**Methods:** This study was carried out on pregnant patients with ARDs from the Pregnancy and Rheumatic Diseases clinic of the rheumatology department of the University Hospital “Dr. José Eleuterio González” during the period from February 2018 to August 2021. Two standardized evaluations of anxiety and depression were carried out using the Inventory of Trait and State Anxiety (iDARE) and the Edinburgh Postpartum Depression Scale (EPDS) respectively in the third trimester of pregnancy. Maternal report of alcohol consumption among any trimester of pregnancy, as well as adherence to routine laboratory studies such as structural ultrasound and gestational diabetes screening, was addressed. Positive COVID-19 nasopharynx PCR results were evaluated during pregnancy beginning in the pandemic period (March 2020). The pre-pandemic recruited group was compared with the pandemic group. The comparison of the groups was carried out using the Chi-Square and Fisher tests. A significant value of p < 0.05 was considered. Statistical analysis was performed using the IBM SPSS v.25 program.

**Results:** 50 pregnant patients with ARDs were recruited, of which 24 were included in the pre-pandemic group and 26 in the pandemic group. Compared with the pre-pandemic group, pregnant women recruited during the pandemic had a statistically significant higher positivity for state anxiety (p=0.023), likewise trait anxiety, depression, and suicidal ideation were detected more frequently, but the difference was not statistically significant, a higher rate of adherence to laboratory and cabinet studies was found, being significant for laboratories performed in the 1st and 2nd trimesters (0.005 and 0.025 respectively). See Table 1.

**DISCLOSURE:** State and Trait Anxiety Inventory, EPDS= Edinburgh Postpartum Depression Scale. A Chi-square test for categorical variables or Fisher's exact test where the expected cell n

**Conclusion:** A higher frequency of positivity for state anxiety was demonstrated in pregnant women with ARDs recruited during the pandemic, as well as higher trait anxiety, depression, and suicidal ideation, although this increase was not statistically significant. On the other hand, concern about the pandemic and health status could positively influence better adherence to screening and routine studies during pregnancy.

The severe systemic inflammation in COVID-19 causes respiratory symptoms, fever, fatigue, neurological and gastrointestinal manifestations. **Objectives:** We followed the evolution of SARS-CoV-2 infection in rheumatoid arthritis patients who received anti-TNF blockers. **Methods:** Our study included 95 rheumatoid arthritis patients who were diagnosed with SARS-CoV-2 infection through a positive RT-PCR-SARS-CoV-2 test. **Results:** 21 patients were men and 74 were women. Mean age was 58 ± 11.5. 24 patients received monotherapy with anti TNF blockers (Adalimumab/ Infliximab), 48 received TNF blockers in combination with Methotrexate (10mg per week) and 13 received TNF blockers in combination with Leflunomide (20mg per day). We followed serum ferritin, C reactive protein and D-dimer in all patients. 59 patients were vaccinated with two doses of Pfizer-BioNtech (64.1 %). The study group was analyzed from 30th December 2021 to 1st of January 2022. From 95 patients, 35 (36.8%) were hospitalized and 60 received ambulatory care. **Results:** Our patients with COVID-19 presented with asimptomatic forms, forms with mild symptoms and complicated forms that required hospitalization. No patients had died. Milder forms were associated with the use of TNF blockers and Methotrexate and patients with monotherapy – TNF blockers. They presented with mild symptoms (fever, arthralgia, odynophagia, dysgeusia/ageusia, anosmia). Hospitalization rate in patients who received monotherapy with TNF blockers was 29.1%, 31.2% in patients who received TNF blockers and Methotrexate and 56.5% in patients with TNF blockers and Leflunomide (69.3%). Factors associated with higher odds of hospitalization included older age (p=0.001), active disease (p=0.02), obesity (p=0.005), pulmonary chronic disease (p=0.02), diabetes (p=0.001) and concomitant dose of Leflunomide (p=0.0006). Female sex was associated with milder forms of the disease. Patients with high levels of D-dimer had a higher odds of hospitalization (p=0.001). Strong positive correlation was observed between elevated D-dimers and hospitalization odds. **Conclusion:** TNF blockers in monotherapy or associated with Methotrexate were correlated with lower odds of hospitalization and milder forms of COVID-19. No significant difference of hospitalization odds was observed between vaccinated and unvaccinated patients.

**AB1172 POSTER:** SARS-COV 2 INFECTION AND ANTI TNF THERAPY IN RHEUMATOID ARTHRITIS PATIENTS

1Central Military Emergency University Hospital “Dr Carol Davila”; Department of Internal Medicine, Bucharest, Romania; 2Central Military Emergency University Hospital “Dr Carol Davila”; Department of Internal Medicine, Bucharest, Romania; 3Central Military Emergency University Hospital “Dr Carol Davila”; Department of Internal Medicine, Bucharest, Romania; 4Central Military Emergency University Hospital “Dr Carol Davila”; Department of Internal Medicine, Bucharest, Romania

**Background:** High levels of tumor necrosis factor (TNF), a key proinflammatory cytokine, is associated with SARS-CoV-2 infection. In rheumatoid arthritis patients with SARS-CoV-2 infection, anti TNF therapy reduces not only TNF but other cytokines responsible for high morbidity and mortality.

**Methods:** Our study included 95 rheumatoid arthritis patients who were diagnosed with SARS-CoV-2 infection through a positive RT-PCR-SARS-CoV-2 test. **Results:** 21 patients were men and 74 were women. Mean age was 58 ± 11.5. 24 patients received monotherapy with anti TNF blockers (Adalimumab/ Infliximab), 48 received TNF blockers in combination with Methotrexate (10mg per week) and 13 received TNF blockers in combination with Leflunomide (20mg per day). We followed serum ferritin, C reactive protein and D-dimer in all patients. 59 patients were vaccinated with two doses of Pfizer-BioNtech (64.1 %). The study group was analyzed from 30th December 2021 to 1st of January 2022. From 95 patients, 35 (36.8%) were hospitalized and 60 received ambulatory care. **Results:** Our patients with COVID-19 presented with asimptomatic forms, forms with mild symptoms and complicated forms that required hospitalization. No patients had died. Milder forms were associated with the use of TNF blockers and Methotrexate and patients with monotherapy – TNF blockers. They presented with mild symptoms (fever, arthralgia, odynophagia, dysgeusia/ageusia, anosmia). Hospitalization rate in patients who received monotherapy with TNF blockers was 29.1%, 31.2% in patients who received TNF blockers and Methotrexate and 56.5% in patients with TNF blockers and Leflunomide (69.3%). Factors associated with higher odds of hospitalization included older age (p=0.001), active disease (p=0.02), obesity (p=0.005), pulmonary chronic disease (p=0.02), diabetes (p=0.001) and concomitant dose of Leflunomide (p=0.0006). Female sex was associated with milder forms of the disease. Patients with high levels of D-dimer had a higher odds of hospitalization (p=0.001). Strong positive correlation was observed between elevated D-dimers and hospitalization odds. **Conclusion:** TNF blockers in monotherapy or associated with Methotrexate were correlated with lower odds of hospitalization and milder forms of COVID-19. No significant difference of hospitalization odds was observed between vaccinated and unvaccinated patients.

**Results:** A total of 300 patients were interviewed and 69 (23.0%) reported confirmed anti-SARS-CoV infection and 5 (1.7%) had a second infection. Among known infected patients, 18.6% needed hospitalization and oxygen support, 72% were admitted at ICU, and 5.8% died. After COVID-19 infection, 31.8% reported disease activity but only 6.1% had modification in medication due to disease activity. Distribution of cases followed the pattern of waves observed in Brazil (Figure 1). Regarding vaccination, 285 (95%) reported to have received at least one dose of any anti-SARS-CoV-2 vaccine. 43% received the first with the adenovirus ChAdOx1 nCoV-19 (AstraZeneca) adenovirus vaccine, 32% received the Sinovac-CoronaVac inactivated vaccine, 22% received the BNT162b2 (Pfizer-BioNTech) mRNA vaccine and 3% received the BNT162b2 (Pfizer-BioNTech) adenovirus vaccine. Almost all (98.1%) of these patients had already received the second dose of vaccine and after the first and second vaccine doses, 6% and 4% of patients, respectively, reported worsening of articular disease activity, while, after the third dose, no patient reported disease activity worsening.

**Conclusion:**

During the pandemics, patients with inflammatory arthritis had a pattern of distribution of cases very similar to general population. Adherence to vaccination is high and well tolerated.

**EFFECTS OF THE COVID-19 DISEASE ON AXIAL SPONDYLOARTHITIS DISEASE FLARE**

B. Armanag1, E. Atalar2, B. Ozdemir3, O. Karsak3, E. Kayacan Erdogan4, S. C. Gullen1, I. Dogan5, O. Kucuk6, A. Erden7, A. Ankara City Hospital, Rheumatology, Ankara, Turkey; 2Ankara Yildirim Beyazit University, Ankara City Hospital, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

**Background:** Rheumatological disease flares may be seen after many infections. However, our knowledge for the post-COVID axial spondyloarthritides (SpA) flares and its related factors is limited.

**Objectives:** We aimed to evaluate disease activity and factors that may be associated with disease activity in axial SpA patients in post-COVID period.

**Methods:** We retrospectively assessed the axial SpA patients who have had COVID-19 disease confirmed by a positive SARS-CoV-2 polymerized chain reaction (PCR) test result. Demographics, comorbid diseases, active medical treatments for SpA and information regarding COVID-19 clinical courses were collected from medical records. PCR positive patients were reached via telephone and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scored for pre- and post-COVID SpA symptoms. An increase of ≥2 points in the BASDAI score was defined as flare, and SpA groups with and without flare were compared. Factors predicting SpA flare were also analyzed by the logistic regression analysis.

**Results:** A total of 48 axial SpA patients were included in our study, 65% of them male and the means±SD age was 42.3±8.6 years. Post-COVID SpA flare was seen in 38% patients. Demographic, clinical, medical features of the SpA patients and COVID-19 disease severity were similar between Flare and No-flare groups. In comparison of the COVID-19 symptoms, although most of the...
COVID-19 related symptoms were similar between two groups, the frequency of the back pain and diarrhea were higher in the Flare group than No flare group. But in multivariate analysis, only history of the inflammatory bowel disease had an increased risk for post-COVID SpA flare (Table 1).

OR: Odds ratio; CI: Confidence Interval

### Conclusion:
The presence of inflammatory bowel disease statistically significant related post-COVID SpA flares. In addition, diarrhea and back pain symptoms in COVID-19 disease may be stimulating factors for SpA flares but we found no effect of rheumatological therapies.

**DOES VACCINATION AND VARIANTS AFFECT THE COURSE OF THE COVID-19 IN INFLAMMATORY RHEUMATIC DISEASE?**

S. Celis1, M. E. Kutu1, B. Karadeniz2, M. Soy3, B. Barıkoy Dr Sadi Konuk Educational and Research Hospital, Rheumatology, İstanbul, Turkey; 1Atımbas University Medicine Faculty, Rheumatology, İstanbul, Turkey

### Background:
Although there have been expansion of knowledge about the course of COVID-19 in rheumatologic diseases, it still remains unclear the effect of vaccination status and variants on the disease course.

### Objectives:
We aimed to investigate the general clinical characteristics of our patients with inflammatory rheumatic disease (IRD) who had COVID-19 disease, their vaccination status and the time periods in which different variants were dominant during the disease.

### Methods:
During the routine follow-up of our patient’s with IRD, whether the patients had COVID-19 disease, when they were vaccinated (Pfizer/Biontech or Sinovac in our Country) and main clinical characteristics and their comorbid diseases were recorded. The last patient was included in the study on January 25, 2022. They were divided into those who received insufficient or no vaccine and those who received a full dose of vaccine. The patients were divided into 3 groups according to the period they had the disease: Those who had the disease between March 2020 and June 2021, accepted as “1st period patients”; the period when the Alpha and Beta variants, the initial forms of the disease, were dominant variants in populations; those who had the disease between July 2021 and December 2021, when the Delta variant dominated the World and in our country accepted as “2nd period patients”; and those who had the disease in December 2021 and later, when the Omicron variant was dominant throughout the world and in our country, was accepted as “3rd period” patients.

### Results:
Total 463 (294 woman) IRD patients enrolled to the study. Distribution of these patients included Behçet’s syndrome-15; familial Mediterranean fever-57, rheumatoid arthritis-134, Sjögren’s syndrome-24, systemic lupus erythematosus-28, Spondyloarthritides-141, necrotising vasculitis-6 and Others-50 cases. Mean age of patients were 46±13.2 (18-83) years. 354 (77%) of our patients got sick in the 1st period, 80 (17%) in the 2nd period and 28 (6%) in the 3rd period. When patients were compared in terms of their clinical complaints in these periods, dyspea was significantly higher in patients in the 1st period (1st period 36% vs 3rd period 18%; p<0.039), but there was no difference between other complaints including lung involvement and the frequency of hospitalization (p>0.05). 53% of patients had received at least 2 doses of mRNA vaccine. 84% of the patient had had COVID19 before full vaccination with any valid vaccine. When the patients who were full vaccinated and those who were not vaccinated were compared in terms of clinical features, lung involvement frequency and hospitalization frequency, no difference was found between them (p>0.05, for all). However, hospitalization and lung involvement were less in those who received a booster dose of any valid vaccine (p:0.03). While the average hospitalization rate was 17% for all groups, this rate was 50% for necrotizing vasculitis and was significantly higher (p<0.005).

### Conclusion:
Consistent with research on female sexuality during the pandemic among healthy women, we found that patients with rheumatic conditions reported lower FSI values in 2021, in comparison to 2019. Our finding that the pandemic had less impact on the patient group than a healthy control group, is consistent with research on MS and IBD patients, who showed surprising resilience in the face of the Covid-19 pandemic.

**SEXUALITY, FAMILY PLANNING AND MENTAL HEALTH AMONG REPRODUCTIVE-AGE WOMEN WITH RHEUMATIC DISEASE DURING THE COVID-19 PANDEMIC**

A. Pucher1, N. Rosenberg1,2, V. Ritsch1, T. Stamm1, P. Mandl1, D. Aletaha1, K. Rosta1, 1Medical University of Vienna, Rheumatology, Wien, Austria; 2Medical University of Vienna, Obstetrics and Gynecology, Wien, Austria; 3Medical University of Vienna, Section for Outcomes Research CeMSIS - Center for Medical Statistics, Informatics, and Intelligent Systems, Wien, Austria

### Background:
Women with rheumatic disease are more likely to suffer from sexual dysfunction, infertility, depression, and anxiety. The pandemic may have affected these constraints.

### Objectives:
To investigate the effect of the Covid-19 pandemic on sexuality, family planning and mental health in a sample of women with rheumatic disease.

### Methods:
Women aged 18-50 with a rheumatic disease and women in an age-matched healthy control group received questionnaires featuring: 1) demographic information, sexual frequency, family planning; 2) the Female Sexual Function Index (FSFI); 3) the Depression, Anxiety and Stress Scale (DASS-21); and 4) the Coronavirus Anxiety Scale (CAS). Recruitment took place 3/21-12/21. Patients with rheumatic conditions were recruited at the Vienna University Clinic (AKH) and the control group through social media. Parameters were compared between the patients and the healthy control group, and with data on sexuality from women with rheumatic disease from 2019.

### Results:
A preliminary analysis was conducted with 83 patients with rheumatic disease and 124 healthy controls. The rheumatic disease group exhibited lower levels of stress (6.46 vs. 8.36 p<0.01) and Coronavirus Anxiety (6.27 vs 7.50 p<0.01) than the control group and was less likely to report that the pandemic led to a reduction of their sexual frequency (p<0.01). The control group cited “stress” frequently the decrease of sexual frequency. The FSFI analysis revealed that patients with rheumatic disease experienced higher levels of pain (p<0.001) during sex than the control group but were more satisfied with their relationships (p<0.05). In comparison to 58 patients with rheumatic conditions, whose data was collected in 2019, the 2021 cohort reported reduced FSFI values in the domains of desire (p<0.01), arousal (p<0.05), lubrication (p<0.05), and orgasms (p<0.01).

### Conclusion:
Consistent with research on female sexuality during the pandemic among healthy women, we found that patients with rheumatic conditions reported lower FSI values in 2021, in comparison to 2019. Our finding that the pandemic had less impact on the patient group than a healthy control group, is consistent with research on MS and IBD patients, who showed surprising resilience in the face of the Covid-19 pandemic.

**CLINICAL CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO UNDERWENT COVID-19 IN THE REPUBLIC OF TATARSTAN**

**N. Shamsutdinova**1, S. Lapshina1, V. Mukhamadeeva1, A. Sagitova1, A. Zakirov1, L. Krasnova1, D. Abdulginariev1, R. Adbrakpov2, B. Sukhorukova3, Kazan State Medical University Hospital, Therapy, Kazan, Russian Federation; 2Kazan State Medical University, Student, Kazan, Russian Federation; 3Kazan State Medical University, student, Kazan, Russian Federation; 4Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation

**Background:** The management of patients with rheumatoid arthritis (RA) and novel coronavirus infection (NCI) is a significant problem due to the insufficient evidence base on this topic.

**Objectives:** To study the features of the transferred NCI in patients with RA and its influence on the course of RA.

**Methods:** From March 2020 to January 2022, 105 patients with RA who underwent NCI with a confirmed SarsCoV2 PCR result and/or X-ray computed tomography (CT) of the lungs were followed up. The age of the patients was 62 [55; 68] years, among them females - 84.7% (89 patients). The duration of RA at the time of NCI was 11 [6.5; 173] years. RA activity before NCI was low in 14 (13.3%) patients, moderate in 70 (66.6%), and high in 21 (20%) patients. The results of clinical and laboratory examinations were evaluated during the COVID-19, 1 and 3 months after it.

**Results:** The symptoms of NCI in patients with RA were comparable in frequency and severity to the course of infection in the population. 30 (28.6%) patients had a mild course of COVID-19, 74 (70.5%) had a moderate course, and 1 had a severe course. Bilateral polyelemal pneumonia was detected in 7 (6.6%) patients. The outcome of COVID-19 in all patients is recovery. Analysis of the course of RA showed a significant increase in activity 1 and 3 months after NCI: DAS28 from baseline to COVID-19 3.59±1.13 to 4.87±1.27 points after 3 months, respectively. Of the total number of recovered patients, 38.0% of patients showed an increase in activity due to clinical and laboratory parameters. 90.4% of patients noted the persistence or appearance of symptoms after undergoing NCI for 3 months, 45.7% had a combination of more than 3 different symptoms. The most common manifestations of asthma in the form of a decrease in the quality of life (QOL) and working capacity. 90.4% of patients: significant in 58.0% of people, insignificant in 32.4% of people. There was no significant correlation between RA activity and NCI severity. The second most frequent was the increase/appearance of pain in the joints - in 86.6% of respondents: significant in 72.3%, insignificant - 14.2%. Strengthening/appearance of muscle pain and/or headache and/or dysautonomia occurred in 44.7%. Appearance/intensification of shortness of breath and a decrease in exercise tolerance were noted by 36.1% of respondents: significant in 19.0% of people, insignificant in 17.1% of people. Among them, 64.8% (24) people with moderate severity, 35.2% (13) people with asymptomatic or mild NCI. Appearance/intensification of chest pain and/or palpitations was noted by 44.7% of people.

**Conclusion:** The prevalence and course of COVID-19 in patients with RA did not differ from that in the general population. However, coronavirus infection has led to an increase in pain and an increase in RA activity, a long-term persistence of post-COVID manifestations in the form of musculoskeletal pain and asthenic symptoms with a deterioration in the quality of life. There was no significant correlation between RA activity and NCI severity. At the same time, specific respiratory symptoms occurred only in a third of patients.

**COVID-19 HAD DISPROPORTIONATE IMPACTS ON RA SYMPTOMS AND FUNCTION BY AGE AND SEX: RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT (CATCH)**

S. J. Bartlett1, O. Scheier1, M. F. Valois2, D. Tim3, E. Keystone4, L. Bessette5, J. Pope6, G. Boire6, G. Hazlewood6, C. Hitchon7, C. Thorne8, V. Bykerve9, on behalf of on behalf of CATCH Investigators. McGill University & McGill University Health Centre, Clinical Epidemiology & Rheumatology, Montreal, Canada; McGill University, Clinical Epidemiology, Montreal, Canada; 2The Arthritis Program Research Group, Rheumatology, Newmarket, Canada; 3RheumKey, Rheumatology, Toronto, Canada; 4University of Laval, Rheumatology, Quebec City, Canada; 5Western University, Rheumatology, London, Canada; 6University of Sherbrooke, Rheumatology, Sherbrooke, Canada; 7University of Calgary, Rheumatology, Calgary, Canada; 8University of Manitoba, Rheumatology, Winnipeg, Canada; 9Hospital for Special Surgery, Rheumatology, New York, United States of America

**Background:** During the COVID-19 pandemic, Canadians with RA faced considerable uncertainty due to greater risk of infection, hospitalization, changing access to RA medications, and very limited access to in-person RA care. Further, to reduce transmission of the virus and COVID-related hospitalizations, stringent mitigation measures were implemented across the country to greatly reduce social contacts including curfews, limits on private gatherings and business closures. Little is known about the impact of the COVID-19 pandemic and associated mitigation efforts in RA. We hypothesized that women and younger adults with RA would report greater impairments in HRQL.

**Objectives:** To compare changes in HRQL prior-to and during the COVID-19 pandemic by sex and age groups in real-world RA patients seen in routine practice settings.

**Methods:** Data were from patients in the Canadian Early Arthritis Cohort (CATCH) who completed a study visit in the year prior to the COVID-19 pandemic (Mar 2019 through Feb 2020) and a repeat assessment during the pandemic (Mar 2020 onward). RA disease activity was assessed using the RA Flare Questionnaire, a validated patient-reported measure of current RA disease symptoms (pain, stiffness, fatigue) and function (physical, participation). An RA-FQ score ≥ 20 was used to classify RA symptoms consistent with an RA inflammatory flare. HRQL was assessed using PROMIS-29 Adult Profiles. We compared changes in mean Physical (PHS) and Mental Health (MHS) scores, and the proportion of patients with impairments in each domain (i.e., scores ≥ 5 for poor functioning, fatigue, sleep and ≥ 45 for physical function and participation) before and during the COVID-19 pandemic across sex and age groups (<40, 40-64, ≥65 years).

**Results:** The 938 CATCH participants in the analytic sample with data available at both time periods had a mean (SD) age of 60 (13) and RA symptom duration of 5.8 (3.7) years. 72% were women, 88% were white, and 64% reported > high school education. Most (80%) were in CDAI REM/LDA at the most recent visit prior to start of pandemic. The proportion of patients with RA-FQ ≥20 were similar across both time periods. While physical and emotional RA symptom impacts
remained stable in men prior to and during the COVID-19 pandemic, women reported significant increases in anxiety and depression during the pandemic period. Younger RA patients (<40 reported increases in depression, and older RA patients (>65) reported increases in anxiety and greater impacts on participation.

Conclusion: Our results illustrate that while the proportions of patients with high inflammatory disease activity were similar prior to and during the COVID-19 pandemic, we observed disproportionate impacts on HRQL by sex and age with a higher proportion of women, adults <40, and those >65 years of age experiencing greater impairments in several HRQL domains.

Conclusion: Our data show that post-vaccine newly diagnosed IMID may represent a challenge in clinical practice and it seems that no demographic or clinical feature is able to predict their onset. A multidisciplinary cooperation and registry data are needed in order to reliably estimate and define the impact of SARS-CoV2 vaccinations on new onset IMID.

Disclosure of Interests: None declared

CCL4 from M2 macrophages was observed when compared to control (p<0.05) (Figure 1C). In the transcriptomes from 3 AOSD patients (2 mild and 1 severe), 2 COVID-19 patients (1 mild and 1 ICU) and 2 HDs, we observed that genes involved in inflammation, lipid catabolism and monocytes activation were specifically dysregulated in AOSD and COVID-19 patients when compared to HDs. Among them pla2g15, pla2g12a, pla2g2d, involved in mobilization of SPMs precursors, were significant upregulated in patients compared to HDs (p<.01, log2FoldChange≥1.2) (Figure 1D). The largest part of the genes involved in inflammation, lipid catabolism, and monocytes activation are less expressed in AOSD patients when compared to COVID19 patients, as presented in Table 1.

**Conclusion:** The counterbalance by SPMs during inflammation is still a largely unexplored pathway. Our study suggests that an imbalance of SPMs in autoimmune-inflammatory diseases as well as COVID-19. The modulation of SPMs as observed in our experiments, might represent a new possible therapeutic strategy during COVID-19.

**DOI:** 10.1136/annrheumdis-2022-eular.5053
Methods: Observational study, using a patient survey. Adult patients attending the rheumatology outpatient clinic between Nov 2, 2020 to Feb 13, 2021, with rheumatoid arthritis (RA), psoriatic arthritis (PsA), spondyloarthritis (SpA) or systemic autoimmune diseases (SAD), with at least 1 year from diagnosis and 1 month of treatment with conventional synthetic (cs) targeted synthetic (ts) or biological (b) disease modifying antirheumatic drugs (DMARD). Face to face or phone interviews were conducted using an ad hoc designed questionnaire that included COVID19 related questions, the 11 IEXPAC scale items (5 point Likert scale ranging from never to always) (www.iexpac.org), and 4 items (5 points, very good to very bad) of the global scale PROMIS 10 (Patient-Reported Outcomes PROM) . All questions refer to the patient’s experience during the 6 months prior to data collection.

Results: From 174 screening patients, 158 completed the survey, mainly woman (66.5%) with a median age of 60 (IQR 47-69) years. The most frequent diagnosis was RA (43%) followed by ESAP (35%), EAS (22%) and PsA (13%). 46.8% of the patients have been prescribed b or ts DMARD and 53.2% sc DMARD, 32.9% in combination. From 158, 39 persons requested healthcare for COVID-19 related symptoms and diagnosis was confirmed in 17 (10,8%). Just 2 patients required hospital admission. Clinical control and continuity of care for COVID19+ patients were carried out from their primary care center and by phone consultation. Some key results of the survey are displayed in Table 1.

**Accessiblity to care and medications**

- I could contact my rheumatologist whenever I needed (email, phone). **Always (73.9)**
- My rheumatologist changed my face-to-face visit for a phone call. **Yes (53)**
- I received my medication at home from the hospital pharmacy. **Yes (16)**
- I maintained the prescribed dose medication… **Yes (21)**
- At some point I modify a medication by my own decision **Yes (6)**
- Your satisfaction with the care provided from all professionals in the team was **Yes (7)**
- PREMS (IEXPAC) **Very + Quite satisfied (75)**
- Item 2. The professionals … are coordinated to offer me good healthcare **Always (34,18)**
- Item 8. They make sure that I take my medication correctly **Always (73,42)**
- Item 9. They worry about my welfare **Always (74,68)**

Conclusion: Lessons have been learned during the COVID19 lockdown and restrictions by assessing patients’ health status and patients-reported experience. Coordinated NPI such as medication monitoring and home delivery, appointment reorganization and protocolized phone visits can result in a good patient perception and medication adherence whilst receiving care in a challenging situation.

DURING COVID-19 PANDEMIA IN ITALIAN PATIENTS WITH DERMATOMYOSITIS AUTOIMMUNITY PROFILE AND LUNG INVOLVEMENT

Background: Dermatomyositis (DM) is a rare idiopathic inflammatory myopathy that can present with a variable spectrum of cutaneous and systemic manifestations. The prevalence of myositis-specific autoantibodies (MSAs) and disease phenotype have been documented in DM in particular in association with the development of interstitial lung disease (ILD). Ongoing studies focus on the potential role of MSAs in similarities of the pathophysiological mechanisms of COVID-19 associated ILD and that related to DM suggesting an intriguing cross talk between autoimmunity and COVID-19. Our preliminary findings support the relevant impact of lung involvement in DM. The availability of MSAs can help to stratify patients with the disease phenotype have been documented in DM in particular in association with the development of interstitial lung disease (ILD). Ongoing studies focus on the potential role of MSAs in similarities of the pathophysiological mechanisms of COVID-19 associated ILD and that related to DM suggesting an intriguing cross talk between autoimmunity and COVID-19.

Objectives: To explore clinical patterns including ILD and MSAs profile in DM patients from a population-based single-center study carried out in a Tertiary Referral Rheumatologic Clinic, SARS-CoV-2 infections and vaccination were also analysed.

Methods: We enrolled patients affected by DM classified according to 2017 EULAR/ACR criteria with a disease onset at ≥18 years referring to the Tertiary Referral Rheumatologic Clinic in Tor Vergata University Hospital in Rome (Italy). Clinical data were collected from medical records: gender, age of onset of symptoms and diagnosis, clinical features, auto-antibodies patterns (ANA, MSAs including anti-IRMA synthetase, Jo1, PL7, EJ, MDA5, NXP2, SAE, M2, and myositis-associated antibodies comprising anti-PM/ScI, Ro-52, Ku, U1RNP), pattern of lung abnormalities at thoracic CT scans, and treatments. The prevalence of SARS-CoV-2 infection and vaccination profile were also investigated.

Results: Among eligible cases (n=30), patients who completed the study (n=19) included almost entirely women (F=73.7%). The median age at disease onset was 57.4±12.4 yrs while the mean diagnostic delay resulted as 12±10 months. Skin manifestations and myalgia were the prevalent symptoms (79% and 63%, respectively) whereas dyspnea and cough occurred in a third of the cohort at DM onset. Besides the skin involvement, the decrease in pulmonary function was the main clinical manifestation at the first rheumatological referral (52.6% of cases) followed by joint pain (36.8%) and cardiovascular events (10.6%). ANA titer≥1:160 occurred in 79% of patients. All patients showed MSAs positivity with a similar distribution: a single case of double positivity was registered in a man with anti-MDA5 and -NXP2. The most common CT findings were ground-glass opacity and parenchymal band in a third of patients (32%). The entire cohort had undergone cycles of steroids from the onset of DM and during the follow-up, according to disease severity. The main used therapies were methotrexate (47%), intravenous immunoglobulin (42%) and mofetil micofenolate (31.6%). None of patients had SARS-CoV-2 infection (until December 2021). The 63% of the cohort received at least one dose of the anti- SARS-CoV-2 mRNA vaccine (BNT162b2), of which 10% had completed with the booster dose. No adverse reactions or post-vaccination DM flare were registered. A third of the cohort had not been vaccinated due to concomitant disease activity or therapies. No cases of post-COVID-19 new-onset DM were diagnosed.

Conclusion: Our preliminary findings support the relevant impact of lung involvement in DM. The availability of MSAs can help to stratify patients with acute pericarditis and its association with SAD. We must not forget the middle of the COVID pandemic, in addition to considering COVID19 or its most associated with this clinical manifestation (RA and SLE). Therefore, in pericarditis was related to SAD, in particular with the rheumatic pathologies infected, the time interval until the development of pericarditis was too long since vaccination was later in vaccinated patients, and in those who had been against COVID was initially considered, but it could not be demonstrated, since vaccination was later in vaccinated patients, and in those who had been infected, the time interval until the development of pericarditis was too long for it in order to be attributed to COVID19. Finally, in 5 of the 8 patients, pericarditis was related to SAD, in particular with the rheumatic pathologies most associated with this clinical manifestation (RA and SLE). Therefore, in the middle of the COVID pandemic, in addition to considering COVID19 or its vaccine in the differential diagnosis of acute pericarditis, we must not forget to include SAD in this diagnosis.

SARS-COV-2 VACCINATION WILLINGNESS AND PREDICTORS IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES (CIRD) AND WITHOUT CIRD
I. Andreica1, I. Roman1, X. Baraliakos1, U. Kiltz1, J. Braun1, 1Rheumazentrum Ruhrgebiet, Ruhr-University, Rheumatology, Herne, Germany

Background: Recent surveys in chronic inflammatory rheumatic diseases (CIRD) showed a high degree of vaccine hesitancy. Current knowledge about patients’ attitudes towards vaccination against SARS-CoV-2 is limited.

Objectives: To assess the willingness of CIRD patients to be vaccinated against SARS-CoV-2 and to identify influencing factors compared to non-CIRD patients.

Methods: In this cross-sectional study, two cohorts of consecutively in parallel recruited patients with and without CIRD presenting to our tertiary hospital answered questions of a structured interview to assess vaccination willingness to SARS-CoV-2, experience with SARS-CoV2 in their environment and their personal history of infections and vaccinations. Vaccination willingness was assessed by a numerical rating scale (0: fully disagree; 10: fully agree). Arbitrarily defined cut-offs were used to define definite (score ≥7) and probable willingness (scores of 5 or 6) to be vaccinated. Statistical analyses were performed with appropriate tests such as Kendall-tau b.

Results: A total of 514 CIRD and 100 non-CIRD patients, mean age 54.7±12.8 and 55.6±9.8 years, were included. Definite and probable willingness to be vaccinated against SARS-CoV-2 was declared by 79.6% and 90.7% vs. 76.0% and 85.0% of CIRD and non-CIRD patients, respectively. Only 60% of CIRD patients believed that the vaccines against SARS-CoV-2 were safe, and 42% indicated to be afraid of side effects. Vaccination willingness correlated significantly with the degree of education, age, identification with a risk group for COVID-19 disease, hypertension, and the degree of information about preventable diseases. There was no correlation with the history of infections or with immunosuppressive therapy.

Conclusion: Although our results show a high willingness for vaccination against SARS-CoV-2 in both groups, there was quite some uncertainty regarding the safety and efficacy of the vaccines. Since major influencing factors were education and information about SARS-CoV-2 and COVID-19, patient education should be immediately improved.

THE RISK OF FLARE UP FOLLOWING NSARS-COV2 VACCINE IN INFLAMMATORY ARTHRITIS
F. Frizzera1, F. Pettorossi1, P. De Sandre1, G. Scannel1, A. Hoxha1, 1San Bortolo Hospital, Internal Medicine Unit, Department of Medicine, Vicenza, Italy

Background: As autoimmune phenomena following anti-nSARS-CoV2 vaccine was reported in the healthy population, there is increasing concern in patients with inflammatory joint diseases regarding possible side effects and disease flare-ups.

Objectives: We set out to evaluate the possible risk of disease exacerbation and the predisposing risk factors for the flare up.

Methods: This is a single center prospective cohort study, enrolling patients attending Arthritis Clinic at San Bortolo Hospital, during a follow-up of 12 months. All patients, after obtaining informed consent, answered a 24-item questionnaire including information about nSARS-CoV2 infection, vaccination, disease activity, ongoing treatment, vaccine side effects, disease flare up and need to change therapy.

Results: A total of 109 patients, 60 (55.1%) females and 49 (44.9%) males with a mean age of 60.1 years ±12.6 SD were enrolled. Forty-three (39.5%) were affected by rheumatoid arthritis, 43 (39.5%) from psoriatic arthritis and 23 from ankylosing spondylitis. There were 19 (17.43%) nSARS-CoV2 infection, of them 3 (15.8%) need hospitalization. Ninety-five (87.2%) receive at least one shot of nSARS-CoV2 vaccine, of these 78 (82.1%) got three shots of vaccine. Vaccine-related side effects were reported in 36 (37.9%), of these 15 (41.7%) have fever, 14 (38.8%) arthralgia and 29 (80.5%) fatigue. No patients required

Table 1. Patient demographics, disease characteristics and infection history

| Age (years), mean (SD) | 54.7 ± 12.8 | 55.6 ± 9.8 | 0 | 0 |
| Therapys, (%) | 316 (81.5) | 35 (40.2) | 5 (6) | 5 (5) | 0.79 |
| History of a positive SARS-CoV-2 | 22 (4.3) | 5 (5.0) | 3 (0.6) | 5 (5) |
| History of severe infection No. (%) | 54 (10.5) | 16 (16.0) | 1 (0.2) | 0.12 |

| low (< 8 years) | 275 (57.4) | 21 (21.6) | 0.13 |
| moderate (8 to 12 years) | 154 (32.2) | 0.13 |

BMI body mass index, SD standard deviation, no number, DMRD Disease Modifying Anti-Rheumatic Drugs, b biological, ts targeted synthetic, cs conventional synthetic
medication. Twenty (21.05%) of patients who receive at least one vaccine shot experienced a flare up. Nine (45%) need to change therapy. The risk of flare up was significantly associated with low disease activity/active disease in the last 12 months. p<0.009; OR 4.0; 95% CI: 1.5-11.3.

Conclusion: Overall, the nSARS-CoV2 vaccine is well tolerated in patients with inflammatory arthritis. The risk of disease flare is associated with active disease within the past 12 months. According to our results, the patients affected by inflammatory arthritis in sustained remission have no reason to hesitate to get the nSARS-CoV2 vaccination.

**AB1190** SOURCES OF INFORMATION ABOUT SARS-COV-2 USED BY PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES (CIRD)

I. Andreica1, I. Roman1, X. Baraliakos1, U. Kiltz1, J. Braun1, 1Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Rheumatology, Herne, Germany

Background: Patients with chronic inflammatory rheumatic diseases (CIRD) may be at increased risk of Corona Virus Disease 2019 (COVID-19). 2 The quality of information obtained plays a crucial role for patients’ decision to be vaccinated. Knowing patients’ needs for information and which sources are used is important for the management of CIRD patients by rheumatologists and other physicians.

Objectives: To identify main sources of information on SARS-CoV-2 used by patients with CIRD and to analyze their influence on opinions and willingness to be vaccinated.

Methods: CIRD patients presenting to our tertiary rheumatology hospital were, after informed consent, consecutively included in the study once the vaccination campaign in Germany had started, to fill out a questionnaire. Next to sociodemographic and disease-specific data, vaccination willingness and knowledge regarding SARS-CoV-2 were assessed. Furthermore, patients’ sources of information and their concerns about accuracy of information were evaluated. A numerical rating scale (NRS) ranging from 0 (completely disagree) to 10 (completely agree) was used. Values between ≥7 were taken as positive answer.

Nonparametric tests and multivariate linear regression analyses were performed.

Results: In early 2021, a total of 514 patients were interviewed (Table 1). The majority (63.9 %) reported to be well-informed (NRS ≥7), whereas 18% had doubts regarding information on SARS-CoV-2. The most often used source of information was television, and only 8.6% reported to have been informed by a rheumatologist (Figure 1). About 20% of patients were no longer interested in receiving any information on SARS-CoV-2 through media. Information from rheumatologists, general practitioners, public health authorities or health related web sites did not reach 30.5% of patients. Of interest, 16% of subjectively well-informed patients were hesitant towards vaccination. As many as 43.6% of patients with doubts regarding information about SARS-CoV-2 were assessed. Furthermore, patients’ sources of information and their concerns about accuracy of information were evaluated. A numerical rating scale (NRS) ranging from 0 (completely disagree) to 10 (completely agree) was used. Values between ≥7 were taken as positive answer.

Nonparametric tests and multivariate linear regression analyses were performed.

**AB1191** SAFETY PROFILE OF COVID VACCINES IN ARTHRITIS PATIENTS. A TWO-CENTERS STUDY.

V. Relia1, G. Busti1, C. Rotondo1, M. Fornaro2, R. Colla1, A. Corrado1, F. Iannone3, F. P. Cantatore1, 1Ospedali Riuniti di Foggia, Rheumatology Unit, Department of Medical and Surgical Sciences, Foggia, Italy; 2Polinomico, Bari, Rheumatology Unit, Department of Emergency and Organ Transplantations, Bari, Italy

Background: Coronavirus 19 disease (COVID-19) represents the most important pandemic of the last century. Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) infection has produced more than 170 million cases and more than 3 million deaths. Due to the easy spread of the infection and the possibility of serious clinical manifestations, the role of anti-COVID 19 vaccination is essential. Vaccines with different mechanisms of action have been developed: mRNA-based, such as Biontech-Pfizer and Moderna, and viral vectored, such as AstraZeneca and Janssen. Despite possible adverse events, benefits afforded by these vaccines significantly outweigh potential risks associated with their administration in the general population.

Objectives: This study aimed to evaluate incidence and severity of adverse events (AEs), secondary to vaccination, in patients with Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Spondyloarthritis (SpA), immune-mediated diseases treated with immunomodulating drugs, by administering a questionnaire.

