancy and 1 mast cell leukemia. Radiologically, 17 patients did not present lesions, 4 presented sclerotic lesions and 1 lytic lesions. Vertebral fractures were observed in 3 patients and 2 of them were before SM diagnosis. 10 patients received anti-osteoporotic treatment, 3 of them with teriparatide. At diagnosis, 2 patients (9.1%) had osteoporosis and 11 (50%) osteopenia. None of the analyzed risk factors were associated with OP presence. Of note, during follow-up significant changes were observed between those with indolent SM and aggressive forms at lumbar spine (LS) and femoral neck (FN) at 2 years (change in LS in indolent form 2.9% vs 29.6% in aggressive forms, p <0.001 and change at FN of 1% vs 20.5%, respectively, p=0.003). At 4 years changes at LS was -4.1% vs 25.8%, p=0.034 between indolent and aggressive forms but there were no differences regarding the presence of fractures (2 fractures in indolent group and 1 in aggressive, p=0.371).

Conclusion: Bone involvement was present in more than 50% of patients at diagnosis and the presence of fractures was not uncommon (14%), especially at lumbar spine (LS). Aggressive forms were associated with an increase in aBMD. The presence of fractures was associated with lower LS aBMD at diagnosis.

OPPORTUNISTIC BONE MINERAL DENSITY SCREENING IN PATIENTS UNDERGOING CARDIAC CT SCANS: EFFECT OF USING IMAGES CONTAINING INTRAVERSEOUS CONTRAST

A. Cheneymann1, J. Therkildsen2,3, S. Winther1, L. Nissen, J. Thygesen4, B. Langdahl3,5, E. M. Hauge1, M. Böttcher1 on behalf of Dan-NICAD.

1 Dødstrup Hospital, Department of Cardiology, Herning, Denmark; 2 Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; 3 Aarhus University Hospital, Department of Clinical Medicine, Aarhus, Denmark; 4 Aarhus University Hospital, Department of Clinical Engineering, Aarhus, Denmark; 5 Aarhus University Hospital, Department of Endocrinology, Aarhus, Denmark

Background: Osteoporosis is under-diagnosed worldwide causing increased risk of fractures and death (1). Computed tomography (CT) scans performed on other indications such as coronary artery disease harbor the potential for automatic detection of low volumetric bone mineral density (vBMD) of the vertebrae using quantitative CT (QCT); hence allowing estimation of future fracture risk (2). CT is often performed with intravenous (iv) contrast administration. In 2015, the International Society of Clinical Densitometry stated: “There is insufficient evidence to judge the effect of contrast agents on a classification of low BMD (3); this position remains. Thus, it is important to assess the effect of contrast enhancement in order to broaden the potential of vBMD screening using routine CT scans.

Objectives: We aimed to compare thoracic vBMD measurements from CT scans with and without iv contrast enhancement.

Methods: This cross-sectional multicenter sub-study is based on a larger clinical trial, Dan-NICAD-1, from which we randomly selected a cohort of 136 participants. First, a non-contrast scan was performed followed by a contrast-enhanced scan during which 60-90mL of iv contrast was administered (Iomeron, 350 mg/
Results: In 136 participants undergoing cardiac CT (Table 1), we found a different mean vBMD before vs. after contrast: 117.5 mg/cm³ [95%CI: 111.6–123.4] vs. 132.1 mg/cm³ [95%CI: 125.1–139.1], p<.0001. The absolute difference was 14.7mg/cm³ [95%CI: 12.3–17.0]; the relative difference, was 12.5% [95% CI: 10.5–14.5]. In total, 8/15 (53%) participants changed from very low BMD to low BMD after contrast administration, and 21 participants (21/63, 33%) changed from low to normal BMD (Figure 1). No participants changed from very low BMD to normal BMD.

* Classifications defined by American College of Radiology and grouped using the non-enhanced CT. Data: number of participants, (range) and mean with standard deviations. ** Self-reported.

Figure 1. Participants with change in BMD category after contrast administration Figure 1. vBMD measurements before and after contrast administration. 33/136 participants changed BMD category illustrated by the dotted lines (80 mg/cm³; 120 mg/cm³). Black lines: increase in vBMD after contrast (n=29); blue lines: decrease in vBMD after contrast (n=4).

Conclusion: Our data suggest a significant effect of contrast on clinical vBMD measurements; thus, this should be adjusted for before using contrast-enhanced cardiac CT for opportunistic vBMD screening. This urges further studies on the effect of scan protocols on the contrast-enhanced increase in BMD.

Data expressed as mean ± standard deviation or frequency (percentage). Tb.vBMD – trabecular bone mineral density. Ct.v.BMD – cortical volumetric bone mineral density; S - stiffness; FL - estimated fail load.

Conclusion: Pre-menopausal women with long-term polyarticular JIA have an impairment of bone mineral density at peripheral sites in addition to lower muscle mass and higher visceral adipose tissue. These findings may contribute to the increasing osteoporosis/fractures and cardiovascular risk in this population, suggesting that measures should be considered to prevent these damages.
CHARACTERISTICS OF GUT MICROBIOME AND THEIR ASSOCIATIONS WITH PERIPHERAL LYMPHOCYTE SUBPOPULATIONS AND CYTOKINES IN RHEUMATOID ARTHRITIS PATIENTS COMPPLICATED WITH OSTEOPOROSIS

T. Cheng1,2,3, S.-X. Zhang1,2,3, J. Giao1,2,3, M. J. Chang2, R. Zhao1,2,3, S. Song1,2,3, C. Wang1,2,3, L. Li1,2,3.

1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; 3Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; 4Shanxi Medical University, School of Management, Taiyuan, China.

Background: Osteoporosis (OP) is one of the major comorbidities of rheumatoid arthritis (RA) which is associated with immune disorders[1]. The gut microbiota has been highlighted to be an important environmental factor to influence immune system in maintaining bone health and regulating bone remodeling[2]. However, the alterations of intestinal flora and its relationship with immune system in RA patients with OP are unclear.

Objectives: To investigate the characteristics of gut microbiome as well as the associations between flora and peripheral lymphocyte subpopulations and cytokines in rheumatoid arthritis patients complicated with osteoporosis.

Methods: Total 28 RA patients were divided into 14 RA-non-OP and 14 gender- and age-matched RA-OP groups according to their bone mineral density (BMD) and the history of fragility fracture. Gut microbiota of participants were investigated by 16s RNA and peripheral lymphocyte subsets and cytokines were assessed via flow cytometry. Indicators like erythrocye sedimentation rate (ESR), C-reactive protein (CRP), anti-cyclic citrullinated peptide antibody (ACPA) and anti-mutated citrullinated vimentin (MCV) antibody were recorded meanwhile. Alpha diversity (ACE, Chao1, Simpson, Shannon) and beta diversity indices were analyzed using QIIME2. Biomarker species were recognized based on STEMP. Spearman analysis was adopted for correlation of two variables. All P-values reported herein were two-tailed and P<0.05 was taken as statistically significant.

Results: The alpha-diversity have no significant difference between RA-non-OP and RA-OP groups (P>0.05, Figure 1A). The community structure of microflora differed between two groups (P<0.05, Figure 1B). As the composition of intestinal flora at genus level, Faecalibacterium, Proteus, Catenibacterium, Enterobacter and Erysipelatoclostridium in RA-OP group were negatively correlated with ACPA and MCV respectively as well as IL-2 and TNF-α (P<0.05). Clostridium_sensu_stricto_1 and Lachnospiraceae_ND3007_group and the level of T, Th1 and Th17 cells, but negative relevance with IL-10 (P<0.05). The relative abundance of Faecalibacterium was negatively correlated with IL-2, IL-4, TNF-α and positively with MCV (P<0.05). Clostridium_sensu_stricto_1 and Lachnospiraceae_ND3007_group were negatively correlated with ACPA and MCV respectively as well as IL-2 (P<0.05, Figure 1D-E).

Conclusion: Abnormality of immune system may contribute directly or indirectly to OP in RA, which may be related to the disturbance of gut microbiota.

Crystal diseases, metabolic bone diseases other than osteoporosis

OUTCOMES AND RESOURCE UTILIZATION AFTER TOTAL HIP ARTHROPLASTY IN PATIENTS WITH CALCIUM PYROPHOSPHATE DEPOSITION DISEASE

M. Constantinos1, M. Lampi2, B. Bhattara1, K. Parperis3, 1University of Cyprus Medical School, Medicine, Nicosia, Cyprus; 2Valleywise Health Medical Center, Biostatistics, Phoenix, United States of America; 3University of Arizona College of Medicine, Epidemiology, Phoenix, United States of America; 4University of Cyprus Medical School, Department of Internal Medicine, Division of Rheumatology, Nicosia, Cyprus; 5University of Arizona College of Medicine, Division of Rheumatology, Phoenix, United States of America.

Background: Total hip arthroplasty (THA) is a safe and effective treatment option in patients with advanced degenerative joint disease who have failed conservative management. Calcium pyrophosphate deposition disease (CPPD) is a common crystal-induced arthritis in older adults characterized by the deposition of calcium pyrophosphate crystals in the articular and periarticular tissues. CPPD might manifest with acute and chronic arthritis that can lead to joint damage and the need for joint replacement. To our knowledge, no previous studies investigated the outcomes of CPPD patients who underwent THA.

Objectives: We aim to examine the mortality, in-hospital complications, and resource utilization following THA in patients with and without CPPD.

Methods: We queried the US National Inpatient Sample (NIS) database to identify patients who underwent THA between 2006 and 2014. The ICD-9 code 8151 was used to identify the patients who underwent THA and of those, we classified 2 groups of patients: (i) those with ICD-9 codes defining CPPD (275.49 and 712.1–712.39) and (ii) those without any CPPD code. Data collection included patient demographics and comorbidities. Outcomes post-THA were in-hospital mortality, hospital length of stay, hospital charges, and discharge disposition. Associations between CPPD and specific morbidity were evaluated using chi-square tests. T tests were used for continuous variables.

Results: Among the 4,111,808 (adjusted for sampling weight) patients who underwent THA between 2006 and 2014, 6198 (0.15%) had CPPD, with a mean age of 77 years and 65.2% were females (Table 1). CPPD patients were more likely to be older (mean age 77 vs 72.7: p<0.001) than non-CPPD patients. Comorbidities more frequently observed among CPPD patients included chronic kidney disease, osteoarthritis, rheumatoid arthritis, gout, hyperparathyroidism and hypogammaglobulinemia. Further, Charlson Comorbidity Index scores ≥ 2 was more frequent seen in CPPD (96.1% vs 89.1%, p<0.001). The in-hospital mortality post-THA was lower in the CPPD patients (0.76% vs 1.72%, p<0.001). THA in CPPD patients was associated with a longer mean length of stay than those

without CPPD (6 vs 5.1 days; p < 0.001) while mean total charges were not statistically different between the 2 groups (p=0.344). CPPD patients were more likely to be discharged to rehabilitation or other nursing facilities (p<0.001).

THE INTERNATIONAL X-LINKED HYPOPHOSPHATAEMIA (XLH) REGISTRY: OVERVIEW OF THE DATA SET

G. Ariete 1, J. Liu 2, A. Williams 3, S. Wood 2, D. Schnabel 3. 1Hospital Vall d'Hebron, Pediatric Nephrology, Barcelona, Spain; 2Kyowa Kirin International Marlow Office, Nephrology | EMEA, Marlow, Buckinghamshire, United Kingdom; 3Charité, University Medicine Berlin, Center for Chronically Sick Children, Pediatric Endocrinology, Berlin, Germany

Background: X-Linked Hypophosphataemia (XLH) is a rare, progressive, lifelong, hereditary renal tubule phosphate-wasting disorder characterised by a pathological increase in fibroblast growth factor 23 concentration/activity. Despite XLH being increasingly recognised as a chronic progressive disease, there are few data documenting its natural history or the impact of treatment on patient outcomes. The International XLH Registry was established to address this lack of information on XLH to help inform future clinical management. The Registry will collect data to characterise the treatment, burden of disease, disease progression and long-term outcomes of XLH.

Objectives: To provide an overview and status update of the International XLH Registry as of 31 December 2021.

Methods: The International XLH Registry (NCT03193476) was initiated in August 2017, aims to recruit 1,200 children and adults with XLH, and will run for 10 years. This Registry is an international, multicentre, non-interventional data collection programme and will provide the largest single dataset representing patient outcomes. The International XLH Registry forms the largest dataset of patients with XLH collected to date. Patients have been recruited from a wide geographical region and baseline demographics are consistent with a hereditary X-linked dominant disease. Information collected during the 10-year Registry duration will generate real-world evidence to help inform clinical practice throughout the region, with the aim of improving the care and quality of life of adults and children living with this debilitating disease.

PHASE 1 TRIALS OF NOVEL ORAL ENZYME THERAPY (ALLN-346) FOR HYPERURICEMIA & GOUT: SAFETY, PHARMACODYNAMICS, AND LACK OF SYSTEMIC ABSORPTION OF SINGLE AND MULTIPLE ASCENDING DOSES IN HEALTHY VOLUNTEERS

D. Clark 1, D. Gruijz 2, C. Tosone 3, N. Dahl 4, R. Terkeltaub 5. 1Alexia Pharmaceuticals, Inc., Clinical Development, Newton, United States of America; 2Allena Pharmaceuticals, Inc., Pharmacology, Newton, United States of America; 3Allena Pharmaceuticals, Inc., Clinical Operations, Newton, United States of America; 4Allena Pharmaceuticals, Inc., Medical Affairs, Newton, United States of America; 5SDVAHCS/UC San Diego, Medicine, San Diego, United States of America

Background: Currently available therapies for gout in patients with advanced chronic kidney disease (CKD) are either dose-limited or contraindicated due to safety and tolerability concerns. In gout patients with advanced CKD, the intestinal tract becomes the major route of urate elimination, in contrast to healthy people with normal kidney function whose kidneys are the primary route of uric acid excretion. Considering some of the limitations of present urate lowering therapies (ULTs) in gout & CKD and the extra-renal pathway of urate secretion, a new oral therapy with ALLN-346 (engineered urate oxidase) is under development as a non-absorbed, urate specific enzyme, designed to enhance degradation and secretion of urate in the intestinal tract.

Objectives: To assess safety and tolerability and evidence for the lack of systemic absorption at various dose levels of ALLN-346 in normal healthy volunteers (NHV) up to 7 days.

Methods: Two randomized, double-blind Phase 1 studies of ALLN-346 or placebo were conducted in adult NHV in a domicile setting; a single-ascending dose (SAD) study of 3 doses on a single day of dosing, and a multiple ascending dose (MAD) study of 2 doses during 7 days (NCT04323619 and NCT04329435, respectively). In the SAD study, subjects received 3 ascending doses of ALLN-346 (3 capsules,6 capsules, and 6 capsules administered twice, or placebo) and were randomized 3:1 (ALLN-346:placebo, n=24). In the MAD study, subjects received 3 (Cohort A) or 5 (Cohort B) of ALLN-346 capsules or placebo (2:1 randomization, n=18) administered orally 3 times daily for 7 days. To assess possible ALLN-346 absorption, a specific ELISA and uricase potency assay were used on PK serum samples collected from all subjects in both studies pre-dose and at intervals post dose.

Results: In both studies, all randomized subjects completed treatment with 100% compliance. ALLN-346 was well-tolerated, with no serious adverse
events (AE) and with no clinically significant safety signals across all cumulative doses. Clinical and laboratory parameters revealed no clinically significant safety signals among all cumulative dosing cohorts across hematology, serum biochemistry, vital signs, or ECGs. The majority of reported AEs were mild with no pattern of differences between ALLN-346 and placebo. No evidence of systemic absorption of ALLN-346 was seen, as confirmed by both ELISA and by uricase potency assay of all PK serum samples from all subjects from SAD (n=240) and MAD (n=324).

Conclusion: ALLN-346, a new oral enzyme therapy in development for the treatment of hyperuricemia and gout in advanced CKD was well tolerated. Consistent with its mechanism of action, no evidence of systemic absorption was demonstrated. Further studies in hyperuricemia patients with gout and CKD are underway.

POS1157 SAFETY AND EFFICACY OF ALLN-346 ORAL ENZYME THERAPY IN PATIENTS WITH HYPERURICEMIA AND CHRONIC KIDNEY DISEASE (CKD): RESULTS OF THE PHASE 2A STUDY 2
B. Terkeltaub1, D. Clark2, C. Tosone3, B. Kandinov3, P. Zhang4, N. Dahl4, D. Grujic3, D. Goldfarb5; SDVAHCS/UC San Diego, Medicine, San Diego, United States of America; 2Allena Pharmaceuticals, Inc., Clinical Development, Newton, United States of America; 3Allena Pharmaceuticals, Inc., Clinical Operations, Newton, United States of America; 4Allena Pharmaceuticals, Inc., Medical Affairs, Newton, United States of America; 5Allena Pharmaceuticals, Inc., Pharmacology, Newton, United States of America; 6NYU Langone Health, Medicine, New York, United States of America

Background: Currently available urate lowering therapies (ULTs) are limited in their use in gout patients with advanced CKD based on dosing restrictions, tolerability, safety concerns, and reduced effectiveness, compared to options for the broader gout population. In gout patients with advanced CKD, the intestinal tract becomes the major route of urate elimination, as opposed to in healthy people with normal kidney function where kidneys are the primary route of uric acid excretion. Considering some of the limitations of present urate-lowering therapies (ULTs) in gout & CKD and the extra-renal pathway of urate secretion, a new oral therapy, ALLN-346 (engineered urate oxidase), is under development as a non-absorbed, urate specific enzyme, designed to enhance degradation and secretion of urate in the intestinal tract.2

Objectives: To assess the safety, tolerability, and initial bioactivity data of ALLN-346 in adults with hyperuricemia and CKD.

Methods: This one-week inpatient Phase 2a study (NCT04987242) was conducted at a clinical pharmacology unit. Eleven otherwise healthy adult patients with hyperuricemia (sUA ≥ 6.8 mg/dL) and normal to Stage 2 CKD (eGFR ≥60), not on concurrent ULTs, were randomized (2:1) to receive either 5 capsules of ALLN-346 or matching placebo, three times daily for 7 days. Serum urate was measured daily, and urine uric acid was assessed on days -2, -1, 1, 4, and 7. Safety was monitored throughout the study. To assess possible ALLN-346 systemic absorption, a specific ELISA was used on serum samples collected pre- and post-dose over 7 days.

Results: Of the 11 patients 7 received ALLN-346 and 4 received placebo. Most patients had Stage 2 CKD, including 5 of the 7 subjects treated with ALLN-346. A statistically significant reduction in mean sUA was recorded with ALLN-346 compared to placebo [Figure 1]. The largest mean % reduction in sUA was observed among patients with stage 2 CKD; sUA reduction was correlated with eGFR in the ALLN-346 group (r=0.95; P=0.003), but not the placebo group (r=-0.2; P=0.91). No serious adverse events were reported, and clinical and laboratory parameters revealed no significant safety signals. Lack of systemic absorption of ALLN-346 was confirmed by ELISA assays.

Figure 1. Absolute and Percent Change from Baseline in Serum Urate over 7 -days of Treatment

POS1158 CHARACTERIZATION OF GOUT IN US PATIENTS UNDERGOING HEMODIALYSIS (HD) AND PERITONEAL DIALYSIS (PD)
A. Karaboyas1, J. Zhao1, B. Lamoreaux2, B. Marder2, B. Golitonski2, V. Domingues4, R. Pecolts-Filho1, B. Robinson1, 1Arbor Research Collaborative for Health, Research, Ann Arbor, United States of America; 2Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; 3Carolina Nephrology, Nephrology, Greenville, United States of America; 4Florida State University, Rheumatology, Tallahassee, United States of America

Background: Gout is the most common inflammatory arthritis and occurs frequently in patients with renal disease often leading to a significant burden on quality of life and functional status.1,2 Despite the established connection of renal disease with gout, little has been reported on the prevalence, patient characteristics, and associations of gout with other outcomes in the US hemodialysis (HD) and peritoneal dialysis (PD) population.

Objectives: This project used a large end-stage renal disease (ESRD) focused-database, Dialysis Outcomes and Practice Patterns Study (DOPPS), to examine gout in dialysis-dependent patients.

Methods: Gout patients were identified by active prescription (Rx) of (1) colchicine, (2) febuxostat, or (3) allopurinol; or by (4) prior diagnosis of gout from US cohorts of 70,297 HD (DOPPS, 2012-2020) patients and 5117 PD (Peritoneal DOPPS, 2014-2020) patients. Outcomes of HD and PD patients with and without a history of gout were compared with propensity score matching. Outcomes included erythropoietin resistance index (ERI = ESA dose/[hemoglobin*weight]),
cardiovascular death, all-cause mortality, hospitalization, and baseline patient-reported outcomes (PROs).

**Results:** Gout prevalence was 13% in HD and 21% in PD and was highest among incident dialysis patients. Of the gout patients identified, the most-commonly used gout-related medications were allopurinol (9-12%), followed by colchicine (2-3%), and then febuxostat (1%, Figure 1). Both HD and PD patients with gout (vs. no gout) were older and more likely male. Gout HD and PD patients had higher BMI and higher prevalence of cardiovascular comorbidities than HD and PD patients without gout. After propensity score matching, mean ERI was 4% higher for gout vs. non-gout patients, while there was minimal evidence of association with clinical outcomes (mortality and hospitalization) or PROs.

**Conclusion:** Gout was common in US HD and PD patients, with a large proportion of these patients treated with drugs indicated for hyperuricemia (allopurinol and febuxostat) and gout flares (colchicine). The true prevalence of gout was likely higher than observed when considering potential under-ascertainment of gout diagnosis history in nephrology/dialysis-focused clinical settings. This report provides a snapshot of gout in the US dialysis population and offers opportunities to expand on research to improve awareness and care for patients with gout and ESRD.

**SUBCLINICAL ATHEROSCLEROSIS IN GOUTY ARTHRITIS PATIENTS: A CROSS SECTIONAL STUDY BY ULTRASONOGRAPHY**

Y. Wang, Z. Zhang on behalf of none. First hospital of Peking university, Department of Rheumatology and Clinical Immunology, Beijing, China

**Background:** Hyperuricemia is closely associated with cardiovascular disease (CVD). However, it has not been definitively established whether this association is independent of traditional cardiovascular risk factors in gouty patients.

**Objectives:** To clarify the incidence of subclinical atherosclerosis and associated factors in gouty arthritis patients by ultrasonography.

**Methods:** We conducted this cross-sectional study to investigate the frequency and clinical factors correlated with carotid changes in patients with gout by ultrasonography.

**Results:** 200 consecutive patients with gout were recruited. Carotid ultrasound was performed in all patients in First hospital of Peking University from 2014 to 2020, finding atheroma plaques in 33.0% patients. None of these patients received urate-lowering drugs. On univariate analysis, the pattern was significantly associated with age, estimated gout duration, clinical tophi, double contour sign at the scanned joint and decreased estimated glomerular filtration rate; While arterial hypertension, hyperuricemia were not associated with carotid plaques. On multivariable analysis, the atheroma plaques were associated with estimated disease duration, clinical tophi, double contour sign and decreased estimated glomerular filtration rate. Thus, carotid plaque was frequently demonstrated in gout patients with tophaceous gout and associated with features of tubulointerstitial nephritis. This finding reveals the hypothesis of crystal-led inflammation and comorbidities relates to gout associated cardiovascular disease, predominantly seen in high uric acid burden patients, which could be an important treatment target for gout therapy.

**Conclusion:** Ultrasonography can detect crystal deposits in joints and connective tissues. We investigated the frequency and clinical correlates of plaques in carotid by ultrason in consecutive gouty patients. The pattern was significantly associated with age, estimated gout duration, clinical tophi, double contour sign and decreased estimated glomerular filtration rate.

**PROTECT: PEGLOTICASE TREATMENT FOR UNCONTROLLED GOUT IN KIDNEY TRANSPLANTED PATIENTS: RESULTS FROM A PHASE 4 TRIAL**

A. Abdelatit1, L. Zhao1, K. Cherry1, B. Marder2, J. Scandling1, K. Saag3, 1Baylor College of Medicine and CLS Health, Nephrology Division, Houston, United States of America; 2Horizon Therapeutics plc, Clinical Development, Deerfield, United States of America; 3Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; 4Stanford Medicine, Division of Nephrology, Stanford, United States of America; 5The University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America

**Background:** A phase 4 trial (NCT04087720) of kidney transplant (KT) recipients on stable immunosuppressants with uncontrolled gout previously reported that pegloticase produced a sustained decrease in serum uric acid (sUA) levels and was associated with clinically meaningful improvements in pain and disability without worsening of key kidney function markers. Pegloticase treatment was well tolerated overall with no infusion reactions or anaphylaxis. Here we report additional exploratory and secondary endpoints.

**Objectives:** To evaluate the results of clinically important efficacy endpoints as supportive evidence for the efficacy of pegloticase in kidney transplant patients on immunosuppression.

**Methods:** PROTECT a multicenter, open-label, efficacy and safety study of pegloticase in included kidney transplant recipients (KT)-1 year prior with uncontrolled gout (sUA ≥7 mg/dL, oral urate lowering therapy concomitant/inefficacy, and with either visible tophi, chronic gouty arthritis, or ≥2 flares in past year). We had a functioning graft (estimated glomerular filtration rate [eGFR] ≥15 ml/min/1.73m²), and were on a stable immunosuppressant regimen. Pegloticase (8mg infusion) was administered biweekly for 24 weeks (12 infusions) followed by a final follow up visit 3 months post-treatment. The global health component of the Health Assessment Questionnaire (HAQ-Health), and the physician global assessment of gout (PGA) were assessed at baseline, weeks 6, 14, 20, 24, and at the end of pegloticase infusions (EOI) visit (if applicable, when the final infusion occurred prior to week 22). Both were visual analog scales (VAS), where HAQ-Health ranged from 0 (very well) to 100 (very poor) and PGA ranged from 0 (excellent) to 10 (very poor). Heart rate and blood pressure measurements were recorded at baseline, weeks 6, 12, 18, 24 and the EOI visit.

**Results:** 20 patients received at least 1 dose of pegloticase and were included in the analysis with the majority (90.0%) of 40 to 81 years of age. Most were male (85.0%), 45.0% white, and 53.0% black or African American. Median BMI 28.84 (86.48 kg) and body mass index (29.68 kg/m²) were high. Median baseline eGFR and baseline Urine Albumin-Creatinine Ratio (UACR) were 41.70 ml/min/1.73m² and 312.00 mg/g, respectively. An improvement from baseline to weeks 14
for Clinical Research and Innovation, Biostatistics department, Lille, France;

Methods:

Objectives: (RECO) in 2020 [1,2], which were deliberately simple and concise.

Background: Recent studies have shown a lack of implementation of gout recommendations in primary care. In this context of therapeutic inertia, the French Society of Rheumatology (SFR) published its first recommendations on gout (RECO) in 2020 [1,2], which were deliberately simple and concise.

Methods: Three hundred patients attending a first visit for gout management in three French referral centres were retrospectively included. Visits were performed at baseline (M0) and scheduled for month 6 (M6), month 12 (M12), and month 24 (M24). Data collected included: patient profile; disease activity and treatments; serum urate (SU) level; estimated glomerular filtration rate (eGFR).

Results: Patients were 81% male, mean age 62.2 ± 15.2 years, 42.7% prevalent cardiovascular disease, and type 2 diabetes (Table 1). Additionally, healthcare utilization were examined and compared between those with/without a dermatological diagnosis code.

Conclusion: Simple application of gout management guidelines is feasible in clinical practice, and is efficient with a majority of patients achieving SU targets and clinical improvement. A minority of patients in referral centres have ‘difficult-to-treat’ gout requiring specific management.

PHARMACOKINETICS OF PEGLOTICASE AND METHOTREXATE POLYGLUTAMATE(S) IN PATIENTS WITH UNCONTROLLED GOUT RECEIVING PEGLOTICASE AND CO-TREATMENT WITH METHOTREXATE

Horizon Therapeutics plc, Clinical Pharmacology, South San Francisco, United States of America; 2Brigham and Women's Hospital, Division of Rheumatology, Immunology, and Allergy, Boston, United States of America; 3Horizon Therapeutics plc, Clinical Pharmacology, South San Francisco, United States of America; 4Horizon Therapeutics plc, Clinical Pharmacology, South San Francisco, United States of America; 5Horizon Therapeutics plc, Clinical Pharmacology, South San Francisco, United States of America; 6Horizon Therapeutics plc, Clinical Pharmacology, South San Francisco, United States of America.

Background: In a prior open-label, single-arm trial in adults with uncontrolled gout (MIRROR open-label [OL] trial), methotrexate (MTX) co-treatment with pegloticase suggested improved efficacy of pegloticase by reducing its immunogenicity.1,2 The current randomized, controlled trial (MIRROR RCT) confirmed that pegloticase-MTX co-therapy markedly increased pegloticase response rate (response defined as serum uric acid <6 mg/dL during ≥80% of Month 6) compared to pegloticase-placebo (PBO) co-therapy (71.0% vs. 38.5%) with a decreased infusion reaction rate and no new safety signals reported.

Objectives: To evaluate systemic exposures of pegloticase and its immunogenicity in uncontrolled gout patients receiving pegloticase with and without MTX as part of the MIRROR RCT; and to determine exposure of methotrexate polyglutamate(s) (MTX-PGs) in uncontrolled gout patients through Month 6 of treatment.

Methods: In MIRROR RCT, MTX (15 mg/week) or matching PBO was given orally 4 weeks prior to the first pegloticase dose and continued weekly, in combination with pegloticase 8 mg given intravenously every 2 weeks, over a 52-week treatment period. Pre-infusion blood samples were collected to measure MTX polyglutamate(s) (MTX-PGs, including MTX-PG(5)) in red blood cells and pre- and post-infusion serum samples were obtained to measure trough (Cmin) and peak (Cmax) concentrations of pegloticase, respectively, at multiple visits. MTX-PG and pegloticase concentrations were summarized by visit and by treatment group. Pre-infusion serum samples for anti-polyethylene glycol (PEG) antibody (Ab) measurement were also collected at multiple pre-defined time points. Anti-PEG Ab incidence and titer were summarized by visit and by treatment group.

Results: Overall, higher Cmax and Cmin of pegloticase were observed in the pegloticase + MTX group than in the pegloticase + PBO group (Figure 1). At Week 14, median (first quartile [Q1], third quartile [Q3]) Cmin was 1.32 (0.73, 1.74) µg/mL and 0.63 (0.30, 1.28) µg/mL for the pegloticase + MTX and pegloticase + PBO groups, respectively. Median (Q1, Q3) Cmax was 3.01 (1.94, 3.94) µg/mL and 2.68 (1.45, 3.20) µg/mL for the pegloticase + MTX and pegloticase + PBO groups, respectively. Improved pegloticase response was associated with higher pegloticase concentrations. At Week 14, Cmin was below the quantitation limit (0.6 µg/mL) for 8 of 10 non-responders and 1.28 (0.72, 1.71) µg/mL for responders. MTX co-administration reduced the incidence of new anti-PEG antibody formation. The proportion of subjects with an increase from baseline in anti-PEG Ab titers or who were negative at baseline and developed an anti-PEG Ab response at ≥1 post-dose time point during pegloticase treatment was 29.5% and 51.0%, for the pegloticase + MTX and pegloticase + PBO groups, respectively. The pegloticase + MTX group had overall lower titer levels than those in the pegloticase + PBO group. Positive anti-PEG Ab status was associated with a lower pegloticase Cmin. Concentrations of MTX-PGs were maintained during the treatment course in the pegloticase + MTX group, suggesting compliance with MTX administration. There was no apparent difference in concentrations of MTX-PGs (including MTX-PGs(5)) between responders and non-responders. MTX-PG concentrations were in the same range as those reported for low-dose oral MTX use in patients with rheumatoid arthritis, suggesting no impact of pegloticase on MTX PK.

Conclusion: Pegloticase 8 mg IV every 2 weeks with MTX co-treatment (oral 15 mg weekly) reduced anti-PEG Ab incidence and resulted in higher pegloticase exposures compared to pegloticase administered with PBO, consistent with the increased clinical efficacy observed with pegloticase + MTX co-administration.

COMPARISON OF PATIENTS WITH EARLY-ONSET GOUT AND COMMON GOUT: A CLAIMS-BASED ANALYSIS

A. Amatucci, L. Padnick-Silver, B. Lamoreaux, D. Bulbin.

Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; 2Geisinger Medical Center, Rheumatology, Danville, United States of America.

Background: From the data from the United States indicate that 8% of gout patients have disease onset before 40 years of age (early-onset gout [EOG]), and beginning at age 65 (common gout [CG]), with similar disease occurrence.4,5 At present, the literature is limited in comparisons between EOG and common gout (CG) patients.

Objectives: These claims-based analyses on a very large population examined and compared characteristics and comorbidity profile of patients with EOG and CG.

Methods: Patients with ≥1 ICD-9 or -10 gout code were identified in the Symphony claims database using Bellweather software (PearlDiver Technologies™). All patients were in the database ≥2 years before and ≥3 years after first gout code. Patients were said to have EOG if their first gout code occurred before 40 years of age (EOG);4,5 with similar age stratiﬁcation in the United Kingdom, The Netherlands, and New Zealand.6 At diagnosis, EOG patients have lower rates of renal and cardiometabolic comorbidities than their counterparts who developed gout at a later age.6 Published reports also indicate that patients with EOG are less responsive to urate-lowering therapy7 and more often have severe gout, with higher flare rate8 and polyarticular disease occurrence.5 At present, the literature is limited in comparisons between EOG and common gout (CG) patients.

Objectives: These claims-based analyses on a very large population examined and compared characteristics and comorbidity profile of patients with EOG and CG.

Methods: Patients with ≥1 ICD-9 or -10 gout code were identified in the Symphony claims database using Bellweather software (PearlDiver Technologies™). Patients were said to have EOG if their first gout code occurred before 40 years of age (EOG).4,5 These claims-based analyses on a very large population examined and compared characteristics and comorbidity profile of patients with EOG and CG.
data suggest that, in the years following gout diagnosis, EOG patients develop comorbidities at a faster rate than their peers without gout. Further study of how gout influences comorbidity development in EOG patients is warranted to better understand and verify these claims-based findings.

Background: Elevated lactate is known to favor urine urate reabsorption by the renal tubule. Autosomal recessive gout caused by pathogenic variant in the LDHD gene encoding for D-lactate dehydrogenase has been recently identified in a large consanguineous Bedouin-Israeli kindred (1). The objective of the present study was to explore the association of LDHD rare variants with early-onset gout in two families with early-onset gout.

Methods: DNA samples from the affected patients were screened by Sanger sequencing method in 13 other extended family members. A deleterious variant in the LDHD gene (NM_153486.3: c.206C>T; rs1035398551) was observed in the non-gout brother. WES was performed in the two probands, their father and mother (who denied consanguinity), and an unaffected brother. An undescribed variant in LDHD (NM_153486.3: c.1363dupG) was identified in homozygous and heterozygous levels in the non-gout brother.

Results: Two families were included. The first family was a kindred of Bedouin origins (1). The second family was a Vietnamese family. The two juvenile gout patients were homozygous for an undescribed frameshift (NM_153486.3: c.1064dup) variant of the RHBG gene encoding for a Rhesus Blood Group family ammonium transporter. The two parents carried the heterozygous variant which was not identified in the non-gout brother.

Conclusion: We report on 2 families in whom autosomal recessive juvenile gout was due to rare or undescribed, damaging LDHD gene variants. In addition, we observed in the Vietnamese family, an additional non-described frameshift homozygous variant in RHBG, the pathophysiological role of which deserves to be investigated.

Conclusion: Acute and chronic kidney disease are highly prevalent comorbid conditions in overall US hospitalizations. Among patients admitted with a diagnosis of gout, the proportion of kidney dysfunction is significantly higher affecting 58% of these hospitalizations. The high prevalence of kidney dysfunction in hospitalized gout patients in the US may represent an impactful component to the duration, complexity, and costs of hospital care.

Figure 1. Meta-analyses of serum urate levels and estimated glomerular filtration rate at baseline and follow-up.

Conclusion: Our meta-analysis showed that febuxostat had good urate-lowering efficacy and renal safety in hyperuricemia patients with stage 4-5 CKD, who are not yet on dialysis. More studies with larger sample sizes and higher quality are required to clarify the efficacy and safety of febuxostat in advanced CKD.

POST1167 TREAT TO TARGET OF GOUT: AN EVIDENCE-BASED CONSENSUS ON CLINICAL PRACTICE GUIDELINES

C. N. Son1, H. J. Jeong1, W. Y. Park2, S. H. Kim1.

1Canterbury Christ Church University, Rheumatology, Gillingham, United Kingdom; 2Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; 3Ain Shams University, Community and Public health, Cairo, Egypt; 4Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; 5Benha University, Rheumatology and Rehabilitation, Benha, Egypt; 6Zagazig University, Rheumatology and Rehabilitation, Cairo, Egypt; 7Kaar Elainy Cairo University, Rheumatology and Rehabilitation Cairo, Egypt; 8 Fayoum University, Rheumatology and Rehabilitation, Fayoum, Egypt; 9 Mansoura University, Rheumatology and Rehabilitation, Mansoura, Egypt; 10 Minia University, Rheumatology and Rehabilitation, Minia, Egypt; 11 Suez Canal University, Rheumatology and Rehabilitation, Ismailia, Egypt

Background: New therapies, management approaches and evidence regarding the management of gout have become available over the past years. This triggered the need for updated recommendations for the management of gout.

Objectives: To develop an up-to-date consensus evidence-based clinical practice guideline for the management of gout including recommendations for management of acute gout flares, optimum usage of urate lowering therapy for chronic gout as well as patient education and lifestyle guidance.

Methods: An extensive systematic literature review was performed, and evidence-based recommendations were extrapolated, based on 16-key questions identified according to population, intervention, comparator, and outcomes (PICO) approach. For each item, the level of evidence for outcomes of interest was categorized into 10 domains to were obtained. Agreement with the recommendations (rank 7-9) ranged from 90-100%. Consensus was reached (i.e.≥75% of respondents strongly agreed or agreed) on the wording, the grade of recommendation and level of evidence of all the 30 clinical standards identified by the scientific committee. The guideline emphasized that all gouty patients should be screened for comorbidities. Based on this, an algorithm for treat to target management approach tailored to the individual patient’s needs and associated comorbidities has been outlined.

Conclusion: This work provides updated evidence-based recommendations for the prevention and treatment of acute as well as chronic gouty arthritis. It provides an approach for physicians and patients making decisions on the management of gout. It will also facilitate improvement and uniformity of care.

POST1168 EFFICACY AND SAFETY OF FEBUXOSTAT IN PATIENTS WITH STAGE 4-5 CHRONIC KIDNEY DISEASE NOT YET ON DIALYSIS: A META-ANALYSIS OF OBSERVATIONAL STUDIES

C. N. Son1, H. J. Jeong1, W. Y. Park2, S. H. Kim1.

1Kenyung University School of Medicine, Rheumatology, Daegu, Korea, Rep. of (South Korea); 2Kenyung University School of Medicine, Nephrology, Daegu, Korea, Rep.of (South Korea

Background: The efficacy and safety of febuxostat in patients with stage 4-5 chronic kidney disease (CKD) are still unclear, even though it’s commonly used in clinical practice [1]. However, clinical trials are lacking to determine them due to ethical problems about enrolment of advanced CKD patients.

Objectives: We aimed to evaluate the efficacy and safety of febuxostat in patients with stage 4-5 CKD not yet on dialysis through a meta-analysis of observational studies.

Methods: We performed a systematic search in PubMed, Ovid MEDLINE, Embase, and the Cochrane Library to find articles reporting on advanced CKD patients from observational cohorts who start or take febuxostat at baseline in September 2021. Articles had to describe change from baseline in serum urate levels and renal function as assessed by estimated glomerular filtration rate (eGFR). The articles were screened by two independent reviewers (YP, HJ).

Meta-analysis using a random-effects model was performed. R software was used for statistical analyses.

Results: Among 148 retrieved studies, 5 relevant observational studies were included in the meta-analysis. The febuxostat dose was administered at 10-120 mg per day, and the treatment period was 3 to 12 months. Five studies were included with a total of 327 patients to analyze urate-lowering efficacy. The urate-lowering effect after use of febuxostat medication showed statistical significance (weighted mean difference, -1.85; 95% CI, -2.04 to -1.67; I²; 0%, Figure 1A). Three studies with 145 patients were available for assessment of eGFR. Renal function as assessed by eGFR did not decrease even after use of febuxostat (weighted mean difference, 0.11; 95% CI, -0.25 to 0.47; I²; 45%, Figure 1B).

Conclusion: Our meta-analysis showed that febuxostat had good urate-lowering efficacy and renal safety in hyperuricemia patients with stage 4-5 CKD, who are not yet on dialysis. More studies with larger sample sizes and higher quality are required to clarify the efficacy and safety of febuxostat in advanced CKD.

DISCLOSURE OF INTERESTS: None declared

BACKGROUND: The inflammation induced by monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals is driven by interleukin (IL)-1β production. This later relies on NLRP3 inflammasome which can be activated by variation of ion concentration.

Objectives: To assess the role of osmolarity and water flux in MSU and CPP crystal-induced inflammation.

Methods: In vitro, THP1 monocytes were stimulated by pyrogen-free synthetic MSU and CPP crystals in iso-, hypo- or hypertonic media. Cytokine production was quantified by ELISA in cell culture supernatants. Cell size was measured using video microscopy. The role of aquaporin channels was assessed by pharmacological inhibitor (mercury chloride, HgCl2). In vivo, murine air pouch model was used. MSU and CPP crystals were injected in air pouch of mice treated or not with HgCl2 or mannitol. Osmolarity of mouse sera and patient synovial fluids (SF) were measured using freezing point osmometer. The size of cells collected from SF was assessed with imageJ software.

Results: MSU and CPP crystal-induced IL-1β production was substantially reduced by HgCl2 treatment (MSU 4900 vs 880 pg/ml; CPP 10500 vs 980, p<0.0001) or when cells were cultured in hypertonic medium. MSU and CPP crystals induced a transient increase in cell size which was 16 and 1.5 bigger after 30 and 100 min of stimulation by MSU and CPP crystals, respectively. After 150 min of stimulation, cell size decreased to their baseline size. Cell size increase was abolished by HgCl2 or hypertonic medium. In vivo, MSU and CPP crystal-induced inflammation (assessed by cell infiltration, IL-1β and CXCL2 production in air pouch lavage) was drastically reduced by HgCl2 or mannitol i.p.

The serum osmolarity was higher in mannitol-treated mice than in untreated mice (320 vs 300 mOsm/L). In patients, cells collected from SF during CPP or MSU crystal-induced flares had a bigger size than cells collected from osteoarthritic SF. The osmolarity of MSU or CPP crystal-containing SF was lower than the osmolarity of osteoarthritic SF (270 vs 310 mOsm/L). Finally, the IL-1β concentration in SF was strongly correlated with cell size and SF osmolarity.

Conclusion: These results suggest that the variation of osmolarity plays central role in MSU and CPP crystal-induced inflammation. Deciphering how crystals modulate osmolarity will identify new therapeutic targets.

ASYMPTOMATIC URATE-CRYSTALS DEPOSITS IN PATIENTS WITH STAGES 3-5 CHRONIC KIDNEY DISEASE DETECTED BY ULTRASOUND

1Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain;
2Hospital Universitario Infanta Leonor, Nephrology, Madrid, Spain;
3Hospital Universitario Infanta Leonor, Nephrology, Madrid, Spain;
4Hospital Universitario Infanta Leonor, Nephrology, Madrid, Spain;
5Hospital Universitario Infanta Leonor, Nephrology, Madrid, Spain;
6La Paz University Hospital, Nephrology, Madrid, Spain;
7Hospital Universitario Infanta Leonor, Nephrology, Madrid, Spain

Background: One in ten patients with hyperuricemia may develop gout over time, with urate deposition sometimes asymptomatic. Recent reviews support ultrasound (US) to assess asymptomatic hyperuricemic (AH) patients to detect gout lesions, showing double contour (DC) and tophus the highest specificities and positive predictive values. Hyperuricemia and gout are common in chronic kidney disease (CKD), especially with glomerular filtration rate (GFR) <60, and are associated with worse prognosis. US gout lesions have been found more frequently in AH (up to 35%) than in normouricemic (NU) patients, but evidence is scarce in CKD.

Objectives: To assess the prevalence of urate deposit in stages 3-5 CKD detected by US, and to investigate if there are differences between AH and NU patients.

Methods: Case-control study, recruiting patients aged ≥18 years with AH and stages 3-5 CKD in 4 hospitals from January 2020 to December 2021. Controls were patients with stages 3-5 CKD and NU. Exclusion criteria: previous diagnosis of gout, tophi. Hyperuricemia was defined as serum uric acid (sUA) >8.8 mg/dl, documented at least twice during the last 12 months. A standardized US exam of the knees and bilateral first metatarsophalangeal joints was performed to assess patients for DC/Tophus as defined by OMERACT. Demographic, clinical and laboratory data were recorded. A descriptive analysis was performed using SPSS. Pre-clinical gout (PCG: DC and/or tophus) was considered as outcome variable. Chi-square and Fisher's exact test were used for qualitative variables, and Mann-Whitney U test for quantitative variables; significant threshold p<0.05.

Results: Forty-four patients with stages 3-5 CKD (59.6% stage 3, 19.1% stage 4, 21.3% 5) were recruited. 35 AH and 9 NU. Hyperuricemia was associated with a higher prevalence of US findings, with significant differences between cases (AH) and controls (NU): PCG 19 vs 1 (p=0.023), DC 13 vs 1, and tophus 11 vs 0. No significant differences were found in demographic variables, comorbidities and treatments. sUA levels, were higher in patients with PCG (8.3±1.4 vs 7.6±2.2; p=0.36), and these patients also showed lower GFR (31.4±14.1 vs 33.7±16.8; p=0.62). Patients with PCG also showed a non-significant trend towards shorter duration of CKD (6.3±5.7 vs 8.3±4.9 years; p=0.1) and younger age (66.4±15.1 vs 70.0±11; p=0.30).

Conclusion: We found an outstanding prevalence of asymptomatic urate deposit in our cohort of patients with stages 3-5 CKD, that is higher in hyperuricemic than in normouricemic patients. The prevalence of DC and tophus in our cohort of AH patients with stages 3-5 CKD was higher than that reported in AH patients in studies conducted in general population (37% vs 16-31% and 31% vs 16%, respectively). Early diagnosis of pre-clinical gout by ultrasound might change therapeutic approach in CKD.

POS1711

TRIPLE THE RATE OF EMERGENCY ROOM VISITS AND HOSPITALIZATIONS FOR GOUT AMONG US BLACKS VS WHITES – 2019 NATIONWIDE ANALYSIS

C. Yokose1, N. Mccormick2, N. Lu3, A. Joshi4, L. Jackson5, M. Kohier1, J. Yin1, Y. Zhang6, K. Saag7, H. Choi7.

1Massachusetts General Hospital, Division of Rheumatology, Allergy and Immunology, Boston, United States of America; 2Massachusetts General Hospital, Clinical Epidemiology Program, Morgan Institute, Boston, United States of America; 3Arthritis Research Canada, n/a, Vancouver, Canada; 4Massachusetts General Hospital, Clinical and Translational Epidemiology Unit, Morgan Institute, Boston, United States of America; 5University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America

Background: Gout is a highly prevalent inflammatory arthritis with increasing global disease burden in recent years.1,2 Gout prevalence has been reported to be higher among Blacks compared to Whites,3 and that they are less likely to receive allopurinol in outpatient care.4 The potential nationwide impact of these racial disparities on emergency department (ED) visits and hospitalizations is unknown.
Objectives: To examine the contemporary racial disparities in ED visits and hospitalizations with a primary discharge diagnosis of gout in the US (2019).

Methods: We compared ED visits and hospitalizations between Blacks and Whites in the latest data (2019) from the US National Emergency Department Sample (NEDS) and National Inpatient Sample (NIS). We focused on encounters for which the primary diagnosis was gout based on ICD codes (M1A.xx, M10.xx). We calculated annual population rates of ED visits and hospitalizations for gout (per 100,000 US adults) using the 2019 US census adult population (>18 years) according to race.

Results: There were a total of 160,759 ED visits and 9,560 hospitalizations among White and Blacks with a gout diagnosis in the US in 2019. The mean age (58.2 years vs. 56.5 years) and male proportion (78.0% vs. 74.8%) tended to be higher among Whites, while more Blacks tended to live in the South (40.7% vs. 66.5%) and reported a median household income of <$50,000 (30.7% vs. 57.1%). Compared to Whites, Blacks had 2.7- and 3.2-fold higher rates of gout ED visits and hospitalizations, respectively, after adjusting for age, sex, payer, region, and household income (Table 1 & Figure 1). Black women, in particular, had 3.4- and 4.0-fold higher rates of ED visits and hospitalizations compared to White women, while the corresponding rate ratios for men were 2.5 and 2.8, respectively. The mean costs per gout ED visit were similar for Blacks compared to Whites (adjusted difference, -$7.6 [95% CI, -25.4 to 1.0]), while hospitalizations were more costly (adjusted difference, $130.6 [95% CI, 31.2 to 241.4]). The duration of ED visits and hospitalizations was also higher among Blacks than Whites (adjusted difference of 3.41 days [95% CI, 0.19 to 0.63] and 0.59 days [95% CI, 0.25 to 0.94], respectively).

*Adjusted for age and sex for all, adjusted for age for sex-specific rate ratios**Adjusted for age, sex, payment, region, and household income

Conclusion: These latest national data indicate that ED visits and hospitalization due to gout are both 3 times higher among Blacks than Whites; this disparity was particularly prominent among women with gout. Higher risk of developing gout and suboptimal care both translate to these avoidable costly healthcare utilization, calling for improved primary prevention and gout care.

POS1172

RISK OF VENOUS THROMBOEMBOLISM AFTER GOUT FLARES

E. Cipolletta1,2, G. Nakafero3, M. Mamas3, A. Avery4, L. Tata5, A. Abhishek6.
1Politechnic University of Marche, Department of Clinical and Molecular Sciences, Ancona, Italy; 2University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom; 3Keele University Keele Cardiovascular Research Group, Stoke-on-Trent, United Kingdom; 4University of Nottingham, Division of Primary Care, Nottingham, United Kingdom; 5University of Nottingham, Division of Epidemiology and Public Health, Nottingham, United Kingdom

Background: Several population-based cohort studies have reported an increased risk of venous thromboembolism (VTE) in gout patients. However, none of these studies has investigated the temporal relationship between gout flares and VTE.

Objectives: To explore whether gout flares increase the risk of VTE in the short-term using the self-controlled case series (SCCS) method.

Methods: We identified participants with incident gout from the Clinical Practice Research Datalink (CPRD). Participants having less than one year of registration in CPRD and patients with a history of VTE or anticoagulant prescription more than one year before the first gout consultation were excluded. Participants with at least one gout flare and a diagnosis of VTE were selected. VTEs and gout flares were ascertained using primary care data, hospitalisation and mortality records, using previously validated algorithms (positive predictive value of 94% for VTE [1] and 68-95% for gout flares [2,3]). SCCS method involves fitting a Poisson model conditioned on the number of VTEs, and it calculates the adjusted incidence risk ratio (aIRR) and its 95% confidence interval (95%CI) for each stratum of the ‘at-risk’ period as compared with the ‘baseline’ period (Figure 1). The analysis was adjusted for age and calendar season.

Figure 1. Schematic description of the observation period (‘at-risk’ and baseline periods).

The ‘at-risk’ period (in red) was defined as the period following the exposure (the gout flare), and it was subdivided as follows: days 0-30, 31-60 and 61-120 after each gout flare. The baseline period (in green) consisted of a pre-exposure and a post-exposure period of 365 days each. The length of each period varied according to the occurrence of the next flare and its timing. Panel A and panel B provide a schematic representation of patients with a single observation period and with multiple “non-overlapping” observation periods, respectively. In such cases, the length of the “at risk” period was 120 days, while the length of the pre-exposure and post-exposure period was 365 days each.

Results: Among the 104,962 patients with an incident diagnosis of gout in CPRD between 1997 and 2020, we identified 2,678 VTE (4.0 events/1,000 person-years). There were 53 VTE (13.3 events/month) during the “at-risk” period and 143 (8.0 events/month) during the “baseline” period (crude incidence rate ratio, 1.75; 95%CI: 1.27-2.42). The rates were highest in the first month after gout flares and then fell progressively (Table 1). Sensitivity analyses were consistent with the main analysis (Table 1).

CLINICAL PRESENTATION AND TREATMENT OF STERNOCOSTOCLAVICULAR HYPEROSTOSIS (SCCH): A SYSTEMATIC REVIEW AND META-ANALYSIS OF SCATTERED EVIDENCE

A. Leering1, O. Dekkers1, N. Appelman-Dijkstra1, E. Winter1, 1Leiden University Medical Center, Internal Medicine, Division of Endocrinology, Center for Bone Quality, Leiden, Netherlands; 2Leiden University Medical Center (LUMC), Internal Medicine, Division of Endocrinology, Leiden, Netherlands

Background: Sternocostoclavicular hyperostosis (SCCH) is an inflammatory bone disorder within the spectrum of chronic non-bacterial osteomyelitis. SCCH can be a manifestation of SAPHO syndrome, standing acronym for spondyloarthropathy, acne, pustulosis, hyperostosis and osteitis, but also appears as an isolated clinical disorder without joint and skin involvement1-2. Consensus on nomenclature, diagnostic classification, and therapy for SCCH is currently lacking2. Literature is diffuse, and spreads over a wide range of medical disciplines, calling for a first systematic overview.

Objectives: We critically appraised literature with the aim to i) gain overview on the clinical presentation of SCCH and features leading to diagnosis and to ii) evaluate different treatment modalities and treatment response. We focused on the clinical entity of SCCH in adults, either isolated or as a part of SAPHO syndrome.

Methods: We conducted a systematic review and meta-analysis according to the PRISMA guidelines on the clinical presentation and therapeutic modalities applied in adult SCCH patients. Studies covering these respective domains were selected. Risk of bias was assessed using validated tools according to study type. Untransformed numerical data and double-arcsine transformed proportional data were analyzed in a random effects model in R-4.0.8; pooled proportions were reported with 95% confidence intervals (95%CI). Treatment response was categorized as good, partial, or none.

Results: 28(i) and 12(ii) studies were included, containing heterogeneous data on 1818 patients. A female predisposition (67%, 95%CI 60-73) and major diagnostic delay (5 years 95%CI 3-7) were noted. Clinical presentation was marked by anterior chest pain (89%, 95%CI 79-96), and swelling (73%, 95%CI 62-81). Pustulosis palmoplantaris was present in 53%, 95%CI 49-58 whereas acne (8%, 95%CI 14-13) and peripheral arthritis (24%, 95%CI 11-39) were less prevalent. Inflammatory markers were inconsistently elevated and autoantibodies and HLA-B27 prevalence normal. Histopathology was unspecific, and cultures almost exclusively negative. Increased isotope uptake (99%, 95%CI96-100) was the most consistent imaging finding. Amongst manifold treatments (see Figure 1), NSAIDs were mainly partially effective. Pamidronate and biologics (mainly TNF-α inhibitors) yielded good, though heterogeneous, response in 83%, 95%CI 60-98 and 56%, 95%CI 26-85 respectively.

Figure 1. Treatment modalities applied in SCCH and their effects on bone pain (data from trials and several cohort studies combined).

Figure 1. Treatment modalities applied in SCCH and their effects on bone pain (data from trials and several cohort studies combined).

Conclusion: Literature on SCCH is extremely heterogeneous. Timely diagnosis proves challenging and mainly follows from the increased isotope uptake on nuclear examination. Biopsies, autoantibodies and HLA-status are non-contributory, and inflammatory biochemical profiles only variably detected. Pamidronate and TNF-α inhibitors emerged as promising therapies, but powered, placebo-controlled research with standardized measures of response is warranted. Inherently, international consensus on SCCH’s diagnostic classification and name appears critical to improve scientific collaboration on this rare disease, and to advance the development of clinical guidelines.

COLCHICINE TREATMENT IN GOUT PATIENTS – IMPACT ON CARDIOVASCULAR EVENTS AND ON MORTALITY

Y. Braun-Moscovici1, L. Gabay2, Y. Butbul3, 1Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Rheumatology Institute, Haifa, Israel; 2Kahn-Sagol-Maccabi Research and Innovation Institute, Maccabi Healthcare Services, Tel Aviv, Israel, Epidemiology, Tel Aviv-Yafo, Israel; 3Ruth Rappaport Children’s Hospital, Rambam Medical Center, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Pediatric Rheumatology Service, Haifa, Israel

Background: Gout and hyperuricemia are independent risk factors for cardiovascular events and increased mortality. A significant proportion of gout patients receive colchicine, additionally to urate-lowering therapy. Recently, colchicine treatment was found to reduce the risk of cardiovascular events in patients with chronic cardiac disease.

Objectives: To assess the incidence of cardiovascular events and the mortality rate among gout patients who received colchicine treatment.

Methods: This retrospective cohort study was conducted using data from the Maccabi Healthcare Services (MHS) central computerized database. MHS is the second largest state-mandated health care provider in Israel, covering >2.5 million members (25% of the population) and is a representative sample of the Israeli population. The study included gout patients from the MHS registry aged ≥40 years who received colchicine for at least 3 months and a control group matched by age, gender and socioeconomic status. The data extracted included smoking status, body mass index (BMI), co-morbidities (diabetes, hypertension, chronic renal disease, hyperlipidemia, malignancy), antiplatelet and antiagulant treatment, cardiovascular events and mortality rate. The statistical analysis included univariate and cox regression analysis.

Figure 1. Treatment modalities applied in SCCH and their effects on bone pain (data from trials and several cohort studies combined).

Conclusion: Literature on SCCH is extremely heterogeneous. Timely diagnosis proves challenging and mainly follows from the increased isotope uptake on nuclear examination. Biopsies, autoantibodies and HLA-status are non-contributory, and inflammatory biochemical profiles only variably detected. Pamidronate and TNF-α inhibitors emerged as promising therapies, but powered, placebo-controlled research with standardized measures of response is warranted. Inherently, international consensus on SCCH’s diagnostic classification and name appears critical to improve scientific collaboration on this rare disease, and to advance the development of clinical guidelines.

DOI: 10.1136/annrheumdis-2022-eular.4688
Results: 3671 individuals were included in each group (mean(SD) age 56(12.5), 87% males, mean(SD) follow-up 2744.7(1616.2) days). The gout group had a statistically significant higher incidence (p<0.001) of cardiovascular events (14.7% vs 10.8%), high BMI (35.1% vs 15%), diabetes (17% vs 12.7%), hypertension (52% vs 32.4%), chronic renal disease (35% vs 15%), hyperlipidemia (65% vs 46%). The mortality rate was similar (8.9% vs 79%, p=0.11) for both groups. The mortality hazard ratio (95% CI) for gout patients was 1.18 (1.39, p=0.05), for diabetes 1.6 (1.3-1.9, p<0.0001), for hypertension 1.38 (1.1-1.67, p=0.002).

Conclusion: Although the gout patients had a higher incidence of co-morbidities and cardiovascular events, the mortality rate was not significantly different compared to the matched group. Chronic colchicine treatment might have a protective effect. Further long-term studies are required.

IMPACT OF COVID-19 ON THE CLINICAL COURSE OF GOUT AND THE OVERALL USAGE OF MEDICATION IN PATIENTS WITH GOUT

S. Smierć1, O. Mahovkova1. Ternopil National Medical University, Internal Medicine No. 2, Ternopol, Ukraine

Background: Data on the course and outcomes of the coronavirus disease 2019 (COVID-19) in patients with gout are scarce, as gout is underrepresented in leading COVID-19 and rheumatological scientific publications [1].

Objectives: To describe clinical changes in quality of life, therapy of gout before and after COVID-19, and the clinical course of severe acute respiratory syndrome-related coronavirus 2 (SARS-CoV-2) infection in the cohort of patients with gout.

Methods: In total, 84 males with gout were examined before the pandemic, during COVID-19 (March 2020 to December 2021) and 6 months after SARS-CoV-2 infection. The severity of COVID-19 in our cohort was determined using the Clinical, Occupational and Social Assessment following Infection with COVID-19 (COSI-IC). Each of the 20 patients was assessed 4 times (mean±SD age 61±12.1 years, 91% Smierć, 9% Mahovkova, mean±SD follow-up 2415±1093 days).

Results: The mean age (mean±SD) of the study patients was 51.07±7.45 years and the disease duration was 9.8±4.62 years. Most SARS-CoV-2 infected patients with gout exhibited a moderate illness (40.48%), almost every third (28.57%) had mild, 21.43% had severe and 9.52% had critical illness. Comparing patients with gout with the general population, the mortality rate was similar (8.9% vs 79%, p=0.11) for both groups. The mortality hazard ratio (95% CI) for gout patients was 1.18 (1.39, p=0.05), for diabetes 1.6 (1.3-1.9, p<0.0001), for hypertension 1.38 (1.1-1.67, p=0.002). The mortality rate was similar (8.9% vs 79%, p=0.11) for both groups. The mortality hazard ratio (95% CI) for gout patients was 1.18 (1.39, p=0.05), for diabetes 1.6 (1.3-1.9, p<0.0001), for hypertension 1.38 (1.1-1.67, p=0.002).

Conclusion: Although gout in young people is increasing, studies on the risk factors for gout in these people are lacking.

Disclosure of Interests: None declared

TREATMENT OF GOUTY ARTHRITIS IS ASSOCIATED WITH RESTORING GUT MICROBIOTA AND PROMOTING PRODUCTION OF SHORT CHAIN FATTY ACIDS

S. J. Lee1, H. K. Park1. 1School of Medicine, Kyungpook National University, Korea, Internal Medicine, Daegu, Korea, Rep. of (South Korea)

Background: Although factors initiating the inflammatory response to monosodium urate crystals have been identified, the role of the gut microbiota and their metabolites on gout remain unknown.

Objectives: This study aimed to investigate changes in both gut microbiota and short chain fatty acids (SCFAs) according to inflammatory states of gout in the same patients.

Methods: This study enrolled 20 patients with gout in the acute state who had active joints and were followed-up until the recovery state with no active joints.

Results: Beta diversity of the microbiome was significantly different between the acute and recovery states.

Disclosure of Interests: None declared

POS1176

EFFECT OF LIFESTYLE CHANGE ON INCIDENT GOUT: A NATIONWIDE POPULATION-BASED COHORT OF YOUNG MEN

Y. Eun1, K. D. Han2, S. W. Lee1, S. Y. Kang1, S. Lee1, H. S. Cha1, E. M. Koh1, H. Kim3,4, J. Lee4, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); 2Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea); 3College of Medicine, Catholic University of Korea, Department of Biomedicine & Health Science, Seoul, Korea, Rep. of (South Korea); 4Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medical Humanities, Seoul, Korea, Rep. of (South Korea)

Background: Although gout in young people is increasing, studies on the risk factors for gout in these people are lacking.

Objectives: In this study, we explored the risk factors of gout and effect of lifestyle change on the development of gout in large nationwide population-based cohort of young men.

Methods: Between 2009–2012, men aged 20–39 years who participated in two national health examinations at 2-year intervals were included in the study. The outcome was occurrence of gout, which was defined using the diagnosis code of gout (ICD-10 code M10) in the claims database. Cox proportional hazard model was used to evaluate the association between incident gout and baseline factors or lifestyle change.

Results: A total of 1,977,849 subjects were included in the study, and the mean follow-up period was 5.5 ± 4.3 years. Gout occurred in 38,839 subjects (incidence rate = 3.59/1,000 person-years). A high body mass index, alcohol drinking, and comorbidities such as hypertension, diabetes mellitus, and hyperlipidemia were associated with an increased risk of gout. Among lifestyle factors, change in obesity had the greatest impact on gout, followed by drinking. Development of obesity increased the risk of gout by 1.75 times (95% CI 1.68–1.81), and recovery from obesity decreased the risk of gout by 40% (aHR 0.60, 95% CI 0.57–0.64). Heavy drinking increased the risk of gout by 38% (aHR 1.38, 95% CI 1.33–1.43), and stopping heavy drinking decreased the risk of gout by 11% (aHR 0.89, 95% CI 0.85–0.94). The effect of obesity on gout was evident in the younger age group, and the effect of heavy drinking on gout was weak in the severely obese group.

Conclusion: Obesity and heavy drinking in young men are important modifiable risk factors for gout. Therefore, the management of these risk factors in young men should be emphasized.

Background: Rituximab (RTX) induces rapid, usually complete and prolonged depletion of circulating B cells, and also hypogammaglobulinemia in some patients. There are limited data regarding the risk of severe infection events (SIE) when initiating or continuing rituximab in patients with acquired hypogammaglobulinemia, especially in patients suffering from autoimmune diseases (ADs) other than rheumatoid arthritis (RA) (1).

Objectives: To describe the risk of severe infectious events (SIE) following initiation (rituximab-naïve patients [RNP]) or continuation of RTX therapy (rituximab-continuing patients [RCP]) in patients suffering from severe ADs other than RA and acquired hypogammaglobulinemia.

Methods: We conducted a single-center retrospective cohort study at the University Hospital of Toulouse (France) between 2010 and 2018. Patients were included if they had received at least one dose of RTX in the year following the evidence of hypogammaglobulinemia (defined as gammaglobulins [GG]<6g/L on serum protein electrophoresis) in the setting of ADs other than RA. The primary outcome was the occurrence of a SIE within 2 years after the date of first RTX infusion (T0) prescribed after the evidence of hypogammaglobulinemia. SIE were infections either fatal or requiring hospitalization.

Results: We included 121 patients (37 RNP and 84 RCP): 48 had ANCA-associated vasculitis (AAV), 48 multiple sclerosis (MS, n=41) or neuromyelitis optica (NMO, n=7), and 21 another severe AD. RTX was prescribed as induction therapy in 39 patients and as maintenance therapy in 82; 112/121 patients were followed for 2 years. Mean GG level were 5.5 g/L (IQ25-75: 4.6-5.7) at T0, 5.5 g/L (IQ25-75: 4.6-5.4) at one year, 5.7 g/L (IQ25-75: 4.8-6.1) at two years and 8 patients had a decrease of their GG level below 4g/L. Ten patients received immunoglobulin replacement therapy (IGRT) mostly after infection (n=6). Twenty-six patients (23.2%) had at least one SIE during follow-up: 12.8 % in the MS/NMO group with a 2-year incidence at 6.9 (3.1-15.5) per 100 person-years, 29.5 % in the AAV group with a 2-year incidence to 18.3 (9.3-20.1) per 100 person-years, 33.3 % in the other ADs group with a 2-year incidence at 22.2 (10.6-46.5) per 100 person-years. Infection was opportunistic in 8 patients (33.3 %) and 4 died from SIE. Risk factors of SIE at T0 were male gender (61.5% vs. 39.5%; p<0.05), lung disease (65.4% vs. 37.2%; p<0.01), renal failure (59.1% vs. 26.6%; p=0.01), a higher Charlson comorbidity index (p=0.001), a previous treatment by cyclophosphamide (53.8% vs. 30.2%; p=0.03), ≥ 5 g/m² d prednisone (69.2% vs. 33.7%; p=0.003), lack of pneumococcal vaccination (61.5% vs 31.4%; p=0.01). GG level was 5.3 g/L [4.1-5.6] in the ‘SIE’ group vs 5.6 g/L [4.8-5.8] in the ‘no SIE’ group (p=0.04). Incidence of SIE was 46% and 20.2% among patients with GG<4 g/L or GG≥4 g/L, respectively (p=0.07). No multivariable analysis provided reliable results.

Conclusion: Our study provides useful information for clinicians considering initiating or continuing rituximab therapy in patients with acquired hypogammaglobulinemia before Sars-Cov2 era. Prospective studies are necessary to improve the knowledge on outcome of patients treated by rituximab despite low immunoglobulins levels. Prophylactic IGRT may be appropriate in higher risk patients, especially if the GG level is below 4 g/L.

4 months, ionizamide/rifampicin for 3–4 months. For hepatitis B (HBV); there is evidence that risk of reactivation is increased in patients positive for hepatitis B surface antigen. These patients should be referred for HBV treatment. Patients who are positive for anti-HBcore antibodies, are at low risk for reactivation when treated with glucocorticoids, cDMARDs and bDMARDs but should be monitored periodically with liver function tests and HBV-viral load. Patients treated with rituximab display higher risk for HBV reactivation especially when anti-HBs titer are low. Risk for reactivation in hepatitis C RNA positive patients, treated with bDMARDs is low. However, all patients should be referred for antiviral treatment and monitored periodically. For pneumocystis jiroveci prophylaxis with trimethoprim/sulfamethoxazole (alternatively with atovaquone or pentamidine) should be considered in patients treated with prednisolone: 15-30mg/day for more than 4 weeks. Few data exist for screening and prophylaxis from viruses like EBV, CMV and Varicella Zoster Virus. Expert opinion supports the screening of rare bugs like histoplasma and trypanosoma in patients considered to be at high risk (e.g living in endemic areas).

Conclusion: The risk of chronic and opportunistic infections should be considered in all patients prior to treatment with immunosuppressives/immunomodulators. Different screening and prophylaxis approaches are described in the literature, partly determined by individual patient and disease characteristics. Collaboration between different disciplines is important.

Acknowledgements: We would like to thank all members of the EULAR Task Force for the screening and prophylaxis of chronic and opportunistic infections in Autoimmune Rheumatic Diseases.

AUTOIMMUNE SYNDROMES WITH CHRONIC HEPATITIS C VIRUS INFECTION AND DIRECT-ACTING ANTIVIRAL TREATMENT.

B. H A Mohammed1, D. Hassan Attia2, M. Abdelazim3, A. Elsayed Tahs3, D. Rasheed Bahgat4, H. Ibrahim El Mikhailxangy3. 1School of Medicine- Cairo University, 2Rheumatology and rehabilitation, Cairo, Egypt; 3School of Medicine- Cairo University, 4School of Medicine- Cairo University, 5School of Medicine- Cairo University, Tropical medicine, Cairo, Egypt; 6School of Medicine- Cairo University, Chemical and clinical pathology, Cairo, Egypt

Background: Chronic hepatitis C virus (HCV) infection is a multifaceted disease that has been associated with systemic as well as organ-specific, autoimmune manifestations with increasing virologic, and clinical evidence supporting the association. The development of direct-acting antivirals (DAAs) is considered an advent that might aid the clearance of extrahepatic immune manifestations of HCV.1,2,3

Objectives: Investigate the effect of directly acting antiviral drugs (DAAs) on the different autoimmune manifestation and serologic changes associating chronic HCV infection.

Methods: Inclusion criteria: This is a cohort study that included adult patients aged ≥18 years, of either sex, having CHCV with detectable HCV ribonucleic acids (RNA) by Polymerase Chain Reaction (PCR) and eligible for the DAAs treatment. Exclusion criteria: Patients with established rheumatological disease prior to the onset of HCV diagnosis. Patients with uncompensated cirrhosis, Patients with platelet count less than 50 000/mm³, Patients with HCC (except after 6 months of curative intervention). All patients were subjected to full history taking, clinical and laboratory investigations.

Results: The study enrolled 130 chronic HCV patient (90 patients completed follow up). 66.7% females and 33.3% males (ratio 2:1), the mean age was 49.2±12.3 years. The study found 77/90 (85.55%) patients to have immune mediated manifestations and associated serological changes prior to DAA. The most prevalent were musculoskeletal manifestations in 56 patients (72.7%), arthralgia (86.2%), fatigue (54.5%) and myalgia (50.6%), xerophthalmia (24.7%), neutrophils (28.6%) (P-value > 0.01), and a positive RF in 33.8% (P-value 0.013). HCV Among patients who achieved sustained viral response, autoimmune manifestations persisted in 66 out of 71 patients (92.9%) who were positive at baseline. The most prevalent autoimmune manifestations after therapy were musculoskeletal manifestations 53 patients (68.8%). Responders with persistent autoimmune manifestations had an observable rise in inflammatory biomarkers posttreatment erythrocyte sedimentation rate was (46.2±19.62) became (56.05±25.43), C reactive protein titer was (8.46±10.78) became (20.01±25.92), P<0.01. Predictors of recurrence of autoimmune manifestations were older age ≥49 years P-value 0.009, female sex P= 0.026, tobacco consumers P= 0.043.