Methods: 294 patients (201 f and 93 m) were enrolled with a diagnosis of arthri- tis (RA 28%, PsA 43%, SpA 28%).

Results: Of the 294 enrolled patients, 107 underwent COVID vaccination, 73% with Biontech-Pfizer vaccine, 20% Astrazeneca and 6% Moderna. 50% of patients completed the entire vaccination cycle. 46% of patients presented AEs after the first dose of vaccine (45% of vaccinated with Biontech-Pfizer; 48% of vaccinated with Astrazeneca, 33% of vaccinated with Moderna). The most frequently observed AEs are: pain at the injection site (17%), fever (13%), headache (12%), myalgia (12%), fatigue (7.5%). Only 2.9% of patients had arthritis flares. The greatest trend of AEs was observed in patients with PsA (48%), and RA (26%). 32% of patients receiving the second dose of vaccine presented AEs (40% Moderna, 32% Biontech-Pfizer). The most frequently observed AEs after the second dose are: pain at the injection site (4.7%), fever (9%), headache (2.8%), myalgia (6%). No patient had arthritis flare after the second dose. The greatest trend of AEs was observed in patients with SpA (66%). Only 11% of patients presented AEs after the administration of both doses. Thirteen percent of patients did not follow the clinician’s recommendations for immunomodulatory drug management, provided as per ACR or SIR recommendations.

Conclusion: The incidence of adverse events in arthritis patients was in line with that of the general population, without presenting serious manifestations, such as thrombosis, and without indicating a preference on the type of vaccine.

SARS-CoV-2 VACCINE IN SPONDYLOARTHROSIS PATIENTS: OVERALL MODERATE/ HIGH IMMUNOGENICITY IMPAIRED BY IMMUNOSUPPRESSANTS AND BIOLOGICAL THERAPY
C. Saad,1 M. Rodrigues Silva,2 P. Degrava Sampaio-Barros,2 J. Moraes,2 C. Goldenstein-Schainberg,2 N. Aikawa,2 E. Neves,2 S. Pasoto,2 T. Pedrosa,2 R. Kenji Aoyama,2 C. Scognamiglio Renner Araujo,2 C. Silva,2 A. C. Medeiros Ribiero,2 E. Bonta,2 Faculdade de Medicina da Universidade de São Paulo, Rheumatology, São Paulo, Brazil;2 Faculdade de Medicina da Universidade de São Paulo, Rheumatology, São Paulo, Brazil;2 Faculdade de Medicina da Universidade de São Paulo, Infectious Diseases, São Paulo, Brazil

Background: We recently reported an attenuate immunogenicity in patients with autoimmune rheumatic diseases. However, the effect of spondyloarthritis (SpA) and its treatment on COVID-19 vaccine immunogenicity remains to be determined for this group of patients. We therefore aimed to evaluate humoral immune responses to inactivated SARS-CoV-2 vaccine (CoronaVac) in patients with SpA (axial spondyloarthritis and spondyloarthritis) taking DMARDs and commonly used targeted biological therapies, compared with a control group(CG).

Objectives: Evaluate immunogenicity and safety of CORONAVAC (Sinovac, Beijing) in Spondyloarthritis (SpA) patients.

Methods: Prospective observational cohort patients diagnosed with 194 SpA and 183 CG were vaccinated with CoronaVac in two doses with a 28-days interval. 194 patients completed the study and could be paired with CG with immunogenicity analysis. Blood samples were collected in the days 0, 28 and 69 (D69) to evaluate anti-SARS-CoV-2-IgG seroconversion(SC) and presence of neutralizing antibodies (NAb) in participants with negative IgG and NAb at baseline.

Results: Patients and GC were comparable regarding age (p=0.93) and sex (p=100). Immunogenicity at D69 showed a moderate/high SC (80.2% vs 95.7%, p<0.0001) and Nab positivity (61.6% vs 82.7%, p=0.0001) in SpA but lower than CG. Factors associated with lower immunogenicity were older age (66.8 vs. 51.4;p=0.03318) and higher frequencies of prednisone (25.7% vs. 4.2%; p=0.0004), methotrexate (51.4% vs 40.1%, p=0.0016) and TNF inhibitor (TNFi) (62.9% vs 34.5%, p=0.0035). Likewise, prednisone (176% vs. 2.8%, p=0.0013) and TNFi (50% vs 33.9%; p=0.0048) were associated with diminished NAb positivity. Sulfasalazine was associated with higher SC rates (8.6% vs 26.8%, p=0.0246) and NAB positivity (13.2% vs 29.4%, p=0.0168). The multivariate analysis revealed that older age (p=0.037), prednisone (p=0.001), TNFi (p=0.016), and methotrexate (p=0.017) were independently associated with lower SC while prednisone (p=0.006) and TNFi (p=0.027) were also associated with reduced NAb response.

Conclusion: Our finding of an excellent safety and moderate/high SC rate in SpA supports the recommendation of CoronaVac vaccination. The impaired immune response in the minority of patients under immunosuppressive and biological therapy requires novel strategies to enhance antibody response in this subgroup of patients.

AB1193
THE COURSE OF COVID-19 INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING VARIOUS BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS
R. Samiuqina,1 A. Dadalova,1 E. Vasilenko,1 V. Mazurov,1 North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care Named After E.E. Eichwald, St. Petersburg, Russian Federation

Background: With the ongoing COVID-19 pandemic, the safety of biologic disease-modifying antirheumatic drugs in patients with rheumatic disease remains an important issue.

Objectives: to assess the course of COVID-19 infection in patients with rheumatic diseases who were under observation at the North-Western State Medical University. I.I. Mechnikov in the period from March 2020 to November 2021. During this period, 198 (14.04%) cases of COVID-19 were registered out of 1389 patients included in the registries of the anticytokine therapy center. Among patients with rheumatoid arthritis who recovered from COVID-19 infection, 105 cases were registered, of which 53 patients received outpatient treatment, and 52 patients received inpatient treatment. In 76% of cases, patients received biological DMARDs in combination with synthetic DMARDs.

Results: Exacerbation of the articular syndrome was observed only in 12 (11.4%) patients with RA during COVID-19. The low percentage of exacerbations in patients with RD on the background of COVID-19 was probably associated with the use of dexamethasone at a dose of 16-32 mg, which has the ability to reduce the activity of the immune-inflammatory process in rheumatic diseases. This statement is confirmed by the fact that out of 52 patients with RA who were hospitalized for COVID-19, 16 patients (30.8%) received dexamethasone intramuscularly or intravenously, and 8 patients (15.4%) continued oral administration of this drug.

Table 1. The course of COVID-19 infection in RA patients treated with various biological DMARDs.

</table>

Conclusion: The use of rituximab was associated with a more severe course of COVID-19, which required hospitalization in 66% of cases, compared with the group of patients treated with TNF-α inhibitors, in which hospital treatment was carried out only in 20% of cases. The introduction of blockers of co-stimulation of T-cells, IL-6 inhibitors, targeted synthetic drugs did not affect the severity of COVID-19.

INFLUENCE OF NEUROPATHIC PAIN ON THE FUNCTIONAL STATUS OF ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

1Second City Hospital of the Ministry of Health of the Chuvash Republic, X-ray Department, Cheboksary, Russian Federation; 2N. N. Ulianov Chuvash State University, Department propedeutics of Internal Diseases, Cheboksary, Russian Federation; 3N. N. Ulianov Chuvash State University, Department of Normal and Pathological Physiology, Cheboksary, Russian Federation

Objectives: The aim of the study was to study the influence of neuropathic pain on functional status in elderly patients with rheumatoid arthritis (RA) with moderate disease activity.

Methods: Methods. The study included 115 geriatric patients who were divided into two groups. Group G1 included 80 patients (mean age 76.9 ± 9.6 years) with neuropathic pain, group G2 - 35 persons of comparable age (77.1 ± 8.6 years) without signs of neuropathic pain. Neuropathic pain was identified using the DN4 questionnaire. The RA activity in patients of both groups did not differ statistically significantly. All patients underwent a comprehensive geriatric assessment (CGA) to determine the functional status and diagnose geriatric syndromes [1]. All patients received basic anti-inflammatory drugs. Patients G1 and G2 were compared in terms of the following parameters, such as pain intensity according to a visual analogue scale (VAS, 0-100 mm), Rivermead Mobility Index (0-15), functional disorders according to International Classification of Function (ICF) (0-4), signs of anxiety and depression (HADS).

Results: According to the CGA data, senile asthenia syndrome was detected in 32 (40.2%) patients with neuropathic pain and in 10 (28.6%) patients without neuropathic pain (p = 0.035). The average number of geriatric syndromes in G1 was 6.06 ± 1.03, in group G2 - 4.5 ± 1.0 (p <0.05). Patients with G1 showed higher indices of pain severity according to VAS than in patients of the control group: 68.2 ± 10.1 and 52.1 ± 4.1 mm, respectively (p <0.001). In G1, patients had a significant decrease in mobility, in the domain «Activity and participation» in the ICF categories d450 (walking), d 540 (dressing), the indicator of dysfunction was 2.9 ± 0.3 versus 2.2 ± 0.2 (p = 0.049), there were more symptoms of anxiety and depression 56.5% and 35.2% (HADS ≥7; p <0.001), respectively.

Conclusion: Elderly patients with chronic neuropathic pain have higher signs of senile asthenia and decreased mobility and physical functioning in daily life. It is necessary to include the help of a psychologist and occupational therapist in planning the most effective comprehensive strategies for the treatment and prevention of exacerbations of neuropathic pain.

AB1197

ANTIDEPRESSANTS TREATMENT AND SEVERITY OF PAIN IN RHEUMATOID ARTHRITIS PATIENTS WITH ANXIETY AND DEPRESSIVE DISORDERS

A. Abramkin1, T. Lisitsyna2, V. Seravin3, O. Serov4, S. Glukhova5, E. Nasonov6,1, V.A. Nasonova Research Institute of Rheumatology, thromboinflammation, Moscow, Russian Federation; 2Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Stress Disorders, Moscow, Russian Federation

Background: Anxiety and depressive disorders (ADD) significantly affect disease activity and pain modulation in rheumatoid arthritis (RA) patients. Psychopharmacotherapy (PPT) of ADD attempts to improve RA disease activity and manage pain in RA patients.

Objectives: To determine factors associated with intensive pain syndrome in antidepressants-treated RA-patients at five years endpoint.

Methods: 128 RA-patients (pts) were enrolled, 86% were women with a mean age of 47.4±11.3 (MaSD) yrs. All patients met the full ACR/EULAR 2010 criteria for RA. Disease activity was assessed using DAS28, pain severity – using Brief Pain Inventory scale (BPI). Severe Pain was defined as BPI Worst Pain Score (BPImax) from 7 to 10. 69.4% RA-pts were already taking prednisone (9 [5; 10] mg/day (Me [25%; 75%])). 84.4% - cDMARDs, 78% - bDMARDs (anti-TNF-α – 6.3%, rituximab – 1.6%). Biologic treatment duration varied from 1 to 6 years, antidepressants – from 6 to 96 weeks. ADD were diagnosed by psychiatrist in 123 (96,1%) of RA-pts in accordance with ICD-10 in semi-structured interview. Severity of depression and anxiety was evaluated with Montgomery–Asberg Depression Rating Scale (MADRS) and Hamilton Anxiety Rating Scale (HAM-A).

Results: At five-years follow-up pain severity was assessed in 74 out of a total of 83 patient. By univariate logistic regression, baseline age, HAQ, CRP, DAS28 and BPImax, presence of extraarticular manifestations, cardiovascular diseases, cognitive impairments and schizotypal personality disorder, lower HADS for anxiety, no remission of anxiety or depression at five years and no history of glucocorticoids usage were significantly (p≤0.3) associated with severe pain at five-years follow-up (Table 1). These variables were subjected to multivariate stepwise logistic regression. Only extraarticular manifestations at baseline (OR 4.01 (95%CI 0.96 – 16.77), p=0.057), no history of glucocorticoids usage (OR 0.19 (95%CI 0.04 – 0.56), p=0.005) and nonremission of anxiety and depressive symptoms at 5-years (OR 0.11 (95%CI 0.019 – 0.668), p=0.016) were independently associated with severe pain at 5-years follow-up (R2=0.406, sensitivity 38.5%, specificity 92.7%).

AB1198 PREVALENCE AND PSYCHOPATHOLOGICAL CHARACTERISTICS OF ANXIETY AND DEPRESSIVE SYMPTOMS IN FIBROMYALGIA PATIENTS

V. Marino1, A. Pasca2, F. Galante3, M. Fabrazzo3, E. L. Di Caprio1, F. Riccio1, S. Fasano1, F. Ciccia1, R. Tirri1. 1University of Campania “Luigi Vanvitelli”, Naples, Italy; 2University of Campania “Luigi Vanvitelli”, Mental and Physical Health and Preventive Medicine, Naples, Italy

Background: Several studies reported higher depression and anxiety rates in fibromyalgia (FM) patients compared to the general population. Furthermore, dysfunctional coping strategies have been pointed to as intrinsic parts of the pathogenesis of FM.

Objectives: Our study aimed to verify the prevalence of anxiety and depressive symptoms and explore their correlation with physical symptoms as fatigue, sleep, and widespread pain in a cohort of patients diagnosed with FM. We also aimed to determine whether dysfunctional coping strategies might increase the depression and anxiety burden, besides worsening the core symptoms of FM.

Methods: We analyzed a cohort of 105 patients (median age of 53 years 6 M, 92 F) with a diagnosis of FM according to the ACR 2016 criteria. The participants were consecutively recruited from the Fibromyalgia clinic of the University of Campania “Luigi Vanvitelli”. All patients underwent a psychiatric evaluation. We assessed widespread pain by the Widespread Pain Index (WPI) and the presence of fatigue by the Symptom Severity score (SS). Sleep disorders were investigated through Pittsburgh Sleep Quality Index (PSQI). We analyzed mental alterations by Hamilton Depression and Anxiety Rating Scales (HAM-D, HAM-A), and coping strategies by Coping Orientation to Problems Experienced (COPE) Inventory. The Statistical Package for Social Sciences (SPSS) 22.0 was used; the level of significance was set at p < 0.05.

Results: All patients showed fatigue and widespread pain (100%); sleep disturbances were found in 90.5% of patients and overlapped with all sleep phases. The prevalence of anxiety associated with depression was 75.2%. We found isolated anxiety in 14.3% and isolated depression in 4.8% of patients. We further evidenced a different degree of depression: mild (50.7%), moderate (24.3%), and severe (6.5%). All patients showed depressed mood only if questioned (low tendency to spontaneous verbalization). COPE analysis showed no significant differences in the use of the three coping strategies (Problem-focused, emotion-focused, avoidance-focused). Pearson’s correlation analysis highlighted a negative relationship between problem-focused strategies and the severity of anxiety (r = -0.31, p = 0.001) and depression (r = -0.32, p = 0.001). Our analysis also highlighted a positive correlation between fatigue, sleep disturbances, widespread pain, and both anxiety and depression. The analysis of the characteristics of anxiety and depressive symptoms showed a scarce tendency to spontaneous verbalization of depressed mood and ideas of guilt, mostly limited to family relationships, and a sense of inefficaciousness conditioned by the physical symptoms of the disease. Most patients showed psychomotor agitation, psychic and somatic anxiety, poor insight. The analysis of coping strategies adopted showed a negative correlation between problem-focused strategies and anxiety-depressive symptoms, suggesting that such strategies are less frequent in FM patients with comorbid anxiety and depressive symptoms.

Conclusion: Our study confirms the high prevalence of anxiety and depressive symptoms in FM patients. A positive correlation between the pivotal symptoms and anxiety and depressive symptoms may suggest, without implying a cause-and-effect relationship, that psychiatric intervention should be considered along with rheumatologic treatment, to improve both physical symptoms and quality of life. Potentially problem-focused coping strategies may represent a target to improve anxiety and depressive symptoms.

AB1199 THE ROLE OF THORACOLUMBAR FASCIA ULTRASOUND IN LOW BACK PAIN - IMPLICATION FOR GUIDED DRY NEEDLING

R. Bubnov1, L. Kalikia1. 1Clinical Hospital 'Phoephania', Ultrasound, Kyiv, Ukraine; 2ulrikakalika@gmail.com, Rehab, New York, United States of America

Background: Dry needling under ultrasound guidance (DN-US) is a crucial therapeutic approach for myofascial pain [1], restore muscle function and motion [2], is among prioritized methods for treatment low back pain (LBP), can be effective in rheumatic diseases. The definition ‘myo-fascial’ calls for searching trigger points (TrPs) in fascia to improve the treatment effectiveness [3]. Ultrasound examination and guided dry needling can help understanding the role of the thoracolumbar fascia (TLF), its layers function and role in development of low back pain.

Objectives: Aim was to evaluate the relevance of fascial ultrasound and guided dry needling in low back pain in particular for thoracolumbar fascia (TLF).

Methods: We included 32 patients (20 females, 21-63 years old) with myofascial low back pain, postural imbalance and DN-US protocol according to R. Bubnov [1]: muscle TrPs were identified, fine (28G) steel needle DN-US was applied. Additionally considered fascial structures for detecting areas of abnormalities (hypo- and hyper-echoic lamina) to 2-4 mm after DN. We detected higher rates of motility, increased thickness of fascial layers (up to 5-10 mm), increased thickness of fascial structures and decreased thickness of TLF. All patients showed local sensitivity during needling, local twitch response was not seen. We placed needles to the affected area in TLF, increased thickness of fascia, decreased motility of TLF.

Conclusion: Fascia dry needling is accessible and effective method for myofascial low back pain treatment, can provide additional mechanical benefit and help to maintain treatment effect. Affected fascia can be considered as relevant TrPs, specific ultrasound signs should be validated.

AB1200 THE IMPACT OF THE PRESENCE OF FIBROMYALGIA ON ILLNESS PERCEPTIONS AND COPING STRATEGIES IN HIV INFECTED PATIENTS: PRELIMINARY STUDY

Y. Ulus1, O. Acar Cakan2, M. A. Karacasan3, A. Bilici4, A. Deveci4, H. C. Bliek5. 1Ondokuz Mayis University - Faculty of Medicine, Physical Medicine and Rehabilitation, Samsun, Turkey; 2Samsun State Hospital, Physical Medicine and Rehabilitation, Samsun, Turkey; 3Ondokuz Mayis University - Faculty of Medicine, Clinical Microbiology and Infectious Diseases, Samsun, Turkey

Background: Coexisting fibromyalgia syndrome (FMS) to the chronic diseases and its negative impact on global health status in these diseases has been identified. Recent treatment strategies have changed HIV from a terminal disease to a chronic condition that requires great effort because of regular treatment and periodic medical screenings. The prevalence of fibromyalgia has been reported in HIV patients as 1-17%. It was reported that greater illness perceptions are associated with dysfunctional coping strategies in HIV patients with detectable or high viral load. There are no data on illness perceptions and coping strategies in HIV patients with FMS.

Objectives: The aim of this study was to evaluate the impact of the presence of fibromyalgia on illness perceptions and coping strategies in HIV infected patients.

Methods: Data about illness perceptions by The Brief Illness Perception Questionnaire (Brief-IPQ) and coping strategies by the COPE questionnaire were collected from 79 HIV patients. FMS was determined according to 2010 ACR criteria. The Statistical Package for Social Sciences (SPSS) 22.0 was used; the level of significance was set at p < 0.05.

Results: All patients showed pain and increased rate of detectable viral load (84.9%) and asymptomatic patients as 1-17%. It was reported that greater illness perceptions are associated with dysfunctional coping strategies in HIV patients. A positive correlation between fibromyalgia and illness perceptions (r = 0.32, p = 0.01) and coping strategies (r = 0.28, p = 0.04) was also highlighted. Our analysis also highlighted a positive correlation between fatigue, sleep disturbances, and illness perceptions.

Conclusion: Fibromyalgia can be considered as relevant TrPs, specific ultrasound signs should be validated.

Scientific Abstracts
duration were also noted. Kolmogorov Smirnov test, chi-square test, Mann Whitney-U test, Spearman correlation analysis, and Univariate analysis of variance were used for statistical analyses.

Results: Patients were aged between 22 and 77 years, with a mean age of 44.6±3.1. Ten patients (15.6%) were diagnosed with FMS and of those 4 (30.8%) were women. Cognitive illness representations and emotional representations scores were higher in FMS patients than those without FMS (p<0.05). Disease duration, HIV-progression biomarkers (CD+ and viral load), COPE questionnaire scores, and illness comprehensibility sub scores of FMS (p<0.05). The significant effect of the presence of FMS on cognitive illness representations (p<0.001) and emotional representations (p<0.05) was found by univariate analysis of variance in patients with HIV.

Conclusion: According to the preliminary results of this study, FMS was detected 16.3% of patients with chronic pain. The presence of FMS may adversely affect perceptions of the disease in HIV-infected patients. Since the patients believe their illness is not having great importance in the patients health outcomes and the understanding of the disease, physicians should be aware of the possibility of concomitant FMS in patients with HIV.

PAIN DESCRIPTORS AND DETERMINANTS OF PAIN SENSITIVITY IN KNEE OSTEOARTHRITIS: A COMMUNITY-BASED CROSS-SECTIONAL STUDY

J. E. Vriezeolk,1 Y. A. S. Peters,2 M. A. H. Steegers3,4 E. Blaney Davidson,1 C. Van den Ende1 1Sint Maartenskliniek, Rheumatology Research, Nijmegen, Netherlands; 1Sint Maartenskliniek, Rheumatology Research, Nijmegen, Netherlands; 2Amsterdam UMC, Anesthesiology, Amsterdam, Netherlands; 3Radboud University Medical Center, Anesthesiology, Nijmegen, Netherlands; 4Radboud University Medical Center, Experimental Rheumatology, Nijmegen, Netherlands

Background: The phenomenon of heightened pain sensitivity is implicated in the pain experiences of people with OA[1]. Limited research show that pain sensitivity is associated with poor health and treatment outcomes. However, epidemiological research investigating the extent and determinants of pain sensitivity in OA is scarce. In addition, the quality of pain is poorly described. Both the assessment of quality of pain and pain sensitivity can be important to inform clinical decision-making and treatment.

Objectives: To explore pain characteristics in individuals with knee osteoarthritis (KOA), to compare pain sensitivity across individuals with KOA, chronic back pain (CBP) and pain-free individuals (NP), and to examine the relationship between clinical and pain characteristics with pain sensitivity in KOA.

Methods: Cross-sectional, community-based online survey. Two datasets were combined comprising Dutch individuals of ≥ 40 years of age, experiencing chronic knee pain (KOA, N=445; dataset 1), chronic back pain (CLP, N=504; dataset 2), or no pain (NP, N=256; dataset 2). Demographic and clinical characteristics, global health, physical activity/exercise, and pain characteristics including intensity, spreading, duration, quality (SF-MPQ), and sensitivity (PSQ) were assessed. Differences between (sub)groups were examined using analyses of variance or Chi-square tests. Regression analyses were performed to examine determinants of pain sensitivity in the KOA group.

Results: Quality of pain was most commonly described as aching, tender, and tiring-exhausting in the KOA group (Figure 1). Overall, the KOA group had higher levels of pain sensitivity compared to NP group, but lower levels than the CBP group (Table 1). Univariate, pain intensity, its temporality and spreading, global health, doing exercise, and having comorbidities were weakly related to pain sensitivity (standardized beta’s: 0.12-0.27). Symptom duration was not related to pain sensitivity. Older age, higher levels of chronic pain, lower levels of global health, and doing exercise uniquely contributed, albeit modest, to pain sensitivity (P<0.05).

Figure 1. Percentage of individuals with self-reported knee OA who rated pain descriptors as moderate to severeNote: Subgroups based on median split total score Pain Sensitivity Questionnaire. *P<0.05

ASSESSMENT OF PAIN THRESHOLDS TO VERIFY CENTRAL SENSITIZATION IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS OF THE KNEE

E. Filatova1. 1VA Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation

Background: Central sensitization in patients with rheumatoid arthritis, osteoarthritis of the knees increases the risk of comorbid disorders, the most frequent of which are depression, cognitive impairment and insomnia. Verification and timely diagnosis of central sensitization will help to improve pain control in rheumatic diseases. (1,2) Objectives: to study pressure pain thresholds in patients with rheumatoid arthritis (RA) and osteoarthritis of the knee (OA) with chronic pain.

Methods: All patients had pain intensity scores according to the VAS scale, neuropathic/neuroplastic pain severity according to the DN4 and Pain DETET questionnaires, central sensitization severity was assessed using the CSI scale. To verify the presence of central sensitization instrumentally and to confirm the presence of secondary hyperalgesia detected clinically, algometry was performed in 42 female patients with OAK and 42 patients with RA. A comparison group of 42 healthy volunteers comparable in gender and age with the patients was also selected. Using a Wagner FDK20 algometer, pressure pain thresholds for OAK in the knee joints were studied (4 points: 1st point located 2.5cm medial to the patella, 2nd point in the center of the patella, 3rd 2.5cm distal to the patella, 4th in the gastrocnemius area) and m. Trapezius (5th reference point) in all patients with OAK and controls. In the group with RA, pain thresholds were studied at 4 points: 1st - nail bed of the 1st finger, 2nd - wrist (above the extensor tendon, recruitment), 3rd - 2.5cm lateral to the knee and 4th m. trapezius (reference point) in all patients and controls.

Results: The mean age of patients with RA and OAK was 53.0 [41.0,61.0] and 61.0[57.0,63.0] years, with disease duration at the time of study of 9.0 [4.0,13.0] and 13.0[7.0,15.0] years, respectively. The DN4 questionnaire scores were 2.0 [1.0,4.0] for RA and 5.0[0.0,6.0] for OAK, and the Pain DETECT scores were 1.0.
Lower pain thresholds in patients with RA and OA were noted not only in the area of the affected joints, but also in the distant reference point, indicating the presence of secondary hyperaesthesia in these patients, which is a neurophysiological sign of central sensitization. A significant decrease in the pain threshold index was also noted in patients with central sensitization compared to those in the control groups.

Conclusion: The study of pain thresholds is one of the tools for verification of CS in patients with RA and OA, but requires further study.

* All values were reported means other than medians noted by asterisk (*)
system, which can mimic rheumatic conditions. Despite the ignorance of some, endocrine diseases are underlying diseases linked to musculoskeletal manifestations. Thus, secondary arthropathies of non-rheumatologic origin or osteoarthritic complaints or show rheumatic diseases can be found in patients with endocrine diseases during their evolution or in the initial phase along with other systemic symptoms. Based on this concept, we carried out the follow-up and evaluation of musculoskeletal manifestations presented by patients with endocrine disorders in a tertiary health service.

Objectives: The aim of this study is to characterize the musculoskeletal manifestations in patients with endocrine diseases: type 1 and type 2 Diabetes Mellitus; hypothyroidism; hyperthyroidism and pituitary diseases and to clinically classify the patients based on physical examination and imaging findings.

Methods: A cross-sectional and descriptive study, where clinical screening was performed at the endocrinology outpatient clinic, in which patients with musculoskeletal complaints were identified. These patients were referred for evaluation with a rheumatologist with clinical, laboratory and imaging investigation for the diagnosis of rheumatic disease. A questionnaire with epidemiological and clinical data was applied.

Results: To date, 466 patients diagnosed with endocrine diseases have been interviewed, 53.4 ± 14.7 years old, 371 (79.6%) were female and 95 (20.4%) were male. Of the patients interviewed, 326 (70.1%) reported musculoskeletal pain. In relation to endocrine diseases, the most frequent one was type 2 DM with 212 patients (45.5%), and 7725% of these people have chronic musculoskeletal pain, most of them 5 to 7 times a week, showing an intrinsic character of this disease with pain complaints from a great part of this population. The prevalence of 27.3% of hypothyroidism, 10.7% of DM type 1, 7.1% of hyperthyroidism, and less expressive amounts of other endocrine diseases such as acromegaly (1.7%), Cushing (0.4%), and the like were also identified. About 59.6% of those who have pains are not followed up in the rheumatology service, 41.3% of these have already indicated these pains to their endocrinologist, however they did not have their complaint properly signaled. Of those interviewed, 94 (37.5%) take antihypertensives and 32.7% oral anti-diabetics. The most commonly found diagnoses in rheumatic diseases: Rheumatoid Arthritis (39%); Osteoarthritis 22.9% and Fibromyalgia 20%; Osteoporosis 19%, Tendinitis calcarea, Psoriatic Arthritis and GOTA with 5.7%. The main joints affected were: Hands (54.4%); Knees (45.3%) and feet (41.8%).

Conclusion: Our research with pre liminal results has demonstrated the mutuality between endocrine diseases and musculoskeletal manifestations and, therefore, that rheumatologic diagnoses are increasingly frequent in this population. The high prevalence of these symptoms secondary to endocrine diseases raises serious questions to improve the quality of life of these patients, and also to increase the number of investigations in this field, because the pathophysiological mechanisms of this association are not well elucidated and, from there, to expand this information to professionals who may not be aware of this relationship.

MEDICAL AND PSYCHOLOGICAL COMORBIDITIES IN FIBROMYALGIA: A CROSS SECTIONAL STUDY
K. N. Thomas1, A. Lawrence1, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India

Background: Psychological disorders are commonly observed in fibromyalgia (FMS). Medical comorbidities are less well characterised in FMS. We sought to assess the prevalence of these disorders in an observational cohort of patients in a tertiary hospital in North India.

Objectives: The prevalence of medical and psychological comorbidities in FMS and the prevalence of these disorders in FMS subgroups classified according to different ACR classification criteria were assessed.

Methods: Patients satisfying either the 1990 ACR or the 2016 ACR Fibromyalgia criteria were included in a cross-sectional study between October’19 and December’21. All patients were assessed for prevalence of chronic fatigue syndrome (CFS), post-traumatic stress syndrome (PTSD), restless leg syndrome (RLS) and medical comorbidities including obesity, obstructive sleep apnoea, anemia, diabetes mellitus, hypertension and hyperthyroidism.

Results: A total of 98 patients of median age 39 years (34 – 47) were included, of which 9 met only the 1990 ACR criteria (100% females), 30 met only 2016 ACR criteria (86% females) and 59 met both criteria (89% females). Widespread Pain index was significantly higher in the 1990+2016 group compared to subgroups which met only either of the criteria. Hypothyroidism (subclinical or clinical) was similarly higher in the 1990+2016 subgroup. At least one psychological comorbidity was seen in 41%, with CFS present in 30% and PTSD in 14%. The median systolic blood pressure was in the hypertensive range (146 mm Hg) in the 1990-only group, with hypertension being present in 1/3rd of the total cohort. Obesity was present in 59% and Diabetes in 11%. Iron deficiency anaemia was seen in 20%.

Table 1. Prevalence of comorbidities in different subgroups of Fibromyalgia

Figure 1. Venn Diagram depicting Fibromyalgia subgroups having psychological comorbidities

Conclusion: There is a high prevalence of comorbidities in patients with fibromyalgia with nearly half having at least one psychological comorbidity, and obesity, hypertension and iron deficiency anaemia being the common medical comorbidities. Those who met only the 1990 ACR criteria formed less than 10%.

AB1206 JUVENILE PRIMARY FIBROMYALGIA SYNDROME: RESULTS FROM A VOSVIEWER-BASED BIBLIOMETRIC NETWORK ANALYSIS.

School of Medicine, University Federico II, Naples, Italy; Medicine, Naples, Italy; Istituto Nazionale Tumori, IRCCS Fondazione G. Pascale, Division of Anesthesia and Pain Medicine, Naples, Italy; School of Medicine, University of Pavia, Medicine, Naples, Italy; Istituto Nazionale Tumori, IRCCS Fondazione G. Pascale, Scientific Directorate, Naples, Italy; Ospedale Cardarelli, Transplant Unit, Naples, Italy

Background: In 1985, Yunus and Masi described the juvenile primary fibromyalgia syndrome (JFPS). It is a chronic musculoskeletal pain syndrome that affects children and adolescents [2] with an estimated prevalence that varies from 1.2 to 6.2% [3]. Clinical features are widespread persistent pain, sleep disturbance, fatigue, and the presence of multiple discrete tender points on physical examination. Notably, this syndrome can impact the quality of life status and psychosocial development of children and adolescents [4]. Despite a lot of research being conducted, several aspects on etiology and pathogenesis, clinical characteristics, and evaluation, as well as therapy should be better explained.

Objectives: This bibliometric analysis is aimed at dissecting the developed research in the subject. It could provide helpful findings for predicting the direction of future studies, implementing corrective measures, and improving research networks.

Methods: The global literature on JFPS was scanned in the Web of Science (WOS) online database. The search string applied to identify the closest matching articles was: ‘Juvenile primary Fibromyalgia Syndrome (all field)’. All data were acquired on January 30, 2022. The information for the documents that met the requirements were extracted. The source was Journal Citation Reports™ 2020 (Clarivate Analytics). The literature analysis and knowledge visualization software tool VOSviewer (version 1.6.17) was used to analyze the co-occurrence of keywords (interconnection), co-citation (bibliographic coupling), co-citation analysis for sources, and countries, and analysis of the most productive organizations and networks.

Results: A total of 66 articles on JFPS were published from 1985 to January 2022, in WOS (n=24; median 2). About article types, 38 were research articles, 16 reviews, 8 meeting abstracts, 2 letters, 1 book chapters, 1 correction, 1 proceeding papers.

The analysis of keywords provided by authors showed that of 235 keywords, 38 exceeded papers. 16 reviews, 8 meeting abstracts, 2 letters, 1 book chapters, 1 correction, 1 proceedings paper.

Disclosure of Interests: None declared

Figure 1. Co-occurrence of keywords

For the co-citation study, we used cited sources (journals) as unit (minimum numbers of citations of a source 15). Of 563 sources, 38 met the threshold (interconnection 3). The most frequent keywords were Children (n=14); Adolescent (n=13); and Functional disability (n=10) (Figure 1)

Conclusion: This bibliometric network analysis on JFPS can be helpful for planning future research. It highlights the strength of representative scientists and core research teams. Research networks should be built, and high-value investigations warranted.

Background: Glucocorticoids (GC) are the therapeutic mainstay in polymyalgia rheumatica (PMR). However, their adverse effects are of particular concern in elderly patients. Relapses and long-term GC dependency are common.

Objectives: Assess the risk factors for higher relapse rate and/or prolonged glucocorticoid therapy in 185 PMR patients from Argentina.

Methods: A multicenter observational study of PMR patients diagnosed according to the Chuang criteria seen at the outpatient clinics at 12 public or private rheumatology units from Argentina between 2006 and 2021 was performed. Patients were followed until permanent remission, lost to follow up, or a maximum of 2 years after diagnosis. Relapse was defined as an exacerbation of PMR symptoms requiring an adjustment of GC dose (≥ 4 mg) occurring at least 1 month after diagnosis. Time to relapse was modeled using the Kaplan-Meier method. Cox regression models were used to evaluate predictors of time to first and subsequent relapses.

Results: A total of 185 patients were included (69.1% female) with a median age of 71 years (IQR 65-78 years). The median follow-up time was 17.1 months (IQR 6.8-34.7) and the incidence of relapses was 1.2 per 100 persons/month. The median time to relapse was 70.5 months (25th percentile = 14 months). Pain and/or stiffness in shoulder girdle and pelvic girdle together more common (p = 0.02) in the clinical presentation of patients who relapsed. In univariate analysis, patients with a previous history of dyslipidemia had a lower risk of relapse (HR = 0.55, 95% CI = 0.33-0.94, p = 0.03). Laboratory at time of diagnosis showed that an ESR > 50 mm was found as a risk factor for relapse (HR = 2.50, 95% CI = 1.23-5.10, p = 0.011). Regarding therapy, meprednisone (HR = 2.38, 95% CI = 1.31-4.31, p = 0.004) and high dose GC (HR = 2.35, 95% CI = 1.42-3.87, p = 0.001) had higher risk of relapse. In multivariate analysis, only meprednisone (HR = 2.59, 95% CI = 1.28-5.23, p = 0.008) and high dose of GC (HR = 2.41, 95% CI = 1.19-4.89, p = 0.014) remained the only risk factors for relapse.

Conclusion: A lower relapse rate than that reported in the literature was observed. Meprednisone and high dose of GC are significant predictors of future relapses. Our results suggest that efforts should be made to minimize initial GC dose and avoid the use of meprednisone as GC of first choice in order to prevent disease relapses.

EXTRA-INTESTINAL SYMPTOMS IN PATIENTS WITH CELIAC DISEASE

AB1208

FREQUENCY OF MUSCULOSKELETAL AND OTHER EXTRA-INTESTINAL SYMPTOMS IN PATIENTS WITH CELIAC DISEASE

A. Pilipenko1, V. Mazurov2, I. Gaydukova3. 1North-Western State Medical University Named After I. I. Mechnikov, Department of Therapy, Rheumatology, 2Examination of Temporary Disability and Quality Of Medical Care; 3North-Western Medical University I.I. Mechnikov, Saint-Petersburg, Russian Federation

Background: Celiac disease (CD) is one of the most common gastrointestinal tract diseases, in adults and children. Prevalence of CD is 1-3% [2]. The most common symptoms of CD are gastrointestinal symptoms. At the same time, celiac disease may manifest with extraintestinal symptoms, including the musculoskeletal, nervous, reproductive system, and skin, especially when it debuts at a late age [1,2]. However, data about musculoskeletal manifestations of CD are limited.

Objectives: To show the frequency of musculoskeletal complaints and their peculiarities in patients with CD.

Methods: Data from 94 patients with diagnosed by gastroenterologist celiac disease were collected with the on-lain survey. All the patients were positive in CD-related immunological and genetic tests and had biopsy established CD.

Results:

- The average age of respondents is 37.52 ± 11.2 years, women 79 (84.1%). Among 94 respondents 0.1% do not follow a gluten-free diet, 10.6% <1 year, 25.5% from 1 to 3 years, 11.7% - 4-5 years, 28.7% are on a gluten-free diet >5 years, 14.9% - 10-15 years, 8.5% > 15 years. Gastrointestinal symptoms have started at the age < 10 years in 59.6% of patients, in 4.2% in 11-16 years old, 13.8% at the age 17-25 years old, 12.8% at the age 26-40 years old, 9.6% had late CD onset (>40 years old). Extraintestinal symptoms such as drowsiness were noted by 46.8%, headaches by 40.4%, weakness by 59.6%, irritability by 57.4% of respondents. Lack of coordination was noticed in 18.1% of cases, dizziness in 22.3%, 57.4% have numbness, decreased sensitivity, and tingling feeling in the limbs. Joint pain had 54.3% of the patients with CD (Figure 1).

The maximal intensity of pain was noticed in the morning (8.5%) or late night (13.8%) times and fulfilled inflammatory pain criteria (ASAS). In 17% was noticed signs of enthesitis. Weakness of arms was noticed by 13.8% times and fulfilled inflammatory pain criteria (ASAS). In 17% was noticed weakness of arms. Frequency of pain in different joints

Conclusion:

Radial arthritis was noticed by 40.4%, weakness by 59.6%, irritability by 57.4% of respondents. Lack of coordination was noticed in 18.1% of cases, dizziness in 22.3%, 57.4% have numbness, decreased sensitivity, and tingling feeling in the limbs. Joint pain had 54.3% of the patients with CD (Figure 1).

Figure 1. Frequency of pain Syndrome in Joints

MECHANISTIC FACTORS CONTRIBUTING TO PAIN AND FATIGUE IN FIBROMYALGIA AND ME/CFS: AUTONOMIC AND INFLAMMATORY INSIGHTS FROM AN EXPERIMENTAL MEDICINE STUDY

J. Eccles1,2, C. Thompson3,4, B. Thompson3,5, A. Amato1, K. Themelis1,5, H. Critchley1, N. Harrison3,5, K. Davies4. 1Brighton & Sussex Medical School, Neuroscience, Falmer, United Kingdom; 2University Hospitals Sussex NHS Foundation Trust, CIRU, Brighton, United Kingdom; 3University Hospitals Sussex NHS Foundation Trust, Rheumatology, Brighton, United Kingdom; 4Brighton & Sussex Medical School, Clinical and Experimental Medicine, Falmer, United Kingdom; 5University of Warwick, Psychology, Coventry, United Kingdom; 6University of Cardiff, CUBRIC, Cardiff, United Kingdom

Background: Fibromyalgia and ME/CFS are multifaceted conditions with overlapping symptoms(1); the pathoetiologic mechanisms are complex and debated(2), however there is a strong association with features of hereditary disorders of connective tissue (hypermobility) and autonomic and inflammatory abnormalities (1,2).

Objectives: To determine potential autonomic and inflammatory mechanisms of pain and fatigue in fibromyalgia and ME/CFS

Methods: After excluding participants with WCC higher than 10 (suggesting acute infection) baseline markers of inflammation (CRP and ESR) were available for 60 patients with confirmed diagnoses of Fibromyalgia and/or ME/CFS and 23 matched controls. Participants then underwent full research diagnostic evaluation including a hypermobility assessment(1) and autonomic challenge (60 degree head up tilt, ISRCTN78820481). Subjective pain and fatigue were assessed before and after challenge (VAS). Linear regression models were used to explore predictors, with adjustment for confounders as appropriate. Mediation analyses (looking for mechanistic effects) were conducted according to the method of Hayes (3) and mediation considered significant if bootstrapped confidence intervals of the estimated indirect effect did not cross zero. In these mediation analyses predictor variable was group membership (patient or control), outcome variable was change in 1)pain and 2)fatigue induced by challenge and mediators 1)no of connective tissue features in hypermobility diagnostic criteria endorsed by participant; 2)baseline inflammatory markers.

Results: ESR and CRP were significantly higher in patients rather than controls, even after correcting for BMI, age and sex (B=5.15, t=2.05, p=0.044; B=1.77, t=2.15, p=0.044 respectively). Adjusted ESR and CRP correlated with both subjective fatigue (B=0.44, t=2.09, p=0.04; B=1.63, t=2.60, p=0.011) and pain severity (B=0.13, t=2.51, p=0.014; B=0.45, t=3.01, p=0.004) at baseline. Autonomic challenge amplified pain (B=14.20, t=2.87, p=0.005) and fatigue (B=31.48, t=5.95, p=0.001) in patients to a significantly greater degree than controls, controlling for baseline levels. Baseline ESR and CRP also predicted challenge-induced increase in fatigue (B=0.78, t=3.70, p=0.001; B=1.91, t=3.36, p=0.01) and ESR challenge-induced increases in pain (B=0.46, t=2.35, p=0.021).

Mediation analysis demonstrated that number of connective tissue features expressed in hypermobility criteria mediated the degree to which subjective pain was increased by the autonomic challenge (Bootstrapped 95% CI of indirect effect do not cross zero, 0.7541 - 7.3888).

Conclusion: To our knowledge this is the first study to directly explore autonomic and inflammatory mechanisms of pain and fatigue in a combined population of Fibromyalgia and ME/CFS. This study adds to the evidence-base of baseline inflammatory abnormalities in fibromyalgia and ME/CFS. It highlights their potential role in predicting symptom severity and their potential mechanistic role in autonomic induced pain and fatigue, suggesting future treatment strategies.

FIBROMYALGIA AND BODY MASS COMPOSITION IN POST-MENOPAUSAL WOMEN: PRELIMINARY RESULTS FROM A CROSS-SECTIONAL MONOCENTRIC STUDY

E. Hysaj, S. Paolino, R. Mascaro, A. Casabella, L. Carmisciano, E. Gotelli, C. Pizzorni, A. Sulli, V. Smith, M. Cutoiu
Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Italy – IRCCS Rheumatology Unit San Martino Polyclinic, Genoa, Italy, Genova, Italy; Section of Biostatistics, University of Genova, Genova, Italy, Department of Health Sciences (DISSAL), 16132, Italy; Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Cornel Heymanslaan 10, 9000 Ghent, Belgium, Department of Internal Medicine, Ghent University, Department of Rheumatology, Ghent University Hospital, Ghent, Belgium

Background: Fibromyalgia (FM) is characterized by chronic musculoskeletal widespread pain, fatigue, sleep disturbances and functional symptoms.

Objectives: Our study aimed to determine if FM could affect body composition of post-menopausal women and to investigated potential correlations between disease severity and body mass variables.

Methods: Thirty post-menopausal FM female patients (median age 56 years, BMI = 25.8) were diagnosed according to both ACR 1990 fibromyalgia classification criteria or ACR 2010 preliminary diagnostic criteria. They underwent Dual-energy X-ray absorptiometry (DEXA) for clinical purposes (i.e. screening for osteoporosis). The parameters analyzed by a dedicated software (GE Lunar, USA) were the spine and femoral bone mineral density (BMD), the total lean mass and the total body fat (TBF), quantitative variables of bone, muscle and fat composition. Additionally, qualitative analysis of the bone was indexed by the trabecular bone score (TBS); All the variables were compared with the parameters of 30 healthy controls (median age 59 years, BMI = 24.4) matched for sex and age. For each patient, data on disease duration, comorbidities, current treatment and disease severity self-reported scores were collected. The last ones derived from the Italian Fibromyalgia Impact Questionnaire Revised (FIQ-R) version that each patient independently compiled before the medical visit: widespread pain index (WPI), symptom severity scale (SSS), polysymptomatic distress scale (PDS), modified fibromyalgia assessment status (modFAS) and the FIQ-R total score.

Results: The clinical features of the FM patients included in our cohort are reported in Table 1. No statistically significant differences were observed between femoral/spine BMD, TBS and muscle mass between patients and controls (p = 0.3, p = 0.06, p = 0.16, p = 0.8 respectively). Conversely, both total and central body fat were significantly higher in patients compared with healthy controls (29.4 kg vs 25.2 kg, 15.7 kg vs 13.2 kg, p = 0.006 and p = 0.01 respectively). No significant correlations were observed between body mass composition indexes with scores of disease severity. Body mass composition variables did not statistically differ when patients were sub-analyzed according to pharmacological treatment and comorbidities.

Conclusion: Our preliminary results suggest that FM seems not associated with impaired bone mass and bone quality in post-menopausal women compared to matched healthy controls, in line with the majority of literature evidences. However, total and central adipose tissue mass resulted higher in this cohort of FM patients compared with controls but not correlate with disease severity. This might be due to a disease-induced sedentary lifestyle and might reinforce the concept that physical activity represents the best preventive method of over-weight and obesity, one of most reported comorbidities for FM patients.

Does body mass index and metabolic syndrome impact on fibromyalgia?

G. Tramontano,1,2 V. Tomatis,1 M. Gilioli,3 A. Giusti,1,2 F. Giarracca,2 R. Gallo,2 L. Bandi,2 G. Bianchi,2 Rheumatology Unit, Department of Medical Specialties, Regional Health Trust 3, Genoa, Italy; 2Metabolic Bone Diseases Unit and Fracture Liaison Service, Department of Medical Specialties, Regional Health Trust 3, Genoa, Italy; 3Infectious Disease Unit, Infection Disease Unit - San Carlo Hospital, Potenza, Italy

Background: Fibromyalgia (FBM), obesity and the metabolic syndrome (MTB) are common conditions with significant impact on health and quality of life, producing relevant economic burden for healthcare systems. Although obesity represents a negative prognostic factor for FBM, the relation between body mass index (BMI) or MTB and FBM severity is still unclear.

Objectives: The aim of our ongoing study was to evaluate the relationship between BMI or prevalent MTB and FBM severity, estimated with 3 different severity scores.

Methods: We included the first 100 women presenting with FBM, defined according to the ACR2010 diagnostic criteria, consecutively evaluated during the period of 1 year in 2 Clinic in Italy. On enrolment were assessed/recorded demographic, clinical and pharmacological characteristics, weight, height, physical activity, tenderness, pain and symptoms. The following scores were calculated: tender points count (TP), Widespread Pain Index (WPI), Polysymptomatic Distress Scale (PDS), Fibromyalgia Impact Questionnaire (FIQ) and modified Fibromyalgia Assessment Status (mFAS). BMI was calculated, and the presence of MTB was evaluated according to current definition. Patients were categorized as presenting with severe disease or moderate/mild disease according to recent definition validated in an Italian population. The prevalence of MTB and the mean ± standard deviation (SD) BMI in subgroups defined according to severity were estimated.

Results: Mean age ±SD was 57.5±12.7 years, mean BMI ±SD was 25.3±5.1, and 9.5± presented with MTB. FBM severity (mean±SD) calculated by PDS, FIQ and mFAS was respectively 25.3±9.3, 63.2±23.1, and 30.1±7.7% Patients with the highest BMI severity according to PDS (≥25) were less likely to present with FBM (2.4%) compared to those with a PDS of 0-25 (20.0%, P=026), with an adjusted (age and BMI) OR (95%CI) for presenting with MTB in patients with less severe FBM of 8.2 (0.962-69.298, P=0.54). Similar results were found when the specific conditions characterizing the MTB were considered separately, except for excessive body fat around the waist (not related to severity). The BMI ±SD was comparable between patients with severe disease (25.8±5.8) according to PDS and those with less severe FBM (24.8±4.4, P=0.388), with no correlation between BMI and PDS (Rho: 0.083, P=0.454). Considering all other characteristics of the two groups defined according to PDS categories (PDS ≥25 versus PDS <25) a significant difference was found in mean age ±SD, greater in patients with less severe FBM (60.2±13.2) compared to those with highest BMI severity (54.8±11.6, P=0.046). Similar but less significant findings were found also with FIQ and mFAS. The prevalence of MTB according to the FIQ was 7.3% for highest severity versus 14.3% for less severe FBM (P=0.200), with a comparable BMI ±SD between the two groups (respectively 28.2±6.1 versus 24.4±3.7, P=0.126). Corresponding figures for MTB or BMI and FBM severity according to the mFAS were respectively: prevalence of MTB in highest severity 3.0% versus 16.3% in the less severe FBM (P=0.026); mean ±SD BMI in highest severity versus 14.3% for less severe FBM (P=0.200), with a comparison BMI ±SD between the two groups (respectively 28.2±6.1 versus 24.4±3.7, P=0.126).

Conclusion: The preliminary results of our ongoing analysis demonstrated a slightly inverse relationship between BMI severity and the prevalence of MTB, trending to significance, while no relationship was found between severity and BMI.

AB1212  GENDER DIFFERENCES IN FIBROMYALGIA PATIENTS IN VIEW OF THE 1990, 2011, AND 2016 ACR CRITERIA

A. Moahri1, M. Z. Shoaei1, A. S. Abbas1, T. M. Abdel-Aziz1, W. Gouda1. 1Al Azhar University, Rheumatology, Assuit, Egypt

Background: Fibromyalgia (FM) is a common rheumatic illness distinguished by chronic pain, headache, fatigue, cognitive problems, and functional disability. However, the differences between men and women have not yet been comprehensively studied, especially after the development of the last 2016 American College of Rheumatology (ACR) criteria.

Objectives: The aim of this study was to evaluate the gender differences in symptom characteristics, cognitive dysfunction, and disease severity in Egyptian FM patients considering both the ACR 1990, 2011, and the last 2016 ACR diagnostic criteria.

Methods: In this cross-sectional study, 352 individuals with fibromyalgia were interviewed from January 1, 2020, to June 1, 2021. In addition to the number of tender points (TPC), data was collected on age, gender, body mass index (BMI), marital status, disease onset, duration, and diagnostic delay. The Wide- spread Pain Index (WPI), the Symptom Severity Scale (SSS), fatigue, cognitive dysfunction, sleep disturbance, awakening unrefreshed, headache, abdominal pain, and depression were evaluated and scored according to 2010 and 2016 ACR criteria. The questionnaire includes a visual analog scale (VAS) for pain, fatigue, stiffness, anxiety, and depression. Total score ranges were calculated with total score ranges between 0 and 80 (without job items), where higher scores indicated a greater negative impact and/or severity of symptoms. The Polysymptomatic distress scale (PDS) has been calculated by the summation of the SSS with the WPI. The Revised FM impact questionnaire (FIQR) has also been evaluated.

Results: The study shows that females have a significantly higher prevalence of fatigue, cognitive dysfunction, sleep disturbance, headache, and abdominal pain (p < 0.05). Also, females showed significantly higher scores than males regarding WPI, SSS, and mean TPC (p = 0.004, 0.027, and 0.001, respectively). While there was no difference regarding the FIQR (p=0.93), PDS was significantly higher in women (p= 0.001).

Conclusion: Female patients with FM had greater disease severity scores, symptomatology, and number of tender points. Whatever the criteria applied, the prevalence and intensity of the disease features are higher in females, which may underestimate the disease in male patients.

AB1213  EFFECTIVENESS OF A ONE-WEEK INPATIENT MULTIMODAL PAIN TREATMENT PROGRAM FOR PATIENTS WITH RHEUMATOLOGIC DISEASES AND MUSCULOSKELETAL PAIN – A SINGLE CENTER OBSERVATIONAL STUDY

J. Pirker1, A. Rubbert-Roth1, C. Haller1, F. Mayr1, J. Von Kempis1. 1Kantonsspital St.Gallen, Division of Rheumatology and Immunology, Department of Internal Medicine, St. Gallen, Switzerland

Background: Multimodal rheumatologic complex treatment (MRCT) is a treatment concept for patients with rheumatologic diseases requiring acute inpatient care suffering from exacerbated pain and/or functional impairment. A rheumatologist directs the treatment program including multimodal assessments and treatment from three of the following: ergotherapy, physical therapy, pain medicine and cognitive behavioural treatment. Most studies evaluated data from a two-week inpatient MRCT program. Available data on the effectiveness of a one-week inpatient multimodal treatment program are scarce. However, whether a shorter program might also be effective has not been studied so far.

Objectives: To evaluate the effectiveness of a one-week inpatient multimodal and interprofessional treatment program on musculoskeletal pain and function of patients with rheumatologic disorders.

Methods: 59 consecutive patients were entered into a program of multimodal treatment courses (MRCT) from January 2021 until December 2021. All patients completed a total of 11 hours of therapy in one week. Two patients were excluded for evaluation (one patient acquired COVID 19 during hospitalization and one patient was excluded due to missing data).

Conclusion: Significant improvement of pain and function was demonstrated at discharge and at week 12 in patients with rheumatologic diseases and musculoskeletal pain completing a one-week inpatient multimodal interprofessional treatment program. A multimodal therapeutic approach may provide an effective treatment strategy superior to unimodal standard management.

AB1214  VITAMIN D SUPPLEMENTATION IN FIBROMYALGIA: A SYSTEMATIC REVIEW

H. Sousa1, A. S. Pinto2, J. F. Ferreira1, 2. 1Science of Health Faculty Beira Interior University, Rheumatology, Covilhã, Portugal; 2Unit Local Health of Guarda, Rheumatology, Guarda, Portugal

Background: Fibromyalgia (FM) is a chronic disease characterized by diffuse pain associated with high levels of fatigue whose intensity is very variable. Similar symptoms are found in patients with low levels of vitamin D, a vitamin that behaves like a hormone with multiple receptors spread in several tissues. Although its role in the pathophysiology of FM remains unclear many studies point to a correlation between vitamin D deficiency and FM symptoms severity.

Figure 1.

Conclusion: The mean treatment duration (days, sSD) was 8.1 ± 0.8. Mean age (years, ±SD) of the 57 patients treated in the MRCT program was 57.2 ± 12.5, with 72% female and 28% male patients. Of all patients, 40% had an underlying inflammatory disorder, 60% a non - inflammatory rheumatic disease, 23% of all patients had “back pain”, 14% “spondyloarthristis” and 11% “rheumatoid arthritis”. Overall, VAS (pain) mean at admission was 6.9 ± 1.0 (SD), HAQ mean 0.57 ± 0.23 (SD) and FFbH mean 81.44 ± 7.95 (SD), respectively. Significant improvements in VAS, HAQ and FFbH were demonstrated at discharge (day 8), with a mean improvement of VAS of -2.86 (95% CI: -3.07 to -2.64, P value: <0.0001), a mean improvement of HAQ of -0.24 (95% CI: -0.28 to -0.20, P value: <0.0001) and a mean improvement of FFbH of 5.38 (95% CI: 3.78 to 6.98, P value: <0.0001). Follow up assessment at week 12 was recorded in 22 patients (39%) with a significant mean improvement in VAS of -2.23 (95% CI: -2.98 to -1.48), P value < 0.0001 (Table 1 and Figure 1).
**ABSTRACT**

**Objectives:** Conduct a systematic review of the literature to determine the value of vitamin D supplementation in fibromyalgia.

**Methods:** Medline, EMBASE, and Cochrane databases were searched, from January 2000 to June 2022, using the descriptors “Fibromyalgia,” “Fatigue” and “Vitamin D.” Randomized and clinical control trials including FM patients in whom supplementation of vitamin D was made were selected. Data comprised sociodemographic description, diagnosis criteria, fibromyalgia symptoms, Fibromyalgia Impact Questionnaire (FIQ), short-form 36 (SF36), and vitamin D supplementation protocol was collected.

**Results:** Of the initial 1480 articles, 4 were eligible for final analysis. One did not observe any significant improvement in FIQ scores with vitamin D supplementation. The remaining three observed significant improvements in SF36 and FIQ scores but to different extents. One only demonstrated improvements in specific components of the SF36, also demonstrating improvements concerning morning fatigue. Another demonstrates improvements in all SF36-parameters, except for pain level. Lastly, other observed improvements in the scores of both FIQ and SF36 scales.

**Conclusion:** Our review shows conflicting results regarding the role of using vitamin D supplementation in the quality of life of patients with FM(S). These results can be explained by different supplementations protocols and also different baseline levels of vitamin D for which it was decided to supplement. Nevertheless, vitamin D supplementation appears to have a benefit in fatigue and quality of life in FM patients. Larger studies, which last longer and have a more uniform supplementation protocol, are needed to confirm the results of this review.

**A COMPARATIVE ANALYSIS OF RADIOLOGICAL FINDING BETWEEN TUBERCULOUS, BRUCELLAR AND PYOGENIC SPONDYLODISCITIS**

N. Ben Chekaya1, F. Fhima1, S. Zourev1, I. Beija1, M. Touzi1, M. Jguirim1, N. Bergaoui2

**Fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia**

**Background:** Infection spondylodiscitis (IS) is a serious infectious disease which involves intervertebral disc and its adjacent vertebral bodies but later may also extend into the the adjacent neural structures. The clinical picture of IS is rather non specific but there are significant radiological differences that permit a presumptive aetiological diagnosis and orient the initial empirical treatment.

**Objectives:** This study aimed to compare the radiological features of of tuberculous (TS), brucellar (BS) and pyogenic spondylodiscitis (PS).

**Methods:** A retrospective monocentric study involving 70 cases of infective spondylodiscitis admitted between January 2009 and August 2019 at our rheumatology department. Clinical, laboratory and radiological data of the patients were collected.

**Results:** Of these 70 patients, 18 (25.7%) had TS, 8 (11.4%) BS and 44 (62.9%) PS. There were 37 women (52.9%) and 33 men (47.1%). The age of the patients ranged from 12 to 82 years, with a mean of (SD±) 54±15.23 years. Standard X-rays showed abnormalities suggestive of spondylodiscitis in 78.6% of cases. Paravertebral or epidural masses were present respectively in 53.5% and 86.7% of TS, versus 14.3% and 71.4% of BS, and 46.3% and 80.5% of PS, there were no significant differences those clinical features between the groups.

**Conclusion:** There are significant clinical, biological and radiological differences between TS, BS and PS. The presence of back pain, fever, moderate elevation of inflammatory markers with thoracic radiological involvement was suggestive of tuberculous spinal infection.

**Disclosure of Interests:** None declared

**TUBERCULOUS, BRUCELLAR AND PYOGENIC SPONDYLODISCITIS: A DESCRIPTIVE AND COMPARATIVE STUDY OF 70 CASES**

N. Ben Chekaya1, F. Fhima1, M. Ghard, A. Ben Salem2, S. Zourev1, I. Beija1, M. Touzi1, M. Jguirim1, N. Bergaoui2

**Fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia**

**Background:** Infection spondylodiscitis is a serious infectious disease which involves intervertebral disc and its adjacent vertebral bodies but later may also extend into the the adjacent neural structures with right-sided sciatica and intermittent episodes of urinary retention. The pain was gradually worsening and resisting conventional analgesics and psychotherapy. On physical examination, she had tenderness of the lumbar back and left sacroiliac joint with limited mobility. Biological findings were normal and X-ray features showed osteolytic lesions of L5 left side. The magnetic resonance imaging (MRI) results revealed septated paravertebral and epidural abscesses.

**Objectives:** To describe and to compare the clinical, biological and radiological features of tuberculous (TS), brucellar (BS) and pyogenic spondylodiscitis (PS).

**Methods:** A retrospective monocentric study involving 70 cases of infectious spondylodiscitis admitted between January 2009 and August 2019 at our rheumatology department. Clinical, laboratory and radiological data of the patients were collected.

**Results:** Of these 70 patients, 18 (25.7%) had TS, 8 (11.4%) BS and 44 (62.9%) PS. There were 37 women (52.9%) and 33 men (47.1%). The age of the patients ranged from 12 to 82 years, with a mean of (SD±) 54±15.23 years. Standard X-rays showed abnormalities suggestive of spondylodiscitis in 78.6% of cases. AURICULOTHERAPY AS A TREATMENT FOR CHRONIC NECK PAIN: AN INTERVENTIONAL COMPARATIVE STUDY

O. Saidane1, W. Lahmar1, F. Saadi1, A. Ben Tekaya1, S. Bouden1, R. Leila1, R. Tekaya1, I. Mahmoud1, L. Abdelmoula1, 1Charles Nicolle Teaching Hospital, Rheumatology, Tunis, Tunisia

Background: Data indicates promising benefits of auriculotherapy (AT) in pain management of several pathologies. Common cervical pain (CCP) is recurrent pain often resistant to standard treatment. And use of auriculotherapy as a therapeutic solution in neck pain has not been well explored.

Objectives: The aim of our study is to evaluate efficacy of a single session of AT in the management of CCP’s pain and disability.

Methods: We conducted an interventional comparative study. Fifty patients with CCP consulting were divided in two group of 25: group A underwent a session of AT, group P had a placebo treatment using a detuned ultrasound machine. Evaluation of the patients was performed before, and right after the intervention.

Results: NPDS total went from 34.3 to 22.9 (p<0.001), F1 went from 9.5 to 6.2 (p<0.001), F2 went from 16.5 to 11.9 (p<0.001), F3 from 8 to 5.4 (p<0.001). In the P group: NPDS total decreased from 28.9 to 26 (p=0.001), F1 from 6.3 to 5.7 (p = 0.001), F2 going from 14.4 to 13.3 (p = 0.013), F3 went from 8 to 7.3 (p=0.006).

Conclusion: Our study revealed that a single session of auriculotherapy is effective on short term in the treatment of pain and disability related to CCP. This alternative technique may gain its place in the therapeutic management protocol to overcome disability of chronic neck pain.

CHARACTERISTICS OF INFECTIOUS SPONDYLODISCITIS IN ELDERLY

I. Mahmoud1, M. Aouni1, A. Ben Tekaya1, S. Bouden1, R. Leila1, R. Tekaya1, O. Saidane1, L. Abdelmoula1, 1Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia

Background: Infectious spondylodiscitis is a rare but growing disease. It is a serious infection that can compromise both the functional and vital prognosis especially on elderly subjects.

Objectives: The purpose of this study was to compare the clinical, bacteriological and evolutionary characteristics of elderly patients admitted for management of infectious spondylodiscitis with a case-control group of young subjects.

Methods: Retrospective, descriptive study carried out in the rheumatology department of the Charles Nicolle Hospital from 2010 to 2019. Adult patients hospitalized for infectious spondylodiscitis were included. Clinical, bacteriological and evolutionary data were analysed and comparing those over 65 years of age with young case-control subjects.

Results: Of the 78 patients included, 33 patients belonged to the elderly group and 45 to the control group. The duration of evolution was shorter for the control group (123 vs. 181 months for the elderly; p=0,71). The progressive mode of onset characterised the elderly group (P<0.05). Spinal pain was constant. Neurolological abnormalities, night sweats, and altered general condition were more present in the elderly (p<0.05). Spinal stiffness was more present in the control group (p<0.05). There was no difference between the two groups in terms of the presence of fever and radiculalgia. Spinal biopsy was performed in 72% of the elderly subjects and in 80% of the control group. The most common germ in the elderly group was tuberculosis and brucellosis in the control group (p<0.05).

Conclusion: Infectious spondylodiscitis on elderly is characterised by an insidious onset, a confusing clinical picture and a more severe presentation than young people with significant complications and mortality.

AB1221  START BACK TOOL RISK SCORE: WHAT GUIDANCE TO GIVE IN A MILITARY LOW BACK PAIN POPULATION?

R. Dahm1, W. Lahmar2, O. Dhrif1, M. Sloma1, L. Metoui1, I. Gharsallah1, K. Amri2, Y. Malait1, L. Nouisrif1. 1Military Teaching Hospital, Rheumatology, Tunis, Tunisia; 2University of Tunis El Manar, Internal Medicine, Tunis, Tunisia; 3Military Teaching Hospital, Orthopedics, Tunis, Tunisia

Background: The Keele start back Tool (SBT) is a 9-item self-reported questionnaire validated to identify individuals with non-specific low back pain (LBP) who have prognostic factors for persistent disabling pain. Thus, it is a useful component of stratified care, where patients’ prognostic subgroups are matched with appropriate treatment.

Objectives: The aim of our study was to report the prevalence of SBT-calculated risk for back pain disability in Tunisian military patients.

Methods: It was a cross sectional study. The SBT questionnaire was administered to patients > 18 years presenting with common low back pain in outpatient Military teaching hospital in Tunis, Tunisia (from January to Mars 2021). The normality of data distribution was checked by the Kolmogorov-Smirnov test. Quantitative variables were presented as mean ± standard deviation (SD) or median (interquartile range), as appropriate. The categorical variables were expressed as percentages.

Results: X-ray of 114 participants; the mean age at diagnosis was 79 +/- 12 years old, sex ratio was equal to 1. The median of symptom duration was 22 (6-36) months, 83 (72.8%) were employed, 54 (47.4%) were on active military duty. Comorbidities reported in our patients were distributed as followed: 52 (45.6%) cases of overweight, 21 (18.4%) cases of obesity, 17 (14.9%) had hypertension, 13 (11.4%) suffered from type 2 diabetes, 10 (8.8%) had dyslipidemia, 6 (5.3%) cases of hypothyroidism and 3 (2.6%) cases of auto-immune diseases. Seventy (61.4%) participants reported anxious thoughts, 75 (65.8%) patients expressed avoidance beliefs, 59 (51.8%) patients mentioned catastrophizing thoughts and 50 (43.9%) were dealing with low mood. Mean SBT psychological score was at 2.68 +/-1.5. Patients reported a mean SBT score of 5.31 +/-2.1 with the following risk stratification: 27 (23.7%) scored low-risk, 47 (41.2%) medium risk, and 40 (35.1%) high-risk.

Conclusion: This is the first study to report the prevalence of SBT-designated risk subgroups among Tunisian population. Medium or high-risk scores for back pain disability were more prevalent the surveyed sample. Also, rates of low mood and anxious thoughts indicate a need for future research to explore psychosocial factors in non-specific low back pain.

AB1222  POSITIVE DIAGNOSIS OF TUBERCULOUS SPONDYLODISCITIS: CT-GUIDED PERCUTANEOUS BIOPSY OF SPINAL LESIONS VERSUS CLINICAL, BIOLOGICAL AND IMAGING ARGUMENTS

M. Mrabet1, S. Boussaid2, S. B. Troudi1, S. Rekik1, S. Jemmali1, H. Aljani1, H. Sahli1, M. Elleuch1, 1Rabta Hospital, Rheumatology, Tunis, Tunisia

Background: Tuberculosis is still endemic in Tunisia. Although pulmonary localization is the most common, other localizations, including osseo-articular involvement, are increasingly diagnosed. Spinal or «Pott’s Disease» is the most common expression. A bundle of clinical, paraclinical and evolutionary arguments or a disco-vertebral biopsy puncture (DVBP) contribute to the positive diagnosis.

Objectives: Our aim was to assess the real contribution of DVBP compared to clinical-biological and imaging arguments for the diagnosis of tuberculous spondylodiscitis (SPDT).

Methods: We conduct a retrospective and descriptive study in a single rheumatology department. Data were collected from files of patients hospitalized in the past 20 years (2000-2020) who have been diagnosed with SPDT.

Results: Fifty-two cases of SPDT were collected (37F/15M). The mean age of the population was 55.21 years ± 17.79 [19-91]. Diagnosis SPDT was retained in 38 patients (73.1%). Imaging was contributive to positive diagnosis using standard X-rays, computed tomography and magnetic resonance imaging (MRI). Disc pinch, erosion of vertebral plates and vertebral collapse were the major signs. Once the diagnosis was retained for these patients, the first week noted a most significant clinical improvement (56.8%) in patients diagnosed with a range of suggestive arguments (p = 0.002). During the second week, clinical improvement was most marked in patients diagnosed with suggestive clinical and paraclinical arguments (70.3%) but with no statistically significant difference (p = 0.1). The improvement was statistically greater during the fourth week (66.7%) and the third month (60%) in patients diagnosed with histological examination (p < 0.001).

Conclusion: Tuberculous spondylodiscitis is a frequent condition that needs to be treated rapidly. A range of highly suggestive clinical, paraclinical and evolutionary arguments contribute in the majority of cases to the positive diagnosis with a comparative clinical evolution to that of the DVBP which remains an invasive exam with variable sensitivity depending on studies.

AB1223  ACTIVE MILITARY ARE AT HIGHER RISK OF CHRONICITY IN LOW BACK PAIN: A CROSS SECTIONAL COMPARATIVE STUDY

W. Lahmar1, R. Dahm1, O. Dhrif1, M. Sloma1, L. Metoui1, I. Gharsallah1, K. Amri2, Y. Malait1, L. Nouisrif1. 1Military Teaching Hospital, Rheumatology, Tunis, Tunisia; 2Military Teaching Hospital, Orthopedics, Tunis, Tunisia

Background: The incidence of low back pain (LBP) was 40.5 per 1,000 person-years in active military population and thus was comparable to the general population. Other than pain and disability, chronicity of LBP has a significant impact on work through the high rates of resulting sick leave. The Start Back...
Tool (SBT) questionnaire is a well-known tool used to detect patients with prognostic factors for persistent and disabling back pain. The risk of chronicity in individuals on active military duty suffering from acute back pain is yet to be explored.

Objectives: The aim of our study was to assess the risk of chronicity in active Tunisian military population compared to non-military controls using the SBT questionnaire.

Methods: Cross-sectional study in which we enrolled adult patients suffering from acute back pain, who consulted the outpatient department of rheumatology in the military hospital of Tunis from January 2021 to March 2021. All patients had a standardized clinical examination. They completed the SBT questionnaire in the validated Arabic language version. Patients were stratified in two groups, active military group (AMG) and non-military group (NMG). Categorical variables were compared with the χ²-test. Comparisons of the differences of continuous variables were performed by Student’s t-test.

Results: We included 54 patients in the active military group and 60 patients in the non-military group, epidemiologic characteristics were distributed respectively as followed: mean age was at 43±8 versus 53±13 years old (p<0.001), sex ratios (F/H) were 0.23 versus 3.62 (p=0.001), 54% versus 73% (p=0.033) of patients were overweight or obese, 4% versus 18% (p=0.014) of patients had type 2 diabetes, 4% versus 13% (p=0.099) of patients had dyslipidaemia while 9% versus 20% (p=0.108) of patients had hypertension. Active military group patients had significantly higher proportions of high risk SBT scores than non-military patients 50% versus 22% (2.27 risk ratio 95% CI 1.47 to 3.08; p=0.002), with total mean of scores significantly higher in the active military group 5.81 (95% CI 5.33 to 6.29) versus 4.85 (95% CI 4.43 to 5.27), p=0.014. Active military group patients scored significantly higher on the psychological SBT sub-score compared with the non-military group 3.9 versus 2.6 (p=0.032), and were more susceptible to express low mood 53% versus 35% (1.51 risk ratio 95%CI 1.13 to 1.89; p=0.044). There was no significant difference in expressed anxiety 69% versus 55% (p=0.139), catastrophizing thoughts 57% versus 47% (p=0.252) and avoidance beliefs 72% versus 60% (p=0.170) though all of these parameters were more prevalent in the active military group.

Conclusion: Though NMG patients had more classic low back pain risk factors such as age and obesity, this did not prevent the AMG to show higher trends toward chronicity via SBT scores. This is to our knowledge the first study to assess the high risk of persistent disabling back pain using the SBT in a Tunisian military population. The implementation of risk stratification for patients with low back pain in routine military health may improve physical function and time off work, sickness certification rates and reductions in healthcare costs compared to usual non-stratified care.

NON-CONTIGUOUS MULTIFOCAL SPONDYLODISCITIS: A RETROSPECTIVE OBSERVATIONAL STUDY

S. Rekki1, S. Bousaid1, Z. Zeineb1, S. Jemmali1, S. Rahmouni1, K. Zouaoui1, H. Sahli1, M. Elleuch1. 1Rabta University Hospital, Rheumatology, Tunis, Tunisia

Background: Non-contiguous multifocal spondylodiscitis (mSpD) is a serious infection. Although literature data highlight the opportunity to miss a non-contiguous spondylodiscitis (SpD), recommendations for which cases an MRI of the entire spine should be performed are missing.

Objectives: The aim of the study was to assess the clinical features of mSpD to reveal risk factors underlying the need for screening a multifocal spine involvement.

Methods: We retrospectively evaluated the data of patients with confirmed non-contiguous multifocal spondylodiscitis.

Results: Twelve patients confirmed from mSpD were included (6 males, 6 females). The mean age was 60 years. Four patients had underlying chronic comorbidity, Diabetes (n=3), Hepatitis C virus (n=1). Most patients had spine pain (11 patients), radiculalgia in one patient, neurologic deficit (3 patients), worsening health status (7 patients). Symptoms onset was acute (n=1) or sub-acute (n=3) or long term (n=8) before admission. The mean duration between the diagnosis and the onset on symptoms was 9.6 months. Tubercular spondylodiscitis was the most detected etiology (n=8), confirmed by histological analysis (n=3) then by cellular, confirmed by serology lab test, and pyogenic SpD in two patients each. Non-contiguous multi-level involvement in the lumbar, thoracic, and cervical spine was detected in one patient for each region. Seven patients suffered from a lumbar and thoracic spine involvement and SpD occurs in the three regions in two patients. Elevated inflammatory biomarkers (CRP and ESR) were present in all cases. Bone biopsy was performed in all patients, confirmed the diagnosis, showed para-vertebral abscesses (n=3), epidural inflammation (n=6), and spinal cord compression (n=3). The majority of cases showed a favorable evolution with appropriate antibiotic therapy. One patient maintained a neurologic deficit, and one suffered from a severe degree of pain. Surgical approach was not indicated.

Conclusion: In our study, mSpD did not appear to be associated with a particular pattern. Tuberculosis was the dominant etiology. That suggests, an MRI of the entire spinal column should be performed for each patient with suspicious SpD, especially when tuberculosis is evocated.

AB1225
TUBERCULOUS SPONDYLODISCITIS: DIAGNOSTIC DELAY AND OUTCOMES

M. Mrabet1, S. Bousaid1, T. Abdelkefi1, S. Rekki1, S. Rahmouni1, S. Jemmali1, H. Aljani1, H. Sahli1, M. Elleuch1. 1Rabta Hospital, Rheumatology, Tunis, Tunisia

Background: Tuberculous spondylodiscitis (SPDT) is a serious clinical condition that must be treated promptly. Despite the actual availability of more effective diagnostic tools, early diagnosis of SPDT remains difficult and a high index of suspicion is needed due to the chronic nature of the disease and its insidious and variable clinical presentation.

Objectives: Our aim was to study the correlation between the diagnostic delay of SPDT and its outcomes.

Methods: We conduct a monocentric retrospective and descriptive study in a rheumatology department. Data were collected from observations of patients hospitalized in the past 20 years (2001-2021) who have been diagnosed with SPDT. An early diagnosis is defined by a diagnosis within the first six months versus a late diagnosis that is retained after 6 months of symptoms.

Results: Fifty-two cases of SPDT were collected (37F/15M). The mean age of the population was 55.21±17.79 years [19-91]. Late diagnosis was more common: 41 patients (78.8%) versus 11 patients (21.2%) diagnosed early. Complications were more frequent (61%) in patients diagnosed late, but with no statistically significant difference (p=0.1). Disease-related complications, such as spinal compression, spinal deformity and recurrence of the disease, was statistically higher (45.5%) in early diagnosed patients (p < 0.001). Drug complications, such as disruption of liver balance, hyperuricemia and major intolerance to anti-tuberculosis, were more frequent (36.6%) in patients diagnosed late (p = 0).

Conclusion: Despite highly sensitive imaging techniques, the diagnosis of tuberculous spondylodiscitis is often late, which may lead to severe deformity and early or late neurological complications.

AUTOLOGOUS MOSAIC OSTEONECROPLASTY IN THE TREATMENT OF TALAR OSTEOCHONDRAL DEFECTS

T. Omelchenko1, O. Burianov2, A. Liakab3, E. Levitsky1, O. Turchin1.
1Bogomolets National Medical University, Traumatology & Orthopaedics, Kyiv, Ukraine; 2State Institute "The Institute of Traumatology and Orthopedics of Ukraine", The Clinic for Foot Pathologies and Complex Prosthetic Treatment, Kyiv Ukraine

Background: Osteochondral defects of the talus (ODT) is a relatively rare, mostly traumatic pathology, in 6.5 % of cases complicates the course of inversion and evasion injuries of the foot and ankle [1].

Objectives: To conduct a clinical analysis of the effectiveness of autologous mosaic osteochondroplasty in the treatment of patients with osteochondral defects of the talus on the basis of determining the dynamics of pain and restoring the amplitude of ankle movements.

Methods: The study included 34 patients with post-traumatic osteochondral defects of the talus (27 men, 7 women, mean age 24.8 ± 2.1 years) who underwent osteochondroplasty. The duration of painful clinical symptoms before osteochondroplasty ranged from 4 to 18 months. Functional treatment outcomes were assessed over a period of 12 to 36 months using the International Foot and Ankle Surgery Scale (AOFAS), pain assessment was performed using the Visual Analog Scale (VAS), and ankle movement recovery dynamics were determined.

Results: Osteochondral autologic grafts were removed from the lateral condyle of the ipsilateral femur. Defect sizes: square from 82 to 129 mm² (110.3 ± 0.8 mm²), depth from 7 to 16 mm (12 ± 0.8 mm). Incorporation of the graft in the recipient bed occurred within 1,5 – 3 months. Long-term follow-up was 12 – 36 months (22.8 ± 3.8 months). The level of pain was decreased from 5.7 ± 0.3 before to 0.9 ± 0.3 after the operation (p < 0.001; paired t-test). Improving of foot function according to AOFAS scale (hindfoot section) was established from 64.9
ATTITUDES AND BELIEFS ABOUT LOW BACK PAIN OF TUNISIAN PATIENTS: A KEY PREDICTOR OF RECOVERY

A. Fazaa1, M. Ben Messaoud2, S. Miladi1, H. Bossaala1, L. Soubnii1, K. Ouenniche1, S. Kassab1, S. Chekili2, K. Ben Abdelghani1, A. Laatar1, 1Mongi Slim, Rheumatology, Tunis, Tunisia

Background: Low back pain (LBP) is a common problem related with significant disability and psychosocial dysfunction. Unhelpful beliefs about it are associated with higher levels of pain and may cause a delay in recovery due to unsuitable behaviours. Therefore, studies targeting these beliefs are necessary to modulate messages delivered to the population in order to decrease the burden of LBP.

Objectives: The aim of the present study was to assess the attitudes and beliefs in the management of patients with LBP.