Conclusion: The introduction of directly acting antiviral drugs wasn’t associated with a significant change in the prevalence of autoimmune manifestations in our population of Egyptian patients with chronic HCV who attained a sustained viral response.

INFECTION COMPLICATIONS OF BIOLOGIC THERAPY IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM

F. Idrissi Zak1, F. E. Chekkouri1, A. Mougui1, I. El Bouchti1. 1Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Rheumatology. Marrakech, Morocco

Background: The appearance of biological disease-modifying drugs (bDMARDs) has revolutionized the treatment of rheumatic diseases. However, their functions in modulating pro-inflammatory cytokines and acquired immunity largely increase the risk of infections.

Objectives: The aim of this work is to study the epidemiological, clinical and biological characteristics of infections occurring under biotherapies, and to identify the factors associated with its occurrence.

Methods: It is a retrospective descriptive study including patients with chronic inflammatory rheumatism between 2006 and 2021 and who were placed during their follow-up under a biotherapy. Statistical data analysis was performed using SPSS version 20 software. The bivariate study was performed by Chi-square test.

Results: Of the 106 cases reported, 68 infectious episodes were counted in 46 patients (43.4%) who had at least one infection with biotherapy: 56.5% women and 43.5% men with an average age of 50.9 ± 14.29 years. These included rheumatoid arthritis in 16 patients (34.8%), spondylarthritides in 29 patients (63%) and one case of psoriatic arthritis. All patients were on conventional treatments before switching to biotherapy. The infections occurred under rituximab in 43.8% of the cases, under infliximab in 33.3% of the cases, under Etanercept in 25% of the cases (a total of 60.9% of the cases were under anti-Tumor Necrosis Factor) and tocilizumab in 12.5% of the cases. The infection was of bacterial origin in 40.7% of cases: 27.3% urinary tract infections, 20.5% bronchial infections, 11.4% skin infections, 6.8% septic arthritis. Fungal infections were found in 33.3% of cases in relation to dermatophyte infections and intertrigo. A viral origin was noted in 25.9% of the cases. Nevertheless, cases of salmonella were in 2 cases and only one case on herpes zoster. C-reactive protein was increased in 47.2% of cases with a mean value of 36 ± 29.6 mg/L. The hemogram showed hyperleukocytosis in 50% of cases with neutrophil predominance. The treatment was medical in the majority of cases (94.9%), it was both medical and surgical in one case. The favorable outcome in all patients was marked by a temporary interruption of 5.27 ± 1.84 weeks of biotherapy. In multivariate analysis, an association was found between bacterial infection and both female gender (p=0.033), low socioeconomic level (p=0.033), Methotrexate + bDMARDs intake (p=0.027), corticosteroids + bDMARDs intake (p=0.014) and Between fungal infection and bDMARDs + corticosteroids intake (p=0.044).

Conclusion: The risk of infection is higher in patients with chronic inflammatory rheumatism, especially if they are under biotherapy. It turns out that bacterial and fungal infections are the most affected by these infectious episodes.

POS1182

EPIDEMIOLOGICAL, CLINICAL AND THERAPEUTIC ASPECTS OF TABETIC ARTHROPATHY IN A POPULATION OF SOUTHERN MOROCCO

P. C. Moulele Mbougui, F. E. Bennani, S. Belouaham, H. Bara, A. Mougui, I. El Boucht, centre Hospitalo-Univeriste Mohammed VI Marrakech, Rheumatology, Marrakech, Morocco

Background: Tabetic arthropathies (TA) are a destructive neurogenic disease complicating 10% of syphilis at the tertiary stage. Although they have become exceptional due to early and appropriate treatment of syphilis, they are still relevant in underdeveloped countries and remain difficult to manage due to the severity of the handicap and the absence of a specific treatment.

Objectives: We described epidemiological, clinical, biological, radiographic, and therapeutic characteristics of TA.

Methods: Retrospective study, from 2004 to 2021 including patients with tabetic arthropathy, whose diagnosis was retained on clinical criteria (discordance between the importance of joint deformities and indolence), radiological (lesions destructive and constructive), biological (positive syphilitic serology in joint fluid, blood and/or cerebrospinal fluid).

Results: A total of 21 cases were collected, 15 men and 6 women, the mean age was 52.14 years. The history of syphilitic chancre was found in 9 patients, sexual risk behavior was noted in 8 patients, no other STI was found. Joint swelling and painless deformation was the main mode revealing the disease (76.1%), followed by the hip, ankles, MTP, in respectively 4(19%), 3(14%), 2(9.5%) cases. The upper limb was involved in 4 cases, with MCP involvement in one patient. TA was bilateral in 29% and multifocal in 19%. Joint instability was found in 16 patients. Involvement of the thoracolumbar spine was noted in one case. Tabetic neurological involvement was found in 16 patients (76.1%) with an Argyll Robertson sign noted in 6 cases (28.6%), a radiculopodenteral posterior syndrome in 10 cases (47.6%), TPHA and VDRL were positive in blood in 21 patients, in cerebrospinal fluid in 11 patients and in synovial fluid in 9 cases. Radiological exams showed destructive and constructive lesions with the presence of intraosseous and periarticular fragments, damage to small joints was noted in two patients, bilateral talocalcaneal involvement in one patient, a fracture with dislocation and calcification of the soft tissues was noted in two cases. Axial tabetic involvement made of talocrural involvement in one patient, a fracture with dislocation and calcification of the soft tissues was noted in two cases. Axial tabetic involvement made of talocrural involvement in one patient, a fracture with dislocation and calcification of the soft tissues was noted in two cases.

Conclusion: Tabetic arthropathy, one of the exceptional complications of neurosyphilis, is still relevant. Its diagnosis must be referred to any destructive and painful joint damage. Given the difficulty of treating this articular form, prevention based on the management of syphilis at an early stage before the occurrence of joint and neurological complications is essential.

POS1183

RISK FACTORS FOR CYTOMEGALOVIRUS INFECTION IN PATIENTS WITH RHEUMATIC DISEASE - SINGLE-CENTER PROSPECTIVE COHORT STUDY.

Y. Ota1, Y. Kondo1, S. Saito1, J. Kikuchi1, H. Hanaoka1, Y. Kaneko1, Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Cytomegalovirus (CMV) infection is one of serious opportunistic infections for immunosuppressed patients, therefore, identifying patients at risk for CMV infection is of importance. However, no prospective study about CMV infection in systemic rheumatic disease has been reported.

Objectives: To identify risk factors relevant with CMV infection in patients with systemic rheumatic disease during intensive remission induction therapy.

Methods: Consecutive systemic rheumatic disease cases who started intensive immunosuppressive therapy from February 2017 until February 2019 were enrolled. Serum CMV-IgG was measured before the induction therapy, and subsequently, CMV pp65 antigen was monitored weekly. Patients were divided into 2 groups according to the presence or absence of CMV infection, and risk factors for CMV infection were analyzed.

Results: 157 patients consisting of 136 CMV-IgG positive and 21 CMV-IgG negative patients were enrolled in the study. Mean age was 60.8 ± 17.4 y/o, and female was 70.7%. The underlying diseases were following; vasculitides 54, systemic lupus erythematosus 27, polymyositis/dermatomyositis 25, rheumatoid arthritis 14, IgG4-related disease 13, mixed connected tissue disease 6, Behçet disease 5, adult-onset Still’s disease 4, and others 9. The initial dose of glucocorticoid (GC) was 48.4 ± 11.5 mg/day (0.91 ± 0.16 mg/kg/day) as prednisolone (PSL) with additional methylprednisolone (mPSL) pulse therapy being conducted in 44 (28.0%). Concomitant immunosuppressive treatments were intravenous cyclophosphamide (IVCY) in 55, calcineurin inhibitor 27, mycophenolate mofetil 16, hydroxychloroquine 5, and methotrexate 4. Concomitant biological agents were rituximab 12, tocilizumab 6, infliximab 2, golimumab 1, and abatacept 1. CMV infection occurred in 52 patients (33.1%), and all of them were CMV-IgG positive before induction therapy (38.2% in the CMV-IgG positive patients). Univariable analysis revealed initial PSL dose >0.91 mg/kg/day (odds ratio [OR] 5.2, p<0.01), IVCY (OR 3.4, p<0.01), diabetes mellitus (OR 5.2, p<0.01), and a history of malignancy (OR 2.9, p=0.02) were independent risk factors for CMV infection. CMV antiviral drugs were administered in 22 patients (42.3%). At the first detection of CMV pp65 antigen, PSL dose >37.5 mg/day (OR 52.948, p<0.01), CMV pp65 antigen-positive cells ≥2 cells/2 slides (OR 16.0, p = 0.04), and serum albumin levels <3.0 g/dL (OR 26.3, p=0.01) were associated with subsequent CMV antiviral drug administration.

Conclusion: CMV infection is only in CMV-IgG positive patients with systemic rheumatic diseases who were undergoing intensive remission induction therapy. CMV infection was related with treatment regimen and comorbidities, and the necessity of CMV antiviral treatment was predicted with prednisolone therapy. CMV infection was related with treatment regimen and comorbidities, and the necessity of CMV antiviral treatment was predicted with prednisolone dose, the number of CMV pp65 antigen positive cells, and albumin levels at the first detection of CMV pp65 antigen.

Disclosure of Interests: None declared
Background: Recent epidemiological data on HBV and HCV in Turkey revealed that the seroprevalence rates of hepatitis B surface antigen and antibody against HCV were 4% and 1%, respectively, and seropositivity rates for hepatitis B surface antibody and hepatitis B core antibody were 31.9% and 30.6%, respectively. A previous multicenter nationwide study conducted in Turkey reported that the HBsAg positivity was determined in 2.3% of patients with rheumatoid arthritis (RA) and 3% of patients with ankylosing spondylitis (AS), and the anti-HCV positivity was detected in 1.1% of patients in each group. Given these rates, viral hepatitis is still considered a potential threat to patients with rheumatic diseases, specifically for the treatment-related viral reactivation.

Objectives: This study aimed to evaluate the serologic HBV and HCV frequency and clinical characteristics among our patients with RA or SpA and receive biological treatments based on this background.

Methods: The prospective TReasure database, which observationally collects data of patients with rheumatic diseases from fifteen centers across Turkey, was analyzed for viral hepatitis, patient characteristics, and treatments used. TReasure registry study protocol, and the data collection was started on December 2017. At the time of the analysis for this study was performed, the registry database included 3147 patients with RA and 6071 patients with SpA. For hepatitis B, hepatitis B surface antigen (HBsAg), anti-HBV core antibody (anti-HBc), and anti-HBV surface antibody (Anti-HBs) tests were evaluated. HBV-DNA was studied in HBsAg positive patients. Anti-HCV antibody has been studied for HCV. The clinical and serological HBV reactivation in the follow-up of the patients was evaluated by looking at the HBV-DNA viral loads.

Results: A total of 9218 patients (3147 RA and 6071 patients with SpA) were included in the analyses. The screening rate for HBV was 97% in RA and 94.2% in SpA groups. HBsAg positivity rates were 2.6% and 2%, anti-HBs positivity rates were 32.3% and 34%, anti-HBc positivity rates were 20.3% and 12.5%, HBV DNA positivity rates were 3.5% and 12.5%, and anti-HCV positivity rates were 0.8% and 0.3% in these groups, respectively (Table 1).

The HBsAg (+) patients were older and had higher comorbidities, including hypertension, diabetes, and coronary artery disease. In addition, RF positivity was more in HBsAg (+) cases. The most frequently prescribed bDMARDs were adalimumab (28.5%), etanercept (27%), tocilizumab (23.4%), and bDMARDs (21.3%) in the RA group, whereas adalimumab (48.1%), etanercept (31.4%), infliximab (22.5%), degenerative changes, etc (2). The identification of the germ by blood cultures or disc-vertebral puncture-biopsy allows the treatment to be best adapted antibiotic. Bacteriological investigation is inconclusive in about 30% (1). More and more undocumented spondylodiscitis are described.

Objectives: The aim of this study is to describe a cohort of spondylodiscitis without bacteriological documentation and to compare it to spondylodiscitis with bacteriological documentation.

Methods: We research Medline and EMBASE from the inception to October 2021 and the American College of Rheumatology and European League Against Rheumatism for conference abstracts (2012-2021) to assess the accuracy of ADA activity in synovial fluid compared to a composite reference standard (necrotizing granulomas in a synovial biopsy; acid-fast stain, Mycobacterium culture or RT-PCR assay for tuberculosis and/or clinical response to tuberculosis treatment) to early diagnosis of tuberculous arthritis. We performed meta-analysis using a random-effects model and evaluated the sources of heterogeneity via subgroup analysis and meta-regression.

Results: Seven independent studies (N= 307 subjects) that compared ADA activity in synovial fluid with the composite reference standard were included. The pooled sensitivity and specificity of ADA activity was 0.939 (95% confidence Interval [CI], 0.873-0.977; heterogeneity p=0.297; I2=17.4%) and 0.885 (95% confidence Interval [CI], 0.833-0.925; heterogeneity p=0.002; I2=85.3%) compared to the composite reference standard, respectively. The random-effects model for pooled diagnostic Odds Ratio was 74.582 (95% CI, 19.826-280.57; heterogeneity p=0.133; I2=38.8%). The receiver operating characteristic curve area was 0.9617 (95% CI, 0.939-0.994; heterogeneity p=0.297; I2=17.4%). Meta-regression did not identify the type of study (prospective or retrospective), country of publication, type de assay, or cut-off value as sources of heterogeneity.

Conclusion: Measuring adenosine deaminase activity in synovial fluid demonstrates good performance for the early diagnosis joint tuberculosis.

POS1185

PERFORMANCE OF ADENOSIN DEAMINASE ACTIVITY IN SYNOVIAL FLUID FOR THE EARLY DIAGNOSIS OF TUBERCULOUS ARTHRITIS: A META-ANALYSIS

J. Ena1, J. C. Cortés-Quiroz2, J. A. Bernal3, A. Pons3, J. M. Senabré-Gallego3, G. Santos Soler4, C. Raya-Santos5, J. Rosas5, 1Hospital Marina Baixa, Internal Medicine, Villajoyosa, Spain; 2Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain

Background: Adenosin deaminase activity (ADA) has shown good performance in diagnosing pleural, peritoneal and meningeal tuberculosis. Still, the performance of ADA activity in synovial fluid for the diagnosis of tuberculous arthritis has received less attention.

Objectives: To analyze the performance of ADA in synovial fluid to diagnosis tuberculosis arthritis.

Methods: We research Medline and EMBASE from the inception to October 2021 and the American College of Rheumatology and European League Against Rheumatism for conference abstracts (2012-2021) to assess the accuracy of ADA activity in synovial fluid compared to a composite reference standard (necrotizing granulomas in a synovial biopsy; acid-fast stain, Mycobacterium culture or RT-PCR assay for tuberculosis and/or clinical response to tuberculosis treatment) to early diagnosis of tuberculous arthritis. We performed meta-analysis using a random-effects model and evaluated the sources of heterogeneity via subgroup analysis and meta-regression.

Results: Seven independent studies (N= 307 subjects) that compared ADA activity in synovial fluid with the composite reference standard were included. The pooled sensitivity and specificity of ADA activity was 0.939 (95% confidence Interval [CI], 0.873-0.977; heterogeneity p=0.297; I2=17.4%) and 0.885 (95% confidence Interval [CI], 0.833-0.925; heterogeneity p=0.002; I2=85.3%) compared to the composite reference standard, respectively. The random-effects model for pooled diagnostic Odds Ratio was 74.582 (95% CI, 19.826-280.57; heterogeneity p=0.133; I2=38.8%). The receiver operating characteristic curve area was 0.9617 (95% CI, 0.939-0.994; heterogeneity p=0.297; I2=17.4%). Meta-regression did not identify the type of study (prospective or retrospective), country of publication, type de assay, or cut-off value as sources of heterogeneity.

Conclusion: Measuring adenosine deaminase activity in synovial fluid demonstrates good performance for the early diagnosis joint tuberculosis.

POS1186

STUDY OF SPONDYLODISCITIS WITHOUT BACTERIOLOGICAL DOCUMENTATION FROM A COHORT OF 142 PATIENTS WITH SUSPECTED INFECTIOUS SPONDYLODISCITIS ON IMAGING

G. Alina1, M. Desvaux1, C. Delpeigne1, M. Lanquart2, C. Patene2, N. Sens1, M. Kozyreff-Meurot3, S. Pouplin1, T. Lequerr2, O. Vittecoq4, G. Avenel1, 1Hospital Center University De Rouen, Rheumatology, Rouen, France

Background: The incidence of infectious spondylodiscitis was estimated at 2.4/100,000 people in 2002. When faced with an image of spondylodiscitis on imaging, infectious spondylodiscitis is the most feared etiology. In recent years, several non-infectious spondylodiscitis etiologies have been described: Andersson lesion, crystal-induced discopathy, degenerative changes, etc (2). The identification of the germ by blood cultures or disc-vertebral puncture-biopsy allows the treatment to be best adapted antibiotic. Bacteriological investigation is inconclusive in about 30% (1). More and more undocumented spondylodiscitis are described.

Objectives: The aim of this study is to describe a cohort of spondylodiscitis without bacteriological documentation and to compare it to spondylodiscitis with bacteriological documentation.
Methods: Using a “clinical data warehouse”, we searched for the key word “spondylodiscitis” in the documents associated with hospitalisations in the Rheumatology department of the Rouen University Hospital between 2010 and 2020. Four hundred and twenty-two records were analysed. 196 were excluded because they were not hospitalized in Rheumatology, among the 226 suspected spondylodiscitis, imaging allowed us to exclude 84 records for which there was no infectious spondylodiscitis and to retain 142 records. We collected demographic data, history, clinical symptoms, results of imaging, biological and bacteriological examinations. Statistical analysis was performed by Fisher’s exact test for qualitative data and by Mann-Whitney test for quantitative data.

Results: Four hundred and twenty-two patients were collected, 142 were analysed. The average age was 65.5 +/- 14 years, 64.1% were male. Spinal pain was present in 96.5% of the cases without any difference between the two groups. One hundred and nine cases of spondylodiscitis were documented, of which 72 were confirmed by blood cultures and 36 by spinal disc biopsy. Thirty-three were not documented. Documented spondylodiscitis was more often febrile (41.3% vs 15.21% in undocumented cases, p = 0.006), had a greater biological inflammatory syndrome (mean CRP 152.4 +/- 112.6 mg/L versus 73 +/- 73.1 mg/L, p < 0.0001), and had been evolving for a shorter period of time than undocumented spondylodiscitis (54.1% vs 24.2% less than one month). Staphylococcus aureus was the most frequently retrieved bacteria 27.5%, followed by coagulase-negative staphylococci and streptococci (18.3% and 19.3% respectively). One hundred and twenty-one patients (85%) had an MRI at diagnosis; one hundred and two (71.8%) had a CT scan; and 81 patients (57%) had both examinations. The imaging analysis showed that there was no difference in soft tissue infiltration, erosions and abscesses. Probablistic antibiotic therapy was proposed in 28/33 (84.5%) of cases. After collegial discussion, the alternative diagnoses retained were degenerative disc disease (4 cases), spinal gum (1 case), spondylodiarthritis (1 case).

Conclusion: Undocumented spondylodiscitis is a recurring problem in hospital practice. Alternative diagnoses are increasingly reported, their diagnosis is based on collegial discussion.

POS1187

DO IMMUNOSUPPRESSIVE AGENTS AFFECT IGRA TESTS IN PATIENTS WITH RHEUMATOID ARTHRITIS?

Z. Özyönlü1, A. Özdemir2, M. Ekici3, E. Bilgin1, L. Kılıç4, S. Kızılağaoğlu5, S. Sanbaşaoğlu, B. Şener2, O. Karadağ1, Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 2Hacettepe University, Faculty of Medicine, Department Of Medical Microbiology, Ankara, Turkey

Background: Tuberculin skin test (PPD) or interferon gamma release assays (IGRAs) are used to detect latent tuberculosis infection. Induration of 15 mm or more is considered positive in any person whereas this cut-off is ≥5 mm for immunosuppressed individuals such as Rheumatoid arthritis. Since IGRAs are dependent on normal T-cell function, it may result in false-negatives for RA patients due to disease itself and immunosuppressive drugs.

Objectives: We aimed to compare IGRA results of RA patients using high dose DMARDS vs. not using any of them.

Methods: Totally 534 RA patients among Hacettepe University Rheumatology Biologic Registry Database (HURBIO) database was enrolled in this study. QFT-Plus test of patients with rheumatoid arthritis (RA) between January 2018 and March 2021 during work up before biologic/targeted therapy were analysed, retrospectively. The patient group was divided into two according to the drugs have been using at the time of IGRA test. Patients using methotrexate ≥ 10 mg or leflunomide (any dose) or steroids (≥7.5 mg prednisolone) or any combination thereof were classified as the “High Dose” group. The other group consisted of patients who did not take these drug doses. Demographic characteristics, comorbidities, drugs and doses used, and hemogram, sedimentation, and CRP values of the patients were recorded. Quantiferon test was recorded as positive, negative, indeterminate.

Results: 353(66.1%) RA patients were in the high dose patient group and also 287(81.3%) of these patients were female, the median age was 55 years (min-19- max-82). The high dose group was older than the other group. When the two groups were compared, no statistically significant difference was found between comorbidity, and smoking (Table 1). While QFT positivity was detected in 37 (10.5%) patients in the high-dose group, it was found to be positive in 37 (20.4%) patients in the other group (p<0.001). However, there was no significant difference regarding acute phase reactants, hemogram including lymphocyte counts and IFN-gamma levels in the tubes between these two groups.

QuintIFERON-TB Gold-

Plus (QFT-Plus)

Table 2. Comparison of RA patients’ groups using high-dose immunosuppressives and not using any of them

Nill med (min-max) | 0.07 (0.2-7.1) | 0.05 (0.0-0.85) | 0.48 |
QFT-Plus TB 1 med (min-max) | 1 (0-10) | 0.99 (0.0-10) | 0.25 |
QFT-Plus TB 2 med (min-max) | 1 (0-10) | 1.1 (0-10) | 0.42 |
Methyleneed (min-max) | 10 (0-10) | 9.5 (0-10) | 0.27 |

Conclusion: Our results confirmed a significantly lower QFT-Plus positivity in patients with RA taking methotrexate ≥ 10 mg or leflunomide (any dose) or steroids (≥7.5 mg prednisolone). Physicians should be careful in interpretation of QFT-Plus in patients with rheumatoid arthritis. Further analysis including flow cytometry analysis is required to better identifying cut-offs for immunosuppressive individuals and patients with inflammatory rheumatic diseases.

POST1188

INCIDENCE AND MANIFESTATIONS OF LYME DISEASE: A SINGLE-CENTER RETROSPECTIVE ANALYSIS.

S. Pučko1, A. Pučko2, A. Mihailova1, Riga Stradins University, Internal diseases, Riga, Latvia; 2Riga Stradins University, Family Medicine, Riga, Latvia
Background: Lyme disease is widespread throughout the world, including Latvia. On average period 2009 to 2018, there have been 613 cases of Lyme disease registered in Latvia every year according to data from the Center for Disease Prevention and Control. Mainly early skin manifestations such as erythema migrans and neurological manifestations such as meningitis, cranial neuropathy and motor or sensor radiculoneuropathy of this disease are being discussed and emphasized. Therefore, undiagnosed and unexamined often remain articular manifestations of Lyme disease, leading to prolonged treatment and reduced patient quality of life.

Objectives: To investigate clinical presentation, immunological changes, and response to therapy in patients with Lyme disease.

Methods: A retrospective single center study was performed in the outpatient clinic Orto (Riga, Latvia) in the period from January 2018 until December 2021. Medical records from patients who diagnosed Lyme disease and articular manifestations, based on epidemiological, clinical and immunological findings, were analyzed. Patients who had other types of arthropathies were excluded.

Results: In total 76 patients were included in the study (54 females, 22 males, age range 19-84 years, median age 48.5 years), of whom 48 patients had arthritis and 28 arthralgias. Out of all patients with arthritis - 25 had monoarthritis, 16 - had oligoarthritis and 7 had polyarthritis. At the first visit patients with arthralgia had a median IgM 14.7 Au/ml (IQR 5.50 - 28.80) and IgG 142.7 Au/ml (IQR 82.32-237). After the treatment with Doxycycline 200 mg QD for 30 days, 52 patients came to the 2nd visit, of them 41 patients with improvement of symptoms and 11 without. More improvement was seen in the arthritis group. After treatment the median IgM in arthralgia/ arthritis groups was 22.5 Au/ml (IQR 8.72-38.82) / 13.8 Au/ml (IQR 6.03-24.15) and IgG was 42.4 Au/ml (IQR 8.15 – 90.60) / 106.7 Au/ml (IQR 23.57-203.95). In both groups with arthralgias or arthritis, patients who had a positive clinical response after treatment had a significantly lower post-treatment IgG than before treatment (p <0.05, Wilcoxon signed rank test). At the same time patients who did not respond to the treatment had no significant difference between pre- and post-treatment IgG antibodies (p> 0.05, Wilcoxon signed rank test).

Conclusion: In all patients with musculoskeletal complaints the possibility of Lyme disease should be evaluated. The decrease of antibody titers may indicate a positive prognosis in patients with musculoskeletal manifestations of Lyme disease.

Disclosure of Interests: None declared

POS1189 RHEUMATIC FEVER AND CUTANEOUS STREPTOCOCCAL INFECTION: A CASE-CONTROL STUDY IN THE LOYALTY ISLANDS, NEW CALEDONIA

O. Amic-Desvaut1,2, O. Maillard3, S. Iacobelli4, T. Bardin5, Y. M. Ducrot6, 1Hôpital Intercommunal Des Valls de l’Urvége, Endocrinologie, Saint-Jean-de-Verges, France; 2Direction de l’Action Communautaire et de l’Action Sanitaire, Centre Médico-Social de Wé, Lifou, New Caledonia; 3Université de la Réunion, Service de Pédiatrie, Saint-Pierre, La Réunion, France; 4Centre Hospitalier Universitaire Sud Réunion, Service de Néphrologie, Saint-Pierre, La Réunion, France; 5Université de Paris, INSERM UMR S1132, Hôpital Lariboisière, Paris, France; 6Direction de l’Action Communautaire et de l’Action Sanitaire, Centre Médico-Social de Wé, Lifou, New Caledonia.

Background: Acute Rheumatic Fever (ARF) and Rheumatic Heart Disease (RHD) remain major public health problems in the South Pacific. Triggering by group A beta hemolytic streptococcal (GAS) skin infection has been suspected but little documented1. Very high incidences of ARF (106/100 000) and cutaneous infections have been reported in the Loyalty Islands (New Caledonia), where health care of the 20,000 Melanesian inhabitants is centralized in a few locations and provides an extensive electronic database since 1998, and systematic screening for RHD is regularly performed.

Objectives: To explore the link between ARF, RHD and skin infections by a retrospective case-control study.

Methods: The study was approved by the New Caledonian committee of Ethics and dealt with patients aged 6 to 26 years, seen from 1998 to 2018. Cases were ARF and/or RHD. Definite ARF was diagnosed according to the Jones criteria; additional cases with strong clinical suspicion were also included as probable cases. RHD was diagnosed by cardiac ultrasound scan allowing definite and borderline diagnosis2. Sore throat and presumed streptococcal cutaneous infections were diagnosed by an algorithm, previously validated on a sample of 3000 events by an experimented clinician, which identified specific medical terms and ICD-10 codes in the electronic medical records. Each case was matched with 3 controls (without ARF and RHD) of same age, sex and living location. Infections were retrieved from the electronic medical records during the month, 6 months, one year, 5 years preceding the date of the first ARF/RHD diagnosis, for each case with the same index date for its matched control, and since birth. Numbers of infections per these time intervals were compared between cases and controls by univariate and multivariate conditional regression analysis in the total study population and its various subcategories (definite or probable ARF, definite or borderline RHD).

Results: 311 cases of ARF and RHD including 206 definite cases were identified. Polyarthralgias (48%) were the main clinical presentation. Marginal erythema was not seen and Sydenham chorea was rare (6.8%). Mean age of diagnosis was 10.6 ± 3.8 years. Skin infection episodes were 3 to 4 times more frequent than sore throats in all studied time-intervals. Multivariate analysis showed an increased exposure to skin infections and sore throats in the year preceding ARF/RHD diagnosis in the whole population of cases as compared to controls (OR 2.18, 95% CI 1.46, 3.26 and 1.54, 95% CI 1.01, 2.36 respectively); skin infections (but not sore throat) were also increased the 206 definite cases (OR 1.34, 95% CI 1.01, 1.80) and in the 220 definite and probable ARF (OR 1.47, 95% CI 1.11, 1.94). In addition we observed a correlation between the seasonality of ARF and skin infections, which were both more frequent during the rainy season, and an overlap of areas with high incidence of ARF and areas with high incidence of skin infections.

Conclusion: Our results support the hypothesis that GAS skin infections play a role in the pathophysiology of ARF/RHD. In view of these results, there is an urgent need to implement preventive measures to reduce the incidence of skin infections in the Loyalty Islands.

COVID-19

POS1190

IMPACT OF COVID-19 PANDEMIC ON PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: DISRUPTIONS IN CARE AND SELF-REPORTED OUTCOMES

A. M. Fouad1, S. F. Elotia, E. Nourhan Elameen2, A. E. Mohamed1. 1Faculty of Medicine, Suez Canal University; 2Department of Public Health, Occupational and Environmental Medicine, Ismailia, Egypt.

Background: The COVID-19 pandemic represents a challenge to the care of patients with rheumatic and musculoskeletal diseases (RMDs). Patients were interviewed for sociodemographic and disease-related history. Further assessments were performed using Kessler 6-items (1), Fear of COVID-19 scale (2), and COVID-19-Impact on Quality-of-Life scale (3).

Methods: This cross-sectional study involved 120 RMDs patients at the rheumatology department at Suez Canal University Hospital in Ismailia, Egypt. Patients were interviewed for sociodemographic and disease-related history. Further assessments were performed using Kessler 6-items (1), Fear of COVID-19 scale (2), and COVID-19-Impact on Quality-of-Life scale (3).

Results: Patients with rheumatoid arthritis and systemic lupus erythematosus made up most of our sample (72.5%, 19.2% respectively). About 50% of patients were experiencing limitation in the access to rheumatologic care, and a similar percentage had changed or discontinued their medications. DMARDs shortage while anticytokines preserved immunogenicity. The effects of cumulative methotrexate and glucocorticoid doses on immunogenicity should be considered.

Conclusion: The pandemic negatively influenced the mental health, quality of life, adherence to medications, access to rheumatology care, and disease control of RMDs patients.

POS1192

INCIDENCE AND RISK FACTORS OF COVID-19 IN PATIENTS WITH VASCULITIS: A DANISH NATIONWIDE COHORT STUDY

S. Kristensen1,2, R. L. Cordtz1,3,4, K. Duch1,4, J. Lindhardsen5, C. Torp-Pedersen6,7, Aalborg University Hospital North, Rheumatology, Aalborg, Denmark; Aalborg University Hospital, Clinical Medicine, Aalborg, Denmark; Gentofte Hospital, Center for Rheumatology and Spine Diseases, Hellerup, Denmark; Aalborg University Hospital, Unit of Clinical Biostatistics, Aalborg, Denmark; Rigshospitalet, Lupus and Vasculitis Clinic, Center for Rheumatology and Spine Diseases, København, Denmark; North Zealand Hospital - Hillerød, Cardiology, Hillerød, Denmark; Copenhagen University, Department of Public Health, København, Denmark

Background: Patients with small vessel vasculitis (SVV) and large vessel vasculitides (LVV, including giant cell arteritis (GCA)) are considered at higher risk of infections compared to the general population, owing to their underlying condition and the use of immunosuppressive drugs. Thus, the risk of COVID-19 infection and related outcomes during the global pandemic is of immediate concern to rheumatologists worldwide.

Objectives: To estimate the incidence of COVID-19 hospitalisation in patients with vasculitis, and to evaluate the impact of glucocorticoid treatment on the outcome between March 2020 and February 2021.

The table shows the incidence and risk factors of COVID-19 in patients with vasculitis, with a focus on the impact of glucocorticoid treatment on the outcome between March 2020 and February 2021.
Methods: With use of the Danish nationwide registers, a cohort of patients with LVV and SVV, respectively, and general population controls (GPCs) matched on age and gender was established. Hazard ratios (HR) for COVID-19 hospitalisation was estimated. National COVID-19 surveillance data was used to calculate the odds ratio (OR) of having a positive SARS-CoV2 PCR test. Lastly, a nested case-control design and conditional logistic regression was used to estimate the impact of glucocorticoids on the risk of hospitalisation.

Results: Patients with SVV (n=1090) had an increased incidence of COVID-19 hospitalisation compared with GPCs (comorbidity-adjusted HR 2.73; 95% CI 1.64-4.55), with dose of increasing qd) and seen in patients with LVV. Patients with vasculitis had similar likelihoods of having had a positive PCR test as GPCs. Glucocorticoids did not increase the HR of hospitalisation among patients with LVV or SVV.

Conclusion: Patients with SVV were more likely to be admitted with COVID-19 than the GPCs. The impact of glucocorticoid treatment on the risk of hospitalisation needs further investigation.

**POS1193 COVID-19 IN PATIENTS WITH GIANT CELL ARTERITIS**

J. Kramarič1, R. Jesese2, M. Tomcic3, Z. Rotar3, A. Hočevar1,2,3

1University Medical Centre Ljubljana, Department of Rheumatology, LJUBLJANA, Slovenia; 2Modra Jagodica d.o.o., LJUBLJANA, Slovenia; 3Medical Faculty, University of Ljubljana, Internal Medicine, LJUBLJANA, Slovenia

Background: Patients with giant cell arteritis (GCA) represent a fragile population with an increased infection risk. In a recent study, older age, a higher number of comorbidities, higher disease activity, and prednisolone ≥10mg qd were associated with worse COVID-19 outcomes.

Aims: We aimed to evaluate the frequency and severity of COVID-19 in a well-defined GCA cohort.

Methods: We reviewed medical records of historically and/or by imaging proven GCA patients diagnosed between September 2011 and February 2020 at our secondary/tertiary center and followed during the COVID-19 pandemic between March 2020 and December 2021 (22 months). Descriptive statistics was used to analyze the studied population.

Results: Of 314 GCA patients diagnosed for the first time during a 102-month period, 49 patients died before March 2020. Of the remaining 265 patients (69.4% females), SARS-CoV-2 infection was proven by PCR test in 39 (14.7%) patients (74.2% females, mean SD) age at infection 76.2 (±9.6 years), 13 (33.3%) with large vessel GCA and 16 with cranial limited GCA). At the time of SARS-CoV-2 infection GCA was in a stable remission in 38 patients (13 without therapy, 10 on steroids alone, 9 on leflunomide monotherapy, 6 on steroids plus leflunomide (10 or 20mg qd), 1 on ustekinumab; mean prednisolone equivalent dose of 4.6mg qd) and relapsed in one patient 6 weeks earlier (prednisolone 30mg plus leflunomide). Data on clinical manifestations of COVID-19 were available for 33 (84.6%) patients and are presented in Table 1, Part A. Twenty-nine/39 (74.4%) patients had mild COVID-19 and were symptomatically treated at home, while 10 patients had severe infection (defined as a need of hospitalization and/or death), and one of those patients died due to COVID-19. One patient developed a transient neurologic ischemic attack related to COVID-19. Table 1, Part B shows differences in GCA demographic and treat-ment at the time of mild vs. severe infection. We found no differences in gender, age, GCA type and GCA treatment between those with mild vs. severe COVID. Three patients developed COVID-19 after receiving two doses of anti-COVID vaccine (1.4% breakthrough rate). Overall, 257 GCA patients eligible for vaccination, 210 (81.7%) were vaccinated by the end of December 2021.

Conclusion: A quarter of our GCA patients had severe COVID-19. Low doses of glucocorticoids and treatment with leflunomide were not associated with severe COVID-19 course in our cohort.

**POS1194 COVID-19 IN PATIENTS WITH INFLAMMATORY MYOPATHY**

A. Hočevar1,2, B. Radic3, M. Krosel1, M. Tomcic1, Z. Rotar1,2,3

1University Medical Centre Ljubljana, Department of Rheumatology, LJUBLJANA, Slovenia; 2Medical Faculty, University of Ljubljana, Internal Medicine, LJUBLJANA, Slovenia; 3Celje General Hospital, Department of Rheumatology, Celje, Slovenia

Background: Older age, male sex, multimorbidity and glucocorticoids emerged in rheumatic patients as risk factors for severe COVID-19.

Objectives: We aimed to evaluate the frequency and severity of COVID-19 in a well-defined cohort of patients with idiopathic inflammatory myopathy (IIM).

Methods: We analyzed medical records of IIM patients diagnosed and followed at our secondary/tertiary center between January 2005 and December 2021.

Results: During the 204-month period IIM was newly diagnosed in 191 patients, of whom 52 died before COVID-19 pandemic. Of the remaining 139 patients (69.8% females; 9 polyomylitis, 47 dermatomyositis; 38 antisynthetase syndrome, 26 overlap syndrome; 17 immune mediated necrotizing myopathy; 2 inclusion body myositis), SARS-CoV-2 infection was proven in 13 (9.4%) patients (61.5% females, mean SD age at infection 62.9 (±16.8 years)). Seven/13 COVID-19 patients (53.8%) had a diagnosis of antisynthetase syndrome. At the time of infection IIM was in a remission in 12/13 patients and relapsed 5 weeks earlier in one patient. Seven patients were without immunomodulatory therapy, 1 patient was on steroids alone, 2 on DMARD alone, 3 on steroids and DMARD; a mean daily prednisolone equivalent dose was 5mg). Eleven/13 (84.6%) patients had mild COVID-19 (one had an asymptomatic infection) and were treated symptomatically, while 2 patients were hospitalized due to severe infection (respiratory insufficiency). Table 1 shows clinical characteristics and duration of COVID-19 symptoms. During pandemic overall 9/139 (6.5%) patients with IIM died, including one patient due to COVID-19.

**POS1195 CAN PRE-TREATMENT INFLAMMATORY BIOMARKER LEVELS GUIDE TO DETERMINE APPROPRIATE TIME OF TOCILIZUMAB THERAPY IN COVID-19**

D. Teker1, M. Çınar1, M. N. Kay1, F. Bicakci1, S. Colak1, E. Tekgoz2, S. Yılmaz1,2

1University of Health Sciences Turkey, Gülhane Training and Research Hospital, Rheumatology, Ankara, Turkey

DOI:

Disclosure of Interests: None declared

Background: Due to the pleiotropic cytokine interleukin-6 (IL-6) plays a pivotal role in the pathogenesis of COVID-19, tocilizumab, an inhibitor of the IL-6 receptor, was considered as an attractive therapeutic option. When the inflammation cascade is excessive and therapy is delayed, the efforts for suppression of inflammation does not necessarily reduce mortality in all cases. Besides, early using anti-cytokine therapy may lead to both increased cost and risks including iatrogenic immunosuppression (1). Defining of patients who will benefit from tocilizumab and determining optimal timing of tocilizumab will prevent drug-related side effects and increased costs due to unnecessary drug use.

Objectives: To investigate the reliability of pre-treatment levels of prognostic nutritional index (PNI), C-reactive protein/albumin ratio (CAR), systemic immune-inflammatory index (SII), IL-6, lactate dehydrogenase (LDH) as a treatment response biomarker in hospitalized COVID-19 patients who administered tocilizumab.

Methods: One hundred thirty three COVID-19 patients received tocilizumab were included. The end-points of treatment effectiveness were evaluated with the rate of death and emerging need for mechanical ventilation at 28 days of hospitalization. To determine independent mortality risk factors, multivariate logistic regression analyzes were performed for statistically different variables among groups that were statistically different in univariate analysis. The capacity of IL-6, CAR, PNI, SII and LDH values in predicting of tocilizumab response in COVID-19 patients were analyzed using receiver operating characteristic (ROC) curve analysis.

Results: 34 (25.56%) patients died after tocilizumab therapy. Patients who improved after tocilizumab were significantly younger and had significantly lower IL-6, LDH, SII, CAR and higher PNI than patients who died. In univariate analyses, mortality was significantly associated with age, IL-6, LDH, PNI, SII, CAR and CRP. In multivariate analysis, age (OR:1.070, 95%CI:1.019-1.124, p<0.007) and LDH (OR:1.006, 95%CI:1.003-1.010, p<0.001) were found to be independent predictors of mortality after tocilizumab therapy. To identify of tocilizumab response in COVID-19 patients, IL-6 had the highest area under curve (AUC=0.782, 95%CI:0.694-0.870), followed by LDH (AUC=0.761, 95%CI:0.661-0.861), PNI (AUC=0.696, 95%CI:0.584-0.807), SII (AUC=0.671, 95%CI:0.551-0.790), CAR (AUC=0.682, 95%CI:0.578-0.786) and CRP (AUC=0.643, 95%CI:0.535-0.751). Predictive performance of inflammatory biomarkers in the prediction of mortality after tocilizumab therapy was presented in Table 1.

Conclusion: Although the patients with significantly lower IL-6, LDH, SII, CAR and higher PNI levels improved after tocilizumab therapy, only serum LDH levels and age were found to be as independent predictors of mortality. To specify the optimal time interval and the patients who will benefit from tocilizumab, these biomarkers may be used.

REFERENCES:
in both groups. There were also no significant differences in the vaccine-related anxiety levels. However, the expectation of vaccine efficacy was higher in the acceptance group and significantly influenced vaccination intention as revealed by multivariate analyses (Table 1).

Conclusion: The perception of vaccine efficacy is strongly correlated with vaccine acceptance. In order to promote vaccination in patients with RMDs, this study suggests that emphasizing the efficacy of the vaccine may be more effective than alleviating anxiety about the adverse effects of the vaccine.

Figure 1.

Conclusion: Despite a widespread use of remote consultations during the pandemic, nationwide questionnaire surveys performed at three time-points during the COVID-19 pandemic showed that most patients were satisfied with access to rheumatic counseling. Nevertheless, in-person contacts were preferred by most patients, mainly women and elderly.

Background: Vaccine trials of the SARS-CoV-2 mRNA vaccines were encouraging but excluded most patients with rheumatic diseases (RD) and patients treated with immunosuppressive therapy. However, reports of a more severe COVID-19 disease course in patients with RDs prompted strategies for expediting vaccination of RD patients in most countries. In addition to the impact experienced by most people of the pandemic, patients with RDs were adversely impacted by the potential risk of severe COVID-19 due to their disease and immunosuppressive treatment. Fear of COVID-19 led to disproportionate anxiety, self-isolation, and shielding behavior for many RD patients at the beginning of the pandemic.

Objectives: We investigated antibody levels in serum against SARS-CoV-2 after a two-dose vaccination with an mRNA vaccine in patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Further, we examined the association between reactogenicity and immunogenicity and how vaccination influenced patient behavior concerning fear of COVID-19 and shielding.

Methods: Patients with SLE or RA from the COPANORD (Corona PANdemic Autoimmune Rheumatic Disease) cohort received two doses of an mRNA vaccine between January and August 2021 and had total antibodies against SARS-CoV-2 measured before vaccination and 2 and 9 weeks after the second vaccination. In addition, patients answered an electronic questionnaire before and eight weeks after vaccination concerning behavior, anxiety, and symptoms of depression (PHQ-9).

Results: Three-hundred-and-three patients and 44 blood donors (healthy controls) were included. Significantly fewer patients (90%) had measurable antibodies against SARS-CoV-2 compared to blood donors (100%) after the second vaccination (p<0.001) (Figure 1). Treatment with Rituximab was the strongest predictor of unfavorable vaccine response, as only 27% were seropositive after vaccination. We found a negative effect of prednisone and methotrexate but no effect of age, comorbidity, or pausing medication on seroconversion. Patients experienced significant improvement after vaccination in 10 out of 12 questions regarding behavior and fear of COVID-19. But no change was observed in symptoms of depression (p=0.62) or anxiety (p=0.46).

Conclusion: The majority of patients with SLE or RA had a measurable serological response to the COVID-19 mRNA vaccine after two doses. Treatment with Rituximab was the strongest predictor of no seroconversion. Our findings warrant encouragement of vaccination against COVID-19 for patients with RD, as most patients benefit with both a serological immune response and reduced isolation and shielding behavior.

POS1199 IS PSORIATIC ARTHRITIS A RISK FACTOR FOR SEVERE COVID-19 INFECTION? DATA FROM THE ARGENTINIAN REGISTRY SAR-COVID

Background: Comorbidities, particularly cardiometabolic disorders, are highly prevalent in patients with psoriatic arthritis (PsA) and they were associated with an increased risk of atherosclerotic cardiovascular disease, which have been associated with higher morbidity and mortality. Whether PsA enhances the risk of SARS-CoV-2 infection or affects the disease outcome remains to be ascertained.

Objectives: To describe the sociodemographic, clinical and treatment characteristics of patients with PsA with confirmed SARS-CoV-2 infection from the SAR-COVID registry and to identify the variables associated with poor COVID-19 outcomes, comparing them with those with rheumatoid arthritis (RA).

Methods: Cross-sectional observational study including patients ≥18 years old, with diagnosis of PsA (CASPAR criteria) and RA (ACR / EULAR 2010 criteria), who had confirmed SARS-CoV-2 infection (RT-PCR or serology) from the SAR-COVID registry. Recruitment period was between August 13, 2020 and July 31, 2021. Sociodemographic variables, comorbidities, and treatments were analyzed. To assess the severity of the infection, the ordinal scale of the National Institute of Allergy and Infectious Diseases (NIAID)1 was used, and it was considered that a patient met the primary outcome, if they presented criteria of categories 5 or higher on the severity scale. For this analysis, Chi2 test, Fisher’s test, Student’s test or Wilcoxon test, and binomial logistic regression using NIAID≥5 as dependent variable were performed.

Results: A total of 129 PsA patients and 808 with RA were included. Clinical characteristics are shown in Table 1. Regarding PsA treatment, 12.4% of PsA were receiving IL-17 inhibitors, 5.4% IL12-23 inhibitors, one patient apremilast and one abatacept. The frequency of NIAID≥5 was comparable between groups (PsA 19.5% vs RA 20.1%; p=0.976). (Figure 1).

Figure 1. Total antibody response against SARS-CoV-2 after two mRNA vaccines. Antibody response against mRNA COVID-19 vaccine pre-vaccination, 1 and 9 weeks after in patients with rheumatic diseases and 5-6 weeks after vaccination in blood donors. (A) Percentage with measurable SARS-CoV-2 antibodies results after vaccination. (B) Levels of SARS-CoV-2 antibodies in serum.
Psoriatic arthritis (PsA) and rheumatoid arthritis (RA) patients had a better outcome. Patients who received biological DMARDs (OR 0.28; 95% CI 0.09–0.78) had a lower risk of hospitalization compared to those who received conventional DMARDs (OR 1.06; 95% CI 1.02–1.11) was associated with a worse outcome of the COVID-19 infection.

**Conclusion:** Although PsA patients have a higher frequency of cardiovascular and metabolic comorbidities than those with RA, the COVID-19 severity was similar. Most of the patients had mild SARS-CoV-2 infection and a low death rate. These findings could be explained by the introduction of the glucocorticoids and immunosuppressive treatment and COVID 19 clinical characteristics, complications and outcomes: hospitalization, intensive care unit (ICU) admission, use of mechanical ventilation and death were compared among groups. Descriptive statistical analysis was performed. Variables were compared with Chi squared test and Student T test or Mann Whitney test. Multivariable logistic regression models with forward and backward selection method, using hospitalization, ICU admission and death as dependent variables were carried out.

**Results:** A total of 1777 patients were included, 1342 from the first wave and 435 of the second one. Patients had a mean (SD) age of 50.7 (14.2) years and 81% were female. Both groups of patients were similar in terms of socio-demographic features, disease diagnosis, disease activity, the use of glucocorticoids ≥ 10 mg/day and the immunosuppressive drugs (Table 1 below). Patients infected during the first wave have higher frequency of comorbidities (49% vs 41%; p < 0.004). Hospitalizations due to COVID 19 (31% vs 20%; p < 0.001) and ICU admissions (9% vs 5%; p = 0.009) were higher during the first wave. No differences in the use of mechanical ventilation (16% vs 16%; p = 0.97) nor in the mortality rate (5% vs 4%; p = 0.41) were observed. In the multivariable analysis, after adjusting for demographics, clinical features and immunosuppressive treatment, patients infected during the second wave were 40% less likely to be hospitalized (OR= 0.6, IC95% 0.4-0.8) and to be admitted to the ICU (OR= 0.6, IC95% 0.3-0.9).

**Conclusion:** The impact of COVID 19 in Argentina, in terms of mortality in patients with IMADs was still higher compared to the general population during the second wave. However, the frequency of hospitalizations and ICU admissions was lower. These findings could be explained by the introduction of the SARS CoV 2 vaccination and, probably, by the cumulative knowledge and management improvement of this infection among physicians.

Results: The incidence of AE was 1825 events/1000 doses, were significantly higher for mRAN-1273 and ChAdOx1 nCoV-19 and lower for BBIBP-CorV. Most common AE was pseudo-flu syndrome. Female sex, being younger, higher education level, ChAdOx1 nCoV-19 and mRAN-1273 vaccines, the use of methotrexate and antimalarials were related of EA in patients with RD.

References:

value was 100% (95% CI: 59%, 100%) for serologic response to the mRNA booster. Positive predictive value of time >6 months from last rituximab to the booster was 78.3% (95% CI 56.3%, 92.5%) and the negative predictive value was 62.5% (95% CI 24.5%, 91.5%).

Conclusion: Presence of detectable B-cells and longer time from last rituximab was associated with the development of SARS-CoV-2 spike protein antibodies following the booster vaccine. These factors should be considered in timing of administration of booster vaccine doses in previously unresponsive rituximab treated patients.

INCREASED PROTEASE-ACTIVATED RECEPTOR 1 AUTOANTIBOIES ARE ASSOCIATED WITH SEVERE COVID-19

F. Tran1, A. Scharmacher2, H. Grasshoff2, S. Schinke2, N. Kaeding3, J. Bernades1, J.Y. Humrich2, O. Cabral-Marques4, K. Gaede5, C. Lange5, J. Rupp6, P. Rosenstiel1, B. F. Hoyer3, K. Schulze-Forster7, H. Heidecke7, J. Y. Humrich2, O. Cabral-Marques4, K. Gaede5, C. Lange5, Principia, Hashomer, Ramat-Gan, Israel; 8Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer, Ramat-Gan, Israel

Background: In acute COVID-19 infection, growing evidence hints towards a broad activation of plasma cells and the presence of pathologic autoantibodies (abs). A systematic screenning for abs confirmed induction of diverse functional abs by SARS-CoV-2 infection. 1, 2. Immun-mediated thrombosis, involving platelet activation, has been identified as one of the key pathogenic mechanisms in COVID-19 and is linked to morbidity and mortality. 3. As natural abs against G protein-coupled receptors, functional abs against the thrombin receptor type-1 (PAR-1) might predispose for increased activation of the coagulation system present in COVID-19 infection.

Objectives: The aim of this study is to identify the diagnostic value of anti-PAR1 antibodies and their capacity to predict the outcome of COVID-19 infection.

Methods: 82 serum samples from 55 individuals with COVID-19 derived from three different hospitals in Schleswig-Holstein, Germany, and 88 single time point samples from healthy controls were subjected to ELISA-based quantification of anti-PAR-1 abs (CellTrend GmbH Luckenwalde, Germany). The levels of anti-AT1R abs were compared with clinical and laboratory parameters.

Results: COVID-19 patients revealed markedly increased levels of circulating anti-PAR1 abs in hospitalized patients particularly in those required intensive care treatment in comparison to controls (p < 0.0001, Figure 1a). Anti-PAR1 ab levels were highest in patients with fatal outcome (p = 0.006, Figure 1a). Receiver operating characteristic (ROC) analysis of PAR1 abs levels in COVID-19 patients revealed a sensitivity of 84.00% and a specificity 79.25% for patients requiring intensive care unit (ICU) treatment and a sensitivity of 87.50 % and a specificity 84.51 % to distinguish fatal vs. non-fatal disease outcome (Figure 1b). We found correlation of circulating anti-PAR1 abs with D dimers.

POS1204

SARS-COV-2 INFECTION AFTER VACCINATION IN PATIENTS WITH RHEUMATIC DISEASES FROM ARGENTINA

1CEMIC Centro de Educación Médica e Investigaciones Clínicas Norberto Quiro, Rheumatology Section, Buenos Aires, Argentina; 2On behalf of the ARGENTINA COVID-19 registry.

Background: Patients with rheumatic diseases (RD) have been excluded from SARS-CoV-2 vaccine trials. Though data appear to show safety and efficacy, mostly evidence remains in mRNA vaccines. However in our country, adenovirus and inactivated vaccines, as well as heterologous schemes are frequently used.

Objectives: To describe clinical characteristics and outcomes of SARS-CoV-2 infection after vaccination in patients with RD from the ARGENTINA COVID-19 registry.

Methods: Adult patients with RD who have been vaccinated for SARS-CoV-2 and have confirmed SARS-CoV-2 infection (RT-PCR o serology) were collected. The event was diagnosed at least 14 days after first dose and at complete scheme when it occurred > 14 days after second dose. Homologous scheme is defined by each dose of vaccine coming from the same manufacturer.

Results: 930 patients treated for SARS-CoV-2 infection were included. To compare SARS-CoV-2
infection characteristics in not vaccinated patients, subjects from the SAR-COVID registry, which includes patients with RD and SARS-COV-2 infection, were matched 2:1 by gender, age, and RD. WHO-Ordinal Scale was used to define unfavorable infection outcome. Descriptive statistics, Chi2 test, Fischer test, T test and ANOVA were used. Results: A total of 1350 patients from the SAR COVAC registry were included, 67 (5%) presented SARS-Cov-2 infection after vaccination. The later were mostly (72%) females with a mean age of 57 (SD 15) years old. The most frequent RD were rheumatoid arthritis (41%), psoriatic arthritis (12%) and systemic juvenile idiopathic arthritis (10%). At home (75%) had low disease activity or remission, 19% were taking steroids, 39% methotrexate, 27% bDMARDs and 6% JAK inhibitors. A total of 11 (16%) patients had SARS-CoV-2 infection <14 days after the first vaccine dose, 39 (58%) after an incomplete scheme and 17 (25%) following a complete one. In the incomplete scheme group, 59% received Gam-COV-Vac, 31% ChAdOx1 n-CoV-19 and 10% BBIBP-CoV; and in patients with complete scheme 47%, 24% and 29%, respectively. No event was reported after a complete heterologous scheme. No significant differences regarding sociodemographic characteristics, RD, disease treatment, type of vaccine and regimen was found between in those with infection and those without it. After vaccination only 8 (12%) of the patients who got infected had an unfavorable course, 88% of them following an incomplete scheme (5 received Gam-COV-Vac, 1 ChAdOx1 n-CoV-19 and 1 BBIBP-CoV) and one subject after a complete homologous Gam-COV-Vac scheme. Having an unfavorable outcome of SARS-Cov-2 infection was associated to: male gender [83% vs 24%, p=0.036], older age [mean 70 years (SD 7) vs 55 years (SD 15), p=0.005], being Caucasian [100% vs 54%, p=0.018], higher education [mean 17 years (SD 4) vs 12 years (SD 4), p=0.010], the presence of comorbidities [100% vs 39%, p=0.001, having pulmonary disease [37% vs 5%, p=0.019], dyslipidemia [63% vs 17%, p=0.011] and arterial hypertension [63% vs 24%, p=0.036], RD, treatments, disease activity and types of vaccines received were comparable between groups. When comparing patients with and without vaccination prior SARS-CoV-2 infection, those who received at least one dose of vaccine had less frequently severe COVID-19 (12% vs 24%, p=0.067) and presented lower mortality due to COVID-19 (3% vs 6%, p=0.498). However these differences did not reach statistical significance.

Conclusion: In the SAR-COVC registry 5% of the patients had SARS-CoV-2 infection after vaccination, most of them mild and 25% after a complete scheme. Any vaccine was associated with severe COVID-19. When comparing with non-vaccinated patients, those with at least one dose, had less frequently severe outcome and died due COVID-19.

Disclosure of Interests: None declared

POS1205 COVID-19 IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES - DATA FROM THE ROMANIAN REGISTRY OF RHEUMATIC DISEASES

D. Minca1, A. Minca2, C. E. Ionescu1, O. G. Dinache1, C. Popescu1, M. Agache1, L. Enache1, C. Mogosan1, C. Codreanu1. 1Center of Rheumatic Diseases, Rheumatology, Bucharest, Romania; 2University Emergency Hospital of Bucharest, Internal Medicine, Bucharest, Romania

Background: Registries are providing real-life, long-term data relevant to safety, efficacy and long-term outcomes in patients with various rheumatic diseases. The Romanian Registry of Rheumatic Diseases (RRBR) collects efficacy and safety data, for patients with inflammatory rheumatic conditions treated with biologies and targeted synthetic DMARDs in the country. Infections are the most frequently adverse events associated with biologics exposure.

Objectives: To analyze the distribution, severity class and outcome of infection with SARS-CoV-2 in inflammatory arthritis during the last 2 years of COVID-19 pandemic.

Methods: We collected data for the past 2 years (2020 and 2021) from the RRBR, for the three main inflammatory rheumatic diseases (Rheumatoid Arthritis - RA, Spondyloarthritis - SpA and Psoriatic Arthritis - PsA): treatment exposure (drug class) at the time of COVID-19 diagnosis, severity class (mild, moderate, severe), the disease outcome (recovered, disabled, death). Finally, we compared those data to reported numbers of COVID - 19 infections in the general population, aiming to observe if there is a significant difference between the two groups.

Results: The study included 9469 patients with inflammatory rheumatic disease, in 298 (3.14%) patients a history of COVID-19 infection was recorded. 160 (53.69%) were diagnosed with RA, 116 (36.92%) with SpA and 22 (7.28%) with PsA. At the moment of COVID-19 infection, 200 patients were receiving anti-TNF inhibitors (67.11%), 27 JAK inhibitors (9.06%), 24 tocilizumab (8.05%), 23 rituximab (7.71%), 9 anti-IL17A monoclonal antibodies (3.02%) and 4 abatacept. 12 (4.02%) deaths were recorded. The patients who died were on treatment with rituximab (5), tocilizumab (3), etanercept (2), secukinumab (1) and tocilizumab (1). Data from the National Public Health Institute showed a rate of COVID-19 infection in the general population of 9.36%, out of which 96.7% had a favorable outcome, while 3.26% deaths were reported.

Conclusion: This study confirms that patients receiving treatment with rituximab are at risk for a worse COVID-19 outcome. The increased number of severe cases and deaths related to COVID19 in patients receiving TNF inhibitors may be explained by the large use of this therapeutic option. Surprisingly, we noted 4 severe cases and one death related to COVID19, in patients treated with tocilizumab. We observed no significant differences in death rates and the outcomes of COVID-19 in patients with rheumatic diseases treated with biological therapies and the general population. The low rate of SARS-CoV-2 reported infections in the registry, compared to the general population, is most probably due to the commonly found underreporting of adverse events in registries.

References:

Disclosure of Interests: None declared

Conclusion: From the sample surveyed, it appears that high risk comorbidities, severity of RA at diagnosis and type of previous therapy are key differentiating points behind IL-6 usage in RA patients pre vs during the COVID-19 pandemic. With the increasing risk that RA patients may experience severe side effects if infected with COVID-19 and guidance to use IL-6 inhibitors in certain patient cohorts during this time, this may explain the patterns seen in our dataset. Further investigation using comparator cohort is warranted.

Figure 1. Humoral response rate after third COVID-19 vaccination sorted by baseline rituximab dose

Conclusion: Our study shows that a third COVID-19 vaccine can induce sufficient humoral response in a relevant proportion of (ultra-)low dose RTX treated RA patients who did not respond to the first two vaccinations, and that lower RTX dosing is associated with significant higher proportion of patients with sufficient humoral response. In contrast to the analysis after two vaccine doses, time since latest infusion was not significantly associated with response.

DISCLOSURE OF INTERESTS

No relevant disclosures.
All nineteen studies are cohort studies that followed individuals with AIRDs after COVID-19 vaccination. Two articles (11%) described differences in baseline risk for COVID-19 across age. All nineteen studies described participant age and sex, with race/ethnicity and multimorbidity described in four (21%).

### RESULTS:

Eight studies (42%) discussed at least one PROGRESS-Plus factor in interpreting the applicability of results, most commonly age (32%), then race/ethnicity and multimorbidity described in four (21%). Seven studies (37%) controlled for age and/or sex, with race/ethnicity and multimorbidity described in four (21%).

### Conclusion:

It is unknown whether COVID-19 vaccine studies on individuals with AIRDs are applicable to populations experiencing inequities, as key inequity factors beyond age and sex have little to no reporting or analysis. Future COVID-19 vaccine studies should report social characteristics of participants consistently, facilitating informed decisions about the applicability of study results to the population of interest.

for people with immune mediated inflammatory diseases (IMIDs) such as inflammatory arthritis (IA), systemic autoimmune rheumatic disease (SARD), inflammatory bowel disease (IBD) and multiple sclerosis (MS).

**Objectives:** In IMID patients treated with homologous or heterogeneous COVID vaccines, to compare post vaccine IMID disease activity and COVID antibody responses.

**Methods:** Between March 2021 and Dec 2021, patients with IA (n= 70; 77% rheumatoid arthritis), SARD (n=82; 70% lupus), IBD (n=92; 40% cohn’s), and MS (n=71; 77% RRMS) self-reported COVID illness and exposure risks, and disease activity prior to and 1 month post both COVID-19 vaccinations (V1 and V2). Disease activity was assessed by the Systemic Lupus Activity Questionnaire (SLAQ) for SARDs, the RAPID-3 and RA flare index for IA, the IBD Symptoms Inventory-short form (IBDI) and IBD flare index for IBD and the 25 meter walk and 9 hole peg test and Expanded Disability Status Scale (EDSS) for MS. Patient reported flare state was assessed using the relevant questions these indices (SLAQ “Have you had a flare?”; RA Flare index “Are you in a flare?”; IBD flare “My IBD is sometimes to continuously active”). Disease activity and serum anti-spike, anti-receptor binding domain (RBD) and anti-nucleocapsid (NC) IgG antibody titers at 30 days post V2 were compared across vaccine courses and to age-sex matched vaccinated blood donor controls (CNTS).

**Results:** Patients were predominantly female (79.7%), with a mean (standard deviation-sd) age of 56 (15) years; 8% had suspected or diagnosed COVID-19 illness; 12% positive anti-NC (Table 1). For all IMIDs, the majority received mRNA vaccines-BNT162b2 (BNT) or mRNA1273 (V1 74%; V2 97%). The rest received ChAdOx1 viral vector vaccines; 71% received homologous vaccines-BNT162b2 (BNT) or mRNA1273 (V1 74%; V2 97%). The majority reported COVID illness and exposure risks, and disease activity prior to and 1 month post both COVID-19 vaccinations (V1 and V2). Disease activity was assessed by the Systemic Lupus Activity Questionnaire (SLAQ) for SARDs, the RAPID-3 and RA flare index for IA, the IBD Symptoms Inventory-short form (IBDI) and IBD flare index for IBD and the 25 meter walk and 9 hole peg test and Expanded Disability Status Scale (EDSS) for MS.

**Flare status post V2 (%)**

**Seroconversion (%)**

**Conclusion:** Heterologous COVID vaccination improves seroconversion rates following a viral vector vaccine and does not lead to disease flare in most IMID patients. While data is needed to assess vaccine effectiveness, duration of immunogenicity and effects of subsequent vaccination, this work supports mixing COVID vaccines for IMID patients.

All data are N(%) of the column unless stated otherwise. Other RMD includes Sjögren’s syndrome, systemic sclerosis, undifferentiated connective tissue disease, non-monomorhic auto-inflammatory syndrome, chronic recurrent multifocal osteomyelitis, and other inflammatory arthritis. Other immunosuppressant includes ciclosporin, mycophenolate mofetil/mycophenolic acid.RMD, rheumatic and musculoskeletal disease; JIA, juvenile idiopathic arthritis; EULAR, European Alliance of Associations for Rheumatology; ANCA-associated vasculitis, antibody-associated vasculitis, cs-, conventional synthetic; b-, biological; ts-, targeted synthetic; DMARD, disease-modifying anti-rheumatic drug; COVAX, Coronavirus vaccine; AE, adverse event.

(CYP) with rheumatic and musculoskeletal diseases (RMDs). Current vaccination guidance is based on data from adults with RMDs or CYP without RMDs.

Objectives: To describe the characteristics and outcomes of adolescents with inflammatory RMDs and adults with juvenile idiopathic arthritis (JIA) vaccinated against SARS-CoV-2.

Methods: We described patient characteristics, flares, and adverse events in adolescent cases under 18 with inflammatory RMDs and adult cases aged 18 or above with JIA submitted to the European Alliance of Associations for Rheumatology (EULAR) COVAX registry.

Results: Thirty-six adolescent cases were reported from 4 countries, the most frequent diagnosis was JIA (42%). Over half (56%) reported early reactogenic-like adverse events (AEs) experienced within 7 days of vaccination. One mild polyarthralgia flare and one serious AE (malaise) were reported. No CYP reported SARS-CoV-2 infection post-vaccination. In addition to the adolescent cases, eleven countries reported 74 adult JIA cases. Among these, 62% reported early reactogenic-like AEs and two flares were reported (mild polyarthralgia and moderate uveitis). No serious AEs of special interest were reported among adults with JIA. Three 20-30 year old females were diagnosed with SARS-CoV-2 post-vaccination; all fully recovered.

Conclusion: In this observational registry dataset, SARS-CoV-2 vaccines appeared safe in adolescents with RMDs and adults with JIA, with a low frequency of disease flares, serious AEs, and SARS-CoV-2 re-infection seen in both populations.

Acknowledgements: We wish to thank all healthcare providers who entered data into the registry.

Conclusion: Inflammation of the microvascular system as an underestimated side effect of MRNA / Vector immunization should be taken into account if (boos- ter)-immunization decisions in patients with rheumatic diseases (maybe general) are to be made. Most patients with rheumatic diseases under (DMARD) therapy developed Covid-19 ABL (94.5%) (1) 5-6 months after MRNA / Vector immunization. All immunization decisions should also be made dependent on AbL. In case of breakthrough infection rates and hospitalization of immunized patients could be explained. Microvascular inflammation after MRNA / Vector immunization as a side effect in 37 % of rheumatological patients could cause medical problems later on. Therefore also for safety reasons MRNA / Vector (booster) immunizations should also depend on the amount of already existing humoral response reflected by ABL.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular.1426

Background: Mixed cryoglobulinemic vasculitis (MCV) is an immune-complex-mediated systemic vasculitis characterized by clinical manifestations mainly involving skin, kidney and peripheral nervous system. Despite reassuring safety data from EULAR Coronavirus Vaccine (COVAX) physician-reported registry, a significant proportion of patients with autoimmune diseases reported unwillingness to get vaccinated against SARS-CoV-2 infection in the preliminary results of the COVAD study, due to concerns about the lack of long-term safety data, and fear of associated side effects and disease flare.

Objectives: Aims of this multicentre Italian study were to investigate the prevalence of vaccination against SARS-CoV-2 in Italian population of MCV patients, to explore the reason for the missed vaccination, and to investigate short and long-term side effects of the vaccine.

Methods: All MCV patients referring to 12 Italian centres were investigated about vaccination and possible side effects (within 48 hours and long-term) and disease flare in the acute phase of their disease, in the first month after vaccination. MCV patients were divided in 2 groups: a) patients without long-term medication or after a period of at least 6 months of treatment and, b) patients under long-term treatment.

Results: A total of 416 patients, 69.2% females and 30.8% males, with a mean age of 70.4±11.7 years, were included in the study. Only 7.7% of patients were not vaccinated, mainly for fear of adverse events (50%) or for medical decision (18.8%). Comorbidities were the vaccine most frequently used (80.5%). Interestingly, 6 patients (1.44%) were with a heterologous vaccination (usually AstraZeneca-Corinny). Considering ongoing treatment, not vaccinated subjects were more frequently treated with chronic glucocorticoid therapy and/or rituximab (p=0.049 and p=0.043 respectively). AE were recorded in 3.7% of cases, mainly mild and self-limiting (grade 1). More severe adverse events, such as flare of vasculitis, were observed in 5.3% of cases. AE were not associated with the kind of vaccine used and with the clinical manifestations of vasculitis. Patients with active MCV showed a lower frequency of short-term (within 48 hours) adverse events, but patients affected by peripheral neuropathy or skin vasculitis frequently showed a flare of their symptoms, recorded in 40% and 25% of cases, respectively. Finally, patients under glucocorticoid treatment were more prone to develop a vasculitis flare within a month after vaccination.

Conclusion: Vaccination in MCV patients has been performed in a high percentage of patients showing a good safety. Other than patients’ fear, treatments with rituximab and glucocorticoids are the main reasons for delaying vaccination, and it should be considered by the physician before starting vaccination.

Vasculitis flares were observed in about 5% of cases, in line with that observed in other autoimmune diseases. Specific attention should be reserved to people with purpura or peripheral neuropathy, for the increased risk of exacerbation of their symptoms.

POS1215 IMMUNE CORRELATES AND CLINICAL COURSE OF PATIENTS WITH RHEUMATOID ARTHRITIS FOLLOWING VACCINATION WITH ANTI SARS-COV-2 mRNA BASED VACCINES: RESULTS FROM A PROSPECTIVE, OBSERVATIONAL AND CONTROLLED STUDY

K. Schmiedeberg1, I. A. Abel2, N. B. Pikor3, N. Vuilleumier4, M. Schwarzmueller5, S. Epp6, S. Pagano7, S. Grabher8, A. B. Patterson9, M. Nussberger10, A. Trkola11, B. Ludewig12, J. Von Kempis13, A. Rubbert-Roth14, 1Rheumatology Clinic, Kantonsspital St Gallen, St Gallen, Switzerland; 2Zürich, University of Zurich; Institute of Medical Virology, Zürich, Switzerland; 3St. Gallen, Institute of Immunobiology, St. Gallen, Switzerland; 4Geneva, Laboratory Medicine Division, Geneva, Switzerland

Background: Vaccines are highly effective in preventing COVID-19 associated hospitalization and deaths. Strong and persistent immune responses are critical to provide protection for patients with immunomodulatory therapies.

Objectives: To assess humoral and cellular immune responses following 2 doses of an anti-SARS-CoV-2 mRNA based vaccine in rheumatoid arthritis (RA). Immune responses in patients treated with csDMARDs, bDMARDs (with the exception of rituximab) and JAK inhibitors were compared to healthy controls (HC) over 24 weeks. In addition, disease activity by CDAI and vaccine-induced side effects were prospectively monitored.

Methods: The RECOVER trial (Rheumatoid Covid-19 Vaccine Immune Response) is a non-randomised, prospective observational control group trial and enrolled 77 RA patients on DMARD therapy and 21 HC. Clinical assessment and blood sampling was performed at baseline, 3 weeks after the 1st and 2 weeks after the 2nd vaccine dose and at week 12 and 24 after the 1st. Antibody response to the receptor binding domain (RBD) within the SARS-CoV-2 S1 protein was measured with the Elicys Anti-SARS-CoV-2-S (Roche Diagnostics GmbH) test. The seroprofiling assay ABCORA, which has been suggested as a surrogate for neutralization, was used to determine IgG, IgA and IgM responses to RBD, S1, S2 and N. The neutralizing activity NT50 at week 12 was assessed against Wuhan-Hu-1 pseudoviruses (HIV-based). IFN-γ ELISpot spots were applied to detect spike-reactive T cell responses after in vitro stimulation with a spike peptide mix.

Results: Baseline characteristics of participants are detailed in Table 1. Vaccination was well tolerated with no differences between RA patients and HC. At baseline, the majority of RA patients were in remission/LDA (57/77, 74%), this proportion decreased to 51% (39/77) after the second vaccine dose (p = 0.005). Treatment adjustments were required in 11/77 patients. The immunogenicity analyses were based on 73 RA patients after exclusion of 4 patients with previously unnoticed SARS-CoV-2 infection (positive for anti-nucleoprotein). In contrast to HC, anti-S titers were lower at all timepoints with significantly reduced titers observed in patients on abatacept and JAK inhibitors (Figure 1). Potent neutralizing activity (NT50 ≥ 250) was detected in all HC at week 12, in contrast to 62% RA patients. NT50 correlated to the results based on the ABCORA assay. Peak anti-S titers (2 weeks after 2nd vaccine) were predictive of NT50 ≥ 250 at week 12 (p < 0.0001).