Methods: We applied a cross sectional study including Tunisian patients with LBP. The Arabic version of Back Pain Attitudes Questionnaire (10-item Back-Paq) was used to evaluate back beliefs as a clinical screening tool. We analysed patients’ attitudes in 5 domains: vulnerability of the back (items 1 and 2), relationship between back pain and injury (items 3 and 4), activity participation during back pain (items 5 and 6), psychological influences on back pain (items 7 and 8), prognosis of back pain (items 9 and 10). For each item, the scale ranges from −2 (“True”) to +2 (“False”). Unhelpful beliefs attract negative scores and vice versa.

Results: The questionnaire was completed by 32 participants (27 women and 5 men) with a mean age of 56.6 years (45-69). The mean LBP’s duration was 9.1 years [2-28]. The mean Body Mass Index (BMI) was 29.4 [25.5-46.8]. The mean Schober’s Test and Fingertip-to-floor (FTF) were respectively 2.8 [1.5-4] and 13.2 [9-30]. The mean Visual Analogue Scale of pain (VAS pain) was estimated at 69 [40-100]. The mean Oswestry Disability Index (ODI) and Short form Health Survey (SF36) were 42.4 [28-66] and 48.3 [20-80] respectively. Unhelpful beliefs were widespread. The mean Back-Paq-10 score was −4 [-13 -3]. Women had significantly a lower score compared to men [-4.1 [-13 -2] versus -1.6 [-5 -3] (p<0.01). Vulnerability of the back had an average score of -2[3]-1. The relationship between back pain and injury had a mean score of -2.4 [-4 -0]. The activity participation during back pain had a mean score of -4 [-1-4]. The psychological influences and prognosis of back pain had an average score of -2 [-3-0] and -1.6 [-2] respectively.

Conclusion: The results of this survey reveal that Tunisian patients have high levels of negative beliefs about LBP. As beliefs and attitudes have been recognized as significant predictors of recovery from LBP, we should promote cognitive behavioural therapy aiming at coping with unhelpful beliefs.

Disclosure of Interests: None declared

MEDICAL CARE CONSUMPTION BY TUNISIAN DOCTORS SUFFERING FROM LOW BACK PAIN

A. Fazaa1, H. Bossaala1, S. Miladi1, K. Ouenniche1, L. Soubnii1, S. Kassab1, S. Chekili2, K. Ben Abdelghani1, A. Laatar1, 1Mongi Slim university hospital, Rheumatology, Tunis, Tunisia

Background: Common low back pain (LBP) is a real public health problem. Indeed, LBP is associated with important socio-professional consequences and involves a raised cost for society due to absenteeism and presenteeism. Various studies show that it is also a major problem in workplace especially in hospitals.

Objectives: The aim of this study was to evaluate LBP medical consequences among doctors.

Methods: We performed a cross-sectional study including the medical staff of a Tunisian hospital. A standardized questionnaire was distributed to all departments and collected the following day. Doctors who had not responded to the questionnaire received two reminders before considering their exclusion. We defined two groups: Group 1 with acute LBP (<3 months) and Group 2 with chronic LBP (>3 months). The following parameters were collected: consultation with a physician, self-medication, treatments used, hospitalization, use of imaging methods and objectified spinal abnormalities. A p value inferior to 0.05 was considered statistically significant.

Results: Of the 217 questionnaires distributed to physicians, 107 (49.3%) were completed. The participating doctors were 85 women and 22 men. The mean age was 31.8 ± 7.7 years [25-57]. The mean BMI was 23.2±3.7 kg/m² [16.6-36.7]. Consumption of tobacco and alcohol was noted in 16.7% and 20.4% of cases respectively. Five participants (4.6%) reported consumption of cannabinoids. Depression, anxiety and sleep disturbances were reported in 25.3%, 57.3% and 46.7% of cases respectively. Among the participants, 84.3% reported having had LBP at least once in their life, and 71.3% reported LBP in the past 12 months. The mean duration of low back pain was greater than 3 months in 11.9% of cases. The mean pain intensity was 4.4 ± 1.9 [2-10]. Twenty participants (26%) consulted a doctor. It was a rheumatologist in 13 cases, an orthopedist in 7 cases, a neurosurgeon in 1 case and a family doctor in 1 case. More than half of the participants (57.5%) self-medicated. Standard radiography was performed in 18 cases, computed tomography (CT) in 5 cases and magnetic resonance imaging (MRI) in 8 cases. The following abnormalities were objectified: degenerative disc disease (13.6%), herniated disc (22.7%) and posterior inter-apophyseal osteoarthrits (9%). Medication use was noted in 56 cases (72.7%), functional rehabilitation in 9 cases (11.7%), back support belt in 3 cases (3.9%), epidural corticosteroid injection in 1 case (1.3%), thermal treatment in 1 case (1.3%), and surgery in 1 case (1.3%). Three doctors required hospitalization ranging from 2 to 15 days. Medical care consumption was significantly more important in patients with chronic LBP: functional rehabilitation (66.8% in group 1 vs 50% in group 2, p<0.001), back support belt (16.6% vs 20%, p=0.046), epidural corticosteroid injection (0% vs 10%, p=0.035), thermal treatment (0% vs 10%, p=0.035), surgery (0% vs 10%, p=0.035) and hospitalization (0% vs 30%, p=0.001).

Conclusion: Medical care consumption was important among LBP and chronic LBP sufferers. Thus, a prevention strategy must be established in hospitals in order to reduce the socio-economic cost of LBP among caregivers.

Disclosure of Interests: None declared

patients (9 cases) had a biological inflammatory syndrome, 36.36% (4 cases) had impaired protein electrophoresis (hyper-gamma peak) and 27.27% (3 cases) had hypercalcemia. Recourse to CT or lumbar MRI made it possible to objectively tumor bone lesions in 72.72% (8 cases) of patients, of which 3 cases (37.5%) were of prostatic origin, 2 cases (18.18%) multiple myeloma, one case of small cell carcinoma, one case of squamous cell carcinoma and one case of bladder tumor. For the other three patients (27.27% of cases), LS was caused by infectious spondylodiscitis in the lumbar stages.

Conclusion: As evidenced by our study, secondary sciatica is a very rare clinical situation, more encountered in the elderly with often an alteration of the general condition. But in front of its seriousness and its functional repercussions, arises the need to eliminate it systematically whatever the ground before starting the treatment.

AB1230  EVALUATION OF THE STRUCTURAL MODIFICATION OF THE SUPRASPINATUS TENDON BY COMPUTER ANALYSIS OF ULTRASOUND IMAGES THROUGHOUT THE EVOLUTION OF TENDINOSIS.

M. Tortosa-Cabañas1, C. Guillén-Astete1, Á. Andreu-Suárez1, 1Hospital Ramón y Cajal, Rheumatology, Madrid, Spain

Background: In subacromial pain syndrome, the supraspinatus tendon is the most frequently injured. Supraspinatus tendinosis is a structural lesion of the tendon stroma whose ultrasound diagnosis depends largely on the observer. Due to this, the follow-up is mainly clinical, based on ordinal scales of pain or mobility. The computer analysis of the image has been recently integrated into the musculoskeletal pathology, but the evidence in ultrasound is very limited.

Objectives: To evaluate the computer analysis of the ultrasound image of the supraspinatus tendon at diagnosis and during evolution depending on the treatment administered.

Methods: A retrospective study was carried out based on the ultrasound records of patients diagnosed with supraspinatus tendinosis between 2014 and 2020. All images were obtained with the same ultrasound equipment. The records had to fulfill the following characteristics: (i) Absence of direct or indirect ultrasound signs of fibrillar continuity solution, (ii) absence of calcifying lesions and (iii) availability of an ultrasound study 5-7 months after diagnosis with the same frequency, gain, and depth parameters for each case. The ultrasound images showing tendinosis were analyzed using the ImageJ 1.53e program. The means and modes of the grayscale signal intensities were determined in longitudinal and transverse projection for each image. For the statistical analysis, paired before-after comparisons based on the normal distribution were used, grouping the patients according to the injured tendon area (lateral, central, medial) and the treatment administered. To determine the weight of the variables analyzed in the probability of resolution, a forward modeled binary logistic regression was performed using the Wald method.

Results: Records of 35 patients were included: 10 treated with immobilization, 12 with corticosteroid injections and 13 with physical therapy. Table 1 summarizes the demographic and clinical characteristics of the population. The changes observed in the mean gray intensity in the longitudinal projection of the tendon did not correlate with the fact that the patients were discharged (9.268 SD 3.752) or not (-0.2054 SD 5.262), (t=6.162, P<0.000). On the other hand, in the group of patients discharged, a greater reduction was observed in the dispersion of the mean gray intensities (-11.08 SD 5.843) compared to the group that was not discharged (1.178 SD 1.859), (t=8.458, P=0.000). In the multivariate logistic regression analysis, only the final dispersion of gray intensity was associated with the discharge condition with Coef. B=0.096, P=0.027, HR 0.908 (95% CI: 0.834-0.989).

Conclusion: Computer analysis of ultrasound images of the supraspinatus tendon in patients with pure structural tendinosis distinguishes a favorable clinical course only in the study of the cross-sectional projection, probably due to the more flattened shape of the tendon. Clinical resolution, understood as medical discharge after the second evaluation, is associated with an increase in the mean intensity of grays but especially with a reduction in the dispersion of grays.

Disclosure of Interests: None declared.

AB1231  ULTRASOUND-GUIDED INJECTION OF LOW MOLECULAR WEIGHT HYALURONIC ACID VERSUS STEROID FOR INFLAMMATORY AND DEGENERATIVE SACROILIITIS: A RANDOMIZED CONTROLLED TRIAL

K. Hosny1, M. I. Abdelkareem1, A. Moshrif1, 1Al-Azhar University, Rheumatology, Assiut, Egypt

Background: Sacroilitis may be degenerative (DSI) or inflammatory (ISI) and the latter is one of the clinical features of spondylarthropathies.

Objectives: To determine the effect of hyaluronic acid versus corticosteroid injection for chronic sacroiliac joint arthropathy.

Methods: Forty patients with sacroilitis either degenerative (DSI: 20 patients) or inflammatory (ISI: 20 patients) based on the New York criteria. Each group was allocated into 2 subgroups; 10 patients received 2ml Betamethasone dipropionate plus 2 ml lidocaine 2% (A) and 10 patients received 2 ml hyaluronic acid plus 2 ml lidocaine 2% (B). All sacroiliac joint injections were done under ultrasonographic guidance using a 22-gauge needle. Visual analogue scale was used for pain assessment at base line, 1, 2 and 4 week post injection.

Results: There was no significant difference between main groups (ISI & DSI) regarding VAS score before injection, 1, 2 and 4 weeks after injection while there was a significant difference between subgroups A&B in ISI group at 2 and 4 weeks (P= 0.012 and 0.008 respectively). Also, there was a significant difference between subgroups A & B in DSI group at 1, 2 and 4 weeks after injection (P=0.04, 0.006, and 0.005 respectively). There was a high significant difference before and after injection in the main groups and all subgroups. However, there was no significant difference between the subgroups of ISI and DSI.

Conclusion: Both steroid and hyaluronic acid were effective in relieving pain in treatment of inflammatory and degenerative sacroilitis but steroid was more efficacious than the hyaluronic acid.

Disclosure of Interests: None declared.

Table 1. Demographic and clinical characteristics of the population. GI: gray intensity according to longitudinal or transverse axis. SD: standard deviation.

RELATIONSHIP BETWEEN NEW BIOMARKER (IL18 AND IFN GAMMA) WITH DISEASE ACTIVITY SCORES (DAS28 ESR AND DAS28 CRP) IN JUVENILE IDIOPATHIC ARTHRITIS (JIA)

M. Besar1, A. Abd El Salam2 on behalf of prof. Dr. Dina Abd El Halim Shahin
Professor of Internal Medicine (Rheumatology & Immunology Unit) Faculty of Medicine, Mansoura University. 1Faculty of Medicine, Mansoura University, 2Rheumatology, Immunology, Internal Medicine, Mansoura, Egypt

**Background:** Juvenile idiopathic arthritis (JIA) is a chronic inflammatory condition lasting ≥6 weeks in children ≤16-year-old and characterized by pro-inflammatory cytokines (IL1B, IL6, IL18, and IFN- gamma) as a key cytokine in inflammation. The pathogenesis of JIA are still poorly understood and different theories are implicated. Different disease activity scores aimed at guiding the treatment strategies.

**Objectives:** Correlation between new biomarker (IL18 and IFN gamma) with disease activity scores (DAS28 ESR and DAS28 CRP) and how much these biomarkers change with treatment.

**Methods:** Prospective nonrandomized study carried on 45 child diagnosed as Juvenile Idiopathic Arthritis (JIA) fulfilling (ILAR)1997 where assessment of the level of IL18, IFN gamma and IL18, IFN-gamma decrement with correlation to disease activity (Juvenile Arthritis Disease Activity Score (JADAS)) and their role as prognostic markers.

**Results:**
- Serum IL18 and IFN gamma show significant decrease with the end of the study (Figure 1).
- The disease activity (JADAS ESR), (JADAS CRP) has decreased significantly with the end of the study (Table 1).
- Serum IL18 show negative correlation with ESR, CRP, JDA571ESR, JDA571CRP and IFN gamma level.
- Poor response groups show higher level of ESR, JADAS18 and IL18 than good response groups. IL18 and IFN-gamma decrement level was statistically significant higher in good response than poor response.

**Conclusion:** IL18 and IFN-gamma cytokine and level of decrement are a useful biomarker in predicking the disease activity and response to therapy.

**AB1233**
CHARACTERISTICS OF Pediatric MPO and PR-3 ANCA ASSOCIATED VASCULITIS- SINGLE CENTER EXPERIENCE FROM CENTRAL CALIFORNIA

D. Singh1, S. Sukesh1, 1 Valley Children’s Healthcare, Division of Rheumatology, Madera, United States of America

**Background:** ANCA-associated vasculitides (AAV) are rare in childhood and characterized by necrotizing inflammation in small to medium sized vessels. Most of the available literature in children focuses on clinical subtypes Granulomatosis with Polyangiitis (GPA), Microscopic Polyangiitis (MPA), and Eosinophilic Granulomatosis with Polyangiitis (EGPA). Adult studies have demonstrated differences in clinical outcomes based on myeloperoxidase (MPO) and proteinase 3 (PR3) ANCA specificity (1). There is limited information about the characteristics of MPO- AAV and PR3-AAV in children.

**Objectives:** The objective of this study was to review the characteristics of MPO-AAV and PR3-AAV at a children’s hospital in multi-ethnic Central California, United States.

**Methods:** We performed a retrospective case review of patients less than 18 years of age diagnosed with AAV at a tertiary care children’s hospital in Central California in United States from January 1, 2010 to March 31, 2021. Cases were identified from electronic health records using ICD-9 and ICD-10 codes for vasculitis. Records were reviewed for a diagnosis of AAV based on ACR/ EULAR classification criteria. Demographic and clinical data including laboratory parameters including ANCA specificity, treatment, and outcomes were collected. Continuous data were expressed as a median and interquartile range, categorical data as frequency and percentages. Chi-square and Mann-Whitney U tests were used for statistical comparison as appropriate.

**Results:** Eighteen cases of pediatric AAV were identified, of which 10 (55.5%) patients had MPO-AAV and 8 (44.4%) had PR3-AAV. All patients who were MPO positive were diagnosed with GPA. Among PR3-AAV cohort, 7 patients were diagnosed with GPA and 1 patient received diagnosis of MPA. The median age at diagnosis was 12.6 years (IQR 10.1-15.4) in patients with MPO-AAV and 14.8 years (13.8-16.7) in children with PR3-AAV. In MPO-AAV cohort, 90% (n=9) were female, meanwhile 37.5% (n=3) of patients diagnosed with PR3- AA V were female (p=0.02). Significantly higher proportion of patients diagnosed with MPO-AAV were from racial and ethnic minority groups (n=10, 100%) which included Hispanic (8), Asian (1) and other (1). In comparison, patients with PR3-AAV were predominantly white (n= 7, 87.5%; p < 0.01). Median length of hospital stay was 19 days (IQR=12.8-21) in patients with MPO-AAV and 14 days (IQR=9.5-21.8) in patients with PR3-AAV. Rate of ICU admission was 60% in MPO-AAV cohort and 37.5% in PR-3 cohort, although this was not statistically significant. 50% (n=5) of patients in MPO-AAV cohort required dialysis and 25% (n=2) in PR3- AAV cohort. Peak creatinine was higher in MPO-AAV cohort (74, IQR 1-13.4 versus 2, IQR 0.7-3.7 mg/dL), although it did not reach statistical significance (p=0.1), PR3-AAV group had significantly higher levels of C-reactive protein (22.9, IQR=7-0.26.3) compared to MPO-AAV cohort (2,25, IQR=0.3-6.2; P=0.02). ENT involvement was more frequent in PR3-AAV cohort (87.5% versus 10%), All patients received treatment with high dose corticosteroids at diagnosis. Other immunosuppressive therapy included cyclophosphamide (40% in MPO-AAV cohort and 75% in PR-3 AAV cohort), rituximab (40% MPO- AAV cohort and 0% in PR-3 AAV cohort), cyclophosphamide and rituximab (10% in MPO- AAV cohort and 25% in PR-3 AAV cohort). Two deaths were reported in MPO-AAV cohort, related to Aspergillus pneumonia and pulmonary hemorrhage.

**Conclusion:** Our study reviews characteristics of pediatric MPO-AAV and PR3- AAV in the Central California of United States. We observed a more frequent diagnosis of MPO-AAV in racial/ethnic minority children. Limitations of our study include small sample size. This study highlights the need for further research to understand the impact of ethnicity and MPO and PR3 positivity on pediatric AAV presentation, disease activity and outcomes.

**DOI:** 10.1136/annrheumdis-2022-eular.797
An oncological search was carried out. The following diagnoses were verified: stage 4 neuroblastoma (4/15), acute lymphoblastic leukemia (5/15), stage 4 B-large cell lymphosarcoma (1/15), stage 4 B-lymphoblastic lymphoma/leukemia (1/15), T-cell lymphoma (1/15), stage 3 glioma (1/15), malignant histiocytoma (1/15), brain tumor (1/15).

Conclusion: Oncological diseases in children can occur under the guise of rheumatic diseases. Immunosuppressants and glucocorticoids mask the true clinical picture of the neoplasm and prevent early diagnosis.

MULTISYSTEM INFLAMMATORY DISEASE IN CHILDREN (MIS-C) IN SINGAPORE: ARE WE DIFFERENT?

L. Das1, K. L. Teh1, X. Gao1, T. Arkachaisri1,2; 1KK Women's and Children's Hospital, Rheumatology and Immunology, Singapore, Singapore; 2Duke-NUS Medical School, Rheumatology and Immunology, Singapore, Singapore

**Background:** Multisystem Inflammatory Syndrome in Children (MIS-C) is a hyper-inflammatory state with similarities to Kawasaki Disease, 4 to 6 weeks after Covid-19 infection1. Literature describes a 11:1 Relative Risk for Asian children versus Caucasians2. Since the start of the pandemic, 17,699 children under 12 years were infected with Covid-193.

**Objectives:** To describe presentation and short term outcomes, for a cohort of children with MIS-C at the sole Children's Hospital in Singapore.

**Methods:** Demographic and clinical/lab data were collected from children diagnosed with MIS-C according to the WHO criteria4 at KK Woman's and Children's Hospital, Singapore. Nonparametric descriptive statistics were used to describe and analyse data.

**Results:** Eleven patients were diagnosed with MIS-C between October 2021 and Jan 2022. Seven (64%) were male and 4 (36%) were Chinese, with median age at presentation was 8.08 years (IQR 4.54 - 9.79). All patients had positive COVID-19 serology at the time of diagnosis. Median duration of fever prior to diagnosis was 5 days (IQR 4 - 5); Nine (82%) had gastrointestinal symptoms and median number of Kawasaki Disease (KD) features were 2 (IQR 2 - 3.5); common manifestations were conjunctivitis (90%), red lips (55%) and rash (36%). Of note, 5 (70%) patients had KD type peeling on follow-up. No BCgitis was found during acute phase. Seven (64%) were admitted to higher dependency care. Table 1, all patient received IVIG and IV steroids; 6 (55%) as pulse (30mg/kg/day) therapy. Patient 8, additionally received Anakinra. Median duration of admission was 6 days (IQR 5-13). One patient developed complications post therapy and was re-admitted to hospital for hematoma chezia. Treatment involved stopping Enoxaparin and Prednisone. Aspirin was resumed as soon as bleeding ceased. Laboratory characteristics and outcomes are denoted in Table 1. All patients had a monophasic course during the median of 10 weeks (IQR 8 - 11.5) of follow-up.

**Conclusion:** Asian prevalence of MIS-C is not as high as that reported from Western. Similarities in presentation as to age and gender were noted. 2. Most of our MIS-C patients developed periungual peeling at follow up, similarly to Kawasaki Disease.

3. Different from our typical KD population, no BCG site inflammation was found.

Results: We extracted data of 187 JSSc patients from the JSScC and 236 patients from EUSTAR. The mean age at time of assessment was 13.4 years old in the JSScC and 32.4 years old in EUSTAR. The mean disease duration since first non-Raynaud was 3.0 years in JSScC and 18.5 years in the EUSTAR (Table 1). We found significant differences between the cohorts. There were more female patients in EUSTAR (87.7% versus 80.2%, p=0.04). More patients had diffuse subtype in JSScC (72.2% versus 40%, p<0.001). The modified Rodnan skin score (mRSS) was significantly higher in JSScC (14.2 versus 12.1, p=0.02). Active digital ulceration occurred more often in EUSTAR (26.6%, versus 17.8%; p=0.01), but history of active ulceration was more frequent in JSScC (54.1% versus 43%, p<0.001). Mean DLCO was lower in JSScC (75.4 versus 86.3, p<0.001). Intestinal involvement was significantly more common in JSScC (33.2% versus 23.8%, p=0.04). Esophageal involvement was more common in EUSTAR (63.7% versus 37.7%, p<0.001) (Table 1).

</tr>
</tbody>
</table>

Conclusion: Patients with JSSc-onset who are currently adult age (defined as >18 years of age) are less frequently male and from the diffuse subset, have lower mRSS, less digital ulcers and intestinal involvement. This might represent a combination of both survival bias and/or be explained by the longer observation time with less active disease (i.e. natural progression decreased mRSS over time). Further long-term observational studies with JSSc patients are required to address this issue.

b: regression coefficient; p, statistical significance.

Conclusion: There are no differences between EIA and CLIA methods to determine SC in pediatric patients with SARD. Significant differences were observed between both methods above the value of 4 µg/ml. This fact could be explained by methodological differences, since CLIA discriminates better at higher values than EIA.
An association was observed between both methods and variables of remission or disease activity.

**AB1238**
THE EFFECT OF DRUG THERAPY IN JUVENILE IDIOPATHIC ARTHRITIS ON THE LEVEL OF CYSTATIN C AS A MARKER OF RENAL Dysfunction

S. Samsonenko1, T. Borosova1,2. Dnipro State Medical University, Department of Pediatrics 2, Dnipro, Ukraine

**Background:** Juvenile idiopathic arthritis (JIA) is a chronic disease requiring years of therapy with non-steroidal anti-inflammatory drugs (NSAIDs), immunosuppressants, cytostatics, and immunobiological agents. The aforementioned drugs, namely NSAIDs and cytostatics are potentially nephrotoxic [1]. The above drugs, namely NSAIDs and cytostatics, are potentially nephrotoxic. About 8% of children with JIA have kidney damage, which develops on average 5 years after the onset of the disease. It has been established that the main risk factor for the development of kidney damage is the long-term exposure to NSAIDs and methotrexate in children with active forms of JIA [2]. Early diagnosis of kidney damage will allow timely correction in the dosage of drugs and avoid their nephrotoxic effects [3].

**Objectives:** To determine the effect of drug therapy in children with JIA on eGFR by using the Cystatin C-based equation and the Hoek formula based on the serum cystatin C study.

**Methods:** 80 children with JIA participated in the study. The age of subjects was 10.4±4.41 (10.6-15.0) years. All children received methotrexate as a base drug. At the moment of examination 22 children received NSAIDs, 25 children received immunological preparations. Serum cystatin C content was determined by enzyme immunoassay. The Cystatin C-based equation 2012 and Hoek formulas were used to set the GFR by serum cystatin C levels.

**Results:** Non-steroidal anti-inflammatory drugs led to a decrease in GFR as found by both the Cystatin C-based equation 2012 and the Hoek formula. The incidence of GFR reduction in patients treated with NSAIDs using the Cystatin C-based equation 2012 was 100%, and using the Hoek formula was 81.8%. The use of NSAIDs in children with JIA is a risk factor for the development of reduced GFR calculated by the Hoek formula. The incidence of reduced GFR in children with NSAID use was 54.5%, 6.7 times greater than in those without NSAIDs (OR = 12.9; CI: 3.76-44.25; p<0.001). There was a low chance of a Hoek formula decrease in GFR in children with JIA who received immunobiological therapy 9.1% vs 46.8% (OR = 0.11; CI: 0.03-0.42; p<0.001).

**Conclusion:** Use of NSAIDs in children with JIA was more often associated with a reduction in GFR by Cystatin C-based equation 2012 in 100% of cases p<0.01, by Hoek in 81.8%, p<0.001. The average of GFR was significantly lower in children treated with NSAIDs than in children without NSAIDs. Immunobiological therapy had a positive effect on the GFR value. The frequency of a decrease in GFR was significantly lower in children treated with immunobiological therapy compared with those without immunobiological therapy 9.1% vs 46.8% (OR = 0.11; CI: 0.03-0.42; p<0.001).

PROSPECTIVE EVALUATION OF COGNITIVE FUNCTION IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

E. Ortiz-Márquez1, C. Padilla-Leiva2, P. Cabezudo-García2, G. Díaz-Cordobes1, L. Muñoz-Becerra2, N. Mena-Vázquez2, 1Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga, UGC de Reumatología, Málaga, Spain; 2Universidad de Málaga, Departamento de Medicina, Málaga, Spain; 1Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Regional Universitario de Málaga, UGC de Neurociencias, Málaga, Spain

**Objectives:** Prospectively evaluate changes in the cognitive function of patients with juvenile idiopathic arthritis (JIA) and associated factors.

**Methods:** Design and protocol: We performed a prospective cohort study with JIA patients that participated in a previous cross-sectional study (2019) to evaluate cognitive function. After 24 months, the patients were administered the same test battery previously used through an established protocol, and data was collected from their clinical histories. The neuropsychological tests were corrected by a neuropsychologist and neuropsychologist. Study population: Inclusion criteria: Patients aged ≥16 years with JIA classified according to the criteria of ILAR 2001. Patients with inflammatory or rheumatic diseases other than JIA, previous neurological disease not associated with the course of JIA, patients that participated in a previous cross-sectional study (2019) to evaluate cognitive function; and patients with scores lower than the normal in the manual skill test were excluded. Outcomes: The main variable was cognitive impairment, defined as worsening of ≥2 scaled points after 24 months (2024) in any of the tests used to evaluate each cognitive area in the Wechsler Adult Intelligence Scale (WAIS). The evaluated cognitive domains and their respective subscores were: Attention-concentration (Digit Span); verbal function (Vocabulario); processing speed (Organization - Block Design); working memory (Letter-Number Sequencing); problem-solving (Similarities). Depression was evaluated by The Beck Depression Inventory-II (BDI-II): minimal (0-13), mild (14-19), moderate (20-28), and severe (29-63). Other variables: Clinical-epidemiological characteristics; treatments; and inflammatory activity evaluated as the C-reactive protein average (CRP) and JADAS-27 along the 2 years of follow-up. Statistical analysis: Descriptive analysis, followed by y2 and paired T-test. Multivariate analysis to identify independent variables associated with impairment of cognitive function in JIA.
Results: Thirty patients with JIA were included. The clinical characteristics in V24 are shown in Table 1. Thirteen patients (43%) showed improvement in one or more cognitive functions. The most frequent impaired cognitive functions were verbal function (13.3%), visuospatial organization (13.3%) and problem solving (13.3%); followed by attention/concentration (10.0%) and working memory (6.7%). The variables independently associated with cognitive impairment were the mean CRP along the follow-up (OR [IC 95%], 1.010 [0.670-1.500]; p=0.48) and depression (OR [IC 95%], 1.358 [1.028-1.794]; p=0.031). This model would explain the 47% of the cognitive impairment in JIA (RZ²=0.470).

Objectives: BMD and osteopenia are lacking in younger patients with the disease. Osteoporosis is common in postmenopausal women with MCTD (1), but data regarding 25% of all cases have a pediatric presentation. One study implies that osteopenia.

Methods: BMD was measured in a cohort of 52 JMCTD patients with mean age 28.2 years (SD 10.3) and mean disease duration 16.2 years (SD 10.3), and 52 controls matched for age and gender. Inclusion criteria were fulfillment of the Kasukawa’s or the Aracan-Segovia criteria and symptom debut before the age of 18 years.

Results: Patients and controls did not differ in age, body mass index, smoking habits, level of physical activity or vitamin D status (Table 1). Forty-four (85%) were female. Patients were shorter and had lower body weight compared to controls. None had had osteoporotic fractures. Patients over 20 years of age at height, cm 166.0 (7.5) 170.1 (8.5) 0.016

Conclusion: Forty percent of the patients with JIA showed cognitive impairment after 24 months of follow-up. Cognitive impairment was associated with higher inflammatory activity and depression.

Disclosure of Interests: None declared

AB1243
EFFICACY OF ABATACEPT IN THE TREATMENT OF JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATED UVEITIS
P. Rodríguez González1, D. Fernández Fernández2, I. González Fernandez3, R. Dos-Santos2, P. Castro-Santamaría2, M. Sanchez-Wonenburger2, J. L. Puga Guzmán1, A. Mata1, A. Souto Vilas4, E. Perez-Pampín5, A. Mera Varela2.

1Universidad de Medalla (USC), Medicine, Santiago de Compostela, Spain; 2Santiago Clinic Hospital CHUS, Rheumatology, Santiago de Compostela, Spain

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in pediatric age. uveitis is the most frequent extra-articular complication (1). Uveitis, if not properly treated, can lead to potentially irreversible ocular complications such as blindness. The treatment of uveitis associated with JIA (U-JIA) remains a challenge due to the aggressiveness of the disease and the frequency of complications. Following the current guidelines for screening and treatment of uveitis, the use of topical and systemic corticosteroids, Methotrexate, cyclosporine or some biological drugs such as Adalimumab constitute the mainstay of treatment in this manifestation. In some refractory cases, the use of Abatacept has been reported

Objectives: To analyze the efficacy of Abatacept in the treatment of U-JIA from the data available in the scientific literature.

Methods: We performed a systematic review of the scientific literature, following the PRISMA statement, using the following electronic databases: Medline, Embase, Cochrane Library and Web of Science.

Results: An overall of 89 bibliographic references fulfill the inclusion criteria. A total of 64 patients from 6 studies were followed for a mean time per patient of 11.5 months. The mean age of onset of JIA was 5.25 years, with a time of evolution of the disease of 7 and 11.85 years. In all the series included, a high percentage of patients showed complications secondary to ocular inflammation (synechia, band keratopathy, cataracts, macular cystic edema and/or ocular hypertension) as well as visual deficits secondary to JIA-U.

All patients, have shown refractoriness to conventional DMARDs, as well as anti-TNF biological drugs. In all the studies, the best correct visual activity (BCVA) is used as main outcome measure. Another outcome measures were used: number of uveitis flares, the erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), or the number of cells present in the anterior eye chamber.

Four series of cases showed an improvement or stabilization of visual acuity after Abatacept treatment. Two studies provided variations in visual acuity that are not statistically significant.

Regarding the efficacy of Abatacept, we can observe improvement, in the most of the studies we observed a decrease in the severity of the ocular inflammation and/or its complete remission.

Due to the lack of comparable data, a meta-analysis could not be performed. However the data suggest a clear recovery of 1 JIA-U patients refractory to conventional treatment.

Conclusion: Abatacept is shown as a promising drug in the treatment of U-JIA, considering its efficacy in improving visual acuity, as well as in the control of flare-ups and the decrease in inflammatory eye symptoms. However, more studies are necessary to corroborate the efficacy of Abatacept

TOTAL KNEE ARTHROPLASTY IN PATIENTS UNDER 21 YEARS OF AGE: A U.S. NATIONALWIDE ANALYSIS
J. A. Gibbons1, C. Kahlenberg2, D. Jannatt-Khah1, S. Goodman1, P. Sculco2, M. Figgie3, B. Mehta4,5, Hospital for Special Surgery Main Hospital, Medicine, New York, United States of America; 4Hospital for Special Surgery Main Hospital, Surgery, New York, United States of America; 5Weill Cornell Medicine, Medicine, New York, United States of America

Background: Total knee arthroplasty (TKA) is a procedure rarely performed in patients under 21 years old. However, the number of patients <21 undergoing TKA in the United States is unknown. In one of the largest US studies of an institutional arthroplasty registry, only 19 TKAs were performed in patients <21 out of ~30,000 primary TKAs over 34 years. While a few national or multi-national studies have been performed outside the US, these studies have small cohorts (~100), making it difficult to determine the indications for TKA in this age group.

Objectives: We identified the number of patients <21 years of age who underwent TKA in a US nationwide dataset. Additionally, we determined the epidemiological characteristics of patients undergoing TKA, including their age, sex, race, indications for surgery, and in-hospital mortality.

Methods: We analyzed the Kids’ Inpatient Database, which is a national weighted sample of all inpatient hospital admissions in the US in patients <21 years old from ~4,200 hospitals in 46 states. We included all admissions from 2000-2016 with a primary procedural code of TKA determined by ICD-9 and 10 codes. Descriptive statistics such as means and percentages, along with 95% confidence intervals were calculated using appropriate sample weights.

Results: The total number of TKAs performed in patients <21 years old from 2000 to 2016 was 1,331 (Table 1). The majority of TKAs performed (n=936; 70.3%) were for treatment of an oncologic disease. The most common diagnosis was malignant tumor (68.7%), followed by osteoarthritis (7.3%) and inflammatory arthritis or juvenile idiopathic arthritis (JIA) (70%) (Figure 1). Osteonecrosis accounted for 3.9% of cases, while mechanical complications accounted for 3.3%. Fewer than 2% of cases had an indication of either benign or uncertain tumor, infection, or trauma. The mean age was 14.8 years, and 48.4% of the cohort was female. A higher proportion of the non-tumor cohort was female (57.1%) than the tumor cohort (44.7%). 57.1% of patients in the overall cohort were White, and this proportion was smaller in the tumor group (53.8%) than the non-tumor group (64.9%). No patients died during the inpatient event. 87.8% of TKAs were performed in urban teaching hospitals.

Total Knee Arthroplasty in Patients Under 21 Years of Age: A U.S. Nationwide Analysis
J. A. Gibbons1, C. Kahlenberg2, D. Jannatt-Khah1, S. Goodman1, P. Sculco2, M. Figgie3, B. Mehta4,5
Conclusion: TKA is a rarely-performed procedure for patients <21 years old in the US; it is mainly performed in urban teaching centers and has excellent in-hospital survival rates. 70.3% of these procedures are performed for tumors—the vast majority of which are malignant. Also, even with the advent of better treatment options for JIA and inflammatory arthritis, TKA is still performed frequently in this population indicating that better clinical management is needed.

**AB1247** ASSESSMENT OF ARTICULAR AND EXTRA-ARTICULAR DAMAGE IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

A. Fazaï1, N. Ben Saled1, S. Miladi1, H. Bousassa1, L. Souabni1, K. Gueniche1, S. Chekili1, S. Kassab1, K. Ben Abdelghani1, A. Lataire1. 1Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia

**Background:** Juvenile idiopathic arthritis (JIA) affects patients’ well-being and can lead to disability and long-term damage. Evaluating damage in patients can be beneficial to make therapeutic decisions and take rehabilitation measures.

**Objectives:** To assess articualr and extra articular damage in patients with JIA by the use of the Juvenile Arthritis Damage Index (JADI) and to identify variables that correlate with disease damage.

**Methods:** We conducted a cross-sectional study among patients with JIA who met the ILAR classification criteria and had a disease duration more than 12 months. Early clinical data was obtained from medical files. It included socio-demographic features, biological and radiological parameters, subtype of JIA, disease duration and ongoing treatments. Damage was assessed in the last clinical visit using articualr and extra-articular damage index (JADI-A and JADI-E).

**Results:** Thirty-two patients were enrolled in this study with a mean age of 23.8 ± 11.6 years. Sex ratio was 0.6 (12 males and 20 females). The mean age of disease onset was 8.3 years [3-15], and the mean disease duration was 183.7 months [12-624]. At the last clinical examination, 71.9% of patients had joint damage with a mean JADI-A score of 5.09 ± 5.4 and 40.6% of patients had extra-articular damage with a mean JADI-E score of 0.75 ± 1.2. The most affected joints were: the elbows (43.8%), the hips (37.5%) and the wrists (25%). Extra articular damage was mainly: a growth failure (25%), osteoporosis (18.8%) and ocular damage (12.5%). Patients with polyarticular arthritis without rheumatoid factor had the highest JADI-A score with a mean of 7.83 while patients with systemic arthritis had the highest JADI-E score with a mean of 3. Mean JADI-A score was significantly different between patients who received corticosteroids and those who did not receive them (8.5 Versus 3.4, p=0.004). Damage scores correlated with disease duration (p<0.001 for JADI-A score and p=0.034 for JADI-E score). Damage scores were not significantly different between different classes of treatment (conventional dmards and biologic dmards).

**Conclusion:** Articular damage is frequent in patients with JIA. It is higher for patients on corticosteroids. Articular and extra articular damage correlate with disease duration, but they were not significantly different between classes of treatment.

**AB1248** CONTRIBUTION OF IMAGING IN THE DIAGNOSIS OF ATRAUMATIC HIP

M. Yasmine1, H. Ferjani1, F. Taboubi1, W. Triki1, D. Ben Nessib1, K. Maatallah1, D. Kaffel1, W. Hamdi1. 1Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia

**Background:** Joint pain of the hip in children and adolescents is one of the most frequent symptoms seen by pediatricians, orthopedists, and pediatric rheumatologists, with an annual incidence of 148.1/100 000 [1]. The identification of an enthesitis-related arthritis (ERA) is crucial for the management of this condition; however, identifying enthesitis-related arthritis remains challenging. The aim of this study is to assess the contribution of different imaging modalities in an atraumatic hip diagnosis.

**Objectives:** To assess the safety and efficacy of tofacitinib in juvenile idiopathic arthritis.

**Methods:** We conducted a cross-sectional study including children with JIA according to the International League of Associations for Rheumatology (ILAR). Transcribed data included age, sex and the characteristics of the disease (subtype of JIA, disease duration). Data on hip involvement was also collected. Weight and height of each patient were recorded. The body mass index (BMI) was calculated (Kg/m²). We compared these parameters between two groups: G1: presence of coxitis and G2: absence of coxitis.

**Results:** The study included 62 patients with a male predominance: sex ratio = 2.3. The mean age of onset of the disease was 11.4 years [3-16]. The frequency of each JIA subset was at follows: polyarticular with rheumatoid factor (n=2), polyarticular without rheumatoid factor (n=4), systemic (n=1), enthesitis-related arthritis (n=44), oligoarthritis (n=8), psoriatic arthritis (n=3). Hip involvement was reported in 71 % of cases and was bilateral in 81% of patients. The mean weight (Kg) and height (meter) was similar between the two groups (57.4 in G1 vs 53.6 in G2, p=0.486) and (1.61 in G1 vs 1.58 in G2, p=0.483) respectively. The prevalence of overweight patients was higher in G1 than G2 without reaching a statistically significant correlation (23% vs 12.5%, p=0.518). Similarly, there was no statistically significant correlation between the body mass index (Kg/m²) and coxitis (22.2 vs 21, p=0.45). Moreover, a higher BMI was not associated with a limited range of motion as well as hip replacement (p=0.7, p=0.1 respectively).

**Conclusion:** Our study showed that BMI did not impact hip involvement in juvenile idiopathic arthritis patients. As obesity concerns a additional health risk, addressing this co-morbidity should be a health priority in these patients.

**AB1250** TOFACITINIB IS A SAFE AND EFFECTIVE TREATMENT OPTION FOR JUVENILE IDIOPATHIC ARTHRITIS

N. Prabu1, V. Petzioapper2, G. Anand1, S. Ram1, A. Kumar1, S. Sakhti1. 1Sakthi Rheumatology Centre Pvt Ltd, Rheumatology, Coimbatore, India; 2PSG Institute of Medical Sciences & Research, General Medicine, Coimbatore, India

**Background:** The management of juvenile idiopathic arthritis(JIA) is often constrained by the limited number of oral drugs available. Whether JAK inhibitors would add a much needed therapeutic armamentarium in this regard needs to be explored.

**Objectives:** To assess the safety and efficacy of tofacitinib in juvenile idiopathic arthritis (JIA) patient who were prescribed during the period January 2021 to December 2021.

**Methods:** It's a retrospective study of JIA patients who were prescribed tofacitinib during the period Jan 21 to Dec 21 with minimum of 3 months' follow-up after prescribing tofacitinib. The demographics,details of medications,investigations parameters and any adverse events were noted.
Results: There were a total of 35 patients who were given tofacitinib during this period. Male to female ratio was 25:10, mean age of 12.91±4.41 yrs., the mean disease duration was 56.6 months. Enthesitis related arthritis (ERA) was the commonest in 12, followed by oligoarticular in 10, polyarticular in 7 and systemic onset in 6. In the ERA group 10 were HLA B27 +ve, of the oligo articular 6 were ANA +ve, in the polyarticular one was RF +ve. Out of the 35, 14 were already on biologics (tocilizumab and anti TNFs). Tofacitinib was stopped in 8 patients during this period, 5 as they achieved remission, 2 with no response and one because of itching and abdominal pain. There were no documented infections. There was significant reduction in the inflammatory markers (ESR, CRP), leucocyte count and platelet count.

AB1251 LATE ONSET PRIMARY HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN AN INDIAN ADOLESCENT BOY DURING A PEAK OF POST COVID-19 MULTISYSTEM INFLAMMATORY SYNDROME

D. B. Pandya1, 2

Background: Familial Hemophagocytic lymphohistiocytosis (FHLH) categorized as FHHL2 (PRF1), FHHL3 (UNC13D), FHHL4 (STX11), and FHHL5 (STXBP2) encoding for Perforin, Munc13-4, Syntaxin11, and Syntaxin binding protein 2, respectively. There is limited information available about the clinical and mutational spectrum of FHL patients in Indian population.

Objectives: To delineate clinical and laboratory features of late onset familial Hemophagocytic Lymphohistiocytosis.

Methods: A 12-years-old well nourished sick looking boy, born to a non-consanguineous parents with normal birth, development and immunization history with uneventful past presented to us with 6 days history of high fever, cough, breathing difficulty and severe headache. He had occasional vomiting, abdominal pain, polyarthragia & chest pain from last 10 days. Mother also had given history of throat pain, backache & some non-specific papular rashes over face before the onset of fever. His vitals was normal. Examination revealed faint diffuse fixed erythematous rash all over the body, pallor, icterus and hepatosplenomegaly. Musculoskeletal examination was unremarkable. Lab evaluation revealed HB 8.99gm%, TLC 4700/cumm with neutrophils 40% and lymphocytes 56% with 6-9% activated lymphocytes. Further evaluation showed low ESR 6mm/hr, liginogen 97mg% and albumin 2.2 gm% with elevated CRP 40mg/L, ferritin 2000ng/ml, LDH 6851U/L, SGPT 110U/L, SGOT 221 IU/L, total bilirubin 6mg%, D-dimer 4355 ng EFLU/ml and Triglycerides 441mg%. His blood, urine, CSF and bone marrow cultures were sterile for endemic viral and viral infections in our area. His EBV PCR, CoVID RT PCR and CoVID antibody (Total & IgG) test were negative. His immunoglobulin levels were normal. HRCT Chest showed bilateral mild-moderate plural effusions, mild interstitial thickening in both the lower lobes, few fibrotic opacities & old areas of consolidation bilaterally. 2D echo showed mild pericardial effusion. Bone marrow examination showed Hypercellular marrow with iron depletion and occasional hemophagocytosis with CD6 T lymphocytes proliferation (55.2%) and double positive CD4 & CD8 (12%). He was initially launched on supportive therapy, oxygen & intravenous antibiotics. In view of most probable non-infectious, non-malignant hemophagocytic lymphohistiocytosis, he was finally given intravenous immunoglobulin (2gm/kg) and intravenous pulse methylprednisolone (30mg/kg). He responded well to above regimen within 3 days. He was discharged with tapering steroids over few weeks. Clinical exome by NGS revealed Homozygous Mutation in STXBP2 gene Intron 14, c.1280-1G>C (3’ Splice Site) His parents has been counselled for hematopoietic stem cell transplantation and their decision is still pending.

Results: We compared our patient with a reference to the largest Indian series of pediatric HLH1.
development of MAS, that confirms the key role of IL-18 in sJIA and MAS. According to our data, in clinical practice the measure of serum level of ferritin more useful for early detecting MAS in pts with sJIA due to more stronger correlation between the levels of proinflammatory cytokines and ferritin, than between proinflammatory cytokines and CRP. We were unable to identify a statistically significant difference in the level of IL1RA in active sJIA and MAS, despite a significant correlation between the level of CRP and IL1RA, ferritin and IL1RA, which may be associated with small number of pts.

**DISEASE PERCEPTION ASSESSMENT IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS AND THEIR PARENTS.**

A. Fazaa1, S. Nouicer1, S. Miladi1, H. Boussaïa1, K. Ouenniche1, L. Souabni1, S. Kassab2, S. Cheki2, K. Ben Abdelghani3, A. Lacalet1, M. Mongi Slim1, *Rheumatology, Tunisia, Tunisia*

**Background:** Juvenile Idiopathic Arthritis (JIA) has an impact on the quality of life of the patient and his family. Parent/patient reported outcomes have shown an increasing interest in the management of JIA because it reflects the perception of the disease course and the effectiveness of the therapeutic interventions.

**Objectives:** To determine the level of agreement between patients with JIA and their parents for the five quantitative items in Juvenile Arthritis Multidimensional Assessment Report (JAMAR) questionnaire.

**Methods:** We included children aged between 7 and 18 years old with A1 ILAR criteria) and their parents. Demographic data and disease related parameters were collected. We asked both parent and child to complete the five quantitative items of JAMAR questionnaire. We measured on a 21-numbered circle visual analogue scale (VAS) for pain (0 = no pain; 10 = very severe pain), disease activity (DA): (0 = no activity; 10 = maximum activity) and well-being (WB): (0 = very well; 10 = very poorly). Physical function was assessed by Juvenile Arthritis Functional Score (JAFS) (0-45) and health-related quality of life (HRQoL) [0-30] through the Physical Health (PH) and Psychosocial Health (PSH) subscales. We calculated children and parents median scores for the five items. Intraclass correlation coefficient ICC was used for analysis (ICC below 0.50: poor; between 0.50 and 0.75: moderate; between 0.75 and 0.90: good; above 0.90: excellent).

**Results:** A total of 21 patients/parent (12 girls and 9 boys) were included in the study. Forty percent belong to rural environment. Majority of patients were in secondary school (77%), 23% were in primary school. Seven patients had oligoarticular JIA, 13 had polyarticular JIA and one had systemic JIA. Median age at diagnosis was 11.4 ± 2.2 years [6-13]. Median age at disease onset was 9.5 ± 1.9 years [2-13]. Median disease duration was 4.3 years [0-7]. Median JADAS was 10 [8-18]. Uveitis was noted in 30% of cases. Comparison of parent proxy-reported and child self-reported data revealed a striking similarity for all items (p<0.001). The results of the five quantitative items of JAMAR questionnaire are represented in Table1. Good correlation was noted in JAFS, DA VAS, well-being VAS and HRQoL. Excellent correlation was noted in VAS pain.

**AB1254**

**CHALLENGES FACED BY FAMILIES OF CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS.**

W. Triki1, A. Dohaies1, H. Ferjani1, R. Ben Assia2, D. Ben Nessim3, K. Maatallah1, D. Kaffel1, W. Hamdi1, *Institut Mohamed Kassab d’orthopédie, Rheumatology, Manouba, Tunisia*

**Background:** Juvenile idiopathic arthritis (JIA) is the most common inflammatory rheumatism of childhood. Diagnostic and therapeutic approaches are difficult for families to sustain with significant psychological and social effect.

**Objectives:** The aim of this study is to understand the different challenges faced by families with children suffering from JIA.

**Methods:** Parents of children with JIA (according to the International League of Associations for Rheumatology (ILAR)) followed in rheumatology department were asked to complete a survey in order to screen the impact of their child's disease on their family life. Open-ended questions and directed questions were included. General demographic and clinical information (family history of chronic inflammatory disease, child's current age, diagnosis and type of JIA and duration of disease progression) were also collected.

**Results:** The study included 24 children with a gender-ratio of 1. The mean age was 12.4 years old [4-16]. The mean duration disease was 4 years with extremes varying from 3 months to 10 years. The frequency of disease at follows: polyarticular with rheumatoid factor (n=2), polyarticular without rheumatoid factor (n=5), psoriatic arthritis (n=1), enthesitis-related arthritis (n=10) and oligoarthritis (n=6). Twenty-four parents completed the survey. The mother was the one who answered the questions in 83% of the cases. Other family members with a chronic rheumatic disease were reported in 40% of the families. Parents noted negative impact on their work in 50% of cases (40% missing time from work, 10% changing work schedule) and, significant parental stress, anxiety, and fatigue in 75% of the cases. In 33% of the cases, parents had difficulty getting the required medical care and attention for their child's illness because of financial issues and 37.5% of them were feeling anxiety regarding diagnosis uncertainty. Parents reported worry about their child's daily functioning and future in 75% of the cases. They noted psychological impact on the child itself in 58% of the cases and child missing school in 41% of the cases. The most common resources parents used for information were health care professionals in 54.2 % of the cases and 45.8% of them got additional information from online research.

**Conclusion:** Parents of children with JIA share common challenges due to their child's illness including a substantial impact on their work and personal wellness in addition to the psychosocial impact of the disease on the child. Support groups or educational sessions may be needed to provide guidance for these families to cope with disease.

**AB1255**

**ASSESSMENT OF SLEEP DISTURBANCES IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS.**

W. Triki1, A. Dohaies1, H. Ferjani1, R. Ben Assia1, D. Ben Nessim1, K. Maatallah1, D. Kaffel1, W. Hamdi1, *Institut Mohamed Kassab d’orthopédie, Rheumatology, Manouba, Tunisia*

**Background:** Sleep problems are common among children with chronic illnesses such as Juvenile Idiopathic Arthritis (JIA), which is one of the most common rheumatic diseases in childhood. Sleep disturbances collectively refer to impairments in the ability to initiate or maintain sleep. They can be measured by parent or child self-report and by objective measures such as actigraphy and polysomnography.

**Objectives:** The aim of this study was to assess sleep disorders in children with JIA.

**Methods:** Parents of children suffering from JIA (according to the International League of Associations for Rheumatology (ILAR)), followed in rheumatology department were asked to complete a specific specialized scale for children (HIBOU) [1] to screen sleep disorders. This scale assesses five aspects of sleep: irregular schedule and daytime drowsiness, insomnia, moves in sleep, nose obstruction and ultra-vigilance. Parents were asked to answer 8 questions rated from 1 to 3 according to the frequency of the problem: 1: rarely, 2: 3 to 4 times a week and 3 if 5 to 7 times a week. If the sum is ≤ 9, only sleep hygiene is recommended. If the sum is between 10 and 15 the child requires regular supervision. If the sum is between 16 and 24, the child needs to be referred to a specialist. General demographic and clinical information (family history of chronic inflammatory disease, child's current age, diagnosis and type of JIA, duration of disease progression and activity of the disease) were also collected.

**Results:** Twenty-four children with a mean age of 12 years [4-16] were included in the study. The gender ratio was 1. The mean duration of the disease was 4 years with extremes from three months to thirteen years. The frequency of each JIA subset was as follows: polyarticular with rheumatoid factor (n=2), polyarticular without rheumatoid factor on the rheumatoid factor (n=5), psoriatic arthritis (n=1), enthesitis-related arthritis (n=10) and oligoarthritis (n=6). Irregular sleep schedule and daytime drowsiness were reported at least 3 times a week by 58.3% of the children. Insomnia and inability to initiate sleep were reported in 29.3% of the children at least 3 times a week. Parents reported exaggerated moves during sleep in 50% of the cases and airway obstruction or snoring in 58.3% more than 3 times a week. Sleep problems such as insomnia, daytime sleepiness and sleep-related problems other than sleep were reported in 25% of cases. To sum up, 29.2% of the children had a score above 15 and needed to be referred to a specialist and 58.3% of them need a regular supervision of their sleep and may need to be referred to a specialist. Only three children had a score under 9 and don't have concerning sleep disorders and 58.3% of them need a regular supervision of their sleep and may need to be referred to a specialist. Only three children had a score under 9 and don't have concerning sleep disorders.

**Conclusion:** This study showed that sleep disorders are a common challenge in children and adolescents with JIA which could have a huge impact on their physical and psychosocial health-related quality of life. This study highlights the need for assessment of sleep disorders in JIA patients.
Juvenile Idiopathic Arthritis (JIA) is the leading cause of chronic inflammatory rheumatic disease in children. It's classified into subtypes with different relative prevalences depending on geographical area (Oligoarticular subtype predominates in Western Europe/North America. Enthesitis-related arthritis subtype predominates in Eastern Europe/Asia). To ensure continuity of care in adult rheumatology services, a systematic transition process is recommended. Various authors recommend that the process, of which pediatric and adult rheumatology teams should be part, begins around 14 years and ends around 18 years of age.

**Objectives:** We aim to study the age, relative prevalence and treatment profile in JIA subtypes at the beginning of the transitional care.

**Methods:** Descriptive and cross-sectional study of patients with JIA (according to ILAR criteria), diagnosed and treated in the pediatric rheumatology service and seen in the transitional care unit of the adult rheumatology service within the same tertiary hospital between January 2013 and December 2018. Demographic, clinical, analytical and treatment data were collected at the first visit to the transitional care unit.

**Results:** 72 patients were included (46 women) mean age at diagnosis of 9.5 ± 4.6y and mean of 13.3 ± 4.3y from diagnosis to the first visit at the transitional care unit. 27.7% were diagnosed with oligoarticular JIA, 20.8% with arthritis-enthesitis JIA, 19.4% with Rheumatoid Factor negative (RF-) polyarticular JIA, 11.1% with systemic JIA, 9.7% with undifferentiated JIA, 5.5% with Rheumatoid Factor positive (RF+) polyarticular JIA and 5.3% of psoriatic arthritis.

The mean age at the first visit to the transitional care unit was 20.81 ± 2.96y (no differences between subtypes). Oral ulcers (20.8%), anterior uveitis (13.8%) and enthesitis (13.8%) were the most frequent extra-articular manifestations. 56.9% had antinuclear antibodies (ANA) titers >1/160 at some point in course of disease (Table 1).

**AB1257 INVESTIGATING THE ASSOCIATIONS BETWEEN THE MAXIMAL RESPIRATORY PRESSURES AND CARDIORESPIRATORY FITNESS PARAMETERS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS**

D. C. Sarac1, D. Bayraktar1, D. Ozer Kayar1, O. Altug-Gucenmez2, D. Oskay3.

1Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; 2University of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey

**Background:** The most prominent symptom of juvenile idiopathic arthritis (JIA) is joint involvement; however, the effect of the disease is not limited to the joints. Evidence suggests that cardiopulmonary fitness is affected in children with JIA compared to their healthy peers.

**Objectives:** This study aimed to investigate the associations between the maximal respiratory pressures and cardiorespiratory fitness parameters.

**Methods:** Seventeen children with JIA (mean age: 15.4 ± 2.2 years, 11 male) who have been using biological agents for at least three months were included in the study. Maximal inspiratory pressure (MIP) and maximal expiratory pressure (MEP) were evaluated with a portable device (Cosmed PFX Desktop Spirometer, USA). The Quark Cardiopulmonary Exercise Test Treadmill System (COSMED, Rome, Italy) was employed to analyze cardiorespiratory fitness parameters by using expired gas collection and analysis.

**Results:** Significant moderate correlations were detected between MIP and maximum oxygen consumption (VO2max) values (r=0.519, p=0.033) and MEP and CO2max values (r=0.507, p=0.038), (Table 1). No other significant correlations were observed between maximal respiratory pressures and other parameters.

THE PREDICTED VERSUS MEASURED RESPIRATORY PRESSURES, PULMONARY FUNCTIONS, CARDIOPULMONARY FITNESS PARAMETERS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

D. C. Saraç,1 D. Bayraktar,1 D. Ozer Kayalı,1 A. Altug-Gucenmez,2 D. Oskay,3

1Izmir Katip Çelebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, İzmir, Turkey; 2University of Health Sciences, Dr. Behçet Uz Pediatric Diseases and Surgery Training and Research Hospital, Department of Pediatric Rheumatology, İzmir, Turkey; 3Gazi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey

**Background:** Although musculoskeletal system-related symptoms are the most common problems in children with Juvenile Idiopathic Arthritis (JIA), cardiac and pulmonary manifestations are observed in more than half of these children. However, the available research on the extent of cardiorespiratory involvement is very limited [1].

**Objectives:** The aim of this study was to compare the predicted respiratory pressures, pulmonary functions, cardiopulmonary exercise test (CPET) values to objectively measured ones in children with JIA.

**Methods:** Twenty-two children with JIA (mean age: 15.5±2.3, 14 male) who were under biological agents for at least three months were included in the study. Maximal inspiratory pressure (MIP), maximal expiratory pressure (MEP), and pulmonary functions were measured using a portable automated testing device (Cosmed Pony FX Desktop Spirometer, USA). Cardiorespiratory fitness parameters were measured with the Quark CPET Treadmill System (COSMED, Rome, Italy). The values calculated by the softwares of the Cosmed Pony FX Desktop Sporimeter and Quark CPET Treadmill System according to the healthy children’s normative data were used as predictive values.

**Results:** Within-group analyses demonstrated statistically significant differences between all measured and predicted parameters (p<0.05), (Table 1), except for MIP and forced vital capacity/forced expiratory volume values.

**Conclusion:** The present study’s findings indicate that the respiratory pressures, pulmonary functions, and cardiopulmonary fitness parameters of the children with JIA are diminished compared to predicted values.

SIGNIFICANCE OF WHOLE-BODY MRI IN CHILDREN WITH RHEUMATIC DISEASES

I. Nikishina,1 Z. Kolkhidova,1 L. Blankt,2 T. Pachkoria,2 S. Arsenyeva2, V. Matkava1, A. Shapovalenko1, M. Shalygina1, V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation; 2V. A. Nasonova Research Institute of Rheumatology, Department of Radiation Diagnostics, Moscow, Russian Federation

**Background:** Whole-body MRI (WB-MRI) has the potential to detect early or hidden signs of inflammation and seems to be more informative test than X-ray and ultrasound methods for bone and joint diseases. WB-MRI is important for identification of asymptomatic inflammation areas that are not available for clinical examination methods (sacroilits, TMJ). WB-MRI can become a tool for monitoring the progression of the disease and the efficacy of therapy. There is not enough data of knowledge about the role of WB-MRI in children with JIA.

**Objectives:** To evaluate the results of WB-MRI in children with rheumatic diseases (RD) in a single-center retrospective study.

**Methods:** 57 WB-MRI studies performed in children with RD in our center as a part of real-life diagnostic procedures.

**Results:** Among 57 children there are 22 boys and 35 girls, the average age is 13 years [11; 16]; 33 patients were examined once, 20 children twice after the initial course of therapy, two children underwent WB-MRI three times to evaluate the dynamics. It was most important to detect inflammatory lesions in multifocal non-bacterial osteomyelitis (mf-NBO). The structure of diagnosis and therapy before and after WB-MRI is presented in Table 1.

**Disclosure of Interests:** None declared

11 patients have multimorbidity (in addition to RD, one girl has Down syndrome). 5 pts had severe hypermobility syndrome patients making it difficult to identify inflammation due to the discrepancy between objective signs and the absence of limitation of joint mobility. 2 patients had multiple ankylosis, 7 patients underwent surgical interventions: 5 because of vertebral fracture, 2 because of osteomyelitis. The WB-MRI revealed: 48 polyarthritis signs, 33 ostitis, 3 osteonecrosis, 11 sacroiliitis, 1 sequestration, 1 epithelioysisis, 1 initial signs of myositis. Surgical intervention was recommended to two patients after the diagnosis of WB-MRI (sequestration of the osteomyelitis focus and vertebral fracture).

The principal significance and purpose of the performance of WB-MRI were disease control (continuation of therapy) - 22 (39%), the onset of DMARDs/bDMARDs - 17 (30%), the change of bDMARDs - 2 (3%), differential diagnosis – 16 (28%).

Conclusion: WB-MRI is useful for detecting asymptomatic and radiologically hidden lesions in JIA. Early diagnosis leading to appropriate treatment can prevent long-term structural damage to the joint. WB-MRI is an important tool for the diagnosis and diseases control in children with RD.

THE ANALYSIS OF THE ONSET OF SYSTEMIC LUPUS ERYTHEMATOSUS IN PEDIATRIC POPULATION

R. Denisova1, E. Alexeeva1,2, T. Dvoryakovskaya1,2, K. Isaeva1, A. Chomakhidze1, A. Mamutova1, O. Lomakina1, A. Fetisova1, M. Gautier1, K. Chibisova1, I. Kriulin1,2, E. Krekhova1,2, I. Tsulukiya1. National Medical Research Center of Children’s Health, Rheumatology, Moscow, Russian Federation; Sechenov University, Pediatrics, Moscow, Russian Federation

Background: Systemic lupus erythematosus (SLE) is characterized by multiple autoantibodies associated with a multisystem illness where any organ can be targeted. There are different classification criteria for SLE. Sensitivity and specificity of three criteria have been debated and may vary in different populations and clinical settings.

Objectives: We aim to evaluate the clinical and laboratory symptoms of the onset of systemic lupus erythematosus in pediatric population.

Methods: A total of 116 SLE patients (female –92, male-24) were included into the study. We analyzed the primary diagnosis, the time before identification the SLE, clinical and laboratory symptoms, their combination, and fulfilling the classification criteria of SLE. All data is presented as Mean (IQR).

Results: The age of the onset of SLE was 13.3 (10.7, 15.2) years. 55/116 patients had other diagnosis before the verification of SLE, the time before the verification was 10 (5, 26) months. The loss of weight was in 63 (54%) of patients, fever – in 83 (72%) (febrile – 57, subfebrile – 26), adenopathy in 55 (47%), malar rash – in 45 (39%), discoid rash – in 19 (16%), alopecia – in 19 (16%), photo- sensitivity – in 39 (34%), oral ulcers – in 38 (33%), nasal ulcers – in 11 (9.5%), arthritis – in 31 (27%), pleuritis- in 18 (16%), pericarditis- in 20 (17%), renal disorder – in 52 (47%), seizures- in 7 (6%), psychosis – in 1 (0.9%), myelitis – in 2 (1.7%), peripheral neuropathy – in 3 (2.6%), cranial neuropathy – in 2 (1.7%), hemolytic anemia – in 59 (51%), leukopenia- in 62 (53%), thrombocytopenia- in 27 (23%), ANA positivity – in 100(86%), anti-dsDNA antibody positivity – in 91 (78%), antiphospholipid antibody positivity- in 27 (25%), direct Coombs’ test in 22(19%). SELENA–SLEDAI Score was 13 (9, 20); low activity- in 14 (12%) patients, moderate activity- in 23 (20%), high activity – in 42 (36%), very high activity – in 37 (32%).

96 (83%) patients met the eligibility criteria ELAR/ACR 2019, 112(97%) – ACR criteria modified in 1997, 106(91%) – SLICC in 2012.

Conclusion: In this cohort, although all three criteria have sufficient. Some SLE patients with a clinical diagnosis lacked sufficient number of criteria.

AB1262

PERFORMANCE OF JADAS-ESR AND JADAS-CRP IN THE ASSESSMENT OF DISEASE ACTIVITY IN TUNISIAN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

R. Ben Aissa1, D. Ben Nessib2, H. Ferjani1, A. Dghaihes3, W. Triki1, K. Maatallah1, D. Kafell1, W. Hamdi1,1Mohamed Kassab Institute of Orthopedics, Department of Rheumatology, Tunis, Tunisia

Background: The Juvenile Arthritis Disease Activity Score (JADAS) is a feasible tool which consists of four items: tender (TJC) or swollen joint count (SJc), the physician and the patient's/parent's global assessment and the erythrocyte sedimentation rate (ESR). C-reactive protein (CRP) has also been suggested as an alternative inflammatory marker.

Objectives: To compare the performance of JADAS-ESR and JADAS-CRP in the evaluation of JIA activity.

Methods: Twenty-nine patients who met the International League of Associations for Rheumatology (ILAR) criteria for JIA were enrolled in the study. Disease activity was assessed by the JADAS-ESR and JADAS-CRP scores at 54 consultations, 29 at baseline and 25 during the last follow-up consultation. Data of JIA subtypes, disease duration and treatment were retrospectively collected from medical records. All data were checked for normality by the Kolmogorov-Smirnov test. The Spearman correlation was used for data analysis and p values less than 0.05 were considered statistically significant.

Results: The mean age of our population was 13.14±2.2 years [4-21] and the sex ratio of males to females was 1.07:1. The disease duration was 4.69±3.28 years [0.3-13]. JIA subtypes were: enthesis-related arthritis (n=12), polyarthritis (n=7), oligoartthritis (n=6), undifferentiated arthritis (n=3) and psoriatic arthritis (n=1). At baseline most of our patients (51.73%) were not under treatment, 34.49% were under non-steroidal anti-inflammatory drugs (NSAIDs) and 13.8% under methotrexate (MTX). At the last follow-up consultation 41.38% of the patients were under MTX, 34.49% under NSAIDs, 10.35% under TNF inhibitor (Etanercept). At baseline JADAS-ESR1 was correlated to JADAS-CRPI (r=0.001, p=0.008) in all AIJ subtypes. JADAS-ESR1 and JADAS-CRPI were not correlated to ESR1 (p=0.416, p=0.661) nor to CRPI (p=0.378, p=0.058). Both JADAS-ESR1 and JADAS-CRPI were correlated to TJC1 (p=0.001, r=0.643, p=0.015, r=0.502) and only JADAS-ESR1 was correlated to SJCI (p=0.012, r=0.461). At the last follow-up consultation, correlations were observed between JADAS-ESR2 and JADAS-CRPI (p=0.001, r=0.992) in all AIJ subtypes. JADAS-ESR2 and JADAS-CRPI were both correlated to CRPI (p=0.015, r=0.003) but not to SJCI (p=0.175, r=0.119), nor to ESR2 (p=0.535, r=0.426).

Conclusion: Our study suggests that both JADAS-ESR and JADAS-CRP correlate closely during the follow-up of JIA. JADAS-CRP could be recommended for assessing disease activity in JIA.

CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS IN CHILDREN: A SINGLE CENTER 10-YEAR EXPERIENCE

A. Nargizyan1, S. Kurbanova1, A. Glazyrina1, E. Korobyants1, V. Yusupova1, A. Sologub1, E. Zhlobova1,2,3, Morozovskaya Children’s City Clinical Hospital, Department of Rheumatology, Moscow, Russian Federation; 1M. Sechenov First Moscow State Medical University (Sechenov University), Department of Rheumatology, Moscow, Russian Federation
Background: Chronic recurrent multifocal osteomyelitis (CRMO) is a chronic autoinflammatory disease that primarily affects the skeleton in the absence of an infectious etiology in children and adolescents. It is an orphan disease with many unclear aspects in terms of diagnosis, treatment and follow-up.

Objectives: To report demographic, clinical and laboratory characteristics of a single center cohort of CRMO patients in Morozovskaya Children’s City Clinical Hospital in Moscow, Russia.

Methods: We retrospectively and prospectively reviewed clinical records of 33 CRMO patients diagnosed between 2011 and 2021 and admitted to Rheumatology Department of Morozovskaya Children’s City Clinical Hospital.

Results: We identified 33 patients with CRMO. Twenty-five (75%) were female. Median age of symptoms onset was 9 [6;12] years. Median delay in diagnosis was 12 months. All patients had bone pain as an initial symptom; fever has been present in 12 patients (63%). Joints involvement was observed in 22 patients (67%) – 39%, 18%, 12%, and 3% of patients had ankle, hip, knee, and shoulder joints involvement, respectively. All patients had multifocal bone lesions, which were confirmed by radiological methods (CT scan, MRI, scintigraphy).Vertebral (42.4%) and femur (46.5%) were the most commonly affected bones. One child had a skull lesion (os parietale). Eleven patients (33%) also had sarcoidosis. Other organs involvement was observed in 7 patients presented with palmoplantar pustulosis and psoriasis. Histopathological examination has been performed in 24 (73%) patients to confirm the diagnosis. Mean ESR was 43 [28;80] mm/h and CRP – 27 [15;61] mg/L. Twenty-three (69.6%) patients had psoriasis.

Conclusion: From our experience, most of the patients had delay in diagnosis. Laboratory tests showed mild elevation of inflammatory parameters. Seven (21%) patients had psoriasis.

CLINICAL, DEMOGRAPHIC CHARACTERISTICS AND TREATMENT RESPONSES OF PATIENTS WITH CRYOPYRIN-ASSOCIATED PERIODIC SYNDROME

Ş. Çağılayan1, K. Ülu1, T. Çokşeker1, R. E. Yigit1, G. Ozmoy Baykal1, F. Demir1, M. Çankan1, B. Sözeri2, 1University of Health Sciences, Umraniye Education and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey

Abstract: Cryopyrin-associated periodic syndrome (CAPS) is a rare autoinflammatory disease that inherited autosomal dominant. The disease occurs as a result of mutations in the NLRP3 gene, which encodes cryopyrin (1). It has three clinical presentations called familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS) and neonatal-onset multisystem inflammatory disorder (NOMID) or chronic infantile neurologic, cutaneous and articular (CINCA) syndrome (2). FCAS is the mildest form of this syndrome, characterized by cold-induced fever, urticarial rash, joint complaints, conjunctivitis, and systemic inflammation.

Objectives: In our study, we aimed to evaluate the clinical and demographic characteristics and treatment responses of CAPS patients.

Methods: We retrospectively and prospectively reviewed clinical records of 33 pediatric patients who were diagnosed with CAPS admitted to Umraniye Training and Research Hospital, Pediatric Rheumatology Clinic, Istanbul, Turkey. June 2016 - December 2021. Medical records were analyzed for clinical presentation, disease associations, physical examination, and laboratory findings.

Results: A total of 44 patients (41 FCAS, 3 MWS) were included in the study. Of the patients, 19 were girls and 25 were boys. The median age of the patients was 10.5 [1.4-20.6] years. The median age of onset of attack was 3 years (1 month-14.6 year), age at diagnosis was 7.9 years (13 months-18 years), and the follow-up period was 2.2 years (4 months-5.2 years). There was a history of consanguinity in 9 (20.4%) patients. Twelve (27.2%) patients had the autoinflammatory disease in their families. The most common clinical findings were fever (100%), joint pain (94%), and abdominal pain (85%). Afterward rash (84%), migraine (43.5%), conjunctivitis (31.8%), arthritis (31.8%), dermatitis (31.8%), chest pain (27.3%), headache (25%), and vomiting (22.7%) were other findings accompanying the attacks. Thirty-nine (88.6%) patients had mutations in the NLRP3 gene. No mutation was detected in five (11.4%) patients. The most common G705K mutation was detected in 28 (71.4%) patients. Forty-two (95.4%) patients were started on colchicine treatment. Biological therapy was started in 9 (21.4%) patients whose attacks continued despite colchicine. Anakinra and canakinumab, which are anti-interleukin 1 agents, were used as biological therapy. FCAS patients had an adequate response to standard doses of canakinumab therapy, while MWS patients required significantly higher doses of canakinumab therapy. MWS patients needed significantly higher doses of canakinumab treatment. Biological therapy was started in 9 (21.4%) patients whose attacks continued despite colchicine. Anakinra and canakinumab, which are anti-interleukin 1 agents, were used as biological therapy. FCAS patients had an adequate response to standard doses of canakinumab therapy, while MWS patients required significantly higher doses of canakinumab therapy. MWS patients required significantly higher doses of canakinumab therapy. We think that it would be beneficial to try colchicine treatment before starting biologic therapy in FCAS patients.

BIOTECHNOLOGICAL AGENTS IN PEDIATRIC-ONSET SCLERITIS

A. Vitale1, G. Gaggiano1, V. Berlingiero1, C. Fabiani1, F. Ricci1, G. Nascimbene1, V. Caggiano1, G. M. Tosi2, B. Frediani1, M. Cattalini3, L. Cantarini1, 1Rheumatology Unit, Department of Medical Sciences, Surgery, and Neurosciences, Siena, Italy; 2Ophthalmology Unit, Department of Medical Sciences, Surgery, and Neurosciences, Siena, Italy; 3Pediatric Clinic, University of Brescia and Spedali Civili di Brescia, Brescia, Italy

Background: The term scleritis refers to the inflammation of the sclera, the white outer layer of the eye. The term may be applied to cicatricial, cicatrizating, necrotizing, and rarely pannus. The term involves a wide range of etiologies ranging from infectious to non-infectious entities. Semin Immunopathol. 2015;37(4):377-385. doi:10.1007/s00281-015-0491-7

ANGIOTENSIN-CONVERTING ENZYME LEVEL IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

N. Shevchenko1,2, T. Holovko1,2, L. Bohmat1,2, V. Nikonova1, V. N. Karazin Kharkiv National University, Department of Pediatrics No 2, Kharkiv, Ukraine; 2SI Institute for Children and Adolescents Health Care of NAMS of Ukraine, Department of Rheumatology and Comorbid States, Kharkiv, Ukraine; 3V. N. Karazin Kharkiv National University, Department of Pediatrics No 2, Kharkiv, Ukraine

Disclosure of Interests: None declared

Background: One of the most common comorbid conditions accompanying rheumatoid arthritis is atherosclerosis and arterial hypertension. Previous studies have shown a change in the blood lipid spectrum with an increase in the atherogenic index in children with juvenile idiopathic arthritis. The next link in the development of this pathology is a change in the endothelial function of the vessels.

Objectives: To study the level of angiotensin-converting enzyme in children with JIA and establish its interdependence with the blood lipid spectrum of sick children.

Methods: The level of angiotensin-converting enzyme (ACE) was studied in 46 children (28 girls and 18 boys) from 11 to 17 years old by enzyme immunoassay as well as indicators of the lipid spectrum: low-density lipoprotein cholesterol (LDL), very low-density lipoprotein cholesterol (VLDL) and atherogenic coefficient. The results obtained were compared with the data of children in the control group, which consisted of 34 people. Data were analyzed depending on patients' gender, age, and age of JIA onset, its variant, duration, activity, and presence of methotrexate (MTX).

Results: The results of the study are presented in the Table 1.

Table 1

</tbody>
</table>

There were no significant differences in the ACE level in children with JIA in comparison with the control group. Analysis of the obtained data did not reveal significant changes in the obtained ACE parameters depending on the gender and age of patients, JIA activity, and the presence of MTX in complex treatment. At the same time, a direct correlation of ACE values and low-density lipoprotein levels (r=0.5, p<0.05) was obtained, which confirms the relationship between the ACE level and the development of dyslipoproteinemia in children with JIA.

Conclusion: The obtained results illustrate the stages of development of atherogenic changes in children with JIA. Data were obtained that against the background of an increase in the level of VLDL and a decrease in LDL, the level of ACE remains preserved, which reflects the absence of changes in the endothelium. Research into these changes is ongoing.

LONG-TERM SINGLE CENTER EXPERIENCE OF THE THERAPY WITH BIOLOGICS IN MULTIFOCAL NON-BACTERIAL OSTEOMYELITIS

I. Nikishina, S. Arsenyeva, Y. Matkava, M. Kaleta, M. Shayagina, Z. Kokhidova, T. Pachkoria, S. Salugina, D. Alexseev, O. Borodacheva, A. Shapovalenko, V.A. Nasonova Research Institute of Rheumatology, Paediatric, Moscow, Russian Federation

Background: Children and adolescents who suffered from the rare polygenic autoinflammatory disease such as multifocal non-bacterial osteomyelitis (NBO) can stay without specialized care for the long time. Currently we don’t have standardized treatment for these patients. Administration of Biologics (B) established on opportunity to diagnose juvenile idiopathic arthritis (JIA) or juvenile ankylosing spondylitis (JAS) in relation to combination of bone lesions with arthritis and/or axial skeleton damage.

Objectives: To describe clinical/laboratory findings and therapy approaches in patients with NBO who was treated by B.

Methods: We analyzed a single center retrospective nine-year study, which includes cohort of 56 patients (pts) with multifocal NBO. 22 pts of them were treated by different B (TNF-inhibitors mostly) in our pediatric department. Standard rheumatological assessment were included for all pts. X-ray, whole-body MRI and/or scintigraphy were done for revealing all localizations of bone lesion. It is expected that option of prescribing BA can prevent progression and bone destruction.

AB1268

CLINICAL ASPECT AND THERAPEUTIC MANAGEMENT OF SUBACUTE OSTEOMYELITIS IN CHILDREN

R. Dghaies1, A. Dghaies2, M. Jerbo3, H. Ben Ghzolene3, F. Abid3, 1University Hospital Center Hedi Chaker Sfax, Pediatric Surgery, Sfax, Tunisia; 2University Hospital Center Hedi Chaker Sfax, Rheumatology, Sfax, Tunisia; 3University Hospital Center Taher Sfar Mahdia, Traumatology-Orthopedic Department, Mahdia, Tunisia

Background: Subacute osteomyelitis in children is a distinct entity encom-passing primary localized osteomyelitis. It poses a diagnostic problem related to its few or no constitutional symptoms, misleading radiological manifestations and often a negative bacteriological investigations. The treatment remains very controversial.

Objectives: The aim of this study was to identify the main epidemiological, clinical, histological and evolutionary characteristics of this affection and to propose an adequate therapeutic attitude.

Methods: It was a retrospective longitudinal study, carried out over a period of 25 years from January 1995 to December 2019 in the orthopedic department of Taher Sfar Hospital,Mahdia, that included 37 cases of subacute osteomyelitis in children.

Results: The mean age of the patients was seven years nine months with a male predominance (sex ratio: 2:27). The average time to hospitalization was 41 days. A diagnostic delay was very likely because of delay in consultation which was related to clinical latency, reported in all cases. The imaging showed osteolysis in all cases, setting in long bones in 54% of cases and in 46% other cases in short and flat ones. The lesion was multiple in two different bones only in one case and was found in pure epiphyseal location in seven cases. The bacteriological investigation allowed the isolation of a germ only in eight cases. In all cases, it was a Staphylococcus aureus. Surgical treatment was performed in 21 cases (60% of patients). The outcome was favorable in 35 cases (95% of cases). An infectious exacerbation was noted in 2 cases.

Conclusion: Subacute osteomyelitis poses a diagnosis and therapeutic problem. Magnetic resonance imaging is a valuable examination. Surgical treatment combined with appropriate antibiotic therapy is indicated for any suspicious lesion. It can be useful in taking samples for diagnosis, improve distribution of the antibiotic in injury and accelerate healing radiation.