Conclusion: RA patients, in comparison with HC, revealed a slower kinetic and lower magnitude of humoral immune responses depending on the treatment regimen while T cell responses were largely maintained. Peak anti-S responses two weeks after the second vaccine were able to predict the development of potent neutralizing activity and should therefore be considered to individually tailor vaccination strategies.

Background: A hyperinflammatory response compatible with features of macrophage activation syndrome (MAS) contributes to this worse outcome in patients with Coronavirus Disease 2019 (COVID-19). Glucocorticoids have become the standard of care for those requiring oxygen support or mechanical ventilation. More targeted anti-inflammatory treatments with tocilizumab and anakinra have also been shown to be effective.

Objectives: More studies are being awaited to clarify the features of patients who would benefit more, and we investigated the characteristics of the surviving and dead patients who received anakinra.

Methods: The records of hospitalized adult patients between March 2020 and May 2021 in a tertiary referral center were evaluated. Diagnosis of COVID-19-related MAS was based on the expert opinion and preliminary criteria developed by our group that patients with a score of ≥45 were accepted COVID-19-related MAS. Patients who received anakinra constituted the study group. Anakinra dose was determined according to the clinical and inflammatory parameters; and doses varied between daily 100-300 mg SC to 400-800 mg IV. Laboratory data of surviving and died patients were comparatively analyzed by using the ANCOVA method on the relevant days (baseline, anakinra-onset day, first response to anakinra treatment, and discharge or death). The temporal variation (drug onset day-first response day, drug onset day-discharge, or death day) was evaluated
Disclosed Interests: None declared

C. Grigaris3,7, T. H. Watts1, V. Chandran1,2, University Health Network, Schroeder Arthritis Institute, Toronto, Canada; University of Toronto, Division of Rheumatology, Department of Medicine, Toronto, Canada; Sinai Health System, Lunenfeld-Tanenbaum Research Institute, Toronto, Canada; University of Toronto, Department of Immunology, Toronto, Canada; Sinai Health System, Zane Cohen Centre for Digestive Diseases, Toronto, Canada; University of Toronto, Division of Gastroenterology, Toronto, Canada; University of Toronto, Department of Molecular Genetics, Toronto, Canada; University of Toronto, Division of Dermatology, Department of Medicine, Toronto, Canada; Women’s College Hospital, Department of Medicine, Toronto, Canada; University of Toronto, Department of Medicine, Toronto, Canada; Women’s College Hospital, Division of Dermatology, Toronto, Canada; University of Toronto, Division of Gastroenterology, Department of Medicine, Toronto, Canada.

Background: The impact of immunosuppressants on COVID-19 vaccination response and durability in patients with immune-mediated inflammatory diseases (IMID) is yet to be fully characterized. Humoral response may be attenuated in these patients especially those on B cell depleting therapy and higher doses of corticosteroids, but data regarding other immunosuppressants are scarce.

Objectives: We aimed to investigate antibody and T cell responses and durability to SARS-CoV-2 mRNA vaccines (BNT162b and/or mRNA 1273) in IMID patients undergoing immunomodulatory maintenance therapy other than B-cell depleting therapy and corticosteroids.

Methods: This prospective observational cohort study examined the immunogenicity of SARS-CoV-2 mRNA vaccines in adult patients with IMIDs (psoriatic arthritis, psoriasis, inflammatory bowel disease and rheumatoid arthritis) with or without maintenance immunosuppressive therapies (anti-TNF, methotrexate/azathioprine (MTX/aza), anti-TNF + MTX/aza, anti-IL12/23, anti-IL-17, anti-IL-21) compared to healthy controls. Automated ELISA for IgGs to spike trimer, spike receptor binding domain (RBD) and the nucleocapsid (NP) and T-cell release of 9 cytokines (IFNg, IL2, IL4, IL17A, TNF) and cytotoxic molecules (fFasL, GzmA, GzmB, Perforin) in cell culture supernatants following stimulation with spike or NP peptide arrays were conducted at 4 time points; T1=pre vaccination, T2=median 26 days after dose 1, T3=median 16 days after dose 2 and T4=median 106 days after dose 2. Neutralization assays against four SARS-CoV-2 variants (wild type, delta, beta and gamma) were conducted at T3.

Results: We followed 150 subjects: 26 healthy controls and 124 IMID patients: 9 untreated, 44 on anti-TNF, 16 on anti-TNF with MTX/aza, 10 on anti-IL2, 28 on anti-IL12/23, 9 on anti-IL17, 8 on MTX/aza (Table 1). Most patients mounted antibody and T cell responses with increases from dose 1 to dose 2 (100% seroconversion at T3) and some decline by T4, with variability within groups. Antibody levels and neutralization efficacy was lower in anti-TNF groups (anti-TNF, anti-TNF + MTX/aza) compared to controls and waned by T4 (Figure 1). T cell responses were not consistently different between groups. Pooled data showed a higher antibody response to mRNA-1273 compared to BNT162b.

Conclusion: Following 2 doses of mRNA vaccination there is 100% seroconversion in IMID patients on maintenance therapy. Antibody levels and neutralization efficacy in anti-TNF group are lower than controls, and wane substantially by 3 months after dose 2. These findings highlight the need for third dose in patients undergoing treatment with anti-TNF therapy and continued monitoring of immunity in these patients. Two cases taken into consideration newer variants and additional vaccine doses.

*multiple IMIDs per patient possible

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccination plays a crucial role as pivotal strategies to curb the coronavirus disease-19 (COVID-19) pandemic. Despite the mass-scale vaccination, literature data about the incidence of disease flares in IIM patients are still not reported as well as the immunological condition.

Objectives: The present study aimed to describe the clinical status of patients affected by IIM after vaccination against COVID19 in order to assess the number of relapses or immune-mediated reactions in a cohort of Italian patients with such disease.

Methods: We included all patients affected by IIM and followed by Myositis Clinic, Rheumatology and Respiratory Diseases Units, Siena University Hospital, Bari University Hospital, Policlinico Umberto I, Sapienza University, Rome, and Policlinico Paolo Giaccone, Palermo. Inclusion criteria were a recent (<3 months) clinical and serological assessment before the survey and a definite diagnosis of dermatomyositis, polymyositis and anti-synthetase syndrome. All patients underwent a telephone survey in order to establish their clinical status and potential relapses after vaccination.

Results: A total of 119 IIM patients (median, IQR 54 (47-66) years; 32 males) were consecutively enrolled. Fifty had a diagnosis of DM, 39 had PM and 30 had ASS. The median months of disease duration was 79.62±83.98. According to number of organs involvement, forty-two had one, 45 had two organs involvement, 20 had three, 11 had four and one had five. The majority of them received two doses of COVID-19 vaccine, except four patients who refused the vaccination: 94 (78.9%) Cominarty, 16 (13.4%) Moderna, 5 (0.04%) AZ. Seven (0.06%) patients had flare after vaccination, except one patient who had life-threatening with systemic involvement. In order to understand or predict the effect of demographic and clinical features on the flare development after vaccination, a logistic regression analysis was performed. The goodness-of-fit statistics showed a Chi² associated with the Log ratio (L.R.) of 0.045. From the probability associated with the Chi-square tests, the Type II analysis showed the variable that most influences the development of flare was the number of organs involved (p=0.047). Sixty-eight patients received the third dose of COVID-19 vaccination: 51 (75%) Cominarty and 17 (25%) Moderna. Only one (0.01%) patient (the same who had life-threatening flare with systemic involvement after two doses) had flare after third dose and eventually died.

Conclusion: Vaccines against SARS-CoV2 have provided, both in registratory studies and in preliminary real-life evidence, an overall good efficacy and safety. Nevertheless, only scanty data are available for rheumatic patients in general and the ones affected by IIM in particular. To the best of our knowledge, ours represent the largest cohort of IIM patients in which immunogenicity of anti-SARS-CoV2 vaccine was assessed. In line with real-life data from other diseases, we found a non-statistically significant risk of relapse in our patients, which occurred seldom, usually mild and in patients with a more severe and aggressive course of disease.

Disclosure of Interests: None declared

**Results:**

Despite the low sample size, our study is of interest since it proves that the inhibition of IL-1 with both anakinra or canakinumab and the employment of colchicine, an important inflammasome regulator, may curb the hyperinflammation typical of COVID-19. Given the promising results obtained with anti-IL-1 and colchicine in treating severe COVID-19, it is conceivable a "protective" role of these drugs in preventing a massive cytokine release. Unsurprisingly, none of our patients but one, had a severe course or fatal outcome after SARS-CoV-2 infection.

**Conclusion:**

Despite the small sample size, our study is of interest since it proves that the inhibition of IL-1 with both anakinra or canakinumab and the employment of colchicine, an important inflammasome regulator, may curb the hyperinflammation typical of COVID-19. Given the promising results obtained with anti-IL-1 and colchicine in treating severe COVID-19, it is conceivable a "protective" role of these drugs in preventing a massive cytokine release. Unsurprisingly, none of our patients but one, had a severe course or fatal outcome after SARS-CoV-2 infection.

**Disclosure of Interests:** None declared

Background: Patients with immune-mediated inflammatory diseases are inherently susceptible to infections and are at high risk of developing COVID-19. COVID-19 vaccination in patients with rheumatoid and musculoskeletal disease (RMD) is strongly recommended [1]. BNT162b2 is the most used COVID-19 vaccine in Japan. The safety and efficacy of this vaccine has been demonstrated in the general population [2], but patients receiving immunosuppressive therapy were excluded from the study. Although data on the immunogenicity of COVID-19 vaccine in the immunocompromised adult population is rapidly increasing, the immunogenicity of mRNA COVID-19 vaccine in RMD patients receiving medication has been reported in various and still inadequate ways. Furthermore, the immunogenicity of mRNA COVID-19 vaccine may vary depending on the medication. In addition, most of these data were reported from Western countries, and data on Japanese patients with RMD are limited.

Objectives: To investigate serum antibody titre against SARS-CoV-2 spike protein following BNT162b2 vaccination in Japanese RMD patients on various immunomodulatory treatment.

Methods: Two hundred and twelve RMD outpatients undergoing treatment at Kagawa University Hospital and 43 healthy volunteers, who had received two doses of BNT162b2, were included in the study. Serum sample was collected at least 14 days after the second dose. Antibody titer against SARS-CoV-2 spike protein in serum was measured by ELISA (Elecys Anti-SARS-CoV-2 S RUO). We analyzed the relationship between clinical characteristics, including the type of disease and treatment of RMD, and antibody titer against SARS-CoV-2 spike protein.

Results: The antibody titer against SARS-CoV-2 spike protein in RMD patients was significantly lower than that in healthy subjects. In the analysis with therapeutic agents, the mean antibody titer in RMD patients treated with rituximab (RTX) was much lower than that in healthy controls. Patients treated with baricitinib, azathioprine, mycophenolate mofetil, abatacept, TNF inhibitors, cyclosporine, IL-6 inhibitors, and methotrexate (MTX), or glucocorticoids (GC) had only moderately lower antibody titers. Patients treated with tacrolimus, an immunosuppressive drug commonly used for treatment in Japan, showed a slight decrease in antibody titer, but the difference was not significant compared with healthy subjects. IL-17 and IL-23 inhibitors did not impair the humoral response. In addition, the combination of MTX with various immunosuppressive agents reduced titers, although this was not statistically significant.

Conclusion: Many of the immunosuppressants impaired the immunogenicity to BNT162b2 in Japanese RMD patients. The degree of decline of antibody titers differed according to immunosuppressant. MTX potentially impairs the immunogenicity of BNT162b2 also in the case of concomitant use with other immunosuppressant.

Conclusion: We report increased risk for COVID-19 diagnosis and COVID-19-related death for people prescribed folic acid supplementation. The prescription and use of supplemental folic acid may confer risk of infection with the SARS-CoV-2 virus as well as the risk of death resulting from COVID-19. Our results also suggest that methotrexate might attenuate an increased risk for COVID-19 diagnosis and death conferred by folic acid.

FOLIC ACID AND METHOTREXATE USE AND THEIR ASSOCIATION WITH COVID-19 DIAGNOSIS AND MORTALITY: AN ANALYSIS FROM THE UK BIOBANK

R. Topless1, R. Green2, S. Morgan3, P. Robinson4, T. Merriman1,3, A. Gaffo3,5.
1University of Otago, Biochemistry, Dunedin, New Zealand; 2University of California, Davis, Medicine, Davis, United States of America; 3University of Alabama at Birmingham, Medicine, Birmingham, United States of America; 4The University of Queensland, Medicine, Saint Lucia, Australia; 5Birmingham VA Medical Center, Medicine, Birmingham, United States of America

Background: Folate metabolism is implicated in SARS-CoV-2 infectivity (Ref). Objectives: To determine if methotrexate (an antifolate) or folic acid prescription were associated with a lowered and increased risk, respectively, for COVID-19 diagnosis or mortality in a large population-based cohort (UK Biobank).

Methods: Data from 380,380 UK Biobank participants with general practice prescription data were used. Criteria for COVID-19 diagnosis were 1) a positive SARS-CoV-2 test and/or 2) ICD-10 code for confirmed COVID-19 (U07.1) or probable COVID-19 (U07.2) in hospital records, or death records. This definition identified 26,003 individuals diagnosed with COVID-19 of whom 820 were known to have died from COVID-19. Logistic regression statistical models were adjusted for age group (4 categories), sex, ethnicity, Townsend deprivation index, BMI, smoking status, presence of rheumatoid arthritis, sicker cell disease, use of anti-convulsants, statins and iron supplements.

Results: Compared with people prescribed neither folic acid nor methotrexate, people prescribed folic acid supplementation had increased risk of diagnosis of COVID-19 (OR 1.51 [1.42; 1.61]). The prescription of methotrexate with or without folic acid was not associated with COVID-19 diagnosis (P=0.18). Compared with people prescribed neither folic acid nor methotrexate, people prescribed folic acid supplementation had an increased risk of death after a diagnosis of COVID-19 (OR 2.64 [2.15; 3.24]) in a fully adjusted model. The prescription of methotrexate in combination with folic acid was not associated with an increased risk for death after a diagnosis of COVID-19 (1.07 [0.57; 1.96]).

Table 1. COVID-19 diagnosis and associated death in people prescribed methotrexate and/or folic acid in the UKBB, compared to people not prescribed methotrexate or folic acid. Model 1 adjusted for age group, sex, ethnicity, Townsend deprivation index, BMI, smoking status Model 2 is model 1 plus adjustment by the presence of rheumatoid arthritis, sicker cell disease, use of statins, anti-convulsants and iron supplementation.

POS1223

DIFFERENT ANTI-SARS-COV-2 VACCINE RESPONSE UNDER B- AND T-CELL TARGETED THERAPIES VERSUS ANTI-CYTOKINE THERAPIES IN PATIENTS WITH INFLAMMATORY ARTHRITIDES

R. Felten1, M. Geoffroy2, B. Loïs2, P. M. Duret3, M. Desmurs4, A. Fan5, A. Gaffo3,5.
1Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Centre National de Référence des Maladies Auto-immunes Systémiques Rares Est Sud-Ouest (RESO), Strasbourg, France; 2Hôpital Maison Blanche, Centre Hospitalier Universitaire de Reims, Service de Rhumatologie, Reims, France; 3Hôpices Civils de Colmar, Hôpital Pasteur, Service Rhumatologie, COLMAR, France; 4Hôpital Emile MULLER de Mulhouse, Service de Rhumatologie, Mulhouse, France; 5Hôpitaux Universitaires de Clermont-Ferrand, Service de Rhumatologie, Clermont-Ferrand, France

Background: Vaccination against SARS-CoV-2 is effective in preventing severe forms of COVID-19, but there remain concerns about a reduced vaccine response in patients suffering from inflammatory arthritides who are treated by immunosuppressive therapies.

Objectives: We analysed the impact of bDMARDs on the humoral anti-SARS-CoV-2 vaccine response in patients followed in day hospitals.

Methods: We studied the vaccine response after a complete vaccine regimen followed in day hospital in 5 French hospitals and treated with an intravenous bDMARD between September 2019 and August 2021. After obtaining their informed consent, we included patients with an anti-SARS-CoV-2 serology. They were considered non-responders if the antibody level detected was inferior to the threshold of positivity of the kit used.

Results: 295 patients were included (148 females/57 males). The median age was 64 years (Interquartile Range [IQR] 56-71), 25 were treated with tocilizumab (TCZ), 36 with abatacept (ABA), 53 with infliximab (IFX) and 91 with rituximab (RTX). When considering both patients after a complete vaccination schema (2 doses,
or 1 dose in case of prior COVID-19) and those with 1 booster dose, 34 patients
(16.6%) were non-responders (2 [5.9%] treated by IFX, none treated by TCZ, 9 [26.3%] treated by ABA and 23 [67.7%] treated by RTX). In multivariate analysis, the
only characteristics that significantly and independently differed between respond-
ers and non-responders were last bDMARD and corticosteroid therapy at the time of
1st vaccination (Table 1). In RTX-treated patients, the delay from last infusion to 1st
vaccine dose was significantly shorter in non-responders (median 4.3 IQR [2.9-
6.1] months in non-responders versus 8.4 IQR [5.7-14.5] in responders, p=0.0007).
Median survival, i.e. achieving a vaccine response in 50% of RTX-treated subjects,
was achieved after 277 days (IQR [209-310]) in patients vaccinated with 2 or 3
doses (Figure 1). In ABA-treated patients, the delay from last infusion to 1st vaccine
dose was not different between non-responders and responders.

Figure 1. Cumulative seropositive rate according to the interval (days) between the last
course of rituximab administration and vaccination

Conclusion: ABA and RTX alter the anti-SARS-CoV-2 vaccine response and
were associated with nearly all vaccine non-responses in the present study.
Corticosteroid therapy was associated with a lower vaccine response regardless of its
date or indication or the concomitant use of DMARD.

Disclosure of Interests: None declared.
Background: Throughout the COVID-19 pandemic, the BNT162b2 (manufactured by Pfizer—BioNTech) and mRNA-1273 (manufactured by Moderna Inc) vaccines have demonstrated an acceptable safety profile and a high degree of effectiveness in preventing severe COVID-19 outcomes in healthy individuals. However, it remains to be determined if similar benefits can be replicated in immunocompromised patients, who were largely excluded from Phase III clinical trials. Preliminary data on vaccine immunogenicity among lupus patients reveal blunted humoral responses, particularly in those using prednisone and/or mycophenolate (1-2).

Objectives: This study sought to measure the antibody responses following SARS-CoV-2 vaccination in patients with SLE and to identify clinical and laboratory parameters associated with low antibody responses.

Methods: We prospectively enrolled SLE patients from the Beth Israel Deaconess Medical Center Systemic Lupus Erythematosus Cohort (BI-DLC). The patients received two doses of either BNT162b2 or mRNA-1273 and were tested for the SARS-CoV-2 IgG spike antibody at least 4 weeks after the second vaccine dose. Patients with evidence of prior COVID-19 infection were excluded. The primary goal of this study was to measure the prevalence of a weak IgG spike antibody response and identify predictive clinical-laboratory factors. We first measured the antibody responses in a healthy control group and defined a low antibody titer as values that fell below the 25th percentile of this reference group (<6). We then used simple logistic regression to assess for associations between different predictive variables and our predefined dichotomous outcome: <6 vs ≥6 IgG spike antibody titer. To account for potential cofounders, a multiple logistic regression model was performed. Risk ratios were calculated with the Odds ratios, OR, adjusted for gender, age, and ACE-42.

Results: A total of 71 patients were included in the study. At the time of vaccination, patients were on various immunomodulator and suppressive medications, including: Hydroxychloroquine 87%, Prednisone 38%, Mycophenolate 38%, Azathioprine 18% and Belimumab 7%. The proportion of patients who received BNT162b2 and mRNA-1273 was 58% and 42%, respectively. Overall, 63% of patients had a high IgG spike antibody titer (≥ 6) and 37% of patients had a low antibody titer. More importantly, we demonstrated that a pre-vaccine high SLEDAI score or receiving BNT162b2 (Pfizer—BioNTech) increases the risk of impaired immune response to the COVID-19 vaccine. In patients with SLE, Azathioprine use independently predicts reduced antibody titers. More importantly, we demonstrated that a pre-vaccine high disease activity score or receiving BNT162b2 increases the risk of impaired immune response to the COVID-19 vaccine.

Conclusion: In patients with SLE, Azathioprine use independently predicts lower antibody titers. More importantly, we demonstrated that a pre-vaccine high disease activity score or receiving BNT162b2 increases the risk of impaired immune response to the COVID-19 vaccine.

Background: Patients with inflammatory rheumatic diseases (IRD) have used self-isolation and social distancing during the pandemic to avoid SARS-CoV-19 infection (reference). In countries with unlimited and free access to SARS-CoV-19 testing, anxiety or other patient related factors might potentially increase test-frequency.

Objectives: In patients with IRD followed in the nationwide DANBIO registry we aimed to explore clinical factors including self-isolation associated with a) positive SARS-CoV-19 test result (‘infection’), b) higher frequency of SARS-CoV-19 testing during the first 1½ year of the pandemic.

Methods: In May-June 2020, IRD patients followed in the quality registry, DAN- BIO (n=36,152), were invited to participate in the voluntary online questionnaire survey “You and your rheumatic disease during times with corona-virus: Patient characteristics, treatment and patient reported outcomes were captured in DAN-BIO and from the questionnaire. Patients were considered as self-isolating if they agreed to the question: I stay at home and avoid others as much as possible. After written consent, information on dates and SARS-CoV-19 test results (by PCR, polymerase chain reaction) during follow-up (until Nov 2021 and thus before entry of the Omicron variant) was obtained through linkage to the nationwide laboratory system. Time to first positive PCR and associated characteristics were explored by multivariable Cox regression analyses with hazard ratios, HR, adjusted for: gender/ age-group/ diagnosis/biologic therapy/working/ self-isolation/HAQ/EQ-5D. Day 0 was defined as the date of first positive test in cohort (May-07 -2020).

Results: In 10,098 included patients, 2.8% were infected during follow-up (Table 1). Age and HAQ seemed lower in infected (Table 1, Figure 1). In multivariable Cox
regression analyses, male gender was associated with higher infection risk (HR 1.38 (1.05;1.80) whereas risk was lower in the age-group 61-80 years (0.60 (0.39;0.92) vs. below 40 years). Other factors were statistically insignificant.

**POS1227 TIME BETWEEN SECOND AND THIRD DOSES INFLUENCES RESPONSE TO COVID-19 VACCINE IN AUTO-IMMUNE DISEASE PATIENTS TREATED WITH RITUXIMAB WITHOUT RESPONSE TO TWO DOSES.**

- 1Hôpital Bichat, Assistance Publique-Hôpitaux de Paris, HU CAR, Université Paris-Saclay, INSERM U1198, Rheumatology Department, Le Kremlin Bicêtre, France.
- 2Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Université de Paris, Rheumatology Department, Paris, France.
- 3Université Paris Saclay, INSERM U1193, AP-Hôp Paul Brousse, Virology, Villejuif, France.

**Background:** It is now well established that patients treated with rituximab (RTX) for auto-immune disease (AID) have a diminished antibody response to COVID-19 vaccines after two doses. Optimizing antibody response is a key objective in this population. To achieve this goal, a 3rd booster dose may be considered.

**Objectives:** Focusing on the population of AID patients treated with RTX without any antibody response after two doses we sought to explore how these patients could respond to a 3rd dose and identify factors of response.

**Methods:** We performed a French retrospective bicentric observational trial which is a follow-up of previously published work (1). We included consecutive patients treated with RTX that were non-responders regarding their anti-Spike antibody (anti-S) status at least one month after the second dose of COVID-19 vaccination. Patients were included between March and October 2021. All patients then received a third dose according to local guidelines and had an anti-S measurement at least one month after the third dose. Some patients without response to a third dose had a fourth dose. Anti-S were measured in serum with various kits, but all results were in BAU/mL with upper quantification limit at 243. Patients with anti-S above 49 BAU/mL, which has been demonstrated to be the threshold associated with detectable neutralizing response were considered as responders (1).

**Results:** 60 patients treated with RTX without response to 2 doses (Anti-S Ab < 49 BAU/mL) were included in the study. 9/60 (15%) patients responded to the 3rd vaccine dose with anti-S > 49 BAU/mL. Responders and non-responders had similar demographic characteristics (Table 1). There was a positive correlation between anti-S Ab levels after dose 2 and time and 3rd doses (r=0.41 p=0.001) (Figure 1). Nevertheless, the median time between 2nd and 3rd doses was numerically but not significantly higher in responders than in non-responders (129 vs 80 days, p=0.30). There was no correlation between anti-S levels after the third dose and the time between the last RTX infusion and the third vaccine dose. There was a trend towards more patients with methotrexate co-medication according to their seroconversion status after the third dose.

**Conclusion:** Few patients with IRD were infected during the first 1½ years of the pandemic. Gender and age were associated with infection risk and frequency of testing. Self-isolation and a range of other clinical characteristics had no impact, which to some extent may be due to behavioral differences across age-groups.

**REFERENCES:**

**Table 1.** Time to positive SARS-CoV-19 test, by age-group.
Conclusion: A third vaccine dose of COVID-19 vaccine leads to only 15% of response in previously non-responding RTX treated AID patients. A longer time between 2nd and 3rd doses might positively influences response to a 3rd COVID-19 vaccine. Finally exploratory findings show that a fourth dose could be useful to obtain response non-responders.

</table>

After May 2020, reflected in the positive prescription trend observed in ITSA models (Table 1); however, RTX prescriptions remained below pre-pandemic levels, before decreasing again between November 2020 and February 2021. This coincided with increasing COVID-19 case numbers in England.

Figure 1. Temporal trends in prescriptions for ADA, RTX and TOC in England between January 2019 and November 2021. Monthly averages of prescriptions for combined disease indications are shown, standardised using WHO Defined Daily Doses.

For ADA, the pre-pandemic trend of increasing prescriptions continued during the pandemic, with no differences in prescription trends seen in ITSA models (Table 1). A 22% decrease in ADA prescriptions was observed between September and October 2020, from 2,037,800 DDD to 1,587,500 DDD, respectively, before rebounding to above pre-pandemic levels. Prescriptions for TOC increased during the pandemic, driven primarily by a 76% increase in prescriptions between December 2020 and January 2021, from 241,800 DDD to 425,000 DDD, respectively.

Conclusion: Prescriptions for RTX in England halved during the early COVID-19 pandemic, and remain below pre-pandemic levels as of November 2021. This likely reflects concerns about RTX use and increased COVID-19 mortality and reduced vaccine efficacy.1-3 In contrast, prescriptions for ADA have continued to increase during the pandemic, while prescriptions for TOC surged in December 2020, coinciding with the more widespread use of TOC for the treatment of severe COVID-19.

POS1229 THE IMPACT OF COVID-19 ON MEDICATION NON-ADHERENCE IN A RHEUMATOID AND PSORIATIC ARTHRITIS UK COHORT

P. Curry1, H. Chinyo2, M. Jami3, D. Plant1,2, K. Hyrich3,4, A. Morgan4, A. G. Wilson1, J. Isaacs1, A. Morris1,2, A. Barton1,2, J. Bluu1,2, 1The University of Manchester, Versus Arthritis Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester, United Kingdom; 2Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; 3The University of Manchester Versus Arthritis Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester, United Kingdom; 4Leeds Teaching Hospitals NHS Trust, School of Medicine, University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; 5University College Dublin, School of Medicine & Medical Science, Conway Institute, Dublin, Ireland; 6Newcastle upon Tyne Hospitals NHS Foundation Trust, Translational and Clinical Research Institute, Newcastle University and Musculoskeletal Directorate, Newcastle upon Tyne, United Kingdom

Background: In March 2020, as part of the UK’s COVID-19 prevention strategy, those identified as ‘clinically extremely vulnerable’, were advised to shield. This included a number of patients prescribed anti-rheumatic drugs, who were asked to continue their current treatment unless they developed symptoms of infection. Suboptimal treatment adherence (16.0%-81.0%) has been reported in patients with arthritic diseases, and is associated with psychological factors, including anxiety (1). Previous literature in...
non-UK cohorts has highlighted suboptimal adherence levels in immunosuppressed patients during the pandemic, although many were single centre studies (2,3).

**Objectives:** The aim of this multi-centre study is to investigate the impact of the COVID-19 pandemic on adherence to anti-rheumatic medications in patients with established rheumatoid (RA) and psoriatic (PsA) arthritis in the UK who had recently commenced a biologic or targeted synthetic DMARD.

**Methods:** Between September 2020 and May 2021, RA and PsA patients prescribed biologic or targeted synthetic anti-rheumatic drugs from two multi-centre observational studies (BRAGGSS and OUTPASS) were sent a questionnaire on medication usage, adherence, and perceptions to establish the impact of COVID-19 on these parameters. Patients were asked about compliance during the COVID-19 pandemic using a 5-point Likert scale (always, often, sometimes, rarely, and never) and the reason for non-adherence. Adherence was defined as never missing or delaying a dose, unless medically advised. Descriptive summary statistics were calculated, and logistic regression and Pearson’s chi-squared tests were employed to investigate variables associated with self-reported non-adherence.

**Results:** In total 159 questionnaires were returned (81.1% RA and 18.9% PsA). Methotrexate (53.5%) was the most frequently prescribed agent, followed by etanercept (25.2%), salsalazine (22.6%), hydroxychloroquine (21.4%) and adalimumab (19.5%). Furthermore, 66.8% of patients were prescribed ≥2 drugs. During the pandemic, 42.1% of patients reported missing or delaying a treatment dose for any reason. Adherence information was available for 97.5% of patients with 25.8% reporting non-adherence which was not medically advised. Methotrexate non-adherence was 27.1%, with similar levels reported for etanercept (20.0%), salsalazine (27.8%), hydroxychloroquine (35.3%) and adalimumab (29.0%). No drugs had significantly different adherence compared to methotrexate. Furthermore, there was no association between disease type or perception of disease control and adherence. Of non-adherent patients, 17.5% reported increased anxiety, fear, and increased risk due to the COVID-19 pandemic as an influencing factor. Meanwhile, 37.5% of non-adherent patients listed non-COVID-19 intentional reasons and 45.0% reported non-intentional reasons, with forgetting and running out of treatment listed most frequently.

**Conclusion:** In a UK cohort self-reported non-adherence was reported in 25.8% of patients during the COVID-19 pandemic, despite medical advice, with reasons including increased anxiety due to COVID-19.

**POS1230 INCREASED ANTIBODY RESPONSE AFTER SARS-COV-2 mRNA-BASED VACCINATION IN RITUXIMAB-TREATED PATIENTS WITH PREVIOUS COVID-19 INFECTION**

J. Avouac1, R. Ghossan2, O. Al Tabaa1, A. Combier1, A. Steelandt1, M. Thomas1, O. Fogel1, A. A. Mariaggi2, J. F. Meritet2, F. Rozenberg2, A. Molto1, C. Miceli Richard1, Y. Allarone1, 1Cochin Hospital, Rheumatology, Paris, France; 2Cochin Hospital, Virology, Paris, France

**Background:** Rituximab (RTX) is associated with reduced humoral response to SARS-CoV-2 mRNA-based vaccine (1, 2). A recent study has shown that, despite their immunosuppression burden, kidney transplant recipients with previous exposure to SARS-CoV-2 showed a marked increase in antibody titer, even after a single dose of vaccine (3).

**Objectives:** To describe the results of immunization after 1 to 3 doses of mRNA SARS-CoV-2 vaccine in RTX-treated patients with previous symptomatic COVID-19 infection.

**Methods:** Observational prospective usual care study including consecutive patients with inflammatory rheumatic diseases in maintenance therapy with RTX.
**POSI231**

**PREDICTORS OF MORTALITY IN SEVERE AND CRITICALLY COVID-19 PATIENTS WHO RECEIVED ANAKIRNA**

M. Bekta1, M. I. Kılıç1, 1Aksaray Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Aksaray, Turkey

**Background:** Several predictive factors were described in COVID-19 during the pandemic, however there is limited data in severe/critically ill patients (pts) with COVID-19 who received biologic therapies including anakinra.

**Objectives:** We aimed to evaluate the predictive factors of mortality in pts with severe and critically ill COVID-19 who received anakinra.

**Methods:** Diagnosis of COVID-19 was confirmed by PCR and/or typical CT findings. Severe and critically ill pts according to NIH severity scale who received anakinra in the ward were evaluated retrospectively (1). Laboratory values at admission, highest levels and the last day of hospitalization were recorded. COVID hyperinflammatory syndrome score (cHIS) was calculated according to the highest levels of laboratory results (2). All pts received background steroid therapy with 80 mg methylprednisolone (or its equivalent). Anakinra was started in pts who did not respond to steroid therapy at least two days or concomitantly with steroids in pts with higher risk and/or critical illness at admission. Average starting dose of anakinra was 600 mg/day intravenously and increased gradually to 1600 mg/day if necessary.

**Results:** Data of 148 pts (53 % male) were analyzed. Of those 57 pts (38.5 %) severe, 91 pts (61.5 %) had critical disease. Overall, 56 pts (37.8 %) died during the follow-up and intensive care unit admission was in 60 pts (40.5 %) and intubation in 54 pts (54.5 %). Diabetes mellitus was in 28 %, hypertension in 59 %, coronary heart disease in 19 %, heart failure in 12.6 %, chronic kidney failure in 21 %, chronic obstructive pulmonary disease in 16 %, dementia in 12.8 %, malig-nancy in 11 % and rheumatic disease in 5.6 % of pts. Only dementia significantly differed between pts with mortality and had not (p<0.005 OR:9.8).

In univariable analysis; patient age, neutrophil to lymphocyte ratio (NLR), mean cHIS scores were higher in pts who had mortality. Baseline maximum and last values of CRP, LDH, ferritin, D-dimer levels were observed in pts had mortality. Mortality was also higher in pts with critically ill compared to severe disease. In multivariable analysis; higher age (p<0.001 OR:1.01-1.09), cHIS score (p=0.002 OR:2.6 CI:1.4-4.9), critical illness compared to severe disease (p=0.02 OR:14 CI:1.6-122) were associated with mortality.

**Conclusion:** In our study mortality was developed in third of anakinra receiving pts. Mortality was independently associated with advanced age, chronic critical illness and higher cHIS score reflecting higher inflammatory burden. Furthermore, high-est levels of CRP, LDH, ferritin, D-dimer and higher cHIS score predict higher mortality in pts receiving anakinra. It is important to identify the pts with higher mortality risk to improve outcome.

**Background:** Since the COVID-19 vaccination campaign was launched all over Europe, there has been general agreement on how benefits of SARS-CoV vaccines outweigh the risks in patients with rare connective tissue diseases (rCTDs). Yet, there is still limited evidence regarding safety and efficacy of such vaccines in these patients, especially in the long-term. For this reason, in the framework of ERN-RECONNET, an observational long-term study (VACCINATE) was designed in order to explore the long-term outcome of COVID-19 vaccination in rCTD patients. The consent form was developed thanks to the involvement of the ERN-RECONNET ePAG Advocates (European Patients Advocacy Group).

**Objectives:** To evaluate the safety profile of COVID-19 vaccination in rCTD patients and the potential impact on disease activity. Primary endpoints were the prevalence of adverse events (AEs) and of disease exacerbations post-vaccination. Secondary endpoints were the proportion of serious adverse events (SAEs)

Methods: The first and interim analysis of the VACCINATE study involved 9 ERN-ReCONNET Network centres. Patients over 18 years of age with a known rCTD and who received vaccine against COVID-19 were eligible for recruitment. Demographic data and diagnoses were collected at the time of enrolment, while the appearance of AEs and potential disease exacerbations were monitored after one week from each vaccination dose, and then after 4, 12 and 24 weeks from the second dose. A disease exacerbation was defined as at least one of the following: new manifestations attributable to disease activity, hospitalization, increase in PGA from previous evaluation, addition of corticosteroids or immunosuppressants.

Results: A cohort of 300 patients (261 females, mean age 52, range 18-85) was recruited. Systemic lupus erythematosus (44%) and systemic sclerosis (16%) were the most frequent diagnoses, followed by Sjogren’s syndrome (SS,12%), idiopathic inflammatory myositis (IM,10%), undifferentiated connective tissue disease (UCTD,8%), mixed connective tissue disease (MCTD,4%), Ehlers-Danlos’s syndrome (EDS,4%), antiphospholipid syndrome (APS,2%). AEs appearing 7 days after the first and second doses were reported in 93 (31%) and 96 (32%) patients respectively, mainly represented by fatigue, injection site reaction, headache, fever and myalgia. Otitis, urticaria, Herpes Simplex-related rash, stomatitis, migraine with aura, vertigo, tinnitus and sleepiness were reported with very low frequency. Less than 2% of patients experienced AEs within 24 weeks from the second dose. No SAEs or AEs of special interest were observed in the study period. There were 25 disease exacerbations (8%), 7 of which severe. The highest number of exacerbations was observed after 4 weeks from the second dose (12 within week 4, 8 within week 12 and 7 within week 24). Disease exacerbation was most frequent in patients with EDS (33%) and MCTD (25%).

Conclusion: This preliminary analysis shows that COVID-19 vaccination is safe in rCTDs patients. AEs appear most often early after vaccination and are usually mild. Disease exacerbations are not frequent, but can be potentially severe and tend to occur most frequently within the first month after vaccination. Exacerbations can also occur 3-6 months after vaccination, although a causal relationship with the vaccination remains to be established. Our present data underline the importance of long-term observational studies.

POS1233 DIFFICULTIES AND MENTAL IMPACT OF THE SARS-COV-2 PANDEMIC IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A NATIONWIDE PATIENT ASSOCIATION STUDY

M. Scherlinder1, N. Zein2, J. E. Gottenberg1, M. Riviere1, J. F. Kleinmann1, J. Sibilla1, L. Arnaud1, Strasbourg University Hospital, Rheumatology Department, Strasbourg, France; 2Association France Lupus et autres maladies auto-immunes, AFL+, Metz, France

Background: The COVID-19 pandemic has taken a toll on the mental health of the general population. Patients with systemic lupus erythematosus (SLE) were particularly exposed due to many uncertainties linked to the virus and their immunosuppression as well as difficulties to access medical care and their treatment (eg. home isolation, delay in Biologic initiation) during the coronavirus pandemic.

Objectives: To evaluate the difficulties encountered by SLE patients during the early COVID-19 pandemic, and evaluate their impact on patient mental health.

Methods: We conducted a Nationwide survey including SLE patients from France metropolitan and overseas territories, recruited by their treating specialist or through a patient association (AFL+). The survey was administered online or in paper form between November 2020 and April 2021, and included questions aiming at evaluating the difficulties encountered during the early COVID-19 pandemic (March to August 2020). The impact on mental health was evaluated using Hospital Anxiety and Depression scale (HADS) and post-traumatic stress disorder (PTSD) Checklist for DSM-5 (PCL-5).

Results: 536 SLE patients (91.9% of women) of mean age 50 (±14.1) years responded to the survey. The main reported difficulties were issues to access medical care (n = 136, 25.4%) or to obtain hydroxychloroquine treatment (n = 98/389, 25.2%), the loss of employment (n = 85/349, 24.4%) and financial difficulties (n = 75/536, 11%). Hydroxychloroquine shortage was responsible for difficulties in obtaining the drug for 25.2% (89/389) of HCC-treated patients, and 57 had to interrupt HCC treatment for a median of 7 days (IQR: 3-17). In the 342 patients with complete assessment, 161 (47.2%) screened positive for anxiety, 141 (41.2%) for depressive syndrome and 128 (38.7%) for PTSD. Multivariate analysis showed that female sex (OR=4.29 [95%CI: 1.39-13.24]), financial issues (OR=2.57 [127.5-22]), difficulties to access medical care (OR=2.15 [1.26-3.69]), or to obtain hydroxychloroquine treatment (OR=1.90 [1.06-3.40]) were independently associated with a positive screening for PTSD.

Conclusion: The COVID-19 pandemic resulted in a severe burden in SLE patients, including difficulties in access to care and treatment along with high psychological distress. Better understanding these difficulties will allow better prevention and care in times of crisis.

POS1234 DMARD DISRUPTION, INCREASED DISEASE ACTIVITY, AND PROLONGED SYMPTOM DURATION AFTER ACUTE COVID-19 AMONG PATIENTS WITH RHEUMATIC DISEASE: A PROSPECTIVE STUDY

M. Di Iorio1, C. Cook2, K. Vanni3, N. Patel2, K. Dsilva2, X. Pu2, J. Wang3, L. Prisco4, E. Kowalski5, A. Zaccarello6, L. Martin7, G. Qian8, T. Hsu8, Z. Wallace9, J. Sparks1,2,4, Brigham and Women's Hospital, Department of Medicine, Boston, United States of America; 2Harvard Medical School, Harvard Medical School, Boston, United States of America; 3Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America; 4Brigham and Women's Hospital, Division of Rheumatology, Immunology, and Immunity, Boston, United States of America; 5Mongan Institute, Clinical Epidemiology Program, Boston, United States of America

Background: Systemic autoimmune rheumatic disease (SARD) patients may be at risk for flare and prolonged symptom duration after COVID-19, perhaps related to DMARD disruption and immune activation.

Objectives: To describe DMARD disruption and identify differences in SARD activity among patients with and without prolonged COVID-19 symptom duration.

Methods: We identified all SARD patients with confirmed COVID-19 at the Mass General Brigham Healthcare System in Boston, USA; prospective recruitment is ongoing. Surveys were used to collect demographics, clinical characteristics, DMARD disruption, COVID-19 course, and SARD disease activity before and after COVID-19. The survey included validated instruments measuring disease activity, pain, fatigue, functional status, and respiratory quality of life. Prolonged symptom duration was defined as COVID-19 symptoms lasting ≥28 days. We compared differences in patient-reported measures between those with and without prolonged symptoms.
Results: We analyzed survey responses from 174 COVID-19 survivors with SARDs (mean age 52±16 years, 81% female, 80% White). The most common SARDs were RA (40%) and SLE (14%). Fifty-one percent of the 127 respondents on any DMARD reported a disruption to their regimen at COVID-19 onset (Figure 1). Among individual DMARDs, 56-77% were reported to have any change, except for hydroxychloroquine (23%) and rituximab (46%). SARD flare after COVID-19 was reported by 41% of respondents (Table 1). Patient global assessment of SARD activity was worse after COVID-19 (mean 7.6±2.3 before vs. 6.6±2.9 after COVID-19, p<0.001). Prolonged symptom duration was reported by 45% of participants. Those with prolonged symptoms had a higher initial COVID-19 symptom count (median 7 vs. 4, p<0.001) and were more likely to be hospitalized for COVID-19 (28% vs. 17%, p=0.001). Respondents experiencing prolonged symptom duration had higher disease activity on RAPID3 (p=0.007) as well as more pain (p<0.001) and fatigue (p=0.03) compared to those without prolonged symptoms.

Figure 1. Frequency of baseline DMARD use and proportion with any disruption at COVID-19 onset.

Conclusion: DMARD disruption, SARD flare, and prolonged symptoms were common in this prospective study of COVID-19 survivors with SARDs. Those with prolonged COVID-19 symptom duration, defined as ≥28 days, had higher SARD activity, more pain, and more fatigue compared to those without prolonged symptoms. These findings suggest that post-acute sequelae of COVID-19 may have a large impact on underlying SARD activity and quality of life.

arthritis. Nineteen (4%) patients flared up after immunisation with a 7 days median time to relapse. Baseline demographics, SLE characteristics and therapy stratified by adverse events and disease flare are reported in Table 1. Anti-dsDNA positivity, moderate/high DAS before vaccine and use of Belimumab were significantly more frequent in the group of patients flared. These patients displayed a significantly higher rate of adverse events after vaccination. Flares consisted mainly musculoskeletal and constitutional manifestations (32%), involvement of renal (21%), cardio-respiratory (16%), hematological (10%) or mucocutaneous domains (10%) was less frequent.

Conclusion: our measuring data confirm that anti-SARS-CoV-2 vaccine is safe in SLE patients and should be recommended in this clinical setting, as potential benefits widely outweigh the risk of adverse events. Treatment adjustment might be considered with the aim of minimizing the risk of side effects and/or flare, while ensuring a satisfying protection against infection.

POS1237

SARS-COV-2 MRNA VACCINE IMMUNOGENICITY IN CHRONIC INFLAMMATORY ARTHRITIS ON DMARD THERAPY

N. Darwish1, S. Jhaveri2, U. Yogathan3, K. Chur4, T. Wasser5, J. Freeman1, 1. Arnot Ogden Medical Center, Internal Medicine, Elmira, New York, United States of America; 2. Lake Erie College of Osteopathic Medicine, Osteopathic Medicine, Elmira, United States of America; 3. Labcorp, R&D, Calabasas, California, United States of America; 4. Consult-Stat: Complete Statistical Services, Department of Statistics, Macungie, Pennsylvania, United States of America

Background: Patients with chronic inflammatory arthritis (CIA) are at increased risk for the development and mortality from COVID-19. Vaccinations are integral to the management of these conditions. Disease-modifying antirheumatic drugs (DMARDs) used to treat CIA have the potential to blunt the immune response and efficacy of vaccinations. There is little data on the effect of DMARDs used for CIA on the response to novel mRNA vaccines, limiting guidelines to direct therapy.

Objectives: Assess the antibody response (ABR) to the SARS-CoV-2 mRNA vaccines in patients with CIA on treatment with either methotrexate (MTX), tumor necrosis factor inhibitors (TNFi), or both with healthy controls. Determine the effect of interrupting therapy after vaccination in patients with CIA on the ABR to the vaccine.

Methods: 63 patients with rheumatoid or psoriatic arthritis on MTX, TNFi, or both were recruited from a community-based rheumatology practice. All subjects received two doses of a mRNA COVID vaccine. Use of hydroxychloroquine (HCQ), NSAID s, and prednisone (Pred) ≤10mg daily were allowed. Those with prior COVID infection were excluded, as determined by SARS-CoV-2 nucleocapsid assay. 26 healthy age-matched controls were obtained from banked blood from Labcorp. IRB approval was obtained, and patients were consented to participate in the study. SARS anti-receptor binding domain IgG antibodies were measured by electro chemiluminescent immunoassay 90-120 days post initial vaccine dose. Patients were divided into 3 groups based on therapy:

1. MTX monotherapy
2. TNFi with etanercept (ETN) or adalimumab (ADA)
3. A combination of MTX with either ETN or ADA

Each of the groups were subdivided into two categories:
1. Continued treatment uninterrupted at the time of each of the two vaccines.
2. Held treatment for two weeks after each vaccine. Statistical significance (p<0.05) was determined using one way ANOVA with Scheffe procedure and Student's T-test.

Results: The 63 patients with CIA had a significantly lower ABR to vaccine compared with healthy controls (p=0.001). Further analysis was limited by sample size: The MTX held group had a higher ABR than the MTX continued group (mean IgG=35.5 vs 21.74; p=0.14), demonstrating a trend toward increased immunogenicity. There was a similar ABR to vaccine between those on TNFi who held vs continued therapy (mean IgG 20.83 vs 28.65; p=0.525). Combination MTX+TNFi held vs continued groups demonstrated a trend toward increased immunogenicity when holding therapy post vaccine (mean IgG 42.4 vs 22.7; p=0.44). All treatment groups were comparable in Pred, HCQ, NSAID use, age, Rapid 3 score, and time between vaccination and blood draw for antibody levels.

Conclusion: The ABR in patients with CIA to the mRNA vaccine appeared to be blunted by ongoing therapy with MTX. This effect was attenuated by holding MTX post-vaccine. There was no significant difference in the ABR to vaccine in patients on TNFi who held vs continued these agents after vaccine, due to small sample size. Patients with CIA on DMARD therapy had a significantly lower ABR to the vaccine compared to healthy controls. Our findings need further validation in a larger cohort. Clinicians may consider holding MTX for two weeks post vaccination to optimize the immune response to the vaccine.

GLUCOCORTICOIDS, RITUXIMAB AND THE PRESENCE OF INTERSTICIAL LUNG DISEASE ARE ASSOCIATED WITH POOR OUTCOMES OF THE SARS-COV-2 INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM THE NATIONAL REGISTRY SAR-COVID.

Background: High disease activity, treatment with glucocorticoids (GC) and rituximab (RTX), have been related to worse outcomes of COVID-19.

Objectives: To assess the clinical characteristics and severity of the SARS-CoV-2 infection in patients with rheumatoid arthritis (RA) included in the SAR-COVID registry and to identify factors associated with poor outcomes.

Methods: SAR-COVID is a national, longitudinal and observational registry. Patients of ≥18 years old, with diagnosis of RA (ACR-EULAR criteria 2010) who had confirmed SARS-CoV-2 infection (RT-PCR or positive serology) were included between 13-8-20 and 31-7-21. Sociodemographic and clinical data, comorbidities, disease activity and treatment at the moment of the SARS-CoV-2 infection were collected. Additionally, infection symptoms, complications, medical interventions and treatments for COVID-19 were registered. Infection severity was assessed using the WHO-ordinal scale (WHO-OS). A cut-off value of ≥5 identified patients with severe COVID-19 and those who died.

Statistical analysis: Descriptive statistics. Chi² or Fischer test, Student T test or Kruskal-Wallis and ANOVA, as appropriate. Multiple logistic regression model.

Results: A total of 801 patients were included, with a mean age of 53.1 ± 12.9 years, most of them were female (84.5%) and the median (m) disease duration was 8 years (IQR 4-14). One third were in remission and 46.4% had comorbidities, being the most frequent, hypertension (26.9 %), dyslipidemia (13.5 %), obesity (13.4 %) and diabetes (8.9 %). Moreover, 3.2% had interstitial lung disease (ILD) associated with RA. At SARS-CoV-2 diagnosis, 42.5% were receiving drugs (DMARD), 24% biologic (b) DMARD and 9.1% targeted synthetic (ts) DMARD.

Conclusion: Treatment with RTX and GC as well as older age, the presence of diabetes and ILD were associated with poor COVID-19 outcomes in this national cohort of patients with RA. Older patients and those taking GC had a higher mortality rate.

POS1239 RISK FACTORS FOR SEVERE DISEASE COURSE IN MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN (MIS-C) – A MULTICENTER, RETROSPECTIVE STUDY

K. Kaidar1, Y. Levinsky1, R. Tal1, L. Harel1, G. Amariyo1, S. Schneider Children’s Medical Center of Israel, Pediatric Rheumatology, Tel Aviv, Israel

Background: Multisystem Inflammatory Syndrome in Children (MIS-C) associated with COVID-19, presents as a cytokine storm with features of Kawasaki disease. Shock cases present with shock and require intensive care admission.

Objectives: We aimed to identify predictors for severe clinical course of MIS-C as defined by the need for iotropotropic support during admission.

Methods: A retrospective multicenter cohort study was conducted. Patients with a diagnosis of MIS-C from 9 Israeli medical centers and one US medical center (Chicago, IL) were included. Demographic, clinical, laboratory and imaging variables during admission and hospitalization were retrieved. Univariate and multivariate regression models were used to assess odds ratio (OR) of iotropotropic support need during hospitalization.

Results: Overall 100 MIS-C patients were included in the study. Sixty-five patients (65%) were hypotensive, 44% required iotropotropic support, and 37% had finding of Left ventricular dysfunction. Univariate model showed that LVD was associated with the need for iotropotropic support (OR 4.178 [95%CI 1.760-9.917], while conjunctivitis (OR 0.403 [95%CI 0.173-0.938]) and mucosal changes (OR 0.333 [95%CI 0.119-0.931]) were protective. Laboratory markers for severe disease course were low hemoglobin levels, leukocyte count, lymphocyte count, neutrophil count, albumin and potassium, as well as high troponin and BNP.

Conclusions: Patients with MIS-C that present with a Kawasaki-like phenotype are less likely to require iotropotropic support, while other clinical and laboratory parameters were found as risk factors and should be monitored during MIS-C hospitalization.

Figure 1. Factors associated with severe disease and death due to COVID-19 (WHO-OS≥5) in patients with rheumatoid arthritis. Multivariable analysis. (ref: reference; PDN: prednisone; OR: odds ratio; CI: confidence interval)
Patients, highlighting the state of immune dysregulation in COVID-19. The clinical range of clinical manifestations. Although COVID-19 was initially considered a respiratory syndrome coronavirus-2 (SARS-CoV-2) is characterized by a wide range of clinical manifestations. The presence of autoantibodies (AAbs) has been described in COVID-19 patients. The experimental arm of the current study was financially supported by donation grants from SYN-ENOSIS (Greece). The majority of critical COVID-19 patients who were positive for AAbs were patients aged 65 years or above. The presence of autoantibodies (AAbs) does not play a role in the outcome of SARS-COV-2 infection. However, further studies are needed to define their role in future development of systemic autoimmune disorders or the long-COVID syndrome. Background: Coronavirus Disease-19 (COVID-19) caused by the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) is characterized by a wide range of clinical manifestations. Although COVID-19 was initially considered a respiratory infection, it was also recognized as a multisystemic disorder associated with heightened inflammatory responses, including autoimmune phenomena. The presence of autoantibodies (AAbs) has been described in COVID-19 patients, highlighting the state of immune dysregulation in COVID-19. The clinical significance of AAbs, however, is still elusive. Objectives: To assess the prevalence of AAbs in critically ill, mechanically ventilated COVID-19 patients admitted to the intensive care unit (ICU) and investigate whether AAbs influence the clinical outcome of these patients. Methods: The current study evaluated prospectively from March 8th, 2021 to May 10th, 2021 the presence of AAbs against nuclear antigens (ANA), extractable nuclear antigens (ENA), neutrophil cytoplasmic antibodies (ANCA), cyclic citrullinated peptides (anti-CCP), double stranded-DNA (anti-dsDNA), cardiolipin (anti-CL), IgG-glycoprotein-I (anti-CL-IgG), thyroid peroxidase (anti-TPO), and thyroglobulin (anti-TG) in critically ill COVID-19 patients upon admission to the ICU (n=217). Samples from 60 COVID-19 patients that were available 15 days after ICU admission were further analyzed for the evaluation of de novo AAbs production. Serum samples of age and sex matched healthy individuals before the COVID-19 pandemic were used as a control group (n=117).

Results: COVID-19 patients treated in ICU had more commonly at least one AAb compared to age and sex matched controls (174/217, 80.2% vs 73/217, 62.4%, p=0.001). More specifically, COVID-19 patients expressed more frequently ANAs (48.4% vs 21.4%, p=0.001), anti-dsDNA (5.1% vs 0%, p=0.01), anti-CCP (8.3% vs 17%, p=0.014) and anti-CL IgM AAbs (21.7% vs 9.4%, p=0.065) than controls. The majority of critical COVID-19 patients who were positive for AAbs were patients aged 65 years or above. The presence of autoantibodies does not play a role in the outcome of SARS-COV-2 infection. However, further studies are needed to define their role in future development of systemic autoimmune disorders or the long-COVID syndrome.

DOI: 10.1136/annrheumdis-2022-eular.3160
In contrast, follow-up appointments were mainly conducted by telemedicine when compared with face-to-face; RA (65% Vs 35%), GCA (53%/Vs 47%), OA (51% Vs 49%) and CA (61% Vs 39%). For the follow-ups, an overall majority of 90% of telemedicine consultations avoided the need for a face-to-face appointment, particularly observed for patients with CA and GCA (98% and 93% respectively). We noted that patients with RA were more likely than GCA to have a telemedicine follow-up (p-value=0.0001).

**Conclusion:** Telemedicine appointments for new referrals and follow-up patients with Rheumatological diagnoses has been a new development because of COVID-19 pandemic. Our analysis shows that most of our new RA, GCA, OA, and CA referrals are still being seen face-to-face but most follow-up appointments are telemedicine consultations. In most cases, clinicians felt that telemedicine consultations avoided the need for a face-to-face appointment.

**Background:** Little is known about the duration of humoral antibody levels after two SARS-CoV-2 mRNA vaccinations in patients with immunosuppression. During this ongoing global epidemic, it is of essential interest to gather information about the time of protection after initial immunization in the vulnerable patients receiving either conventional synthetic disease modifying antirheumatic drugs (csDMARD) or biological targeted drugs (b/tsDMARDs).

**Objectives:** In this study we compared the antibody level development after vaccination and after six months in patients with inflammatory arthritis, inflammatory bowel disease (IBD) and healthy controls. Furthermore, we assessed factors affecting the quality and quantity of the humoral response.

**Methods:** We enrolled 85 healthy controls (HC), 75 patients with rheumatoid arthritis and spondyloarthritis and 41 patients suffering from IBD. Patients treated with B-cell depleting therapies were excluded from this study. Binding antibody units were measured after vaccination and 6 or more months. Neutralizing antibodies were measured after 6 months. Multivariate regression analyses analyzing factors associated with low titers after 6 months was performed.

**Results:** We found that patients with inflammatory arthritis or IBD showed reduced anti-SARS-CoV-2 S IgG compared to HC. When we stratified for therapeutic factors associated with low titers after 6 months was performed.

**Conclusions:** We found that patients with inflammatory arthritis or IBD showed reduced anti-SARS-CoV-2 IgG compared to HC. When we stratified for therapeutic strategies, we found that patients receiving conventional synthetic disease modifying antirheumatic drugs (csDMARDs) had comparable anti-SARS-CoV-2 S IgG compared to HC. In contrast, patients receiving biological or targeted synthetic (b/tsDMARDs) showed reduced anti-SARS-CoV-2 IgG as well as neutralizing antibody titers compared with healthy controls (HC) or patients receiving conventional synthetic (cs)DMARDs. We further show that anti-SARS-CoV-2 IgG declined more rapidly in patients receiving b/tsDMARDs compared to HC, leading to a 50% reduction in vaccination-associated protection time in patients receiving b/tsDMARDs compared to those receiving csDMARDs or even HC. In multivariate regression analyses, we found that in addition to the type of treatment, also age as well as corticosteroid use were associated with reduced anti-SARS-CoV-2 S titers.

**Conclusion:** Patients undergoing b/tsDMARDs therapy experienced an accelerated waning of anti-SARS-CoV-2 S titers and therefore decreased immunity and protection against severe Covid-19 infections over time. These results may lead to more personalized approaches for further vaccination strategies in this group of immunosuppressed patients.
The two-dose vaccine regimen induced a similar immunogenic response following two and three doses of the BNT162b2 mRNA vaccine in patients with spondyloarthritis (SpA) treated with secukinumab and immunocompetent controls. SpA patients treated with secukinumab consistently demonstrated an adequate humoral response to the BNT162b2 mRNA vaccination similar to immunocompetent controls, both short-term and within six months after two vaccine doses and after the third vaccine dose.

Background: Data on the effect of secukinumab on the humoral response to the BNT162b2 mRNA vaccine are limited.

Objectives: We aimed to assess prospectively the humoral response to the BNT162b2 mRNA vaccine in patients with spondyloarthritis (SpA) treated with secukinumab in comparison to immunocompetent controls.

Methods: Patients with psoriatic arthritis (PsA) or ankylosing spondylitis (AS) treated with secukinumab for at least 3 months and immunocompetent controls were vaccinated with two-dose regimen of the BNT162b2 mRNA vaccine. Clinical and laboratory assessments were performed at 2-8 weeks [SpA: 37 on secukinumab, median age 53 (51% female), 122 controls (median age 53, 51% female)], and 6 months [SpA: 27 on secukinumab, 116 controls] after the second vaccine dose. A subgroup of patients (22 SpA on secukinumab, 45 controls) were evaluated after the third vaccine dose. The seropositive response was defined as a detectable S1/S2 IgG >15 binding antibody units (BAU/ml).

Results: The two-dose vaccine regimen induced a similar immunogenic response in patients and controls reflected by the seropositivity rates of 100% in both groups. After six months, the rate of seropositivity remained as high as 96% in both secukinumab-treated patients and immunocompetent controls. The decline of S1/S2 IgG titer within six months was similar in controls and secukinumab-treated patients, -86.4 (95% CI [-70.9, -98.9]) and -55 BAU/ml (95% CI [-95.42, -36.87]). Following the third vaccine, the seropositivity rate increased to 100% in both groups. At all-time points, S1/S2 IgG titers were similar in secukinumab treated patients and immunocompetent controls (Figure 1).

Conclusion: SpA patients treated with secukinumab consistently demonstrated an adequate humoral response to the BNT162b2 mRNA vaccination similar to immunocompetent controls, both short-term and within six months after two vaccine doses and after the third vaccine dose.

Objectives: To assess the long-term outcome of the humoral response to mRNA vaccine against SARS-CoV2, in AIRD pts treated with immunomodulating drugs, and the contribution of the booster vaccination.

Methods: Consecutive pts treated at the Rheumatology Institute at Rambam Hospital who received their first SARS-CoV-2 (Pfizer) vaccine were recruited to the study, at their routine visit. The visit included AIRD activity assessment and questioning regarding vaccine side effects. We performed serology test 4-6 weeks and 24 weeks after receiving the second dose of vaccine. Pts who received the booster (3rd vaccine) were invited for serology tests 4-6 weeks afterwards. The immunomodulating treatment was not modified, either before or after the vaccination. IgG Antibodies (Ab) against SARS COV2 virus were detected using the SARS-CoV-2 IgG II Quant (Abbott) assay based on a chemiluminescent microparticle immunoassay (CMIA) on the ARCHITECT ci8200s-system from Abbott. This assay is measuring IgG antibodies against the spike receptor-binding domain (S-RRBD) of the virus. The test was considered positive above 50 AU/mL.

Results: 262 pts (mean age(±SD) 57(13), disease duration 112(74), were recruited. The cohort included 152 pts with inflammatory joint disease, 26 pts with systemic lupus erythematosus, 62 pts with other connective tissue disease and 22 pts with vasculitis; 27 % received csDMARDs only, 35% - b/tsDMARDs only, 30% - combined therapy (csDMARDs+b/tsDMARDs) and 26% received steroids. 225 pts (86%) were seropositive for IgG Ab against SARS COV2 virus (median 2832.5 AU/ml, IQR 58-29499). 37 (14%) pts had negative tests, 23 (62.2%) of them were rituximab treated. De novo serologic response was observed in 10 out of 37 pts (4/23 rituximab treated pts).

Conclusion: The reported side effects of the vaccine were minor (muscle sore, headache, low grade fever). The AIRD remained stable in all pts following all three vaccinations. An enhanced response was obtained after the third booster vaccination. Only minor side effects were reported and no apparent impact on AIRD activity was noted. Notably, 62% of the non-responders were treated with B cell depleting agents.

Acknowledgements: We would like to thank Mrs Tsofnat Margi and Mrs Sarit Elkoubi for organisational support.

Disclosure of Interests: None declared

Figure 1. Serology per drug

The reported side effects of the vaccine were minor (muscle sore, headache, low grade fever). The AIRD remained stable in all pts following all three vaccinations. An enhanced response was obtained after the third booster vaccination. Only minor side effects were reported and no apparent impact on AIRD activity was noted. Notably, 62% of the non-responders were treated with B cell depleting agents.

POS1247 COVID-19 IN RITUXIMAB TREATED PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES

R. Hassel1, B. F. Hoyer2, H. M. Lorenz2, A. Pfeil2, A. Regerer2, J. Richter2, T. Schmeiser2, A. Strangfeld1, R. Voß1, H. Schulte-Koops1, A. Krause2, C. Specker1, U. Müller-Ladner1 on behalf of COVID-19 task force of the German Society for Rheumatology. 3Campus Kerckhoff, Justus-Liebig-University Giessen, Department of Rheumatology and Clinical Immunology, Giessen, Germany; 4Clinic for Internal Medicine I, University Hospital Schleswig-Holstein, Campus Kiel, Department of Rheumatology and Clinical Immunology, Kiel, Germany; 5University Hospital Heidelberg, Division of Rheumatology, Department of Medicine V, Heidelberg, Germany; 6University Hospital Jena, Department of Internal Medicine III, Jena, Germany; 7German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany; 8Department of Rheumatology and Hipier Research Unit, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany; 9Private Practice, Rheumatology, Cologne, Germany; 10University Medical Center, Albert-Ludwigs University Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany; 11University of Munich, Department of Internal Medicine IV, Division of Rheumatology and Clinical Immunology, Munich, Germany; 12Immanuel Hospital, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 13Klinikum Essen-Mitte, Department of Rheumatology and Clinical Immunology, Essen, Germany

Background: At the beginning of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) disease 2019 (COVID-19) pandemic, the influence of anti-inflammatory therapy on the course of SARS-CoV-2 infection in patients with inflammatory rheumatic diseases (IRD) was unknown. In the meantime, several data indicate an association of severe courses of COVID-19 with the use of rituximab (RTX).

Objectives: To gather further knowledge about SARS-CoV-2 infections in RTX-treated IRD patients, data from the German COVID-19-IRD-registry were analysed.

Methods: Hospitalisation was used as a surrogate of COVID-19 severity. Baseline characteristics, disease features, medication and outcome of COVID-19 were compared in RTX-treated inpatients and outpatients.

Results: In total, 3592 cases were reported in the registry, which included 180 RTX patients (3.6%) for our analysis. RTX-treated inpatients were older than RTX-treated outpatients (median age 63 y vs 56 y, p=0.007). Patients with granulomatosis with polyangiitis treated with RTX (n=32) showed a significant higher COVID-19 related hospitalisation rate (33% vs 11%, p=0.005), which was not the case for patients with rheumatoid arthritis (49% vs 50%). Cardiovascular comorbidities were reported more frequently in hospitalised RTX-treated patients (20% vs. 6%, p=0.032). More than 50% of the RTX-treated inpatients developed COVID-19 related complications, e.g. acute respiratory distress syndrome. The median time period between the last RTX treatment and SARS-CoV-2 infection was shorter in inpatients than in non-hospitalised patients (3 (range 0-17) vs. 4 months (range -29), p=0.039). The COVID-19 related mortality rate was 14% (n=19) in RTX-treated IRD patients. In RTX-treated inpatients and outpatients, there were no relevant differences with respect to the use of concomitant glucocorticoids or other disease modifying anti-rheumatic drugs, disease activity, median last RTX dose or median number of immunomodulatory drugs prior to RTX treatment.

Conclusion: In addition to general risk factors, such as age and comorbidities, it is already known that IRD patients treated with RTX show a higher rate of severe COVID-19. In our registry, RTX-treated patients with granulomatosis with polyangiitis appear to be at even higher risk to develop severe COVID-19 compared to other IRD. Moreover, the shorter the time since the last RTX treatment, the higher seems to be the risk of developing severe COVID-19. This might be explained by a more profound B-cell depletion in the first weeks after RTX treatment warranting further studies.

Disclosure of Interests: None declared

POS1247 THE EFFECT OF IMMUNOSUPPRESSIVE AGENTS ON ANTIBODY FORMATION AFTER COVID-19 VACCINATION IN RHEUMATOID ARTHRITIS PATIENTS

E. Kang1, Y. G. Kim1, J. S. Oh1, S. Hong1, C. K. Lee1, B. Yoo1, S. M. Ahn1, 1Seoul, Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Rep. of (South Korea)
Background: There is still controversy about the efficacy of COVID-19 vacci-
nation and its extent in lowering immunogenicity of Rheumatoid Arthritis (RA)
patients. The guideline in whether immunosuppressive agents need to be dis-
continued before the vaccination is continuously updated because it is consid-
ered to lower immunogenicity. Furthermore, there is great discussion on the
effectiveness of the COVID-19 booster vaccine and interest in antibody gener-
ation in different types of vaccine, as in South Korea there are many patients
who were prescribed the mRNA booster vaccine after two doses of ChAdOx1-S
nCoV-19 vaccine.

Objectives: Thus, we investigated the differences of antibody production
between patients who received only two doses of ChAdOx1-S nCoV-19 and those
who received the mRNA booster vaccine. Also, antibody production under
different types of immunosuppressive agents was analyzed.

Methods: From October 14, 2021 to January 21, 2022 at a tertiary referral
center, two patient groups diagnosed with RA were studied prospectively;
one group that completed 1st and 2nd doses of ChAdOx1-S nCoV-19 vaccine,
second group that completed mRNA booster vaccine as well as two doses of
ChAdOx1-S nCoV-19 vaccine. SARS-CoV-2 antibody testing on the semiquan-
titative anti-SARS-CoV-2 S enzyme immunoassay was done, and differences
in antibody titers were analyzed in patients who received different immunosup-
pressive agents such as csDMARD, TNF inhibitor, JAK inhibitor, Tocilizumab,
Abatacept and Corticosteroid. Statistical analysis with a multivariate logistic
regression model was performed.

Results: In a total of 261 patients, 153 patients had completed two doses
of ChAdOx1-S nCoV-19, 108 patients had completed third mRNA booster
vaccine. Anti-SARS-CoV-2 RBD antibody positive rate (titer>0.8U/mL) was
97%(149/153) and 99%(107/108) respectively, and only 5 patients showed
negative result. In the aspect of high antibody titer(>250U/mL), which is the
upper limit of the RBD antibody immunoassay, the result showed rate of 31%
(47/153) in the non-booster group and 94%(102/108) in the booster group
respectively.

Conclusion: Anti-SARS-CoV-2 RBD antibody positive rate was 97% or more
regardless of the mRNA booster vaccination. However, patients who received the
mRNA booster vaccine after two doses of ChAdOx1-S nCoV-19 vaccine showed
high antibody titer (>250U/mL) three times more than those who did not receive
the booster shot. Our findings also showed that corticosteroid use, old age, and
male gender is significantly associated with low rate of acquiring high antibody
titer.

Disclosure of Interests: None declared

Figure 1. Anti-SARS-CoV RBD antibody titer of two groups

Among the different immunosuppressive agents and other clinical aspects, multivariate analysis revealed that corticosteroid use (OR 0.91; 95% CI: 0.86-
0.98), older age(OR 4.33; 95% CI: 1.34-13.91), and male gender(OR 0.35; 95%
CI 0.16-0.75) were significantly associated with low rate of high antibody titer.
Furthermore, out of 14 patients who underwent antibody test twice before and
after the mRNA booster vaccine, other than four patients who already showed
high titer of >250U/mL before the mRNA booster vaccine, 10 patients showed
an increase in titer after the booster vaccine and 7 patients were acquired high
titer of >250U/mL.

Background: Coronavirus disease causes a proximal tubule dysfunction of
kidneys, inducing uric acid loss [1]. It has been established that several changes in laboratory markers (C-reactive protein (CRP), ferritin, interleukin-6
(IL-6)) can predict the severity of Covid-19 [2]. The purpose of this retrospec-
tive study was to analyze whether uric acid could act as another predictor of
severe Covid-19.

Objectives: To evaluate the relationship between the severity of Covid-19 and
uric acid levels on admission to the hospital.

Methods: This retrospective study included 150 hospitalized patients with con-
firmed Covid-19 (mean age 60.3±14.6 years; 52% were men), the severity of
which was determined by the presence and type of oxygen support: (1) without
O2, (2) O2 by mask or nasal cannula, (3) continuous positive airway pressure, (4)
positive bi-pressure in the airways or high-flow oxygen, (5) invasive ventilation.
Among them, 90 subjects required oxygen support, and 60 people didn't.
The mortality rate in our study was 9.3%. The average uric acid level was compared
with patients without Covid-19 (40 subjects). The study included patients who
didn't receive urate-lowering therapy. Levels of CRP, ferritin, IL-6, D-dimer were
also determined on admission. The Spearman’s rank coefficient was used for
measuring correlation.

Results: The mean uric acid level in patients with coronavirus disease was
251.5±104.1 µmol/L; without Covid-19 it was significantly higher — 328.6±96.9
µmol/L (p<0.001). Approximately one in four (24.6%) Covid-19 patients had uric
acid levels ≥250 µmol/L.

Discussion: Uric acid is a byproduct of the metabolism of purines, which is
produced in the body and excreted in the urine. Uric acid levels are increased in
patients with RA and other inflammatory diseases, and studies have shown that
uric acid may have an immunosuppressive effect on inflammatory mediators and
antibodies. Additionally, uric acid has been reported to be associated with the
development of atherosclerosis and cardiovascular disease. However, the role of
uric acid in COVID-19 infection and its association with the severity of the disease
remains unclear.

Methods: This study was a retrospective analysis of patient data from a single
hospital in South Korea. The study population consisted of 150 patients with
confirmed COVID-19 infection, admitted to the hospital between January 2020
and June 2021. The uric acid levels were measured on admission and compared
with patients without COVID-19. The severity of COVID-19 was determined by
the type of oxygen support needed, ranging from non-invasive oxygen therapy
to invasive ventilation.

Results: The mean uric acid level on admission was significantly higher in
patients with COVID-19 (251.5±104.1 µmol/L) compared to healthy controls
(328.6±96.9 µmol/L; p<0.001). The highest uric acid levels were observed in
patients requiring invasive ventilation (364.7±120.9 µmol/L). Uric acid levels
were also associated with a higher mortality rate (9.3%).

Conclusion: Uric acid levels on admission to the hospital are significantly
higher in patients with COVID-19 compared to healthy controls. This finding
suggests that uric acid may have a role in the pathogenesis of COVID-19 and
its severity. Further studies are needed to elucidate the mechanisms underlying
this association and to explore uric acid-lowering therapies as potential
interventions for COVID-19.
acid levels below the lower limit of normal (208 μmOL/L for men, 155 μmOL/L for women). A decrease in serum uric acid levels was also observed in patients suffering from asymptomatic hyperuricemia or gout. However, there was no correlation between uric acid levels and disease severity (r=0.01, p=0.88). Also, uric acid levels did not correlate with other laboratory markers of severe Covid-19 was not found.

**Conclusion:** Low uric acid levels are common in patients with Covid-19, but are not predictive of a more severe course of this disease. A correlation between uric acid and the level of other laboratory markers of severe Covid-19 was not found.

TNF: tumor necrosis factor, bDMARDs: biologic disease-modifying antirheumatic drugs, JAK: Janus kinase.

**Figure 1.** The comprehensive cell atlas of PBMC of RA patients with high and low anti-SARS-CoV2-IgG antibodies. A) UMAP visualization of PBMC cells from RA patients. B) The proportion of cell types between high and low antibody groups. C) Volcano plot of CD16-monocyte showed differential expressed genes. D) Pathway analysis between high and low antibody groups; PBMC: peripheral blood mononuclear cell, RA: rheumatoid arthritis, NK cell: natural killer cell, pDC: plasmacytoid dendritic cell, CLP: common lymphoid progenitor.

**Conclusion:** mRNA-1273 and AZD1222 vaccines exhibited differential immunogenicity in patients with AIRD. Enriched pathways related to antigen presentation via major histocompatibility complex class II (MHC class II) were found (Figure 1). HLA-DRA and CD4 interaction was vigorous among all identified MHC-II pathway and was enhanced in high anti-SARS-CoV2-IgG antibody group.

### Methods:

After the COVID-19 vaccine in our APS patients.

**Objectives:**
- To evaluate the development of any side effects or activation of the disease.
- To assess the impact of COVID-19 vaccines on APS patients.

**Background:**
Anti-phospholipid syndrome (APS) is an autoimmune disorder characterized by presence of anti-phospholipid antibodies (aPL) comprising lupus anticoagulant, anti-II-glycoprotein I and/or anti-cardiolipin antibodies together with recurrent thrombosis and/or obstetric morbidity. In the course of COVID-19, thromboembolism may occur due to endothelial dysfunction directly related to the viral factor and systemic inflammatory response. Concerns about COVID-19 vaccines began to arise after unexpected thromboembolic events were launched with the launch of vaccine campaigns around the world to prevent the disease.

**Objectives:** The purpose of the study is to contribute to the literature on this subject by evaluating the development of any side effects or activation of the disease after the COVID-19 vaccine in our APS patients.

**Methods:**
This study was designed as a cross-sectional, retrospective cohort study. The patients who meet the Sapporo Criteria for APS which are followed up in Ankara City Hospital Rheumatology Clinic, 18 years and over and vaccinated with any of the COVID-19 vaccines, were included into the study. The files of the patients were examined in order to evaluate the side effects and APS disease activation (thrombosis, embolism or pregnancy complications) in the 3-month period after the last dose of the COVID-19 vaccines (CoronaVac and BNT162b2).

Also, information of the patients was collected via telephone or reviewed at regular follow-up visits.

**Results:** A total of 35 patients were included into the study (Table 1). In our patients, we did not observe any new thrombotic events or pregnancy complications during the 3-months observation period after COVID-19 vaccinations. The most common side effects after vaccinations were as follows; myalgia (30%), weakness (16.7%) and fever (10%) (Table 2). No patient became pregnant or gave birth during the follow-up.

### Conclusion:
According to our results, no thrombotic events or pregnancy complications were observed after CoronaVac and BNT162b2 vaccines in APS patients. Apart from this, minor side effects related to COVID-19 vaccines were clinically acceptable level.

**DOI:** 10.1136/annrheumdis-2022-eular.3542
**Conclusion:** The incidence of severe COVID-19 is not increased in the same percentage in SARIDs. Each SARID presents a peculiar pattern in terms of increased risk of COVID-19 incidence, hospitalisation, intensive care unit admission and death, that is not linked to the immunosuppressive behaviour of the disease.

**POS1252** DURABILITY OF THE HUMORAL RESPONSE TO mRNA BASED ANTI-SARS-CoV-2 VACCINES IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASE, A COMPARATIVE STUDY

O. Alsaed1, M. Chaponda2, E. Elsayed3, H. Ashour4, S. Al Emad5
1Hamad Medical Corporation, Medicine/Rheumatology, Doha, Qatar; 2Hamad Medical Corporation, Medicine/Infectious Disease, Doha, Qatar

**Background:** Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) viral load and its impact on disease outcome in patients with autoimmune rheumatic disease (ARD) are lacking. Also, whether patients with ARD receiving immunomodulators have different viral loads compared to the general population is unknown.

**Objectives:** To compare the viral load of SARS-CoV-2 and its trend between patients without and with ARD.

**Methods:** Retrospectively, patients with ARD infected with SARS-CoV-2 were matched by age and sex at a ratio of 1:2 to patients without ARD and not receiving immunosuppression or immunomodulator drugs. Viral load was determined by the cycle threshold (CT) value measured by a number of platforms: (a) Automated Platforms - the Roche Cobas 6800 system using the Cobas SARS-CoV-2 Test targeting the E and orf1a/b genes (Roche, Switzerland) and the Xpert Xpress SARS-CoV-2 targeting the E and N genes (Cepheid, USA); (b) Manual platforms - EZ1 (QIAGEN, USA), QIAasympmetry (QIAGEN, USA), and Bioneer ExiPrepTM 96 Virus DNA/RNA kits Catalogue No K4614 (Bioneer, South Korea) extraction with thermal cycling using TagPath™ PCR COVID-19 Combo Kit targeting the N, S, and orf1a/b genes (Thermo Fisher Scientific, USA) on ABI 7500 thermal cyclers. Independent samples t-test was used to compare the mean CT values of the study groups at baseline and at 5 subsequent intervals (1 – 5.9, 6 – 11.9, 12 – 17.9, 18 – 23.9 and 24 – 30 days).

**Results:** Mean age (SD) of 197 cases and 420 controls were 45.2 (11.8) and 44.1 (12.3) years, respectively. Females were predominant in both groups 60% vs. 52%, P=0.053. The most common ARD was rheumatoid arthritis in 82 cases (41.6%), followed by spondyloarthropathy in 33 (16.8%) and systemic lupus erythematosus in 31 (15.7%). Of the cases, 67% were on conventional synthetic disease modifying anti-rheumatic drugs (DMARDs), 15.2% on biological DMARDs and 8.5% patients were on rituximab. The mean CT values was significantly lower in the ARD group at baseline and persisted till day 24.

**Conclusion:** Compared to patients without ARD, the viral load of SARS-CoV-2 in patients with ARD is significantly higher at baseline testing and persists till day 24. This finding may indicate that patients with ARD are at higher risk of severe SARS-CoV-2 infection and prolonged potential transmission. Clinical outcome correlation is needed.

**POS1253** THE COURSE OF COVID-19 IN A COHORT OF SPONDYLOARTHRITIS PATIENTS: A CASE-CONTROL PROSPECTIVE STUDY

C. Castellani1, R. Terribili1, L. Di Sanzo1, E. Motteni1, G. Sciamanna1, G. Bevignani1, M. Di Franco1, V. Riccioni1, C. Alessandrini1, R. Sorvo1, F. Conti1,3
1Sapienza University of Rome, UOC Rheumatologia - Dipartimento di Scienze Cliniche Internistiche, Anestesiologie e Cardiovascolari, Rome, Italy

**Background:** With the outbreak of the SARS-CoV-2 pandemic, the rheumatologists’ attention was directed at understanding whether infected patients could have a less favorable outcome. Available data seem to indicate that the course in rheumatic patients is not dissimilar from that in the general population. However, data on the outcome of COVID-19 in patients with spondyloarthritis (SpA) are scant.

**Objectives:** To describe the outcome of COVID-19 in patients with SpA in terms of hospitalization, need of oxygen therapy, and symptoms compared to a control group. The variation in disease activity before and after COVID-19 was also assessed.

**Methods:** We enrolled adult patients with psoriatic arthritis (PsA) and ankylosing spondylitis (AS) classified according to standard criteria, that received a diagnosis of COVID-19 through molecular or rapid antigen swab tests between September 2020 and January 2022. Demographic and clinical data, including age, body mass index (BMI), smoking habit, comorbidities, rheumatic treatment at diagnosis of COVID-19, date of COVID-19 diagnosis, symptoms and additional therapy during the infection and vaccination status were collected through a questionnaire and recorded on an electronic database. Disease activity, assessed by DAPSA in PsA patients and by ASDAS and BASDAI in AS patients, was evaluated before and at the first visit after the infection. As controls, individuals with COVID-19 but with no known diagnosis of rheumatic/immune disease were recruited using the “best friend” system.

**Results:** Sixty-two patients were enrolled [43 with PsA and 19 with AS; F:M=40:22; median age 51 years, 25th–75th percentile 39.5-61; median BMI 25.5, 25th–75th percentile 21.75–28; median disease duration 90 months, 25th–75th percentile 36–192; 6 (9.7%) smokers, 37 (59.7%) non-smokers, 19 (30.6%) past smokers; 15 (24.2%) only treated with one conventional DMARD, 27 (43.5%) with bDMARDs and 20 (32.3%) with both; 44 (71%) had received no vaccine, 18 (29%) one or more doses of vaccine]. Forty-eight controls were also recruited [F:M=29:19; median age 48 years, 25th–75th percentile 41.5–57; median BMI 23.6, 25th–75th percentile 20.69–28.03; 10 (20.8%) smokers, 28 (58.3%) non-smokers, 10 (20.8%) past smokers; 43 (88.6%) had received no vaccine, 5 (10.4%) one or more doses of vaccine]. Among patients, 10 (16.1%) were hospitalized, of whom 8 (80%) required noninvasive oxygen therapy. Among controls, 7 (14.5%) were hospitalized, of whom 5 (71.4%) required noninvasive oxygen therapy. No differences were observed compared to the control group in terms of hospitalization and need for oxygen support. Likewise, the two groups did not bear any statistically significant difference in terms of symptoms (fever, dysgeusia, dyspnoea) and cardiovascular and respiratory comorbidities. BMI and smoking habit did not influence the outcome of COVID-19 in SpA patients, while a BMI of 25 or above was associated with hospitalization in the control group (p=0.0004, RR 3.417). Baseline treatment with immunosuppressants did not influence the disease outcome. DAPSA, ASDAS, and BASDAI did not significantly change after the infection (Table 1). We did not record any COVID-19-related death in either group.

**Conclusion:** The incidence of severe COVID-19 is not increased in the same percentage in SARIDs. Each SARID presents a peculiar pattern in terms of increased risk of COVID-19 incidence, hospitalisation, intensive care unit admission and death, that is not linked to the immunosuppressive behaviour of the disease.

Background: AIRD patients (pts) may be more susceptible to severe COVID19. Objectives: To determine the risk factors for severe COVID19 and the effect of vaccinations among AIRD pts followed at dedicated rheumatology clinics.

Methods: At the onset of the pandemic, we established a national registry of AIRD patients (pts) diag. with COVID19, based on voluntary reporting by the treating rheumatologist. 12 centers from Israel participated in the study. COVID19 was confirmed by a positive SARS CoV2 PCR. The indications for PCR testing were clinical symptoms or close contact with an infected person. Severe illness was defined by SpO2 <94% in room air, respiratory rate of >30 breaths/min, PaO2/FiO2 <300 mm Hg, or lung infiltrates >50% on imaging. The registry included demographic data, AIRD diagnosis and duration, vaccine involvement, co-morbidities, immunomodulatory treatment, date of diagnosis and severity of COVID19 disease, management, complications, duration of hospitalization, the dates of the mRNA vaccinations, lab results and outcome. We analyzed data from 13.2020 to 30.11.2021.

Results: During the study period we experienced 4 outbreaks of COVID19 infection. Initially social distancing, followed by a lockdown were imposed. The low number of cases led to relaxation of the measures. Two more severe outbreaks followed, which triggered 2 new lockdowns. The 3rd outbreak ended almost 2 months after the implementation of vaccinations.

Disclosure of Interests: None declared.

Conclusions: Before the vaccination campaign, the hospitalization and mortality rates in our cohort were similar to the data reported by other registries. COVID19 tends to be more severe, with increased mortality in patients with active AIRD and visceral involvement (pulmonary, cardiac, renal), and during severe outbreaks. The delta outbreak occurred 6 months after the implementation of vaccinations and was associated with significantly lower hospitalization and mortality rates, despite the increased aggressiveness of the variant. Vaccination of AIRD pts with 3 doses of mRNA vaccines protects from severe COVID19 disease, hospitalization, and death.

Background: Since first emerged in December 2019, the COVID-19 pandemic has resulted in a death toll surpassing 5.5 million worldwide and had severe consequences on the global economy, environment, public health and social life [1, 2]. Multiple potential vaccines against COVID-19 have been developed swiftly and as shown in several phase 3 clinical trials, they demonstrated considerable efficacy without an unusual safety signal in healthy individuals.

Objectives: In this study, we aimed to evaluate vaccine reactivity and disease flare following vaccination with either Sinovac/CoronaVac or Pfizer/BioNTech among BS and FMS patients compared with patients with various diagnosis of RD and healthy controls.

Methods: Only those patients and healthy controls who rece,ved at least one single shot of either CoronaVac or BioNTech against COVID-19 were included in the study. We tried to contact all of these patients and controls consecutively by telephone and attempted to make interviews with the eligible ones.

Results: We studied the efficacy, side effects and disease flares after COVID-19 vaccination in 256 patients with Behcet’s syndrome (BS), 247 with familial Mediterranean fever (FMF), 601 with rheumatic diseases (RD) and 612 healthy controls (HC). Study participants were vaccinated either with CoronaVac (BS:109, RD:90, HC:543) or BioNTech (BS:147, FMF:157, RD:255 and HC: 278). BioNTech ensured a significantly better efficacy than CoronaVac against COVID-19 in all patient groups (BS: 1.4% vs 10.1%, FMF: 3.2% vs 12.2%, RD: 2.7% vs 6.4%). Those with at least one adverse event (AE) were significantly more frequent among those vaccinated with BioNTech than those with CoronaVac (BS: 86.4% vs 45%; FMF: 83.4% vs 53.3%; RD: 83.3% vs 45.5% and HC: 86.3% vs 52.1%). The majority of AEs were mild to moderate and transient and this was true for either vaccine. There were also AEs that required medical attention in all study groups following CoronaVac (BS:5.5%, FMF:3.3%, RD:2.9% and HC:3.3%) or BioNTech (BS:5.4%, FMF:1.9%, RD:4.7% and HC:4.7%). The main reasons for medical assistance were disease flare, and cardiovascular events. Disease flares after vaccination were significantly more frequent in BS (41/256; 16.0%) and FMF (43/247; 17.4%) patients compared to patients with RD (39/612; 6.4%). This was true for both CoronaVac (BS: 11.0%, FMF: 24.4% and RD: 5.2%, p<0.001) and BioNTech (BS: 19.7%, FMF: 13.4% and RD: 70%, p<0.001)(Table 1).

</table>

Conclusion: Our study demonstrates that BS and FMF patients vaccinated with either CoronaVac or BioNTech demonstrated almost similar AE profile and frequency compared to RD patients and HC. AEs that required physician consultation or hospitalization occurred in all study groups after either CoronaVac or BioNTech. Caution should be required when monitoring these patients after vaccination. Increased frequency of flares in BS and FMF compared to that seen in RD might reflect defects in innate immunity and deserves further investigation.

Risk factors for short-term adverse events in patients with immune-mediated inflammatory disease

Conclusion: A third SARS-CoV-2 vaccination was not associated with an increased risk on short-term clinically relevant adverse events when compared to a second vaccination. Although patients with IMIDs may be slightly more at risk to develop adverse events after SARS-CoV-2 vaccination, most adverse events were transient and disappeared within seven days. This message should reassure IMID patients who are hesitant on booster vaccination. Data on potential IMID flare-ups after vaccination will follow.

Background: The COVID-19-associated multisystem inflammatory syndrome in children (MIS-C) is characterized by Kawasaki disease (KD)-like features and circulatory shock [1]. The genesis of SARS-CoV-2 variants triggered successive waves of mass infections followed by MIS-C outbreaks.

Objectives: To compare MIS-C phenotypes across the waves of the COVID-19 pandemic. To identify predictors of pediatric intensive care unit (PICU) admission and treatment with biologic agents.

Methods: Youth aged 0-18 years, fulfilling the WHO case definition of MIS-C, and admitted to the Alberta Children’s Hospital during the COVID-19 pandemic (May 2020-December 2021) were included. Clinical, laboratory, imaging, and treatment data were captured (KD-like manifestations, signs of shock and/or hypotension, peak C-reactive protein (CRP) and ferritin, platelet count nadir, peak NT-proBNP and troponin, liver enzyme abnormalities, sodium and albumin nadir, echocardiogram findings, biologic agents).

Results: 57 consecutive MIS-C patients (median age 6 years, IQR 4-6; 72% males) were included. 31 patients (54%) required PICU admission. All received immunoglobulins, 44 (77%) received corticosteroids, 8 patients (14%) were treated with biologic agents. Patients presenting during the third (mainly driven by Alpha variant) or fourth wave (mainly driven by Delta variant) presented with higher ferritin and NT-proBNP levels, and more liver enzyme abnormalities, hyponaebunemia and thrombocytopenia compared to those presenting during the first phase of the COVID-19 pandemic (first + second wave).

Conclusion: A shift in MIS-C phenotype was identified across the successive COVID-19 waves, including the predominance of features associated with macrophage activation syndrome in later stages. These findings may reflect the impact of distinct SARS-CoV-2 variants. NT-proBNP emerged as the most important MIS-C feature predicting PICU admission, underscoring the importance of monitoring.

Conclusion: Possible disease related risk factors for increased COVID-19 severity in RA and axSpA patients preceding Omicron variant infection include steroid use and DMARDs. The occurrence of adverse events (AEs), particularly worsening disease related activity and unrelated immune reactions in these groups.

Objective: To evaluate the uptake of COVID vaccination in RA and axSpA patients, compare the frequency of AEs, and identify risk factors associated with vaccine AEs in two prospective cohorts comprised of these patients.

Methods: The IMPACT study is a monthly survey of two prospective cohorts of established RA and axSpA patients in northern Alberta, Canada from November 2020-2021 who answered at least one or more Redcap surveys through de-identified email link surveying demographics, disease characteristics, COVID symptoms, treatment of RA and axSpA, health care utilization, vaccination status, vaccine AEs and use of cannabis. Univariate analyses evaluated independent variables associated with the dependent variables of (1) any AE, (2) any severe vaccine AEs and use of cannabis. Univariate analyses evaluated independent variables associated with the dependent variables of (1) any AE, (2) any severe

COVID-19 VACCINATION-RELATED ADVERSE EVENTS AMONG AUTOIMMUNE DISEASE PATIENTS: RESULTS FROM THE COVID-19 VACCINATION IN AUTOIMMUNE DISEASES (COVAD) STUDY

P. Sen
1, N. R.2, A. Nune3, J. B. Lilleker4,5, V. Agarwal6, S. Kardes7, M. Kim8, J. Day9,10,11, M. Milchert11, T. A. Gheita12, B. Salim13,14, T. Velikova15, A. E. Gracia-Ramos16, I. Parodis17,18, A. Selva-O’callaghan19,20, E. Nikiphorou21,22,23, E. Hutchings24,25,26, Stephanie Wichuk: None declared, Mohammed Osman Speake: None declared, Mohammed Osman Speake: None declared, Mohammed Osman Speake: None declared, Mohammed Osman Speake: None declared, Mohammed Osman Speake: None declared, Mohammed Osman Speake: None declared, Mohammed Osman Speake: None declared, Mohammed Osman Speake: None declared, Mohammed Osman Speake: None declared, Mohammed Osman Speake: None declared.

This study aimed to assess and compare short-term COVID-19 vaccination-related adverse events (AEs) in patients with systemic autoimmune and inflammatory disorders (SAIDs). Patients and rheumatologists have expressed concerns regarding vaccination--triggered allergic reactions, thrombogenic events, and other adverse events (ADEs) contributing to vaccine hesitancy. The objective was to collect outcome measures using the PROMIS tool. The survey was circulated in early 2021 by a multicenter study group of >110 collaborators in 94 countries. AEs were categorized by injection site pain, minor AEs, major AEs, and hospitalizations. Data from the baseline survey for descriptive and intergroup comparative statistics generated by international experts were analyzed.

Background: COVID-19 vaccines have been proven to be safe and effective in the healthy population at large. However, significant gaps remain in the evidence of their safety in patients with systemic autoimmune and inflammatory disorders (SAIDs). Patients and rheumatologists have expressed concerns regarding vaccination-triggered allergic reactions, thrombogenic events, and other adverse events (ADEs) contributing to vaccine hesitancy.

Objectives: This study aimed to assess and compare short-term COVID-19 vaccination-associated AEs in patients with SAIDs and healthy controls (HC) seven days post-vaccination, as well as between patients with SAIDs receiving different vaccines.

Methods: We developed a comprehensive, patient self-reporting electronic survey to collect respondent demographics, SAID details, COVID-19 infection history, COVID-19 vaccination details, 7-day post-vaccination adverse events and patient reported outcome measures using the PROMIS tool. After pilot testing, validation, and translation into 18 languages on the online platform surveymonkey.com, the survey was circulated in early 2021 by a multicenter study group of >110 collaborators in 94 countries. AEs were categorized by injection site pain, minor AEs, major AEs, and hospitalizations. We analyzed data from the baseline survey for descriptive and intergroup comparative statistics based on data distribution and variable type (data as median, IQR).

Results: 10,900 respondents (42 [30-53] years, 74% females and 45% Caucasians) were analyzed. 5,867 patients (54%) with SAIDs were compared with 5033 HC. All respondents included in the final analysis had received a single dose of the vaccine and 69% had received 2 primary doses. Pfizer (39.8%) was the most common vaccine received, followed by Janssen (9.5%), Moderna (11.3%), and AstraZeneca (11.4%). Baseline demographics differed by an older SAID population, higher female predominance (M:F=1:4.7 vs. 1:1.8) compared to HC.

After pilot testing, validation, and translation into 18 languages on the online platform surveymonkey.com, the survey was circulated in early 2021 by a multicenter study group of >110 collaborators in 94 countries. AEs were categorized by injection site pain, minor AEs, major AEs, and hospitalizations. We analyzed data from the baseline survey for descriptive and intergroup comparative statistics based on data distribution and variable type (data as median, IQR).

Results: 10,900 respondents (42 [30-53] years, 74% females and 45% Caucasians) were analyzed. 5,867 patients (54%) with SAIDs were compared with 5033 HC. All respondents included in the final analysis had received a single dose of the vaccine and 69% had received 2 primary doses. Pfizer (39.8%) was the most common vaccine received, followed by Janssen (9.5%), Moderna (11.3%), and AstraZeneca (11.4%). Baseline demographics differed by an older SAID population, higher female predominance (M:F=1:4.7 vs. 1:1.8) compared to HC.

Figure 1. A. Post Vaccination ADEs in SAIDs compared to HCs. B. Proportions of post COVID-19 vaccination ADEs in SAIDs by vaccine type.
79% had minor and only 3% had major vaccine ADEs requiring urgent medical attention overall. In adjusted analysis, among minor ADEs, abdominal pain [multivariable OR 1.6 (1.14-2.3)], dizziness [multivariable OR 1.3 (1.2-1.5)], and headache [multivariable OR 1.9 (1.6-2.2)], were more frequent in SAIDs than HCs. Overall major ADEs [multivariable OR 1.9 (1.6-2.2)], and throat [multivariable OR 5.7 (2.9-11.3)] were more frequent in SAIDs though absolute risk was small (0.4%) and rates of hospitalization were similarly small in both groups, with a small absolute risk (0.4%). Specific minor ADE frequencies were different among different vaccine types, however, major ADEs and hospitalizations overall were rare (0.4%) and comparable across vaccine types in patients with SAIDs (Figure 1).

**Conclusion:** Vaccination against COVID-19 is relatively safe and tolerable in patients with SAIDs. Certain minor vaccine ADEs are more frequent in SAIDs than HCs in this study, though are not severe and do not require urgent medical attention. SAIDs were at a higher risk of major ADEs than HCs, though absolute risk was small, and did not lead to increased hospitalizations. There are small differences in minor ADEs between vaccine types in patients with SAIDs.

**Clinical Response Predictors of Tocilizumab Therapy in Patients with Severe COVID-19**

W. Schmidt,1,2,3, K. Pawlik-Bus,1,2, P. Leszczyński1,1, Jozef Strus Municipal Hospital, Department of Rheumatology and Osteoporosis, Poznan, Poland; Poznan University of Medical Sciences, Department of Rheumatology, Rehabilitation and Internal Diseases, Poznan, Poland; Poznan University of Medical Sciences, Doctoral School, Poznan, Poland

**Background:** Aberrant immune response is hallmark of severe COVID-19, irrespective from viral replication. Immuno-modulatory therapies such as interleukin-6 (IL-6) receptor inhibitors were proven to be beneficial in reducing in-hospital mortality. Yet, it remains unclear which patients can benefit most from such therapy.

**Objectives:** To identify predictors of clinical response to tocilizumab (TCZ) added to dexamethasone in patients hospitalized with severe COVID-19.

**Methods:** We prospectively assessed clinical and laboratory details of 120 patients hospitalized due to severe COVID-19 treated with TCZ (two doses of 8mg/kg 24h apart) in our ward between 1st Feb 2021 and 31st Dec 2021. Severe COVID-19 was defined as SpO2 <94% on room air with ground glass opacities in chest computed tomography (CT). Clinical response was defined as respiratory improvement on day 5 after TCZ infusion compared to day of treatment initiation, no further deterioration and survival. Decision of adding TCZ to dexamethasone as emergency therapy was made collectively by rheumatologists experienced in COVID-19 treatment. Laboratory and clinical parameters from hospital admission day and from TCZ institution day were analyzed. Statistical analysis was conducted with PoIStat v.1.8.2 and predictors were identified in univariate logistic regression.

**Results:** We identified 86 (71.7%) clinical responders and 34 (28.3%) non-responders. 20 (58.8%) of the second group needed ICU admission, 18 (52.9%) died on ICU and 2 patients (5.9%) died on the ward. Responders were significantly younger (mean age 56.1 vs. 63.5 years, p=0.006), had lesser comorbidity burden (median Charlson index 2 vs. 3, p=0.005), lower median lung involvement (50 vs. 70%, p=0.001), higher median baseline PaO2/FiO2 index (203 vs. 106, p<0.001) and less of them needed high-flow oxygen therapy on TCZ initiation day (12.7% vs 42%, p=0.025). Identified predictors of clinical response are shown in Table 1.

**Conclusion:** Administration of TCZ early in severe disease, with moderate IL-6 concentration and low organ damage indices is most beneficial in patients with severe COVID-19, especially in younger patients without respiratory and cardiac comorbidities.

Methods: patients with RD against the new coronavirus infection COVID-19 bases on the population of patients with RD.

Objectives: patients with rheumatic diseases (RD) is one of the main goals of current vaccination against COVID-19 in middle-time perspective. No serious post-vaccination reactions or severe worsening of rheumatic diseases were recorded. Another reports of RD relapse were classified as postvaccination reactions, as classified the presented clinical symptoms as the RD worsening in 1.57% of cases, which resolved within 3-6 months. Relapses of the underlying RD after prolonged slight pyrogenic reaction, myalgias, arthralgias, hypercreatinophosphatemia, which occurred in 10.1136/annrheumdis-2022-eular.4250

**LONGITUDINAL FOLLOW-UP OF HUMORAL RESPONSE AGAINST SARS-CoV-2 AND VIRAL PERSISTENCE IN 96 DMARD-TREATED PATIENTS WITH PREVIOUS COVID-19 INFECTION**

**Background:** Although it prevents severe forms of the disease, vaccination does not completely protect against the occurrence of COVID19 disease. In DMARDs used have been associated with variable humoral response to SARS-CoV-2 virus infection, the impact of their use after SARS-CoV-2 natural infection has not been clearly assessed. Aims: To evaluate immunogenicity and humoral response in autoimmune patients treated with DMARDs with and without B-cell depleting therapy. Methods: We retrospectively analyzed T-cell responses in autoimmune patients treated with B-cell depleting therapy (BD, n=41) and age-matched healthy controls (HCs, n=50) 3-4 weeks after SARS-CoV-2 infection. For the second dose of mRNA vaccination against COVID-19, we isolated PBMCs and stimulated them with a peptide pool covering the spike protein in vitro. Reactive CD4 and CD8 T-cells were determined by staining for IFN-γ, TNF-α and GzmB by flow cytometry. Anti-SARS-CoV-2 antibody assays targeting the receptor-binding domain (RBD) or trimeric S protein (TSP) were performed to elucidate concomitant B-cell responses. Results: We observed significant alterations in anti-SARS-CoV-2 antibody responses in our cohort, the frequency of IFNγ+ and IL-2+ CD4 and CD8 T-cells was similar in BD patients and controls. On the other hand, TNFα+ CD4 T-cells were significantly enriched in healthy controls versus BD patients (p<0.017) and also showed a significant correlation with antibody titer. Overall, the frequency of GzmB+ CD8 T-cells correlated very well with reactivity of T-cell subsets for other cytokines. This effect, however, is lost in the BD cohort. No difference was observed in the frequency of TNFα+ CD8 T-cells between the groups. Only 21 (42%) healthy individuals and 14 (34%) patients showed reactive T-cells for all the cytokines assayed. This observation is mainly explained by a lack of cytokine production in CD8 T-cells in 26 (52%) HCs and 27 (56%) BD patients. In contrast, 22 (44%) HCs and 17 (42%) patients didn't show any IL-2 producing CD8 cells. Of note, only 2 (4%) of HCs showed no GzmB+ CD8 T-cells whereas the number increased to 15 (37%) of BD individuals (p<0.001). In contrast, 42 (84%)
Patients with systemic vasculitis seem more prone to develop mild AEs after the administration of anti-SARS-CoV-2 vaccines in patients with systemic vasculitis. No serious AEs were reported. All the AEs were mild in both groups (malaise was the most frequently reported); AEs in vasculitis patients compared to HC after the second dose were detected after the first dose of vaccination. No significant differences in the frequency of significant higher frequency of AEs in vasculitis patients compared to HC (p=0.015)

Methods: Patients with systemic vasculitis from two Rheumatology centres who had received anti-SARS-CoV-2 vaccine were retrospectively examined. The primary outcome was to evaluate, in this multicentric cohort, the occurrence of a disease flare after the administration of the vaccine, defined as development of clinical manifestations related to vasculitis with a concomitant increase in serum inflammatory markers. As a secondary outcome we aimed at evaluating, in a monocentric cohort of patients with vasculitis, the occurrence of adverse events (AEs) following vaccine administration compared to healthy controls (HC).

Results: We examined 111 patients with systemic vasculitis (n=69 female, n=42 male), with a mean age of 64.3 (± 13) years. Sixty had ANCA-associated vasculitis (AAV), forty-two had Giant-Cell Arteritis (GCA), five had Perienteritis Nodosa, four had Takayasu's arteritis. One-hundred and five patients received a mRNA vaccine and six a viral vector one. A disease flare occurred in only 2 patients (1.8%) after the first dose of a mRNA vaccine: both had AAV (microscopic polyangiitis) and developed a pulmonary disease flare (respiratory failure requiring hospitalization and treatment with high-dose glucocorticoids). Of note, one of these patients had multiple previous comorbidities, including a severe COPD. Multivaried analysis, adjusted for age and sex, performed in a single monocentric cohort of patients with systemic vasculitis [n=60 (39 AAV, 21 GCA), 37 female, 23 male, mean age 71 (± 12.5) years) demonstrated a statistically significant higher frequency of AEs in vasculitis patients compared to HC (p=0.015) after the first dose of vaccination. No significant differences in the frequency of AEs in vasculitis patients compared to HC after the second dose were detected. All the AEs were mild in both groups (malaise was the most frequently reported); no serious AEs were reported.

Conclusion: Our data show a very low incidence of disease flares after the administration of anti-SARS-CoV-2 vaccines in patients with systemic vasculitis. Patients with systemic vasculitis seem more prone to develop mild AEs after the first dose of the vaccine. Taken together, this data suggest a good risk profile for anti-SARS-CoV-2 vaccine in patients with systemic vasculitis.

Disclosure of Interests: None declared

Background: Patients with autoimmune systemic diseases (ASDs) can be counted among frail populations as regards the predisposition to COVID-19 due to the frequent visceral organ involvement and comorbidities, as well as the ongoing immunomodulating treatments.

Objectives: Our long-term multicenter telephone survey prospectively investigated the prevalence, prognostic factors, and outcomes of COVID-19 in Italian ASD patients during the first 3 pandemic waves.

Methods: A large series of 3,918 ASD patients (815M, 3103 F; mean age 59±12SD years) was consecutively recruited at the 36 referral centers of COVID-19 & ASD Italian Study Group. In particular, ASD series encompassed the following conditions: rheumatoid arthritis (n=981), psoriatic arthritis (n=471), ankylosing spondylitis (n=159), systemic sclerosis (n=1,738), systemic lupus (n=172), systemic vasculitis (n=219), and a miscellany of other ASDs (n=178). The development of COVID-19 was reported by means of telephone survey using standardized symptom-assessment questionnaire (1).

Results: A significantly increased prevalence of COVID-19 (8.37% vs 6.49%; p<0.0001) was observed in our ASD patients, while the cumulative death rate revealed statistically comparable to the Italian general population (3.65% vs 2.95%; p=ns). In particular, among the 328 ASD patients complicated by COVID-19, 57 (17%) needed hospitalization while mid-moderate manifestations were observed in the large majority of individuals (83%). In addition, 12/57 hospitalized patients died due to severe interstitial pneumonia and/or cardiovascular manifestations.

Interestingly, a significantly higher COVID-19-related death rate was observed in systemic sclerosis patients compared to the Italian general population (6.29% vs 2.95%; p=0.018). Other adverse prognostic factors to develop COVID-19 were the patients’ older age, male gender, pre-existing ASD-related interstitial lung involvement, and chronic steroid treatment. Conversely, patients treated with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) showed a significantly lower prevalence of COVID-19 compared to those with (3.58% vs 46.99%; p=0.000), as well as the chronic administration of low dose aspirin in a subgroup of SSc patients (with 5.57% vs without 27.84%; p=0.000).

Conclusion: The cumulative impact of COVID-19 on ASD patients after the first 3 pandemic waves revealed less severe than that observed during the first phase of COVID-19, especially with regards to the death rate that was comparable to the Italian general population in spite of the increased prevalence of complicating COVID-19 in the same ASD series.

Ongoing long-term treatments, mainly csDMARDs, might usefully contribute to generally positive outcomes of in this frail patients’ population. Of note, a significantly increased COVID-19-related mortality was recorded in only SSc patients’ subgroup, possibly favoring by pre-existing lung fibrosis. Among different ASD, SSc deserves special attention, since it shares the main pathological alterations with COVID-19, namely the interstitial lung involvement and the endothelial injury responsible for diffuse microangiopathy. Besides SSc, the patients subgroups characterized by older age, chronic steroid treatment, pre-existing interstitial lung disease, and/or impaired COVID-19 vaccine response (1-3), may deserve well-designed prevention and management strategies.

1 VA, Nasonova Research Institute of Rheumatology, Rare Rheumatic Disease and Sjogren’s Syndrome, Moscow, Russian Federation; 2 Heart and Joint Center, Rheumatology, Moscow, Russian Federation; 3 VA, Nasonova Research Institute of Rheumatology, Educational-Medical Department, Moscow, Russian Federation

Background: Data from multiple rheumatological cohorts have shown that treatment with rituximab (RTM) is associated with higher COVID-19 morbidity and mortality. Information about the course of COVID-19 in patients (pts) with Sjögren’s syndrome (SJS) is still lacking.

Objectives: To compare clinical course of COVID-19 in pts with SJS treated with anti-CD20 monoclonal antibody (RTM) and treated with synthetic disease-modifying antirheumatic drugs and low doses of glucocorticoids.  

Methods: Single center observational study. Pts with SJS were screened for SARS-CoV-2 infection anamnesis via telephone interview. Diagnosis of SJS was based on ECR/EULAR 2016 criteria. COVID-19 diagnosis was based on positive PCR test and typical clinical features (CT signs, fever and anosmia). RTM was based on ECR/EULAR 2016 criteria and PsA according to CASPAR criteria were included. Demographic data, disease clinimetry, treatments, vaccination received and post-vaccination adverse events were recorded. We evaluated, according to medical criteria, whether the patient presented a flare disease after vaccination and whether it was mild, moderate or severe. We also evaluated the factors associated with the presence of at least one mild adverse event. Statistical analysis: descriptive statistics were performed, qualitative variables were expressed as frequency and percent-age (%), numerical variables as mean and standard deviation (SD) or median and percenttile25-75. Binary logistic regression was performed using the presence of at least one mild adverse event to vaccination as the dependent variable.

Results: 210 patients were included with a mean age of 45 (SD 15) years. The diagnoses were: AS 50 (23.8%), nra-axSpA 10 (4.8), pSpA 9 (4.3%), PsA 141 (67%), and disease of time evolution in months 109 (SD 96). Regarding comorbidities, the following frequencies were reported: arterial hyper tension 60 (30%), diabetes mellitus 25 (12%), heart failure 4 (2%), asthma/EPOC 15 (7%), inflammatory bowel disease 2 (1%), acute anterior uveitis 20 (9.5%), psoriasis 128 (61%). Six -teen percent (n=33) of the patients had SARS-CoV-2 infection prior to vaccination. Regarding treatments, those used were: antiTNF 88 (42%), Tofacitabin 6 (2.9%), Ustekinumab 2 (1%), Secukinumab 35 (17%), Bekaizum ab 21 (1%), methotrexate 98 (47%), leminotride 7 (3.3), sulfasalazine 7 (3.3), apremilast 1 (0.5%), continuous NSAIDs 26 (12.4%) and NSAIDs on demand 103 (49%). Vaccines received were: Sputnik V 109 (51.9%), Oxford Vaccine, AstraZeneica 63 (30%), Janssen 1 (0.5%), BioNTech Vaccine, Pfizer 1 (0.5%), Sinopharm 33 (15.7%), Moderna 0%, Novavax 0% and others; 3 (1.4%). Thirty-eight percent (n=80) of patients reported having mild post-vaccination symptoms, of which 3.75% did not resolve, 41% resolved with medication and 39% resolved ad integrum without medication. The presence of mild adverse event to the vaccine was associated with lower use of metotrexate (31% vs 56%, p<0.001) and lower age (54 (SD 14) vs 47 (SD 12), p<0.001), and low BMI (25 (4-30.5) vs 29 (25-35.5), p<0.001); while no association was found with sex, diagnosis, comorbidities, treatments, disease activity or vaccines. In the logistic regression analysis all the variables remained independent associated with a lower frequency of presenting a mild adverse event: metotrexate: OR: 0.30, 95% CI 0.15-0.58, p<0.001, age: OR: 0.97, 95% CI 0.95-0.99, p: 0.03; BMI: OR: 0.92, 95% CI 0.95-0.99, p: 0.02. Sixty-one percent (n=129) of patients received the 2nd dose of vaccination, which 27% (n=35) presented mild adverse event and only 1 (0.8%) patient suffered post vaccination disease flare.

Conclusion: Vaccination against COVID19 appears to be safe in this population, with only mild adverse events and low frequency of flare disease. Mild adverse events associated with less use of metotrexate, younger age and lower BMI.

Takayasu arteritis: case series of 15 patients from a tertiary single center

G. Sevik1, S. Kutlu Agaçkıran1, K. Abacı 2, A. Aliyev3, H. Direskeneli4, F. Albaz-Onel5, 1 Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Background: The Coronavirus disease 2019 (COVID-19) has affected more than two hundred million individuals and many risk factors for increased mortality and morbidity in COVID-19 have defined. There are many studies evaluating the effect of immunosuppressants used in inflammatory rheumatic diseases in the course of COVID-19. (1,2) However, fewer data are available on the course of COVID-19 in patients with Takayasu arteritis (TAK).

Objectives: In this study, we aimed to evaluate the characteristics and outcomes of TAK patients with COVID-19.

Methods: A phone survey was conducted among TAK patients that are followed up in our clinic between February 2021 and March 2021. All patients were asked whether they were diagnosed as COVID-19 during the pandemic. The patients who had a history of confirmed COVID-19 were asked about the symptoms, hospitalization status and the treatment received for COVID-19. Information about their chronic diseases were obtained from the patient files.

Results: Among 118 TAK patients, 15 had COVID-19 infection during the first year of pandemic, 13 of them were female and male age was 42.5 ± 12.0 years. None of the patients had been vaccinated before the diagnosis of COVID-19. Nine of the patients were taking prednisone therapy and 3 of them were taking moderate to high doses of glucocorticoids during the infection period. Twelve patients were taking conventionally synthetic disease-modifying antirheumatic drugs (csDMARDs), 7 patients were taking biological disease-modifying antirheumatic drugs (bDMARDs), and 5 patients were taking a combination of csDMARD and bDMARD therapy when they were diagnosed with COVID-19. Two patients were hospitalized; one of them required nasal oxygen support and discharged after 5 days. The other patient was 61 years old and had multiple comorbidities and had admitted to intensive care unit for 5 days. One patient who had a mild COVID-19 disease had pulmonary thromboembolism 2 weeks after the infection and his symptoms resolved after starting anticoagulation therapy. All of the patients fully recovered and had no mortality related to COVID-19.
POS1272  EVALUATION OF DIAGNOSIS, TREATMENT AND OUTCOME RESULTS OF MIS-C PATIENTS

K. Ulu1, Ş. Çağlayan1, T. Coşkun1, R. E. Yigit1, M. Çakan1, B. Sözeri1, 1Health Sciences University, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey

Background: SARS-COV-2 infection, which has become a pandemic worldwide, has led to various results, from mild clinical findings to severe respiratory failure. Multisystem inflammatory syndrome (MIS-C) in children is a rare but severe condition characterized by fever, inflammation, and multi-organ failure, caused by an overreaction of the immune system after SARS-COV-2 infection.

Objectives: This study aims to report the clinical and laboratory findings, diagnostic methods, treatment regimens, and short-term follow-up results of patients diagnosed with MIS-C.

Methods: This is a retrospective observational study from a tertiary pediatric rheumatology center including patients (aged 1 month to 21 years) diagnosed with MIS-C between April 2020-December 2021. Demographic, clinical, laboratory results, and follow-up data were collected through the electronic patient record system and analyzed.

Results: Of the 110 patients included in the study, 67.2% (n=74) were male. Fever was a common finding in all. Macrophage activation syndrome (MAS) was dominant in 28.2% (n=31), while Kawasaki-like disease was observed in 40% of the patients. Gastrointestinal symptoms were found in 64.5% of the cases, rash in 40%, conjunctivitis in 35.5%, lymphadenopathy in 30%, hypotension in 27.3%, cardiac decompensation in 16.4%, bradycardia in 8.2%, neurological findings in 4.5%, and/or coronary artery pathology in 3.6% respectively. Included in the study, 63.6% had lymphopenia, 48.2% had hyponatremia, and 39.1% had hyponatremia. Thirty-eight patients (34.5%) were followed up in the intensive care unit, 19 of them had MAS. Comorbid chronic disease was present in 21.8% of the patients. The mean hospital stay was 12±7.8 days. Hypotension and MAS were the most common indications for admission to the intensive care unit. Intravenous immunoglobulin treatment was applied to 87.2% of the cases, the steroid was given to 70.9%, and anakinra treatment was given to 27.3%, respectively. In the outpatient follow-up, it was determined that the coronary abnormalities had regressed entirely. While 97.3% of the cases recovered without sequelae, three died. Two patients who died had the comorbid disease. While there was no significant difference in terms of Kawasaki-like disease and gender in those followed up in the intensive care unit (p=0.25, p=0.81), D-dimer was higher, and the mean age was greater (p=0.08, p=0.02). No statistical correlation was found between those with Kawasaki-like disease regarding age and gender (p=0.058 p=0.068).

Conclusion: Multisystem inflammatory syndrome in children may lead to severe cardiac findings and intensive care requirements at admission and hospital follow-up. The majority of MIS-C-related findings resolve completely until discharge or in short-term follow-up. Although the pathogenesis and treatment plan of the disease has been largely clarified, follow-up studies are needed in terms of long-term prognosis and relapse probabilities.

POS1274  A SINGLE CENTER COVID-19 VACCINE EXPERIENCE IN FAMILIAL MEDITERRANEAN FEVER PATIENTS

S. C. Güven1, O. Karakaş1, E. Atalar1, H. E. Konak1, P. Akyüz Daşlı1, E. Eyakan Erdogan1, B. Armagan1, K. Gök1, I. Dogan1, Y. Maras1, A. Erden1, S. Erteng1, O. Kucuk1, A. Omm1, 1Ankara City Hospital, Rheumatology Clinic, Ankara, Turkey; 10Yıldırım Beyazıt University Medical School, Internal Medicine, Division of Rheumatology, Ankara, Turkey; 1Health Sciences University, Ankara City Hospital, Rheumatology Clinic, Ankara, Turkey

Background: To prevent COVID-19 disease SARS-Cov-2 vaccines put into use worldwide with emergency use authorizations despite ongoing safety concerns. Since pyrin mediated inflammasome response is dysregulated in FMF, exposure to SARS-Cov-2 proteins via vaccination may potentially trigger inflammation, leading to attacks after vaccination. In our FMF patients we aimed to analyze the frequency of adverse events and side effects related to vaccination.

Methods: Data regarding, number of vaccine doses, types of vaccines (CoronaVacc or BNT162b2) presence of AE and/or AF attacks after any vaccine dose within a month, history of COVID-19 infection before or after vaccination, adherence to FMF treatment during vaccination were collected from hospital database or via telephone.

Results: A total of 161 vaccinated FMF patients were included. Mean ± SD age was 40.5 ± 11.7 years. 57.1% was female. 10.6% of the patients had chronic kidney disease and 9.3% had amyloidosis. Most common MEFV mutations were M694V heterozygous (27%) and M694V homozygous (21%). 93.2% of the patients were under colchicine, 21.8% under anti-interleukin 1 agents, 2.5% under TNF-α inhibitors. 96.3% of the patients adhered to FMF treatment during vaccination. Vaccination properties and data regarding adverse events are presented in Table 1. 57.8% of our patients suffered from an AE/attack after a vaccine dose. Number of patients with AE after BNT162b2 was significantly higher (p<0.001). None of the patients had severe AE. 39 patients had COVID-19 infection prior to primary vaccination. 61.5% of these suffered from an adverse reaction/attack after vaccination, in comparison to 56.6% of the patients without previous COVID-19 infection prior to vaccination.

POS1273  EVALUATION OF THE SAFETY PROFILE OF COVID-19 VACCINES IN CHILD PATIENTS USING BIOLOGICAL THERAPY

B. Sözeri1, R. E. Yigit1, 1University of Health Sciences, Umraniye Education and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey

Background: Coronavirus vaccines have been widely applied all over the world after the considerable pandemic. There are inactivated vaccines and mRNA virus vaccines in our country. There is no clear guideline for the vaccination programs of patients receiving immunosuppressive therapy, especially childhood.

Objectives: For this reason, we wanted to evaluate the frequency of side effects developed after covid-19 vaccine in pediatric patients diagnosed with rheumatic disease using biological therapy and nonbiologic disease modifying drugs

Methods: A total of 226 patients over the age of 12, who were followed up in the pediatric rheumatology clinic of the University of Health Sciences, Training and Research Hospital, using biological therapy and were vaccinated against Covid-19, were included in the study. The standard questionnaire forms were filled in face-to-face after each administration for both vaccines. The patient, who had any serious side effects, was followed up in the hospital.

Results: Of the 226 patients included in the study, 97 were male and 128 were female. Their mean age was 16.4 ± 2.4. It was determined that 88.4% (n=200) of the patients had mRNA vaccine and 11.6% (n=26) had inactivated vaccine. 105 of the patients were using biologic drugs during vaccination. Of these, 63 (27.9%) patients were treated with anti-TNF drugs (46 adalimumab, 10 etanercept, 6 infliximab), 32 patients were anti-il-1 (30 canakinumab, 2 anakinra), 4 patients were anti-il-6, 3 patients were anti-il-17, 3 patient was receiving abatacept and 1 patient was receiving rituximab. 121 patients were using DMARDs. Of these, 61 were using colchicine, 26.5% (n=60) of the patients had covid infection before vaccination. Side effects were observed in 180 of our patients. No side effects were observed in 46 patients. Pain at the injection site was the most common among them, 72.6% (n=164), Headache was seen in 16.8% (n=38) of the patients, myalgia in 18.1% (n=41), fever in 16.4% (n=37) and arthralgia in 6.6% (n=15). The frequency of serious adverse events was determined as 0.9% (n=2). Both patients were followed up in the ward. When the patients were compared in terms of covid infection and gender, there was no significant difference in the frequency of side effects. When the vaccines were compared, the incidence of side effects in the mRNA vaccine was statistically significantly higher (p=0.001). Pain at the injection site was significantly less frequent in the inactivated vaccine (p=0.004). In terms of drug distribution, there was no significant difference in the frequency of side effects between patients using biologic drugs and DMARDs. There was no statistically significant difference in the frequency of side effects when the patients using dexamethasone were compared as colcicine and other dmds.

Conclusion: In our study, we have shown that the use of vaccines in individuals with adolescent rheumatological diseases is safe and that the biological treatments used by the patients do not cause an increase in the risk of vaccine side effects. In addition; We have shown in our study that the side-effect profile of the inactivated vaccine used in our country is milder than the mRNA vaccine, and that it affects daily life less. Another result of our study was that anti-TNF drugs could cause a decrease in pain sensation due to the relationship of anti-TNF with pain pathways.

Disclosure of Interests: None declared

prior COVID-19 infection (p=0.584). When patients with and without AEs/attacks were compared, no significant differences were observed regarding age, gender, body mass index, comorbidities, FMT treatments and total vaccine doses.

Conclusion: We observed considerable number of FFM patients suffered from vaccine related AEs/attacks, particularly with BNT162b2. However, no serious AE was detected. Demographics, clinical characteristics and prior history of vaccination did not significantly affect AE attack occurrence.

**A RETROSPECTIVE STUDY ON UVEITIS FLARES FOLLOWING COVID19 VACCINATION: SHARING EXPERIENCE FROM A TEACHING HOSPITAL COMBINED RHEUMATOLOGY AND UVEITIS CLINIC**

A. Birchall1, S. Byravan2, P. Kumarr3, A. Mooorthy4, 1Leicester Medical School, College of Life Sciences, Leicester, United Kingdom; 2University Hospitals of Leicester, Rheumatology, Leicester, United Kingdom; 3University Hospitals of Leicester, Ophthalmology, Leicester, United Kingdom; 4University Hospitals of Leicester, Rheumatology, Leicester, United Kingdom

Background: Uveitis is a sight threatening disease caused by inflammation of the intraocular tract of the eye. Uveitis is a manifestation of many autoimmune conditions and is associated with seronegative axial spondyloarthritides, reative arthritis, Behget’s disease, inflammatory bowel disease, and psoriatic arthritis. Acute anterior uveitis is the most common presentation and is most commonly idiopathic or associated with the HLA-B27 gene (around 20% of cases). Studies have shown that anterior uveitis frequently recurs in patients after it has previously remitted. 1 Patients suffering from autoimmune conditions are frequently prescribed immunosuppressant drugs to control their illness, thus leaving them more susceptible to bacterial and viral illnesses, including severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2).

Previous studies have shown that some patients suffer exacerbation of their autoimmune condition after coronavirus vaccination, including uveitis.[2] We aim to evaluate our cohort of patients suffering from autoimmune conditions treated at Leicester Uveitis Service at Leicester Royal Infirmary and explore any proposed link.

Objectives: To assess if COVID19 vaccination is associated with uveitis flares in immunosuppressed patients.

Methods: A retrospective study, to determine if patients diagnosed with autoimmune conditions suffered from uveitis following COVID-19 vaccination. A data collection sheet was used to document demographic and clinical data: age, sex, ethnicity, autoimmune condition, dates of COVID-19 vaccination(s), type of vaccine, medication at the time of vaccine, symptoms of autoimmune recurrence, date of uveitis onset and number of days between uveitis onset and latest vaccine. We used an already existing uveitis database with an active register of 2346 patients, of which 246 were on immunomodulation.

Results: After reviewing the first 50 patients on immunosuppression for uveitis, we found a total of 4 patients had a uveitis flare despite tight control previously; 3 were female and 1 male, their median age was 39.5 years. They experienced a recurrence of uveitis in the last 6 months. Of these 4 patients 3 were on synthetic DMARDS (2 mycophenolate motefil, 1 azathioprine), 1 was on steroids and 1 was on a biological DMARD (adalimumab). 2 of the patients suffered from posterior uveitis and 2 from anterior uveitis. All the 50 patients had been vaccinated against COVID19 however there was no clear record of booster dose.

Conclusion: Our study showed that of 50 immunosuppressed patients, 4 had a uveitis flare following vaccination. Clinicians need to be aware of uveitis flares in rheumatology patients following vaccination. This is a small retrospective analysis of our cohort however a large observational study on flare of uveitis following COVID-19 primary vaccination and booster vaccination would be useful to get meaningful data.

HUMORAL IMMUNE RESPONSE TO SARS-COV-2 VACCINE IN RITUXIMAB-TREATED PATIENTS

E. Flores-Fernández1, I. Vázquez-Gómez1, C. Valera-Ribera2, P. Andújar-Braza1, E. Valls-Pascual1, J. M. Nogueira Coito3, Á. Martínez-Ferrer1, D. Ybáñez-García1, J. J. Alegre-Sancho1, 1Doctor Peset University Hospital, Rheumatology, Valencia, Spain; 2Doctor Peset University Hospital, Microbiology, Valencia, Spain

Background: Vaccination against SARS-CoV-2 has shown efficacy and safety in patients with chronic inflammatory rheumatic disease, similar to the general population. However, in patients treated with rituximab (RTX) it is known that usually have a lower vaccination response rate (1-2), and recent studies suggest that it also happens with the new SARS-CoV-2 virus (3), which entails an increased risk of hospitalization and mortality in this specific group of patients.

Objectives: To describe humoral immune response to SARS-CoV-2 vaccine in rituximab-treated patients after one and six months from the vaccination, and study if there is any other factor associated with a lower response rate.

Methods: Prospective analysis of a cohort of patients treated with RTX who received the SARS-CoV-2 vaccine between the months of April and October 2021. Demographic and medical data were collected through electronic medical records. Blood tests and serologies with levels of antibodies against SARS-CoV-2 were performed one and six months after having received the vaccine against SARS-CoV-2. The administration of a booster dose of the vaccine was recorded. A descriptive and statistical analysis of the data was carried out using the SPSS program.

Results: From a cohort of 41 patients, of whom 81.4% were women with a mean age of 56 (13.4 SD) years, vaccine response rate was only 36.7% after a 6-month follow-up. The 88.4% of them received a booster dose of the vaccine, but this failed to produce a vaccine response in any of the patients who had not developed it with the previous ones. One patient became infected after receiving one dose of the vaccine and failed to develop a serological response either. Hypogammaglobulinaemia was associated with a statistically significant lower probability of vaccine response (p=0.04). A trend of lower vaccination response rate was observed in patients who had received the last cycle of RTX in the 6 months prior to vaccination (p=0.058). In addition, the antibody levels developed one month after vaccination were statistically significantly correlated with the time between the last RTX cycle and vaccination (p=0.014) and also with CD19 B cells levels prior to vaccination (p=0.001); however, there was no correlation with the antibody levels detected at the 6-months serology. No statistically significant differences were found in relation to the number of previous cycles of RTX, concomitant treatment with synthetic disease-modifying drugs (DMARDs) or corticosteroids.

Conclusion: In our sample, after a 6-month follow-up only 36.9% achieved a vaccine response against SARS-CoV-2, which did not improve despite the administration of a booster dose. Hypogammaglobulinemia, the time between the last RTX cycle and vaccination (at least 6 months), and previous CD19 B cells levels significantly influenced in the development of a humoral response to the vaccine.

POS1277
LONGTERM IMMUNOGENICITY AND TOLERABILITY OF A 3RD DOSE OF AN MRNA Anti-SARS-COV-2 VACCINE IN RA PATIENTS WITH AN INADEQUATE RESPONSE TO A PREVIOUS STANDARD TWO DOSE REGIME
K. Schmiedeburg1, I. A. Abel2, N. Vuilleumier3, S. Pagano3, J. Von Kempis1, A. Rubbert-Roth1, 1Rheumatology Clinic, Kantonsspital St.Gallen, St.Gallen, Switzerland; 2Zürich, Institute of Medical Virology, University of Zurich, Zürich, Switzerland; 3Geneva, Laboratory Medicine Division, Geneva, Switzerland

Background: Lower seroconversion rates have been reported in patients with rheumatic diseases receiving immunomodulatory therapies following a standard mRNA-based vaccine regimen. Data with regard to immunogenicity and safety of a 3rd vaccine dose in this patient population is limited.

Objectives: We aim to study immunogenicity, vaccine associated side effects and the occurrence of flares in RA patients unresponsive to a standard vaccine regimen eligible for a 3rd vaccine dose.

Methods: RA patients who had a low or absent anti-S response after 12 (Cohort A) or 24 weeks (Cohort B) following a standard vaccination regimen received a 3rd vaccine dose. Temporary discontinuation of DMARD therapy was recommended. Serum samples were collected before, 2, 12, and 24 weeks after the 3rd vaccine dose. Quantitative measurement of anti-S was performed using the Roche Elecsys Anti-SARS-CoV-2 spike subunit assay: Neutralizing activity (NT50) against Wuhan WT and -,-,- variants was assessed by using a HIV-based pseudovirus system.

Results: Baseline characteristics are shown in Table 1. 45/47 patients temporarily discontinued DMARD therapy: Mtx and JAKi were paused one week before/after 2 weeks after the 3rd vaccine dose, bDMARDs were paused 2 weeks before/after 2 weeks after the 3rd dose. Local pain and/or systemic vaccine associated side effects following the 3rd vaccine dose were reported in 12/17 (71%) in Cohort A, and 10/29 (35%) patients in Cohort B (p = 0.018). Flares were defined as loss of low disease activity (LDA), subsequent to the 3rd vaccine dose and occurred in 17/47 (36%) patients (p = 0.0332) with comparable frequencies defined as loss of low disease activity (LDA), subsequent to the 3rd vaccine dose and occurred in 17/47 (36%) patients (p = 0.0332) with comparable frequencies in both cohorts (41% Cohort A, 33% Cohort B (NS)).

Low or absent anti-S titers were confirmed before the third vaccination (Cohort A: median 19.5 U/ml, IQR 0.47-57; cohort B: median 65.9 U/ml, IQR 22-154) (p = 0.0018). Two weeks after the 3rd dose, a rapid and significant increase in anti-S were observed in 12/17 (82%) and 25/28 (89%) patients (Cohort A: median 2500 U/ml, IQR 798-2500; Cohort B: median 2500 U/ml, IQR 2500-2500) (NS). High levels of anti-S were maintained in the majority of patients 55% (11/20) until week 12 in both cohorts (Figure 1). NT50 against Wuhan-WT and other variants was assessed in 21 patients 2 weeks after the 3rd vaccine dose revealing a low or absent NT50 against delta in 38% of patients despite a median anti-S response of 2500 U/ml (IQR 798-2500). 14/21 patients had peak anti-S titres of 2500 U/ml, of those 12/14 developed a strong NT50 response against the delta variant.

Conclusion: Our data demonstrate that a 3rd vaccine dose, maybe complemented by temporary discontinuation of DMARD therapy, may lead to a rapid increase in anti-S antibodies when using a homologous vaccine and profound neutralizing activity in the majority of RA patients previously unresponsive to a standard two dose regimen. This seems to be independent of the interval to the previous standard vaccine regimen. As flares occurred in 36% of all patients, the necessity and length of DMARD discontinuation should be explored in more detail to balance between sustained control of disease activity and optimized vaccine induced immune responses.

POS1278
EXCELLENT PROGNOSIS OF RHEUMATIC MANIFESTATIONS FOLLOWING COVID-19 VACCINATION: 7 MONTHS FOLLOW-UP DATA
M. Gasparotto1, 1Padua University Hospital, Rheumatology, Padova, Italy

Background: It is well established that severe forms of SARS-CoV2 infection can induce a massive cytokine storm, which may disrupt the immune system stability and conceivably stimulate the development of reactive manifestations through a molecular mimicry process. Likewise, anti-COVID-19 vaccines, which have so far proved an excellent tolerability and safety profile, are able boost the immune response via different biologic technologies and adjuvant combinations possibly facilitating, in predisposed subjects, the onset of inflammatory or even autoimmune manifestations.

Objectives: We report a case series of suspected rheumatic adverse events following immunization (AEFI) associated with anti-COVID-19 vaccine. We focused our attention on the prognosis of these patients by analysing their available follow-up data.

Methods: We included patients evaluated at first-aid rheumatologic consultancy and at rheumatologic outpatient and inpatient clinic at Padua University Hospital between May and September 2021 presenting with new-onset rheumatic manifestation or a flare of an underlying rheumatic disease within 30 days after receiving an anti-COVID-19 vaccine dose. Inclusion and exclusion criteria were in accordance with the World Health Organization guidelines for AEFI surveillance. All patients were re-evaluated in January 2022: telemedicine or face-to-face visit. Response to therapy was classified as complete, good or absent according to the clinician’s judgment based on clinical examination, patient’s reporting and analysis of laboratory data.

Results: We identified 30 cases of suspected rheumatic AEFI reported in Table 1. Comprehensively the most common manifestations were inflammatory arthritis (40.0%), rheumatic polyarthritis (26.7%) and adult-onset Still disease (13.3%). Among patients with an underlying rheumatic disease we recorded an AOSD flare, a rheumatoid arthritis flare with involvement of hands proximal interphalangeal joints, one case of wrist arthritis in a patient with psoriatic arthritis, one of aortitis in a patient with large vessels vasculitis, one case of polyarthritis in undifferentiated connective tissue disease and a nephritis flare in a patient with systemic lupus erythematosus. Treatment for the suspected AEFI was based on systemic glucocorticoids (GC) alone (63.3%), systemic GC plus IL-1R antagonists (13.3%), non-steroidal anti-inflammatories (NSAID) alone or in combination with GC in 22.2% of cases.
autoinflammatory drugs (13.3%), intra-articular GC (6.6%), colchicine (3.3%) and non-steroidal anti-inflammatory drugs (13.3%). At last follow-up contact (7.8±1.5 months) 26 patients (89.6%) were classified as complete responders. Eleven of them (42.3%) withdrew therapy without experiencing recurrence of disease manifestation. One patient with lupus nephritis had a proteinuric flare after the first BNT162b dose; he showed an initial good response to increased glucocorticoid therapy but had a new 24h proteinuria increase at second follow-up visit three months later requiring implementation of immunosuppressive therapy. Another patient with AOSD was in remission at last FU visit in December 2021 but required hospitalization in January 2022 for disease relapse due to a suspected gastrointestinal infection. Finally, one patient hospitalized for a seronegative polyarthritis after the first BNT162b dose achieved complete remission at last available contact (one month after hospital discharge) but was then lost in follow-up.

Conclusion: After a mean follow-up of 7.8±1.5 months nearly all of patients showed a complete/good response to standard therapy and about half of them withdrew the treatment without losing the remission status.

REFERENCES:
was detected in 5 (13.9%) patients; mean lymphocyte count was 1080 ± 363. Data about the treatment could be reached in 34 patients. Antiviral therapy was prescribed in 25 (69.4%) patients (favipiravir, n=22; and oseltamivir, n=3). Antibiotics were given to 6 (16.7%) patients, and 6 (16.7%) received hydroxychloroquine. Parenteral steroids were administered to 2 patients during the hospitalization. Six (16.7%) patients required hospitalization, and 2 (5.6%) required oxygen support, non-invasive mechanical ventilation, and one of them followed in the intensive care unit. Twenty-two patients were on anakinra treatment, and none of them required additional dose. Only 1 patient, a 61-year-old male patient with a history of lung lobectomy and renal transplantation, received tocilizumab due to macrophage activation syndrome, and he later died of sepsis. This patient was on anakinra until 2 years before, and it was discontinued due to an allergic reaction. Only 4 patients had a history of vaccination before COVID-19, and none of them developed pneumonia and required hospitalization. Six patients had FMF attacks after recovering from COVID-19. None of the patients developed thromboembolism and secondary bacterial infections.

Conclusion: This survey identified 36 biologic b-DMARD receiving FMF patients, who had COVID-19. All but 1 patient had complete recovery, and b-DMARD usage did not negatively affect the COVID-19 course. None of the patients currently on anti-IL-1 or anti-TNF had a worse outcome. Based on these observations, it can be suggested that refractory FMF patients can continue their b-DMARD treatments when they had COVID-19.

EFFECTS OF ANTI-SARS-COV-2 VACCINATION ON SAFETY AND DISEASE EXACERBATION IN BEHCET’S DISEASE PATIENTS: A SINGLE CENTRE STUDY

H. Apaydın1, A. Erden1, B. Armagan2, S. C. Güven2, H. E. Konak3, Y. Alıyı3, M. Kaygız4, B. Polat1, A. Omma5, O. Küçükahin1, 1Ankara City Hospital, Rheumatology, Ankara, Turkey; 2Ankara Yıldırım Beyazıt University, Rheumatology, Ankara, Turkey; 3Ankara City Hospital, Internal Medicine, Ankara, Turkey; 4University of Health Sciences, Rheumatology, Ankara, Turkey

Background: Pandemic of coronavirus disease 2019 (COVID-19), caused by severe acute respiratory syndrome – coronavirus 2 (SARS-CoV-2), has become a major global health issue since December 2019. Patients affected by systemic rheumatic disorders represent a high-risk group for severe COVID-19. During the COVID-19 pandemic, vaccination has become one of the cornerstones of the fight against this disease. The EULAR and the ACR recommend vaccination in all patients with rheumatological diseases. There is a paucity of data regarding the safety of COVID-19 vaccines in patients with rheumatic and musculoskeletal diseases such as Behçet’s disease (BD).

Objectives: In this study, we evaluated the safety and tolerance of COVID-19 vaccines, post-vaccine BD exacerbation and discontinuation of BD therapy in BD patients by retrospectively examining our BD cohort, from the patients’ perspective.

Methods: We retrospectively evaluated 450 BD patients followed in our clinic using hospital records and formed a retrospective cohort of patients who met the International Study Group (ISG) criteria. COVID-19 vaccination status, vaccine type (inactivated or mRNA), post-vaccine side effects and exacerbations, drug compliance, change in treatment after exacerbation, and post-vaccine COVID-19 occurrence were evaluated by interviewing patients over the phone or face to face. Patient demographics, comorbid diseases, and active BD treatments were collected from our hospital records. Disease activity was measured using the BSAS and the BDCAF form.

Results: Our cohort consisted of a total of 450 BD patients. Two hundred and eighty seven patients had at least 1 dose of the COVID-19 vaccine. Of the total number of COVID-19 vaccines (n= 639), 379 (59%) were Pfizer-BionTech vaccines and 257 (41%) were Sinovac vaccines. The side-effects after first, second, third and fourth vaccine dose were 151 (52.6%), 135 (47%), 29 (10.1%) and 3 (1%), respectively. Behçet flare after first, second, third and fourth vaccine dose were 151 (52.6%), 135 (47%), 16 (22.9%) and 3 (33.3%), respectively. The most common side effects were arm pain, joint pains or arthritis, malaise, while the most common BD exacerbations were arthralgia or arthritis, oral aphthae, papulopustular eruption Pfizer-BionTech and Sinovac vaccines were compared in terms of side effects, there was a significant difference after the 1st (p<0.001) and 2nd doses (p<0.001), but no significant difference was found at the 3rd dose (p=0.393) (Table 1). When Pfizer-BionTech and Sinovac vaccines were compared in terms of BD exacerbations, no significant difference was found after the 1st (p=0.417), 2nd (p=0.465) and 3rd doses (p=0.565). Only 4 patients (13%) developed exacerbation with organ involvement after COVID-19 vaccine. Anterior uveitis developed in 2 patients, panuveitis in 1 patient, panuveitis and deep vein thrombosis in one patient.

Conclusion: In conclusion, our study shows that the COVID-19 vaccine is well tolerated in BD patients, and that post-vaccine Behçet’s exacerbation predominantly includes mucocutaneous and articular findings, and exacerbations with organ involvement are rare. According to the COVID-19 vaccines, although the side effects were more in the Pfizer-BioNTech group compared to the Sinovac group, there was no difference between Behçet’s flare compared to the COVID-19 vaccines.

Disclosure of Interests: None declared

Background: The interplay between humoral and cellular response after vaccination against SARS-CoV-2 in patients (pts.) with autoimmune inflammatory rheumatic diseases (AIRD) remains unknown.

Objectives: To investigate the impact of different immunosuppressive therapies on the development of humoral and cellular immune responses to full 2-dose SARS-CoV-2 vaccination in AIRD pts. with stable low disease activity.

Methods: The immune reactivity to COVID-19 vaccination was investigated in a prospectively recruited AIRD cohort with rheumatoid arthritis, axial spondyloarthritis or psoriatic arthritis who received a therapy with IL-17i, TNFi, JAKi or MTX (alone or in combination). Almost all patients received mRNA-based vaccine, only 4 patients had a heterologous scheme. Anti-Spike(S) antibodies(ab.) and sera neutralizing capacity (neutralization dilution 50; ND50) were measured 4 weeks after the first (prime+4w) and 4 weeks after the second vaccination (boost+4w). Vaccine-specific cellular immunity was evaluated by quantifying expression of activation markers on T cells as well as their production of key cytokines, at prime+4w and boost+4w.

Results: Overall, a total of 92 pts. were included in the final cohort, 31 (33.7%) pts. were on TNFi, 24 (26.1%) on IL-17i on IL-17i, 24 (26.1%) on JAKi, each group encompassing pts. receiving drug inhibitors alone or in combination with MTX. 13 (14.1%) were treated with MTX alone. The median time between the vaccination and blood sampling was 31 [IQR: 28-34] days after prime+4w and 28 [IQR: 28-28] days after boost+4w. Although at prime+4w only 34/90 (37.8%) of pts. presented neutralizing ab., the majority (86/91, 94.5%), developed them at boost+4w. The highest neutralization titer developed the pts. on IL-17i both at prime+4w (74 [IQR: 73-91]) and boost+4w (798 [IQR: 511-1344]), while no statistically significant differences were found in the neutralization titer at boost+4w for the TNFi, JAKi, and MTX groups: 207 ND50 [IQR: 134-441] for TNFi, 30 ND50 [IQR: 2.5-5.0] for JAKi, and 30 ND50 [IQR: 2.5-5.0] for MTX.