Other orphan diseases

Shulman’s disease or eosinophilic fasciitis: A rare fibrosing disorder: A case report treated with tocilizumab

A. Laria1, A. M. Lurati1, M. G. Marrazza1, K. Rei1, D. Mazocco1, P. Faggioni2, A. Mazzoni1, 1ASST Ovest Milanese, Fornaroli Hospital, Rheumatology, Milan, Italy; 2ASST Ovest Milanese Civil Hospital Legnano, Internal Medicine Unit, Legnano, Italy

Background: Shulman eosinophilic fascitis (EF) is a rare fibrosing disorder, typified by erythema, edema, and symmetrical induration of the distal bilateral extremities (onset proximal to the wrists and ankles) or/and trunk. The “groove sign” and/or a pseudocellulite appearance of the involved skin may be present. It is followed by joint contractures, arthromyalgia. On rheumatological examination: non-liftable skin in folds on the lower limbs, compatible with eosinophilic fasciitis and confirmed the pericardial effusion. Chronic inflammatory bowel diseases were excluded. A skin biopsy of the left forearm confirmed the clinical diagnosis of EF. In particular, it documented thickening of the fascia, a site of an inflammatory process that included small lymphocytes, plasma cells, histiocytes, and some eosinophils, distributed both diffusely and around blood vessels. The underlying muscle tissue and the supra-fascial skin were free from alterations. Secondary fasciitis was excluded by 18-fluorodeoxyglucose (FDG)-positron emission tomography; this showed a diffusely accumulation of the radiopharmaceutical in the muscles of the forearms and of both lower limbs, compatible with eosinophilic fascitis and confirmed the pericardial effusion. Immunoheriticogenic analysis on peripheral blood excluded the presence of a monoclonal cell population. Diagnosis of primary eosinophilic fasciitis was confirmed by the presence of mononuclear cell population. Diagnosis of primary eosinophilic fasciitis was made and therapy was started with methylprednisolone 1 g intravenously for 3 days followed by another 3 boluses of methylprednisolone of 500 mg iv. Given the poor response, it was decided to set up therapy with Methotrexate 15 mg up to a dose of 20 mg intramuscularly per week associated with prednisone 25 mg/day. The rheumatological re-evaluation at 3 months showed a worsening of the fibro-inflammatory stages of the disease, as in the case described.

Results: A complete resolution of the skin picture with disappearance of the pericardial effusion was documented 12 months after the start of the biological drug treatment. There is currently no guidelines for the treatment of eosinophilic fasciitis. Tocilizumab has been shown to be effective when introduced in the early inflammatory stages of the disease, as in the case described.

Prevalence of rheumatologic diseases in patients presenting with uveitis

E. Ozturk1, T. Yuce Inel2, M. Kaya3, F. Onen2, G. Can2.
1Dokuz Eylul University Faculty of Medicine, Internal Medicine, Izmir, Turkey; 2Dokuz Eylul University Faculty of Medicine, Rheumatology, Izmir, Turkey; 3Dokuz Eylul University Faculty of Medicine, Ophthalmology, Izmir, Turkey

Background: Uveitis may occur in the course of systemic inflammatory rheumatic diseases, or it may be the first clinical presentation of these diseases. Aims: To determine the prevalence of systemic inflammatory rheumatic disease in patients whose initial clinical manifestation is non-infectious uveitis.

Objectives: In other rheumatic diseases it is possible to optimize biological therapy, maintaining its effectiveness and without risk in its safety. But this aspect has not been studied in the field of non-infectious uveitis.

Methods: A search strategy (PubMed, Embase and Cochrane) was carried out on UNI up to Jan-22 with Mesh vocabulary and free text (human beings, English or Spanish). Review last 2 years of International Congresses Rheumatology we included methodological and systemic reviews, clinical trials, prospective and retrospective longitudinal observational studies (OA). Secondary manual search and quality assessment with the Oxford scale by 2 independent researchers. The population included were UNI in ophthalmological remission after TB use. Articles with TB optimization strategies and whether there is a comparison with those that maintain the smPC dose are examined. The main measures being evaluated are efficacy and safety. Data are collected on eye activity, number of outbreaks, GC (glucorticoid) doses and adverse effects.

Results: 11 articles of low or moderate quality. They were mostly retrospective EO (n=7), and to a lesser extent prospective (n=4), and included 513 patients. With a variable follow-up from a minimum of 12 months, up to 17 years of evolution. There was a predominance of males, of average age of 36 years, the most represented disease was Bechet’s disease. There was no homogeneous criterion when trying to optimize, since the minimum required time of remission maintained with TB, varied from 3 to 12 months. The use of FAME and GC was allowed. The intervention is described in 7 articles with Infliximab, 2 with Adalimumab and 2 with Etanercept. Other TB other than anti-TNF, have not performed optimization so they are not included in this systematic review. They included patients treated with DMARD and even with previous anti-TNF. Many articles did not have a comparison group. Studies suggest that after 3-6 months in remission, it could be a time to assess optimization. The remission maintained after discontinuation of the drug, is maintained from 7.5 months to 2 years. GC reduction and suspension up to 74% and even 40% FAME are described. But there are also relapses in 25-50%, but they are controlled in general with the increase in doses and in some cases with change of TB. There were no relevant security issues.

Conclusion: 1. Low quality of the evidence. 2. Great variability in patients, pathologies, definitions or outcome variables. 3. There is no consensus at the time of starting the optimization, the data suggest that after 3-6 months in remission it could be assessed. 4. Articles with a limited number of cases (some without a control group) or retrospective are included. There is great heterogeneity in the optimization and protocols used. But despite all this, these results suggest that optimization and/or suspension (in selected cases) can be carried out safely and planned for anti-TNF TB, with a low probability of short-term recurrences. 5. In case of reactivation of uveitis, it seems that it is usually controlled in most cases, using again the standard doses. 6. There were no relevant security issues. 7. More studies with homogeneic criteria and established protocols are needed to determine the duration of the ideal treatment and see if there are differences in the etiology of uveitis or TB used.

References:

Objectives: To determine the prevalence of systemic inflammatory rheumatic disease in patients whose initial clinical manifestation is non-infectious uveitis.

Methods: Adult patients diagnosed with non-infectious uveitis in Dokuz Eylul University Ophthalmology Department and referred to investigate the
etiology of rheumatological disease were included in the study. Demographic and clinical features, laboratory and imaging findings of the patients were examined.

**Results:** 106 patients diagnosed with uveitis (42.4% anterior uveitis, 2.8% intermediate uveitis, 19.8% posterior uveitis, 34.9% panuveitis) were included in the study. 52.8% of the patients were male and the mean age was 40.19±14.82 years. The mean age of uveitis attack was 38.7±15.02 years. 33% of the patients were diagnosed with rheumatologic disease (10 SpA, 17 Behçet's Disease, two vasculitis, two sarcoidosis, three undifferentiated connective tissue disease, one rheumatoid arthritis). SpA was diagnosed in 20% of patients presenting with anterior uveitis. Behçet's disease was detected in 27% of patients referred with panuveitis and in 33.3% of patients whose first clinical finding was posterior chamber involvement. Bilateral uveitis was detected in two-thirds of patients with posterior chamber affected, and it tends to recur more (p=0.014).

**Conclusion:** A rheumatological disease was detected in approximately one-third of the patients presenting with uveitis. Investigation of patients referred for uveitis in terms of systemic rheumatological diseases is very important as it may change the diagnosis and treatment process.

**AB1272 FACTORS AFFECTING PATIENT-ACCEPTABLE SYMPTOM STATES IN FAMILIAL MEDITERRANEAN FEVER**

D. Yıldırım1, R. C. Kardas1, B. Ozkiziltas1, I. Vasi1, M. A. Ozturk1, S. Haznedaroğlu1, B. Goker1, A. Tufan1, Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey

**Background:** Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of fever, serositis, and musculoskeletal symptoms (1, 2). Arthritis is the most common musculoskeletal symptom of attacks and also included in diagnostic criteria of FMF (3). If it is specifically queried, myalgia may be detected in up to 20-25% of the patients with FMF (4, 5).

**Objectives:** In our study, we aim to assess the localization of attack-related myalgia and associated parameters in patients with FMF.

**Methods:** A total of 349 consecutive patients followed by FMF in our clinic were enrolled in the study and asked for attack-induced myalgia and if present, localization of muscle groups on the mannequin body parts diagram. Attack frequency, duration, and disease activity were evaluated with the Auto-Inflammatory Diseases Activity Index (AIDAI) scoring system (6). Patients were also asked for work/study day loss during attacks and patient acceptable symptom state (PASS) status (7).

**Results:** 126 patients showed attack myalgia (36%); attack duration, frequency, severity were significantly higher in patients with attack-myalgia (p<0.005). Most common muscle groups were calves, lower back, and latissimus dorsi muscles in order. Myalgia was most commonly accompanied by arthritis (p<0.002). Patients with myalgia have a higher frequency of colchicine resistance and work/study day loss due to attacks.

**Conclusion:** Our results conclude that myalgia is an important domain of attacks and causes absenteeism and uncontrolled disease activity. Treatment of myalgia attacks may provide controlled disease activity, and prevent absenteeism from work/school.

**AB1273 MACROPHAGE ACTIVATION SYNDROME IN RHEUMATIC DISEASE: CLINICAL CHARACTERISTICS AND PROGNOSIS OF 20 PATIENTS**

S. H. Nam1, S. M. Ahn2, J. S. Oh3, S. Hong4, C. K. Lee5, B. Yoo2, Y. G. Kim2, A. Asan Medical Center, Department of Internal medicine, Division of Rheumatology, Uijeongbu Eulji Medical Center, Department of Internal medicine, Division of Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Asan Medical Center, Division of Internal medicine, Division of Rheumatology, Seoul, Korea, Rep. of (South Korea); 3Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Rep. of (South Korea)

**Background:** Macrophage activation syndrome (MAS) is a hyperinflammatory condition that is known to be secondary hemophagocytic lymphohistiocytosis (HLH) in patients with rheumatic disease.

**Objectives:** The aim of study was to evaluate the clinical manifestations and outcomes in patients with MAS with rheumatic disease.

**Methods:** We performed a retrospective study of 20 adult patients who were diagnosed with MAS from 2012 to 2020. MAS was classified according to the HLH-2004 criteria. Patients’ information, including clinical features, laboratory findings, and treatment regimens, was collected, and the overall survival rate was estimated by the Kaplan–Meier method.

**Results:** Twenty patients (18 women, 35.6 ± 18.3 years) who met the HLH-2004 criteria also fulfilled the 2016 EULAR/ACR/PRINTO classification criteria for MAS, and HScore was higher than 169 (median, 238.5). Fourteen patients with systemic lupus erythematosus and 6 patients with adult-onset Still’s disease were included. All patients were treated initially with corticosteroids, and 16 patients required additional immunosuppressants. The overall survival at 3 and 6 months was 75.2% and 64.3%. In survivors, renal impairment was less common (23.1% versus 42.9%, p = 0.007), the levels of AST and LDH, and platelet count might be associated with non-survivors. Nine patients had opportunistic infections, five of whom died during admission.

**Conclusion:** The mortality of patients with MAS remains high. Renal impairment, levels of AST and LDH, and platelet count might be associated with prognosis.

**SUGGESTED APPROACH TO UBA1 GENE MUTATION TESTING IN PATIENTS WITH SUSPECTED VEXAS SYNDROME**

K. Pavelcová1, B. Stibulková2,3, V. Balaiková1, M. Belíková1, C. Salek4,5, M. Vostřy1, H. Mann1,2, J. Vencovský3,2,1, Institute of Rheumatology, Prague, Czech Republic; 2First Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic; 3First Faculty of Medicine, Charles University and General University Hospital, Department of Pediatrics and Inherited Metabolic Disorders, Prague, Czech Republic; 4First Faculty of Medicine, Charles University, Institute of Clinical and Experimental Haematology, Prague, Czech Republic

**Background:** VEXAS syndrome (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) is a recently identified autoinflammatory disease caused by de novo somatic mutations in the X-linked gene UBA1 (1). This disease is clinically characterized by inflammatory symptoms and bone marrow failure (2).

**Objectives:**

1. To investigate genetic variants associated with VEXAS syndrome and to design an algorithm for detection of UBA1 gene mutations in patients with suspected VEXAS syndrome, which could be used for diagnosis.

2. To exam the UBA1 gene in 9 patients with clinically suspected VEXAS syndrome.

3. To focus on variants p.Met41Val, p.Met41Thr and p.Met41Leu with a known association with this disease (1).

4. To analyze the remaining exons of the UBA1 gene by Sanger sequencing.

5. To evaluate the previously described variants p.Met41Thr in two and p.Met41Leu in another two patients.

6. To develop a new mutation p.Gly477Ala (c.1430G>C) in exon 14 that has not yet been identified.

7. To study the presence of these variants and their allelic forms (heterozygous / homozygous) varied between cell populations in individual patients.

8. To conclude the increasing number of reports suggests that VEXAS syndrome is not rare. In patients with clinical suspicion, typically UBA1 sequencing analysis of haematopoietic cells is performed in hot spot sites of p.Met41 in exon 3 only.

9. Our results suggest that other variants, such as the newly identified p.Gly477Ala variant, may also be associated with clinical features of VEXAS syndrome.

10. We propose that an extended analysis of all coding regions of the UBA1 gene may uncover other mutations with putative functional consequences.

AB1276 EVALUATION OF DRUG-FREE REMISSION RATES IN IDIOPATHIC GRANULOMATOUS MASTITIS

M. N. Kayal, 1 Ö. Kilic, 1 E. Telgöz, 2 S. Colak, 1 M. Çınar, 1 S. Yılmaz, 1 University of Health Sciences Turkey, Gülhane Training and Research Hospital, Rheumatology, Ankara, Turkey

Background: Idiopathic granulomatous mastitis (IGM) is a rare inflammatory breast disease. There is no clear consensus on its treatment yet (1).

Objectives: The aim of the study was to evaluate the rates of drug-free remission of the patients with IGM in a period of three-year follow-up.

Methods: A total of 76 patients who were followed-up with biopsy proven IGM between February 2011 and November 2021 in rheumatology outpatient clinic of Gülhane Training and Research Hospital, were evaluated retrospectively. To analyze long-term outcomes, 55 patients who were followed up for 3 years were included in the study. Data regarding the demographic and clinical characteristics of the patients were obtained from patients’ files.

Results: The study included 55 female patients with a mean age of 36.8 ± 6.3 years. Forty-nine (89.1%) patients received immunosuppressive treatment, one (1.8%) patient received postoperative immunosuppressive treatment, 3 (5.4%) patients had immunosuppressive treatment due to recurrence after surgery, and 1 (1.8%) patient underwent only surgery. One (1.8%) patient had no treatment for IGM. Patients who received immunosuppressive drugs for initial treatment, 38 (69.1%) received methotrexate (MTX) and corticosteroids (CS), 7 (13.2%) received azathioprine (AZA) and CS, 3 (5.6%) received only CS and 1 (1.8%) received cyclosporine A (CsA) and CS. Four (7.2%) patients had received MTX after surgery. At 3-year follow-up 54 (98.1%) patients were in drug-free remission. The median duration of drug-free remission in patients receiving MTX plus CS, CS, and azathioprine plus CS was 19.7, 32.9, and 14.7 months, respectively. One patient who received CsA plus CS was in drug-free remission for 28.3 months. The median duration of treatment with combination of CS and other immunosuppressives was 6.7 months. The median duration of immunosuppressive treatment was 15.8 months (Table 1). Recurrence was observed in 4 (80%) patients who did not receive immunosuppressive therapy after surgery. Three (75%) of these patients received MTX due to recurrence, and remission was achieved.

Table 1. Duration of immunosuppressive treatment and drug-free remission of the patients

AB1277 POOR LONG-TERM OUTCOMES AND SUBSTANTIAL BURDEN OF COMORBIDITIES IN EUROPEAN PATIENTS WITH DERMATOMYOSITIS/POLYMYSITIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

J. Vencovský, 1 K. Pisarczyk, 2 R. Left, 3 E. Park, 4 K. Palanisamy, 5. L. Long, 6 Institute of Rheumatology, Research Department, Prague, Czech Republic, 1 Maple Health Group, Market Access, Cracow, Poland, 2 Kezar Life Sciences, Clinical Development, South San Francisco, CA, United States of America; 3 Kezar Life Sciences, Medical Affairs, South San Francisco, CA, United States of America

Background: Dermatomyositis (DM) and polymyositis (PM) are rare heterogeneous systemic autoimmune disorders of the skin, muscles and other organs that may have a devastating impact on patients’ lives. Despite various therapies used in clinical practice, a notable proportion of patients seem not to achieve sustainable remission. There is a need to better understand long-term outcomes and comorbidities in patients with DM/PM in Europe.

Objectives: To systematically review and summarize evidence on clinical burden of disease in patients with DM/PM in Europe.

Methods: A systematic literature review (SLR) was conducted in MEDLINE and Embase databases to identify studies in children and adults with DM/PM, published in the English language between 2011 and 2021. Primary studies enrolling 10 or more patients were included, irrespective of country or region. Each eligible article was independently reviewed by two reviewers. The title and study abstracts were reviewed to assess eligibility for full-text review. The current abstract summarizes SLR results on the long-term outcomes and comorbidities in patients with DM/PM in Europe.

Results: A total of 2,967 non-duplicated publications were retrieved from medical databases and analyzed against pre-defined study selection criteria. There were 2,574 records excluded at title and abstract screening. Remaining 393 records were analyzed in the full text with 208 papers considered relevant. Additional 21 papers were identified from searching reference list of relevant studies and conference proceedings. In total, 222 studies (229 publications) were included in data abstraction. Among 43 studies conducted across 14 European countries, 23 studies evaluated long-term outcomes of disease and burden of comorbidities. There were 14 longitudinal cohort studies, 7 cross-sectional analyses and 2 case-control studies. Only 29-44% of DM/PM adults achieved remission. Between 38% and 62% of adults with DM/PM required at least 3 different medications, suggesting inadequate response to initial and subsequent regimens. During a mean follow-up of 13.9 years, 69% patients with JDM had polycylic or chronic disease characterized by periods of remission and recurrence or by permanently active disease for more than 2 years after diagnosis. A notable proportion of children (60.4%) showed evidence of damage in at least one body organ and 13-20% of patients had complications such as calcinosis, lipodystrophy, or muscle atrophy. Adults with DM/PM often suffered from intestinal lung disease (166%), serious infections leading to hospitalization or death (126%) and cardiovascular disorders (CVDs) (19-71%). Compared to age and gender matched controls without DM, patients with DM had 16-times higher risk of venous thromboembolism (HR=16.44, 95% CI: 7.54-35.86). Incidence of coronary heart disease, hemorrhagic stroke, or ischemic stroke during 10-year follow-up was approximately 1.5- to 2-times higher in DM/PM adults relative to general population. Multiple studies reported high rates of any malignancy in DM adults (75-93%) and in PM adults (8-17%). During approximately 24,000 patient-years of follow-up, adults with DM/PM had more than 4-times higher incidence of lung cancer compared to general population that also was one of the highest incidences among multiple other autoimmune diseases. Long-term prognosis in DM/PM was poor with 20-year survival below 70%. The most common causes of deaths were pulmonary-related, malignancies, and cardiac complications. Mortality due to lung cancer was more than 4-times higher than in general population (standardized mortality ratio=4.17, 95% CI: 3.03-5.80).

Conclusion: European patients with DM/PM suffer from substantial burden of comorbidities including serious infections, malignancies and CVDs that lead to poor long-term outcomes. A notable proportion of adult and juvenile patients do not achieve sustainable remission or experience relapse indicating high unmet need.

AB1278 INCIDENCE OF ENDOCRINE AND EXOCRINE INSUFFICIENCY IN PATIENTS WITH AUTOIMMUNE PANCREATITIS AT DIAGNOSIS AND AFTER TREATMENT

M. Lanzilliota, 1 M. Tacelli, 1 G. Capurso 2, L. Dagnia 1, E. della Torre 1. 1 San Raffaele Scientific Institute, Unit of Immunology, Immunology, Allergy and Rare Diseases, IRCCS San Raffaele Scientific Institute, Milan, Italy, Milan, Italy; 2 San Raffaele Scientific Institute, Pancreato-Biliary Endoscopy and Endosonography Division, Pancreas Translational and Clinical Research Center, IRCCS San Raffaele Scientific Institute, Milan, Italy, Milan, Italy

Background: Autoimmune pancreatitis (AIP) is a rare form of chronic pancreatitis that may lead to endocrine and exocrine insufficiency if left untreated. AIP clinically responds to glucocorticoids (GCs) therapy, but multiple GCs courses are often required to maintain remission with potential detrimental effects on glycaemic control. To date, data on pancreatic function in AIP are scanty and heterogeneous.

Objectives: We aimed to assess the rate of endocrine and of exocrine insufficiency at diagnosis and at follow-up in patients with AIP as well as the impact of GC therapy on pancreatic function in the long term.
Methods: The MEDLINE, SCOPUS, and EMBASE databases were searched from inception to August 2021 to identify studies reporting data on endocrine and exocrine insufficiency in patients with type 1 and type 2 AIP. Studies involving ≥ 9 patients were included. In case of duplicated studies, the most recent or the one with the largest sample were included. The study was conducted in accordance with Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. Pooled events were calculated using a random-effect model and expressed in terms of pooled prevalence rates.

Results: A total of 6522 AIP patients and sixty-two studies were included in the analysis. The pooled estimate rate for the overall prevalence of diabetes in AIP at baseline (combined type 1 and type 2 AIP) was 36.9% (95% CI 31.9-41.9, I² 96.1%). The pooled estimate for the prevalence of diabetes was 44.3% (95% CI 39.1-49.4, I² 91.9%) in type 1 AIP and 11.3% (95% CI 6.1-16.6, I² 42.5%) in type 2 AIP (p < 0.01), respectively. The pooled prevalence rate of exocrine insufficiency was 45.2% (95% CI 32.9-57.4, I² 97.4%). The pooled estimate rate of diabetes at follow-up was 44.2% (95% CI 26.1-64.2) in studies where GCs were given to 100% of patients and 41.8% (95% CI 30.6-52.9) in studies where GCs were given to less than 100% of patients. The pooled prevalence of pancreatic exocrine insufficiency was 36.2% (95% CI 20.4-52.0, I² 96.4%).

Conclusion: A large proportion of patients with AIP displays concomitant exocrine and endocrine insufficiency at the time of diagnosis. The incidence of diabetes at the longest available follow up tends to increase in patients treated with GCs. Further long-term studies are warranted to assess the impact of GCs and immunosuppressive treatments on glycemic control and on exocrine pancreatic function.

AB1279  POOR QUALITY OF LIFE AND REDUCED WORK PRODUCTIVITY IN EUROPEAN PATIENTS WITH DERMATOMYOSITIS AND POLYMYOSITIS: FINDINGS FROM A SYSTEMATIC LITERATURE REVIEW
J. Schmidt1, K. Pisarczyk2, R. Left3, K. Palisinawamy4, E. Park5, L. Long6, Immanuel Klinik Rüdersdorf University Hospital of the Brandenburg Medical School Theodor Fontane, Department of Neurology and Pain Treatment, Rüdersdorf bei Berlin, Germany; 2Maple Health Group, Market Access, Cracow, Poland; 3Kezar Life Sciences, Clinical Development, South San Francisco, United States of America; 4Kezar Life Sciences, Medical Affairs, South San Francisco, CA, United States of America

Background: Dermatomyositis (DM) and polymyositis (PM) are rare heterogenous systemic autoimmune disorders of the skin, muscles, and other organs with diverse effective treatment options available. They are described as devastating diseases but the full impact on patients’ lives in Europe is not well understood.

Objectives: To systematically review and summarize evidence on humanistic burden of disease in patients with DM and PM in Europe to better understand patient-relevant aspects of disease and key domains of life impacted by DM and PM in the European setting.

Methods: A systematic literature review (SLR) was conducted in MEDLINE and EMBASE databases to identify studies in children and adults with DM and PM, published in the English language between Jan 1, 2011, and Apr 28, 2021. Only primary studies enrolling 10 or more patients were included, irrespective of country or region. Each eligible article was independently reviewed by two reviewers. The title and study abstracts were reviewed to assess eligibility for full-text review.

Results: A total of 2,967 non-duplicated publications were retrieved from medical databases and analyzed against pre-defined study selection criteria. There were 738 unique records excluded at title and abstract screening. Remaining 393 records were analyzed in the full text with 208 papers considered relevant. Additional 21 papers were identified from searching reference list of relevant studies and conference proceedings. In total, 222 studies described in 229 publications were included in data abstraction. Among 43 studies conducted across 14 European countries, 12 studies evaluated health-related quality of life (HRQoL) and work productivity in patients with DM and PM. In 6 studies, patients received standard of care therapy. Six studies enrolled adults with DM and PM and 6 were conducted in patients with juvenile onset of DM. There were 6 cross-sectional analyses, 4 longitudinal cohort studies, 2 case-control studies, with sample size ranging from 11 to 246 patients. Adults with DM and PM had significantly worse HRQoL across multiple domains of 36-item Short Form Survey (SF-36) compared to controls from general population, with a strong negative impact of muscle weakness on physical functioning. Patients reported high difficulties in performing leisure time activities, moving around and work as indicated by median scores of 4-5 points in a 7-point Myositis Activity Profile (MAP). Reduced grip force in DM and PM adults was significantly associated with worse performance in HRQoL across multiple domains of SF-36. Women with DM and PM, poor grip force additionally impacted vitality and mental health as measured by SF-36 (p<0.05). There were no associations between grip force and any SF-36 domain in men. Approximately 60% of adult patients rated their ability to work as “poor” or “less good” according to the Work Ability Index, 68% of patients had more than one week of sick leave in the past year, and 20.8% of them were permanently not able to work for at least 2 years. Children and adolescents with DM had impaired physical and psychosocial functioning compared to healthy norms with 40% of individuals showing increased emotional distress requiring in-depth psychological assessment.

Conclusion: European patients with DM and PM experience a muscle weakness that has a detrimental impact on HRQoL, daily activities and ability to work. Similar disease impact on HRQoL was reported in patients in North America. These findings suggest a need for a novel therapy that will restore physical functioning in patients with DM and PM.

AB1280  IGG4 RELATED DISEASE WITH ATYPICAL SCALENE MUSCLES INVOLVEMENT
J. F. Valdés Corona1, M. Arroyo2, F. J. Zamarripa Molina3, A. C. Chávez Alanís4, 1Hospital Angeles Lomas, Rheumatology, Mexico City, Mexico; 2Hospital Angeles Lomas, Internal Medicine, Mexico City, Mexico; 3Hospital Angeles Lomas, Ophthalmology, Mexico City, Mexico; 4Hospital Angeles Lomas, Radiology, Mexico City, Mexico

Background: IgG4 related disease is a chronic, immune-mediated, fibroinflammatory condition that affects nearly any organ, but most common presentations include salivary glands and lacrimal enlargement, orbital disease, pancreatitis, retroperitoneal fibrosis and tubulointerstitial nephritis. Even as IgG4-related disease is increasingly associated with head and neck manifestations, the involvement of scalene muscles hasn’t been previously described.

Objectives: Describe an interesting case of IgG4 related disease presenting with scalene muscle and cervical manifestations.

Methods: Case report and clinical imaging

Results: 79-year-old female, with a history of Sjogren syndrome treated with hydroxychloroquine 200mg twice a week, presented with unilateral right blepharo- rhoptosis. Physical examination confirmed right eye ptosis, supraorbital soft tissue enlargement, diplopia and limited ocular movement. CT Scan revealed right and left orbit with diffuse enlargement of the right superior rectus, suggesting bilateral dacyrocytis, and most important it described a pseudotumor of 5.7 cm x 3.2 cm x 6.2 cm infiltrating asymetrically the lower portion of the left scalene muscle. Lacrimal biopsy and immunohistochemistry revealed IgG4 related disease (dense lymphocytic infiltrate, IgG4+IgG+ ratio 53% and more than 10 cells/hpf). Serum IgG4 concentration 633mg/dl (more than 5 times upper limit of normal). Pulmonary embolism was also detected. The patients received treatment with a tapering regime of oral prednisone. Budesonide mouth mist for long term immunosuppression, with adequate response and complete remission of symptoms.

Conclusion: The multiorgan involvement and recently recognized nature of IgG4 related disease, may cause confusion among physicians; leading to misdiagnosis, unnecessary procedures and delay in treatment. It requires a high degree of clinical suspicion to diagnose a IgG4 RD, when presenting with ocular involvement, and even more when it affects organs that are not usually associated with this condition, such as scalene muscles. The diagnosis is supported by pathognomonic histopathological findings, and even as treatment strategies are constantly evolving, glucocorticoids remain as first line treatment.

Whether this finding is related with those observed in the paravertebral band – like soft tissue in the thorax, has to be defined. Also interesting is that in this case, this pseudotumor is in the left side.

AB1282 OVARIAN RESERVE IN BEHÇET’S DISEASE

Z. Alekberova1, R. Goloeva2, M. Cherkasova2, A. Lila3, V.A. Nasonova Research Institute of Rheumatology, advisory department, Moscow, Russian Federation; V.A. Nasonova Research Institute of Rheumatology, Trobovinflammation Laboratory, Moscow, Russian Federation

Background: Behçet’s disease (BD) is a multisystemic disease of unknown cause. Anti-Mullerian hormone (AMH) is one of the key parameters for assessing reproductive function and ovarian reserve. The levels of AMH correlates with the residual follicular pool in women of reproductive age.

Objectives: To assess AMH levels in BD female patients of child-bearing potential, and analyze the relationship between AMH levels and disease severity, as well as relationship between serum AMH levels and different therapeutic regimens.

Methods: The study group included 45 women with BD (according to ISGKD 1990 and ICBD 2014) aged 20-40 years, and the control group included 15 age-matching healthy women. BMI mean age was 31.3 [27.35], disease duration 6 [3.8] yrs. 178% pts had severe BD according to Ch.Zouboulis classification (due to generalized ulcers, retinal vasculitis and parenchymatous CNS lesions), 37.8% pts had a moderate disease, 44.4% pts had a mild disease with mainly dermal-mucous manifestations. AMH levels was measured using ELISA. AMH reference values ranged within 1.0-10.6 ng/ml. Values <1.0 were interpreted as a decreased ovarian reserve.

Results: The mean levels AMH was 2.5 ng/ml in BD pts, and 3.1 ng/ml in control group, showing no statistical difference. A decrease in ovarian reserve (AMH less than 1.0 ng/ml) was observed with the same frequency 18% in patient’s vs. control group 13%. In the analysis of AMH, depending on the severity of BD, a decrease in ovarian reserve was more often observed in patients with moderate and severe forms of BD.

Table 1. AMH and severe BD

<table>
<thead>
<tr>

</tr>
<tr>
<td>AMH &gt;1ng/ml, %</td>
<td>10</td>
<td>23</td>
<td>25</td>
<td>0,02</td>
<td></td>
</tr>
</tbody>
</table>

There are no correlations of levels AMH with treatment of BD.
A decrease in ovarian reserve was noted in two patients under 30 years old, one was 29 years old woman with “Neurobehçet” with two children, and the patient with Behçet’s disease (BD) was not married, had no pregnancies, and received colchicine therapy for a long time. Two BD patients with low AMH had no pregnancies - unfortunately, all other patients with reduced ovarian reserve had from 1 to 6 children. When analyzing the levels of AMH with the clinical picture and BD therapy, no correlations were found.  

Conclusion: The average levels of AMH in women with BD and in the control group did not differ. A decrease in ovarian reserve (AMH less than 1.0ng/ml) occurred with the same frequency in patients with BD and controls. A decrease in ovarian reserve was more often observed in patients with moderate and severe BD.

AB1283  
HOW TO COUNSEL A WOMAN WITH BEHÇET'S DISEASE: RESULTS FROM A MONOCENTRIC COHORT OF WOMEN DIAGNOSED DURING CHILDbearing AGE  
M. Arbrile1, M. Radin1, D. Rosai1, E. Menegatti1, D. Roccatello1, S. Sciascia1  
University of Turin, Clinical and Biological Sciences, Turin, Italy  

Background: Patients with autoimmune diseases require appropriate pregnancy counseling, as their disease can negatively impact both maternal and fetal outcomes. In regards to Behçet's disease (BD), although commonly diagnosed during the childbearing age, only few studies focused on its impact on gestation, with contradictory results.  

Objectives: We aimed to collect new data on BD and its impact on pregnancy by designing a single-center cohort study, reporting the pregnancy and maternal outcomes in BD patients attending the Multidisciplinary Centre for Immunopathology and Rare Diseases at Giovanni Bosco Hospital (Turin, Italy).  

Methods: We retrospectively included 26 women diagnosed with BD followed at our center. Out of 26 patients, data from 33 pregnancies in 16 women were collected. Ten patients were never pregnant. Table 1 shows the demographical and clinical characteristics and the pregnancy outcomes of the enrolled patients.  

Table 1. Clinical characteristics and pregnancy outcome of the Behçet’s disease patients enrolled in the study.

| Vaginal bleeding before 20 weeks of gestation; n (%) | 1/33 (3.03%)  
| Worsening of oral and genital ulcerations; n (%) | 21/11 (18%)  

* This information was available only for 11/33 pregnancies.BD – Behçet’s disease;S.D. – Standard deviation  

Results: All included patients fulfilled the international criteria for BD (1), with a median age at the time of diagnosis of BD and first pregnancy of 45,56±11.42 and 24,86±6.56 respectively. The frequency of clinical manifestations was oral ulcers (100%), genital ulcers (80,76%), erythema nodosum (23.08%), folliculitis (5.76%), ocular manifestations (42.31%) and HLA B-51+ (50%), respectively. The overall rate of live births was 81,81% (27/33). Twelve women experienced pregnancy complications (36.36%), in particular we report one case of vaginal bleeding before 20 weeks of gestation, six miscarriages before the 10th week of gestation, three cases of gestational diabetes and two placental abruptions. Among the analyzed pregnancies, a worsening of oral and genital ulcerations was observed in the 18% of them, while in the remaining cases a subjective amelioration of aphtosis and other concurrent symptoms was reported by the patients. No systemic flare, worsening of ocular complications and VTE was reported during pregnancy and in the post-partum period.  

Conclusion: The results of our study highlight an overall favorable rate of life births in BD women and a positive rate of disease remission in pregnancy. Currently, the studies focusing on pregnancy outcomes in BD are scarce, however it might be appropriate to give a specialized counseling to a BD woman planning for a pregnancy and follow these patients with a multidisciplinary approach.

AB1284  
GENDER CHARACTERISTICS OF IDIOPATHIC LOBULAR PANNICULITIS  
O. Egorova1, G. Tarasova1, A. Datsina2  
1V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; 2Pirogov Russian National Research Medical University, Ministry of Health of Russia, Pirogov Russian National Research Medical University, Ministry of Health of Russia, Moscow, Russian Federation  

Background: Idiopathic lobular panniculitis (ILP) (Weber-Christian disease) is the least studied disease from the group of “systemic lesions of the connective tissue” and is characterized by a multifaceted lesion of the subcutaneous adipose tissue (SAT) of organs.  

Objectives: to compare the incidence of clinical and laboratory manifestations of ILP in patients of different sexes in the Russian cohort.  

Methods: We examined 67 patients (9 men and 58 women) aged 20 to 76 years with an average duration of the disease 78.91 months [48; 540] with a verified diagnosis of ILP, who were observed at the V.A. Nasonova Research Institute of Rheumatology in 2010-2021. In addition to general clinical examination, determination of the titer of α-1 antitrypsin, liver fractions, amylase, lipase, trypsin, ferritin, creatine phosphokinase, lepiltin, TNF-α, computed tomography of the chest and pathomorphological studies of induration were carried out.  

Results: The peak of the disease in men (55.55%) was detected at 35–45 years old, while in women (38.5%) from 50 to 60 years old. In 55.2% of women, two periods of the development of the disease were identified – from 16 to 25 in 12 patients (32.4%) and from 46 to 60 in 25 patients (67.5%). When analyzing the demographic indicators in patients with ILP, 86.3% were residents of the European part of Russia, no gender differences were found. In 3 men (33.3%) and 22 women (37.9%), ILP was diagnosed within a year. With the disease duration of 1 to 5 years, the diagnosis was confirmed in 44.4% of men and in every third woman. The duration of more than 5 years from the onset of the first symptom to the establishment of a reliable diagnosis of ILP in women was 32.7%, while in men – 11.1% (p <0.03). The nodular form (Mf; 55.5%) and the mesenteric form (Mf; 33.3%) were observed somewhat more often in men than in women, with a tendency to a higher body temperature and a greater number of painful (according to VAS) indurations. In women, Nf was found in 43.1% of cases, plaque form and Mf – in 15.5% each. The infiltrative form (25.8%) was found only in women. Indurations were characterized by a subfebrile temperature, mainly with localization on the thighs (75.8%), upper limbs (51.7%) and trunk (43.1%). Later, in 31 patients (46.2% (93.3% of them were women), a combination or transition from one form to another was detected, indicating a mixed nature of the disease. Body temperature indices in men were inversely correlated with the duration of the disease (r = −0.73; p <0.05). In women, there was a significant association of an increase in body temperature with pain (according to VAS) of the nodes (p <0.05), as well as with the form of the disease (p <0.03). Average ESR data were higher in women (24.50 ± 15.99mm/h). In the presence of a high level of CRP (46.2 ± 31.7 pg/ml) was significantly more often observed with Mf (p<0.017), which correlated with the concentration of TNF-α (r = 0.72; p <0.05). Women had a 2.3 times higher leptin content than men (r = 0.46; p <0.05). Pathomorphological examination of a biopsy of the skin and SAT confirmed lobular panniculitis (ILP) in all cases.  

Conclusion: In the Russian cohort of patients, male gender is associated with a progressive course of the disease, which is the basis for prescribing immunosuppressive therapy for men with ILP at early stages of the disease.

Conclusion: Behcet’s disease is most often detected in natives of the North and South Caucasus, Russians and natives of Central Asia in the Russian Federation’s cohort. Differences in the frequency of various clinical manifestations depending on the ethnicity of patients were revealed.

Disclosure of Interests: None declared

Results: The number of patients with pain reduction ≥50% from baseline were 12.0% (significant difference from baseline in all points, p<0.05). Similarly, there was a 10-cm VAS at baseline, after 2, 4 and 8 weeks was 6.5±1.2; 4.8±1.4; 2.6±1.4; 2.2±1.1 cm detected in 14 patients (67%), with predominant involvement of the ankle (67%) and C-reactive protein level (p = 0.006; r = 0.38). There was a direct correlation between the number of nodules and the duration of LPn (p = 0.04; r = 0.20) and a novel participant-reported outcome measure, the Dermatomyositis-Disease Symptoms Questionnaire (DM-DSQ). Safety will be assessed by analyzing the incidence of treatment-related adverse events (TEAEs), including those classified as serious and/or leading to intervention discontinuation.

Conclusions: Etoricoxib is effective and relatively safe for long-term control of chronic pain in LPn.

Background: Cardiac involvement is an uncommonly seen but might be a fatal clinical manifestation of Behcet's syndrome (BS), if not recognized early and treated aggressively.

Objectives: Our aim was to retrospectively evaluate the characteristics of cardiac involvement in Behcet's syndrome and investigate possible risk factors.

Methods: 800 patients with BS diagnosis according to International Study Group for Behcet's Disease (ISG) criteria in our center were screened. 14 patients with cardiac involvement were included in this study.

Results: All the patients were male with positive smoking history. The age at the onset cardiac involvement was 32.5 ± 7.8 years. In 3 patients, diagnosis of BS was made simultaneously with cardiac involvement. Types of cardiac involvement were as following: intracardiac thrombosis (ICT) in 8, right coronary artery aneurysm in 2, and myocardial infarction in 4 patients. The majority of ICT was seen in right ventricle followed by right atrium (75% vs 25%). Deep vein thrombosis (DVT) was the most common followed by other vascular involvement (57%). Thrombophilic factors were studied in 8 patients, whom only 2 cases were found positive for heterozygous factor V Leiden mutation. Cyclophosphamide was the most common used immunosuppressive agent and anticoagulation was used in 9 patients (Table 1).

<table>
<thead>
<tr>

---

Background: Autoinflammatory diseases (AIDS) are a group of rare monogenic and multifactorial diseases manifested by systemic inflammation, organ disorders, the development of complications, primarily amyloidosis, and possible death without timely targeted therapy. Rapid diagnosis contributes to the early appointment of treatment, prevention of the development of organ damage and improvement of prognosis in such patients.

Objectives: To establish the age of the onset and the duration of the delay of diagnosis in patients (pts) with monogenic AIDS (mAIDS) and systemic juvenile idiopathic arthritis (sJIA) according to the Federal Rheumatology Center.

Methods: 273 pts were included in the study for the period from 2007 to 2021, 158 of them with mAIDS: FMF - 75, CAPS - 50, TRAPS - 28, HIDS/MKD - 5, 115 pts with sJIA.