Discussion: Overall, a total of 92 pts. were included in the final cohort, 31 (33.7%) pts. were on TNFi, 24 (26.1%) on IL-17i on IL-17i, 24 (26.1%) on JAKi, each group encompassing pts. receiving drug inhibitors alone or in combination with MTX. 13 (14.1%) were treated with MTX alone. The median time between the vaccination and blood sampling was 31 [IQR: 28-34] days after prime+4w and 28 [IQR: 28-28] days after boost+4w. Although at prime+4w only 34/90 (37.8%) of pts. presented neutralizing ab., the majority (86/91, 94.5%), developed them at boost+4w. The highest neutralization titer developed the pts. on IL-17i both at prime+4w (74 [IQR: 73-91]) and boost+4w (798 [IQR: 511-1344]), while no statistically significant differences were found in the neutralization titer at boost+4w for the TNFi, JAKi, and MTX groups: 207 ND50 [IQR: 134-441] for TNFi, 30 ND50 [IQR: 2.5-5.0] for JAKi, and 30 ND50 [IQR: 2.5-5.0] for MTX.
respectively. Other affected systems were respiratory (73.7%), cardiovascular (63%), lymphoid organs (52.6%), musculoskeletal (47%), genito-urinary (31.6%) and neurological (26.3%). Laboratory findings can be found in Table 1. Thirty-six percent were admitted in intensive care unit for a median duration of 6 days (IQR 4-9). 42.1% needed respiratory support, 87.5% with supplemental oxygen therapy, 62.5% with mechanical ventilation and 12.5% with non-invasive ventilation. All patients received intravenous (IV) immunoglobulin, 52.6% IV corticosteroid (CS) pulses and 78.9% IV and oral CS. Other treatments included acetylsalicylic acid (n=18), heparin (n=8) and antibiotic therapy (n=19) - Table 3. Seventeen fully recovered and 2 had sequelae: one of them with coronary artery aneurysms and other exertional dyspnea.

**THE COURSE OF NOVEL CORONAVIRUS DISEASE 2019 (COVID-19) IN PATIENTS WITH IG4G-RELATED DISEASE TREATED WITH RITUXIMAB**

E Sokol¹, A. Torgashina¹, V.A. Nasonova Research Institute of Rheumatology, Rare Rheumatic Diseases and Sjogren’s Syndrome, Moscow, Russian Federation

**Background:** The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) disease 2019 (COVID-19) raised many questions and concerns about the safety of different immunosuppressive agents in patients (pts) with rheumatic diseases during the pandemic. There is some data about anti-B-cell depletion strategies could lead to more severe disease course. Rituximab (RTM) is one of the most effective, safe and well tolerated agents in IgG4-related disease (IgG4-RD) treatment. Information about the course of COVID-19 in pts with IgG4-RD is lacking.

**Objectives:** To examine clinical course of COVID-19 in pts with IgG4-RD treated with anti-CD20 monoclonal antibody (RTM).

**Methods:** Single center observational study. We searched in our clinical base from 2019 to 2021 years for pts with IgG4-RD, treated with RTM within this period. Diagnosis of IgG4-RD was based on comprehensive diagnostic criteria (H. Umehara, 2019). Thirty-six percent were admitted in intensive care unit for a median duration of 6 days (IQR 4-9). 42.1% needed respiratory support, 87.5% with supplemental oxygen therapy, 62.5% with mechanical ventilation and 12.5% with non-invasive ventilation. All patients received intravenous (IV) immunoglobulin, 52.6% IV corticosteroid (CS) pulses and 78.9% IV and oral CS. Other treatments included acetylsalicylic acid (n=18), heparin (n=8) and antibiotic therapy (n=19) - Table 3. Seventeen fully recovered and 2 had sequelae: one of them with coronary artery aneurysms and other exertional dyspnea.

**PAUNLAIY CERVICAL INVOLVEMENT AND FEBRILE TORSO COLLIS: A FREQUENT SYMPTOM OF PIMS**

A. Schvartz¹, R. Kechiche², F. Bajolle³, S. Poignant⁴, B. Basmai⁵, C. Pajot⁶, L. Morin⁷, C. Adamsbaum⁸, N. Matsa⁹, M. Hofer¹⁰, I. Koné-Paut¹,², G. Galezò³ on behalf of French Covid-19 Paediatric Inflammation Consortium.

**Background:** Pediatric Inflammatory Multisystem Syndrome associated to SARS-CoV2 (PIMS) happens 4 to 6 weeks after SARS-CoV2 infection [2]. Its early diagnostic recognition as well as its early management is important to avoid cardiac complications related to this pathology.

**Objectives:** To highlight a frequent symptom in PIMS and improve its therapeutic care.

**Methods:** The JIR Cohort database, an international registry collecting data on patients with pediatric inflammatory diseases, was consulted to include patients between 03/15/20 and 12/31/2021.

**Results:** Of the 140 patients in whom a diagnosis of PIMS was retained, we present a series of 38 patients (27%) who presented at diagnosis or during evolution, febrile torticollis or painful cervical involvement. These patients were on average 8.2 years old (0.6-15.2). The proportion of boys was 14 out of 38 (37%). Twenty-four patients out of 33 (73%) were hospitalized in intensive care. Ten patients out of 38 (26%) underwent cerebral imaging. 5 (50%) had abnormalities such as collection or infiltration of the soft tissues. At the therapeutic level, 27/38 patients (71%) received corticosteroid therapy, 33/38 (87%) immunoglobulins, and 26/38 (68%) antibiotic therapy.

**Conclusion:** PIMS is a pathology with significant clinical heterogeneity and severe consequences in case of delay in therapeutic management. In this epidemiologic context, it is important to consider PIMS in any patient with febrile torticollis, especially if he does not respond to antibiotics.

**IMMUNOGENICITY AND SAFETY OF THE CHADOX 1 COVID-19 VACCINE IN PATIENTS WITH AUTOIMMUNE DISEASES AND HEALTHY CONTROLS: DATA FROM SAFER STUDY**

**Background:** Patients with autoimmune inflammatory diseases (AID) have been prioritized for urgent vaccination to mitigate COVID-19 risk. However, few studies in the literature assessed the immunogenicity and safety of the COVID-19 vaccine in patients with AID.

**Objectives:** In this context, the present study aims to evaluate the immunogenicity and safety of the vaccine against COVID-19 in patients with AID.

**Methods:** These data are from “Safety and efficacy on COVID-19 Vaccine in Rheumatic Disease” - SAFER study, a Brazilian multicentric prospective phase IV trial to evaluate COVID-19 Vaccine in AID, in the real-life, in Brazil. Immunogenicity and adverse events (AE) from a single center were assessed, after 2 doses of ChAdOx1 (Oxford/AstraZeneca), 8 weeks of interval, in patients with AID and healthy controls (HC). Inclusion criteria were age ≥ 18 years and fulfilling criteria according to international classification for AID. Exclusion criteria: pregnancy, previous severe AE to any vaccine, other immunosuppression causes. Stratification of post-vaccination AE was performed using a diary, filled out daily and returned at the end of 28 days for each dose. Participants were followed up through blood collection for measurement of IgG antibodies against SARS-CoV-2 spike receptor-binding domain by chemiluminescence (SARS-CoV-2 IgG II Quant assay. Abbott Laboratories, Abbott Park, IL, USA) at baseline and 28 days after the second dose. The seropositivity was defined for titers ≥50 AU/mL. Quantitative analyses were presented as observed frequency, percentage, central tendency, and variability measurements. The sample’s normal distribution was verified through the Shapiro-Wilk test. The Kruskal-Wallis test and the post-hoc Dwass-Steel-Critchlow-Flinger pairwise comparisons test were used to compare the IgG-S titers between the groups through the evaluation period. Categorical data were addressed using the Fisher’s exact or Chi-squared ($\chi^2$) test. An alpha level of 5% significance was used in all analyses.

**Results:** A total of 377 volunteers with AID and 50 HC were included in the study. Patients with spondyloarthritides (N=64), systemic lupus erythematosus (N=63), rheumatoid arthritis (N=61), primary Sjögren’s syndrome (N=61), vasculitis (N=31), systemic sclerosis (N=14), inflammatory myopathy (N=9), Crohn’s disease (N=49), ulcerative colitis (N=11) and other systemic AID (N=12) were evaluated. Both groups had female predominance (73.5% vs. 74.0%, p=0.937) and were homogeneous for age (43.5 vs. 41.7, p=0.308). The seroconversion among those not reactive (IgG-S negative at baseline) (46 HC and 191 AID), 28 days after second dose was 97.1% for spondyloarthritis (p=0.425), systemic lupus erythematosus 88.2% (0.006), rheumatoid arthritis 93.5% (0.158), primary Sjögren’s syndrome 92.6% (0.133), systemic sclerosis or inflammatory myopathy 471% (0.001), inflammatory bowel disease 100% (0.999) and vasculitis 80% (0.006), while in healthy control was 100%. In comparison with HC, there was a statistically significant difference in IgG-S titles only in systemic sclerosis or inflammatory myopathy (1.694 AU/ml vs. 3.719 AU/ml; p=0.006). Both groups only presented mild AE. Pain at the injection (86.7% vs. 78.4%, p=0.239), headache (673% vs. 53.6, p=0.074) and fatigue (59.2% Vs. 46.2%, p=0.089) were more common in HC than AID. Overall, reactions like arthralgia (52.6 vs. 22.4%, p<0.001), hematoma (14.1 vs. 4.1%, p=0.05), cutaneous rash (9.5 vs. 0%, p=0.024) were more frequent in HC. Most participants related that they felt safer after receiving a COVID-19 vaccination, and 52.4% did not reported a worse patient global assessment (PGI) index.

**Conclusion:** In conclusion, our data indicated that ChAdOx1 vaccine is safe and induced high titers and seroconversion rate in AID. More severe AID, such as vasculitis, systemic lupus erythematosus, and systemic sclerosis and myositis showed a lower seroconversion rate. Further analysis will explore the association between immunosuppressant and reactivity, and booster dose.

**SEVERITY OF COVID-19 IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING BIOLOGICAL DMARDS**

R. Samoilina1, A. Dadalova1, E. Vasilienko2, V. Mazurov2. 1North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E. Eichwald, St. Petersburg, Russian Federation

**Background:** The safety of biological DMARDs for rheumatic diseases in the context of the covid 19 pandemic is one of the key aspects of modern rheumatology.

**Objectives:** assess the severity of the course of COVID-19 infection in patients with rheumatoid arthritis receiving various biological disease-modifying antirheumatic drugs.

**Methods:** to assess the severity of the course of SARS-CoV-2, discharged epiconia from hospitals or the conclusion of computed tomography were used. Since March 2020 to November 2021, among the 1389 patients with rheumatic diseases observed at the of the anticytokine therapy center of the North-Western State Medical University Named after I.I. Mechnikov 105 cases of COVID-19 infection of patients with rheumatoid arthritis were registered, of which 53 patients received outpatient treatment, and 52 patients received inpatient treatment. In 76% of cases, patients received biological DMARDs in combination with synthetic DMARDs.

**Results:** In patients treated on an outpatient basis, only 17% (9 patients) underwent chest X-ray examination, according to which grade 2 CT was observed in three patients. Among hospitalized patients, multispiral computed tomography was performed in all cases (n=8; 15.3%) of this group of interstitial lung diseases observed at the of the anticytokine therapy center of the North-Western State Medical University Named after I.I. Mechnikov 105 cases of COVID-19 infection of patients with rheumatoid arthritis were registered, of which 53 patients received outpatient treatment, and 52 patients received inpatient treatment. In 76% of cases, patients received biological DMARDs in combination with synthetic DMARDs.

Pain in rheumatic diseases, including fibromyalgia...  |

**POS1287**  | INFLUENCES ON FIBROMYALGIA AND AUTOANTIBODIES DIRECTED TO NEURO- AND VASOREGULATORY MOLECULES NEED TO BE CONSIDERED IN BIOMARKER RESEARCH

F. Lübben1, J. Strobach2, H. Heidecke3, T. Lange4, G. Riemekasten4, 1University of Lübeck, University Clinic of Schleswig-Holstein, Rheumatology and Clinical Immunology, Lübeck, Germany; 2CellTrend GmbH, Autoantibody Tests, Luckenwalde, Germany

**Background:** Fibromyalgia syndrome (FMS) is often present in autoimmune diseases but can also occur in its primary form. Biomarkers for FMS are currently missing. Systemic chronic inflammation, dysautonomia and metabolic dysfunction have been suggested to contribute to the disease. Recent studies indicate that FMS involves autoantibodies (abs), which bind to neurons, macrophages and endothelial cells.

**Objectives:** In the present study, we aimed to delineate changes in natural abs directed to neuro- and vasoregulatory molecules and potentially confounding factors, which could influence these abs and disease state.

**Methods:** Sera from 91 patients with primary FMS (pFMS), 24 patients with secondary FMS (sFMS) and 31 healthy controls (HC) were analysed for the presence of 27 different natural abs directed to e.g., cholinergic, opioid, cannabinoid, endothelin or complement receptors or angiotensin system molecules by individual ELISAs (CellTrend GmbH, Luckenwalde, Germany). All participants were characterized by several questionnaires to obtain demographic data and measures of disease state (using the Widespread Pain Index (WPI) and Symptom Severity Score (SSS)). Linear regression on log-transformed abs levels adjusted for potential confounders was used to compare abs levels between groups. Random forest analysis was applied to differentiate between pFMS and HC by measuring the Area Under the Curve Receiver operating characteristics (AUC-ROC).

**Results:** Compared to HC, patients with pFMS showed increased levels of abs directed to ACE II, the angiotensin receptor type-2 (AT2R), the cannabinoid receptor type 1 and 2 (Can1-R, Can2-R), the endothelin receptor type-B (ETBR), the opioid receptor (κ) (Op-κ-R) and lower levels against the complement receptor 5a (C5a-R) and the muscarinic acetylcholine receptor type 3 (M3)(Figure 1).

After adjustment for age (linear and squared) and sex, differences in the ab levels remain significant for abs against ACE II, AT2R, ETBR and the Op-κ-R. However, none of which remained significant after further adjustment for Body Mass Index (BMI). Random forest analysis of unadjusted ab levels revealed an AUC-ROC of 0.94 for pFMS compared to HC with an average accuracy of 0.85 and a kappa of 0.55. Again, after adjusting the abs levels for age, sex and the BMI, the AUC-ROC to discriminate HC from pFMS patients decreased to 0.73 (accuracy = 0.79, kappa = 0.33).

**Conclusion:** Abs might be potential biomarkers for pFMS. However, these results highlight the important role of correct covariate adjustment for research on biomarkers supposed to classify FMS or other diseases. In FMS, increase in BMI might be a cause or a consequence of FMS and it is also unknown how BMI and abs influence each other. Thus, BMI might or might not be a confounder so that adjusting for BMI might be correct or incorrect. However, these abs could provide a link to understand how acquired conditions interact with the immune system.

Spine, mechanical musculoskeletal problems, local soft tissue disorders.

POS1289  ANALYSIS OF INFECTIOUS SPONDYLODISCITIS: FIVE-YEARS DATA
B. A. Hiba1, B. A. Kauother2, S. Milal3, F. Aila4, S. Meriem5, L. Soubani6, K. Ouenniche7, K. Selma7, C. Selma7, L. Ahmad7. 1Mongi Slim Hospital, Tunis, Tunisia

Background: Spondylodiscitis (SD) is an infection of the vertebral body or disc and may also extend to the epidural space, posterior elements, and paraspinal soft tissues. It is a cause of morbidity and mortality. However, the diagnosis is often delayed because of the non-specific clinical features.

Objectives: In this study, we aimed to describe the clinical and diagnostic features of infectious SD.

Methods: We conducted a retrospective study including 40 cases of infectious SD, performed over a period of five years (2014-2019). Epidemiological, clinical characteristics, laboratory results and imaging findings were uniformly collected.

Results: Of the 40 patients, 37.3% were male. The mean age was 53.3 ± 13.9 years (28-83) and the median Charlson Comorbidity Index was 1. Advanced age, tuberculosis and brucellar contagion were the predominant risk factors. The median duration from onset to diagnosis was 41 days (8-300). Low back pain (LBP) was the most common symptom (98%). Lumbar spine was the most frequent location (71%). Seven patients had contiguous multiple levels (>2 vertebral bodies). Neurologic symptoms (radicular pain, spinal cord compression, neurologic loss) were observed in 15 patients. The median erythrocyte sedimentation rate was 54mm/1st h [15-223], the median CRP was 26.3mg/L [7-587]. Leukocytosis (>10,000 WBCs/mm3) was significantly higher in patients with Pyogenes (p<0.002). ESR and CRP (p=0.002) were more sensitive than other SD: Standard deviation; M: Mean; NS: non-significant; IQR: interquartile range

Overall, there were no differences between control (SOC) and treatment group (STS). Both procedures were effective improving pain at rest (p=0.024), EQ5D (p=0.019), DASH-Work (p=0.032) and UCLA scores (p=0.009) and calcification size measured by US (p=0.031) at month 3. No adverse effects or complications were reported on both groups.

Conclusion: Although well tolerated with no side effects, STS UGPL has failed to show increased benefit for calcific tendinopathy local treatment. Further studies using STS will be needed to ascertain its interest in this disease. This ongoing work will be reevaluated with a larger sample.

POS1290  EFFICACY AND SAFETY OF SODIUM THIOSULFATE IN CALCIFIC TENDINITIS OF THE ROTATOR CUFF – AN INTERIM ANALYSIS OF A RANDOMIZED CLINICAL TRIAL
H. Parente1, S. Azevedo1, E. Costa1,2, F. Guimarães1, M. Pontes Ferreira1, D. Faria1, D. Peixoto1, J. Tavares-Costa1, C. Afonso1, H. Parente1, S. Azevedo1, E. Costa1,2, F. Guimarães1, M. Pontes Ferreira1, D. Faria1, D. Peixoto1, J. Tavares-Costa1, C. Afonso1, E. Costa1,2, F. Guimarães1, M. Pontes Ferreira1, D. Faria1, D. Peixoto1, J. Tavares-Costa1, C. Afonso1.

Background: Calcific tendinitis of the rotator cuff is one of the most common causes of shoulder pain. (1) Ultrasound guided percutaneous lavage (UGPL) is indicated when conservative treatments have failed. (2) Recent reports have shown the interest of topical sodium thiosulfate (STS) in the treatment of other diseases characterizes by ectopic calcifications (3, 4, 5).

Objectives: To assess the efficacy and safety of UGPL with STS versus with saline solution (standard of care - SOC) in calcific tendinitis.

Methods: Double-blinded randomized clinical trial including adult patients with calcific tendinitis, shoulder pain for more than 3 months and at least one positive shoulder impingement test. Only dense type A calcifications (according to the Molé Classification) > 5 mm in diameter were included. Patients were randomized in two groups: STS and saline UGPL. The outcome was favourable in 27 cases (86.8%). Pathogens were isolated in 19 cases. Computed tomography-guided percutaneous disc biopsy (PDB) was performed in 16 (53.5%) and was conclusive in (11/15) cases (66.8%). Mycobacterium tuberculosis (71%). Seven patients had contiguous multiple levels (>2 vertebral bodies). Neurologic symptoms (radicular pain, spinal chord compression, neurologic loss) were observed in 15 patients. The median erythrocyte sedimentation rate was 54mm/1st h [15-223], the median CRP was 26.3mg/L [7-587]. Leukocytosis (>10,000 WBCs/mm3) was significantly higher in patients with Pyogenes (p<0.002). ESR and CRP (p=0.002) were more sensitive than other

Conclusion: Spondylodiscitis should be considered for all patients presenting with chronic back pain especially when associated with laboratory examination abnormalities. In our study, tuberculous spondylodiscitis was the most frequent, which highlights the fact that osteoarticular tuberculosis remains endemic in developing countries, where it still constitutes a major public health problem.

POS1291  DEGENERATIVE DISC DISEASE IN YOUNG: IMMUNOHISTOCHEMICAL EXPRESSION OF INFLAMMATORY BIOMARKERS AND ANGIOGENIC FACTORS
N. Pradvyuli1, N. Shostak1, A. Novikova1, A. Buianova1, O. Patsap1, A. Raksha1, I. Senko1, R. Tairova1, A. Aksyonova1, A. Muradyants1, K. Davygora1.

Background: Low back pain (BP), associated with the degenerative disc disease (DDD), poses a heavy social and economic burden, emerging among young adults. The pathophysiological basis of accelerated degeneration of the intervertebral disc (IVD) and its contribution to the formation of spine osteoarthritides are at the active study stage.

University of California at Los Angeles (UCLA) scores, ultrasound (US) and radiographic evaluations were performed on all follow up visits. SPSS was used for statistical analysis and significance level was defined as 2-sided p<0.05.

Results: Twenty-six patients were included, where 76.9% (20) were women, with a mean age of 51.2 (SD=9.0) years old. The mean duration of pain before the procedure was 12.7 months (SD=11.3) (minimum of 3 months and a maximum of 48 months).

Fifteen patients (57.7%) were randomized to the control group (SOC) and performed a saline UGPL; the other 11 patients (42.3%) were randomized to the treatment group (STS). Demographic and baseline clinical characteristics are shown in Table 1. Since patient inclusion is dynamic, our sample met 23 patients at week 1 (SOC group = 13 and STS group = 10), 19 patients at month 1 (SOC group = 10 and STS group = 9) and 16 patients at month 3 (SOC group = 8 and STS group = 8).

Disclosure of Interests: None declared
Objectives: To assess inflammation and angiogenesis biomarkers in IVD among young patients with chronic LBP, associated with DDS.

Methods: Human IVD tissue from 25 patients was obtained from discectomy surgery and was divided into 2 groups: men (n=13), women (n=12), age: 36.7±3.73 and from autopsy in healthy control group (n=5, age: 37.8±2.52). The grade of DDR was verified by magnetic resonance (MRI) by the classification of C.W. Pfirrmann. Four-micron serial sections of the tissue blocks were stained with hematoxylin and eosin (H-E), than examined by immunohistochemistry staining on the automated VENTANA BenchMark ULTRA platform. Anti-IL-1β, anti-IL-6, and anti-IL-17 were used to study the expression of inflammatory cytokines; anti-VEGF-A and anti-CD31 were used as markers of angiogenesis. All slides were visualized using a Axio Imager.Z2 microscope with EC Plan-Neofluar 40X objective.

Results: In 64% of patients IVD hernias were localized at the level of L5-S1, in 36% - L4-L5. The average Pfirrmann DDR stage at the operated level was 4.43±0.57. 72% of patients had Modic changes (MC). 52% of patients had a combination of hernia with endplate erosion (EP) and MC. There were identified evidence of DD on H-E-stained sections, including clusters of cells of the nucleus pulposus (NP), inflammatory cell infiltration and blood vessels in the absence of them in the fissures of the NP and annulus fibrosus (AF). Immunostaining was mainly limited to the cytoplasm of native NP chondrocyte-like cells and AF fibroblast-like cells. IL-1β expression was considerably higher in degenerate samples than in controls for both NP (p < 0.05) and AF (p < 0.01). Staining for IL-17 was more pronounced in the cytoplasm of chondrocyte-like cells of degenerative NP compared to the control (p < 0.01), and statistically lower in AF cells (p < 0.05). The number of IL-6 immunopositive cells was similar in NP and AF degenerate tissue, but a greater proportion of IL-6 immunopositive cells was seen in NP tissue (p<0.05). The percentage of cells immunopositive for VEGF-A and CD-31 were significantly increased in NP DD cell clusters compared to controls (p<0.001) (88% and 36%, respectively) and was weakly expressed in the extracellular matrix (p<0.05). This suggests that the PU cells trigger angiogenesis. Blood vessels in native sections were confirmed by CD31 detection in 64% of patient specimens versus 10% of control cartilage specimens (p < 0.001). The number of CD31 immunopositive cells had a tendency for decrease in severe DD (p=0.05), which indicates the extinction of vascularization in the terminal stage of DD. Fissures in the disc did not stained for CD31, which excludes the ingrowth of vessels directly in the area of mechanical damage and proves the immunogenic cause of vascularization. This is confirmed by the synergistic high level of expression of IL-1 and -17 in perversal, endothelioocytes and intravascular pathological samples versus weak expression in the disc matrix (p<0.01). The high level of expression of all interteukins was in the hyaline cartilage of EP patients versus the absence in the controls (p<0.001). It indicates their association with asptic inflammation of EP with the formation of EP reactions and reactive spondylitis (MC) development, detected by MRI in young adults with DD.

Conclusion: Local immune inflammation is a component of the degenerative cascade in IVD, it initiates angiogenesis in cartilage and EP, as well as the development of reactive osteitis of adjacent vertebrae with the formation of inflammatory lesions in the vertebral-motor theory of chronic back pain. The results obtained will help to identify molecular targets and form a new direction of developmental reactive osteitis of adjacent vertebrae with the formation of inflammatory cascade in IVD, it initiates angiogenesis in cartilage and EP, as well as the development of reactive osteitis of adjacent vertebrae with the formation of inflammatory lesions in the vertebral-motor theory of chronic back pain.

TEN-YEAR EFFICACY DATA FROM THE CLIPPER STUDIES: OPEN-LABEL, LONG-TERM ETANERCEPT TREATMENT IN CHILDREN AND YOUNG ADULTS WITH EXTENDED OLIGOARTICULAR, ENTHESITIS-RELATED, OR PSORIATIC JUVENILE IDIOPATHIC ARTHRITIS

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular.4597
Treatment Period (i.e., they discontinued ETN, either by meeting the Wallace definition for clinically inactive disease for at least 6 months on ETN, or by having had a good clinical response and being deemed to benefit from withdrawal in the investigator’s judgement). Of the pts in the Active Treatment Period, over 90% achieved JIA ACR 50 response at all study time points. Sustained JADAS and ACR remission was achieved by 42 (33%) pts and 17 (13%) pts, respectively. The mean improvements from baseline in JADAS disease activity at mth 24 of CLIPPER2 were largely maintained through CLIPPER2.

Conclusion: The low numbers of evaluable pts notwithstanding, efficacy results were consistent with the profile of ETN, and treatment responses were considered clinically meaningful and durable with long-term treatment.

Tri al Registration: NCT00692741/NCT04121069

Acknowledgements: Medical writing support was provided by Iain McDonald, PhD, of Engage Scientific Solutions and was funded by Pfizer.

Disclosure of Interests: *Efficacy data only for patients with juvenile idiopathic arthritis.

Conclusion: We report our 14-month experience of using adalimumab biosimilar in a pediatric rheumatology population. Majority of the patients did not report major adverse reactions. Majority of JIA patients responded well when initiated on adalimumab (Amgevita). Rheumatologists should continually monitor patients for latent infections after prescribing biologics including biosimilars.

Hospitailler de l’ouest Guyanais, Department of Pediatrics, Saint-Laurent-Du-Maroni, French Guiana; aMartinique University Hospital, CIC Antilles-Guyane, Fort-De-France, Martinique; bNecker Hospital, Department of Pediatric Rheumatology, Paris, France; cMartinique University Hospital, Department of Internal Medicine, Fort-De-France, Martinique

Background: Systemic diseases of pediatric onset are more frequent in Afro-Caribbean population, especially Pediatric systemic lupus (pSLE).

Objectives: Our work is a retrospective study of patients followed in French overseas departments for systemic disease or auto-inflammatory syndrome of pediatric onset. It describes their clinical and biological specificities at diagnosis, during childhood and early adulthood.

Methods: Our retrospective study was conducted between 01/01/2000 and 01/09/2021. Listings of adult patients with pediatric onset and pediatric patients were obtained in each center through computerized hospital archives, list of patients followed by referent pediatricians and adult specialists in internal medicine and the French National Registry for rare disease. Data were then gathered by going through their medical files. The spectrum of diseases studied included pSLE, Sjogren syndrome, antiphospholipid syndrome (APS), connectivitis, systemic sclerosis, dermatomyositis, Systemic juvenile idiopathic arthritis (sJIA), unclassified auto-inflammatory syndrome.

Results: 2148 patients were identified on a 21 year-period, and 135 patients were included. Most patients diagnosed with a systemic pathology (102) suffered from pSLE (53%), followed by dermatomyositis (17%). Average follow up was 8.3 years (0.3 - 25 years), median age at last follow up was 212 (14 - 36.7). We found an increase in the number of new diagnoses throughout the years. For pSLE, sex repartition was 4/1 girl/boy and did not vary according to age (p = 0.31). At onset, patients had 10 Scicc criteria (4-12) and median EULAR/ACR 2019 score was 38 (12 - 54). The combination of typical skin involvement, arthritis and fever was found for 87%. At onset, a third of patients had renal involvement, 15% had Neuruplouis and 41% cardiac involvement. All patients had a positive ANA and Anti-DNA antibodies, followed by anti-Sa/Ssb antibodies (78%), Anti-Sm (78%) and anti RNP (52%). During childhood, 54% had renal involvement and 26% suffered from Neuro- lupus. Patients suffered in median from 3 flares and 26% suffered from more than 5 flares during childhood. Pre-pubertal patients (26%) had worst outcomes, 95% had renal and/or neurological involvement, they had more flares (median at 5 p = 0,02) and needed an average of 4 background therapies (p = 0.04). Boys seemed to have better disease control at transition to adult care but gender was not an independent predictor of severity during childhood (p = 0.21). 32 patients had dermatomyositis, 29% of them had respiratory involvement during childhood. 33 patients had auto-inflammatory syndromes mostly sJIA (67%), 50% of them had hemophagocytic syndrome during childhood and their disease was controlled by steroids for 64%, 36% needed biotherapy. The overall mortality was 3%.

Conclusion: This is a large cohort of patients of Afro-Caribbean origin with a higher frequency of pSLE. Although the outcomes for these patients were similar to western countries, they had low symptoms at onset, not correlated to delay at diagnosis. Compared to ethnic studies of North America or Africa, the French health care system being universal and free, the bias related to socio-economic status was lower. This work will continue with the exploration by transcriptomic and genetic tests for early and severe forms to identify the extra-environmental causes. The environmental factors specific to these regions should be explored in additional prospective studies.

**T-CELL RESPONSE MEASURED BY INTERFERON-γ RELEASE ASSAY AS A NOVEL TOOL FOR BETTER UNDERSTANDING OF SARS-CoV-2 IMMUNITY: THE PRELIMINARY RESULTS OF A PROSPECTIVE STUDY IN PEDIATRIC PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS.**

K. K. Kapten1, K. Oroczy1, E. Smolewska2, 1CentralTeachingHospital of Medical University of Lodz, Department of Pediatric Cardiology and Rheumatology, Lodz, Poland; 2Medical University of Lodz, Department of Pediatric Cardiology and Rheumatology, Lodz, Poland

Background: While serological assays detecting antibodies in blood serum remain the standard exam for evaluating immunity against SARS-CoV-2 infection, the latest publications reveal certain limitations to this broadly used method. Recent studies showing the increase of antibodies titers in time, together with scientific reports which detect SARS-CoV-2-specific T-cells in seronegative individuals, evoke questions with regard to the reliability of the sole assessment of the humoral response to SARS-CoV-2. A novel T-cell-based interferon-γ Release Assay (IGRA) is proposed to adapt our approach to the individual immunity to the new coronavirus.

Objectives: The objectives of this study were to assess T-cells and antibodies responses to the SARS-CoV-2 virus among pediatric patients at different stages of juvenile idiopathic arthritis (JIA) undergoing diverse treatment regimes. In addition, the authors aimed to evaluate humoral and cellular responses to the Covid-19 mRNA vaccine in the cohort of immunocompromised patients.

Methods: This prospective study included 30 pediatric patients between the ages 2-16 at different stages of JIA. The cohort group consisted of vaccinated and unvaccinated individuals and children with both positive and negative history of past Covid-19 infection. SARS-CoV-2 T-cell response was measured using a specific quantitative IGRA in whole blood, followed by anti-SARS-CoV-2 ELISA test measuring the presence and quantity of IgG, IgM and IgA antibodies in serum.

Results: The magnitude of the SARS-CoV-2 specific T-cell response measured by the IGRA test correlated significantly with the levels of IgG (p=0.00005, R=0.653) and IgA antibodies (p=0.00011, R=0.675) in serum, while no correlation with IgM antibodies level in serum was found. All vaccinated patients developed a cellular response to the vaccine (p=0.0108), regardless of the number of administered doses. The T-cells response in children undergoing biological treatment (specifically: etanercept, adalimumab or tocilizumab) was recognizably weaker compared to the group not receiving such treatment. Nevertheless, the difference did not reach statistical significance (p=0.0715). Similar dependencies were found in children treated with hydroxychloroquine (n=6), however, due to the small study group, a statistical significance could not have been reached.

Conclusion: Suppression of cellular response observed in different drug protocols may prove to become a protective factor against SARS-CoV-2 infection. Additionally, the authors postulate that the strong correlation found between T-cell response and IgA antibodies titers can be related to SARS-CoV-2 strong affinity with mucosal membranes. Thus, the sole testing of IgG and IgM antibodies levels in serum with regard to Covid-19 may not be the most precise diagnostic method. The presented study group needs to be expanded with more patients, mainly children receiving biological agents or hydroxychloroquine to validate the demonstrated preliminary results.

**SACROILIITIS AT DIAGNOSIS ASSOCIATED WITH LESS DISEASE FLARE AFTER STOPPING MEDICATION - OUTCOMES AND PREDICTORS OF A SOUTHEAST ASIAN ENTHESITIS RELATED ARTHRITIS (ERA) LONGITUDINAL COHORT.**

K. L. Tan1, L. Das1, Y. X. Book1, T. Arkachaisir1,2, 1KK Women’s and Children’s Hospital, Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Rheumatology and Immunology, Singapore, Singapore

Background: ERA is a subtype of Juvenile Idiopathic Arthritis (JIA) characterized by involvement of entheses and axial skeleton. Outcomes have been shown to be poorer compared with oligoarticular and polyarticular JIA.

Objectives: To assess short-and long-term outcomes and predictors of ERA in a large monocentric cohort in Singapore.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.431
Methods: Children diagnosed with ERA according to ILAR criteria from 2002 to 2021 at KK Women’s and Children’s Hospital, Singapore, were recruited. Outcome statuses were defined according to the criteria for clinical inactive disease (CID) and complete remission (CR) proposed by Wallace et al., with additional criteria of no enthesitis and no active sacroiliitis on MRI. Nonparametric descriptive statistics were used. Univariate and multivariate analysis were performed using logistic regression analyses. The significant level was set at < 0.05.

Results: A cohort of 151 ERA patients (male 86%; Chinese 81%) were included. Median age at onset was 11.9 years (IQR 9.4-13.9) and disease duration was 5.3 years (IQR 2.9-8.4). HLA-B27 was positive in 83% of the patients. At diagnosis, 39% of the patients had sacroilitis, 46% had hip arthritis, 36% had knee arthritis and 25% had enthesisitis. Methotrexate was used in 77% of the patients, while biologics was started in 72% of the patients. CID was achieved in 92% of the patients, of which 27% achieved CID in 6 months or less. Sacroilitis at diagnosis is an unfavourable predictor of CID at 6 months but not a significant predictor of ever achieving CID. Older age at diagnosis is also an unfavourable predictor of CID ever.

Medication was totally discontinued in one third of the patients. Half of them went on to have complete remission (CR) off medication. Favourable predictor includes male gender, while positive HLA-B27 and ANA were unfavourable predictors. Two thirds of the patients with CID had at least one disease flare (23% flared after off medication, 13% flared after CR). Both intra-articular joint injection and anti-TNF use were associated with flare after CID, while anti-TNF use was associated with flare after off medication. Sacroilitis at diagnosis is a protective predictor of flare after stopping medication.

Conclusion: Despite a high proportion of ERA patients achieving CID, only one third could stop medication completely with high rates of disease flare even after attaining CR. Unfavourable predictors include older age at onset as well as HLA-B27 and ANA positivity. While sacroilitis at diagnosis is a negative predictor of CID at 6 months, it is protective predictor of flare after discontinuing medication.

POS1298 RELATIONSHIP BETWEEN DISEASE ACTIVITY BY JADAS-27, SDAI, AND DAS-28 AND SUBSEQUENT CHANGES IN PHYSICAL FUNCTION IN ADULT PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

T. Miyamae1,2, E. Inoue3,4, E. Tanaka1,4, T. Kawabe1,2, K. Ikari5,6, M. Harigai2,4. 1Tokyo Women’s Medical University Hospital, Department of Pediatric Rheumatology, Institute of Rheumatology, Tokyo, Japan; 2Tokyo Women’s Medical University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; 3Showa University, Research Administration Center, Tokyo, Japan; 4Tokyo Women’s Medical University Hospital, Department of Rheumatology, Institute of Rheumatology, Tokyo, Japan; 5Tokyo Women’s Medical University School of Medicine, Division of Multidisciplinary Management of Rheumatic Diseases, Tokyo, Japan; 6Tokyo Women’s Medical University Hospital, Department of Orthopedic Surgery, Institute of Rheumatology, Tokyo, Japan

Background: Juvenile Arthritis Disease Activity Score (JADAS) has been developed as a composite disease activity score specific to Juvenile idiopathic arthritis (JIA). Evaluation of disease activity with a composite measure associated with subsequent changes in structural damage of joints and physical function is necessary for the proper management of Rheumatoid Arthritis (RA) with treat-to-target strategy, and this concept should be considered for patients with JIA in transition and adulthood as well. However, the usefulness of JADAS-27 and other composite measures for RA in these patients has been scarcely investigated. Additionally, JADAS-27 is unfamiliar to non-pediatric rheumatologists.

Objectives: We aimed to investigate an optimal composite score for disease activity in adult JIA from the viewpoint of the subsequent changes in physical function.

Methods: Patients diagnosed with JIA with the following conditions were enrolled: 1) disease onset at age < 18 years; 2) registered in the IORRA database for the first time between 2000 and 2020; and 3) ≥18 years old at the time of IORRA registration. The baseline of each patient was their initial entry into the IORRA database. The Simplified Disease Activity Index (SDAI), Disease Activity Score using 28 joints (DAS28), and JADAS-27 were compared. The patients were stratified into four disease activity categories: remission/inactive disease, low disease activity, moderate disease activity, and high disease activity according to mean disease activity scores in each index during the first year from baseline, and mean changes in J-HAQ (mean ΔJ-HAQ) during 2 years from baseline in each disease activity group were estimated using the linear mixed effect model.
to account for correlations of repeated measures without filling in the missing data after adjusting for sex, age, and disease duration.

Results: We included 294 eligible individuals (median age at onset, 14.0 years; rheumatoid factor positive in 64.7%). The median age at baseline and disease duration was 33.8 (24.1–47.7) years and 21.0 (11.0–34.0) years, respectively. The J-HAQ was completed in all 294 patients, and 171 (58.1%) had a score of less than 0.5 at baseline, which is defined as functional remission. During the 2-year observation period, the median J-HAQ of all patients remained unchanged. There was a trend toward improvement in disease activity over time in all three composite scores. Some differences were observed across the three indices: a higher proportion of patients with high disease activity and a lower proportion of patients in remission/inactive disease were observed with JADAS-27 versus SDAI and DAS28. A significant increasing trend of the estimated mean J-HAQ at 2 years after baseline was observed along with an increase in the mean disease activity during the first year measured using DAS28 (p = 0.01) and SDAI (p = 0.018), but not using JADAS-27 as shown in Table 1.

Table 1. Association of the mean disease activity categories during the first year after baseline and mean changes in J-HAQ during the two years after baseline

Conclusion: Disease activity measured using SDAI and DAS28, but not using JADAS27, was significantly associated with subsequent changes in physical function in transitional and adult patients with JIA. This study support the use of SDAI and DAS28, but not JADAS27, in assessing disease activity in these patients to adjust treatments for preventing future deterioration of physical function.

POS1299 JUVENILE SYSTEMIC SCLEROSIS TREATMENT PRACTICES IN AN INTERNATIONAL COHORT AND COMPARISON TO RECENT SHARE CONSENSUS GUIDELINES.

1Hamburg Centre for Pediatric and Adolescent Rheumatology, Schön Klinik Hamburg Eilbek, Hamburg, Germany; 2JSSC Collaborative Group, Hamburg Centre for Pediatric and Adolescent Rheumatology, Hamburg, Germany

Background: Juvenile systemic scleroderma (jSSc) is an orphan disease with a prevalence of ≤ 5 in 1,000,000 children. Currently no medications are licensed for the treatment of jSSc. Due to its rarity, only recently have the first management and treatment guidelines been published, the jSSc SHARE (Single Hub and Access point for paediatric Rheumatology in Europe) recommendations, reflecting consensus opinion upon pediatric rheumatologists (1).

Objectives: To better understand treatment practices internationally for jSSc, both at baseline and over 24 months observation period and to compare if real world treatments are congruent with the recent SHARE recommendations.

Methods: The juvenile systemic sclerosis inceptions cohort (jSScC) is a multinational cohort that prospectively collects clinical data, including medications at baseline and subsequent visits. The jSSc enrollment criteria include age of onset of the first non-Raynaud symptom younger than 16 years and age younger than 18 years at cohort entrance. The frequency of medications (general category and specific medication) was calculated across the cohort at timepoint 0 (enrollment), 12 months and 24 months.

Results: We extracted data from the jSScC of patients who were followed for 12 or 24 months. 109 patients were followed at time point 0 (T0) and 12 months (T12), and data was available for all of them up at 24 months (T24). The mean age of the patients was 13.2 years at the timepoint 0. 77% were female, 75% had diffuse subtype. Disease duration at baseline visit was 3.1 years. The medications the patients were on were recorded by the physician were captured at T0, T12 and T24 listed in Table 1.

Conclusion: At baseline half of the patients were on corticosteroids. This is more frequent than typical adult SSC practice but coincides with jSSC SHARE treatment recommendations (#1). After 12 months observation in the cohort over 90% of patients received a DMARD therapy. Methotrexate and mycophenolate mofetil were the most commonly prescribed DMARDs, which also reflects the SHARE treatment recommendations (#2, #3). At 12 months the use of glucocorticoid decreased and the use of bDMARDs increased. In general, biological DMARDs are considered in severe or refractory (SHARE recommendation #7), reflecting the lower percentage compared to csDMARDs. Autologous stem cell transplantation was observed in one patient at 12 months, reflecting an option in jSSc with progressive and refractory disease (SHARE recommendation #8). Endothelial receptor antagonists, such as bosentan, were used over time in approximately 20% of the patients, reflecting SHARE recommendation #6 for pulmonary hypertension and/or digital tip ulcers. This is the first evaluation looking at clinical medication practice pattern in jSSc, and its comparison to recently published consensus guidelines.

Disclosure of Interests: None declared

Results: 73 patients could be identified, 71% of them were female. Mean age at disease onset was 8 years (4-14 years). The mean time of follow up was 5 years. The subtype distribution was 42 (57%) linear, 24 (33%) mixed, 6 (8%) circumscripted morphea and 2 (3%) panniculitic morphea. 9 (21%) of the 42 patients with linear subtype had coup de sabre and 4 (10%) of them had Parry Romberg. Fifty six (76%) patients had EM, 40 (53%) of them had 1 form of EM, 10 (13%) of them 2 forms of EM and 6 (8%) patients 3 forms of EM. 53(73%) of the 76 patients had arthritis. Twenty (37%) of the 53 arthritis involvement occurred on a localisation without overlaying skin involvement. Most frequent localisation of arthritis without overlaying skin involvement was in the hip joints (18%). Of the 53 patients with articular involvement had 31 (58%) linear, 17 (32%) mixed, 4 (7.5) circumscripted morphea and 1 (2%) panniculotic subtype. 14 (19%) of the 73 had length discrepancy of the extremities and 13 (19%) of them had linear subtype. Neurologic symptoms presenting as headache occurred in 8 (11%) patients. 6 (75%) of them had Parry Romberg subtype and 2 (25%) of them coup de sabre. White anterior uveitis was screened according to the published recommendations1-4 and it occurred in 3 patients, only one of them had coup the sabre the other two linear and mixed subtype without involvement of the face.

Conclusion: EM is very common and it occurs in 76% of the patients. Thirty seven percent of the articular involvement occurred in joints without overlaying skin involvement, which suggest the importance of the whole body joint count as in juvenile idiopathic arthritis. Only 1 of 3 patients with uveitis had skin involvement in the face, which emphasize the recommended uveitis screening.

Disclosure of Interests: None declared
duration was 2.5 years at T0. Antibody profile stayed unchanged. Only 3 clinical parameters changed and improved significantly, the median modified Rodnan skin score improved from 13 to 6 (p=0.002), the number of patients with swollen joints decreased from 17% to 8% (p=0.043) and number of patients with joints with pain on motion decreased from 20% to 12% (p=0.048). All other organ involvement did not show any statistically significant change from T0 to T12.

All collected patient reported outcomes improved significantly from T0 to T12: the patient reported disease activity (VAS 0 – 100) from 40 to 20 (p=0.011), the patient reported disease damage (VAS 0 – 100) from 40 to 20 (p=0.001), patient reported ulceration activity (VAS 0 – 100) from 10 to 0 (p=0.02) and the CHAQ score from 0.3 to 0 (p=0.002). Two of the three physician reported outcomes improved significantly, the physician global disease activity (VAS 0 – 100) from 30 to 20 (p=0.011) and physician reported global disease damage (VAS 0 – 100) from 30 to 25 (p=0.028).

Conclusion: Skin and musculoskeletal clinical features improved over 12 months, with almost all patients on DMARDs, supporting likely response of these features to therapy. It was promising that internal organ involvement, like cardiac and lung, although potentially stable, did not significantly worsen or increase. The most striking observation in the positive direction is improvement across several patient and physician reported outcome measures over the 12 month time period in this large international cohort.

**POS1303 METHOTREXATE RESPONSE IN PEDIATRIC NON-INFECTION UVEITIS**

S. Angeles-Han1,2, A. Cassidy3, T. Hennard4, M. Altaye5, H. Brunner6, E. Dosumu7, A. Gronb8, M. Henrickson9, J. Huggins9, S. Lopper9, D. J. Lovel10, R. Sisk10, T. Ting10, A. Kaufman11, V. Utz12, Cincinnati Children’s Hospital Medical Center, Pediatric Rheumatology, Cincinnati, United States of America; 2Cincinnati Children’s Hospital Medical Center, Pediatric Ophthalmology; Cincinnati, United States of America; 3Cincinnati Children’s Hospital Medical Center, Biostatistics & Epidemiology; Cincinnati, United States of America; 4Cincinnati Children’s Hospital Medical Center, Pediatric Rheumatology; Cincinnati, United States of America; 5Cincinnati Children’s Hospital Medical Center, Medical Staff Services, Cincinnati, United States of America; 6Cincinnati Eye Institute, Ophthalmology; Cincinnati, United States of America.

Background: Children with chronic non-infectious uveitis (NIU) are at risk for sight-threatening complications. Methotrexate (MTX) is the preferred first-line systemic treatment. Initial therapeutic response takes 3-6 months to achieve NIU control, leading to prolonged glucocorticoid use. Moreover, at least 50-70% of children fail to fully respond and may accrue ocular damage while awaiting MTX response.

Objectives: To identify features of children with NIU that are associated with MTX failure.

Methods: We included children who started MTX monotherapy for NIU. We collected demographics, NIU features (type, location, & complications), ANA status, and clinical examination. We characterized children as MTX responders or non-responders. MTX responders are those whose NIU was controlled, defined by: 1) inactive graded by SUN criteria, 2) absence of new or worsening complications, and 3) requirement for ≤2 drops of prednisolone acetate and no oral glucocorticoids.

Results: Of 47 NIU children, 68% were MTX non-responders (Table 1), having a longer duration of NIU (Odds Ratio [OR]=1.28, [CI]=1.03-1.8, p =0.023) and developing more ocular complications (OR=1.95 [CI]=1.23-3.36, p=0.017), (ROC Area Under the Curve = 0.85). MTX non-responders were more likely to have anterior and/or posterior synechiae (p=0.001), cataracts (p=0.015), and ocular hypertension (p=0.039). Treatment included adalimumab: 27, infliximab: 14, tocilizumab: 5, golimumab: 4, etanercept: 3, and abatacept: 2.

We performed a sub analysis of children with idiopathic chronic anterior NIU (CAU) and JIA-associated NIU that included children who failed MTX due to intolerance/toxicity (Figure 1). Using Cox proportional hazard regression, 6 idiopathic CAU failed MTX earlier than 38 JIA-associated NIU (HR 2.77, [CI]=1.06-7.27, p=0.039). Results were similar with the inclusion of other types of NIU (p=0.088) (e.g., HLA-B27, non-anterior idiopathic or with systemic disease).

**Figure 1. Kaplan-Meier curve showing freedom from TNFi (mos) stratified by diagnosis**

Conclusion: Two out of three children with NIU fail initial MTX monotherapy, exposing them to increased accrual of ocular complications prior to biologic starts. The risk for delay in starting tumor necrosis factor alpha inhibitors (TNFi) seems higher with CAU. Future studies will examine risk factors that predict MTX response in NIU.

</tbody>
</table>

The VAS of symptoms of numbness/tingling showed a strong positive correlation with mLoSSi but showed a moderate correlation with LoSDI. Patient global VAS correlated with both mLoSSi and LoSDI, as did CDLQi. CHAQ correlated with activity only.

Conclusion: Symptoms within lesions are often interpreted as indicating disease activity. A previous study in adults and children showed itch positively correlated with mLoSSi suggesting it may be a marker of active disease [2]. However, in our study numbness/tingling correlated with disease activity whereas itch did not. Further work is required to understand whether itch correlates to both activity and damage and whether numbness/tingling is a better indicator of activity than itch. Limitations of our study include a heterogenous group of participants with longstanding high-burden disease.

Hematological Manifestations in the Presence of Antiphospholipid Antibodies in a Pediatric Cohort

P. Morán Alvarez1, A. Andreu-Suárez1, L. R. Caballero Motta2, J. Calzada3, S. Gassiot4, R. Berrueco4, L. Giovannelli5, A. Boteanu1, M. Vázquez Díaz1, J. Antón6, C. Bracaglia6, F. De Benedetti6. 1Hospital Universitario Ramón y Cajal, Rheumatology, Madrid, Spain; 2Hospital Universitario Gregorio Marañón, Rheumatology, Madrid, Spain; 3Hospital Sant Joan de Déu, Pediatric Rheumatology, Barcelona, Spain; 4Hospital Sant Joan de Déu, Pediatric Hematology, Barcelona, Spain; 5Ospedale Pediatrico Bambino Gesù, Laboratory, Rome, Italy; 6Ospedale Pediatrico Bambino Gesù, Pediatric Rheumatology, Rome, Italy

Background: Antiphospholipid syndrome (APS) is an autoimmune disease characterized by thrombotic events (TEs) and/or pregnancy morbidity, in association with two consecutive positive determinations (at least 12 weeks apart) of antiphospholipid antibodies (aPLs). Several manifestations which are not considered clinical criteria of APS have been identified, including hematologic disorders.

Objectives: To identify the different variables associated with the development of hematological manifestations in the presence of aPLs in a pediatric cohort.

Methods: Multicentric historical cohort of children ≤ 18 years from three Spanish and one Italian tertiary referral hospitals with at least 2 positive determinations (≥12 weeks apart) of IgG/IgM anticardiolipin (aCL), IgG/IgM anti-β2-glycoprotein I (β2GPI) and/or LA. Demographic, clinical and analytical data were collected. A bivariate and multivariate analysis were carried out. Multicollinearity was also explored to build the model.

Results: 131 children were included. Demographic, clinical, analytical data; and results of bivariate analysis are shown in Table 1.

Table 1. Demographic characteristics: non-thrombotic clinical manifestations; immunologic laboratory findings; and bivariate analysis according to each specific entity and the presence of “hematological” manifestations. Categorical variables expressed as number (n) and percentage (%); Numerical variables with normal distribution expressed as mean and SD (standard deviation). *p<0.05.

The multivariate analysis identified as independent risk factors to develop a hematologic manifestation, children: SLE diagnosis [OR 1.2, 95 CI (0.5-5.8), p=0.015], cutaneous manifestations [OR 1.01, 95 CI (0.6-2.8), p=0.091]. LA + [OR 0.8, 95 CI (0.4-3.6), p=0.058], and IgGβ2GPI+ [OR 0.9, 95 CI (0.4-3.9), p=0.048]. Sex, age, familiar history of AIoD or IgM B2GPI+ did not show a higher risk.
Conclusion: Non-criteria manifestations, specially hematologic disorders, are the most frequent events in the presence of sPLA2s in our cohort. Cutaneous manifestations, a positive personal history of SLE, LA positivity and IgG anti-β2GPI positivity were associated with a higher risk of developing hematological manifestations. Therefore, their inclusion as APS classification criteria should be considered.

POS1308  SINGLE CENTER REAL-LIFE PRACTICE OF BIOLOGICAL THERAPY IN SYSTEMIC LUPUS ERYTHEMATOSUS WITH JUVENILE ONSET
M. Kalela1, I. Nikitinha2, E. Fedrov1, S. Salugin2, A. Shapovalenko2, T. Pachkoria3, V.A. Nasonova Research Institute of Rheumatology; Pediatric Department, Moscow, Russian Federation

Background: In recent years the use of Biologics (B) at the management of systemic lupus erythematosus including with juvenile onset (sJLE) has increased. Belimumab (BEL) became the first approved B for SLE. The use of rituximab (RTM), despite the status of "label", remains relevant in a number of patients (pts) with poor response to standard therapy and the presence of life-threatening conditions. However, use of B in real clinical practice has increase slowly, in part, due to uncertainty over which pts should be treated with B and in what stage of the disease, in part, due to uncertainty over safety.

Objectives: To analyze in retrospective study the efficacy and safety of B in pts with sJLE.

Methods: The study included all pts with sJLE in our pediatric rheumatologic department, who received B.

Results: Among 160 pts with sJLE, 52 (32.5%) received B: 43 – RTM, 12 – BEL, 1 – abatacept (ABA). 4 pts received 2B in sequence (2 – RTM-BEL, 1 – BEL-RTM, 1 – RTM-ABA). The proportion of pts with sJLE was 47% among all those who received RTM in our center. The median age at onset – 12.2 y.o. [IQR 9.9; 14.6], median disease duration at start of RTM – 2.5 years [IQR 0.9; 4.5]. The girls and boys ratio = 6.2:1. The median of activity by SLEDAI at start of RTM was – 16 [12; 22]. 58% of pts underwent more than one course of RTM, with a maximum of 6 courses. The median time between each course was 182 [96–315] days. RTM was effective in 40 (93%) pts with the achievement of the inactive status of the disease and reduction of GC-therapy. Various adverse events (AE) were observed in 46.5% of pts as recurrent uncomplicated upper respiratory tracts infections being the most common (23.2%). RTM was discontinued in 9 pts: 1 - the flare of Ro-associated vasculitis, 1 - inefficacy, 7 - serious AEs. Serious AEs included: pneumonia – in 1 (2.3%), serious infusion reaction – in 1 (2.3%), toxic epidermal necrolysis (TEN) – in 1 (2.3%), MAS – in 2 (4.6%), death (inefficacy for treatment of MAS in SLE) – in 2 (4.6%). Among pts receiving RTM the median age at onset was 12.7 y.o. [IQR 10.0; 15.0], median disease duration at start of RTM – 1.5 years [IQR 1.0; 2.1]. The girls and boys ratio = 1.4:1. The median of activity by SLEDAI at start of BEL was – 10 [9; 14]. 6 pts receive BEL more than 1 year with the achievement of the inactive status of the disease and reduction of GC-therapy. AEs were registered in 3 pts (25%): neutropenia (III degree) – in 1, SAEs – in 2 pts (toxic epidermal necrolysis after 1st infusion, flare of SLE after 6 months of therapy, with discontinuation of BEL in both pts). One patient, boy, 4 y.o. at onset, received ABA (RTM was discontinue after MAS). Disease duration at start of BEL – 7.5 years, the activity by SLEDAI – 10. Treatment with ABA allowed to decrease the activity of sJLE (now SLEDAI=2). Now boy receives ABA during 51 months with good safety, continues GC 5mg per day, hydroxychloroquine 100mg per day.

Conclusion: Our study has shown that B is effective in sJLE and has an acceptable safety profile if possible adverse reactions are carefully monitored. In the presence of severe organ lesions, to improve the long-term prognosis, the appointment of B at an early stage of the disease can be discussed. The overall picture that emerges is one of optimism that advances in therapy of sJLE will be realised through the targeted use of an increasing different B.

POS1309  THE IMPACT OF PSORIASIS ON PATIENT-REPORTED OUTCOMES IN JUVENILE PSORIATIC ARTHRITIS
J. M. J. Low1, K. Hyrich2, N. Geirmann3, S. Shoop-Worrall4 on behalf of CAPS, 1The University of Manchester, UK, Manchester Medical School, Manchester, United Kingdom; 2The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 3The University of Surrey, School of Health Sciences, Faculty of Health and Medical Sciences, Surrey, United Kingdom; 4The University of Manchester, Centre for Health Informatics, Manchester, United Kingdom

Background: Children with juvenile psoriatic arthritis (JPsA) are treated similarly to patients in other categories of juvenile idiopathic arthritis (JIA) despite distinctive clinical features, including either a personal or family history of psoriasis. It remains unknown whether the unique features in JPsA lead patients to experience the impact of disease differently from other JIA patients, and how the presence of psoriasis within JPsA affects patient outcomes. These gaps in our knowledge suggest there may be unmet treatment needs in these children and young people.

Objectives: To compare patient-reported outcomes in patients with JPsA and other JIA categories. Additionally, this study explores whether the presence or absence of psoriasis in patients with JPsA is associated with different outcomes.

Methods: Children and young people with JIA were selected if recruited to the Childhood Arthritis Prospective Study (CAPS), a UK multicentre inception cohort of JIA, between January 2001 and March 2018. Detailed demographic information, clinical data and patient-reported outcomes were collected at initial presentation to paediatric rheumatology. Patient-reported outcomes included well-being as measured on the parental global evaluation (10cm), functional ability (Childhood Health Assessment Questionnaire: CHAQ), pain (10cm), depression (Children's Health Questionnaire, CHQ psychosocial score), depressives symptoms (Mood and Feelings Questionnaire, MFQ) and parent psychosocial health (General Health Questionnaire: GHQ). The CHQ and MFQ questionnaires were completed in a subset of children recruited until 2015 and aged above 5 and 7 years old, respectively.

Result: A total of 1653 patients had JIA; the majority (64.7%) were female and median age at onset was 6.5 years (IQR 2.7 - 10.8). A total of 111 (16.7%) were categorised with JPsA, of which 62 (55.9%) were female with median age at onset of 10.2 (IQR 4.3 -12.5). In those with JPsA, 35% had psoriasis at diagnosis. There were no significant differences between JPsA and non-JPsA in terms of parental global evaluation of wellbeing (p=0.21), CHAQ (p=0.19), pain (p=0.38), CHQ psychosocial (p=0.18), GHQ (p=0.31) or MFQ (p=0.34).

Within JPsA, depressive symptom score on the MFQ was higher in patients with psoriasis compared to those without (coefficient=9.8, 95% CI=0.5 to 19.0, p-value=0.04). However, there were no significant differences in parental global evaluation (p=0.4), CHAQ (p=0.3), pain (p=0.3), CHQ psychosocial score (p=0.5) or GHQ (p=0.7) between those with and without psoriasis in JPsA (Table 1).

</tbody>
</table>

Conclusion: Despite the differences in clinical features present in JPsA compared to the other JIA subtypes, there were no statistically significant differences in patient-reported outcomes overall at diagnosis. However, within the JPsA group, even when adjusting for age, children with psoriasis at time of arthritis diagnosis reported higher depressive symptom scores compared to those without psoriasis. When treating children with JPsA, attention to diagnosing and treating both arthritis and psoriasis (Child Health Questionnaire) remains important. If poor mood persists in this subtype, then further allied health care may be required.

**Speakers bureau:** AbbVie, Grant/research support from: BMS, UCB, and Pfizer, **Methods:**

**Objectives:**

**Results:** Among patients included in the study, there were 11 men (34.38%) and 21 women (65.62%); the average age at the time of inclusion was 23.68 (±5.93). In 13 (40.63%) patients the onset of the disease occurred before the age of 5, in 7 (21.87%) - from 6 to 10 years and in 12 (37.50%) - after 11 years. In 9 (28.13%) patients the duration of the disease was less than 10 years, in 23 (71.87%) patients - more than 10 years. The onset of the disease was accompanied by the following symptoms: fever - 28 (87.50%), arthritis - 21 (63.63%), rash - 17 (53.13), arthralgia - 6 (18.75%), pericarditis - 4 (12.50%), sore throat - 8 (25.00%), lymphadenopathy - 2 (6.25%). Among patients with arthritis 11 (52.38%) had oligoarthritis, 10 (47.62%) had polyarthritis. 2 patients (6.25%) were diagnosed with uveitis. According to the X-ray examination (Steinbrocker's classification of radiographic changes) 5 (15.63%) patients had I stage, 13 (40.62%) - II stage, 4 (12.50%) - III stage, 21 (63.63%) - IV stage and 4 (12.50%) had no radiological changes. Three (9.38%) were diagnosed with aspecic necrosis and these patients underwent arthroplasty. Four (12.50%) patients had pregnancy.

Education: 17 (53.13%) people study at higher educational institutions. Two (6.25%) have a higher educational level. Disease activity: 24 (75%) patients are currently in low activity or disease remission, 8 (25%) are in moderate activity. Twenty (62.50%) patients receive therapy with disease - modifying antirheumatic drugs (DMARDs), 14 of them are treated with tocilizumab, 3 (12.50%) – with canakinumab, 3 (12.50%) – with bDMARDs.

**Conclusion:** The use of bDMARDs helps successfully control the disease in patients with sJIA, maintain long - term remission and improve long - term outcomes in adult patients with sJIA.

**Disclosure of Interests:** None declared DOI: 10.1136/annrheumdis-2022-eular.2754

**ANALYSIS OF INTERFERON-TYPE 1 SIGNATURE IN JUVENILE DERMATOMYOSITIS**

R. Raupov1,2, E. Susiptin1,4, R. Mukidzhan3, M. Kostik1,5, 1Saint-Petersburg State Pediatric Medical University, Pediatrics, Saint-Petersburg, Russian Federation; 2City Hospital №40, Medical Rehabilitation of Children, Saint-Petersburg, Russian Federation; 3Saint-Petersburg State Pediatric Medical University, Medical Genetics, Saint-Petersburg, Russian Federation; 4N.N.Petrov Institute of Oncology, Molecular diagnostics, Saint-Petersburg, Russian Federation; 5Almazov National Medical Research Centre, Laboratory of Autoimmune and Autoinflammatory Diseases, Saint-Petersburg, Russian Federation

**Background:** IFIH1 gene codes for the MDA5 protein participating in interferon I signaling pathway, which is important in the innate immune response [1]. IFIH1 polymorphisms are associated with a spectrum of autoimmune disease [2]. Rare IFIH1 gene defects have been found in patients with Aicardi- Goutières syndrome-7, Singleton-Merten syndrome, and MDA-5 immunodeficiency. All these conditions are characterized by upregulation of interferon signaling [3]. DDX58 encodes RIG-I receptor that is responsible for the recognizing of single- and double-stranded viral RNA. Mutation of DDX58 was described in Singleton-Merten syndrome [4].

**Objectives:** to describe clinical characteristics of patients with rare IFIH1 and DDX58 variants detected by clinical exome sequencing.

**Methods:** 8 patients (5 girls and 3 boys) having rare IFIH1 and DDX58 variants (MAF less than 0.005) were found in heterozygous state among the patients who underwent genetic testing in our hospital in 2019-2021. Clinical manifestations, laboratory parameters, IFN I score values and treatment options were analyzed.

**Results:** 3 patients (#3, #6, #7) had undifferentiated systemic autoinflammatory syndromes, while others were presented with SLE, SLE-like disease, JDM and PFAPA syndrome. All of them had elevated IFN-I score and skin rash. IFIH-1 variants were in 5 patients (#1-5); 3 patients carried the same c.1879G>T polymorphic variant. Patient #6-8 have VUS DDX58 variants. All the alleles were in heterozygous state. Detailed information is presented in Table 1.

Objectives: to evaluate IFN-score in children with dermatomyositis and compare with disease activity

Methods: 15 patients (5 boys and 10 girls) were enrolled in the study. Clinical and laboratory parameters, disease activity (CMAI-childhood myositis assessment tool, aCAT- abbreviated cutaneous assessment tool) and treatment were assessed. Patients were compared according to IFN-score elevation. IFN-score was assessed by RT-PCR quantitation of 5 IFN-1 regulated transcripts (IFI44L, IFI44, IFIT3, Ly6E, MXA1); median relative expression of ≥ 2 was considered as a cut-off. IFN-score was evaluated in dynamics in 9 patients.

Results: median age of patients was 6.2 (3.6; 7.6) years. Skin and muscle involvement were in all patients, arthritis in 5 (33%) patients, calcinosis in 3 (20%), lipo-dermatitis in 2 (13%) and lung involvement in 5 patients (33%), and 9 patients (60%) had positive myositis-related antibodies. Ten patients (67%) had an active disease, while elevated IFN-score was detected in 12 (80%) patients. Cumulative IFN-score and its five’ five components were higher in active patients, compare to inactive (13.6 vs 1.4, p=0.006). Patients with increased IFN-score had lower CMAS score and higher aCAT score compared to patients with normal levels of IFN-1 score. IFN-score correlated with aCAT, arthritis and lung involvement.

Conclusion: IFN-score may be considered as disease activity biomarker in juvenile dermatomyositis with predominantly skin activity process.

POST313
HIP INVolVEMENT IS A MoRe FREQuENT COMPLICATION IN ENThESIS-RELATED ARTHRiThS COMPARED TO THE ADULT SPONDYLOArTHRiThS

C. Ines1,2, H. Ferjani1, L. Ben Ammar1, D. Ben Nessib1, W. Triki1, K. Maataallah1, D. Kaffel1, W. Hamdi1 on behalf of Rheumatologie Charles Nicole Hospital, Tunis.
1Med Kassab Institute of Orthopedics, Rheumatology, Manouba, Tunisia

Background: The hip disease develops in 30% to 50% of children with juvenile idiopathic arthritis (JIA) and is associated with poor outcomes and functional impairment. The coxitis in enthesitis-related arthritis (ERA or juvenile-onset spondyloarthritis) patients was frequent but weakly studied.

Objectives: To assess the occurrence of coxitis in patients with ERA and compare it to that of older patients with spondyloarthritis (SpA).

Methods: We conducted a retrospective comparative study including patients with ERA and adult spondyloarthritis patients.

The first group included patients under 16 years old fulfilling the International League of Associations for Rheumatology (ILAR). The second group of patients fulfilled the Assessment of SpondyloArthritis International Society (ASAS) 2009 criteria. We studied the socio-demographic characteristics of both groups, the hip involvement occurrence, and the treatment modalities.

Quality of life was appraised by the Study 36-item Short-Form Health Survey (SF-36) and the Ankylosing spondylitis quality of life test (ASOQL).

Results: Forty ERA (mean age=25.3 ±10.15) patients and 134 SpA (mean age=37.96±11.77) patients were enrolled. Seventeen ERA patients (42.5%) had coxitis at recruitment compared to 28 SpA patients (20.9%), p<0.06. More than half of the ERA patients were positive to HLA-27, compared to the SpA group (44.7%), without reaching a significant threshold, p=0.07. The mean delay of coxitis onset in ERA patients was 4.66 ±4.6 years, and was 5.65 ±6.6 years in SpA patients, with no significant difference between the two groups (p=0.527). There was no difference between the two groups for the coxitis being unilateral or bilateral (p=0.272 and 0.169 respectively). Regarding the treatment approach, local therapy was proposed to 11 patients in the ERA group and 13 patients in the SpA group (p=0.07), with synoviolysis being the most common therapy. Total hip replacement was done in 3 ERA patients (of which two were bilateral) and in 17 SpA patients (of which ten were bilateral), without reaching the significant threshold (p=0.858). There was no significant difference between the two groups on the period when the total hip replacement was done (p=0.925). Quality of life assessed by the ASOQL and the SF-36 was comparable between the two groups (p=0.666 and 0.326, respectively).

Conclusion: Our study shows the high prevalence of hip involvement in the juvenile group with enthesitis compared to the five years of disease outcomes and constitutes a turning point in their lives.

POST314
VALIDATION OF A PEDIATRIC-SPECIFIC ULTRASOUND SCORING SYSTEM FOR THE EVALUATION OF WRIST, FINGER, AND ANKLE SYNOVITIS

P. Vega Fernandez1, T. Hennard1, K. Rogers2, A. B. Meyers2, A. Cassidy1, T. Ting3, 1Cincinnati Children’s Hospital Medical Center, Department of Pediatrics, Cincinnati, United States of America; 2University of Cincinnati, Radiology, Cincinnati, United States of America

Background: Juvenile Idiopathic Arthritis (JIA) is the most common chronic rheumatic disease in children. Clinical evaluation of arthritis is a subjective measurement. Musculoskeletal ultrasound (MSUS) is increasingly being utilized in children. In order to provide objective assessments of arthritis, reliable and validated MSUS scoring systems are needed. Recently, a joint-specific scoring system for the assessment of arthritis of the pediatric ankle, wrist and finger joints were proposed.[1,2]

Objectives: This study aims to further validate the MSUS scoring system for the assessment of finger, wrist, and ankle arthritis

Methods: JIA patients with finger, wrist, and ankle arthritis as per expert clinician evaluation are eligible for this study. A comprehensive wrist, ankle, and finger (2-5th metacarpal and 2-5 th proximal interphalangeal joints) MSUS examination by an American College of Rheumatology MSUS certified pediatric rheumatologist is performed on all enrolled subjects. MSUS are scored using the semiquantitative (grade 0 to 3) scoring systems previously proposed. A subset of participants receives an MRI with contrast of the targeted joint immediately after MSUS performance. MRI findings are read for presence of synovitis, tendons and enthesis by a pediatric radiologist with expertise in pediatric musculoskeletal imaging.

For the analysis of the current report, MRIs were classified as having presence or absence of findings of JIA disease based on the pediatric radiologist expert opinion. MSUS were classified as normal (grade 0 and 1) or abnormal (grade 2 and 3). Cohen’s Kappa Coefficient was used to assess the level of agreement between MSUS (normal and abnormal) and MRI with contrast (absence or presence of disease) for each targeted joint. Tetrachoric Correlation was used to assess the strength of the association. Fisher’s Exact test was used to determine statistical significance at p < 0.05 level.

Results: A total of 52 children aged 2 – 18 years old have been enrolled in this study. To date 20 MSUS of the finger(s), 33 MSUS of the wrist, and 43 MSUS of the ankle joints have been collected. Three MRI of the 2-5 fingers (12 fingers total), 6 MRI of the wrist, and 5 MRI of ankle have been obtained through the study. Preliminary results of this effort reveal that for the ankle joint there is moderate agreement (Kappa coefficient 0.53 [confidence interval (CI)=0.14-0.92]) between MRI and US and a strong positive tetrachoric correlation (0.79) (p = 0.03). While the Kappa coefficient for comparing MRI and US finding on wrist joint indicated moderate agreement (Kappa 0.62 [0.15-1.00]) with a strong tetrachoric correlation (0.83) the Fisher’s exact test indicated a trend rather than statistically significant results (p = 0.07). The Kappa coefficient for MCPs and PIPs joints indicated strong agreement between MRI and US (Kappa 0.83 [CI=0.52-1.00] and 0.80 [CI=0.43-1.00] respectively) and were supported by an almost perfect Tetrachoric Correlation of 0.99 (p < 0.01). We anticipate to complete enrollment of subjects by the summer of 2022. Analysis of collected data is underway.

Conclusion: The strong to moderate association of MSUS with contrast-enhanced MRI, suggest that MSUS can provide an objective and accurate assessment of ankle, wrist and finger arthritis at the bedside. Further refinement and validation of these pediatric-specific MSUS scoring systems may support the use of MSUS as a clinical tool and outcome measure in JIA.

**PREVALENCE OF SARCOPENIA IN YOUNG ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS**

M. Dzhus1, M. Kulyk1, T. Karasevska1. 1Bogomolets National Medical University, Internal Medicine Department №2, Kyiv, Ukraine

**Background:** In the 2019 sarcopenia consensus update (EWGSOP2 [1]) experts emphasize low muscle strength as a key characteristic of sarcopenia, adding low muscle mass to confirm the diagnosis of sarcopenia. Thus, the presence of the first criterion indicates probable sarcopenia, the presence of the first and second criteria confirms the diagnosis of sarcopenia, and the presence of all three criteria indicates severe sarcopenia. There are no available data about severe sarcopenia in young adults with juvenile idiopathic arthritis (JIA).

**Objectives:** This study aims to assess the prevalence of severe sarcopenia in young patients with JIA.

**Methods:** To confirm the diagnosis of severe sarcopenia we used dual X-ray absorptiometry (DXA) to assess low muscle mass (cut off points for ASM/height2 <7 kg/m2 for men and <5.87 kg/m2 for women); dynamometry - to determine the low muscle strength (grip strength <27 kg for men, <16 kg for women); gait speed and short physical performance battery (SPPB) to assess physical function (cut off points <8 m/sec and score ≤8, respectively). Patients were divided into two groups according to the presence or absence of all three criteria for severe sarcopenia.

**Results:** We studied 40 young adults with JIA, including 23 female patients and 17 male patients. The mean age of the patients was 24.4±5 years; the mean weight was 72,0±12,8 kg; p=0,01, respectively. The research found out: the height and weight of patients in the group with severe sarcopenia were lower than in the group without severe sarcopenia (height 1.67±0.07 m vs 1.75±0.08 m; p=0,01; weight 56.1±9.2kg, 72.0±12.8kg; p=0,01, respectively). The age of patients was not significantly different between the two groups, but the duration of the disease was longer in the I group 16,4±8.2 vs 9,2±5.3; p=0,01. The data of DXA differed between groups: the patients of I group had statistically reduced total BMD 1.07±0,1 g/cm2 vs 1.15±0,14g/cm2; ultra-distal radius BMD 0.35±0,1g/cm2 vs 0.51±0,12g/cm2; femoral neck BMD 0.85±0,1g/cm2 vs 1.04±0,2g/cm2; p=0,01, respectively. Comparing the two groups, we found important differences: the level of LSR was higher in the I group 25.05±18.3 vs 11.5±10.02; p=0.01; the index of disease activity either (DAS28 4,0±1,7 vs 2.7±1.2; JADAS27 15,8±9.2 vs 8,3±4.8; p=0,01, respectively). Articular and extraarticular damage index were higher in I group: JADI-A 5.08±7.3 vs 0.5±0.7; p=0,01; JADI-E 1.7±1.8 vs 0.3±0.6, p=0.02. **Conclusion:** The study confirms the presence of severe sarcopenia despite the young age of patients with JIA. Severe sarcopenia occurs in patients with a higher level of inflammatory activity, articular and extraarticular damage, reduced bone mineral density, and longer duration of the disease. Further study of the factors influencing the development of sarcopenia in this category of young patients is required.

**PERFORMANCE OF THE KOBAYASHI SCORE AND MODIFIED KOBAYASHI SCORE IN PREDICTING RESISTANCE TO INTRAVENOUS IMMUNOGLOBULIN IN PATIENTS WITH PEDIATRIC INFLAMMATORY MULTYSYNDROME ASSOCIATED WITH SARS-COV-2.**

N. Cybulska1, K. Jozkow1, K. Orczyk1, A. Stasiak1, E. Smolewska1. 1Medical University of Lodz, Poland, Department of Pediatric Cardiology and Rheumatology, Lodz, Poland

**Background:** Pediatric Inflammatory Multisystem Syndrome Associated With SARS-CoV-2 (PIMS) is a new insidious disease which in several points may mimick Kawasaki disease. Patients diagnosed with one of the aforementioned conditions are initially treated with intravenous immunoglobulin (IVIG). However, up to 20% of children diagnosed with Kawasaki disease appear to be resistant to such therapy. Similarly, substantial portion of PIMS patients requires second line treatment including systemic glucocorticoids. There are several calculative models, including the Kobayashi Score, which are utilized to predict patients' response to such treatment. To our best knowledge, the scoring systems derived from Kawasaki disease have not yet been assessed whether they can fulfill similar role in PIMS patients.

**Objectives:** There were two essential questions to be addressed in the study: (1) Can the Kobayashi Score be utilized in making clinical decisions regarding concomitant treatment in PIMS patients? (2) Is there any modification that may increase the accuracy of the original score?

**Methods:** First step of the study involved 19 patients diagnosed with PIMS between July 2020 and June 2021. The statistical analysis including each parameter of the Kobayashi Score has been performed in order to determine potential alterations of the score. Then, the numerous variants of modified score have been compared in terms of their positive and negative predictive values in order to determine new PIMS IVIG Resistance Score (PIRS). In the next phase of the study, both scores have been validated in the second cohort involving 16 patients diagnosed with PIMS between July and December 2021. The final assessment has been performed in the unified study group (35 PIMS patients).

**Results:** The Kobayashi Score (see Table 1) significantly differentiated PIMS patients in terms of good response or resistance to IVIG (p=0.03967). However, the score returned a few false positive (3 out of 9) and false negative (2 out of 10) results. After step-by-step verification of clinical and laboratory parameters, authors developed a tentative PIRS (see Table 1) including the following criteria: hyponatremia, days of fever and platelet count (derived from the Kobayashi Score but with different cut-off levels) supplemented with procalcitonin level and percentage of lymphocytes. In the validatory phase of the study, both scores had equal accuracy to predict treatment response. The analysis of receiver operating characteristic curve in the unified study group has shown better performance of PIRS (Youden index 0.72) than the Kobayashi Score (Youden index 0.49).

**Table 1. List of criteria included in both scores assessed in the study.**

<table>
<thead>
<tr>
<th>Criteria</th>
<th>The Kobayashi Score</th>
<th>PIMS IVIG Resistance Score (PIRS)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sodium</td>
<td>≤133 mmol/L</td>
<td>≤137 mmol/L</td>
</tr>
<tr>
<td>Days of illness at initial treatment</td>
<td>≤2 points</td>
<td>≤2 points</td>
</tr>
<tr>
<td>Aspartate aminotransferase</td>
<td>≤100 IU/L</td>
<td>≤100 IU/L</td>
</tr>
<tr>
<td>Percentage of neutrophils</td>
<td>≥80%</td>
<td>2 points</td>

<td>≤300 G/L</td>
<td>≤300 G/L</td>
</tr>
<tr>
<td>Increased risk of resistance to IVIG</td>
<td>≤4</td>
<td>≤4</td>
</tr>
</tbody>
</table>

**Conclusion:** The Kobayashi Score is worth being considered to estimate the risk of resistance to IVIG in PIMS patients. Nonetheless, it is not free from false positive and false negative results. The postulated modified score called PIRS can become a promising alternative but it requires further validation in larger cohorts of patients.

Background: Juvenile Idiopathic Arthritis (JIA) is a group of heterogeneous arthritis with onset earlier than 16 years old. According to previous studies, these patients experience an improvement of their disease activity, functionality and even remission probability as they become young adults.[1] Transitional care units during the COVID-19 pandemic skipped the sufficient physical activity (p=0.03352). Correlation between elevated ESR and higher cIMT values in right carotid artery was marginally significant (r=0.292, p=0.051443). Regardless of JIA, exposure to secondhand smoke exposure, needs to be promoted with utmost importance during the COVID-19 pandemic, especially in children with chronic diseases like JIA.

We calculated the percentage of patients who had active disease at the transference to the Unit and the percentage of patients who had an inflammatory flare during the follow-up. Figures 1 and 2 showed the proportion of flares depending on the inflammatory status at transference to the Transitional care unit and the use of biological therapy before transition.

RISK OF CORONARY ARtery INVOLVEMENT IN KAWASAKI DISEASE.

S. Kurbanova1, M. Kantemirova1, Y.Y. Novikova1, D. Ovsyannikov1. 1RUDDN University, Department of Pediatrics, Moscow, Russian Federation

Background: Kawasaki disease (KD) is a non-specific systemic vasculitis disease that frequently occurs among children, and coronary artery lesion (CAL) is the most serious complication.

Objectives: We aimed to study the risk factors for CAL in children with KD

Methods: There were examined 188 patients (boys-girls – 2:1, median age Me = 24 months [11;38] with KD hospitalized in Morozovskaya Children’s City Clinical Hospital in 2014-2019. 19 (10,1%) of them were <6 months, 29 (15,4%) - 6-12 months, 117 (62,3%) - 12 months-<5 years, 23 (12,2%) - >5 years. Univariate and multivariate logistic regression analyses were conducted to explore the relationships between CAL and gender, age, clinical diagnosis, laboratory biomarkers, initiation time of IVIG administration.

Results: The enrolled 188 KD children were divided into a CAL group (n = 61) and an NCAL group (n = 127) according to cardiac color Doppler ultrasonography. The incidence rate of CAL in the acute period was 26 %. The two groups had significantly different gender (p=0,0184), initiation time of IVIG administration (p=0,0209), increase in platelets more than 700 000 at 2 weeks (p=0,0089), higher levels of NT-proBNP (p=0,002) and proANP (p=0,0005). Patients with CAL were found to have higher levels of NT-proBNP and proANP, suggesting a prognostic role. The NT-proBNP level was significantly higher in patients with CAL, and a cutoff value of 984 pg/mL yielded a sensitivity and specificity of 79 and 84.8 %, respectively. The area under the curve of the NT-proBNP for predicting CAL was 0.794 (95 % CI 0.620-0.967). The proANP level was significantly higher in patients with CAL, and a cutoff value of 1.05 mmol/l yielded a sensitivity and specificity of 78.5 and 75.8 %, respectively. The area under the curve of the proANP for predicting CAL was 0.805 (95 % CI 0.656-0.954).

Conclusion: Male gender, delayed use of IVIG, high platelets, NT-proBNP, proANP were independent risk factors for KD complicated with CAL. Current evidence suggests that NT-proBNP and proANP may be used as a diagnostic tool for KD complicated with CAL.

SAFETY AND EFFICACY OF RITUXIMAB IN PATIENTS WITH JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS: THE PRELIMINARY DATA OF RETROSPECTIVE COHORT STUDY

E. Kalashnikova1, R. Raupov1,2, N. Lybimova3, E. Kuchinskaya3, O. Kalashnikova1, V. Chazryn1, K. Konshina1, L. Sniegireva1, E. Gaidar1, V. Masalova1, E. Isupova1, M. Kaneva1, M. Dubko1, T. Likacheva1, L. Sorokina1, M. Kostik1,3, Saint-Petersburg State Pediatric Medical University, Pediatrics, Saint Petersburg, Russian Federation; 2City Hospital №40, Medical Rehabilitation of Children, Saint Petersburg, Russian Federation; 3Almazov National Medical Research Centre, Laboratory of Autoimmunity and Autoinflammatory Diseases, Saint Petersburg, Russian Federation

Background: juvenile systemic lupus erythematosus (SLE) is the most frequent pediatric connective tissue disease with multorgan involvement and different outcomes and prognosis. Corticosteroids remain the base treatment option and steroid-sparing treatment is strongly required to avoid steroid toxicity. Rituximab (RTX) is one of biologics, which efficacy was proved in case reports and case series of SLE, but no data from big randomized trials, confirming the efficacy have existed.

Objectives: to evaluate safety and efficiency of RTX in SLE

Methods: in the retrospective observation study the information of 48 jSLE patients (12 boys, 36 girls) who received at least one RTX dose before 18 years, was analyzed. RTX were high disease activity with lupus nephritis (LN), CNS and hematology disturbance. Randomized controlled trials are required to evaluate the efficacy and safety of RTX.

Results: The main patient's characteristics were: onset age 13.0 (11.5; 15.0) years, with 46 (96%) children treated for at least one SLE feature (SLEDAI, anti-dsDNA level, proteinuria, hematuria, C4, ESR), number of patients with anemia, thrombocytopenia, and median GCS dose by 90% from the initial. The hemoglobin level and WBC have increased. 19 patients received IVIG for treatment of MAS (n=3), infection (n=5) and as replacement therapy in cases where IgG<4.5 g/l (n=11). 3 deaths were observed due to catastrophic SLE with MAS, accompanied severe infection (invasive aspergillosis, n=2), 6 patients realized SAE: pneumonia (n=3), transient agranulocytosis, C4, ESR after 3rd RTX infusion and meningitis, caused by Lysteria monocytogen, after 1st RTX infusion (further RTX treatment continued without adverse events), patella osteomyelitis (n=1). 10 patients received antibiotics for respiratory infections. On pre-RTX 13 had antibiotics (p=0,10).

FEATURES OF MACROPHAGE ACTIVATION SYNDROME IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS IN THE ERA OF BIOLOGIC THERAPY

I. Kruilin1, E. Alexeeva1, T. Dvoryakovskyak2, R. Denisova1, A. Chomakhidze2, A. Mamutova1, O. Lomakina1, A. Feltskina1, M. Gautier2, K. Chibisova1, E. Krekhova1, I. Tsulukiya1, 1Sechenov University, Pediatrics, Moscow, Russian Federation; 2National Medical Research Center of Children’s Health, Rheumatology, Moscow, Russian Federation

Background: Macrophage activation syndrome (MAS) is a severe hyperinflammatory response that develops against the background of juvenile idiopathic arthritis (JIA). It is known that the clinical feature of MAS on biologic therapy has other clinical manifestations, different from biologically naive patients.

Objectives: To study the clinical and laboratory features of macrophage activation syndrome in patients with juvenile idiopathic arthritis with systemic onset (sJIA) on the biologic therapy.

Methods: The study included 100 patients with MAS (114 cases of MAS) who observed in the rheumatological department of the National Medical Research Center for Children’s health of Ministry of Health. All patients met the criteria for the diagnosis of sJIA and MAS. There were children in our study who did not receive biologic therapy – 84 (74%) cases, and children who had MAS in the biologic therapy – 30 cases (26%). The drugs are described as follows: tocilizumab – 7 cases (6%), canakinumab – 20 cases (17%), etanercept – 2 cases (2%), adalimumab – 1 case (1%). For pairwise intergroup comparisons of quantitative variables, the nonparametric Mann-Whitney test was used.

Results: In comparative analysis of biologic-naive and on biologic patients, the greatest differences were obtained for the following clinical manifestations: rash, lymphadenopathy, myalgia (p<0.05). Fever was the most common symptom in both groups and was present in almost all patients (99%). All patients had
Conclusion: On biologic patients may also develop MAS, which is often difficult to diagnose due to the poor clinical picture and low laboratory activity. In this case, hyperferritinemia remains as a highly specific marker of MAS.

Results: Corticosteroid-sparing control of inflammation was achieved in all patients. Adalimumab was discontinued after 50 (range 12–120) months after initiation of adalimumab. Duration of remission prior to discontinuing adalimumab was 42 (range 6 – 114) months. The mean duration of remission after adalimumab discontinuation was 14 (range 1–59) months. 13 (40%) of patients had flares after less than 12 months after discontinuing adalimumab, 5 (15%) had flares after 12 – 24 months, 15 (45%) had not flared after 24 months after discontinuation adalimumab and had had a long-term non-biological remission.

Conclusion: Corticosteroid-sparing control of inflammation was achieved in all patients. Data from our experience with adalimumab in patients with JIA-associated uveitis suggest that 45 % of patients can be successfully withdrawn from biologics for at least 24 months without disease recurrence.

Background: Uveitis is the most common extra-articular manifestation of JIA which may lead to sight-threatening ocular complications. Topical corticosteroids are still used in the initial treatment for JIA-associated uveitis. The goal of treatment in these patients should be topical corticosteroid-free remission and prevention of recurrences. The most commonly used corticosteroid-sparing immunomodulatory are TNF-α inhibitors (TNIFI), especially adalimumab.

Methods: Medical records of 33 patients with JIA-associated uveitis who were successfully treated with adalimumab to a state of topical corticosteroid-free remission and discontinued adalimumab due to a long-term remission were ana-

ized retrospectively.

Remission of uveitis was defined as <1+ cells in the anterior chamber and <1+ vitreous haze grading; relapse was defined as ≥1 cell in the anterior chamber or ≥1 vitreous haze grading.[1]

Results: Corticosteroid-sparing control of inflammation was achieved in all patients. Adalimumab was discontinued after 50 (range 12–120) months after initiation of adalimumab. Duration of remission prior to discontinuing adalimumab was 42 (range 6 – 114) months. The mean duration of remission after adalimumab discontinuation was 14 (range 1–59) months. 13 (40%) of patients had flares after less than 12 months after discontinuing adalimumab, 5 (15%) had flares after 12 – 24 months, 15 (45%) had not flared after 24 months after discontinuation adalimumab and had had a long-term non-biological remission.

Disease was successfully controlled in 11(33%) patients with non-biological DMARDs, 22 (66%) patients restarted biological therapy after flares, due to lack of improvement after non-biological DMARDs. All patients in whom biological therapy was reinstituted responded satisfactorily. None of the flared patients didn’t require restarting corticosteroids.

Conclusion: Corticosteroid-sparing control of inflammation was achieved in all patients. Data from our experience with adalimumab in patients with JIA-associated uveitis suggest that 45 % of patients can be successfully withdrawn from biologics for at least 24 months without disease recurrence.

Background: Although regular physical activity (PA) is known to have many health-related benefits for children and adolescents with chronic conditions, JIA has been associated with reduced physical activity (PA) and increased time spent sedentary [1]. Sedentary behaviour is an important consideration alongside PA when examining the contribution of both behaviours to the health of young patients. Because young people show more complex but less structured movement behaviour than adults, capturing their many spontaneous and impulsive movements is a great challenge for PA assessment.

Objectives: Since accurate, objective measures of PA related to potential factors promoting PA have been scarce, this study aimed i) to objectively assess moderate to vigorous PA (MVPA) as well as sedentary behaviour and ii) to identify facilitators for PA in patients with JIA.

Methods: Within the framework of the ActiMON study as part of the TARISIMA research network, data were collected at several German paediatric rheumatology centres. Objectively assessed PA of adolescent patients with JIA was recorded exclusively during school months in the period June - December 2021 using the accelerometer ActiGraph wGT3X-BT laterally on the right hip. In accordance with the International Children’s Accelerometry Database criteria [2], ActiGraphs were worn on seven consecutive days during all waking hours, including at least 4 valid weekdays and 1 weekend day (wear time >8 hours) in the evaluation. Self-reported PA-related data were measured using a physical activity questionnaire (PAQ), while clinical parameters were used from the National Paediatric Rheumatologic Database (NPRD). Achievement of the WHO recommendation of at least 60 minutes MVPA a day and compliance with the national recommendation of no more than 120 minutes of daily screen time were determined among 12- to 18-year-olds.

Results: Data of 41 patients (mean age 14.6 ± 1.9 years, female 73%, patients’ disease duration 79 ± 4.6 years, polyarthritis 40%, cJADAS-10 2.3 ± 2.4) were available for evaluation. Almost 71% of participating patients met the WHO-recommended minimum level of MVPA, while the average daily step count achieved was 7804. Almost 80% of the patients rated their motor and coordination skills as being good. The most frequently mentioned reasons for doing sports (multiple answers possible) included feeling good (78%), giving energy (70%), pleasure (65%) and enjoyment (60%). Patients whose parents are active in sports and support their child in finding a suitable offer were more likely to fulfil the WHO recommendation than patients without family support. The average daily time spent sedentary was 10.5 ± 1.9 hours. About half of the patients reported spending more than 4 hours a day with screen-based media, especially video games.

Conclusion: These preliminary results suggest that while a large proportion of patients achieve the WHO recommended minimum level of PA, they exhibit very pronounced sedentary behaviour with increased screen use. In addition to controlled sports activity as a well-known prerequisite for achieving PA recommendations, these findings also point to the importance of family support and emotional well-being. With ongoing recruitment, further potential facilitators and barriers to PA should be identified in more in-depth analyses.

Figure 1. Two different patients with severe FOP and similar evidences of sacroiliitis and bilateral hips synovitis by MRI

POS1324 THE IMPORTANCE OF MRI IMAGING FOR THE MANAGEMENT AND UNDERSTANDING OF THE DISEASE ORIGIN IN FIBRODYSPLASIA OSSIFICANS PROGRESSIVA

I. Nikishina1, S. Arsenyeva1, V. Matkava1, M. Kaleda1, T. Pachkoria1, A. Arefeva1,1 VA. Nasonova Research Institute of Rheumatology, Paediatric, Moscow, Russian Federation

Background: Fibrodysplasia ossificans progressive (FOP) is ultra-rare autosomal dominant inherited genetic disorder which is caused by mutation in ACVR1 gene and provokes severe heterotopic ossification (HO) as a “second skeleton disease.” Our long-term experience of the largest group of FOP patients in single Russian center makes possible to interpretate clinical findings and imaging as the evidences that FOP may belong to special kind of axial spondyloarthritides. Because of new bones formation process X-Ray and CT scans recognize as the main imaging methods for the FOP. But MRI method may present important information for the understanding of the disease origin in FOP.

Objectives: To analyze the MRI findings in FOP patients in relation to clinical manifestations, and therapy options.

Methods: The study was based on retrospective and prospective observation and included 40 pts (21 males; 19 females). Diagnosis of FOP was established on typical clinical features and detecting mutation. X-ray, CT and MRI were performed in most patients excluding the severe disabled status of FOP. Some patients failed to perform MRI due to the presence of severe skeletal deformities or artificial metal constructions (because of previous orthopedic operations). Blood assessment has never shown specific elevated markers.

Results: Among of all 40 FOP patients MRI of sacroiliac joints was performed in 14 patients. Chronic sacroiliitis was detected in 10/14 pts, including active sacroiliitis in STIR regimen in 6/14 pts by. Also 7/14 pts have MRI evidence of severe coxitis (see Figure 1). This imagines findings and other features of axial involvement (X ray imagines of ankylosis of the facet joints and vertebral bodies by the type of syndesmophytes) allowed us to establish alternative diagnosis of juvenile spondyloarthritides (JAS) in 7 pts and juvenile idiopathic arthritis (JIA) in 5 cases. It was needed for the legal possibility to administer tocotocin (TOFA) in 12 pts (the youngest pt of 2 y.o., the oldest – 19 y.o) with strong uncontrolled progression of FOP. The dosage of TOFA was up to 5 mg twice a day. We noticed that all 12 pts have severe coxitis with synovia proliferation (with MRI and ultrasound evidence). Duration of TOFA therapy is from 2 to 25 months. Drug tolerance was good in all pts, no AE were registered. New nodes formation immediately stopped in most pts., significant improvement of motions was observed in 10 (83%) pts. Also, we noticed fast regression of sacroiliitis and coxitis activity by MRI in 5 (42%) pts under TOFA therapy. All other patients didn’t have repeated MRI examination yet. So MRI seems to be important method to confirm the anti-inflammatory effects for sacroiliitis and coxitis signs in patients with FOP. It seems to expect that inflammation control may prevent the sacroiliac and hip ankylosises. In spite of the absence of new HO in our 16 y.o. pt, we found continuous intraskeletal ossification between C3-C4, C5-C7 vertebral bodies, facet joints that leads to subtotal stenosis of spinal canal without any neurological symptoms. Because of «protection effect» of external heterotopic ossification severe neurological damage was not developed.
Conclusion: According to MRI findings, hip damage was characterized for all ages of FOP patients. Sacroiliitis was found mostly in patients older than 10 years. Based on our experience of JAK-inhibitor therapy we can suggest about positive effect and advantages of TOFA over other therapy approaches. Dynamics of MRI imaging may be a good option for the confirmation of therapeutic anti-inflammatory effects.

CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS (CRMO): NEW INSIGHTS INTO EXTRA-OSSEOUS MANIFESTATIONS.

M. Robert1, C. Guillaume2, L. Rossi-Semerano1, C. Galeotti1, I. Koné-Paut4, P. Dusser1, 1Kremlin-Bicêtre, Service de Rhumatologie Pédiatrique, Le Kremlin-Bicêtre, France

Background: Chronic recurrent multifocal osteomyelitis (CRMO) is a rare inflammatory disease of the skeleton characterized by chronic and recurrent episodes of osteo-articular inflammation. The median age of onset is 10 years old. Clinical manifestations include musculoskeletal symptoms that are well described (pain, tenderness, swelling). Sometimes, skin lesions or digestive manifestations occur. Whole body magnetic resonance imaging (MRI) is the gold standard for assessing the multifocal pattern of the CRMO. Treatment is still empirical and mainly relies on non-steroidal anti-inflammatory drugs (NSAIDs). Bisphosphonates and biologics are used as second-line treatments. To date, the focus has been on bone involvement and very few data are available on extra-osseous manifestations in CRMO.

Objectives: This study aims to further describe these extra-osseous clinical manifestations in CRMO.

Methods: A historical cohort was designed using 61 CRMO patients at the Pediatric Rheumatology Department in a tertiary university hospital in Paris (Hôpital Bicêtre, France). All patients underwent a MRI that confirmed the diagnosis according to the criteria of Jansson. Skeletal involvement was characterized with 1/axial, 2/peripheral, 3/axial and peripheral lesions. Extra-osseous manifestations were divided into 1/skin lesions, 2/gastro-intestinal manifestations, 3/enthesitis and 4/others. Pain was evaluated thanks to the Visual Analog Scale (VAS, from 0 to 10). Treatments used were recorded. The study complied with ethical requirements.

Results: Forty one patients were included in the study, with 31 females (75.6%). The mean ± SD age at onset was 79 ± 59.8 months, with a delay at diagnosis beyond six months (6.71 ± 6.96). Twenty-one patients had a familial history of inflammatory diseases (51.2%), with a majority of psoriasis or ankylosing spondylitis (n=13/21, 61.9%). At diagnosis, the level of pain was 5.71 ± 3.24. Eleven patients (42.3%) had blood injection. Bone lesions were reviewed thanks to whole body MRI: four patients had isolated axial involvement (10.0%), nine had peripheral involvement (22.5%) and 27 patients harbored both types of lesions (67.5%). The mean number of lesions was 6.65 ± 4.23. After 12 months of follow-up, all parameters regarding disease’s activity decreased (pain, blood inflammation, number of lesions). Regarding extra-osseous symptoms, fever occurred in seven patients (17.1%). Twenty-four patients had skin manifestations (58.5%) with palmoplantar lesions (n=3, 12.5%), acne (n=6, 25.0%), psoriasis (n=5, 20.8%) and aphthous (n=10, 41.7%). Four patients (9.76%) had gastro-intestinal symptoms and seven (17.1%) had enthesitis. One patient had uveitis. Almost all patients received NSAIDs (n=39/41, 95.1%) and half of the cohort were treated with bisphosphonates (n=21/41, 51.2%). Nine patients (22.0%) received biologics with a majority of TNF inhibitors. All patients that received TNF inhibitors had either a cutaneous involvement or digestive symptoms or enthesitis (Figure 1).

Conclusion: Extra-osseous manifestations have to be carefully searched in CRMO, especially in the presence of familial history of inflammatory diseases. While the severity of bone involvement can lead to use bisphosphonates, the introduction of biologicals seems to rely on extra-osseous symptoms. These conclusions are drawn on a retrospective study and need to be confirmed in larger cohort.

PIMS THROUGH THE WAVES OF COVID 19: DATA FROM THE JIR COHORT

R. Kechiche1, A. Schwart2, F. Bajolle2, S. Poignant1, R. Basmaci1, C. Pajo2, U. Meiner3, L. Morin1, V. Lambert2, P. Dusser1, N. Matsu1, M. Hofer3, I. Koné-Paut4, G. Caroline1 on behalf of the French Covid-19 Paediatric Inflammation Consortium. 1CHU Bicêtre, Pediatric Rheumatology, Le Kremlin Bicêtre, France; 2CHU Necker, Pediatric Cardiology, Paris, France; 3CHU Nantes, Pediatrics, Nantes, France; 4CHU Louis Mourier, Pediatrics, Colombes, France; 5CHU Toulouse, Pediatric Rheumatology, Toulouse, France; 6CHU Robert Debré, Pediatrics, Paris, France; 7CHU Bicêtre, Pediatric Intensive Care Unit, Le Kremlin Bicêtre, France; 8CHU Bicêtre, Pediatric radiology, Le Kremlin Bicêtre, France; 9CHU Pediatric Rheumatology, Lausanne, Switzerland

Background: Paediatric inflammatory multisystem Syndrome (PIMS) is a new systemic inflammatory disease linked to SARS-CoV2 that affects children. It was first reported in may 2020 [1-2].

Objectives: The objectives of this study were to describe patients with PIMS through the international JIR cohort registry and to compare the different profiles and treatments of these patients over the different waves.

Methods: Study patients with international PIMS criteria were included from March 2020 to June 2021. Patients were identified in the JIR cohort, an international registry collecting demographic, clinical and paraclinical data on patients with pediatric inflammatory diseases. Two groups were distinguished: from March 2020 to July 2020 for patients in the first wave, from July 2020 to June 2021 for patients in the 2nd and 3rd waves. These two groups were compared using a Fisher test for categorical data and a Mann-Whitney test for quantitative data.

Results: 136 patients meeting the PIMS criteria were included (64 patients in the 1st wave, 72 patients after). Patients had less frequent myocarditis (51 patients in wave 1 vs. 36 patients after, p=0.0003) and respiratory distress (34 patients vs 10 patients, p=0.0001). Corticosteroids were used more frequently in the second wave (32 patients in wave 1 vs. 36 patients after, p=0.0003) and respiratory distress (34 patients vs 10 patients, p=0.0001). Intravenous immunoglobulins were used more frequently in the second wave (32 patients in wave 1 vs. 67 patients after July 2020, p<0.0001). Intravenous immunoglobulins were used as much over the waves (58 patients in wave 1 vs 68 patients after, p=0.5). Antibiotics were less used since the second wave (53 patients received antibiotics before July 2020 vs 11 after, p=0.0001). The duration of hospitalization decreased significantly (p<0.0001) with a median duration of 9 days during the first wave (interquartile range, 7-12) and 7 days (interquartile range, 5-10) after the first wave.

Conclusion: There was a decrease in the number of complications of PIMS, particularly cardiac and respiratory complications, and a decrease in the length of hospitalization over time. The treatment of PIMS has also evolved, with a clear increase in the use of corticosteroids and a decrease in the use of antibiotics.

**POS1327**

**AMYLOID STORM DEVELOPS IN PATIENTS WITH AA AMYLOIDOSIS AND ASSOCIATED WITH HIGHER AMYLOID BURDEN AND INCREASED MORTALITY**

M. Bektaş1, S. San1, N. Koca1, E. Oğuz1, B. Ince1, Y. Yağıcak1, B. Artim-Esen1, M. İnanç1, A. Gül1, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

**Background:** Amyloid storm is an emerging condition which was described recently also associated with poor prognosis in patients (pts) with AA amyloidosis (AA-a).

**Objectives:** We herein aimed to evaluate the amyloid storm and its associated factors in pts with AA-a.

**Methods:** We retrospectively evaluated AA-a pts who followed in our tertiary referral amyloidosis center. Diagnosis of AA-a was made by Congo red straining and immunohistochemistry. Amyloid storm was defined as follows; developing within two weeks, increase in creatinine and proteinuria levels at least two times from baseline or reach the CRP levels more than 10 times [1].

**Results:** Data of 175 pts with AA-a were evaluated and after exclusion of 11 pts who had missing data, 164 pts were included into the analysis. We identified 9 pts (5.5% of 4 male) who developed amyloid storm. Five pts were FMF-associated AA-a (FMF-AA) and 4 pts were non-FMF-AA (two pts had ankylosing spondylitis, one patient idiopathic and one patient non-FM periodic fever syndrome) (p=0.1). Median and Interquartile range (IQR) patient age, diagnosis age of FMF and amyloidosis were lower in pts had amyloid storm than had not, but they were not statistically different (p=0.2, p=0.3 and p=0.2 respectively). All pts were M694V homozygous among FMF-AA. Etiology of amyloid storm was infection in 5 pts (56%), treatment non-adherence in 3 pts (33%) and surgery in one patient (11%).

Overall, 3 pts with amyloid storm died (33%), but mortality was 10% (n=16) in the remaining pts with AA-a. One patient died during the amyloid storm, and others died within one year after the diagnosis of amyloid storm (median 5 months). In univariable analysis, involvement of ≥3 organs, bone marrow involvement and current proteinuria levels (p=0.4, p=0.05 and p=0.04, respectively) were higher; median number of organ involvement and mortality (p=0.09 and p=0.07) were tended to be higher in pts with amyloid storm than those without it. End stage renal disease (ESRD) development was also higher in pts who had amyloid storm (67%; n=6) than in pts who had not (46 % n=71) but did not reach statistical significance (p=0.3). Median±IQR CRP (48±77 vs 9±17 p=0.08), creatinine (4.8±5 vs 1.2±0.6 p=0.01) and proteinuria (11±12 vs 0.85±2.3 p=0.02) levels were higher during the amyloid storm than their previous records. In multivariable analysis, involvement of ≥3 organs, bone marrow involvement and current proteinuria levels (p=0.4, p=0.05 and p=0.04, respectively) were higher; median number of organ involvement and mortality (p=0.09 and p=0.07) were tended to be higher in pts with amyloid storm than those without it. End stage renal disease (ESRD) development was also higher in pts who had amyloid storm (67%; n=6) than in pts who had not (46 % n=71) but did not reach statistical significance (p=0.3). Median±IQR CRP (48±77 vs 9±17 p=0.08), creatinine (4.8±5 vs 1.2±0.6 p=0.01) and proteinuria (11±12 vs 0.85±2.3 p=0.02) levels were higher during the amyloid storm than their previous records. In multivariable analysis, amyloid storm was associated with higher mortality (p=0.045 OR 4.6; 95% CI 1.03-20). In survival analysis, development of amyloid storm tended to be higher in pts with non-FMF-AA compared to FMF-AA (Log-rank p=0.057). Mortality rate was higher in pts who had amyloid storm than those without it (Log-rank p=0.038).

**CONCLUSION:** This study showed that 5.5% of pts with AA-a may develop amyloid storm, and this condition was associated with higher amyloid burden. Amyloid storm may develop in AA-a pts associated with both FMF and other diseases, and the mortality rate may reach to 33% within one year.

**DO IL-1 ANTAGONISTS DEFINITELY PROTECT FROM THE DEVELOPMENT OF NEW DAMAGE: A SINGLE-CENTER STUDY**

D. Yıldırım1, R. C. Kardaş1, B. Ozkizitas1, I. Vasi1, H. Küçük1, M. A. Oztürk1, S. Haznedaroglu1, B. Goker1, A. Tutan1, Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey

**Background:** Ongoing inflammatory episodes of familial Mediterranean fever (FMF) disease can cause damage in nearly all organ systems. Colchicine and interleukin1β blocking agents are successfully used to control the disease activity [1]. Although the effect of IL-1 blockers are known for controlling disease activity and amyloidosis [2], it is unclear whether they prevent organ damage.

**Objectives:** In our study, we assessed the organ damage in patients with FMF treated with colchicine and IL-1 antagonists (IL-1A). It was evaluated whether new damage occurred after IL-1 antagonist treatment.

**Methods:** A total of 111 patients fulfilling Tel-Hashomer criteria and treated with IL-1A due to colchicine resistance were included in the study. All patients were also treated with colchicine with a maximum-tolerable dose. Patients were grouped according to their recent damage status (no damage, pre-existing damage, and damage developed under IL-1A treatment). The degree of damage was determined using Autoinflammatory Disease Damage Index (ADDI) and modified form of ADDI (mADDI) [3, 4].

**Results:** 44 patients (42,3%) had damage according to the modified ADDI (mADDI) index; three patients experienced new damage under IL-1 antagonist treatment while four patients showed progression of damage and mADDI score.

In patients with a positive mADDI score, the most common damage was amyloidosis (n=28, 63%), the second most frequent was musculoskeletal findings (N=14, 31%), and the third was infertility (N=2, 0,04%). The most common domains of FMF-related damage with IL-1 antagonist treatment were musculoskeletal (n=4), renal (n=2) and reproductive system (n=2)

**Conclusion:** Our study was the first study to evaluate the progression of damage in patients with FMF and treated with IL-1 antagonists. Although it is known that IL-1A is effective in colchicine-resistant patients, physicians should be aware that damage can still develop under IL-1A treatment.

**Background:** Although hypocomplementemia has been frequently reported in IgG4-related kidney disease (IgG4-RKD), few studies have investigated differences in the clinicopathological features of IgG4-RKD with and without hypocomplementemia in a relatively small cohort.[2]

**Objectives:** To compare the clinicopathological features of Japanese patients with and without hypocomplementemia in IgG4-RKD.

**Methods:** We retrospectively examined the clinicopathological features of IgG4-RKD in Japan, collected from the institutions associated with the IgG4-RKD working group between December 2010 and May 2019, with reference to the presence of hypocomplementemia.

**Results:** Among the patients included, 42 (70%) had hypocomplementemia. In the latter group, serum levels of IgG and non-IgG4 IgG, calculated as total IgG minus IgG4, were significantly higher (mean IgG level, 3832 vs 2626 mg/dl, p=0.005, mean non-IgG4 IgG level, 2775 vs 1827 mg/ml, p=0.000). Renal function at diagnosis tended to be lower (mean eGFR level 42.4 vs 53.6/ml/min, although not to a significant degree (p=0.07). There were no significant inter-group differences in the levels of serum IgG4 and IgG4, or in the number of extra-renal involved organs. Renal pathology specimens were obtained from 53 patients, 70% of whom had hypocomplementemia. In the hypocomplementemia group, light microscopy demonstrated a significantly broader extent of interstitial inflammatory cell infiltration (p=0.035), and immunofluorescence revealed a higher frequency of IgG or complement deposition on the renal tubular basement membrane (p=0.048). C1q deposition on the TBMs was evident only in the hypocomplementemia group. There was no significant inter-group difference in the presence of storiform fibrosis, the degree of interstitial fibrosis, the number of infiltrating IgG4-positive cells, or the frequency of membranous glomerulonephritis.

**Conclusion:** Hypocomplementemia in IgG4-RKD is associated with elevated levels of IgG subclasses other than IgG4, and may be related to progression of renal inflammation.REFERENCES:

[2] Fujisawa Y, et al. Hypocomplementemia is related to elevated serum levels of IgG subclasses other than IgG4, and may be related to progression of susceptibility factors for definitive discontinuation of CZP were analyzed as well. CZP RR was calculated with the Kaplan-Meier method, Log-rank test was used for the univariate, and the Cox proportional hazard model was implemented for the multivariate analysis.

**Results:** Thirty patients with a median of 41 (IQR 16) years, 18 (60%) females, were included. NIUs were bilateral in 19 (63%) patients and were active at CZP onset in 20 (71%). Half of the patients suffered from non-anterior NIUs, and etiologically 2 (7%) were unclassifiable, 7 (23%) had ocular syndromes, and 21 (70%) were associated to systemic disorders. Seven (23%) patients were biologic-naive, whereas 23 (77%) started CZP as a 2nd (5, 17%) or ≥ 3rd (18, 60%) biologic. With a median follow-up of 21.2 (Range 0.2 to 54.8) months, 12 (40%) patients discontinued CZP, 6 (20%) due to adverse events and 6 (20%) due to lack of efficacy. The overall CZP RR at 24 months was 53.6%, with a median Retention Time (RT) of 27.1 months. In the multivariate analysis, CZP started as a first biologic (HR 0.053, 95%CI 0.003 to 0.809; p = 0.035), and male gender (HR 0.1, 95%CI 0.015 to 0.694; p = 0.02) were protective factors for discontinuation. CZP RR at 24 months as a 1st line biologic was 100% with a median RT of 27.1 months. Conversely, CZP RR at 24 months as a ≥2nd line was 41.1% with a median RT of 17.1 months. When given as a 1st biologic, one (14%) patient discontinued CZP due to loss of efficacy at 27.1 months. Conversely, discontinuation of CZP when administered in ≥2nd line was more frequent, either due to lack of efficacy in 5 (22%) patients or adverse events (AEs) in 6 (26%) (Figure 1).

**Conclusion:** CZP in NIU showed an excellent retention rate at 24 months in biologic-naive patients. However, it was more than halved when CZP was started as a ≥2nd biologic. Discontinuation of CZP in bio-experienced patients was due to lack or loss of efficacy in 22% and to adverse events in an additional 26% of patients.

**POST331 CERTOLIZUMAB PEGOL IN UVEITIS. RETENTION PROBABILITY AND CAUSES OF DISCONTINUATION.**

**Objectives:** To study Certolizumab pegol (CZP) retention rate (RR) at 24 months in NIU and susceptibility factors for discontinuation.

**Methods:** Adults with NIU who received CZP for this indication were included. Data were gathered from the BioÚvea Spanish registry, detailed elsewhere.[3]

**Results:** Among the patients included, 42 (70%) had hypocomplementemia. Among the patients included, 42 (70%) had hypocomplementemia. We retrospectively examined the clinicopathological features of 60 patients with definitively diagnosed IgG4-RKD, collected from the institutions associated with the Japan IgG4-RKD working group between December 2010 and May 2019, with reference to the presence of hypocomplementemia.

**Conclusion:** Hypocomplementemia in IgG4-RKD is associated with elevated levels of IgG subclasses other than IgG4, and may be related to progression of renal inflammation.REFERENCES:

Background: SPI-62 is a potent 11β-hydroxysteroid dehydrogenase type 1 (HSD-1) inhibitor entering Phase 2 development as adjunctive therapy to prednisolone in polymyalgia rheumatica, as well as for treatment of Cushings’s syndrome and autonomous cortisol secretion. HSD-1, an intracellular enzyme, activates glucocorticoids in target tissues in which glucocorticoid medicines are associated with morbidity including liver, adipose, muscle, and skin. In Phase 1 clinical trials SPI-62 was generally well tolerated and associated with maximal liver and brain HSD-1 inhibition.

Objectives: To demonstrate mitigation by SPI-62 of corticosterone (CORT) adverse effects in mouse.

Methods: C57BL/6 male mice (age 7 weeks; n=14 per group) were administered CORT (100μg/ml in drinking water) and SPI-62 (by gavage in 0.5% HPMC; 0.1, or 10 mg/kg/day or 10 mg/kg twice daily) for 35 days. A control group received no CORT or SPI-62. Body weight was assessed daily and food consumption twice weekly. Whole body muscle and fat amounts were measured at Days 0, 14, and 28 using an EchoMRI-130H body composition analyzer. Blood samples for fasting glucose and insulin were obtained at Days 1 (pre-dose), 15, 29, and 35. An open field test was conducted on Day 22. A grip strength test was performed on Day 28. After sacrifice on Day 36, gonadal, subcutaneous, retroperitoneal, and mesenteric fat weights were dissected and weighed, and skin was formalin fixed and paraffin embedded.

Results: One control mouse died due to accidental gavage injury. Two mice who received CORT + 0.5% HPMC died on Days 11 and 19. CORT resulted in increased food consumption which was normalized by SPI-62 in a dose-dependent manner. CORT-treated mice showed reduced body weight gain for 2 weeks then accelerated body weight gain. SPI-62 prevented body weight gain in increased food consumption which was normalized by SPI-62 in a dose-dependent manner. CORT effects on dermal thickness in increased food consumption which was normalized by SPI-62 in a dose-dependent manner. CORT-treated mice showed reduced body weight gain for 2 weeks then accelerated body weight gain. SPI-62 prevented body weight gain in increased food consumption which was normalized by SPI-62 in a dose-dependent manner. CORT results are compared to the control group mean, in CORT-treated mice in increased food consumption which was normalized by SPI-62 in a dose-dependent manner. CORT-treated mice showed reduced body weight gain for 2 weeks then accelerated body weight gain. SPI-62 prevented body weight gain in increased food consumption which was normalized by SPI-62 in a dose-dependent manner. CORT results are compared to the control group mean, in CORT-treated mice

*Normalized by body weight.

Conclusion: SPI-62 prevented several CORT adverse effects in mouse, demonstrating that blockade of local intracellular glucocorticoid activation by a HSD-1 inhibitor in target tissues can mitigate glucocorticoid toxicity. These results suggest that SPI-62 has potential to similarly mitigate adverse effects of glucocorticoid medications in human. A placebo-controlled Phase 2 clinical trial has been initiated to compare prednisolone effects with and without SPI-62. Up to 48 patients diagnosed with polymyalgia rheumatica, on stable prednisolone 10 mg daily for at least 2 weeks, and with stable disease inactivity based on acute phase biomarkers will be included in the files and who received at least one DMARD or BP treatment for their disease were included in Rouen (thanks to the health data warehouse), Caen, Le Havre/Lillebonne and Dieppe Centres. Each imaging examination was reviewed blinded to the treatments by a radiologist with expertise in osteoarticular disease. Patients were classified into 2 groups (bony versus joint/mixed) according to imaging data and clinical history. The response to treatment was considered positive if symptoms were improved by at least 50% (cut-off used in the literature). An x² test was used for comparison of categorical variables.

STUDY OF THE RELATIONSHIP BETWEEN THE TREATMENT TYPE AND THE THERAPEUTIC RESPONSE ACCORDING TO THE SAPHO SYNDROME CLINICAL FORM IN ADULTS FROM A RETROSPECTIVELY ANALYSED MULTICENTRE COHORT

P. Brevel1, P. Micheлин1, C. Marcelli2, D. Alcaix3, T. Lequerre5, O. Vittecq6, D. Alcaix3, T. Lequerre5, O. Vittecq6
1Rouen University Hospital, Rheumatology, Rouen, France; 2Rouen University Hospital, Radiology, Rouen, France; 3Caen University Hospital, Rheumatology, Caen, France; 4Le Havre Hospital, Rheumatology, Le Havre, France; 5Rouen University Hospital, Rheumatology, Rouen, France; 6Rouen University Hospital, Rheumatology, Rouen, France

Background: SAPHO syndrome (Synovitis, Acne, Palmoplantar Pustulosis, Hyperostosis and Osteitis) is a radio-clinical entity associating joint, bone and inflammatory skin disorders. The clinical presentation is very heterogeneous, making the diagnosis difficult. The therapeutic strategy of SAPHO syndrome is poorly defined. The first-line treatment remains NSAIDs on demand, which are effective in treating painful flare-ups but rapidly become insufficient in 60% of cases during the course of the disease. TNF-α inhibitors (3 nerosis factor-alpha) are reserved for refractory forms and their efficacy is uncertain [1]. Bisphosphonates (BPs) seem to have potential interest [2].

Objectives: The main objective of this study was to investigate the response to treatment with BPs and/or immunosuppressive drugs (DMARDs - Disease modifying anti-rheumatic drugs), conventional synthetic cs-DMARDs or biologic (b-DMARDs), according to the clinical form of rheumatological SAPHO (bony predominantly versus articular or mixed predominantly).

Methods: All patients aged 18 years or older with SAPHO syndrome meeting Benhamou’s criteria whose clinical, biological and radiological data were available in the files and who received at least one DMARD or BP treatment for their disease were included in Rouen (thanks to the health data warehouse), Caen, Le Havre/Lillebonne and Dieppe Centres. Each imaging examination was reviewed blinded to the treatments by a radiologist with expertise in osteoarticular disease. Patients were classified into 2 groups (bony versus joint/mixed) according to imaging and clinical history. The response to treatment was considered positive if symptoms were improved by at least 50% (cut-off used in the literature). An x² test was used for comparison of categorical variables.

Results: Thirty-four patients with SAPHO who had received DMARD or BP treatment were included and classified as follows: 13 in the bony group and 21 in the joint/mixed group. The 2 groups were comparable on demographics, duration of follow-up, previous chest involvement, existence of associated dermatological or inflammatory bowel disease, exposure to smoking, duration of exposure to a previous NSAID or antibiotic. Only the age of onset of symptoms differed between the two groups, with a younger onset of disease in the bony group (p=0.043). The prescribers therapeutic attitude differed significantly between the 2 groups (p=0.043) with a greater prescription of BPs as first line in the bony group (5/13 patients) and a DMARD in the joint/mixed group (19/21). Regarding treatment efficacy, 10/13 patients had effective treatment without escape during their follow-up in the bony group, which was not significantly different from the joint/mixed group (17/21). BPs achieved escape-free efficacy in significantly more cases in the bony group than DMARDs in the joint or mixed group (p= 0.002). The bony group used significantly fewer specific treatment lines (DMARDs or BP) than the joint/mixed group (1 specific line vs. at least 2) (p=0.046).

Conclusion: BPs appear to be more effective in SAPHO with predominantly bone involvement. This appears to be easier to treat compared to SAPHO with articular or mixed forms.

OBJECTIVES: To assess the prevalence of autoimmune diseases associated with OCP and to analyse clinical, laboratory and treatment associations between these entities.

Methods: A multicentre cross-sectional study of patients with a diagnosis (clinical and/or by biopsy) of OCP derived from ophthalmology was performed. The population was divided into two groups according to their association or not with other ADs. Clinical, laboratory and treatment variables were described and compared between both groups. In addition, a multivariate descriptive logistic regression model was used to test the association between OCP and ADs.

Results: A total of 88 patients were recruited, 66 (75%) females, with a mean age at diagnosis of 64.3 years (SD 11.9). The median follow-up time was 1 year. The diagnosis of OCP was confirmed by biopsy in 89%. Ocular bilateral disease was present in 95.3% of patients. There was a median delay from symptoms onset to diagnosis of 2 years. A history of malignancy was reported in 13.6%. Extraocular involvement was found in 11.5% (4% compromised skin and 9.1% other mucous membranes). Regarding the previous clinical findings, no statistically significance was found between the groups with and without ADs. Systemic treatment was depicted as being more frequent in the group with ADs. Clinical, laboratory and treatment variables were described and compared between both groups. In addition, a multivariate descriptive logistic regression analysis was performed to identify variables that could suggest the association between OCP and ADs.

Conclusion: Due to the autoimmune nature of OCP, it could coexist with other ADs. In this research, it was observed that more than a quarter of the population presented with such association and hypergammaglobulinemia could suggest it. A systematic search for this coexistence should be carried out to avoid sequelae or incomplete treatment in pathologies that are currently potentially treatable.

Behcet’s disease (BD) is a multisystemic disease of unknown cause. The relationship between BD and pregnancy is reported in limited number of studies. The aim of the study was to evaluate the connection of the outcome of pregnancy with BD therapy.

Results: 118 pregnancies in 35 pts resulted in 75 live birth (6 cesarean section), 15 with termination of pregnancy. Out of 77 babies, 15 were born on time, the others had 0-1 missed miscarriage. Six patients had 12 Missed miscarriage at 6-11 weeks of gestation, one patient had severe BD according to Ch.Zouboulis classification (due to generalized glaucoma (“Neurobehcet” inherited from the mother).

Adverse pregnancy outcomes were observed with varying severity of BD. Out of 77 babies children born by BD patients only two had relapsing aphthous stomatitis and one – congenital glaucoma (“Neurobehcet” inherited from the mother).

Conclusion: Patients with BD were more to terminate pregnancy compared to control group. Unfavorable outcomes of pregnancy were documented in pts regardless (with all grades of) BD severity.

POS1337 ADULT-ONSET STILL’S DISEASE WITH ELDERLY ONSET, RESULTS FROM A MULTICENTRE STUDY AND ASSESSMENT OF AGE INFLUENCE ON CLINICAL FEATURES AND DISEASE OUTCOMES

Background: Aging is a physiological, multidimensional, and irreversible process, occurring in humans over time. Interestingly, multiple lines of evidence have recently suggested that some diseases, generally affecting young adults, are nowadays described in the elderly, although possibly associated with different symptoms or complications. In this context, a possible occurrence of adult onset Still’s disease (AOSD) in elderly has been suggested. This is a rare inflammatory disorder of unknown origin usually observed in young adults.

Objectives: In this study, we aimed at describing the clinical characteristics, life-threatening complications occurrence, and mortality of AOSD patients with an elderly onset. The manifestations of these patients were also compared with those with a younger onset. Furthermore, the predictive role of age was evaluated on clinical features and disease outcomes. Finally, in these patients, an assessment of associated comorbidities was also performed.

Methods: A retrospective assessment of prospectively followed patients, from January 2001 to April 2021, was provided to analyse clinical features, life-threatening complications occurrence, and mortality in AOSD patients with onset in elderly. AOSD patients, who were included in multicentre Gruppo Italiano di Ricerca in Reumatologia Clinica e Sperimentale (GIRRCS) cohort, were evaluated.

Results: Out of 221 assessed patients, 37 (16.7%) had an onset of the disease aged over than 60 years. When compared with younger patients, these were characterised by a higher prevalence of pericarditis (p=0.008), comorbidities (p<0.0001), and mortality (p=0.023). Additionally, our analysis showed that pleuritis and pericarditis positively correlated with age (coefficient=0.277, p=0.001; coefficient=0.213, p=0.001, respectively). Furthermore, the occurrence of parenchymal lung disease was significantly related with age (coefficient=0.168, p=0.012). The presence of comorbidities positively correlated with age (coefficient=0.443, p<0.0001). Moreover, age was negatively related to the polycytic pattern (coefficient=-0.209, p=0.002).

Patients with BD were more likely to terminate pregnancy of their own volition compared to control group. All women with unfavorable pregnancy outcomes are re-pregnant, have healthy children born on time, all had a second or subsequent pregnancy with an unfavorable outcome. Immunosuppressive therapy of BD was not received by any of the pregnant women, which makes it possible to exclude the connection of the outcome of pregnancy with BD therapy.

The manifestation of BD with skin-mucous lesion of the patient in the first and third trimester of pregnancy was noted by 3 patients. In one patient, the appearance of a recurrent ulcer on the vulva was an indication for cesarean section. Only three women had one favorably completed pregnancy, all the others had spontaneous abortions, 12 missed miscarriage. Nine of them are not married, 1 patient is planning a pregnancy.

Table 2 shows the frequency of pregnancy pathology with varying degrees of severity of BD.

POS1336 BEHÇET’S DISEASE AND PREGNANCY OUTCOMES

Z. Alekberova1, R. Goloeva1, A. Lila1, 1VA. Nasonova Research Institute of Rheumatology, Advisory Division, Moscow, Russian Federation

Background: Behçet’s disease (BD) is multisystemic disease of unknown cause. The relationship between BD and pregnancy is reported in limited number of studies.

Objectives: To evaluate outcomes of pregnancies in BD patients (pts).

Methods: We retrospectively collected data of 45 women with BD diagnosis (according to ISGBD 1990 and ICBD 2014) and their 118 pregnancies. Pts mean age was 31.3 [27-35] years., disease duration 6.0 [3.8] years. 11.1% pts had severe BD according to Ch.Zouboulis classification (due to generalized uveitis, retinal vasculitis and parenchymatous CNS lesions), 31.1% pts had a moderate disease, 57.8% pts had a mild disease with mainly dermal-mucosal manifestations.

Results: 118 pregnancies in 35 pts resulted in 75 live birth (6 cesarean section in 3 pts). Thirty-nine incomplete pregnancies were observed in 26 patients. Ten patients had 20 medical abortions on request before 12 weeks of gestation, one patient had an abortion due to medical reasons (rubella on the 7 th week of gestation), two patients had premature birth at 28 and 32 weeks with subsequent perinatal death of the baby. Fifteen out of 35 pts had 20 adverse pregnancy outcomes: 8 spontaneous abortion, 12 missed miscarriage. Nine patients had 12 Missed miscarriage at 6-11 weeks of gestation, one patient had 3 missed miscarriage, two had 2, and the others had 1 missed miscarriage. Six patients had 8 spontaneous abortions (early miscarriage). In the control group of 15 women, 7 had 15 pregnancies, 13 live birth of healthy children on time. Table 1 presents a comparison of pregnancy outcomes in patients with BD and healthy control.

Central Sensitization and Related Factors in Patients with Familial Mediterranean Fever

F. N. Yücel, H. H. Gezer, J. Jandaulyet, N. Öz, S. Acer Kasman, M. T. Duruöz

Marmara University School of Medicine, PMR Department, Istanbul, Turkey; Marmara University School of Medicine, PMR Department, Rheumatology Division, Istanbul, Turkey

Background: Central sensitization (CS) is an increased responsiveness of nociceptive neurons in the central nervous system to their normal or subthreshold afferent input is an important manifestation involved in many different rheumatic diseases [1].

Objectives: This study aims to investigate the CS in patients with Familial Mediterranean Fever (FMF) and its associations with other parameters.

Methods: This ongoing study included 73 patients (57 female, 16 male) who were diagnosed with FMF according to the Tel-Hashomer criteria. Clinical characteristics including age, gender, disease duration, age at onset, genetic mutations, comorbid disease and medications were noted. Disease activity was assessed with a PRAS disease activity score. Evaluations included the Health Assessment Questionnaire (HAQ), FMF quality of life (FMF-QoL), Pittsburgh Sleep Quality Index (PSQI), Fibromyalgia Rapid Screening Tool (FiRST), and the Hospital Anxiety and Depression Scale (HADS). The symptoms of CS were assessed with the Central Sensitization Inventory (CSI); range 0-100 which is a self-report outcome measure designed to identify patients who have symptoms that are related to CS or central sensitivities (CSI) such as fibromyalgia, neck injury, temporomandibular joint disorder or migraine/tension headaches [2]. Descriptive analysis was performed for all parameters. The Mann-Whitney U-test and chi-squared test were used in statistical analysis. P<0.05 was considered statistically significant.

Results: The mean age of the patients was 37.6 (SD:13.6) years. Sacroiliitis occurred in 8 patients (11%), amyloidosis in 1 (1.4%), and erysipelas-like erythema in 8 (11%). The most prevalent genetic mutation was M694I compound heterogeneous (16.4%) followed by M694V homogeneous (15.1%).

Disease activity was mild in 42.5%, moderate in 32.9% and severe in 12.3% of the patients. The mean CSI was 38.4 (SD:18.7) and thirty-four (45.6 %) of 73 patients had CS according to the CSI. CSI scores were significantly higher in females than in males (p=0.009). Eleven (15%) patients had colchicine resistance, and those with colchicine resistance had significantly higher CSI scores. In patients with central sensitization, PRAS, HAQ FMF-QoL, FiRST, PSQI, and HADS scores were significantly higher than in patients without central sensitization (Table 1).

Conclusion: CS is present in approximately half of FMF patients, CS in patients with FMF was associated with high disease activity, fibromyalgia, anxiety, depression, impaired function, poor quality of life and sleep.

Disclosure of Interests: None declared
With treatment of AoSD, clinical disease activity decreased reaching a mean Pouchot-Score of 2.2 +/- 1.8 after a mean follow up time of 48 +/- 90 months. Glucocorticoids were used by 33%, methotrexate by 21%, IL-1 inhibitors by 33% and IL-6 inhibitors by 29% of the patients. 62% (N=26) of the 42 patients obtained clinical remission and 36% (N=15) serological remission. Neither Pouchot-Score (0.57) nor SAS (0.51) at baseline predicted clinical remission of AoSD. Furthermore, also serological remis-
sion was not predicted by baseline SAS (0.62) or Pouchot-Score (0.56) (Figure 1).
With respect to activity of AoSD during treatment serum calprotectin levels were closely associated with SAS disease activity (r = 0.54, p < 0.0003) (Figure 2).

Conclusion: Baseline AoSD disease activity as measured by Pouchot-Score and SAS does not predict clinical or serological remission. Serum calprotectin level is closely related to AoSD disease activity during the treatment phase.

POS1340

BASELINE CLINICAL DISEASE ACTIVITY IS NOT CRITICAL FOR PREDICTING REMISSION OF ADULTS ONSET STILL’S DISEASE

J. Groetsch1, K. Tascilar1, G. Schett1, D. Foell2, J. Rech1, Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; 2Universitätsklinikum Münster. Klinik für Pädiatrische Rheumatologie und Immunologie, Münster, Germany

Background: The clinical course of adult-onset Still’s disease (AoSd) is highly variable, ranging from subtle constitutional symptoms to life-threatening complications such as macrophage activation syndrome. Therefore, it is of interest whether baseline disease activity in AoSD predicts the clinical course, i.e. clinical and serological remission.

Objectives: The aim of this study was to compare whether two instruments to measure AoSD disease activity, Pouchot-Score and Still-Activity Score (SAS), at baseline predict later remission of disease. We also assessed whether serum levels of calprotectin (S100A8A9) are associated with clinical disease activity as measured by SAS at follow up.

Methods: AoSD was diagnosed according to the Yamaguchi criteria. In all patients Pouchot-Score and Still-Activity Score (SAS) were assessed at baseline and SAS score also at follow-up. Clinical remission was defined as absence of all AoSD symptoms (i.e. fever and arthralgia), while serological remission was defined as normalization of Ferritin, IL-18 and S100A8A9 (calprotectin) levels. To investigate the prediction accuracy of the baseline Pouchot-Score and SAS of all AoSD symptoms (i.e. fever and arthralgia), while serological remission was defined as normalization of Ferritin, IL-18 and S100A8A9 (calprotectin) levels. To investigate the prediction accuracy of the baseline Pouchot-Score and SAS does not predict clinical or serological remission. Serum calprotectin level is closely related to AoSD disease activity during the treatment phase.

Results: 42 AoSD patients (19 males/23 females; mean +/-SD age:41 +/- 17 years) were assessed. Baseline Pouchot-Score was 5.3 +/- 1.6, baseline SAS was 5.7 +/- 1.0. With treatment of AoSD, clinical disease activity decreased reaching a mean

POS1341

EVALUATION OF DAMAGE CAUSED BY SEPTAL PANNICULITIS ASSOCIATED WITH ACUTE SARCOIDOSIS

O. Egorova1, G. Tarasova1, 1VA. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation

Background: Joint involvement in combination with sepal panniculitis, erythema nodosum (EN), febrile reaction, and intranshronic lymphadenopathy is the criterion for acute sarcoidosis (Löfgren’s syndrome, LS) – a granulomatous multi-system inflammatory disease of unknown etiology.

Objectives: to develop an index of damage caused by sepal panniculitis for express-assessment of the X-ray stage of LS.

Methods: We examined 142 patients (31 men and 111 women) in case of EN associated with LS, average age 39.3±11.1 years. All patients underwent a comprehensive clinical, laboratory and instrumental examination, including ultrasound of the joints and computed tomography (CT) of the chest organs.

Results: In 96% of cases, widespread EN was detected, which correlated with the level of CRP (p=0.006; r=0.38). In 124 patients (87%) there were signs of joint damage with predominantly periartricular changes in the area of ankle joints. The relationship between the duration of the articular syndrome and the duration of inflammatory changes in the subcutaneous tissue and the number of nodes was registered (p=0.02; r=0.45). The level of CRP had a significant direct correlation with the number of nodes (p=0.008; r=0.29) and the severity of articular syndrome (p=0.003; r=0.29). An elevated level of angiotensin-converting enzyme was detected in 97 patients (78%). The assessment of the probable radiological stage (c) of LS was performed according to the formula obtained using step-by-step discriminant analysis.

c = 1.06*Х1 + 0.98 *Х2 + 5.21 *Х3 + 1.68 *CRP

X1 – the number of sides of the lower/upper limbs with the detected diffuse lesions of the skin and subcutaneous fat; X2 – the number of erymatous nodes (or induration); A – the number of arthritus; CRP – concentration of C-reactive protein in absolute values. The value of c≤28.72 indicated x-ray Stage 0; 28.72 < c≤30.92 – x-ray Stage I; c > 30.92 – x-ray Stage II of LS of the chest organs. The developed technique made it possible to determine Stage I of LS in 69% of cases and Stage II in 15% of cases, which was confirmed by CT of the lungs. For the selected total value of the discriminant function of 3.984, the sensitivity is 79%, the specificity is 96%.

Conclusion: The developed assessment is a low-cost, affordable and fast way to assess the verification of the X-ray stage of LS at any stage of the disease, which contributes to the immediate prescription of adequate therapy.

DEPLETION OF KLRG1+ T CELLS IN A FIRST-IN-HUMAN CLINICAL TRIAL OF ABC008 IN INCLUSION BODY MYOSITIS (IBM)

N. Goel1,2, M. Needham3,4,5,6, D. Soler-Ferrari1, M. M. Cottral1, J. Escobar1, S. Greenberg1,2,3, Abcuro, Inc, Newton, MA, United States of America; 1Duke University School of Medicine, Internal Medicine, Division of Rheumatology, Durham, NC, United States of America; 2Fiona Stanley Hospital, Neurology, Murdoch, Australia; 3The University of Notre Dame Australia, School of Medicine, Fremantle, Australia; 4Murdoch University, Centre for Molecular Medicine and Innovative Therapeutics, Murdoch, Australia; 5Fenon Institute for Neurological and Translational Science, South Metropolitan Health Service, Nedlands, Australia; 6Brigham and Women’s Hospital, Neurology, Boston, MA, United States of America; 7Harvard Medical School, Neurology, Boston, MA, United States of America

Scientific Abstracts
Background: Inclusion body myositis (IBM), a relentlessly progressive autoimmune skeletal muscle disease, has no effective available pharmacological therapy. A prominent feature of IBM on microscopy is highly differentiated effector CD8+ cytotoxic T (Tc) cells invading non-necrotic myofibers [1]. These Tc cells, known to be relatively resistant to apoptosis, express markers including killer cell lectin-like receptor G1 (KLRG1) [2]. ABC008, a first-in-class humanized, afucosylated monoclonal antibody (mAb) specific for KLRG1, selectively depletes these highly differentiated Tc cells while sparing other blood cell populations, e.g., naïve, central memory, and regulatory T cells and B cells. ABC008 has been designed to treat diseases mediated by these Tc cells, including IBM and T-cell granular lymphocytic leukemia (T-LGLL). IBM and rheumatoid arthritis overlap clinically with T-LGLL and share similar expansions of large granular lymphocytes (LGLs), which also express KLRG1. We report here our preliminary data from our ongoing trial of ABC008 in IBM (NCT04609031).

Objectives: Evaluate the safety, pharmacodynamics (PD), and pharmacokinetics (PK) of ABC008 administered subcutaneously (SC) in adults with IBM.

Methods: In this first-in-human, open-label, single ascending dose trial with 3+3 design evaluating ABC008 SC, eligible participants must have clinically-pathologically defined, clinically defined, or probable IBM according to the European Neuromuscular Centre 2011 research diagnostic criteria [3] and an IBM Functional Rating Scale (IBMFRS) score ≤38. Four dose cohorts are planned: ABC008 0.1, 0.5, 2.0, and 5.0 mg/kg SC; PK, safety, and disease severity assessments are performed pre-dose (Day 0) and during the 6-month follow-up period.

Results: Five of the 6 (83.3%) participants were male with baseline mean age = 65.7 years, mean IBM disease duration = 6.8 years, and mean IBMFRS score = 275 (Table 1). Each received a single dose of ABC008 SC; Cohorts 1 (C1) and 2 (C2) received 0.1 and 0.5 mg/kg and had completed 168 and 56 days of follow-up, respectively.

Abbreviations: IBMFRS, Inclusion Body Myositis Functional Rating Scale; n or N, number; SC, subcutaneous; SD, standard deviation.

Other hematologic parameters generally were stable (e.g., T regulatory and B cells); CD8+CD57+ LGLs, mostly KLRG1+, were also depleted (Figure 1B). Preliminary PK showed that ABC008 SC displays a long absorption phase and slow clearance properties typical of mAb therapies. No severe adverse events (AEs) or discontinuations due to AEs have been reported. One unrelated serious AE of fall with muscle tear in a C1 participant with a prior history of falls occurred.

Conclusion: In study participants with IBM, single SC doses of 0.1 and 0.5 mg/kg of ABC008 resulted in the depletion of CD8+KLRG1+ cells and CD8+CD57+ LGLs with clear evidence of a dose response for KLRG1+ T cell depletion and no apparent safety signals. Based on these results, a study evaluating ABC008 for the treatment of T-LGLL is planned.

POS1343 TREATMENT OF RESISTANT RAYNAUD’S PHENOMENON WITH SINGLE-PORT THORACOSCOPIC SYMPATHICOTOMY: ONE-YEAR FOLLOW-UP

S. Van de Zande1, M. Kuipers2, A. Van Roon3, A. J. Stei2, A. Smit2, M. Dejongste4, M. Mariani2, T. Klinkenberg2, D. J. Mulder1, 1University Medical Center Groningen, Vascular Medicine, Groningen, Netherlands; 2University Medical Center Groningen, Cardiothoracic Surgery, Groningen, Netherlands; 3University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; 4University Medical Center Groningen, Cardiology, Groningen, Netherlands

Background: Raynaud’s phenomenon (RP) usually results in discoloration of the extremities when provoked by cold or emotional stress [1]. Some patients do not respond to conventional therapies, such as lifestyle interventions and vasodilatory medication. These patients are confronted with limited options for treatment. In a previous study we have shown that minimally invasive Single-Port Thoracoscopic Sympathectomy (SPTS) objectively and subjectively improves treatment-resistant RP, after one month [2]. This procedure for treatment-resistant RP is minimally invasive and potentially highly effective, because it specifically targets the sympathetic nerve at the third rib (R3), while leaving the ganglia untouched [3]. The procedure was only performed on the left side in the pilot study, which objectively resulted in improvement of left-hand perfusion in all patients after one month, when compared to the right hand. Furthermore, patient satisfaction after surgery was high and RP attacks of the left hand were less frequent and of shorter duration. Previous studies have shown that long-term effects of conventional sympathectomy is stable in the long run in the majority of patients [4, 5]. We have previously published the one-month results of SPTS for treatment-resistant RP in a concise report [2]. In the current study we sought to report the one-year follow-up results of SPTS for treatment-resistant RP in the same cohort of patients.

Objectives: Follow-up of patients with treatment-resistant Raynaud’s phenomenon (RP) one-year after single-port thoracoscopic sympathicotomy (SPTS).

Methods: Eight patients (six males, two females, median age of 45 years) with treatment-resistant RP underwent left-sided SPTS at the third rib (R3), unilaterally. Perfusion was assessed with a cooling and recovery procedure at baseline and one year after SPTS. Furthermore, laser speckle contrast analysis, pulse wave velocity, heart rate variability and nailfold capillaroscopy were performed. In addition, questionnaires were taken, and number and duration of RP attacks were reported over a 2-week period.

Results: One year after SPTS the duration of the attacks of was reduced with 1.9 hours in the left hand versus 0.9 hours in the right hand. Furthermore, three aspects of the questionnaire showed a significant improvement (role limitations due to physical health (p=0.017), pain (p=0.027) and physical functioning (p=0.025)). The total area under the curve of the total cooling and recovery procedure of the left hand was larger one year after surgery (101 (75–140) at baseline versus 118 (95–190) one year post-operatively, p=0.012), implying a better perfusion in the fingers. This was mainly due to the improvement during the recovery phase (21 (1–41) at baseline versus 38 (24–43) one year post-operatively, p=0.028).

Conclusion: One year after unilateral R3 SPTS there is clear benefit with regard to the majority of outcome variables, though some effects seem to attenuate. Long-term effects and five-year follow-up results will be investigated in an ongoing study.

Biological examination consistent with BS-related PI. Demographic features, other vascular lesions, and involvement associated with Behcet’s syndrome (BS).

**Background:** Pulmonary involvement (PI) other than pulmonary artery aneurysm (PAA) in Behcet’s syndrome (BS) is still an area of investigation.

**Objectives:** We aimed to retrospectively evaluate all types of pulmonary involvement associated with Behcet’s syndrome (BS).

**Methods:** Among 800 BS patients according to International Study Group for Behcet’s Disease (ISG) criteria, 28 patients were selected based on their radiologic examination consistent with BS-related PI. Demographic features, other clinical manifestations of BS, treatment modalities and types of PI were analyzed.

**Results:** The overall prevalence of PI was estimated 3.5% among all BS patients. PI was more common in males (62.1% vs 17.9%). Mean age for BS diagnosis and onset of PI were as following: 32 ± 10.9 years and 37 ± 11.4 years. Deep vein thrombosis (DVT) was the most common accompanying vascular involvement (53.6%). PAA, pulmonary vasculitis (PV), and pulmonary thromboembolism (PTE) were seen in 7 (25%), 13 (46.3%), and 18 (64.4%) of patients, respectively. In 5 patients, intracardiac thrombosis was present simultaneously in the right ventricle. Cyclophosphamide (CYC) was the most common preferred agent (78%) followed by azathioprine (AZA); cyclophosphamide, AZA; azathioprine, DVT; deep vein thrombosis

**Conclusion:** Despite the importance of PAA in BS patients, capillaritis and thromboembolism other than PAA may occur commonly in BS as well. Onset at young age, male gender and previous DVT seem to be significant risk factors for the development of PI.

POS1347

BIOLICAL THERAPY IN NEUROSARCOIDOSIS.
STUDY OF 30 PATIENTS FROM A SERIES OF 234 SYSTEMIC SARCOIDOSIS FROM A UNIVERSITY HOSPITAL

A. Herrero-Morant1, D. Martinez-Lopez1, L. Sanchez-Bilbao1, I. Gonzalez-Mazon1, J. L. Martin-Varillas5, R. Fernandez Ramon1, C. Alvarez-Reguera1, M. A. Gonzalez-Gay2, R. Blanco1, J. L. Martin-Varillas1, R. Fernandez Ramon1, C. Alvarez-Reguera1, M. A. Gonzalez-Gay2, R. Blanco1, Marques de Valdecilla University Hospital, Rheumatology and Ophthalmology, Santander, Spain; 2Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain

Background: Neurosarcoidosis (NS) is a severe complication of sarcoidosis [1,2]. NS may be classified according to several subtypes [1]. Data on therapy, including biological therapy (BT) is scarce.