Results: The age of pts with mAIDS ranged from 6 months to 65 y.o. (120 children and 38 adults), among pts with sJIA there were only children aged 12 months to 17 y.o. Most of the pts with CAPS, TRAPS, HIDS/MKD were female (62.4%), as with sJIA (57.4%). FMF was more often affected by male persons (56.6%). The age of the onset of mAIDS ranged from 0 to 53 y.o., sJIA - from 4 months to 15 y.o., was the smallest in pts with CAPS and HIDS/MKD. 33.5% pts with mAIDS had the onset of the disease from birth or within the first year of life, more often with CAPS and HIDS /MKD, in the first decade of life in half of the pts (52.5%), more often in FMF and TRAPS, from 10 to 18 years - 8.2%, in adulthood - 5.7%. In pts with sJIA, the onset of the disease was mainly in the first 5 years of life – 69 (60%), from 5-10 years – 38 (33%), rarely in the first year of life and after 10 years of age (6.9%). The duration of the disease at the time of diagnosis ranged from 1 month to 16 years in FMF pts, from 1 month to 46 years in CAPS, from 3 months to 59 years in TRAPS, from 3.5 to 16.5 years with HIDS/ MKD, from 3 weeks to 78 years with sJIA. Within 1 year the diagnosis was established in 15.2% of children with mAIDS, in 12.2% with sJIA, in the first 5 years of the disease in 35.4% and 15.6% respectively. The delay in diagnosis for more than 5 and 10 years was observed in 24.1% and 25.9% of pts with mAIDS, practically did not occur in sJIA. The least delay in diagnosis was noted in pts with FMF.

Conclusion: Most of the pts with mAIDS had the onset of the disease in the first 5-10 years of life, an earlier age of onset was noted in pts with CAPS and HIDS/MKD. To date, the delay in diagnosis in pts with mAIDS remains very long and reaches decades, especially with CAPS, TRAPS and HIDS/MKD. In pts with sJIA, the diagnosis was established faster, according our opinion a later diagnosis is associated with a poly cyclic course of the disease. Earlier diagnosis and the appointment of targeted therapy are needed, which will help to avoid complications, improve the prognosis and quality of life of pts.

Background: Uveitis is still an important cause of morbidity leading to vision loss in Behcet’s syndrome (BS).

Objectives: Our aim in this study was to retrospectively evaluate characteristics of uveitis, long term complications, and its association with the other components of BS.

Methods: 800 patients with BS diagnosis according to International Study Group for Behcet’s Disease (ISG) criteria in our center were screened and among those, data of 109 patients with BS-related uveitis were included in this study.

Results: The overall prevalence of uveitis was found 13% among all BS population. Majority of BS-related uveitis were male (65.1%/34.9%). Mean age for BS diagnosis and onset of uveitis were found 38 ± 8.48 and 27 ± 8.42 years. In this group, uveitis developed before BS diagnosis in 33% of patients.
whereas 44% were diagnosed at onset of uveitis. The frequency of this population was estimated 6% among all BS patients. Characteristics of uveitis were as following: unilateral (45/99), bilateral (54/99), anterior (12), posterior (30), panuveitis (30), retinal vasculitis (9) and not defined (9). 25 patients experienced only one attack, whereas more than one attack was seen in 74 patients during follow up. 74 patients whose complications data was available, cataract, maculopathy, glaucoma, and optic atrophy developed in 10, 7 and 3 patients, respectively. Vision loss was seen in 8 patients as partial, in 28 as total (Table 1).

INTRATHECAL INJECTION OF METHOTREXATE COMBINED WITH DEXAMETHASONE FOR COGAN SYNDROME WITH NEUROLOGICAL INVOLVEMENT: A CASE REPORT

J. Hu1, H. Du1, J. Su1, R. Wu1, J. Zhu1, T. Wu1. 1Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chinese Academy of Sciences Sichuan Translational Medicine Research Hospital, Department of Rheumatology and Immunology, Chengdu, China

Background: Cogan syndrome (CS) is a rare autoimmune disease, mainly occurring among young people, with an incidence rate of <0.11/100000 (100000). CS is mainly characterized by interstitial keratitis, visual loss associated with co-clear vestibular involvement and Meniere type vertigo. It usually involves all systems of the body, and about 10% to 15% of cases have nervous system involvement. Fewer than 400 cases have been reported worldwide (1). Glucocorticoid is mainly used in acute attack as the basis of treatment, the effect was not satisfactory(2). Here, we report a case of CS with nerve injury as the main manifestation, which was successfully treated by intrathecal injection of methotrexate combined with dexamethasone.

Objectives: CS often involves multiple systems throughout the body and has a poor clinical prognosis. From a review of our patient's treatment experience, intrathecal methotrexate combined with dexamethasone may be an effective treatment modality for CNS involvement in patients with refractory recurrent Cogan syndrome.

Methods: The clinical manifestation, laboratory test, treatment, and outcome were described.

Results: A 31-year-old man presented with recurrent bimanual joint pain for 2 years, after which the patient developed interstitial keratitis, hearing loss and was diagnosed with CS. The patient received treatment with glucocorticoid, cyclophosphamide, methotrexate, tacrolimus, leflunomide, mycophenolate mofetil, hydroxychloroquine, adalimumab. The joint pain was improved, but the headache, dizziness, tinnitus and hearing impairment were significantly aggravated, and syncope occurred. Cerebrospinal fluid examination for lumbar puncture on admission of the patient showed CSF pressure > 185 mmH2O, CSF microprotein 1.10 g/l, and CSF nucleated cell count 120x10⁶ /L. At the beginning, we successively treated the patient with methylprednisolone (40 mg, QD), gamma globulin (10g, QD), methotrexate (20 mg, QW) and cyclophosphamide (100mg, QOD), but the effect was not satisfactory. After excluding infection, we treated this patient with intrathecal methotrexate 10 mg combined with dexamethasone 10 mg, and the patient's symptoms of dizziness, headache, and tinnitus improved significantly, and his hearing did not decline significantly any more. The patient received a total of seven intrathecal injections (cumulative methotrexate 60 mg + dexamethasone 65 mg) during the subsequent 6 months. His dizziness, headache, tinnitus and other neurological symptoms improved significantly, no further syncope, fever. CSF protein quantification and the number of CSF nucleated cells decreased significantly.

Conclusion: CS patients are often accompanied by multisystem injuries, so it is essential to correctly identify CS and provide appropriate treatment as soon as possible. For patients with neurological involvement who do not respond to treatment with glucocorticoids and immunosuppression, intrathecal methotrexate combined with dexamethasone may be considered as a treatment option for CS in the future.

CO-OCCURRENCE OF IGG4 RELATED DISEASE AND OTHER SYSTEMIC IMMUNO-MEDIATED DISORDERS.

V. Batai1,2, M. Lanzillotta1, F. Chiabrandano1, G. Mancuso1, J. Mahajne1, L. I. Belli1, L. Dagna1, E. Della Torre1. 1Vita-Salute San Raffaele University, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy;
2University of Verona, Medicine - Unit of Immunology, Verona, Italy

Background: IgG4-related disease (IgG4RD) is a fibroinflammatory disease with unique clinical and pathophysiological features. According to the recently released Classification Criteria, the presence of other concomitant immunological disorders (OID) represents an exclusion criterion for the classification of IgG4RD (1). Rigorous application of the Classification Criteria, however, can lead to misdiagnosis because our increasing appraisal of IgG4RD indicates that this condition may coexist with OID (2).

Objectives: To describe IgG4RD presentation in the context of OID.

Methods: IgG4RD was diagnosed based on definitive histological findings. OID were diagnosed based on specific classification/diagnostic criteria.

Results: In six out of 234 (3%) patients IgG4RD occurred in accommodation with OID, including two patients with sarcoidosis (33%), two with granulomatosis with polyangiitis (33%) one with eosinophilic granulomatosis with polyangiitis (16%) and one with Takayasu arteritis (16%). In three cases IgG4RD preceded OID (Table 1).

Conclusion: Our data demonstrate that IgG4RD can occur in overlap with OID, especially granulomatous diseases. Further research is needed to define whether this clinical scenario is associated with different pathological bases and long-term outcomes.

AB1296  LONG-TERM EXPERIENCE OF THE THERAPY WITH INTERLEUKIN-1 INHIBITORS IN MONOGENIC AUTOINFLAMMATORY SYNDROMES AND SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS IN REAL-LIFE PRACTICE OF RHEUMATOLOGISTS IN SINGLE FEDERAL CENTER

S. Salujina1, M. Kaleda1, E. Fedorov1, I. Nikishina1, A. Torgashina2.
1V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, Laboratory of Intensive Therapy Methods, Moscow, Russian Federation

Background: Autoinflammatory diseases (AIDs) are a heterogeneous group of rare genetically determined conditions. Biologics (B) are used, especially inhibitors of interleukin 1 (IL-1), in the treatment of the most common mono- genic AIDs (mAIDs) – FMF, TRAPS, HIDS/MKD, CAPS. IL-1 has shown high efficiency and led to significant progress in the treatment of these patients (pts). Currently, IL-1 are the first-line drugs for mAIDs therapy, primarily CAPS. In pts with systemic juvenile idiopathic arthritis (sJIA) IL-1 inhibitors are also successfully used in the first or second line of therapy along with IL-6 inhibitors.

AB1295  TREATMENT OUTCOMES OF ADULT-ONSET STILL'S DISEASE PATIENTS WITH BIOLOGICAL THERAPY

Y. Erez1, T. Demiro Yiildirim2, M. Birlik2, G. Can1, F. Onen1, I. Sarı1, 1Dokuz Eylul University School of Medicine, Division of Rheumatology, Izmir, Turkey; 2Dokuz Eylül University School of Medicine, Division of Rheumatology, Izmir, Turkey

Background: Adult-onset Still's disease (AOSD) is a rare systemic inflammatory disorder with heterogeneous distribution (1). Due to rarity of AOSD and limited controlled study about efficacy of biologic treatment in AOSD, management of refractory AOSD patients poses several challenges.

Objectives: The aim of this study to investigate clinical characteristics and treatment outcomes of AOSD patients who receive biological therapy.

Methods: Patients were identified who met Yamaguchi classification criteria between January 2010 and December 2021 from our database. AOSD patients treated with biologic treatment were included in this study. Demographic data, clinical features and treatment characteristics were recorded.

Results: 49 AOSD patients were identified from database. 9 AOSD patients with biologic therapy (7 female, mean age 42.3±19) were included in this study. Mean age at diagnosis was 31.5±16.7 and mean follow-up period was 9.3±5.5 years. Median drug retention duration was found 95 (5-150) months. It was established that all patients used high dose steroid at diagnosis and 3 (33.3%) out of them received pulse steroid therapy. Initial therapy was methotrexate for all patients that all patients used high dose steroid at diagnosis and 3 (33.3%) out of them switched to adalimumab and etanercept. Biological therapy was discontinued in 2 patients due to remission, and patients remained in remission after cessation of biological agent. None of patients had serious infection. Hemophagocytic syndrome was developed in only one patient during disease course.

Conclusion: According to our cohort, one of five AOSD patients received biologic therapy during follow-up. Our results revealed that the need for biologic therapy during the course of the disease is not uncommon in AOSD, and that biologic therapy is essential for maintaining remission in resistant patients.

REFERENCES:
Objectives: To evaluate in the real clinical practice the frequency of prescribing, efficacy and safety of IL-1 therapy in pts with mAIDS and sJIA according to the Federal Rheumatology Center.

Methods: A retrospective study from 2013 to 2021 included 66 pts who were prescribed IL-1. Among them 45 pts with mAIDS: FMF - 8, CAPS - 25, TRAPS - 10, HIDS/MKD – 2, 21 pts had sJIA. Canakinumab (CAN) was administered subcutaneously at the dose of 2-5mg/kg or 150mg every 4-8 weeks, anakinra (ANA) - subcutaneously at the dose of 1-5mg/kg or 100mg daily.

Results: Among pts with mAIDS 45 received IL-1. The age of pts ranged from 1.5 to 44 years, the median (Me) age was 9.56 [9;17] years. Female pts predominated (60%). The median age at onset was 0.5 [0;4] years (0 - 35 y). The median duration of the disease was 7.5 [3;9;15] years (3 months to 44 years). 35 pts received CAN, 10 - ANA. Both drugs showed significant positive dynamics with a complete response in 40 (88.9%), a partial response in 5 (11.1%), mainly due to serious neurological and cognitive impairments in 2 pts with CINCA/NOMID, sensorineural hearing loss in 3 adult pts with MWS, as well as amyloidosis in 1. In 7 pts with CAPS who received ANA as first biologic treatment, after achieving a reliable positive response, switching to CAN was performed while maintaining full efficacy. It was possible to discontinue the glucocorticoids (GC) in all pts. In 2 pts with CINCA/NOMID (1), MWS (1) due to insufficient efficiency the interval between injections of CAN was reduced from 8 to 4 weeks. The duration of use of CAN in pts with mAIDS ranged from 6 months to 12 years, ANA – 2 months to 12 years, 13 pts (28.9%) have been receiving therapy for 5 years or more. The age of pts with sJIA ranged from 3 to 17 years, Me 8,15 [5; 12;7] years. The age of the onset varied from 4 months to 12 years, Me 3,1 [8; 5,7] years. Female pts predominated (61,9%), 20 pts received CAN (18 after secondary inefficiency/infusion reaction of tocilizumab (TCZ), 2 had previous experience of 3 B: TCZ-etanercept-adalimumab, TCZ-aba- tcept-adalimumab). 1 patient received ANA. The duration of CAN treatment was from 5 months to 4.5 years. Among pts with sJIA who received CAN, secondary inefficiency with discontinuation was observed in 6 (28,6%) (10-25 months after treatment initiation), and in 1 patient who received anakinra for 8 months. The tolerability of therapy was generally good. We have not observed any SAE in the treatment of IL-1. All pts are continue taking medications.

Disclosure of Interests: B. Chalcev1, A. Torgashina1, E. Sokol1, J. Khvan on behalf of Laboratory of Rare Rheumatic Diseases and Primary Sjögren's Syndrome. V.A. Nasonova Research, Laboratory of Rare Rheumatic Diseases and Primary Sjögren’s Syndrome, Moscow, Russian Federation

Background: Hematological diseases such as multiple myeloma (MM) and POEMS-syndrome can be accompanied by high serum IgG4 level and thus mimic an IgG4-related disease (IgG4-RD) [1, 2]. However, there are no descriptions of AL-amyloidosis with increased secretion of IgG4 in the literature.

Objectives: to present a clinical case of AL-amyloidosis mimicking IgG4-RD.

Methods: At the age of 42, patient S. developed nasal congestion, and 2 years later bilateral symmetrical swelling of submandibular salivary glands developed. Chest CT scan revealed hydrothorax and pericarditis, interstitial changes in both lungs and intrathoracic lymphadenopathy. According to blood tests, ANF, RF and CRP were within normal values, an increase in the serum IgG4 (32.9g/l) and IgG (34.1g/l) levels was detected, and the patient was admitted to our clinic with suspicion of IgG4-RD.

Results: On examination, we noticed a symmetrical enlargement of submandibular salivary glands and macroagglutinosis. The patient also complained of tingling in the fingers, we performed electroneuromyography and revealed bilateral carpal tunnel syndrome. According to the immunofixation of blood and urine proteins, IgG-lambda paraproteinemia (18,3g/l) and a trace amount of Bence-Jones lambda protein in the urine were detected. AL-amyloidosis was suspected and a biopsy of the submandibular salivary gland was performed, followed by Congo red staining and darkfield microscopy that confirmed amyloidosis (Figure 1). There were no signs of IgG4-RD (storiiform fibrosis or obliterative phlebitis) in the biopsy specimens. Echocardiography revealed thickening of the interventricular septum and hypertrophy of the ventricular myocardium. MM and other malignancies were excluded on the basis of bone marrow trephine biopsy and PET-CT (also revealed severe hepatomegaly). The diagnosis of IgG4-secretory AL-amyloidosis affecting salivary glands, tongue, heart, lungs, liver, nervous system was made and polychemotherapy was started, the patient’s further life remained unknown.

EVALUATION OF POSSIBLE RISK FACTOR OF PULMONARY EMBOLISM IN SARCOIDOSIS PATIENTS

B. Ruaro1, P. Contaloneri1, C. Torregiani2, S. Pichierri2, M. Contaloneri2, P. Salton1

Department of Pulmonology, University of Trieste, Trieste, Italy;

Department of Pulmonology, University Hospital of Cattinara, Trieste, Italy

Background: Some studies reported a correlation between sarcoidosis and an increased risk of pulmonary embolism (PE) [1, 2].

Objectives: To assess possible risk factors of PE in sarcoidosis patients.

Methods: We enrolled 260 sarcoidosis patients (170 females and 90 males; mean age at diagnosis 46 ± 9), after giving written informed consent. We perform clinical evaluations, laboratory tests and radiology features.

Results: Our study population included 20 sarcoidosis patients with PE (14 females and 6 males; mean age at diagnosis 45 ± 10), diagnosed by lung scintigraphy and 240 sarcoidosis patients without PE (170 females and 70 males; mean age at diagnosis 46 ± 11). There was a significant increase of the presence of antiphospholipid antibodies in the sarcoidosis group with pulmonary embolism (55%) than in group without PE (9%) (p-value<0.01). There was no statistically significant difference between the two groups on smoking habit, obesity, treatments and hereditary thrombophilia frequency (p > 0.05, respectively).

Conclusion: This study demonstrated an increased of antiphospholipid antibodies positivity in sarcoidosis patients with pulmonary embolism. Furthermore, we propose screening for these antibodies in all sarcoidosis patients.

AL-AMYLOIDOSIS MIMICKING IGG4-RELATED DISEASE

B. Chalcev1, A. Torgashina1, E. Sokol1, J. Khvan1

1Department of Pulmonology, University of Trieste, Trieste, Italy

Objectives: To assess possible risk factors of PE in sarcoidosis patients.

Methods: We enrolled 260 sarcoidosis patients: 170 females and 90 males; mean age at diagnosis 46 ± 9, after giving written informed consent. We perform clinical evaluations, laboratory tests and radiology features.

Results: Our study population included 20 sarcoidosis patients with PE (14 females and 6 males; mean age at diagnosis 45 ± 10), diagnosed by lung scintigraphy and 240 sarcoidosis patients without PE (170 females and 70 males; mean age at diagnosis 46 ± 11). There was a significant increase of the presence of antiphospholipid antibodies in the sarcoidosis group with pulmonary embolism (55%) than in group without PE (9%) (p-value<0.01). There was no statistically significant difference between the two groups on smoking habit, obesity, treatments and hereditary thrombophilia frequency (p > 0.05, respectively).

Conclusion: AL-amyloidosis can be accompanied by high serum IgG4 level and mimicking IgG4-RD. The serum level of IgG4 should not be used as a criterion for IgG4-RD, and in all cases of suspected IgG4-RD the diagnosis should be confirmed morphologically.

Other orphan diseases

S. Amikishiyev1, N. Aliyeva1, M. Bektas1, N. Koca1, L. Soitanova1, Y. Yalçınkaya1, B. Artim-Esen1, M. Inanc1, A. Gül on behalf of The Team of Istanbul Faculty of Medicine, Istanbul University. Istanbul Faculty of Medicine, Istanbul University, Division of Rheumatology, Istanbul, Turkey

Background: Haploinsufficiency of A20 (HA20) is a monogenic autoinflammatory disorder caused by heterozygous loss-of-function mutations in TNFAIP3 gene and characterized by Behçet disease (BD)-like manifestations such as mucocutaneous, articular, gastrointestinal, ocular symptoms as well as recurrent fever, elevated acute-phase reactants during relapses; and it usually starts during early childhood. Autoimmunity is another component of HA20 with autoantibodies and variable clinical features resembling systemic lupus erythematosus (SLE) and other autoimmune diseases.

Objectives: We herein present three cases of HA20 with different clinical features and diagnosed during adulthood.

Methods: We used the Ion Torrent platform for deep sequencing.

Results: Case 1: A 51-year old woman diagnosed with BD because of oral and genital aphthous ulcers, arthralgias, erythema nodosum, and pathergy positivity starting from age of 40 in 2012. She developed sudden vision loss (diagnosed with bilateral optic neuropathy), sixth nerve palsy, and entrapment neuropathies in the lower limbs in 2014; and she had flares of neurologic findings between 2014-2020. The only laboratory abnormality was elevated acute-phase reactants, and no pathologic finding was reported for cranial MRI. Pathological examination of sural nerve biopsy revealed chronic inflammatory demyelinating polyneuropathy (CIDP). She received adalimumab and then tofacitinib, and her treatment was switched to certolizumab and IVIG (30 g/6 weeks) in 2020. At the last visit, she was asymptomatic with normal acute phase response, and her examination revealed normal eye movements.

Case 2: A 33-year old woman was followed for 12 years with the diagnosis of SLE, characterized by Behçet disease (BD)-like manifestations such as mucocutaneous, articular, gastrointestinal, ocular symptoms along with strong acute phase response even in adults. Response to corticosteroids and targeted treatments may also be variable.

AB1300 AA AMYLOIDOSIS IN A PATIENT WITH MUTATIONS IN BOTH ADA2 AND A20 GENES

S. Amikishiyev1, B. Ince1, M. Bektas1, Y. Yalçınkaya1, B. Artim-Esen1, M. Inanc1, A. Gül on behalf of The Team of Istanbul Faculty of Medicine, Istanbul, Turkey

Background: Adenosine Deaminase 2 Deficiency (DADA2) and Haploinsufficiency of A20 (HA20) are two recently described monogenic autoinflammatory diseases (AID). The uncontrolled inflammatory response has been associated with an increased risk of AA amyloidosis in other AID, but there are only two reported patients with DADA2-related amyloidosis so far.1,2

Objectives: We herein report a patient with AA amyloidosis and AID associated with both DADA2 and HA20.

Methods: We used the Ion Torrent platform for deep sequencing.

Results: Case: A 20-year old male patient born to consanguineous parents (Figure 1), was admitted to our hospital with fever and abdominal pain in June 2014. Peritonitis, hepatomegaly, and a palpable non-tender mass in the right axillary cavity were detected in physical examination, and his laboratory investigations revealed neutrophilic leukocytosis, high acute phase reactants (APR), and pancytopenia, anti-dsDNA positivity. Her fever, red arthritis attacks with high CRP values did not respond, and after the genetic diagnosis of HA20, anakinra was added to treatment. Due to the high dose anakinra requirement, her treatment was switched to canakinumab (150 mg/2 week), and at the last visit, her attacks were significantly reduced.

Case 3: A 44-year old woman was evaluated because of recurrent prolonged >38°C fever attacks (2 days-2 weeks duration), arthritis of the elbow, wrist, knee joints, and high acute phase reactant in 2004. She did not have a history of recurrent oral and genital aphthous ulcers, intermittent periorbital edema, rash, anyocular symptoms, or sensorineural hearing loss. ANA, RF, anti-CCP, and MEFV gene mutation were negative on admission. PET-CT demonstrated FDG uptake in the wall of the ascending aorta, aortic arch, and descending aorta in 2011. She had used colchicine in 2004, but she repeatedly received IV methylprednisolone pulse therapy, but she had no complaints with normal APR, and urinalysis analysis showed >8 mg/day. Her knee arthritis did not respond to adalimumab, and she is currently on infliximab treatment since 2019 with a Daily methylprednisolone dose of 8-12mg.

Conclusion: HA20 can be diagnosed even in adult patients, and the clinical picture of presented cases suggests that monogenic autoinflammatory disorders including HA20 should be suspected in any patient with flares of described manifestations along with strong acute phase response even in adults. Response to corticosteroids and targeted treatments may also be variable.

Scientific Abstracts
A. Demirezen1, A. Avangolu Guler1, H. Karadeniz2, D. Yildirim2, H. Kucuk2, M. Kavuncu2, M. A. Ozturk2, A. Tufan2. 1Gazi University Faculty of Medicine, Internal Medicine, Ankara, Turkey; 2Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey; 3Gazi University Faculty of Medicine, Biochemistry, Ankara, Turkey.

Background: Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by recurrent fever, serositis, arthritis and erysipelas-like ery-thema caused by mutations over activating caspase-1. As Interleukin (IL)-1 beta, IL-33 is a nuclear cytokine from IL-1 family which is activated by caspase-1. IL-33 is known to take part in pathogenesis of several rheumatic diseases.

Objectives: The aim of this research is determining the relationship between serum IL-33 levels and clinical and laboratory features of the disease in patients with FMF disease.

Methods: The research involved 54 FMF patients and 29 healthy volunteers. Serum IL-33 levels were evaluated in both patients and healthy individuals, and its relationship between clinical and laboratory features of FMF.

Results: 28 out of 54 patients (51.8%) had favorable response to colchicine while 26 patients (48.2%) had colchicine resistant disease. FMF patients had lower IL-33 levels compared to healthy control group (p=0.06). There were no difference between colchicine responsive and resistant patients (p=0.12) and no association was found between clinical features and serum IL-33 levels. Additionally, IL-33 did not correlated with C-reactive protein and disease activity assessed by autoinflammatory disease activity index.

Conclusion: No association was found between serum IL-33 levels and FMF disease features and laboratory findings. This may be due to the small size of our patient group, the involvement of IL-33 in tissue homeostasis as well as inflammation, and the use of higher doses of colchicine in the resistant disease group than in the remission group. Additional research is needed to determine IL-33’s role in FMF pathogenesis and its relationship with clinical and laboratory features.

DETERMINING THE RELATIONSHIP BETWEEN SERUM INTERLEUKIN 33 LEVELS AND CLINICAL FEATURES OF THE DISEASE IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

N. Sen1, R. Mercan2, O. Volkan3, E. Bayar4, S. Yilmaz-Oner5, M. E. Tezcan1, 1Kartal Dr. Lütfi Kırdar Şehir Hastanesi, Rheumatology, Istanbul, Turkey; 2Tekirdağ Namık Kemal Üniversitesi, Rheumatology, Tekirdağ, Turkey; 3Sivas Devlet Hastanesi, Internal Medicine, Sivas, Turkey.

Background: Vaccines are the safest and most effective method to prevent invasive and life-threatening infections. Vaccines against influenza, pneumococcal disease, herpes zoster, and human papillomavirus are the main recommended vaccines for adults. In addition, rheumatology patients are advised to receive adult vaccinations according to the vaccines available in their country and local guidelines. In Turkey, both influenza and pneumococcal disease vaccines are commercially available. In addition, these vaccines are strongly recommended for rheumatology patients in local guidelines. Although familial Mediterranean fever (FMF) is one of the most common rheumatological diseases in Turkey, it is often neglected in vaccination recommendations.

Objectives: In this study, we surveyed the vaccination practice against influenza or pneumococcal diseases of adult FMF patients in our cohort. In addition, we evaluated the factors related to favorable vaccination practice.

Methods: We included 360 FMF patients over 18 years of age. All patients fulfilled the Tel-Hashomer criteria for FMF. We asked them if they had ever been vaccinated against pneumococcal or influenza, and how often they received them. In addition, we dichotomised patients in terms of vaccinated against at least one of influenza or pneumococcal diseases. We then compared the groups for demographic (age gender and comorbidities) and disease related characteristics (disease duration, disease activity calculated by ISSF and colchicine dose). We used q-square test to compare categorical variables and Mann-Whitney U test for continuous variables.

Results: Of 360 FMF patients, 238 (66.1%) were female. The mean age of the patients was 34.5±10.7 years. Disease duration of the patients was 9.38±0.7 years. In addition, the mean ISSF score of the patients was 1.83±1.5. The mean dose of colchicine received by the patient was 1.23±0.47 mg. Only 54 (15.0%) of the patients had at least one comorbidity. In our cohort, 22 (6.1%) patients were vaccinated against influenza or pneumococcal disease. Only 18 (6.0%) of the patients had been vaccinated against influenza at least once so far. Half of these patients (9/18) were vaccinated against influenza each year. In addition, 8/360 (2.2%) patients were fully vaccinated against pneumococcal diseases. Here, six of them received the pneumococcal vaccine after the start of the COVID-19 outbreak. There was no statistically significant difference between the groups in terms of demographic and disease related characteristics.

Conclusion: We found that none of the patients answered yes, 22 (6.1%) patients had mild disease, 10 patients had moderate (32%) disease, and there was no patient with severe disease in this group. Among those who answered no, 3 (14%) had mild disease, 14 (83%) had moderate disease, and 5 (23%) had severe disease (p<0.001). When the CRP levels of the patients were compared, the median CRP value of those who answered yes was found to be 4.45 mg/L, and the median value of CRP for those who answered no was 11.25 mg/L (p=0.04). Sensitivity and specificity of PASS for detecting patients in remission was 78% and 61% respectively. Moreover, PASS had a positive and negative predictive value of %68 and %72 respectively, for determining patients in remission. If cut of level of CRP was chosen as 6.5 mg/L for, answering “yes” to PASS, sensitivity of test has been found to be 62.5% while the specificity is 59.1%. On the other hand, if cut off level of CRP is selected as 9.35 mg/L; sensitivity and specificity of the test was found as 75% and 72.7% respectively (p=0.045).

AB1303

VACCINATION PRACTICES OF ADULT FAMILIAL MEDITERRANEAN FEVER PATIENTS IN TURKEY.

A. Demirezen1, A. Avangolu Guler1, H. Karadeniz2, D. Yildirim2, H. Kucuk2, M. A. Ozturk2, A. Tufan2. 1Gazi University Faculty of Medicine, Internal Medicine, Ankara, Turkey; 2Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey; 3Gazi University Faculty of Medicine, Biochemistry, Ankara, Turkey.

Background: Patients with FMF should be vaccinated against influenza and pneumococcal disease. Vaccination is particularly important for patients with inflammatory arthritis. Vaccination of patients with FMF should be routinely assessed during consultations. Therefore, we assessed the vaccination practices in patients with FMF in our cohort.

Objectives: To assess the vaccination practices in FMF patients and to determine the factors associated with favorable vaccination practice.

Methods: We conducted a cross-sectional study including 54 FMF patients from the outpatient clinic of our university hospital. All patients were asked about their vaccination practices for the last year. In addition, we evaluated the factors related to favorable vaccination practice.

Results: Of 54 FMF patients, 29 (53.7%) were vaccinated against influenza and/or pneumococcal disease. The mean age of the patients was 34.5±10.7 years. Disease duration of the patients was 9.38±0.7 years. In addition, the mean ISSF score of the patients was 1.83±1.5. The mean dose of colchicine received by the patient was 1.23±0.47 mg. Only 54 (15.0%) of the patients had at least one comorbidity. In our cohort, 22 (6.1%) patients were vaccinated against influenza or pneumococcal disease. Only 18 (6.0%) of the patients had been vaccinated against influenza at least once so far. Half of these patients (9/18) were vaccinated against influenza each year. In addition, 8/360 (2.2%) patients were fully vaccinated against pneumococcal diseases. Here, six of them received the pneumococcal vaccine after the start of the COVID-19 outbreak. There was no statistically significant difference between the groups in terms of demographic and disease related characteristics.

Conclusion: We found that none of the patients answered yes, 22 (6.1%) patients had mild disease, 10 patients had moderate (32%) disease, and there was no patient with severe disease in this group. Among those who answered no, 3 (14%) had mild disease, 14 (83%) had moderate disease, and 5 (23%) had severe disease (p<0.001). When the CRP levels of the patients were compared, the median CRP value of those who answered yes was found to be 4.45 mg/L, and the median value of CRP for those who answered no was 11.25 mg/L (p=0.04). Sensitivity and specificity of PASS for detecting patients in remission was 78% and 61% respectively. Moreover, PASS had a positive and negative predictive value of %68 and %72 respectively, for determining patients in remission. If cut off level of CRP was chosen as 6.5 mg/L for, answering “yes” to PASS, sensitivity of test has been found to be 62.5% while the specificity is 59.1%. On the other hand, if cut off level of CRP is selected as 9.35 mg/L; sensitivity and specificity of the test was found as 75% and 72.7% respectively (p=0.045).

B. Farisogullari1,2, B. Usta2, E. Enal Deregözü2, G. K. Yardımcı1, Ö. Cennet3, H. Ozdogan1,2, H. Yazici1,2, G. Hateri1,2, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 1Hacettepe University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of General Surgery, Ankara, Turkey; 2Hacettepe University, Faculty of Medicine, Department of Pathology, Ankara, Turkey

Background: Idiopathic granulomatosis mastitis (IGM) is an uncommon, benign, chronic inflammatory disease of the breast of unknown etiology. Although an ideal treatment regimen is controversial in IGM, the ultimate goal is remission.

Objectives: To compare the clinical, radiological, laboratory and treatment features of patients in remission and non-remission, and assess predictor factors of remission.

Methods: The data of patients who were histopathologically diagnosed with IGM between 2010 and 2020 were evaluated retrospectively. The patients were divided into 2 groups as those in complete remission and non-remission. Complete improvement in clinical and physical examination with medical and/or surgical intervention findings at 2 consecutive visits was defined as complete remission. Patients who were not in complete remission including partial remission and refractory to treatment, were defined as non-remission group.

Results: In this study, there were a total of 103 patients with a diagnosis of IGM followed-up in the rheumatology clinic. Of these, 39 (38%) were in remission and 64 (62%) were non-remission. Age, age at symptom onset, comorbidity, pregnancy (ever), disease localization, clinical signs and symptoms, imaging classification, and baseline acute phase reactants and autoimmune markers were similar in the remission and non-remission groups. The use of antibiotics and azathioprine was significantly higher in the remission group than in the non-remission group. These patients were similar in the remission and non-remission groups. The use of antibiotics and azathioprine was significantly higher in the remission group than in the non-remission group. However, there was no difference between the groups in terms of breast surgery, use of corticosteroids and methotrexate (Table 1).

AB1306 AA AMYLOIDOSIS IN CHRONIC RHEUMATIC DISEASES: ABOUT 20 CASES

M. Anthaou1, I. Mahboub2, M. Ghal1, F. Fhima1, N. Ben Chekaya2, S. Zrou1, I. Belja1, M. Touzi1, N. Bergraoui1, Fatouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia

Background: Secondary AA amyloidosis is a complication of certain uncontrolled chronic inflammatory rheumatic diseases. The diagnosis of AA amyloidosis is anato-pathological based on the detection of amyloid deposits within a biopsy specimen.

Objectives: The aim of this study is to determine the clinical, biological, therapeutic and evolutionary aspects of amyloidosis during these diseases.

Methods: This is a retrospective descriptive study conducted in the rheumatology department in Monastir, Tunisia, including patients followed for chronic inflammatory rheumatism complicated by AA amyloidosis.

Results: Our study included 20 patients (13 women and 7 men). Their mean age at the time of diagnosis of amyloidosis was 55.4 years [18-76]. The rheumatic diseases were: Rheumatoid Arthritis (RA) in 13 cases (65%), Ankylosing Spondylitis in 3 cases (15%), Behçet’s disease in 2 cases and Juvenile idiopathic arthritis in its seronegative form in 2 cases (10% for both). Amyloidosis occurred after a mean duration of rheumatic disease of 11.5 years [3-27]. The mean sedimentation rate at diagnosis of amyloidosis was 100.5 mm per hour [21-131]. The mean C-reactive protein at diagnosis was 38.35 mg/L [1.4-135].

Inaugural manifestations of amyloidosis were: edema of lower limbs in 8 cases, nephrotic syndrome in 7 cases, renal failure in 4 cases and an abdominal clinical presentation (diarrhea and abdominal pain) associated with proteinuria in 2 cases. Proteinuria was constant, with a mean level of 7.5g/24h [3.5-20]. It was isolated in 5 cases. Amyloidosis was subclinical in 2 cases and was discovered by an abdominal fat biopsy performed during a research protocol. The diagnosis was confirmed by: renal biopsy (n=4), rectal biopsy (n=3), salivary gland biopsy (n=4) and abdominal fat biopsy (n=2). Amyloidosis extension was assessed for 50% of our patients. Cardiac involvement was the most frequent, revealed in 5 patients. Concentric left ventricular hypertrophy was found in 4 patients. Pulmonary arterial hypertension and pericardial effusion were found in 1 case. Hepatic involvement was detected in 2 cases in the form of hepatomegaly without disturbance of liver function tests. Adrenal gland involvement was detected in 1 case, with homogeneous hypertrophy of the adrenal glands associated with adrenal dysfunction. Only 1 patient had peripheral nerve damage in the form of bilateral carpal tunnel syndrome. Concerning the treatment: 12 patients received Colchicine. Chloraminophen was tried for 4 patients with amyloidosis secondary to RA and Azathioprine for one patient with RA. The evolution was unfavorable in 6 cases marked by death within a mean time of 3.4 years.

Conclusion: Although its prevalence is decreasing, owing to therapeutic progress in chronic rheumatic diseases, AA amyloidosis remains a not exceptional complication. It has a poor prognosis, particularly because of renal disease and cardiac involvement.

Background: Experience with mycophenolate in uveitis associated with Behçet’s syndrome (BS) is limited.

Objectives: We aimed to report the efficacy and safety of mycophenolate mofetil (MMF) and mycophenolate sodium (MPA) in the treatment of BS uveitis.

Methods: All patients with panuveitis or posterior uveitis who used mycophenolate for eye involvement between 2016 and 2018 were included. Patient charts were reviewed and data on demographic features, previous immunosuppressives, concomitant therapies, ocular attacks and outcome, and adverse events were extracted. Follow up was ended on October 2021.

Results: We included 12 BS patients (M/W: 8/4, mean age: 35±7 years) treated with mycophenolate during a mean follow-up of 42±19 months (Table 1). All but 3 patients had bilateral eye involvement. IFX and INF-α had been discontinued due to adverse events in all patients, AZA in 10/12, and Cy-A in 7/10. Seven patients were prescribed mycophenolate for remission induction. One of these patients had had his first uveitis attack while on AZA treatment due to gastrointestinal involvement. The remaining 6 patients were using other immunosuppressives and experienced relapses that led to mycophenolate use. MMF was added to a biologic agent in 2 patients (IFX and ADA) and was initiated in combination with IFX in 1 patient. These 3 patients did not experience further ocular attacks and IFX was stopped due to remission in 1 patient. In the fourth patient, MMF was switched to MPA due to numbness in hands and feet and MPA was stopped due to arthralgia. This patient did not experience ocular attacks during 5 months of MPA therapy. The remaining 3 patients had further uveitis attacks without decrease in visual acuity 2, 6, and 12 months after MMF initiation, and IFX was added in 2 patients, and ADA in 1 patient. Two of these patients were switched to INF-α due to uveitis relapses. MMF was switched to MPA for diarrhea in 1 patient. Five patients had received MMF for maintenance. One of these was using IFX when MMF was started and these 2 agents were used together. This patient discontinued MMF due to remission 17 months after MMF initiation and is still on IFX monotherapy. The second patient is still on MMF for 39 months without further ocular attacks. ADA, IFX and Cy-A were added in the remaining 3 patients due to ocular attacks 2, 5 and 31 months after MMF initiation. One of these 3 patients stopped IFX and MMF due to remission and is off treatment for 2 years.

Conclusion: Mycophenolate may be an alternative treatment modality in addition to biologics for patients with eye involvement who are intolerant to conventional therapies. Further data is needed to show whether it would be effective when used alone.

ANALYSIS OF A MONOCENTRIC COHORT OF IG4-G4-RELATED DISEASE PATIENTS: GREATER REDUCTION OF THE RESPONDER INDEX IN PHARMACOLOGICALLY-TREATED PATIENTS AS COMPARED TO UNTREATED ONES

S. Bertocchi1,2, F. Regola1,2, C. Nalli, L. Andreoli1,2, F. Franceschini1,2, Speciale Civili di Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; 1University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy.

Background: IgG4-related disease (IgG4-RD) is a systemic disease characterized by lymphoplasmocellular infiltration and storiform fibrosis. Pancreas, biliary tract, salivary glands, lymph nodes and retroperitoneum are frequently involved, although the clinical presentation may vary [1].

Objectives: The aim of this study is to retrospectively describe the clinical manifestations of a monocentric cohort of patients with IgG4-RD and analyze their clinical course by applying the validated IgG4-Related Disease Responder Index (RI) [2].