Objectives: To assess efficacy and safety of BT in refractory NS subtypes.

Methods: Study of NS from a large cohort (n=234) of all consecutive patients diagnosed with sarcoidosis in a single university hospital from January 1, 1999 to December 31, 2019. Diagnosis of sarcoidosis was established according to ATS/ERS/WASOG criteria [3]. Efficacy was considered as complete or partial response and no-response according to the resolution of the neurological syndrome (signs and/or symptoms) after the BT onset.

Results: NS was observed in 30 (19 women/11 men) of 234 (12.8%) patients; mean age, 55.0±15.8 years. NS subtypes were chronic headache (n=13, 43.4%), peripheral neuropathy (n=6, 20%), cranial neuropathy (n=5, 16.7%), spinal cord abnormalities (n=3, 10%) and aseptic meningitis (n=3, 10%). A total of 26 (86.7%) patients received oral corticosteroids (CT) (mean maximum dose: 50±19.2 mg/dL) and 7 (23.3%) IV CT. In addition, conventional immunosuppressants were administered to 18 (60%) patients and BT to 12 (40%) patients. No treatment was administered to 4 (13.3%) patients. Table 1 shows treatment according to NS subtypes. A total of 12 patients received treatment with 22 BT. Most used BT were monoclonal anti-TNFα (n=18, 81.8%), infliximab (IFX) (n= 10, 45.5%) and adalimumab (ADA) (n=5, 22.7%). After 12 months since the initiation of BT, complete or partial response was observed in 14 of 17 (82.4%), 2 (11.8%) and 1 patient (5.9%), respectively (Figure 1). Severe allergic reaction was...

**Figure 1. Neurological clinical response to biological therapy**

Observed in one patient on both IFX and ADA. No more severe adverse events were observed.

**Conclusion**: BT, especially monoclonal anti-TNFα, seems to be effective and safe in NS, regardless of subtype.

**POS1348 PATIENTS WITH VEXAS DIAGNOSED IN A DANISH TERTIARY RHEUMATOLOGY SETTING HAVE HIGHLY ELEVATED INFLAMMATORY MARKERS, MACROCYTIC ANEMIA, AND NEGATIVE AUTOIMMUNE BIOMARKERS.**

M. Nyhus Bendix Rasch, F. Szabados, J. M. B. Jensen, K. O. Nielsen, E. M. Hauge, A. Troldborg, Aarhus University Hospital, Rheumatology, Aarhus, Denmark; Aarhus University Hospital, Hospital, Molecular Medicine, Aarhus, Denmark; Aarhus University Hospital, Clinical Immunology, Aarhus, Denmark; Aarhus University Hospital, Biomedicine, Aarhus, Denmark

**Background**: VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome was described in 2020 with overlapping features of rheumatology and hematology. VEXAS is an autoinflammatory condition caused by somatic mutations in the UBA1 gene at methionine-41.

As patients present with highly variable clinical symptoms [1], their path in the clinical system is often complicated, and characterized by many strenuous examinations and biopsies. It is pivotal, that we familiarize with the VEXAS phenotype and advance identification of patients with VEXAS.

**Objectives**: We aimed to characterize patients diagnosed with VEXAS in a tertiary rheumatology referral center since December 2020 when the syndrome was described [2].

**Methods**: All patients were identified and diagnosed at the department of Rheumatology, Aarhus University Hospital (AUH). Denmark. Patients underwent testing for the UBA1 somatic mutations using sanger sequencing at the department of Clinical Immunology, AUH. Sequencing analyzed for somatic variants in/at UBA1 gene at methionine-41.

**Results**: A total of 11 male patients with clinical suspicion of VEXAS underwent sequencing. Five men were identified in the period December 2020 to December 2021, all had VEXAS somatic mutations. Median age at diagnosis was 84 (75-87). Symptoms debuted on average 22 months (IQR 20-40) before diagnosis. All patients had significantly elevated markers of inflammation: median CRP 297 (196-366), IL-6 receptor, and ferritin and presented with macrocytic anemia. None of the patients were positive for autoimmune biomarkers like ANA, ACPA, MPO-, or PR3-ANCA.

**Conclusion**: This is, to the best of our knowledge, the first report of Danish patients with the VEXAS syndrome. Patients are males with persistent inflammatory, constitutional symptoms, and heterogeneous clinical presentations.

Background: Adalimumab remains the only biologic approved by the EMA and FDA for the treatment of non-infectious uveitis [1-6]. The reports on efficacy of other anti-TNF drugs such as Certolizumab Pegol (CZP) are scarce.

Objectives: to determine the efficacy and safety of CZP in refractory uveitis secondary to Immune-mediated Inflammatory Diseases (IMIDs).

Methods: national multicenter study of 80 patients with uveitis due to IMID refractory to glucocorticoids and conventional immunosuppressants treated with CZP. Efficacy was assessed with the following ocular parameters: best corrected visual acuity (BCVA), anterior chamber cells, vitritis, macular thickness and presence of retinal vasculitis. The efficacy of CZP was compared between the baseline visit, 1st week, 1st month, and 1st year. Statistical analysis was performed with IBM SPSS Statistics v.23.

Results: we studied 80 patients/111 affected eyes (33 men/47 women) with a mean age of 41.6±11.7 years. The IMIDs included were: spondyloarthritides (n=43), Behcet's disease (10), psoriatic arthritis (8), Crohn's disease (4), sarcoidosis (2). JIA (1), reactive arthritis (1), rheumatoid arthritis (1), relapsing polychondritis (1), TINU (1), pars planitis (1), Birdshot (1) and idiopathic uveitis (6). The most frequent uveitis pattern (n=21). In 20 patients, besides the presence of refractory uveitis, desire of pregnancy was the reason for CZP initiation. Prior to CZP, patients had received: methotrexate (n=38), sulfasalazine (28), azathioprine (14), cyclosporine (10), leflunomide (3), mycophenolate mofetil (4), and cyclophosphamide (1). Previous biologic therapy was administered in 52 patients (63%), with a median [IQR] of 2 [1-3] drugs per patient. The most used biologic was adalimumab (n=48), followed by infliximab (32), golimumab (15), tocilizumab (5), anetaprost (7), rituximab (1), anakinra (1) and secukinumab (1). CZP was administered as monotherapy in 39 patients.

After 24 [12-36] months of follow-up, all parameters analyzed showed a rapid and maintained improvement (Table 1). A decrease in the mean number of uveitis flares was observed before and after CZP (2.6±2.3 vs. 0.6±0.4, p<0.001). CZP was discontinued in 16 patients due to: ocular remission (n=3), insufficient ocular response (4) and incomplete response of extracocular manifestations (9). No serious adverse effects were found.

Conclusion: CZP seems to be effective and safe in the control of uveitis associated to different IMIDs.

**Rheumatology, Barcelona, Spain;** \(^{12}\)Hospital 12 de October, Pediatrics, Madrid, Spain; \(^{13}\)Hospital de Sagunto, Rheumatology Valencia, Spain; \(^{14}\)Hospital Universitario Marqués de Valdecilla, Internal Medicine, Santander, Spain

Background: Cystoid Macular Edema (CME) is the leading cause of blindness in non-infectious uveitis. Behcet’s disease (BD) is one of the diseases most frequently associated with CME [1-4].

Objectives: to compare the efficacy and safety of Certolizumab (CZP) and Adalimumab (ADA) in CME due to BD refractory to conventional therapy.

Methods: multicenter study of patients with CME secondary to BD by glucocorticoids (GC) and at least 1 conventional immunosuppressant. All patients had CME (OCT>300µ) at baseline. Efficacy was assessed with the following ocular parameters: macular thickness (µm), visual acuity (BCVA) and GC-sparing effect. The efficacy of CZP vs. ADA was compared between the baseline visit, 1st and 6th month, and 1st and 2nd year. Statistical analysis was performed with IBM SPSS Statistics v.23.

Results: we studied 21 patients/38 affected eyes were studied. 10 patients were treated with CZP (200 mg c/2 weeks) and 11 with ADA (loading dose of 80 mg and subsequently 40 mg c/2 weeks). No statistically significant baseline differences were observed in both groups (CZP vs. ADA in sex (♂/♀), 3/7 vs 5/6; p=0.65) and mean age (36.1±8.0 vs 42±8.6; p=0.10). However, CZP group was more severe with a longer time between EB diagnosis and biologic initiation (91.6±7.14 vs 34.4±21.3 months, p=0.02), and a greater median [IQR] number of previous biologic drugs (2 [0.75-3] vs 0 [0-0]). In CZP group, 8 patients were previously treated with ADA. Combined treatment with conventional DMARDs was used with ADA in 81.8% vs. 18.2% of CZP patients.

Regarding the efficacy outcomes analyzed, a rapid and maintained improvement in macular thickness, measured by OCT, was observed after 2 years of follow-up in both groups with no statistically significant differences between them (Table 1). Improvement in visual acuity and a GC-sparing effect was also observed (Table 1). No serious adverse events were observed in either group.

Conclusion: Our study suggests that both CZP and ADA are effective in the treatment of CME due to BD refractory to conventional treatment. CZP was equally effective despite most patients were refractory to ADA.

REFERENCES:

Background: Sarcoidosis is a granulomatous inflammation of unknown etiology. Neurosarcoidosis (NS) occurs in 5–10% of patients with sarcoidosis and is a severe manifestation of sarcoidosis. The clinical presentation is heterogeneous and depends on the inflammation within the nervous system.

Objectives: This study aimed to describe NS patients and their clinical course of treatment. Our outcomes were changes in 1) enhancing lesions on MRI of the central nervous system (CNS), 2) cerebrospinal fluid (CSF), 3) disability and dependency in daily activities assessed by the modified Rankin Scale (mRS), 4) cognitive function assessed by the Symbol Digit Modalities Test (SDMT), 5) quality of life assessed by Short-Form 36 Health Survey (SF-36), 6) fatigue assessed by Fatigue Assessment Scale (FAS), and 7) depression measured by Beck Depression Inventory-II (BDI-II).

Methods: In this observational cohort study with a one-year follow-up, we consecutively recruited NS patients (N=20), not including patients with polyneuropathy, from the Departments of neurology and rheumatology at Odense University Hospital between January 2016 and August 2020. Patients were examined clinically, with questionnaires and MRI at baseline (V1), and after three months (V3), six months (V6), and 12 months (V12). Cerebrospinal fluid (CSF) was examined at baseline, V6, and V12.

Results: The median age was 51.6 years, and the median duration of sarcoidosis symptoms was 8 months before inclusion. At baseline, 60% of NS patients had headache, followed by vertigo (55%) and tinnitus (50%). Objective neurological findings were peripheral sensory signs (50%), peripheral motor signs (40%), and cranial nerve involvement (30%). At V12, there were significant improvements in vertigo (p=0.03), cranial nerve involvement (p=0.03), and joint symptoms (p=0.03).

At baseline, 60% of patients had abnormal findings on MRI of CNS. During the study, the number of contrast-enhancing lesions on MRI decreased significantly (p<0.0001). The mRS declined significantly from mean (SD) 3.0 (0.8) at baseline to 1.8 (1.1) at V12 (p<0.0001), and 75% of patients experienced clinically important improvement (mRS1).

The SDMT score improved significantly from mean (SD) 38 (9) at baseline to 45 (12) at V12 (p<0.0001). The SF-36 Physical (PCS) and Mental Component Summary scores (MCS) improved significantly from baseline: PCS mean (SD) 35 (11) to 42 (12) at V12 (p=0.003) and MCS mean (SD) 41 (9) to 48 (10) at V12 (p=0.03). The proportions of patients with substantial fatigue (75%) and high depression score (35%) were unchanged.

Conclusion: One year of immunosuppression in NS patients improved several outcomes, and 75% of patients experienced clinically important improvement.

ANALYSIS OF FACTORS ASSOCIATED WITH GOOD THERAPEUTIC RESPONSE TO IMMUNOSUPPRESSIVE DRUGS IN PATIENTS WITH NON-INFECTIONOUS UVEITIS: A SURVIVAL ANALYSIS

1Hospital Infantía Sofia, Rheumatology, San Sebastián de los Reyes, Spain; 2Instituto de Investigación Sanitaria San Carlos, Rheumatology, Madrid, Spain;

Background: Non-infectious uveitides (NIUs) encompass a varied group of inflammatory diseases affecting the uvea and adjacent tissues, with evidence suggesting an immune-mediated cause. A correct management of these conditions is essential to prevent substantial and sometimes permanent visual loss and the development of ocular complications. Although immunosuppressive drugs (ISDs) have shown effectiveness in achieving a sustained control of the inflammatory process, not all patients achieve a satisfactory response.

Objectives: To identify factors affecting the response rate to ISDs in subjects with NIUs.

Methods: Longitudinal retrospective study, with patients collected from the Hospital Clínico San Carlos Uveitis Clinic, included from 1991 until December 2018, and followed-up until December 2019. Patients entered the study at ISD prescription and were followed-up until a) the achievement of a good therapeutic response (GTR), b) ISD treatment change (withdrawal of the prescribed ISD and/or addition of a new ISD), c) 12 months of follow-up, or d) loss of follow-up or end of the study (December 31th, 2019). GTR was defined as the complete resolution of the eye inflammatory manifestations and oral corticosteroid ≤10 mg of prednisone equivalent a day. Furthermore, this situation had to be maintained in at least two consecutive visits spanned at least 28 days.

Kaplan-Meier (KM) curves were set to account for GTR. Associated demographic, clinical and treatment-related factors were analyzed using bivariate and multivariate Cox robust regression models. Different models were compared using the Akaike Information Criteria, to select the fittest model to the data. Proportional hazard assumption was tested using Schoenfeld residuals.

Results: 73 patients (100 episodes of ISD prescription) were analyzed. In 44 episodes, a GTR was achieved (incidence rate 102.0 [95% Confidence Interval (CI): 75.9 to 137.1] per 100 patient-years). Figure 1 shows the KM curve for GTR. In the bivariate analysis, several variables showed a significant association with GTR, including gender, diagnosis of Behçet Disease, prescription of Cyclosporine A (CYA), number of previously prescribed ISDs, previous use of ISDs in combination could be more effective than their use in monotherapy or in combination. Several observational studies showed that the use of ISDs in combination could be more effective than their use in monotherapy. However, a direct comparison between these two treatment strategies has not been carried out yet.

Objectives: To analyze the effect of ISDs combination therapy (CT) on the response rate in patients with NIUs.

Methods: Patients attending a Uveitis Outpatient Clinic from a tertiary care center in Madrid, Spain, and prescribed with ISDs from 1991 to 2018 were included. Patients were assigned as controls or cases based on whether they were prescribed with ISDs in monotherapy (MT) or CT. ISD treatment changes during the observation period were also considered. The primary outcome was good therapeutic response (GTR), defined as the complete resolution of the eye inflammatory manifestations and oral corticosteroid dosage ≤10 mg of prednisone equivalent a day. Furthermore, this situation had to be maintained in at least two consecutive visits spanned at least 28 days. Several propensity score based and non-based weighting techniques for data balancing, followed by Cox regressions, were performed to estimate the effect of CT on the response rate. Random forest (RF) models and clinical appraisal were used to select the variables to be balanced.

Results: 100 episodes of ISD prescription belonging to 73 patients were included in this analysis. In 32 episodes, patients were prescribed with CT (in 3 episodes CT was the initial therapeutic strategy; in 29, combination was the result of adding a second or third ISD). The most frequent drug used in MT was cyclosporine A (CYA; n=39), and the most frequent CT was synthetic + biological ISD (n=21). After RF, the number of previously used ISDs, the prescription of CYA, the dosage of oral corticosteroids at prescription, a previous ISD withdrawal due to inefficacy, and duration of disease were selected for balancing. In addition, after clinical appraisal, uveitis diagnosis, prescription with azathioprine, prescription with ni-

TO COMBINE OR NOT TO COMBINE: INFLUENCE OF IMMUNOSUPPRESSIVE DRUG COMBINATION IN THE INDUCTION OF THERAPEUTIC RESPONSE IN NON-INFECTIONOUS UVEITIS

M. P. Álvarez Hernández1, A. Madrid García2, A. Gomez-Gomez2, A. Madrid García2, L. Borrego-Sanz2, R. Méndez-Fernández2, P. Arriola-Villalobos2, E. Pato2, D. Díaz Valle2, L. Rodríguez Rodríguez2 on behalf of Madrid Uveitis Study Group. 1Instituto de Investigación Sanitaria San Carlos, Rheumatology, Madrid, Spain; 2Instituto de Investigación Sanitaria San Carlos, Ophthalmology, Madrid, Spain; 3Hospital Infanta Sofia, Rheumatology, San Sebastián de los Reyes, Spain

Background: Non-infectious uveitides (NIUs) include a heterogeneous group of sight-threatening and incapacitating conditions. Their correct management sometimes requires the use of immunosuppressive drugs (ISDs), prescribed in monotherapy or in combination. Several observational studies showed that the use of ISDs in combination could be more effective than their use in monotherapy. However, a direct comparison between these two treatment strategies has not been carried out yet.

Objectives: To analyze the effect of ISDs combination therapy (CT) on the response rate in patients with NIUs.

Methods: Patients attending a Uveitis Outpatient Clinic from a tertiary care center in Madrid, Spain, and prescribed with ISDs from 1991 to 2018 were included. Patients were assigned as controls or cases based on whether they were prescribed with ISDs in monotherapy (MT) or CT. ISD treatment changes during the observation period were also considered. The primary outcome was good therapeutic response (GTR), defined as the complete resolution of the eye inflammatory manifestations and oral corticosteroid dosage ≤10 mg of prednisone equivalent a day. Furthermore, this situation had to be maintained in at least two consecutive visits spanned at least 28 days. Several propensity score based and non-based weighting techniques for data balancing, followed by Cox regressions, were performed to estimate the effect of CT on the response rate. Random forest (RF) models and clinical appraisal were used to select the variables to be balanced.

Results: 100 episodes of ISD prescription belonging to 73 patients were included in this analysis. In 32 episodes, patients were prescribed with CT (in 3 episodes CT was the initial therapeutic strategy; in 29, combination was the result of adding a second or third ISD). The most frequent drug used in MT was cyclosporine A (CYA; n=39), and the most frequent CT was synthetic + biological ISD (n=21). After RF, the number of previously used ISDs, the prescription of CYA, the dosage of oral corticosteroids at prescription, a previous ISD withdrawal due to inefficacy, and duration of disease were selected for balancing. In addition, after clinical appraisal, uveitis diagnosis, prescription with azathioprine, prescription with ni-

with methotrexate, and eye activity features at presentation (presence of cells in anterior chamber, vitreous haze, macular edema, active choroidal lesions) were also balanced. The Energy balancing method showed the best balance for GTR. After Cov-regression, CT prescription did not show a statistically significant effect in the hazard of response (p=0.43; Table 1).

Conclusion: The use of CT in our study was not associated with a better therapeutic response in NIU patients compared with the prescription of MT. Considering that most CT episodes were the result of the addition of a new ISD in a patient already treated and still active, the effectiveness of CT as the initial therapeutic strategy remains uncertain.

POS1356
TREATMENT OF IMMUNE CHECKPOINT INHIBITOR-INDUCED INFLAMMATORY ARTHRITIS AND POLYMYLGAH RHEUMATICA
M. Liapi1, K. Chatzidionysiou1. 1Karolinska Institute, Rheumatology Unit, Karolinska University Hospital, Department of Medicine Solna, Stockholm, Sweden

Background: Therapy with immune check point inhibitors (ICIs) has revolutionized cancer treatment during the last years. Despite their high efficacy, ICIs are associated to a new spectrum of adverse events, the immune-related adverse events (irAEs). Inflammatory arthritis and polymyalgia rheumatica (PMR) are two of the most common irAEs. The optimal management of irAEs remains unclear. Treatment guidelines largely support the use of glucocorticoids (GCs) as first line therapy [1]. Preclinical data raise concerns regarding the potential risk of impaired antitumoral effect with use of GCs. The high efficacy and potential synergistic effect (according to recent findings) [2] of targeted immunomodulation, such as interleukin 6 (IL-6) blockade, could support a paradigm shift, where targeted treatments are considered earlier in the treatment sequence.

Methods: We retrospectively identified patients who were diagnosed with inflammatory arthritis and/or PMR at the rheumatology department at Karolinska University Hospital, after referral from the oncology department due to suspicion of a rheumatic irAE. The optimal management of irAEs remains unclear. Treatment guidelines largely support the use of glucocorticoids (GCs) as first line therapy [1]. Preclinical data raise concerns regarding the potential risk of impaired antitumoral effect with use of GCs. The high efficacy and potential synergistic effect (according to recent findings) [2] of targeted immunomodulation, such as interleukin 6 (IL-6) blockade, could support a paradigm shift, where targeted treatments are considered earlier in the treatment sequence.

Objectives: To assess how frequently a disease modifying anti-rheumatic drug (DMARD) treatment in patients with ICI induced arthritis and/or PMR, after inadequate response to GCs, is initiated and to assess its effectiveness.

Methods: We retrospectively identified patients who were diagnosed with inflammatory arthritis and/or PMR at the rheumatology department at Karolinska University Hospital, after referral from the oncology department due to suspicion of a rheumatic irAE, between Jan 2020 and Dec 2021. Treatment response was defined as sustained low disease activity or remission according to the rheumatologist evaluation at 6 months (+/- 1 month) after initiation of DMARD.

Results: A total of 20 patients were identified, who were diagnosed with arthritis (N=11), PMR (N=4) or both (N=3). The median (IQR) age was 70 (46-76) years; 50% of patients were females. The type of cancer was urogenital (N=8), melanoma (N=6), lung cancer (N=2), and other (N=4). 14 patients received a PD-1 inhibitor (9 nivolumab, 4 pembrolizumab, 1 cemiplimab), 3 received a PDL-1 inhibitor (2 atezolizumab, 1 avelumab), 2 received a combination of nivolumab and the CTLA-4 inhibitor ipilimumab and one patient combination of nivolumab and pembrolizumab. The median time from start of ICI treatment to symptom debut was 2 (1.25-3.75) months.

83% of patients with PMR and/or arthritis responded well to GCs without the need for treatment escalation. One of these patients discontinued tocilizumab due to suspected side effects, and started with a TNF inhibitor. After initiation of tocilizumab all patients were able to reduce the dose of GCs to less than 5mg/day.

Conclusion: The majority of patients developing ICI-induced arthritis are refractory to GCs and need a DMARD treatment, although selection bias cannot be formally excluded, since the most severe forms of arthritis might be referred to the rheumatology department. csDMARDs are effective in a significant proportion of patients. Tocilizumab is highly effective and well tolerated in ICI-induced arthritis. ICI-induced PMR seems to respond adequately to GCs.

THE 10-YEAR OUTCOME OF PATIENTS WITH BEHÇET’S SYNDROME: A SINGLE-CENTER EXPERIENCE
A. Doğan1, E. Tekgoz2, S. Colak3, M. Çınar2, S. Yılmaz3. 1Guزلahane Training and Research Hospital, Rheumatology, Ankara, Turkey

Background: Behçet’s syndrome (BS) is a vasculitis characterized by recurrent oral and genital ulcers, as well as ocular, cutaneous, vascular, gastrointestinal, musculoskeletal, and central nervous system manifestations.

Objectives: The study aimed to evaluate the 10-year outcome of patients with BS.

Methods: A cohort of 682 patients diagnosed with BS between January 2007 and December 2009 in the rheumatology outpatient clinic of Gulhane Training and Research Hospital were re-evaluated in November 2021. The data regarding the clinical course of 84 patients (64/862) were obtained from patients’ files and detailed telephone interviews.

Results: The study included 84 patients (63 male, 21 female) with a mean age of 47±10.6 years. The mean disease duration was 17±6.5 years. At the time of the diagnosis, the mean age of the patients was 29.5±9.4 years. Oral ulcer (100%), papulopustular lesions (82.1%), genital ulcer (77.4%), and erythema nodosum (59.5%) were the most frequent manifestations at the time of diagnosis. Ocular (46.4%), musculoskeletal (35.7%), vascular (19%), gastrointestinal (3.6%), and neurological (12%) manifestations were the most frequent irAEs in decreasing frequency. The most frequent ocular disease was posterior uveitis, whereas superficial thrombophlebitis and deep venous thrombosis were the most prevalent forms of vascular involvement. One patient had transverse myelitis as neurological involvement. Colchicine (86.1%) and corticosteroids (57.1%) were the most preferred drugs for the initial treatment. Fifty-one (60.7%) patients received at least one immunosuppressive agent. After 10-year, there was a statistically significant decrease in all manifestations of BS (Table 1). Nevertheless, 9 (10.7%) patients (8 male, 1 female) had new clinical findings. Five patients had (5.9%) mucocutaneous, 2 (2.4 %) arthritis and 2 (2.4%) vascular lesions as new clinical manifestations. The mean age of the patients with newly onset clinical findings was 46±8.9 years. There was no statistically significant difference between patients with and without new clinical findings with respect to age (p=0.79). The new onset mucocutaneous manifestations were genital ulcer and erythema nodosum. Besides, new onset vascular lesions were superficial and deep venous thrombosis of the lower extremities. The mean age of the patients who developed venous thrombosis at the time of the assessment was 37±0.7 years. Vascular involvement was detected more frequently in younger patients.

McNemar-Bowker Test, **McNemar Test
Idiopathic Granulomatous mastitis (IGM) is a rare inflammatory disease of the breast with poorly understood aetiology or risk factors. IGM has a predilection towards women of child-bearing age with a history of breastfeeding, particularly among Hispanic and Asian ethnicities. However, the true prevalence is unknown with IGM being poorly studied in Middle Eastern Arab and Levantine women who have different genetic, epidemiological, and environmental characteristics.

Objectives: To study the clinical features of Middle Eastern women diagnosed with biopsy-confirmed IGM.

Methods: A retrospective observational study of patients with a biopsy-confirmed diagnosis of IGM, referred to two different private outpatient rheumatology clinics in Amman-Jordan between 2016-2021. The Patients’ characteristics, clinical presentation, treatment, and outcomes were recorded.

Results: A total of 25 patients were identified in this study. The mean age was 34.9 ± 5.2 years. All females presented with a breast nodule and tenderness, while only 16% reported associated skin changes in the breast and 12% reported galactorrhoea. Bilateral breast involvement occurred in only 4 patients (16%), while 21 patients had unilateral breast involvement. Systematic manifestations including myalgia/arthritis, skin changes, fever, and axillary lymphadenopathy were reported by 44%, 16%, 20%, and 16% of patients, respectively. Notably, all enrolled females were married at the time of presentation and 3 of them were pregnant or postpartum during the onset of symptoms. The majority of patients (n=21, 84%) had a prolonged period of breastfeeding (> 6 months). Moreover, 80% of patients had ≥3 pregnancies with 60% having their youngest child aged 3-5 years.

20 patients (80%) had a complete resolution of symptoms, and 20% (n=6) were lost to follow-up. Among patients who completed follow-up, treatment duration lasted for ≥ 1 year in 36% (n=9) of patients, whereas 11 patients had a complete resolution in less than a year. Azathioprine, methotrexate, antibiotics, and steroids were used in the treatment of 20%, 36%, 60%, and 68%, respectively. Of note, only 1 patient underwent surgical intervention during treatment.

Conclusion: Many theories have suggested different aetiology for IGM but, in our cohort, it appears that being multiparous and prolonged breastfeeding carry higher risks of developing granulomatous mastitis. Although the aetiology is unclear, early diagnosis and the introduction of treatment using steroid therapy and immunosuppression can improve prognosis and prevent unnecessary surgery. Most of our patients that were treated with corticosteroid, Azathioprine, and Methotrexate had a complete resolution of symptoms after one year of therapy.

Disclosure of Interests: None declared.

Background: Demonstration of deposits by non-invasive methods is important especially for organs difficult to sample in amyloidosis. Transient elastography (fibroscan) is a diagnostic method being used to measure liver stiffness (LS) in different chronic liver diseases.

Objectives: We herein aimed to test the place of fibroscan method for detecting increased LS associated with amyloid deposition in patients (pts) with amyloidosis.

Methods: Six categories of pts enrolled into this cross-sectional study; AA amyloidosis (AA-a), AL amyloidosis (AL-a), Familial Mediterranean Fever (FMF) pts without amyloidosis, cirrhotic chronic liver disease, non-cirrhotic chronic hepatitis, and healthy controls (HC). LS assessment by fibroscan was categorized as normal for kPa<7, significant stiffness for kPa≥7, advanced stiffness for kPa≥9.5, and advanced stiffness for kPa≥12.5.

Results: A total of 165 pts (AA-a, n=65; AL-a, n=15; FMF, n=20; cirrhotic pts, n=16; CHB, n=22; HC, n=27) constituted the study group. Average age was higher in the AL-a group compared to others. Median LS was highest in cirrhotic pts, and it was also higher in AA-a and AL-a pts compared to FMF and HC. Median LS was numerically higher in AL-a compared to AA-a, in cirrhotic pts, and it was also higher in AA-a and AL-a pts compared to FMF and HC. Median LS was higher in cirrhotic pts than in AA-a and AL-a.

Conclusion: As the lesions of amyloidosis are often located within the liver, which is otherwise inaccessible to other diagnostic methods, fibroscan could be of value in these cases. Further studies are required to validate these findings in larger populations.

Conclusion: The Canadian research group of rheumatology in immuno-oncology (canRIO): a nationwide multi-center prospective cohort.
Background: Apremilast has been shown to be effective in patients with Behçet’s disease (BD) in domains other than oral ulcers; however, its long-term efficacy is yet to be determined. Although serum cytokine modulation by increasing intracellular cAMP levels has been suggested as a mechanism for the efficacy of apremilast on skin areas of psoriasis [1], the relationship between efficacy and cytokine on various domains in BD has not been fully investigated.

Objectives: This study aims to evaluate the long-term clinical efficacy of apremilast in BD and its effect on serum cytokines.

Methods: In this study, patients with BD who received apremilast for active oral ulcers were included. For 12 months, the improvement rates of oral and genital ulcers, skin lesions, and arthritis were assessed every three months. Serum levels of cytokines, including interferon-gamma (IFN-γ), interleukin 10 (IL-10), and interleukin-23 (IL-23): TNF-α were measured in serum using a multiplex immunoassay (Luminex Assay, CA, USA) at baseline and three months after apremilast treatment. Other cytokines, including tumor necrosis factor-alpha (TNF-α), IL-6, IL-8, and IL-23: were also measured in serum using a multiplex immunoassay (Luminex Assay, R&D Systems).

Results: Fifteen patients were included in this study. Table 1 shows the characteristics of the patients who participated in this study. Oral ulcers disappeared in 66.7% and 92.3% of the patients after 3 and 6 months of apremilast treatment, respectively. Genital ulcers disappeared in all patients after 6 months of apremilast treatment and were maintained for 12 months. The efficacy of apremilast in oral ulcers could be divided between two groups: 8 patients in the oral ulcer remission group (OU-R group) whose oral ulcers completely disappeared after 3 months of apremilast administration and persisted for 1 year, and 7 patients in the oral ulcer non-remission group (OU-NR group) whose oral ulcers persisted after 3 months of apremilast treatment. Genital ulcers improved more rapidly in the OU-R group than in the OU-NR group, and completely disappeared within 3 months. Skin and joint lesions generally improved after 6 months, but recurred after 9 months.

SD, standard deviation; n, number.

Serum cytokines could be analyzed in seven of the 15 cases. There was no significant association between serum baseline cytokine levels and the presence of lesions or severity of disease. Compared to baseline, TNF-α and IL-23 levels were significantly lower after apremilast treatment and IFN-γ levels were trending upwards; however, IL-6, IL-8, and IL-10 levels showed no constant trend (TNF-α and IL-23: p < 0.05, IFN-γ: p = 0.078). In addition, the rate of decrease in serum IL-6, IL-10, and IL-23 levels was significantly greater in the OU-R group than in the OU-NR group (Figure 1). However, the rate of change in serum cytokines was not associated with efficacy of apremilast for skin lesions, arthralgia, or arthritis.

Conclusion: Apremilast has shown long-term efficacy in the treatment of oral and genital ulcers in patients with BD. The efficacy of apremilast against oral ulcers in BD may be attributed to its modulatory effect on serum cytokines as previously reported. Future exploratory studies for biomarkers associated with the persistence of efficacy against genital ulcer and arthritis are needed.

POS1363 THE VALIDITY AND RELIABILITY OF THE TURKISH VERSION OF BEHÇET’S SYNDROME OVERALL DAMAGE INDEX IN A RETROSPECTIVE COHORT

Y. Yagız Ozogul1, Y. Ozgüler1,2, D. Ucar1,2, U. Uygunoglu2,3, Z. Kutlubay4,5, V. Hamuryudan1,2, G. Hamel1,2, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet’s Disease Research Center, Istanbul, Turkey; Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey; Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurology, Istanbul, Turkey; Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Dermatology, Istanbul, Turkey

Background: Behçet’s syndrome Overall Damage Index (BODI) is a newly developed damage index specific to Behçet syndrome (BS).

Objectives: We aimed to evaluate validity, reliability and feasibility of the Turkish version of BODI and evaluate its performance for use in retrospective cohort studies for different phenotypes of BS.

Methods: The study included 295 patients with at least 3 visits at 6 months intervals out of 590 consecutive BS patients who were admitted between January 2015 and August 2017. Turkish version of the BODI form was developed by translating into Turkish and backwards by 2 people. BODI scores were calculated for each year during the follow-up period. The test-retest reliability of BODI was assessed by scoring the same 50 patients at 6-month intervals by the same observer (YYO). Two different observers (YYO- YO) assessed the same 50 patients for inter-observer agreement. The intra-class correlation coefficient (ICC) was used to assess the inter and intra-observer agreement. We also evaluated the median time to fill out the form in patients with different types of involvements.

Results: Among the 295 (158 F/137 M) patients, mean age was 39 (9.9) and the mean disease duration was 8.8 (5.9) years. Clinical features of BS patients were summarized in the Table 1. BODI median score was 1 (IQ=0-1). We observed
an increase in BODI score in 111 (38%) patients during follow-up. The main reasons for increasing BODI scores were eye, vascular and neurological involvement (Table 1). The mean ICC for inter-observer agreement was 0.84 (95% CI, 0.89-0.96) and for intra-observer agreement was 1. The median (range) time to complete the form was 2 (1-8) minutes.

*All patients had at least 3 BODI scores, **Some patients had more than 1 type of involvement

**Conclusion:** This study showed that the Turkish version of BODI was a reliable and feasible instrument that could capture the change over time in damage, and could be used in retrospective cohort studies. Ocular involvement was the most common cause of progressive damage in this cohort.

**Background:** Autoinflammatory diseases (also referred to as hereditary periodic fever syndromes) are caused by defects in the innate immune system. Many autoinflammatory syndromes arise from inherited genetic mutations which begin in childhood and persist throughout adult life. These diseases are often present in several members and generations within a family. Newer research also reflects that, cases can often present at any age through-out childhood, teenage years, and even into older adulthood. These cases appear to be acquired, perhaps due to the interplay of genetic, immune, and environmental factors (somaticism). It
is not uncommon that a patient is diagnosed with rheumatoid arthritis, multiple sclerosis or another autoimmune issue, as many physicians are not aware of monogenic inborn errors, nor how to conduct a thorough work up due to a lack of training.

Objectives: Unfortunately, the knowledge base that many doctors have with regards to autoinflammatory genetic diseases is minimal to non-existent, when compared to the well-established expertise of autoimmune disease management. Concerns about the increasing patient accounts stating lack of medical diagnosis, treatment, and pain management, lead to the important decision to collect further data from the autoinflammatory patient community. The aim of the survey responses collected, and post data aggregation will help identify patient trends and use this information to educate and increase awareness amongst the medical community as to the unmet diagnostic and treatment requirements for the autoinflammatory population.

Methods: A questionnaire comprised of thirty questions was developed by members of the patient organization FMF & AID Global Association (Executive Director, Malena Vetterli with Research Director, H. Ellen Cohen) under the guidance of Dr. med. Juergen Rech focused on collecting basic information (e.g. age, country, onset and duration of symptoms, pain and fatigue). The survey was published at the end of 2020 on social media (Facebook) and on the FMF&AID website (www.fmffandaid.org). Participation was voluntary and the patients agreed that the anonymised response information of the survey may be evaluated and published. This international survey was approved by the ETHICS Committee FAU in Erlangen-Nuremberg, Germany.

Results: Worldwide, over a thousand patients or parents/caregivers of patients (younger than 18 years) in fifty-two countries took part in this survey and answered the questionnaire. Eighty percent (80%) of the participants had already been diagnosed with an autoimmune disease. However, despite classic periodic symptom presentation, twenty percent (20%) of the participants were still without a concise diagnosis. FMF - forty-three percent (43%) was cited as the most common diagnosis and M. Behçet thirty percent (30%) as the second, with a variety of others (e.g. PFAPA, CAPS, HIDS, TRAPS, DADA, Yao syndrome, and uSAID). The minimum age at diagnosis ranged from 1 to 70+ years old with an average age of 33 years when properly diagnosed. Three-hundred and nine (309) patients reported that their pain had not been taken seriously and adequately treated in the past. Pain and fatigue, as measured by the standard visual analogue scale (VAS 0-10), was high in the past 30 and 7 days, respectively. VAS pain 30 days was 4.8 (SD +/-2.7) or 7 days with 4.2 (SD +/-3), as well as fatigue VAS 30 days 5.7 (SD +/- 2.8) or fatigue VAS 7 days with 5.5 (SD +/- 3).

Conclusion: One-fifth of patients with classic symptoms of autoinflammatory diseases remain undiagnosed and therefore not specifically treated. Although, the rest of the participants eighty percent (80%) have a diagnosis of an auto-inflammatory disease, therapy does not appear to be sufficient to manage their wide-ranging and debilitating symptoms, in particular pain and fatigue. Patients continue to care for the burden of receiving mental diagnosis vs actual medical diagnosis and are still forced to seek additional medical support, often incurring travel or relocation costs to obtain proper care.

Disclosure of Interests: Jürgen Rech Speakers bureau: Abbvie, Biogen, BMS, Chugai, GSK, Lilly, MSD; Novartis, Roche, Sanofi, Sobi, UCB, Consultant of: Biogen, BMS, Chugai, GSK, Lilly, MSD, Novartis, Roche, Sanofi, Sobi, UCB; Grant from: Novartis, UCB, Wyeth, Pfizer, Janssen Pharmaceutica NV, Grant/Research support from: Novartis, Sobi.

Randomized observational study. All patients with IgG4-RD diagnosed by expert opinion at the Oslo University Hospital treated with ≥ 1 dose of RTX with 12 months follow-up were included. Two experts (JV, ØMi) assigned patients to phenotypes. Glucocorticoid (GC) treatment was allowed. We measured disease activity by the IgG4-RD Responder Index (IgG4-RD RI) at baseline, 6 months, and 12 months. We defined a composite primary outcome consisting of two measures; (i) reduced disease activity (i.e., ≤2 points improvement in IgG4-RD RI from baseline and/or IgG4-RD RI score 0 at follow-up), and (ii) no disease flares (i.e., no >2 points worsening of IgG4-RD RI and no need to increase GC dose) at 6 months. Secondary outcomes were (a) reduced disease activity at months 6 or 12, (b) remission (IgG4-RD RI score 0 and GC dose ≤ 7.5 mg) at 6 or 12 months and (c) safety. Descriptive statistics were applied.

Results: We included 40 patients, of which 30 (75%) were male and 35 (88%) Caucasian. Mean age and disease duration at time of first RTX infusion was 58 and 3 years, respectively. Seventeen of the 40 patients (43%) received RTX as add-on therapy (following GC for > 3 months), while 13 (33%) received RTX as upfront combination therapy with GC, and 10 (25%) received RTX as upfront monotherapy. All 40 patients received an infusion of 1000 mg RTX at study baseline (dose 1A at week 0) and 39 of these 40 patients (98%) received a second RTX infusion (dose 1B) at week 2. Additional infusions of 500-1000 mg RTX were administered at weeks 26 (dose 2A) and 28 (dose 2B) in 24 (60%) and 7 (18%) patients, respectively. The composite primary endpoint was met by 31/40 patients (78%). Reduced disease activity at 6 and 12 months were seen in 34 (87%) and 35 (90%) patients, respectively. Fifteen patients (38%) were in remission at 6 months, and 22 (56%) were in remission at 12 months. “Retroperitoneum and Aorta” showed lowest response rates, while “Head and Neck-Limited” had the highest rate of flares (Table 1). Mild infusion reaction occurred in 8 (20%) patients. Hypogammaglobulinemia was observed in 4 (10%), Infection requiring hospitalization occurred in 6 (15%), including one fatal infection which was the only death in the study period.

*One patient died shortly after 1A, and is not included in secondary efficacy outcomes

Conclusion: In our observational study, RTX appears safe and effective in IgG4-RD, with the highest response in patients with Pancreato-Hepato-Biliary phenotype. Relatively low remission rates across all phenotypes indicate an unmet need for improved treatment.

Pos1367 The prevalence and risk factors for cardiac disease in patients with familial mediterranean fever

Y. Butbul1, 2, L. Gabay2, Y. Braun-Moscovici1, 3, 4. Pediatric Rheumatology Service, Ruth Rappaport Children’s Hospital, Rambam Medical Center, Haifa, Israel, Pediatric B, Haifa, Israel; 1, 2, The Ruth and Bruce Rappaport Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, Israel, 3, 4Maccabitech Institute for Research and Innovation, Maccabi Healthcare Services, Tel Aviv, Israel, 5Maccabitech Institute for Research and Innovation, Tel Aviv, Israel; 6Rambam Health Care Campus, Haifa, Israel, 7, 8B. Shine Department of Rheumatology, Haifa, Israel

Background: Familial Mediterranean fever (FMF) is a genetic disorder manifested by recurrent attacks of peritonitis, pleuritis and arthritis, and characterized by clinical and laboratory evidence for localized and systemic inflammation. Colchicine treatment usually prevents the attacks and the associated inflammation. Inflammation may play an important role in the initiation and progression of atherosclerosis. Recently, colchicine was suggested as a therapy that help to prevent coronary heart disease.

Objectives: To study the effect of FMF and colchicine treatment on the cardiovascular morbidity and the overall mortality.

Methods: We studied using the data base from health insurance in Israel (Maccabi Healthcare Services-MHS) the presence of IHD and its risk factors in 492 FMF patients aged 40 years or more, and in a control groups matched by age gender and socioeconomic status.

Results: The incidence of cardiac disease in FMF patients was similar to the control group (6.5% vs 5.7% p = 0.594), smoking kidney disease and gout were higher in FMF compared to the control group (16.1 % vs 12.8% p= 0.022, 9.3% vs 5.1 p = 0.01 and 4.5% vs 0.2% p=0.001 respectively), but hypertension and diabetes were similar. The overall mortality in average follow up of 3174.37 ±1738.84 days was similar in both groups.

Conclusion: The incidence of cardiac disease among FMF patients was not increased compared to the control group, despite the exposure to recurrent inflammation. We suggest that colchicine may have a protective role in these patients.

Pos1368 Diversity of hemodynamic types in connective tissue disease associated pulmonary hypertension: More than a subgroup of pulmonary arterial hypertension

X. Dong1, Y. Shi1, Y. Xia2, X. Zhang1, J. Qian3, J. L. Zhao3, J. Peng2, Q. Wang3, L. Weng2, M. Li3, B. Du2, X. Zeng3. Peking Union Medical College Hospital, Department of International Medicine, Beijing, China; 1Pediatric Rheumatology, Medical Intensive Care Unit, Beijing, China; 2Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China

Background: Connective tissue disease (CTD) associated pulmonary hypertension (PH) is classified as a subgroup of WHO group 1 PH, also called pulmonary arterial hypertension (PAH). However, not all CTD-PH fit the hemodynamic definition of PAH. This study investigates the diversity of hemodynamical types of CTD-PH, their different clinical characteristics and outcomes.

Objectives: This study investigates the diversity of hemodynamical types of CTD-PH, their different clinical characteristics and outcomes.

Methods: We performed a retrospective cohort study. CTD-PH patients underwent right heart catheterization (RHC) were enrolled and divided into WHO group 1 PH, WHO group 2 PH and high output PH (PVR<3WU and PAWP<15mHg) according to hemodynamic features. Patients with obtrusive lung diseases, left heart disease and pulmonary embolism were excluded. Baseline characteristics, inflammatory markers, autoantibodies, cardiac function status, echocardiogram parameters, hemodynamics and survival rates were compared.

Results: 207 CTD-PH patients were included, including 139 in WHO group 1 PH, 36 in WHO group 2 PH and 32 in high output PH. Incidence of anti-ribonucleoprotein antibody was lower in WHO Group 2 PH. High output PH is less severe, presenting lower NT-proBNP level, better WHF functional class, lower mPAP and PVR, higher cardiac output, and less cardiac remodeling. Among patients with elevated PAWP, combine pre-post-capillary PH had higher mPAP and larger right ventricle diameter. Association of moderate interstitial lung disease didn't show significant difference in disease characteristics. Short-term survival was significantly worse in WHO group 2 PH, yet 5-year survival rates didn't differ between groups.

Conclusion: Pre-capillary PH is not the only hemodynamic type of CTD-PH. Different types of CTD-PH present different clinical phenotypes and outcome. Carefully phenotyping PH in CTD-PH patients is important.

POS1370
INCENRED INFERIOR VENA CAVA WALL THICKNESS AS A SIGN OF VENOUS INFLAMMATION IN BEHÇET’S DISEASE

S. Kutluş Ajaşkiran1, M. Sunbul2, H. Dişkeseneli1, F. Alibaz-Oner1,2, Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Marmara University Faculty of Medicine, Department of Cardiology, Istanbul, Turkey

Background: Vascular involvement of Behçet’s disease (BD) involves both arterial and venous vessels of all sizes [1]. Femoral (superficial, deep, and common) and popliteal veins are the most frequently affected veins. We have previously shown that femoral wall thickness is increased in BD patients and can be used as a diagnostic test [2]. However, many other sites including vena cava inferior/superior and pulmonary arteries may also be involved [3]. Despite the dominance of venous vessel involvement, there is limited data assessing the large veins in BD.

Objectives: In this study, we aimed to assess inferior vena cava wall thickness (IVC) by transthoracic echocardiography (TTE) in BD compared with healthy controls.

Methods: Patients with BD (n=70) and age and sex-matched healthy controls (n=51) were included in this study. Assessment of inferior vena cava (IVC) wall thickness was performed by an experienced cardiologist blinded to cases. Measurement of IVC wall thickness was made at end-expiration and approximately 0.5 to 2.0 cm proximal to the ostium of the right atrium as demonstrated in Figure 1.

Results: IVC wall thickness of patients with BD (0.29 mm; SD: 0.03) was significantly higher than healthy controls (0.26 mm; SD: 0.03) (p<0.001). Although IVC wall thickness was higher in patients with BD with vascular involvement (0.30 mm; SD:0.04) and history of pulmonary embolism (0.30 mm; SD:0.04)), the difference did not reach statistical significance. There was no difference between IVC wall thicknesses in patients who used immunosuppressive and anti-TNF treatments due to major organ involvement, compared to those who did not. Similarly, no difference was observed between IVC thicknesses among Behçet’s patients according to age, gender, and activity status at the last visit. Although no correlation was found between IVC wall thicknesses, disease duration, and BDCF at the last visit in the BD group, there was a low-grade correlation between age and IVC wall thickness (r=0.31, p=0.09).

Conclusion: Increased IVC wall thickness shows vasculitic involvement of large venous structures in BD and can be easily measured by TTE which is an easily accessible, noninvasive modality without radiation. The role of IVC wall thickness assessment for the diagnosis or management of BD requires further studies.

POS1371
HYPOMETHYLATION OF CIRCULATING IMMUNE CELLS IN PATIENTS WITH GRAVES’ ORBITOPATHY – A PRELIMINARY STUDY

V. Kaskova1, A. Petráčková1, J. Schovánek2, M. Karhanová1, J. Savara1, E. Kriegaon behalf of OLGEN, 1Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Department of Immunology, Olomouc, Czech Republic; 2Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Department of Internal Medicine III – Nephrology, Rheumatology and Endocrinology, Faculty of Medicine and Dentistry, Olomouc, Czech Republic; 3Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Department of Ophthalmology, Olomouc, Czech Republic

Background: Graves’ orbitopathy (GO) is an eye disease occurring in patients with autoimmune thyroid disorders (AITD), most commonly Graves’ disease. It is characterized by inflammation affecting soft tissues of the orbit. A recent study demonstrated an association between fibroblast hypomethylation and disease activity in GO (Virakul et al., Front Endocrinol, 2021). Because procurement of fibroblast from GO patients require an invasive sampling, we wondered whether analysis of global DNA methylation in circulating immune cells obtained from peripheral blood could contribute to early detection of GO from patients with AITD.

Objectives: To compare global DNA methylation pattern in circulating immune cells obtained from AITD patients with GO and without GO history and healthy controls.

Methods: Global DNA methylation was quantified in circulating immune cell populations by flow cytometry using 5-methylcytosine antibody in patients with GO (n=10), AITD without GO history (n=9) and healthy controls (n=8). Immune populations (CD4+ and CD8+ T cells, B cells, monocytes and CD56bright NK cells) and their activation status were identified using CD3/4/8/14/16/19/25/45/56/69 antibodies.

Results: In patients with GO, global DNA methylation was reduced by ~50% in the activated (CD25+) CD8+ T cells and by ~35% in the whole CD8+ T cell population compared to patients with AITD (p=0.006). Moreover, percentage of CD8+ T cells, but not activated subpopulation, was higher in GO compared to AITD (p=0.04). Hypomethylation by ~20% was detected in monocytes as well as in CD56+ NK cells and their activated (CD69+) subpopulation when GO was compared with AITD (p<0.02). Of these cell populations, percentage of monocytes was also higher in GO compared to AITD (p=0.04). Global methylation in B cells, CD4+ T cells and CD56bright NK cells did not differ between patients with GO and patients with AITD (p>0.05). Of these populations, higher percentage of B cells was detected in GO when compared to AITD group (p=0.02). Analysis of larger patient cohorts is in progress with particular emphasis on the relationship of methylation patterns to GO disease activity.

Conclusion: This is the first study identifying the different global methylation profile of circulating immune cells in patients with GO characterized by DNA hypomethylation in CD8+ T cells, CD56+ NK cells and monocytes compared to patients with AITD. Our study nominates hypomethylation as a non-invasive biomarker of GO and should be validated in a larger cohort of patients.

Gaslini, Center for Autoinflammatory Diseases and Clinical Immunology, Genova, Italy; 28Schulich School of Medicine & Dentistry, University of Western Ontario, Department of Paediatrics, Division of Paediatric Rheumatology, Behcet and Autoinflammatory Disease Center and Department of Epidemiology and Biostatistics, London, Canada

Background: The Interleukin-1 (IL-1) mediated systemic autoinflammatory diseases (SAIDs), including the cryopyrin-associated periodic syndromes (CAPS), tumor necrosis factor receptor-associated periodic syndrome (TRAPS), mevalonate kinase deficiency (MKD), and deficiency of the IL-1 receptor antagonist (DIRA) belong to a group of rare immunoregulatory diseases that primarily present in early childhood with variable multorgan involvement. When untreated, patients with severe clinical phenotypes have a poor prognosis, and diagnosis and management of these patients can be challenging. However, recently approved treatments targeting the pro-inflammatory cytokine IL-1 have been life-changing and have significantly improved patient outcomes.

Objectives: We aimed to establish evidence-based recommendations on diagnosis, treatment, and monitoring to standardize the management of these patients.

Methods: A multinational, multidisciplinary task force consisting of physician experts including rheumatologists, patients or caregivers, and allied health care professionals was established. Evidence synthesis including systematic literature reviews and expert consensus (Delphi process) was conducted. Consensus methodology was utilized to formulate and vote on statements to guide optimal patient care.

Results: The task force devised five overarching principles, 14 statements related to diagnosis, 10 on therapy, and 9 focused on long-term monitoring that were evidence and/or consensus-based for patients with IL-1 mediated diseases. An outline was developed for disease-specific monitoring of inflammation-induced organ damage progression and reported therapies of CAPS, TRAPS, MKD, and DIRA, and inform the various stakeholders about optimized patient care to improve disease outcomes.

THE DIAGNOSTIC ROLE OF PATHERYTEST IN PATIENTS WITH BEHÇET’S DISEASE FROM WESTERN EUROPE

A. Vitale1, V. Berlingerio2, J. Sota3, S. Barneschi4, M. Mourabiri5, C. Fabiani6, S. Gentilestchi7, V. Caggiano8, G. M. Tos1, B. Friediani9, L. Cantarini10 on behalf of Research Center of Systemic Autoinflammatory Diseases and Behçet’s Disease Clinics. 1Viale Mario Bracci, Department of Medical Sciences, Surgery and Neurosciences, Siena, Italy

Background: pathergy is the term used to describe the hyper-reactivity of the skin in response to a minimal trauma, as the consequence of an exacerbated response of the innate immune system [1]. Pathergy test has a central role for the diagnosis of Behçet’s disease (BD), especially in doubtful and atypical cases. However, while its incidence has been decreasing over the past few decades, there are significant variations in the frequency of pathergy among different geographical contexts [2]. These aspects affect the diagnostic role of pathergy test for patients with suspected BD.

Objectives: to evaluate the frequency and features of positive pathergy test (PPT) in Italy, its role in the diagnosis of BD, and any association with other BD-related manifestations.
Methods: 29 BD patients, 15 patients with spondyloarthrits (SpA) and 19 healthy controls (HCs) underwent two types of pathergy test, which were performed on the hairless part of the volar forearm ipsilaterally: intradermal injection of 0.5 ml normal saline and intra-dermally needle soaked with fresh self-saliva. Both prick were done with a monouse 25 gauge hypodermic needle inserted with a vertical approach at a depth of 5 mm into the skin. The needle was withdrawn with a twisting movement. Skin reactions were observed 48 hours after prick. The results of pathergy tests were statistically analysed in the light of demographic, clinical, and therapeutic features of subjects enrolled. The BD activity at the time of the pathergy test was assessed with the Behçet’s Disease Current Activity Form (BDCF) [3].

Results: pathergy test performed with saline solution resulted always negative in all groups. Skin prick test using self-saliva resulted in the occurrence of a papule in 2 (6.9%) BD patients and in 1 (6.7%) patient with SpA. A ≥15 mm erythematous area surrounding the needle prick site was observed in 12 (41.4%) BD patients, in 4 (26.7%) patients with SpA (including the patient with the papule), and in 1 (5.8%) HCs (p=0.022). The frequency of skin erythema was significantly higher among BD patients compared to HCs (p=0.015); no statistically significant differences were observed between BD and SpA patients (p=0.53) as well as between SpA patients and HC (p=0.21).

The occurrence of skin erythema was not associated with any of the BD-related clinical manifestations. No statistically significant differences were observed between BD patients with positive and negative pathergy test according to sex (p=0.873); HLA-B51 positivity (p-value=0.461); age at the pathergy test (p=0.929); and disease duration at the pathergy test (p=0.487). The mean BDCF was 1.33±0.65 among patients with PPT and 0.82±0.72 among patients with negative pathergy test (p=0.092).

Conclusion: this study confirms the lower frequency of PPT in Western European BD patients if considering the development of a papule or a pustule in the site of pathergy test. Conversely, the onset of a ≥15 mm erythematous area surrounding the prick site could be sufficient to unveil the hyper-reactivity of the innate immune system in BD patients from Western Europe. Pathergy test is not pathognomonic of BD, as its positivity can be also observed in other innate immune system disorders, as observed for SpA patients.

POS1375 THE EVALUATION OF OBESITY IN ADULT-ONSET STILL’S DISEASE. DATA FROM A MULTICENTRE COHORT.

I. Di Cola1, C. Di Muzio1, F. Sensini1, R. Giacomelli1, P. Cipriani2, P. Ruscitti1 on behalf of AOSD GIRRCS Study Group. 1University of Uqiala, Department of Biotechnological and Applied Clinical Sciences, Uquila, Italy; 2University of Rome Campus Biomedico, Department of Medicine, Rome, Italy

Background: Over the last few decades, obesity has become an increasing public health problem worldwide [1]. This is a complex disease characterised by an abnormal or excessive fat accumulation which is usually assessed by body mass index (BMI). A value of BMI over 30 identifies the threshold to define the obesity. High BMI is common feature among patients with rheumatic disease and it is associated with higher disease activity and disability [2]. Thus, the presence of obesity may be considered as a negative prognostic factor in these patients. Against this background in rheumatic disorders, the prevalence of obesity in adult-onset Still’s disease (AOSD) has not been entirely clarified so far. Similarly, the impact of being obese on disease features and outcomes has not been fully elucidated in these patients. AOSD is a rare inflammatory disease usually characterised by fever, arthritis, and evanescent skin rash associated with a typical hyperferritinaemia [3].

Objectives: In this study, we aimed at evaluating the prevalence of obesity in patients with AOSD. Furthermore, we descriptively assessed the clinical characteristics of these patients. We also described the occurrence of life-threatening complications, the disease courses, and the rate of mortality of obese patients with AOSD than non-obese ones.

Methods: A retrospective assessment of prospectively followed patients, from January 2001 to April 2021, was provided to analyse clinical features of patients with AOSD characterised by a BMI ≥30. AOSD patients were evaluated among those included in the multicentre Gruppo Italiano di Ricerca in Reumatologia Clinica e Sperimentale (GIRFRC) cohort. This is a large cohort of patients with AOSD comprising almost 200 patients [4]. The presence of obesity was evaluated at the time of diagnosis of the disease. In this evaluation, only patients with available data about BMI were included.

Results: In this assessment, 139 patients, who had BMI registered in our database, were evaluated. Out of those, 26 (18.7%) had a BMI ≥30 and were defined as having obesity. These patients had a mean age of 39.3±13.6 years and were 46.2% male. Concerning main clinical features, obese patients with AOSD were characterised by fever (96.2%), skin rash (84.6%), arthralgia (76.9%), myalgia (65.4%), and arthritis (61.5%). An explorative comparison between obese and non-obese patients.

Conclusion: Clinical features of obese patients with AOSD were described in our multicentre cohort. Almost 20% of patients with AOSD were obese at the time of diagnosis of the disease. These patients were characterised by a lower prevalence of novartis, pericarditis and pleuritis, and by higher values of CRP. However, obesity did not appear to influence the main disease features and outcomes in AOSD, although further studies are needed to fully elucidate this issue.

POS1376 LONG-TERM EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH HIDS (HYPER-IgD SYNDROME) - INTERIM ANALYSIS OF THE RELIANCE REGISTRY

P. Oommen1, T. Kallinich2, J. Rech3, N. Blank4, J. Weber-Arden5, J. B. Kuevermeier-Deschner1, Heinrich-Heine-University Düsseldorf, Clinic of Pediatric Hematology, Oncology and Clinical Immunology, Division of Pediatric Rheumatology, Duesseldorf, Germany; 2Charité University Medicine Berlin, Department of Pediatrics, Division of Pulmonology, Immunology and Critical Care Medicine, Berlin, Germany; 3Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätlinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology Erlangen, Germany; 4University Hospital Heidelberg, Rheumatology, Heidelberg, Germany; 5Novartis Pharma GmbH, IHD, Nuernberg, Germany; 6University Hospital Tuebingen, Department of Pediatrics, Division of Pediatric Rheumatology, Tuebingen, Germany

Background: Hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) is a rare autoinflammatory condition caused by a defect in the gene coding for mevalonate kinase. This periodic fever syndrome is characterized by severe systemic and organ inflammation. Treatment with intravenous [+] inhibitor canakinumab (CAN), approved and applied for treatment of HIDS/MKD patients since 2017 [1], resulted in rapid remission of symptoms and normalization of laboratory parameters in most patients in clinical trials [2] as well as in real-life.

Objectives: To explore the long-term efficacy and safety of CAN under routine clinical practice conditions in pediatric (age ≥2 years) and adult HIDS/MKD patients.

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany with a 3-year follow-up period. Patients with clinically confirmed diagnoses of TRAPS, CAPS, FMF or HIDS/MKD who routinely receive CAN are enrolled in order to evaluate efficacy and safety of CAN under standard clinical practice conditions at baseline and at 12, 18, and 24 months.

Results: The present interim analysis shows baseline data of 8 HIDS/MKD patients enrolled by December 2021 as well as preliminary 18-month data. Of these patients, 5 (63%) were females and median age at baseline was 8 years (2–39 years). The median duration of prior CAN treatment at baseline was 1.5 years (0–5 years). Standard, low, and high dose CAN treatment was evenly distributed at every interval.

Preliminary results indicate stable remission and disease control by physicians’ and patients’ assessment as well as laboratory parameters (Table 1). In total, 4 patients were affected by adverse drug reactions, however, none of these events was classified as serious.

**Conclusion:** Baseline characteristics and preliminary data of HIDS/MKD patients from the RELIANCE study indicate good clinical and laboratory disease control and no unexpected safety concerns at the 18 months interim analysis.

**LUNG INVOLVEMENT IN VEXAS SYNDROME**

M. Casal Moura1, M. Baqi1, X. Tandon2, M. Samec1, K. Reichard1, A. Mangaonkar1, R. Go3, K. J. Warrington3, M. Patnaik4, M. Koster3, J. H. Ryu1.

1Mayo Clinic, Division of Pulmonary and Critical Care Medicine, Department of Medicine, Rochester, United States of America; 2Mayo Clinic, Radiology, Rochester, United States of America; 3Mayo Clinic, Division of Rheumatology, Department of Medicine, Rochester, United States of America; 4Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, United States of America; 5Mayo Clinic, Division of Hematology, Department of Medicine, Rochester, United States of America

**Background:** Vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic (VEXAS) syndrome is a recently identified disorder caused by somatic mutations in the UBA1 gene of myeloid cells. Various manifestations of pulmonary involvement have been reported, but a detailed description of lung involvement and radiologic findings is lacking.

**Objectives:** To describe lung involvement in VEXAS syndrome.

**Methods:** A retrospective cohort study was conducted of all patients identified at the Mayo Clinic with VEXAS syndrome since October 2020. Clinical records and chest high resolution computed tomography (HRCT) scans were reviewed.

**Results:** Our cohort comprised 22 white men with a median age of 69 years (IQR 62-74, range 57-84). Hematologic disorders including multiple myeloma, myelodysplastic syndrome and pancytopenia were present in 10 patients (45%), rheumatologic diseases including granulomatosis with polyangiitis, IgG4-related disease, polyarteritis nodosa, relapsing polychondritis, and rheumatoid arthritis were found in 10 patients (45%), and 4 patients had dermatologic presentations including Sweet syndrome, Schnitzler-like syndrome or drug rash with eosinophilia skin syndrome (DRESS). VEXAS syndrome-related features included fever (18, 82%), skin lesions (20, 91%), lung infiltrates (12, 55%), chondritis (10, 45%), venous thromboembolism (10, 45%), myalgias or arthritis (40%). In our study, the male/female ratio was found to be 45%, and 21 (95%), respectively, and were documented prior to VEXAS diagnosis. Most of the patients were non-smokers (14, 64%) and obstructive sleep apnea (OSA) was present in 11 patients (50%). Seven patients (32%) used non-invasive ventilation, 6 used C-PAP, and 1 used Bi-PAP. Bronchoalveolar lavage (BAL) was available in 4 patients, and the findings were compatible with neutrophilic alveolitis in 3. Two patients had lung biopsies (2 transbronchial and 1 surgical) that showed ATTr amyloidosis and organizing pneumonia with lymphoid interstitial pneumonia, respectively. Pulmonary function tests were available in 9 (41%) patients and showed normal results in 5; 3 patients had isolated reduction in DLCO and 1 with mild restriction. On chest HRCT, 16 patients (73%) had parenchymal changes including ground-glass opacities in 9, septal thickening in 4, and nodules in 3; pleural effusions were present in 3 patients, air-trapping in 3 patients and tracheomalacia in 1 patient. Follow-up chest HRCT was available for 8 patients (36%), the ground-glass opacities resolved in 5 patients, 3 patients manifested new or increased ground-glass opacities, and 1 patient had increased interlobular septal thickening. After 1 year of follow-up, 4 patients (17%) had died; 3 due to pneumonia (2 COVID-19, 1 bacterial) and 1 due to heart failure. VEXAS flares occurred in 18 patients (82%), the maximum number of relapses was 7, and they were mainly managed with GC and with changes in the immunosuppressive regimen.

**Conclusion:** Pulmonary involvement was documented by chest HRCT in most patients with VEXAS syndrome. Respiratory symptoms occurred over one half of patients and about 20% had PFT abnormalities. The pulmonary manifestations of VEXAS are nonspecific and characterized predominantly by inflammatory parenchymal involvement.

**POS1378**

**ARTHRITIS IN PATIENTS WITH FAMILY MEDITERRANEAN FEVER**

S. Yenigü1, A. Y. Ayla1, S. N. Baspinar1, M. B. Yuzbasıoglu2, A. Alkan1, I. Duruçoğan1, M. Kirman1, B. C. Poal1, S. Ergün1, H. Ozdogan2, S. Uğurlu1, S. Cerrahpasa Medical Faculty, Internal Medicine, Istanbul, Turkey; 2Cerrahpasa Medical Faculty, Internal Medicine, Division of Rheumatology, Istanbul, Turkey

**Background:** Familial Mediterranean fever (FMF) is an inherited autoinflammatory disease characterized by recurrent episodes of fever and serositis. Arthritis is one of the most common attack manifestations. Arthritis in FMF is usually in the form of acute mono- or oligoarthritis of the large joints of the lower extremities. While acute attacks of arthritis usually heal without causing permanent deformity, the severe, long-lasting form of chronic arthritis can last for months or even years and result in permanent deformity.

**Objectives:** In this study, we described the characteristics of joint involvement in FMF in a single cohort.

**Methods:** The medical records of patients with joint involvement from our cohort of 2350 patients who were diagnosed with familial Mediterranean fever were retrospectively scanned through the files and hospital database. The prevalence, demographic information, genetic test results, clinical features, features of joint involvement, treatments and responses, acute phase values in the attack and remission periods, and family history of patients with joint involvement were recorded.

**Results:** 953 patients (n=953) from a total of 2350 patients had arthropagia or arthritis (40%). In our study, the male/female ratio was found to be 1028:1022.

0.49 (male n=316, female n=637). The number of patients who underwent genetic testing was 787 (82%), and 702 (89%) of these patients had mutations in the MEFV gene. The most common pathogenic mutation is the M694V mutation with a rate of 43%. Concomitant diseases and their frequencies are shown in Table 1, the most common accompanying disease was spondylarthritis at a rate of 27%. Arthritis was present in the first attack in 55% (n=531), while arthritis was found in the ongoing attacks in 45%. The duration of the attack was between 24-96 hours in 77% (n=837) of the patients, and the duration was longer than 96 hours in 23% (n=116).

The most common finding accompanying the attacks was exercise-related leg pain. Family history was present in 61% (n=580). 73% of the patients (n=696) were involved in the ankle and 51% were involved in the knee (n=492). The incidence of sacroiliitis was 14% (n=142). As for the number of joints, 91% of the patients had mono- and oligoarthritis. Asymmetric involvement was detected in 77% of the patients. Red arthritis was present in 73% of our study group. HLA-B27 was examined in 185 patients, 24 of them were positive (12%). It was found that 43% of the patients had treatment changes due to arthritis. Colchicine dose increases and changes were performed in 32% of these patients. NSAIDs were started in 21%, corticosteroids in 15%, DMARDs in 12%, anti-TNF in 10%, and anti-IL-1 in 8%. The mean dose of colchicine was as 1.56 ± 0.5 mg. Unresponsiveness to colchicine was found in 21% (n=122).

Conclusion: FMF diagnosis should definitely be considered in people with red mono-oligoarthritis in the large joints of the lower extremities. One of the most important features of joint involvement in FMF patients is the short duration of arthritis. The accompanying effort-related leg pain is an important symptom that should suggest FMF. In patients with a diagnosis of FMF and arthritis, the required colchicine dose in the treatment and the rate of colchicine unresponsiveness are higher than in other attack types. The incidence of sacroiliitis and spondyloarthropathy increases in patients with FMF, and joint involvement features are similar. FMF should be considered in the differential diagnosis of patients with inflammatory low back pain.

Figure 1.
Background: The presence of anti-citrullinated protein antibodies (ACPAs) and rheumatoid factor (RF) are prognostic for erosive severity by radiography in patients with rheumatoid arthritis (RA) [1]. However, others have shown that RF mainly acts as an enhancer for ACPAs mediated bone loss [2]. High-resolution rheumatoid factor (RF) are prognostic for erosive severity by radiography in patients with RA.

Methods: Patients with RA and disease duration ≥ 5 years had their second and third MCP joints imaged by HR-pQCT. RF status were acquired. From the Danish Clinical Quality Program – The Danish Rheumatologic Database (DANBIO) [3], the average 28-joint Disease Activity Score (DAS28-CRP) and Health Assessment Questionnaire (HAQ) from five years before inclusion were extracted. Statistical significance was investigated by HR-pQCT according to the presence of autoantibodies. The hypothesis is that the presence of RF and especially ACPA is associated with erosive damage in two metacarpophalangeal (MCP) joints assessed by HR-pQCT; this has previously been shown using 44 joints assessment of both hands and feet by conventional radiography.

Results: A total number of 353 patients with RA were included in this study. 203 was RF+/ACPA+ positive, 52 was RF-/ACPA+ positive, 24 were RF+/ACPA- patients, RF-/ACPA- patients, and autoantibodies negative patients. Analysis of variance was used to investigate the difference between the groups for age and sex. Cuzick’s Rank-sum test for trend of ordered groups was used to test for trend for disease duration, 5-year average HAQ, 5-year average DAS28, number of erosions, total erosive volume, and average erosion volume.

Conclusions: In the current study, HR-pQCT scanning of only two MCP joints supports previous findings by radiography of both hands and feet, showing the accumulated erosive burden is higher in patients double-positive for RF and ACPA.
Methods: The rheumatological clinical practice in Italy, and 2) to gauge expert's attitudes on the assessment of rheumatic patients in the Italian clinical setting. This survey aimed: 1) to obtain an overview on the usage of capillaroscopy in the diagnosis of Raynaud's phenomenon (Rp) [2]. Despite growing interest in the use of capillaroscopy as part of the clinical routine in the screening of Rp and as part of the annual checkup of CTDs. Critical issues remain the lack of a specific program and network with the general practitioners. To have a wider vision on this topic, our survey could be further extended to other European countries.

References:

This study has received a grant from the Catalan Rheumatology Society (2019) for the implementation of a virtual annual meeting the same year. Nowadays capillaroscopy is a well-established, non-invasive technique with useful clinical applications in the assessment of microcirculation in rheumatic diseases in Italy are not available. The Rheumatology (SIR) endorsed the Italian study group (SG) on capillaroscopy (CAPSIR) that first convened at the University of Genova—IRCCS San Martino Polyclinic Hospital, Department of Internal Medicine, Research Laboratories and Academic Medicine, Division of Rheumatology, Genova, Italy; 7Università Sapienza, Dipartimento di Scienze Cliniche, Internistiche, Anestesiochirurgiche e Cardiovascolari, Roma, Italy.

Background: In May 2020, the executive committee of the Italian Society of Rheumatology (SIR) endorsed the Italian study group (SG) on capillaroscopy and microcirculation in rheumatic diseases (CAPSIR) that first convened at the annual meeting the same year. Nowadays capillaroscopy is a well-established, non-invasive technique with useful clinical applications in the assessment of connective tissue diseases (CTDs) [1] and mandatory for the differential diagnosis of Raynaud’s phenomenon (Rp) [2]. Despite growing interest in the use of this imaging technique in clinical and research settings, data on its current usage to assess microcirculation in rheumatic diseases in Italy are not available.

Objectives: To obtain an insight into the current utilization of capillaroscopy in the assessment of rheumatic patients in the Italian clinical setting. This survey aimed: 1) to obtain an overview on the usage of capillaroscopy in rheumatological clinical practice in Italy, and 2) to gauge expert's attitudes on the assessment of rheumatic patients in the Italian clinical setting. This survey aimed: 1) to obtain an overview on the usage of capillaroscopy in the diagnosis of Raynaud’s phenomenon (Rp) [2]. Despite growing interest in the use of capillaroscopy as part of the clinical routine in the screening of Rp and as part of the annual checkup of CTDs. Critical issues remain the lack of a specific program and network with the general practitioners. To have a wider vision on this topic, our survey could be further extended to other European countries.

Limitations: All patients with a new primary diagnosis of PMR (International Classification of Diseases – 10th revision [ICD-10] code M35.3) on at least one (in-outpatient) visit during years 2016–2019 were identified from the hospital discharge register of Turku University hospital in Finland. We did a chart review of the patient charts including the full clinical follow-up period (median 34 months).

We studied how often the primary diagnosis of PMR changed after further diagnostic evaluation or during follow-up.
Results: In 125 (32.7%) of the 382 patients, the initial diagnosis of PMR changed during further diagnostic evaluation or follow-up. Most common diagnoses initially misdiagnosed as PMR were inflammatory arthritides 36.0% (45/125), degenerative or stress-related musculoskeletal disorder 12.8% (16/125), infection 9.6% (12/125), malignancy 9.6% (12/125), giant cell vasculitis 6.4% (8/125) and other vasculitis 6.4% (8/125) (Table 1). Diagnosis changed in 19% (39/207) of patients fulfilling the 2012 ACR/EULAR PMR classification criteria and in 49% (86/175) of patients who did not.

Conclusion: In a university hospital setting, a third of initial diagnoses of PMR were changed during further evaluation and follow-up. Our findings highlight that thorough consideration of differential diagnosis is always essential when diagnosing PMR. Especially in patients with atypical presentation, there is a substantial risk for misdiagnosis.

NON-INVASIVE IN VIVO METABOLIC PROFILING OF INFLAMMATION IN JOINTS AND ENTHESES BY OPTOACOUSTIC IMAGING

K. Tascilar1,2, F. Fagni1,2, A. Kleyer1,2, S. Bayat1,2, R. Heidemann1,2, G. Krönke1,2, D. Bohr1,2, A. Ramming1,2, F. Hartmann1,2, D. Kliet1,2, A. Federle1,2, A. Regensburger1,2, A. L. Wagner1,2, F. Knelling1,2, M. F. Neurath1,2, G. Schett1,2, M. Waldner1,2, D. Simon1,2, F. Steiger1,2, K. Tascilar1,2, F. Fagni1,2, A. Kleyer1,2, S. Bayat1,2, R. Heidemann1,2, G. Krönke1,2, D. Bohr1,2, A. Ramming1,2, F. Hartmann1,2, D. Kliet1,2, A. Federle1,2, A. Regensburger1,2, A. L. Wagner1,2, F. Knelling1,2, M. F. Neurath1,2, G. Schett1,2, M. Waldner1,2, D. Simon1,2, F. Steiger1,2

Background: An in-depth metabolic characterization of joints and entheses at the tissue level can help in the early diagnosis and treatment selection for patients with inflammatory arthritis [1]. However, current knowledge about the metabolic profiles of synovitis and enthesitis is limited. Multispectral optoacoustic tomography (MSOT), a novel metabolic imaging technology, could be used to undertake metabolic profiling of joints and entheses non-invasively using near-infrared multispectral laser to stimulate tissues and detect the emitted acoustic energy, enabling quantification of tissue components in vivo based on differential absorbance at multiple wavelengths [2, 3].

Objectives: To explore the metabolic characteristics of arthritis and enthesitis using MSOT.

Methods: We performed a cross sectional study on healthy controls (HC) and patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) (Table 1). Participants underwent clinical, ultrasound (US), and MSOT examination of metacarpophalangeal joints, wrists, entheses of lateral epicondyles, patellar, quadriceps and Achilles tendons. MSOT-derived hemoglobin, oxygen saturation, collagen and lipid levels were measured. We calculated scaled mean differences (SDM) between affected and unaffected joints and entheses as defined by clinical examination of US using linear mixed effects models.

Results: We obtained 1535 MSOT and 982 US scans from 87 participants (36 HC, 34 PsA, 17 RA). Enthoseal tenderness was not associated with metabolic changes, whereas US enthesitis was associated with increased total hemoglobin, oxygen saturation and collagen content. In contrast, clinical and US arthritis showed increased hemoglobin levels but reduced oxygen saturation and reduced collagen content. Synovial hyperpufency was associated with increased lipid content in the joints (Figure 1).

Conclusion: MSOT allows a non-invasive characterization of metabolic changes in arthritis and enthesitis. These findings can be interpreted as a reflection of increased synovial cellularity, collagen degradation, and metabolic demand in synovitis, and of an increased tissue apposition and vascularization in enthesitis. Our results support that synovitis and enthesitis do not only differ at the clinical and anatomical-functional level, but also exhibit divergent metabolic changes.

INTERNATIONAL CONSENSUS FOR ULTRASOUND DEFINITIONS OF TENOSYNOVITIS IN JUVENILE IDIOPATHIC ARTHRITIS: RESULTS OF A DELPHI PROCESS

P. Collado1, S. Lanni2, O. De Lucia3, P. Balint4, S. Guillaume5, C. Hernandez-Diaz6, N. M. K. Sande7, S. Magni-Manzon8, C. Malatsia9, V. Martire10, L. Rossi-Semerano11, J. Roth12, T. Ting12, P. Vega Fernandez12, D. Windschall13, M. A. D’agostino14, E. Naredo15 on behalf of Pediatric Tenosynovitis Task Force of the OMERACT Ultrasound Working Group, 1Hospital Universitario Severo Ochoa, Rheumatology, Madrid, Spain; 2Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Paediatric Rheumatology, Milan,
Background: Musculoskeletal ultrasonography (US) is a suitable tool for the clinical assessment in juvenile idiopathic arthritis (JIA). Recently US definitions for normal components of pediatric joints and synovitis have been developed by the OMERACT US working group. Currently this group is working on development and validation of US definition for tenosynovitis as it is also an essential prerequisite for the reliable use of this technology in the pediatric age group.

Objectives: To produce consensus-based definitions for US tenosynovitis in JIA through a Delphi process.

Methods: We undertook a Delphi process on US-defined tenosynovitis in children that consisted of two steps. As a prior systematic literature review showed that US anatomy of the tendons is similar to adults, a Delphi questionnaire was written based on the consensual definitions developed for and used in adults with rheumatoid arthritis [1, 2]. The Delphi questionnaire was sent to rheumatologists and pediatricians who perform pediatric US examination, asking them to rate their level of agreement with each statement of US-defined tenosynovitis. Group agreement was considered if ≥80% of responders scored an item as 3 or 4 in the second step; validations were performed on 88 standardized US images displaying various degrees of tenosynovitis obtained from JIA patients at various ages. Tendons often involved in JIA were selected (foot and ankle tendons, hand and wrist tendons, bicep tendon.). US images of both normal and tenosynovitis elementary lesions were collected by the 18 experts participating in the OMERACT US task force on pediatric tenosynovitis. An agreement ≥70% was considered mandatory for accepting the definition as applicable in the rated image.

Results: The response rate was 75% (28 out of 37) from the first Delphi questionnaire. Strong group agreement (≥86%) was obtained for the US definitions tested. The response rate was 88.9% (16 out of 18) from the Web-exercise after four rounds. The final definitions were validated on still images for all tendons, tested. The response rate was 88.9% (16 out of 18) from the Web-exercise after four rounds. The final definitions were validated on still images for all tendons, tested. The response rate was 88.9% (16 out of 18) from the Web-exercise after four rounds. The final definitions were validated on still images for all tendons, tested.

Conclusion: US anatomies of the tendons are similar to adults, US definitions of tenosynovitis and its elementary components were successfully developed through a Delphi process.

POS1386

THE OCCURRENCE OF INFUSION-RELATED REACTIONS TO RITUXIMAB IS ASSOCIATED WITH LOW PLASMA LEVELS OF MYELOPEROXIDASE-DNA COMPLEXES.

C. H. Lu1, T. J. Lee1, C. L. Yu1, S. C. Hsieh1. 1National Taiwan University, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China; 2National Taiwan University, Graduate Institute of Clinical Medicine, College of Medicine, Taipei, Taiwan, Republic of China

Background: Rituximab (RTX), a chimeric anti-CD20 antibody, is used in the treatment of rheumatic diseases. Infusion-related reactions (IRRs) are the most common adverse event, and premedication may reduce the incidence [1]. To date, there is still no effective predictor for the occurrence of IRRs.

Objectives: To identify factors predicting the occurrence of IRRs during the first course of RTX therapy in patients with rheumatic diseases.

Methods: We prospectively enrolled 29 patients with rheumatic diseases underwent the first course of RTX infusion, which consisted of two 500-mg intravenous infusions separated by about 2 weeks. Each patient received 100 mg intravenous methylprednisolone 60 minutes prior to each RTX infusion. Complete blood counts and C-reactive protein tests were performed before each infusion. The plasma levels of IL-1α, IL-6, IL-8, TNF-α, B-cell activating factor (BAFF) and plasma levels of myeloperoxidase (MPO)-DNA complexes were measured. All-grade IRRs occurring within 24 hours after infusions were recorded. Mann-Whitney U test was conducted to analyze factors associated with IRRs.

Results: The demographics and characteristics of the patients are shown in Table 1. Two patients reported IRRs in the first infusion, and three patients had IRRs in the second infusion of the first course. Among the five IRRs, four were skin rashes and one was headache. No serious events were found. A significant association between the low levels of MPO-DNA complexes and IRRs in the second infusion was noted ($p = 0.011$). The low plasma levels of MPO-DNA complexes also tended to be associated with the occurrence of IRR in the first infusion. The IRRs were not significantly correlate with absolute neutrophil counts, absolute lymphocyte counts, and the plasma levels of IL-1α, IL-6, IL-8, TNF-α, and BAFF.

Table 1. The characteristics of the patients received the first course of RTX treatment ($n = 29$).

Footnotes: Data are presented in median and interquartile range. *Other diagnoses include systemic sclerosis, dermatomyositis, vasculitis, pemphigus, myasthenia gravis. Data are presented in ratio to positive control.

Conclusion: Plasma MPO-DNA complexes represent neutrophil extracellular traps released by activated neutrophils. Neutrophils could be involved in the response to RTX therapy [2]. In this study, the risk of IRRs to RTX tend to increase when the plasma level of MPO-DNA complexes is low. Further research is needed to clarify the impact of activated neutrophils on RTX therapy.

ULTRASOUND FINDINGS OF JOINTS AND ENTHESES FOLLOWING ONE HOUR OF AGE AND GENDER ADJUSTED WEIGHT TRAINING.

J. K. Schreiner1, F. Recker1, D. Scheich2, P. Karakostas3, J. Zib1, C. Behning4, P. Preus5, P. Brossart1, V. Schäfer1. 1University Hospital Bonn, Clinic of Internal Medicine III, Department of Oncology; 2Haematology, Rheumatology and Clinical Immunology, Bonn, Germany; 3University Hospital Bonn, Department of Obstetrics and Prenatal Medicine, Bonn, Germany; 4Porz am Rhein Hospital, Germany;

Background: It is well known that physical activity and weight training have a positive impact on body composition and bone metabolism. However, it is not clear whether the one-hour weight training has a significant effect on joint and enthesis ultrasound findings, which could provide insights into the potential impact of weight training on joint health.

Objectives: To investigate the effects of one-hour weight training on joint and enthesis ultrasound findings in children.

Methods: A total of 30 children aged 9-12 years were randomly assigned to a weight training group (n=15) or a control group (n=15). Both groups performed a one-hour weight training session. The ultrasound images of the knee joints and enthesis were evaluated before and after the weight training. The ultrasound parameters included joint thickness, enthesis thickness, and synovitis score.

Results: The mean joint thickness decreased by 10% in the weight training group compared to the control group (p<0.05). The enthesis thickness remained unchanged in both groups. The synovitis score showed a non-significant decrease in the weight training group (p=0.08).

Conclusion: One-hour weight training has a positive effect on joint thickness but not on enthesis thickness and synovitis score in children. This study suggests that weight training may have potential benefits for joint health.

Scientific Abstracts

1033
Department of Rheumatology, Cologne, Germany; 
University Hospital Bonn, Department of Dermatology and Allergy, Bonn, Germany; 
University Hospital Bonn, Institute for Medical Biometry, Informatics and Epidemiology, Bonn, Germany; 
University Bonn, University Sports Division, Bonn, Germany

Background: Joint effusion and enthesis are common ultrasound findings in rheumatologic diseases such as rheumatoid arthritis or spondyloarthritides. Physically active individuals and athletes were also found to exhibit structural and vascular changes in their entheses, as well as joint effusion through different imaging approaches [1, 2].

Objectives: The aim of this study was to evaluate the development of joint and entheseal ultrasound findings in large and medium joints of young healthy individuals after one hour of standardized weight training.

Methods: A total of three musculoskeletal ultrasound examinations were performed in healthy individuals under the age of 30 years. The first examination was carried out before the individuals conducted one hour of standardized weight training, the second examination 24 hours later and the third examination 48 hours later. The examination comprised shoulder, elbow, wrist, hip, knee, and ankle joints, as well as associated entheseal sites. Poisson mixed effects models were applied to analyse the development of the ultrasound findings within 48 hours after the weight training.

Results: Fifty-one healthy individuals with a mean age of 23.7 years (± 5.6, range: 19-30) (52.9% female) were enrolled in this study. Fourteen participants (27.5%) presented with at least one abnormal enthesis at baseline, increasing to 24 (47.1%) after 24 hours and to 29 (56.9%) 48 hours after the weight training. Hyperperfusion was the only entheseal pathology detected by ultrasound after the training.

The number of individuals with at least one joint effusion increased from 37 (72.6%) at baseline to 45 (88.2%) after 24 hours and to 48 (94.1%) 48 hours after the weight training. The Poisson mixed effects models showed a significant increase of the number of joints with effusion and entheses with pathologies with time after the weight training (p<0.001, Exp(b)=1.63 and p<0.001, Exp(b)=1.58).

Conclusion: Prevalence of joint effusion in large and medium joints as well as the prevalence of entheseal pathology increase significantly within 48 hours after one hour of weight training. As a result, the individual’s physical activity should be considered when performing a musculoskeletal ultrasound examination.

C. Mazeda1, S. P. Silva1, R. Monteiro2, R. Aguiar1, A. Barcelos1, 1Centro Hospitalar Baixo Vouga, Rheumatology, Centro Académico Clínico Egas Moniz, Aveiro, Portugal; 2Centro Hospitalar Baixo Vouga, Clinical Pathology, Aveiro, Portugal

Background: Anti-Ro/SSA antibodies are directed against different proteins of intracellular small ribonucleic acid (RNA)-protein complexes, Ro60 (60kDa) and Ro52 (52kDa) and are the most frequently detected autoantibodies in patients’ sera. The clinical associations with antibodies to the Ro60 protein is well documented and includes systemic lupus erythematosus (SLE) and Sjögren syndrome (SS). [1] The presence of anti-Ro52 antibodies has been reported in a large variety of diseases, such as neoplastic diseases or viral infections [1, 2].

Objectives: The aim of this study was to analyze the clinical relevance and the disease phenotype of patients with anti-Ro52 and/or anti-Ro60 autoantibodies in a single portuguese tertehospital.

Methods: Retrospective and descriptive study included all patients screened for anti-nuclear antibodies (ANA) in the database of the immunology laboratory of our Hospital between 2017 and 2021. Only adult patients (≥ 18-years-old) with positive anti-Ro52 and/or Ro60 were included in the study and divided into three groups: group 1 – Ro52+/Ro60−; group 2 – Ro52+/Ro60+; and group 3 – Ro52−/Ro60+. The presence of ANA was tested by indirect immunofluorescence (threshold of positivity established at titer 1/160) and further screened for anti-extractable nuclear antigen (ENA) antibodies. Socio-demographic and clinical data were collected. Descriptive analysis was performed, p-values<0.05 was statistically significant.

Results: Among 1210 patients, 277 were positive for the antibody anti-Ro52 and/or Ro60. Most of the patients included were women (79.8%) with a mean age of 58.8±16.12. Immune-mediated rheumatologic diseases were diagnosed in 173 (62.5%) patients, while 104 (37.5%) had non-rheumatologic disease. About 38.6% were exclusively anti-Ro52 positive, 30.3% of patients were anti-Ro60 positive alone and 31% tested positive for both. The clinical data of the patients in these three groups is represented in Table 1. In each of the three groups, the most frequent pattern was nuclear fine speckled (AC-4). In group 2, SS was the most frequent diagnosis (46.5%), followed by SLE (19.6%). Regarding ANA titers, a higher amount was observed in this group (p<0.05). The most frequently associated autoantibodies were anti-La (15.1%). In group 3, the diagnosis of SS was the most frequent (23.8%) followed by undifferentiated connective tissue disease (16.7%). Lupus anticoagulant (7.1%) and anti-RNP (6.0%) were more represented in this group. Finally, in group 1, non-rheumatologic disease was the most represented group of disease. In the case of SLE and systemic sclerosis, there were no statistically significant differences between the three groups and the different types of organ involvement. In SS, sicca symptoms were more prevalent in group 2, with statistically significant differences between the groups (p=0.027).

Conclusion: In line with published studies, our work demonstrated that, among the sera tested, autoreactivity to anti-Ro52 alone was the most often observed and in most patients the presence of this antibody alone was not associated with immune-mediated rheumatologic disease, but mainly with malignancies. We also identified the clinical phenotype of patients with positive anti-Ro52 and/or anti-Ro60. Thus, we reinforce the importance of specific detection such as Ro-52 or Ro60 as they present individual diagnostic utility.

Background: Optical spectral transmission (OST) is a modern diagnostic modality able to assess the blood-specific absorption of light transmitted through a tissue, promising quantification of inflammation in the finger and wrist joints of...
patients with rheumatoid arthritis (RA) (HandScan -Demcon/Hemics, The Netherlands). Early data on OST revealed both correlations with clinical and arthrosonomic activity markers of RA, as well as a high diagnostic value during disease follow-up [1-3]. However, in a previous work we could detect and describe several OST confounding factors that complicate the establishment of universal cut-off values [2].

**Objectives:** Aim of this study was to examine and suggest OST-cut-off values after adjusting for the effect of statistically identified confounding factors. Moreover, we sought to describe a clinical model that would represent the probability of a positive RA diagnosis on the basis of OST values and presence of confounders in every individual patient.

**Methods:** Newly diagnosed RA patients (ACR-EULAR Classification Criteria 2010) were examined by OST and compared with healthy controls. Moreover, RA patients underwent clinical (tender & swollen joint counts, DAS28) and laboratory (inflammation markers) examinations. To identify factors that could have a confounding effect on OST, we performed logistic multivariate regression analyses, taking into account patient-associated characteristics such as age, gender, BMI, hand size, nicotine use. After identifying confounders, we determined OST cut-offs for different patient categories. In addition, we calculated the probability of the presence of an RA-diagnosis, based on the measured OST value and the presence of the identified influencing factors. Finally, we examined correlations of OST with clinical and laboratory RA activity parameters.

**Results:** 74 early RA patients [64%]; median age 59 years (53-70, IQR); median DAS28 4.58 (3.5-5.3, IQR)] and 101 controls [80%; median age 45 years (35-56, IQR)] were recruited. Male gender and advanced age were statistically identified as OST influencing factors. Receiver operating characteristics (patients vs. controls) revealed an OST cut-off of 11.2 (sensitivity 85%, specificity 72%) for female and an OST cut-off of 16.07 (sensitivity 75.7%, specificity 72.7%) for male patients. Two models were shown to be statistically appropriate for calculating the probability of the presence of RA based on the measured OST values and confounders: one model with included age for females and one model with included age and smoking status for males (Table 1). OST showed statistically significant moderate correlations with DAS28 (r=0.42, p<0.001), swollen joint count (r=0.437, p<0.001), VAS (r=0.355, p=0.002) and a weak significant correlation with CRP (r=0.23, p=0.045).

**Table 1. Statistical models for calculating the probability of the presence of rheumatoid arthritis based on measured OST values and OST confounding factors.**

OST: optical spectral transmission; P(\text{RA}): probability of RA diagnosis X1 for age, X2 for OST; X3 for nicotine use

**Conclusion:** The establishment of OST cut-off values adjusted for confounding factors and the suggested statistical models could contribute to an increase of the diagnostic value of HandScan and assist clinicians during patient screening. To our knowledge, this is the first report in the literature on the specific topic. Further patient recruitment and research regarding additional confounders are currently taking place with the aim of improving the diagnostic capabilities of this new and promising diagnostic technology.

**REFERENCES:**

**Disclosure of Interests:** None declared

Conclusion: In RA patients in strict clinical remission, PD assessment at baseline but not clinical joint count could help identify patients who will relapse after the cessation of a bDMARD. Due to insufficient recruitment and limited power of the included study, however, no definitive conclusion can be made.

DEEP LEARNING-BASED PANNUS LOCALIZATION SOFTWARE IN THE HANDS OF INFLAMMATORY ARTHRITIS USING TIME-INTENSITY CURVE (TIC) SHAPE CLASSIFICATION ON DYNAMIC MRI DATASET

W Fang1, Y An2, H Sugimori3, S Ichii4, T Kamishima1. 1Faculty of Health Sciences, Hokkaido University, Sapporo, Japan; 2Graduate School of Health Sciences, Hokkaido University, Sapporo, Japan; 3AIC, Yaezu Clinic, Tokyo, Japan

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with significant functional impairment and disability, linked to inflammatory and structural articular and peri-articular damage [1]. Synovitis is a characteristic feature of RA, and is considered an important factor in disease activity and the best predictive marker of joint damage [2]. Therefore, accurate quantification of synovitis can play an important role in clinical evaluation and treatment serving as a biomarker. Pixel-by-pixel time-intensity curve (TIC) shape analysis is a dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) technique to help visualize differently shaped TICs [3]. Pixels having TIC shape type 4, which is characterized as early enhancement followed by washout phase, were regarded as synovitis pixel [4]. A deep residual network called ResNet50 model, a convolutional neural network (CNN) that is 50 layers deep, might effectively classify TIC shapes.

Objectives: This study aimed to develop software that can automatically demonstrate the distribution of enhancing synovial pannus of patients with inflammatory arthritis on DCE-MRI.

Methods: Modified ResNet50 was used on MATLAB. Two investigators drew regions of interest (ROIs) of muscle, bone, and synovitis under expert guidance and obtained TICs for each tissue on DCE-MRI of ten rheumatoid patients. Through cross-validation and batch evaluation, we verified the confusion matrices for the performance of the classifier. Then we identified the pixels of enhancing synovial pannus by image classification from the obtained pixel-by-pixel TIC shape and displayed them in color. The software performance was evaluated using a visual assessment on seven hand joints of one patient.

Results: 150 ROIs for muscles, 150 ROIs for bones, and 59 ROIs for synovitis on DCE-MRI of the hand joints were drawn in ten patients and obtained 4049, 3825, and 1041 TIC shape images, respectively. The classifier’s accuracy, precision, sensitivity, and specificity were 99.6%, 99.3%, 98.4%, and 99.7%, respectively. Out of seven joints, four were assessed as good, two as fair, and one as fail.

Figure 1. Software performance on contrast enhanced dynamic MRI of the wrist

Conclusion: Our classifier showed high accuracy, precision, sensitivity, and specificity. And through the comparison between manual outlining and the result of software, our software had relatively good performance. This automatic software developed using deep learning with CNN might accurately display the enhancing synovial pannus in RA.

TISSUE DOPPLEROGRAPHY AS A DIAGNOSTIC TOOL FOR MYOCARDIAL DYSFUNCTION IN PATIENTS WITH RHEUMATIC DISEASES

L Feiskhovitch1. 1Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation

Background: Pathology of the cardiovascular system has a significant impact on the mortality rate in the population of patients with rheumatic diseases, including rheumatoid arthritis (RA) and ankylosing spondylitis (AS). Involvement of the cardiovascular system determines the course and prognosis of many rheumatic diseases. In the general population, left ventricular diastolic dysfunction is an independent predictor of mortality and symptomatic chronic heart failure. However, routine screening for diastolic dysfunction is rarely performed in patients with RA and AS, especially in those who do not have clinical symptoms.

Objectives: To identify early preclinical signs of myocardial dysfunction in patients with RA and AS.

Methods: 142 people with verified rheumatic diseases were examined. All patients were divided into 2 groups. The first group consisted of patients with RA - 95 pts (average age 46.5±11.1 years). The second group consisted of patients with AS, 47 pts (average age 42.3±10.3 years). The control group included 70 healthy individuals (average age 43.7±12.1 years). All patients underwent standard laboratory and instrumental diagnostic tests, which included joint radiography...
Background: Intestinal lung disease (ILD) is common in systemic sclerosis (SSc) patients and despite recent advances in the treatment represents still the major cause of death. It may be established within the first 4 years of SSc and frequently is subclinical [1].

To evaluate the presence of ILD, there are different available tools in addition to the clinical evaluation including respiratory functional tests (RFT) and imaging methods, especially HRCT which remain the mainstay for the diagnosis of SSc-ILD.

It has been recently proposed that pulmonary ultrasound (US) may have a potential role for the assessment of ILD in patients with SSc [2, 3]. Despite the growing body of evidence, there are no established data regarding its potential role in both detecting ILD in subclinical stages and on the follow-up of SSc patients.

Objectives: To investigate the validity of US in detecting subclinical ILD in SSc and to determine its potential in the follow-up of these patients.

Methods: 133 patients without respiratory symptoms and 133 healthy controls were included. Borg scale dyspnea index, Rodnan skin score (RSS) and pulmonary auscultation were performed. X-ray and respiratory function tests (RFT) were performed the same day. An expert rheumatologist blinded to clinical assessment performed the US. To determine the concurrent validity high-resolution CT (HRCT) scans was performed. HRCT findings were scored according to Warrick score whereas US findings were classified according the previously proposed scale. An inter-observer reliability was performed. A follow-up including US, RFT and Borg scale was done every 3 months for 12 months.

Results: A total of 54 of 133 SSc patients (40.6%) showed US signs of ILD in contrast to healthy controls (4.8%) (p=0.0001). The clinical and laboratory variables associated with ILD were anti-centromere antibodies (p=0.005) and RSS (p=0.005). A positive correlation was demonstrated between the US and HRCT findings (p<0.001). Sensitivity and specificity of US in detecting ILD was 91.2% and 88.6% respectively. A good inter-observer reliability was also observed (k = 0.72).

In the follow-up, a total of 30 patients (22.6%) that demonstrated US signs of ILD at baseline showed US worsening. Nine patients (30%) developed symptoms of ILD.

Conclusion: US is valid to detect subclinical ILD in SSc. Our results showed a high prevalence of this complication. Despite encouraging data, it seems still controversial its role in monitoring the ILD progression in SSc.

NEUROFILAMENT LIGHT CHAIN, AN EARLY BIOMARKER FOR POLYNEUROPATHY IN HEREDITARY ATTR AMYLOIDOSIS.

A. F. Brunger1, M. Berends2, J. Bijzet3, P. Van der Zwaag4, B. J. Kroesen5, C. Teunissen5, S. In ’t Veld5, G. Drost6, F. Lange6, R. Gans2, B. Hazenberg1, H. A. Nienhuis1 on behalf of Amyloidosis Center of Expertise, University Medical Center Groningen. 1University Medical Center Groningen, Rheumatology & Clinical Immunology, Groningen, Netherlands; 2University Medical Center Groningen, Internal Medicine, Groningen, Netherlands; 3University Medical Center Groningen, Medical Genetics, Groningen, Netherlands; 4University Medical Center Groningen, Laboratory Medicine, Groningen, Netherlands; 5Amsterdam UMC, Locatie VUmc, Clinical Chemistry, Amsterdam, Netherlands; 6University Medical Center Groningen, Neurology, Groningen, Netherlands

Background: Serum neurofilament light chain (sNfL) is a sensitive marker for polyneuropathy (PNP) in hereditary transthyretin-related (ATTRv) amyloidosis patients and correlates with the severity of polyneuropathy [1-4]. We hypothesized that sNfL may diagnose neuronal damage in patients with hATTR amyloidosis before the onset of symptoms and before PNP can be detected by electromyography (EMG) examination.

Objectives: To establish the course of sNfL in three different groups: 1. persistently asymptomatic variant carriers (with and without detected amyloid), 2. ATTRv amyloidosis patients with PNP on treatment, 3. variant carriers who develop PNP.

Methods: sNfL levels were assessed longitudinally in asymptomatic variant carriers (with and without detectable amyloid), ATTRv amyloidosis patients with PNP on treatment (either a transthyretin (TTR) stabilizer or patisiran, an RNA interference therapeutic), and variant carriers who developed PNP. sNfL was established by EMG examination. The single-molecule array (Simoa) assay was used to assess sNfL levels.

Results: sNfL levels significantly increased over 1 year in 20 persistently asymptomatic carriers (p<0.001), with the strongest increase in variant carriers (n=8) with detectable amyloid in the subcutaneous abdominal fat tissue. In 21 symptomatic ATTRv amyloidosis patient with PNP on treatment with a TTR stabilizer, sNfL levels remained stable over 1 year. In 24 patients treated with patisiran, sNfL levels significantly decreased after 1 year of treatment (p<0.01). In 8 out of 9 variant carriers who developed PNP a rise in the sNfL level could be observed before the onset of symptoms and establishment of PNP by EMG examination (Figure 1).

Conclusion: sNfL is a marker for early neuronal damage since a rise in sNfL levels occurs before abnormalities can be detected by EMG examination. Our data support the use of sNfL in monitoring disease progression, screening asymptomatic variant carriers and monitoring of treatment effect.

PSORIASIS, WITHOUT RHEUMATOLOGICAL MANIFESTATIONS, IS ASSOCIATED WITH STRUCTURAL CHANGES OF THE SACROILIAC JOINT, A CONTROLLED STUDY USING CT SCAN

T. Leriche1, O. Fakh1, F. Aubin2, M. Chouk3, C. Prat1, 2, D. Wendling1, 4, F. Verhoeven3, 1, CHU Besançon, Rheumatology, Besançon, France; 1CHU Besançon, Dermatology, Besançon, France; 2Université de Franche Comté, EA 4267 PEPITE, Besançon, France; 3Université de Franche Comté, EA 4266 EPILAB, Besançon, France

Background: Plaque Psoriasis (PsO) is an inflammatory disorder that could be associated with rheumatological manifestations defining Psoriatic arthritis. Moreover, recent studies showed that the presence of plaque psoriasis is associated with more structural damage in axial Spondyloarthritids [1]. To our knowledge, no study has specifically evaluated the extent of structural lesions of the sacroiliac joints (SIJs) on computed tomography (CT) in patients with PsO, without rheumatological manifestations, compared with healthy controls.

Objectives: To describe SJ CT characteristics in patients with PsO and compare them with those of age- and sex-matched controls.

Methods: An observational, retrospective study was performed using medical records from Besançon University Hospital’s rheumatology and dermatology departments, which were screened to identify patients with PsO, diagnosed by a dermatologist. A search was then carried out for patients in the hospitals’ imaging archiving system to identify those who had undergone a CT which included the SIJs in their entirety. Non-inclusion criteria were the existence of pelvic bone lesions and a history of pelvic radiotherapy. Each patient was then matched with a control of the same age and sex, recruited through the hospital’s imaging archiving system.

For each individual, CT was interpreted by two independent readers using a quantitative method to assess structural damage. Specifically, structural damage was assessed using the Chi-2 test. For this study, we also observed the existence of intra-articular gas and diffuse idiopathic skeletal hyperostosis (DISH) lesions for each region. Quantitative variables were compared using Student’s t-test. Qualitative variables were compared using the Chi-2 test.

Results: 60 patients and 457 controls were included. Mean (SD) age was 52.2 ± 17.7 in the PsO group and 53.6 ± 16.7 in the control group. 31% (52%) were male in PsO group and 30% (54%) in the control group. In the PsO group, BMI was 27 ± 5.3 versus 26.9 ± 4.4 in control group (p = 0.08). There is a trend for more frequent active smoking in PsO (49% in PsO group versus 54% in control group; p = 0.078). In PsO patients, mean disease duration was 20.2 ± 17.6 years, the skin area affected with plaque was 41.8% ± 22.6 and the mean number of biologic drugs used was 2.25 ± 1.16. The global SIJ score was higher in the PsO group (6.63 ± 10.7) in comparison with the control group (2.84 ± 4.87). Erosion and sclerosis scores were similar in both groups but joint space narrowing score was significantly higher in the PsO group (0.873 ± 3.48 vs. 0.56 ± 3.24, p = 0.026).

Disclosure of Interests: None declared

Background: Salivary gland ultrasonography is useful to assess salivary gland involvement in primary Sjögren Syndrome. Different publications have describes the association between decreases salivary flow and the degree of involvement with ultrasound.

Objectives: This study aims to assess the association of functional salivary tests evaluated by stimulated and unstimulated salivary flow (SSF and USF) with salivary major gland ultrasound scores (SGUS) and a positive focus score in a minor salivary gland biopsy.

Methods: A cross-sectional study including 98 subjects fulfilling the ACR-EULAR 2017 classification criteria for pSS. All patients underwent salivary functional tests, an ultrasound of salivary glands and a minor salivary gland biopsy requested as per clinical practice. The ultrasound images were graded using three different scoring systems: De Vita (0-3), Salaffi (0-4) and Omeract (0-3), obtained as the highest score achieved in the four evaluated glands, left and right parotid and submandibular. Positive biopsy was considered if focus score ≥1.

Results: This study included 98 patients with pSS. We evaluated the different ultrasound scoring systems and each score individually assessed in parotid and submandibular gland with the salivary functional tests. USF is associated with all SGUS independently of the measurement, with a 2.5 ml/15min higher in negative compared to positive SGUS. Similar results were shown for SSF, with a 3 ml/5 min higher in negative compared to positive SGUS (Table 1). We observed no association between USF or SSF and a positive focus score in the minor salivary gland biopsy.

N: Negative, P: Positive

Conclusion: USF and SSF are associated with SGUS system independently of the salivary gland evaluated but not with positivity in the biopsy, pointing to salivary ultrasound as a good technique to evaluate functionality. Neither USF nor SSF are associated with positivity in the biopsy indicating no link between histology and functionality.

THE INTEREST OF DOPPLER ULTRASOUND IN THE EVALUATION OF THE CARPAL TUNNEL SYNDROME SEVERITY

N. El Amri1, S. Jirri2, S. Guizani3, K. Baccouche1, N. Mahdhi1, E. Bouajina1.
1Farhat Hached, Rheumatology, Sousse, Tunisia; 2Farhat Hached, Family Medicine, Sousse, Tunisia; 3University Hospital Sahliou, Plastic Surgery Department, Sousse, Tunisia

Background: Several studies have proven the value of Doppler ultrasound (DpUS) in the diagnosis of carpal tunnel syndrome (CTS) with satisfactory sensitivity and specificity. Yet, unlike the Nerve Conduction Studies (NCS), the interest of this technique in the severity diagnosis in CTS remains uncertain to this day. Several studies have focused on this subject. However, the morphological signs of gravity are not yet consensual.

Objectives: Compare US data with clinical and electromyographic data in order to determine the place of DpUS in the severity diagnosis in CTS.

Methods: A bicentric cross-sectional study including patients with uni or bilateral CTS, confirmed by NCS, referred from the plastic surgery department. All the patients underwent a clinical examination, a NCS of both hands as well as a DpUS of the wrists by the same rheumatologist.

Results: After screening and application of all exclusion criteria, a total of 72 wrists of 47 patients were included. The median age was 54.23 ± 11 years (21-77 years) and 89.4% of wrists were from female patients. Hand numbness was the most frequent functional sign (94.4%) and the Phalen sign was the most noted examination sign (73.6%). Clinically, the patients presented respectively 32 mild, 14 moderate and 26 severe lesions. According to the NCS, there were 18 mild, 21 moderate and 33 severe CTS with 73.6% of the wrists with sensorimotor impairment. On US, the hypoechoic image was the dominant qualitative sign (84.7%). Regarding the quantitative measures, the mean Median Nerve (MN) cross sectional area (CSA) was 14.5 mm2 [9-30 mm2] and the mean flattening index was 3 [1.8-8.92]. Intraneural hypervascularisation was present in 57 wrists (79.2 %). Statistically significant associations were detected between the MN CSA and both history of diabetes mellitus (p=0.045), diabetes duration (p=0.040) and disease duration (P=0.021). But there was no association between MN CSA and age (p=0.406), gender (p=0.690) and BMI (p=0.414). the mean MN CSA during mild clinical stage was 13.5 mm2. For moderate stage it was 17 mm2 while for severe stage it was 15 mm2. No relationship was found between US quantitative and morphological parameters and clinical severity grades. We detected significant correlation between MN hypervascularization and the CTS severity grades on NCS (p=0.044). For the other qualitative US signs, there was no statistically significant difference between the different grades of electromyographic severity (Notch sign (p=0.364), Hypoechoic image (p=0.000), Disappearance of the fascicular aspect (p=0.248), Decreased mobility of the tunnel contents of the canal during wrist movements (p=0.140)). the mean MN CSA during mild electromyographic stage was 13 mm2. For moderate stage it was 14 mm2 while for severe stage it was 15 mm2 and We did not find a statistically significant difference in MN CSA (P=0.494) between the different grades of severity of CTS on NCS. There is no statistically significant association between qualitative US signs and the type of CTS impairment; pure sensory or sensorimotor. However, we found a significant association between the MN CSA and pure sensory or sensorimotor damage on NCS (P=0.009).

Conclusion: MN DpUS could be a complementary procedure to the clinical examination which allows, in addition to the positive diagnosis, to evaluate the severity of the CTS based on the MN CSA and the intraneural vascularization in power Doppler.

CLINICAL EVIDENCE OF THE DIFFERENCE IN CIRCULATING CALPROTEIN LEVELS BETWEEN RHEUMATOID ARTHRITIS AND HEALTHY INDIVIDUALS, NON-INFLAMMATORY ARTHRITIS OR OTHER INFLAMMATORY ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

C. Andulacia1, R. Aibesa2, M. Mahleri3. 1Werfen, Research and Development, Barcelona, Spain; 2Werfen, Headquarters & Technology Center Autoimmunity, Research and Development, San Diego, United States of America; 3Werfen, Headquarters & Technology Center Autoimmunity, Research and Development, San Diego, United States of America

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease mainly characterized by a chronic inflammation of the joints. Early diagnosis and treatment with disease-modifying anti-rheumatic drugs (DMARDs) is essential to prevent or slow down the structural damage. Diagnosis might be difficult in patients with mild and unspecific clinical signs and symptoms though. A differential diagnosis in patients presenting arthritis is needed for an appropriate patient management. Acute-phase reactants (ESR or CRP) are non-specific inflammatory biomarkers used to aid in the diagnosis of RA and to assess disease activity. In the recent years, studies published have shown that calprotectin may be an alternative biomarker of active inflammatory disorders as well as a prognostic or monitoring biomarker.

Objectives: To collect all available evidence on the difference between circulating calprotectin (cCalpro) levels in rheumatoid arthritis (RA) patients and other control populations such as healthy individuals (HI), osteoarthritis (OA), psoriatic arthritis (PsA) or spondyloarthritis (SpA).

Methods: Electronic database searches (Scopus, PubMed and Cochrane Library), complemented by registry and hand searching, were conducted (February 4th, 2021) to identify fully paired studies comparing cCalpro levels in RA and HI, non-inflammatory arthritis (NIA), or other inflammatory arthritis. As recommended by Cochrane, the Hedge’s standardized mean difference (SMD) and its 95% confidence intervals were used to synthesize the difference in cCalpro levels from studies using different matrices (serum or plasma) or laboratory methods. Sample size, mean and standard deviation of each group were extracted from the individual studies to conduct a random-effects model meta-analysis in STATA MP v17.0. When cCalpro levels were reported in median and range or inter-quartile, a formula was used to estimate the mean and standard deviation. Sensitivity analysis, subgroup analyses and meta-regression analyses on matrix type (serum or plasma) and cCalpro commercial test were performed, when feasible, to investigate heterogeneity.

Results: The systematic review retrieved 27 studies comparing cCalpro levels between RA and controls. One study reported cCalpro levels in three different RA and HI cohorts. Most of RA and controls were age and gender matched. Calprotectin was measured in serum in 72.4% of the comparisons. Thirteen different commercial calprotectin tests and four homemade tests were used. In 21 studies cCalpro levels were measured in 2678 RA and 1096 HI. cCalpro levels were significantly higher in RA than in HI (SMD=2.13;95%CI=1.27-2.98;p<0.0001), while no significant heterogeneity was observed. A meta-regression on matrix and assay manufacturer indicated that 22% of the between-study variance might be explained by the type of calprotectin test used. Five studies compared cCalpro levels in 207 RA and 187 NIA (78,57% OA). cCalpro levels were significantly higher in RA than in NIA (SMD=2.914;95% CI=0.957-4.872;p<0.0035), significant heterogeneity was observed. cCalpro levels in 1217 RA and 411 PsA patients were reported in 5 studies. cCalpro levels were slightly higher in RA than in PsA (SMD=0.54; 95%CI=0.242-0.656; p<0.0001), while no significant heterogeneity was observed. A comparison between cCalpro levels in RA and SpA was included in 4 studies. cCalpro levels were slightly higher in RA than in SpA (SMD=0.35; 95% CI=0.129-0.576; p=0.0020), and no significant heterogeneity was observed.

Conclusion: In this systematic review and meta-analysis, rheumatoid arthritis patients showed significantly higher circulating calprotectin levels than healthy individuals, non-inflammatory arthritis, psoriatic arthritis and spondyloarthritis. Pooled standardized mean difference between groups should be interpreted with cautious due to substantial heterogeneity or small number of studies.
PROGNOSTIC VALUE OF COMMON FEMORAL VEIN WALL THICKNESS IN BEHÇET DISEASE: A PROSPECTIVE FOLLOW-UP STUDY

K. Abacı1, R. Ergelen2, F. Temiz2, Y. Yıldız2, T. Ergun3, H. Direskeneli2, F. Albaz-Oneri1, 1Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Marmara University School of Medicine, Department of Radiology, Istanbul, Turkey; 3Marmara University School of Medicine, Department of Internal Medicine, Istanbul, Turkey; 4Marmara University School of Medicine, Department of Dermatology, Istanbul, Turkey

Background: We reported the first controlled doppler ultrasound study showing increased common femoral vein (CFV) thickness in Behçet Disease (BD). Following that, we recently showed that increased CFV thickness is a distinctive feature of BD, rarely present in other inflammatory or vascular diseases such as ankylosing spondylitis, systemic vasculitides, venous insufficiency, and non-inflammatory DVT (deep venous thrombosis) with a specificity higher than 80% for the cut-off value of ≥0.5mm. However, the association between CFV thickness and any organ involvement, disease course or treatment during the prospective follow-up has not been demonstrated so far.

Objectives: This study aimed to assess the longitudinal course and prognostic value of CFV thickness measurement during prospective follow-up BD patients.

Methods: In this prospective study, we included 195 patients with diagnosed BD. The clinical, demographic, treatment data and laboratory were recorded during the entire follow-up. Both CFV thickness was measured with ultrasonography by an experienced radiologist at the same day. Patients were started to follow up prospectively with 3-6 months intervals and in any urgent visit. In 47 patients, the second CFV thickness measurement was done mean 19.79 (10.10) months after the first visit.

Results: At baseline, 98.6% of patients had increased CFV thickness above the cut-off value of ≥0.5mm. The baseline and last follow-up clinical characteristics were shown in Table 1.

Table 1. The baseline and follow-up clinical characteristics of patients with Behçet’s Disease.

In 47 patients, the second CFV thickness measurement was done mean 19.79 months after the first visit. There was no statistically significant difference between the first and second CFV thickness measurements for both right and left of our patients (First vs. second for right CFV: 0.791 mm vs. 0.753, p=0.264; first vs. second for left CFV: 0.787 mm vs. 0.753, p=0.264). We did not find any change in CFV wall thickness with the treatment, new organ involvement and relapses. 139 of 195 patients had prospective clinical follow-up data with the mean of 26.52 (16.94) months. New major organ involvement or relapse leading to treatment change was seen in 39 (28%) patients. While 22 (15.8%) patients had new major organ involvement, 12 (8.6%) of them were diagnosed with new vascular involvement, seven (5%) with new uveitis. Among 36 patients with only mucocutaneous disease at baseline, new major organ involvement developed in 9 patients during follow-up. These nine patients had higher baseline CFV thicknesses compared to patients not developing major organ involvement despite not achieving clinical significance.

Conclusion: CFV wall thickness measurement with ultrasonography which is a non-invasive diagnostic tool for BD, does not show a major change over time with treatment, new organ involvement or disease relapses. However, our preliminary results suggest that mucocutaneous BD patients with higher CFV thickness may have a higher risk of developing major organ involvement during follow-up. The results of our prospective cohort with longer follow-up and increased patients’ number would clarify the prognostic value of CFV thickness in BD.

Disclosure of Interests: None declared

Background: Rheumatoid arthritis (RA) is a disease with substantial impact on quality of life, healthcare and societal costs [1]. Current treatment strategies, especially biologic drugs, result in high costs [2]. Previous studies have already found that a combination treatment strategy of disease-modifying antirheumatic drug(s) with initially medium-to-high doses of prednisolone resulted in better effects and lower costs compared to the treatment strategies without prednisolone [3, 4]. However, to our knowledge the cost-effectiveness of low-dose glucocorticoids (GCs), and that of GC overall in established RA has not been examined separately.

Objectives: To evaluate the cost-effectiveness and cost-utility of low-dose prednisolone in RA patients aged 65+.

Methods: The economic evaluation was performed as part of the placebo-controlled GLORIA trial of RA patients aged 65+ with a disease activity score in 28 joints (DAS28) ≥2.60. Eligible patients were randomized to 2 years 5 mg/day prednisolone or placebo. Patients were recruited from 28 clinical centers in seven European countries. All co-treatment, except for chronic oral GC, was allowed. The economic evaluation had a societal perspective with a time horizon of two years. Cost data were collected with questionnaires and from recorded events, and valued with unit prices of 2017. The primary effectiveness outcome was the DAS28. For cost-utility, quality-adjusted life years (QALYs) were estimated from the EuroQol-5 Dimension (EQ-5D) questionnaire. Standard regression models were used to estimate incremental costs and effects between the treatment groups. Bootstrapping assessed the uncertainty around the average differences in costs and health outcomes.

Results: In total, 444 of 451 randomized patients were included in the modified-intention-to-treat analysis (see main GLORIA study abstract). Patients were on average 72 years and had median 4 active comorbidities at baseline period, annual total costs were €7564/PY for patients with no flares at Year 9, whereas costs reduced sharply in flare-exposure subgroups.}

Conclusion: With greater effectiveness at non-significantly lower costs, low-dose, add-on prednisolone is cost-effective for RA compared to placebo over two years. QALYs were equal in both groups, most likely due to the impact of multiple comorbidities.

POS1403 CLINICAL CHARACTERISTICS, HEALTH CARE RESOURCE UTILIZATION, AND COSTS ASSOCIATED WITH FLARES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN GERMANY

B. Ding1, M. Pignot2, E. Garal-Pantaler3, B. Villinger4, B. Desta5, K. Schmidt5, S. Golam1, H. Stirnadel-Farrant6, A. Schwartz6
1AstraZeneca, BioPharmaceuticals Medical, Gothenburg, Sweden; 2ZEG Berlin GmbH, Center of Epidemiology and Health Research Berlin, Berlin, Germany; 3Team Gesundheit GmbH, Health Economics Department, Essen, Germany; 4AstraZeneca, BioPharmaceuticals Medical, Nürnberg, Germany; 5AstraZeneca, BioPharmaceuticals Business Unit, Gaithersburg, MD, United States of America; 6AstraZeneca, BioPharmaceuticals Medical, Wedel, Germany; 7AstraZeneca, BioPharmaceuticals Medical, Cambridge, United Kingdom; 8University Medicine of Johannes Gutenberg University Mainz, Rheumatology and Clinical Immunology, Mainz, Germany

Background: Longitudinal data describing real-world systemic lupus erythematosus (SLE) disease characteristics, health care resource utilization (HCRU), and costs associated with flares in Germany are limited.

Objectives: To evaluate the clinical characteristics of patients with SLE and estimate the impact of flares on HCRU and costs in a cohort of adults with SLE in Germany.

Methods: CCharacteristics and impact of flares on clinicAI and econMic OutCoMes in patients with systemic Lupus Erythematosus: a German Claims Database Study (CHAMOMILE) was an observational, retrospective cohort study. Adult patients with SLE were identified from the German Betriebsskrankenkassen health insurance fund database between 1 July 2010 and 31 December 2013, and followed for up to 9 years. Baseline period was defined as the first year since the first quarter with the earliest SLE diagnosis during the identification period, including this quarter. Resource utilization measures included number of hospitalizations, duration of stay, and associated costs per person-year (PY) by follow-up year for patient subgroups defined by flare exposure (no, mild, or moderate/severe flares) during baseline. Cost measures included total PY costs in flare-exposure subgroups.

Results: Of 2088 patients included in the study, the mean (SD) age was 51.4 (16.1) years and 1787 (84.6%) were female. The most common SLE manifestations were cutaneous (66.8%), osteoarticular (28.7%), and vascular (23.0%). Patients were receiving treatment with glucocorticoids (54.8%), antimalarials (40.2%), nonsteroidal anti-inflammatory drugs (39.1%), and/or immunosuppressants (32.7%). During the baseline period, 750 patients (35.9%) experienced moderate/severe flares, 622 (29.8%) experienced mild flares, and 716 (34.3%) experienced no flares. Patients with no flares or mild flares during the baseline period had similar costs, and a similar number and duration of hospital stays per PY, which remained consistent from baseline up to 9 years of follow-up. Patients with moderate/severe flares during the baseline period had 2- to 3-fold higher hospital costs, 1- to 2-fold more hospital stays, and hospital stays that were 2-fold longer in duration, compared with the no-flares or mild-flares groups during baseline and each year of follow-up (Table 1). During the baseline period, annual total costs were more than 2-fold greater for patients with moderate/severe flares (€11,048/PY) than patients with mild (€5,348/PY) or no flares (€4,734/PY). In all subsequent years, costs for patients with moderate/severe flares exceeded costs for patients with mild or no flares. Annual total costs gradually increased over time to €7761/PY for patients with mild and to €7564/PY for patients with no flares at Year 9, whereas costs reduced sharply at follow-up Year 1 to €8601/PY and remained similar to Year 9 for patients with moderate/severe flares (Figure 1).

Conclusion: Patients with moderate or severe flares following diagnosis place a large burden on the health care system in Germany. Earlier diagnosis and treatment may reduce flare severity and the associated high health care costs.

Disclosure of Interests: Writing assistance by Rebecca S. Jones, PhD (Fishawack Health). This study was sponsored by AstraZeneca.

Background: It is well known that providing appropriate health information to patients with systemic lupus erythematosus (SLE) has an advantage in the treatment decision-making process. In modern information society the growing popularity of smartphones and social networking services, patients have more access to online health information. However, there are concerns that Internet use may inversely affect the shared decision making (SDM) process with their attending physicians if they receive inaccurate information.

Methods: In this cross-sectional study, information of 386 patients with SLE, which were enrolled from five Japanese institutions between June 2020 and August 2021, were analyzed. The main exposure was time spent on the Internet per day (excluding time used for working). It was divided into four categories (none, <1 hour, 1-2 hours, ≥2 hours). Patients were asked to select the sources of health care information they would like to access first and were categorized into physicians, the Internet, and other media sources (family and friends, healthcare professionals other than physicians, or TV and radio, etc.). Outcome was shared decision making measured via the 9-item Shared Decision Making Questionnaire (SDM-Q-9, scores 0-100). To assess the relationship between the time of Internet use and SDM, we fitted general linear models adjusted for age, gender, education level, household income, marital status, history of cancer, disease duration, and disease activity. Chained equations were used to impute missing values of covariates.

Results: This study ultimately employed 334 patients whose mean age and female ratio were 45.3 years (standard deviation 13.8) and 87.7%, respectively. 68.9% of the patients indicated that they would like to access physicians first, and 19.5% indicated that they would like to access the Internet first. Compared to patients who chose their physician as their first access to health information, there was no difference in SDM-Q-9 among patients who chose the Internet, but patients who chose other media had significantly lower SDM-Q-9 (<7.7 point, 95% confident interval [CI] -14.4 to -0.92, P=0.026). Besides, SDM-Q-9 scores were significantly lower in patients who did not use the Internet compared to those who used it for more than two hours except for their work activities (-9.6, 95%CI -18.9 to -0.26, P=0.044).

Conclusion: The present study suggests that SDM between physicians and patients is positively rather than adversely associated with online information-gathering behavior. Rheumatologists also need to be aware that how patients prefer to access health information to establish a good physician-patient relationship for SDM. In addition, rheumatologists may need to introduce their patients to websites offering appropriate health information.

**LESS THAN 50% FEMALES WITH CHRONIC RHEUMATITIC INFLAMMATORY DISEASES CONTINUE A DMARD DURING PREGNANCY: A DESCRIPTIVE ANALYSIS OF THE NATIONAL FRENCH SOCIAL SECURITY DATABASE**

Background: Treatment of patients with chronic rheumatic inflammatory diseases (CIDR) during pregnancy has changed in the last decade, namely due to the availability of new DMARDs labelled to be used during pregnancy.

Objectives: To describe the anti-rheumatic drug use during pregnancy in women with CRID (i.e. rheumatoid arthritis (RA) or spondyloarthritids (SpA)) in France over the past decade.

Methods: This is a retrospective cohort study within the French Healthcare database (SNDS), which covers 98% of the French population. Adult women were included if they had RA or SpA according to CIM-10 codes, had started a singleton pregnancy between 2008 and 2017 (index date), and were continuously covered by this health insurance from 1-year before pregnancy onset to 1-year after end of the pregnancy or death (whichever comes first). The treatment exposures of interest were: NSAIDs, oral corticosteroids, csDMARD (methotrexate, leflunomide, sulfasalazine, azathioprine, hydroxychloroquine), biologics (anti-TNF, rituximab, abatacept, tocilizumab, ustekinumab, anakinra). Exposure during pregnancy was defined as at least one drug reimbursement from the 6 months before the last menstrual period (LMP) to the end of pregnancy period.

Results: Among the 35,737 adult women with a CRID (40.7% with RA and 59.3% with SpA) who had a past history of DMARD reimbursement, 11,274 (41.7%) started a singleton pregnancy during the study period. In total, during preconception and pregnancy, 4,773 (42.3%) women were not delivered any DMARD nor corticosteroids and pregnancy was defined as at least one drug reimbursement from the 6 months before the last menstrual period (LMP) to the end of pregnancy period.

Conclusions: Overall, less than 50% of women with a CRID who received a DMARD prior to the pregnancy continued to receive such treatment during pregnancy, and overall less than 20% were delivered biologics during pregnancy. Whether the withdrawal of DMARDs led to unfavorable maternal and pregnancy outcomes needs to be evaluated.

</tbody>
</table>

Conclusion: HF quality indicators are adhered to in a high proportion of patients with IA following HF hospitalization. However, reasons for lower HF medication prescribing in IA compared to other high-risk conditions, such as DM, requires further evaluation. It will also be important to determine if adherence to HF quality of care translates to reduced long-term outcomes such as repeat HF hospitalizations and cardiovascular mortality, which we are currently exploring.

Epidemiology, risk factors for disease or disease progression

**POSI407**  
**THE MANAGEMENT OF CONTEMPORARY EARLY UNDIFFERENTIATED ARTHRITIS: DATA ON EULAR'S RECOMMENDATION ON THE RISK OF PERSISTENT DISEASE**

**Background:** EULAR recommendations for early arthritis recommend assessing the following risk factors for persistent disease in Undifferentiated Arthritis (UA): polyarthritis, acute phase reactants (i.e. C-reactive protein (CRP), erythrocyte sedimentation rate (ESR)), rheumatoid factor (RF), ACPA and imaging findings/erosions. However, these recommendations are based on an outdated definition of UA: not fulfilling 1987 RA criteria and having no alternative diagnosis (conventional UA). Since the introduction of the 2010 RA criteria the characterization of UA has changed. The contemporary definition of UA is: not fulfilling 1987 nor 2010 criteria, and having no alternative diagnosis. Therefore, predictors for persistent disease in conventional UA may not be applicable in contemporary UA.

**Objectives:** Our objective was to assess which risk factors for persistent disease, as mentioned in the EULAR recommendations, are applicable in contemporary UA.

**Methods:** Patients consecutively included in the Leiden Early Arthritis Clinic cohort with contemporary UA between 2006-2019, when DMARD start in UA was recommended, were studied. The outcome was sustained remission, defined as absence of clinical synovitis without DMARD use (including corticosteroids) for the entire follow-up (at least one year). Cox regression was used to test the association between the risk factors as mentioned in EULAR-guidelines and sustained remission. For comparison, patients with conventional UA (not fulfilling the 1987 criteria and no other diagnosis) were studied using similar analyses.

**Results:** Contemporary UA patients (n=710) were mostly ACPA negative (95%) and had a median of 2 swollen joints. Radiographic erosions were rare (1.8%). 60% of contemporary UA patients achieved sustained remission after median 1.5 years (IQR 1-3). After achieving remission patients were followed for 5.5 years without clinical arthritis, demonstrating sustainability. Univariable, CRP, ESR, ACPA and RF were associated with time to sustained remission, while polyarthritis was not. In multivariable analysis, only ACPA and CRP were independently associated with sustained remission (HR 0.10 (95% CI:0.03-0.32) and HR 0.67(0.50-0.91), respectively). 67% of contemporary UA patients had none of these risk factors. In contrast, only 2% had both CRP and ACPA. For comparison, multivariable analysis in conventional UA patients (not fulfilling the 1987 criteria and no other diagnosis) were studied using similar analyses.

**Conclusion:** The contemporary UA population is different from conventional UA and risk factors for disease persistence are partly dissimilar. ACPA and CRP remain to be predictive in contemporary UA. Other factors included in the current EULAR recommendation were uninformative (RF, ESR, polyarthritis) or rare (erosions). Therefore, risk factors recommended in future EULAR recommendations may require alterations.

**AN ULTRASOUND NEGATIVE FOR SUBCLINICAL SYNOVITIS IN PATIENTS WITH ARTHRALGIA: IS IT HELPFUL IN IDENTIFYING THOSE WHO WILL NOT DEVELOP INFLAMMATORY ARTHRITIS? A LONGITUDINAL STUDY IN FOUR ARTHRALGIA COHORTS**

**Background:** Ultrasound (US) has become an established method in the evaluation of joints and is often used in clinical practice to guide management decisions in arthralgia-patients. To date, studies on the prognostic value of MSUS in arthralgia focused on the positive predictive value of subclinical inflammation. However, also the absence of imaging-detected subclinical synovitis is now increasingly used in daily practice to exclude arthralgia-patients from further follow-up. Though, evidence on the value of a negative US in ruling out future IA development in arthralgia-patients (the negative predictive value) is mostly absent. According to the rules of Bayes, predictive values are highly dependent on the prior-risk of developing the disease. The NPV therefore, is strongly related to the prior-risk of not getting IA, which is quite considerable in arthralgia-patients.

**Objectives:** To investigate the negative predictive value (NPV) of musculoskeletal ultrasound (MSUS) in arthralgia patients at risk for developing inflammatory arthritis (IA).

**Methods:** An MSUS examination of hands and feet was performed in arthralgia-patients at risk for IA in four independent cohorts. Patients were followed for one-year on the development of IA. Subclinical synovitis was defined as grey-scale ≥2 and/or power Doppler ≥1. NPVs were determined and compared with the prior-risks of not developing IA. Outcomes were pooled using meta-analyses and meta-regression analyses. In sensitivity analyses, MSUS-imaging of tender joints only (rather than the full US-protocol) was analyzed and ACPA-stratification applied, the latter being in line with the use of US in daily care.

**Results:** After one-year 78%, 82%, 77% and 72% of patients in the four cohorts did not develop IA. The NPV of a negative US was 86%, 85%, 82% and 90%, respectively. The meta-analysis showed a pooled non-IA prevalence of 79% (95% CI: 75%-83%) and a pooled NPV of 86% (95% CI: 81%-89%) (Figure 1). Imaging tender joints only (as generally done in clinical practice) and ACPA-stratification showed similar results.

**Conclusion:** A negative US result in arthralgia has a high NPV for not developing IA, which is mainly due to the high a-priori risk of not developing IA. The added value of a negative US (<10% increase) was limited.

ASSOCIATION BETWEEN SHORT-TERM EXPOSURE TO ENVIRONMENTAL AIR POLLUTION AND PSORIASIS FLARE

G. Adami¹, F. Bellinato², A. Fassio¹, C. Benini¹, G. Girolomoni², P. Gisondi², M. Rossini¹. ¹University of Verona, Rheumatology Unit, Verona, Italy; ²University of Verona, Dermatology Unit, Verona, Italy

Background: Psoriasis is a chronic inflammatory disease with a relapsing-remitting course. Selected environmental factors such as infections, stressful life events or drugs may trigger disease flares. Whether the air pollution could trigger psoriasis flares is still unknown.

Objectives: To investigate whether the short-term exposure to environmental air pollution is associated to psoriasis flares.

Methods: Observational study with both case-crossover and cross-sectional design was conducted. We retrospectively analyzed longitudinal data from 2013 to 2020 of patients with psoriasis attending the outpatient dermatologic clinic of the University Hospital of Verona. For the case-crossover analysis patients with at least one disease flare, defined as PASI increase ≥5 between 2 consecutive assessments in a time frame of 3-4 months, were considered. In the case-crossover analysis each patient serves as its own control; the exposure of interest is compared in two different periods in the same group of patients followed longitudinally (Figure 1). For the cross-sectional analysis, patients receiving any systemic treatment for ≥6 months, with ≥2 consecutive PASI assessment were included. We compared the mean and cumulative (area under the curve) concentrations of several air pollutants (CO, NO₂, NOₓ, C6H6, PM10 and PM2.5) in the 60 days preceding the psoriasis flare and the control visits.

Results: A total of 957 patients with plaque psoriasis with 4,398 follow-up visits were included in the study. More than 15,000 measurements of air pollutants concentration from the official, open-source, bulletin of the Italian Institute for Environmental Protection and Research (ISPRA) were retrieved. Among the overall cohort, 369 (38.6%) patients with psoriasis flare were included in the case-crossover study. We found that concentrations of all pollutants were significantly higher in the 60 days before psoriasis flare (median PASI at the flare 12, IQR 9-18), compared to the control visit (median PASI 1, IQR 1-3, p <0.0001). In the cross-sectional analysis, exposure to mean PM10 over 20 μg/m³ and mean PM2.5 over 15 μg/m³ in the 60 days before assessment were associated with a higher risk of PASI ≥5 point worsening, aOR 1.55, 95% CI 1.21-1.99 and aOR 1.25, 95% CI 1.0-1.57, respectively (Figure 1). Sensitivity analyses that stratified for trimester of evaluation, with various lag of exposure and adjusting for type of treatment yielded similar results.

Conclusion: Air pollution may be a trigger factor for psoriasis flare.

DEVELOPMENT OF PREDICTION MODELS FOR SENIOR PATIENTS WITH RHEUMATOID ARTHRITIS AND COMORBIDITIES TREATED WITH CHRONIC LOW-DOSE GLUCOCORTICOIDS IN THE GLORIA TRIAL

AUC 0.67-0.69.

Another predictive factor (see Figure 1). The quality of the prediction models is different from that of study treatment. In three instances, prednisolone interacted with outcome in one of the models (Figure 1). Their association was much weaker than that of study treatment. Finally, a few additional variables were slightly (but not relevantly) predictive for the outcome in one of the models (Figure 1). The quality of the prediction models was sufficient, the performance low to moderate: explained variance: 12-15%, AUC 0.67-0.69.

In the GLORIA trial 451 RA patients aged 65+ were randomized to 2 years 5 mg/day prednisolone or placebo. Eight prediction models were developed from the dataset in a stepwise procedure. In preparation, to limit excessive statistical testing and false positive results, possible predictors were grouped into five predictor sets based on prior knowledge (Table 1). The first set of four models disregarded study treatment and examined general predictive factors. The second set of four models was similar but examined the additional role of study treatment, as main factor and as interaction factor with other predictive variables. In each set, two models focused on harm (1: occurrence of ≥1 adverse event of special interest (AESI); 2: number of AESIs per year) and two on benefit (3: early clinical response–disease activity; 4: lack of joint damage progression). AESI comprised all serious adverse events, events leading to discontinuation of study treatment, and events related to glucocorticoid exposure (see main GLORIA study abstract). Linear and logistic multivariable regression methods with backward selection were used to develop the models. The final models were developed from the dataset in a stepwise procedure. In preparation, to limit excessive statistical testing and false positive results, possible predictors were grouped into five predictor sets based on prior knowledge (Table 1). The first set of four models disregarded study treatment and examined general predictive factors. The second set of four models was similar but examined the additional role of study treatment, as main factor and as interaction factor with other predictive variables. In each set, two models focused on harm (1: occurrence of ≥1 adverse event of special interest (AESI); 2: number of AESIs per year) and two on benefit (3: early clinical response–disease activity; 4: lack of joint damage progression). AESI comprised all serious adverse events, events leading to discontinuation of study treatment, and events related to glucocorticoid exposure (see main GLORIA study abstract). Linear and logistic multivariable regression methods with backward selection were used to develop the models. The final models were assessed and internally validated with bootstrapping techniques, and their performance was evaluated with model fit and discrimination measures.

RESULTS: Study treatment (i.e. prednisolone) was highly predictive as a main factor in models 5-8, increasing the risk of both benefit and harm. In addition, a few additional variables were slightly (but not relevantly) predictive for the outcome in one of the models (Figure 1). Their association was much weaker than that of study treatment. In three instances, prednisolone interacted with another predictive factor (see Figure 1). The quality of the prediction models was sufficient, the performance low to moderate: explained variance: 12-15%, AUC 0.67-0.69.

Figure 1. Baseline predictive factors for benefit and harm (other than prednisolone), and their interaction with prednisolone. For benefit red means less/better, for harm red means increase of harm.

CONCLUSION: Baseline factors are not helpful to select senior RA patients for treatment with low-dose prednisolone given their low power to predict the chance of benefit or harm.

We present the results obtained via spectral clustering on the similarity matrix obtained in each “case” and “control” population via Euclidean distance. There are 40 LTCs which are represented via two clusters in the “case” and the “control” population network (Figure 1). The LTCs in the same cluster are strongly connected within themselves compared to those in the other cluster. The noticeable part was clustering of diabetes, hypertension and chronic kidney diseases in one group, especially in the “case” population over the “control” population. Interestingly, depression, dementia and chronic heart diseases in one group, especially in the “case” population over the “control” population.

We identified a total of 149,691 cases of ILD over 15 years. Patients with RA had the highest prevalence of ILD amongst the 5 studied autoimmune diseases. The prevalence rate of RA in ILD patients in 2003 was 3.3% which significantly reduced to 0.93% in 2018 with a peak of 6.41% in 2010 (p < 0.0001). Prevalence rate of ILD with myositis decreased from 0.72% in 2003 to 0.46% in 2018 (p < 0.0001). The prevalence rates of SLE, Scleroderma, and MCTD in cases with ILD significantly increased from 1.38% to 1.63%, 1.38% to 1.76%, and 0.14% to 0.54% from 2003 to 2018 respectively. The average age of ILD cases with SLE was significantly younger compared to ILD without autoimmune disease (59.28 vs 72.32 years, p < 0.0001), RA (69.72 vs 72.17 years, p < 0.0008), Scleroderma (62.01 vs 72.28 years, p < 0.0001). Myositis (59.56 vs 72.19 years, p < 0.0001) and MCTD (59.6 vs 72.18 years, p < 0.0001). On examining the racial distribution, the African American population with ILD when compared to other races were more likely to have underlying SLE, MCTD, Myositis or Scleroderma. In ILD with RA, Native Americans were the most affected racial demographic followed by African Americans.

Average cost of hospitalization was higher in ILD with MCTD ($104,631 vs $71,264.6, p<0.0001), Myositis ($105,623 vs $71,232.9, p<0.0001) and Scleroderma ($88,736.2 vs $71,135.5, p<0.0001). Average LOS was significantly longer in RA (7.17 vs 6.66 days, p value 0.0006), MCTD (7.71 vs 6.67 days, p value 0.0008), Myositis (8.33 vs 6.66 days, p value <0.0001) and Scleroderma (7.07 vs 6.67 days, p value 0.0176). Though not significant, average LOS was longer in SLE (6.70 vs 6.67 days, p value 0.4999).

Conclusion: Our study shows that the prevalence of RA in ILD cases has significantly reduced through the years. This can be attributed to the better understanding of the disease and its risk factors as well as the availability and use of newer biologic agents to obtain better control. However, the prevalence of SLE, Scleroderma, and MCTD in ILD cases has increased over the years. This points to the need for better therapies as well as highlights the fact that over the years recognition and diagnosis of these diseases have increased over the years. Racial predilection also comes to light, suggesting the need for special attention to certain races to diagnose the autoimmune disease earlier. Average LOS and cost of hospitalization were also higher in ILD cases with autoimmune disease, reflecting the higher socioeconomic burden.

RISK OF CANCER IN CONNECTIVE TISSUE DISORDERS IN THE NORTH EAST OF ITALY OVER 15 YEARS OF FOLLOW-UP

E. Treppe1, F. Tofofflit2, V. Manfre3, M. Taborelli4, S. De Vita5, D. Serraino5, L. Quattrocchio3. 1Division of Rheumatology, Department of Medicine, Udine, Italy; 2Centro di Riferimento Oncologico (CRO), Unit of Cancer Epidemiology, Aviano, Italy; 3Division of Rheumatology, Department of Medicine, Udine, Italy

Background: Connective tissue diseases (CTD) include systemic lupus erythematosus (SLE), Sjögren’s syndrome (SS), systemic sclerosis (SSc), polymyositis (PM), and dermatomyositis (DM). CTD are characterized by dysfunction of the immune system that leads to the loss of tolerance to self-antigens [1]. Shared risk factors represent a major need for better therapies as well as highlights the fact that over the years recognition and diagnosis of these diseases have increased over the years.

Methods: A retrospective population-based cohort study was conducted using data from healthcare databases of the Friuli Venezia Giulia region, north-east of Italy (1,206,000 inhabitants). Information on demographic characteristics, hospital discharges, exemption from medical charges, drug prescriptions, were individually matched with data from the population-based cancer registry. The cancer risk was assessed in people diagnosed with the following diseases: SLE, SS, SSc, PM, and DM. To compare the cancer incidence in the cohort with the general population, Standardized Incidence Ratios (SIRs) were calculated as the ratio between the observed and the expected number of cancer cases. The cohort included subjects resident in the Friuli Venezia Giulia region, diagnosed with at least one of the following diseases: SLE, SSc, SS, DM, and PM. To guarantee the highest homogeneity and comparability of the exemptions codes, the analysis was restricted to the years 2002-2017. Excluding criteria were: (1) follow-up shorter than 90 days; (2) concurrent diagnoses of rheumatoid arthritis (RA), psoriatic arthritis or ankylosing spondylitis; (3) ever use of biologic drug specific to treat RA (with the exception of rituximab), psoriatic arthritis or ankylosing spondylitis.

The patients were observed starting from 90 days after the first date when the diagnosis was mentioned in hospital discharges or exemptions, and they were followed until cancer diagnosis, death, change of regional residence, or December 31, 2017, whichever came first.

Results: We identified a total of 149,691 cases of ILD over 15 years. Patients with RA had the highest prevalence of ILD amongst the 5 studied autoimmune diseases. The prevalence rate of RA in ILD patients in 2003 was 3.3% which significantly reduced to 0.93% in 2018 with a peak of 6.41% in 2010 (p < 0.0001). Prevalence rate of ILD with myositis decreased from 0.72% in 2003 to 0.46% in 2018 (p < 0.0001). The prevalence rates of SLE, Scleroderma, and MCTD in cases with ILD significantly increased from 1.38% to 1.63%, 1.38% to 1.76%, and 0.14% to 0.54% from 2003 to 2018 respectively. The average age of ILD cases with SLE was significantly younger compared to ILD without autoimmune disease (59.28 vs 72.32 years, p < 0.0001), RA (69.72 vs 72.17 years, p < 0.0008), Scleroderma (62.01 vs 72.28 years, p < 0.0001). Myositis (59.56 vs 72.19 years, p < 0.0001) and MCTD (59.6 vs 72.18 years, p < 0.0001). On examining the racial distribution, the African American population with ILD when compared to other races were more likely to have underlying SLE, MCTD, Myositis or Scleroderma. In ILD with RA, Native Americans were the most affected racial demographic followed by African Americans.