Methods: We enrolled 22 IgG4-RD patients classified with 2011 diagnostic criteria [3] and/or 2019 classification criteria [4].

Results: 22 IgG4-RD patients (M/F=3.4/1), mostly Caucasian (91%), were diagnosed at a mean age of 59 years (44-74) with a median IgG4 concentration at diagnosis of 239 mg/dL (IQR 106-391 mg/dL). 14/22 (64%) patients fulfilled the 2011 classification criteria, while 8/22 (36%) were classified as possible (2), probable (5) or definitive (1) according to the diagnostic criteria of 2011. Organ involvement at diagnosis (TI0) is described in Table 1. The organs most involved were lymph nodes, salivary glands and retroperitoneum. Patients were followed for a median of 49 months (IQR 16-88). Three patients were lost to follow-up. One patient died for pneumonia 96 months after diagnosis. During the follow-up 5 (23%) patients did not receive specific treatment, 1 (5%) was treated surgically, 6 (27%) with steroid only, 10 (45%) with steroid and immunosuppressants and even biological therapy. A statistically significant reduction in RI between T0 and last follow-up (TLF) was observed in all the patients [from 6 (3-6) to 3 (1-4) p=0.010]. A significant reduction was also observed in the group of pharmacologically treated patients [from 6 (3-6) to 3 (1-4) p=0.035] but not in the group of patients without drug treatment (p = 0.174).

Table 1. Organ involvement at diagnosis

</tr>
</tbody>
</table>

Conclusion: In our cohort, patients were predominantly male with mean age at diagnosis of 59 years, consistent with literature data [1]. A statistically significant reduction in disease activity defined by reduction of RI was observed in patients who received immunosuppressive therapy. No significant reduction was observed in patients not pharmacologically treated.

AB1311 INCREASED RISK OF HEPATOTOXICITY WITH DMARDS IN PATIENTS WITH PREVIOUS LIVER TOXICITY WITH ISONIAZID. STUDY IN A SINGLE UNIVERSITY HOSPITAL

D. Martínez-López, C. J Osorio-Chavez, V. Portilla, C. Álvarez-Reguera, A. Herrero-Morant, L. Sanchez-Bilbao, I. Gonzalez-Mazon, M. A. Gonzalez-Gay, R. Blanco, Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander (SPAIN), Spain; Hospital Universitario Marqués de Valdecilla, Pulmonology, Santander (SPAIN), Spain

Background: Isoniazid (INH) is used to treat latent tuberculosis infection (LTBI), and hepatotoxicity is one of the most frequent adverse effect. Several Disease-modifying drugs (DMARDs) can also cause hepatotoxicity. Many patients with rheumatic immune mediated diseases (R-IMID) receive INH prior to DMARDs for prophylaxis of LTBI. This risk of hepatotoxicity with DMARDs after hepatotoxicity with INH is unknown.

OBJECTIVES: To assess the risk of hepatotoxicity with DMARDs in patients who have presented hepatotoxicity with INH.

Methods: Study of all consecutive R-IMID patients evaluated in the last five years (2016-2020) in a University Hospital, who presented hepatotoxicity after INH and later received DMARDs. We study if they also presented hepatotoxicity with DMARDs. Hepatotoxicity was defined as an elevation of liver enzymes (ALT and/or AST) upper the high limit after the introduction of the treatment.

Results: INH was used in 232 of 7218 patients with R-IMID. We finally included 64 patients (45 women; 70.3%; mean age 53.4±10.5 years), who had hepatotoxicity due to INH (Table 1).

Figure 1. Therapeutical approach

Conclusion: JAKINIB may be an effective and safe therapy in IOP refractory to DMARDs after hepatotoxicity with INH.

Targeted synthetic DMARDs (Jakinib) 8 (12.5%)

ABA: Abatacept; AZA: Azathioprine; HCO: Hydroxychloroquine; INH: Isoniazid; LFN: Leflunomide; MMF: Mycophenolate mofetil; MTX: Methotrexate; PsA: Psoriatic arthritis; RA: Rheumatoid arthritis; RTX: Rituximab; SpA: Axial spondyloarthritis; SSc: Systemic sclerosis; TCZ: Tocilizumab; TNFi: TNF inhibitors* Patients with higher liver enzyme elevation are included in the previous groups.

The most frequent R-IMIDs were rheumatoid arthritis, axial spondyloarthritis and psoriatic arthritis. Methotrexate (MTX) (n=34, 53.1%) and TNF inhibitors (n=27, 42.2%) were the conventional and biologic-DMARD more frequently used, respectively. Hepatotoxicity was higher with MTX (14 of 34, 41.2%), and lower with the other DMARDs (Figure 1). Hepatotoxicity was not observed with hydroxychloroquine, azathioprine, mycophenolate mofetil, secukinumab, abatacept or rituximab.
S. Gulle1, M. C. Ataca1, G. Can1, I. Sarı1, M. Birlik1, F. Onen1, Dokuz Eylül University School of Medicine, Rheumatology, Izmir, Turkey; Dokuz Eylül University School of Medicine, Internal Medicine, Izmir, Turkey.

Background: Sarcoidosis is a chronic granulomatous disease that primarily affects the lungs and lymph nodes, and can affect any organ and system (1). The incidence of concomitant iRMD is increased in patients with sarcoidosis. Anti-nuclear antibody (ANA) test are frequently used markers for inflammatory rheumatic diseases (iRMDs) (2). The relationship of this association with ANA is not clear.

Objectives: We aimed to determine the frequency of ANA in sarcoidosis patients and its possible correlation with clinical and laboratory data, and also to reveal the severity of osteoporosis in patients with sarcoidosis.

Methods: Ninety sarcoidosis patients, who were followed up in rheumatology clinic were included in this study. ANA were determined with indirect immunofluorescent method and 1/160 titration was accepted as positive. Demographic, clinical, serological, and bone mineral density (BMD) results of all patients were recorded. BMD results were obtained from the images taken before the last date or osteoporotic fracture of the patients.

Results: Average age of the 90 patients (79 females) with sarcoidosis was 57.5 (IQR: 51–66) years, and median disease duration was 76 (IQR: 4–19) years. 28 (31.1%) patients had a diagnosis of extrapulmonary sarcoidosis (Most commonly skin, n=20, 71.4%); 21 patients had BMD values consistent with osteoporosis, while 9 patients had osteoporotic fractures. In 18 (20%) patients, rheumatologic autoimmune disease combined with sarcoidosis was found. SpA was diagnosed in 6 patients, RA in 2 patients, Lofgren Syndrome in 2 patients, SJög in 2 patients, systemic sclerosis in 1 patient, and morphea in 1 patient. Other rheumatologic diseases were found in uveitis, polyarthritis, Gout, Behçet’s Disease and FMF. ANA test was performed in a total of 83 patients. ANA positivity was found in 30 (36.1%) patients with sarcoidosis (1/100-1/320 in 12 patients; >1/320 in 18 patients). There was no significant relationship between ANA positivity and gender distribution, age, disease duration, development of extrapulmonary sarcoidosis, refractory disease status, and laboratory findings at the time of diagnosis. It was found that ANA positivity at diagnosis time for sarcoidosis increased the risk of developing iRMD 4.8 times in patients [HR: 4.8, CI 95%: (1.455-15.833), p=0.009].

Conclusion: In sarcoidosis, ANA positivity is of great importance in the determination of accompanying iRMDs. It was found that ANA positivity at the time of diagnosis in sarcoidosis patients increased the risk of developing rheumatological autoimmune disease 4.8 fold. Since these patients receive long-term moderate-high-dose steroid-based treatments, they should be closely monitored and screened for osteoporosis.

REFERENCES:
employment was observed. Despite these positive outcomes, at present not enough patients per diagnosis-treatment combination have been included in the registry to draw definitive conclusions on efficacy and safety of specific off-label treatments or to formulate treatment recommendations for certain diseases. Consequently, it is important to continue the registry and include more patients or link various (inter)national registries to obtain sufficient data and promote evidence-based and effective use of biologics in rare therapy-refractory IMIDs. This may eventually also help to facilitate reimbursement of these therapies.

**Background:** Autoinflammatory syndromes are characterized by dysregulation of innate immunity and recurrent episodes of fever, cutaneous and other. Janus Kinase inhibitor (JAKINIB) may inhibit innate and acquired immunity. They have been approved in several immune mediated diseases, but not in autoinflammatory syndromes.

**Objectives:** To assess the efficacy and safety of JAKINIB in refractory autoinflammatory syndromes.

**Methods:** Study of patients from a single University Hospital and Literature review of refractory autoinflammatory syndromes treated with JAKINIB.

**Results:** We have identified 2 cases in our hospital. One of them was a 25-year-old girl diagnosed with Blau syndrome refractory to different conventional and biological therapies. Tofacitinib (TOFA) had a good clinical response but was switched to B Goatitbin (BARI) due to severe lymphopenia. The 2nd patient was a 65-year-old man, diagnosed with an autoinflammatory syndrome (WDRI mutation) and polycytemia vera (positive JAK-2; V617F mutation). Based on the JAK2 mutation, BARI was started with complete improvement. In literature review, we found 59 patients (41 women/18 men), mean age 38.1±13.1 years. TOFA (n=23) was the most used JAKINIB, followed by BARI (n=20) and Ruxolitinib (RUXO) (n=16). After starting JAKINIB treatment, most patients presented clinical complete (n=45, 76.3%) or partial (n=11, 18.6%) improvement, only 3 (5.1%) did not respond. (Table 1)

**Conclusion:** JAKINIB may be an effective therapy in autoinflammatory syndromes refractory to conventional and/or biologic therapy.

**References:**

and a reduction in antibody titers against TSH receptor and anti-thyroid peroxi-
dase. All patients were continuing treatment except for one patient who had dis-
continued treatment due to clinical remission. No adverse events were recorded
except for mild neutropenia in one patient, which did not require dose reduc-
tion. No patient required subsequent immunosuppressive treatment or surgery.

Conclusion: Sarilumab treatment in patients with moderate-severe active OG
appears to be an effective and safe therapeutic alternative, clinically similar to
that obtained with TCZ in our series. This is the first published series of Sari-
lumab use in OG patients.

Conclusion: MAISs prevalence was 0.34%. The diagnostic delay was of years,
more than a decade for HIDS. Colchicine was widely used and well tolerated.

Synthetic DMARDs had little role in treatment. Biological therapies were pre-
scribed in a third of patients, anti IL-1 being the most used.

Table 1.

| ULTRASOUND EVALUATION OF ACHILLES ENTHESIS AND GASTROCEUM ARCHITECTURE IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: PRELIMINARY RESULTS FROM A CROSS-SECTIONAL STUDY |

N. Güven1, S. C. Göver1, A. Kavठ1, M. Bora Karśli1, Ş. Ataman1, 1Ankara University Medical School, Physical and Rehabilitation Medicine, Division of Rheumatology, Ankara, Turkey; 2Ankara City Hospital, Clinic of Rheumatology, Ankara, Turkey

Background: Exertional leg pain and Achilles enthesis are two musculoskele-
tal manifestations which have been described in familial Mediterranean fever
(FMF) patients. Muscle performance is related both with mass and architecture.
Measurements of muscle thickness and pennation angle in muscles with pennate
structure, such as gastrocnemius, are representative of muscle mass and archi-
tecture, both of which can easily be measured via musculoskeletal ultrasound.

Objectives: Aim of this study is to evaluate thickness and pennation angle of
medial gastrocnemius via ultrasound to evaluate muscle structure in FMF
patients in order to detect implications of altered muscle condition and search for
any relations with exertional leg pain/Achilles enthesitis. To our best knowledge
this is the first study on the subject.

Methods: Consecutive FMF patients meeting Tel-Hashomer criteria between the
ages of 18-65 were enrolled. A control group was formed from healthy volunteers

Disclosure of Interests: None declared

Table 1.
**Federation Institute of Rheumatology, Laboratory of Tromboinflammation, Moscow, Russian Federation**

**Methods:**

All ultrasound evaluations were performed by the same observer. Thickness and pennation angle of medial gastrocnemius was measured. Achilles tendon findings were scored according to OMERACT suggested guidelines and total inflammation and structural damage scores recorded.

**Results:**

A total of 40 FMF patients and 17 controls were enrolled. Clinical characteristics and ultrasound findings of subjects were presented in Table 1. All FMF patients were under colchicine treatment and 10% was also under anti- interleukin 1 treatment. Demographics were similar between groups. Right gastrocnemius pennation angle was significantly reduced in FMF group (degree, median [IQR]: 20.8 [3.6] vs 22.7 [4.5], p=0.048). OMERACT ultrasound inflammation total scores were increased on both sides in FMF group. When gastrocnemius and enthesuses ultrasound findings were compared between FMF patients with and without enthesis involvement, no significant differences were observed. When FMF patients with and without enthesis findings in ultrasound examination were compared, again no significant differences in pennation angles and muscle thicknesses were observed.

<tr>
<td>Left</td>
<td>0 (0) vs 0 (0)</td>
</tr>
</tbody>
</table>

Conclusion: Our preliminary results imply altered right gastrocnemius structure in FMF patients regardless of Achilles tendon involvement and enthesis involvement, which may imply altered muscle function. By increasing the number of subjects we plan to achieve more accurate results.

**MUSCULOSKELETAL IMMUNE-RELATED ADVERSE EVENTS IN PATIENTS WITH SOLID CANCER TREATED WITH CHECKPOINT INHIBITORS: A CASE SERIES**

A. Koltakova1, A. Lita2, M. Cherkasova2, A. Fedenko4, I.V.A. Nasonova Research Institute of Rheumatology, Laboratory of Systemic Sclerosis, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, Department of Rheumatology, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Laboratory of Tromboinflammation, Moscow, Russian Federation; 4National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Department of Drug Treatment of Cancer, Moscow, Russian Federation

**Background:** Immune-related adverse events (irAE) are common in cancer patients treated with checkpoint inhibitors. irAE can affect any organs and systems including musculoskeletal. The characteristics of immune-related musculoskeletal disorders (MD) still remain incomplete.

**Objectives:** To determine the characteristics of MD manifested during the treatment of solid cancer with checkpoint inhibitors in case series.

**Methods:** We identified 13 patients with inflammatory MD manifested during treatment with check-point inhibitors. Mean age of patients was 59±10 (ranged 43-74) years, 7 (54%) of them were female. Patients were treated with anti-PD-1 (77%) and anti-PD-L1 (33%) drugs (nivolumab [n=8], pembrolizumab [n=3], atezolizumab [n=3], proglolimab [n=1]). Cancer types include melanoma (n=5), renal cell carcinoma (n=3), bladder cancer (n=2), non-small cell lung cancer (n=1), breast cancer (n=1), cervical cancer (n=1). 7 (54%) patients had another irAE also including thyroiditis (n=3), neuroopathy (n=2), rash (n=1), sicca syndrome (n=1), hepatitis (n=1). The median time of musculoskeletal manifestation after the treatment’s onset was 20 [9-48] weeks.

**Results:** Musculoskeletal manifestations were performed by synovitis in 9 (69%) cases, tenosynovitis in 11 (85%) patients, enthesitis in 4 (31%), morning stiffness(>30min) in 4 (31%). The most commonly affected areas were knees (77%) shoulders (69%), hands (69%) and feet (46%). Bilateral involvement was in 9 (69%) cases. MD was started in 2 cases and was transient in 11 (9 patients with inflammatory arthritis and 2 patients with parathriitis). Clinical characteristic of inflammatory arthritis was represented by tenosynovitis more than synovitis in 3 cases (2 patients with symmetrical inflammatory polyarthritis and severe tenosynovitis, 1 patient with RSIPE-syndrome). In 6 cases inflammatory arthritis was represented by synovitis primarily (3 patients with symmetrical polyarthritis, 2 patients with oligoarthritis, 1 patient with monarthrosis). Severity of MD was assessed according to Common Terminology Criteria for Adverse Events V5.0. Grade 1 was in 2 cases, grade 2 in 9 (69%), grade 3 in 2 (15.5%). Laboratory findings include ESR ≥30mm/h in 7/12 (58%) cases (the median of ESR was 34 [14-42] mm/h); CRP >5mg/l in 7/10 (70%) cases (the median of CRP was 7.2 [4.8-12.9] mg/l). RF, ACRA were negative in all cases. ANA test was positive without any specificities in 7/10 (70%) cases in dilution 1:160 (n=2), 1:320 (n=3), 1:840 (n=2). Treatment of these conditions include NSAIDs, oral systemic corticosteroids (n=5), intra-articular corticosteroids (n=1), and csDMARDs (hydroxychloroquine [n=5] methotrexate [n=1] as corticosteroid-sparing agents. 2 patients with polyarthralgia and generalized tenosynovitis and 1 patient with symmetrical polyarthritis required treatment with ≤20mg daily of prednisone. 2 patients with poly- or oligoarthritis were treated with 5-10mg daily of prednisone. 5 patients with arthritis required long-term treatment with NSAIDs, corticosteroids and csDMARDs (the median of follow-up was 12 [3-12] months). 1 case of the inflammatory polyarthritis with severe tenosynovitis required to suspend the anticancer treatment with checkpoint inhibitor.

**Conclusion:** Our data demonstrated that the musculoskeletal irAE may be represented by heterogeneous manifestation and required long-term treatment. In rare cases musculoskeletal irAE can lead to suspension of the anticancer treatment with checkpoint inhibitors.

</tbody>
</table>

Conclusion: Even after the discovery of colchicine and identification of the MEFV gene diagnosis of FMF remains a challenge. Previous studies reported a median diagnostic delay of 8.2-11 years. In these studies, 28%–32% of the patients went under abdominal surgical intervention before the diagnosis of the FMF [2,3]. The most common symptoms of FMF (fever and abdominal pain) are also the most common symptoms of acute abdomen. Thus distinguishing between FMF and acute abdomen in undiagnosed FMF patients represents an understated problem. These patients have a longer diagnostic delay (8(IQR 2-15) vs 3.5(IQR1-10) years), worse control of attacks, poorer quality of life. In conclusion, most of the appendectomies were unnecessary in the FMF patients. Thus we recommend investigating the patient for FMF if the evidence of the acute abdomen does not expand beyond the symptoms.

**ABSTRACT**

**Differences in Peripheral Blood B-Cell Subsets in Patients with IgG4-Related Disease: Primary Sjogren’s Syndrome and Healthy Donors**

E. Sokol, E. Torgashina, J. Khvan, D. Tabakov, A. Aleksankin, M. Kireeva, V. Kulikova, V. Deshpande, S. Pali, S. Stone, J. Della Torre, E. Nasonova

**Background:** The level of circulating plasmablasts has been proposed as a good marker for diagnosing and monitoring IgG4-related disease (IgG4-RD) independent of serum IgG4 level [1]. However, elevated plasmablasts can be a good marker for diagnosing and monitoring IgG4-related disease (IgG4-RD). Ann Rheum Dis 2015 Jan;74(1):190-5.

**Methods:** Two hundred patients were randomly selected among individuals who were routinely followed-up with FMF diagnosis in our centre. Patients carrying a culprit condition. Patients usually stated more than one factor, however some patients reported only one. The most-reported trigger factors by the cohort are summarized as following: 76 emotional stress (38%), 60 menstruation (30%), 40 cold exposure (20%), 34 fatigue (17%), 13 seasonal changes (6.5%). The distribution of trigger factors between Group A, B, and C were non-significant (p=0.88).

**Results:** Detailed distribution of trigger factors is shown in Table 1. 144 out of 200 patients described a culprit condition. Patients usually stated more than one factor, however some patients reported only one. The most-reported trigger factors by the cohort are summarized as following: 76 emotional stress (38%), 60 menstruation (30%), 40 cold exposure (20%), 34 fatigue (17%), 13 seasonal changes (6.5%). The distribution of trigger factors between Group A, B, and C were non-significant (p=0.88).

</tbody>
</table>

**Conclusion:** We concluded that trigger factors did not vary between distinct mutant genotypes. Although emotional stress is the most reported trigger factor by the participants, one should bear in mind that emotional stress influences most chronic diseases negatively. We also observed that menstruation overtly triggers an FMF attack. Additionally, cold exposure should be considered as a notable trigger factor. It is still unclear what triggers an FMF attack in 28% of the patients, remains a mystery.

**ABSTRACTS**

**DIAGNOSTIC DELAY IN FAMILIAL MEDITERRANEAN FEVER: IS IT STILL A PROBLEM?**

M. B. Yuzbashvili, A. Y. Avulya, I. Besisroglu, S. N. Baspina, S. Yenigun, I. Durucan, A. Alkan, M. E. Gazioğlu, M. F. Hiyanli, I. Sarac, H. Ozdogan, S. Ugurlu, 1 Istanbul University-Cerrahpaşa, 1 Internal Medicine, Division of Rheumatology, Istanbul, Turkey

**Background:** Familial Mediterranean fever (FMF) is a rare hereditary autoinflammatory disease with disease onset in childhood in most cases. Although autoinflammatory disease awareness is increasing among physicians, delayed diagnosis is still prevalent as a cause of greater morbidity[1].

**Objectives:** We aimed to study the characteristics of FMF patients diagnosed between 2000-2010 and 2011-2021 and to see if there was a difference in diagnostic delay.

**Methods:** We retrospectively evaluated the medical records of the FMF patients followed up in our rheumatology clinic that were diagnosed between 2000-2021 and split them into two groups according to the year they received their diagnosis. There were no significant differences in the number of all studied B-cell subsets between pts with IgG4-RD and with SjS. But there were no differences between IgG4-RD and SjS pts.

**Conclusion:** Immunophenotyping showed disturbed homeostasis of the B-cells subpopulations in IgG4-RD pts with a significant increase in plasmablasts compared to HD, but there were no differences between IgG4-RD and SjS pts. Further research is needed to evaluate the diagnostic utility of circulating plasmablasts in IgG4-RD.

**REFERENCES:**

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.5257
Conclusion: There was some increase in the diagnostic delay in 2011-2021 compared to 2000-2010. This may be partly due to the later onset of symptoms in patients diagnosed in 2011-2021, which could have led the physicians to consider other differential diagnoses. Nevertheless, diagnostic delay in FMF still seems a prevalent problem that should be addressed to prevent excess morbidity and mortality.

Disclosure of Interests: None declared.

AB1327 PREVALENCE OF IMMUNORELATED MUSCULOSKELETAL ADVERSE EFFECTS IN PATIENTS WITH LUNG CANCER OR MELANOMA TREATED WITH IMMUNO-CHECKPOINT INHIBITORS

1Hospital Universitario Clínico San Cecilio, Reumatología, Granada, Spain
2Hospital Universitario Clínico San Cecilio, Reumatología, Granada, Spain

Background: Immunotherapy in the field of medical oncology, consisting of inhibiting key immune checkpoints, is revolutionising the way patients with these pathologies are treated, being mainly used in skin and lung tumours. These molecules are aimed at controlling T-cell activation by interacting with cytotoxic T-lymphocyte antigen 4 (CTLA-4) protein (Iplimumab); by acting on the programmed cell death receptor (PD-1) (Pembrolizumab, Nivolumab); or by binding to programmed cell death ligand 1 (PDL1) such as Atezolizumab or durvalumab. Despite the improvement in survival in the management of cancers with poor prognosis, this type of therapy is characterised by a series of side effects, including dermatological, gastrointestinal, endocrine, rheumatological and other effects. In this study, we focused mainly on rheumatological adverse effects, ranging from mechanical and/or inflammatory musculoskeletal involvement to dry syndrome, vasculitis, polyarthritis, inflammatory myopathy, among others.

Aims: To assess the prevalence of immunorelated adverse effects (Eair) in cancer patients with lung cancer or melanoma treated with immunotherapy targeting check-points, such as anti-CTLA-4, anti-PD-1, anti-PDL-1.

Methods: Observational study of a series of 115 patients diagnosed with lung cancer or melanoma, in treatment with checkpoint inhibitors (nivolumab, pembrolizumab, durvalumab, atezolizumab), from 2016 to 2021 at the Hospital Universitario Clínico San Cecilio. Patients who developed some type of rheumatological symptomatology after the start of immunotherapy were included. The clinical history of these patients was reviewed to confirm or rule out these adverse effects. The following musculoskeletal Eair were included: arthralgias, arthritis, generalised musculoskeletal pain, myalgias, osteoporosis and/or osteopenia. In the Eair registry, the following entitics were not included: polymyalgia rheumatica, vasculitis and myositis.

Results: Out of a total of 115 patients who received immunotherapy, with age, type of tumour and treatment received (Table 1); 24 developed non-specific arthromyalgias considered to be grade 1 or 2 in severity, for which patients do not require specific treatment or suspension of treatment doses. However, several of the patients did develop active arthritis, requiring corticosteroid treatment and in some cases, the suspension of at least one treatment session. In our study, there is no clear relationship between one immunosuppressive drug or another for the development of Eair.

Disclosure of Interests: None declared.

## Diagnostics and imaging procedures

### AB1328 A FEASIBILITY STUDY ON A NOVEL COMBINED THERMAL IMAGING AND CLINICAL JOINT ASSESSMENT APPROACH USING ULTRASOUND DETECTED JOINT INFLAMMATION OUTCOMES IN RHEUMATOID ARTHRITIS

Y. K. Tan1, C. Hong1, H. Li2, J. C. Allen Jr3, J. Thumbol1. 1Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore; 2Singapore General Hospital, Health Services Research Unit, Singapore, Singapore; 3Duke-NUS Medical School, Centre for Quantitative Medicine, Singapore, Singapore

**Background:** Thermal imaging (TI) is a portable, low cost imaging tool with high feasibility for use. Clinical joint assessment is routinely performed in rheumatoid arthritis (RA) patient care.

**Objectives:** To assess a combined TI and clinical joint assessment (CTCA) approach in comparison with TI alone using ultrasound (US) detected joint inflammation outcomes as a gold standard.

**Methods:** Bilateral (BL) hand and wrist (22 joint sites) were assessed in this cross-sectional study. For TI (performed in a draft free room with a controlled temperature of around 22°C), the adjusted maximum (Tmax), minimum (Tmin) and average (Tavg) temperatures were derived by subtracting a control temperature (lowest Tmin at the joints per subject) from the Tmax, Tmin and Tavg per joint. US power Doppler (PD) and greyscale (GS) joint inflammation were graded semi-quantitatively (0-3) using validated scoring methods. Joint swelling and tenderness were graded as yes = 1 or no = 0. To increase the relative weightage of CTCA-MAX, CTCA-MIN and CTCA-AVG on the CTCA scores, if the joint was swollen and/or tender, the adjusted Tmax, Tmin and Tavg at each joint were multiplied by a factor of 2; otherwise, they remained unchanged. Receiver operating characteristic (ROC) analysis assessed the performance of TI and CTCA in identifying joint US PD score > 1 and GS score > 1. A parameter was selected as a univariate predictor if statistically significant (P < 0.05) with area under the ROC curve (AUC) ≥ 0.70.

**Results:** This study included 814 joints from 37 RA patients (mean disease duration, 30.9 months; mean DAS28, 4.43). For both TI and CTCA, out of the 22 joint sites, 3 joint sites were evaluated for PD score > 1 and 14 joint sites for GS score > 1; the remaining joint sites had AUC results unavailable due to small number of outcomes. For TI (Table 1), 3 joint sites had > 1 predictive parameter for either PD score > 1 and/or GS score > 1 as follows: left (L) wrist and right (R) MCPJ 1, AUCs (0.813 to 0.897) for PD score > 1; L wrist and R MCPJs 1 and 3, AUCs (0.806 to 0.947) for GS score > 1. For CTCA (Table 1), 6 joint sites had > 1 predictive parameter for either PD score > 1 and/or GS score > 1 as follows: BL wrists, AUCs (0.726 to 0.899) for PD score > 1; BL wrists, MCPJs 2 and 3, AUCs (0.739 to 0.931) for GS score > 1.

**Conclusion:** A novel CTCA approach helps discriminate the severity of US detected joint inflammation in RA at more joint sites when compared to TI alone; this includes the commonly affected BL wrists, MCPJs 2 and 3. Further validation work in a larger RA cohort will be required.

### AB1329 INTEROPHYSSEAL JOINTS INJECTION UNDER ULTRASOUND GUIDANCE AN ALTERNATIVE TO FLUOROSCOPY GUIDANCE

E. Touboul1, S. Salomon-Goeb1, V. Deprez2, M. Boistelle1, V. Goeb1. 1Chu Amiens-Picardy Site Nord, Rheumatology, Amiens, France

**Background:** Ultrasound-guided injections are an alternative to evaluate, it eliminates the risk of ionizing radiation for both the patient and the practitioner as fluoroscopic procedures require a radiology technician, increase the overall support time and cost, decrease accessibility.

**Objectives:** The main objective of the study was to compare the short-term efficacy of posterior inter-apophyseal joint infiltrations under ultrasound versus scopic guidance.

**Methods:** Observational, retrospective, single-centre study. Patients benefited from posterior zygapophysial joints injection(s) under fluoroscopy or ultrasound and a follow-up consultation at one month.

**Results:** Data from 54 patients was collected. The evolution of VAS at 1 month was on average - 31.4cm (p <0.001) in the ultrasound group and - 31.3cm (p <0.001) in the fluoroscopy group with no statistically significant difference between the two groups (p =0.835). There were no injection-related complications in either group during the follow-up. The decrease in the consumption of NSAIDs was no statistically significant difference between both groups (p = 1.00).

**Conclusion:** A corticosteroid injection of the posterior zygapophysial joints under ultrasound allows for a significant reduction in pain after one month with no difference found between the two techniques. Injection under ultrasound are a reliable, accessible and safe alternative.

**Disclosure of Interests:** None declared

### AB1330 AUTOMATIC SUBPIXEL MEASUREMENT OF RADIOGRAPHIC FINGER JOINT SPACE NARROWING IN RHEUMATOID ARTHRITIS PATIENTS UNDER TOCILIZUMAB TREATMENT

T. Oikawa1,2, Y. Ota3, M. Ikebe2, A. Furusaki1, A. Sagawa4, M. Kato5, T. Asumi2, T. Kamishima5, Sapporo University, Graduate School of Health Sciences, Sapporo, Japan; 2Sapporo City General Hospital, Department of Rheumatology and Immunology, Sapporo, Japan

**Background:** Routine monitoring with dedicated imaging methods: clinical examinations, radiographs and ultrasonography of swollen joints are time-consuming and somewhat subjective. They are also expensive and inadequate for timely intervention. In addition, these imaging modalities are invasive and unaffordable to the general population.

**Objectives:** To investigate radiographic joint space narrowing (JSN) assessment under tocilizumab treatment in rheumatoid arthritis (RA) patients. An automatic subpixel method was developed that enables high resolution measurements of JSN in radiographs. This study aims to evaluate the reliability of the developed method and its potential as a monitoring tool.

**Methods:** An automatic subpixel measurement method based on active contour techniques was developed and validated retrospectively on 1100 radiographs of 220 RA patients (70% treatment-naive, 30% tocilizumab treated) followed for 6 months. JSN was evaluated in 52 hand and 100 finger joints. The method was compared with manual measurements performed by experienced radiologists.

**Results:** The developed method showed good correlation with manual measurements, with a high degree of reliability (intraclass correlation coefficient (ICC) between 0.81 and 0.98). The method was also able to accurately detect JSN changes in individual patients, with a high sensitivity and specificity (91% and 88%, respectively). The method showed potential as a monitoring tool for tocilizumab treatment, providing reliable and consistent measurements of JSN in radiographs.

**Conclusion:** The automatic subpixel measurement method for radiographic finger joint space narrowing in RA patients under tocilizumab treatment shows good reliability and potential as a monitoring tool.

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.8
Background: The conventional scoring methods of radiographic joint space narrowing (JSN) in rheumatoid arthritis (RA) such as the Genant-modified Sharp score (GSS) are widely accepted but include subjective and time-consuming nature. Therefore, we have developed an in-house software equipped with partial image phase-only correlation (PIPOC) which can automatically quantify joint space width (JSW) change.

Objectives: The purpose of this study was to investigate whether the in-house software can predict the inhibitory effect of tocilizumab on joint destruction in a short period of time.

Methods: The study included 39 RA patients (35 female) who were treated with tocilizumab (Table 1). Radiological progression of the metacarpophalangeal and the proximal interphalangeal joints was evaluated according to the GSS at 0, 6, and 12 months. Automatic measurement was performed by the in-house software (Figure 1). We then validated in-house software in terms of accuracy in detecting the JSN.

![Figure 1. The algorithm flow of in-house software equipped with PIPOC](image)

RA, rheumatoid arthritis; SD, standard deviation; DAS28, disease activity score with 28 joints; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein.

Results: To ensure homogeneity of the subjects, we targeted the joints with GSS = 0 at baseline in the software analysis. The success rate of the in-house software for JSW measurement was 96.8% (449/464). Here, the GSS (+)/PIPOC (+) were defined as joints with JSN progression according to the GSS and the software analysis, respectively. Otherwise, joints were defined as the GSS (-)/PIPOC (-) namely non-progressive JSN. The 0–12-month GSS with the 0–6-month GSS (+) group was significantly more JSN progression than the 0–6-month GSS (-) group (Mann-Whitney U test, p < 0.001). Similarly, the 0–12-month PIPOC with the 0–6-month PIPOC (+) group was significantly more JSN progression than the 0–6-month PIPOC (-) group (p < 0.001). The 0–12-month JSW change of finger joints with the 0–12-month GSS (+) detected by the in-house software was significantly greater than the 0–12-month GSS (-) (p = 0.02).

Conclusion: Our in-house software equipped with PIPOC might be able to predict the subsequent joint destruction with 6 months observations.

Conclusion: Evidence regarding the diagnostic capability of anesthetic intra-articular hip injections for FAIS is sparse. In order to accurately answer our research question, future studies that use standardized and optimized protocols of injection and pain assessment after injection are still essential. Furthermore, the need to take into account the different biases surrounding diagnostic studies was highlighted in our study.

AB1332 - INSIGHTS INTO DISEASE ACTIVITY SCORE IN 28 JOINTS (DAS28) AND ITS COMPONENTS FROM AN ULTRASOUND PERSPECTIVE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

J. Kow1, G. H. Lim2, Y. K. Tan3, 4, Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore; 5, Singapore General Hospital, Health Services Research Unit, Singapore, Singapore

Background: Disease Activity Score in 28 Joints (DAS28) is a composite disease activity score commonly used to evaluate disease activity in rheumatoid arthritis (RA). Musculoskeletal ultrasound (US) allows visualization and assessment of joint inflammation and structural damage in RA.

Objectives: The aim of this study is to gain insights into DAS28 and its components through studying their relationship with US detected joint inflammation and bone erosion (BE).

Methods: At each joint recess, US power Doppler (PD) and greyscale (GS) joint inflammation were semi-quantitatively (0 to 3) graded using validated scoring methods while BE was scored as present=1 or absent=0 based on Outcome Measures in Rheumatology (OMERACT) consensus definition of BE. At the patient level, Pearson’s correlation coefficient was used to correlate US PD, GS and Erosion scores with the following clinical variables: DAS28 and its components (including the erythrocyte sedimentation rate (ESR)) in mm/hr; swollen joint count (SJC) ranging from 0 to 28; tender joint count (TJC) ranging from 0 to 28; and patient’s global assessment (PGA) of disease activity ranging from 0 to 100). Bonferroni correction was used to account for the above multiple testing. Among associations which were statistically significant, simple linear regression was used to describe the relationship between variables.

1 Based on subset of 30 patients. 2 Accounted for multiple testing. Statistically significant: *p<0.05; **p<0.01; ***p<0.001

Results: A total of 2520 joints and 2800 joint recesses from 36 joint sites (bilateral proximal interphalangeal joints, thumb interphalangeal joints, metacarpophalangeal joints, metatarsophalangeal joints, wrists, elbows and ankles) were scanned in 70 adult RA patients (baseline characteristics: 81.4% female; 74.3% Chinese; mean (SD) DAS28 3.99 (1.25); mean (SD) disease duration 75.3 (61.2) months). All 70 patients underwent US joint inflammation assessment with a subset of 30 patients assessed for US BE. Table 1 summarizes the correlation results between the US and clinical variables. US PD scores were correlated with DAS28 (R²=0.34, p=0.02) and SJC (R²=0.33, p=0.03). US GS scores were correlated with DAS28 (R²=0.42, P=0.002), US Erosion scores were correlated with SJC (R²=0.69, P<0.001). Simple linear regression (see scatter plots in Figure 1) demonstrated a statistically significant relationship between the following variables: US PD score versus DAS28 (R²=0.13, p=0.004); US PD score versus SJC (R²=0.11, p=0.008); US GS score versus DAS28 (R²=0.18, P<0.001); US Erosion score versus SJC (R²=0.48, p<0.001).

Conclusion: Both DAS28 and SJC have significant correlation with US detected joint inflammation. However, among the clinical variables, only SJC appears to be associated with structural damage and has significant correlation with US detected BE. Therefore, it appears that the results from both DAS28 and SJC can be more reflective of the RA disease status when compared to DAS28 alone. The role(s) of both DAS28 and SJC versus DAS28 alone as patient outcome measures in RA need to be further explored.

SCANGRAFO EVALEUATION OF BONE FRACTURE 2 YEARS AFTER BARIATRIC SURGERY IN OBESE PATIENTS: AN OBSERVAITONAL STUDY

M. Faurn1, M. Halm1, E. Allado2, D. Quilicott2, L. Brunaud2, E. Albuison2, I. Chay Valci/nae1, D. Loeuille1, 1University Hospital of Nancy. Rheumatology, Nancy, France; 2University Hospital of Nancy, University Center of Sports Medicine and Adapted Physical Activity, Nancy, France; 3University Hospital of Nancy, Department of Endocrinology Diabetology and Nutrition, Nancy, France; 4University Hospital of Nancy, Department of Digestive, Hepato-Biliary and Endocrine Surgery, Nancy, France; 5University Hospital of Nancy, Data Management et Statistiques, Nancy, France;

Background: Osteoporosis is a common disease whose progression can be seriously impacted by the development of fractures that lead to functional limitations and may even have life-threatening sequelae (1). CT is useful for diagnosing vertebral fracture (VF) and measuring the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1). Osteoporosis is associated with rapid radiographic progression (RRP) and may even have life-threatening sequelae (1). CT is useful for diagnosing vertebral fracture (VF) and measuring the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1). Osteoporosis is a common disease whose progression can be seriously impacted by the development of fractures that lead to functional limitations and may even have life-threatening sequelae (1). CT is useful for diagnosing vertebral fracture (VF) and measuring the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1).

Methods: This descriptive study included obese patients who underwent bariatric surgery between January 2014 and December 2019 and CT before and two years after bariatric surgery. The secondary objectives were to identify risk factors for a decrease in the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1).

Results: Among the 78 included patients, 85.9% were women, with a mean age of 48.5 years (±11.4); the mean body mass index (BMI) was 46.2kg/m² (±7) before surgery and 29.8kg/m² (±6.7) 2 years after surgery. There was a significant change in SBAC-L1 two years after surgery (p=0.037). In multivariable analysis, the risk factors for an SBAC-L1 < 145 HU 2 years after bariatric surgery in those with an SBAC-L1 > 145 HU before surgery were age and sex, and men and older patients having a higher risk (OR = 32.6, CII%5 = [1.86-568.77], and OR = 0.85, CI%5 = [0.74-0.98], respectively).

Conclusion: SBAC-L1 was significantly lower two years after bariatric surgery than before surgery. When the SBAC-L1 was over 145 HU before bariatric surgery, men and sex and older patients were the risk factors for having an SBAC-L1 below the fracture threshold 2 years after surgery.

BONE MARROW EDEMA SCORE IN HAND X-RAY FILM BY AI DEEP LEARNING ASSOCIATE WITH MBI BONE EDEMA IN RHEUMATOID ARTHRITIS.

K. Katayama1, D. Parr2, M. Oda3, T. Okubo4, K. Mori5. 1Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan; 2Graduate School of Informative, Nagoya University, Information and Communications, Nagoya, China; 3Graduate School of Informative, Nagoya University, Information and Communications, Nagoya, Japan; 4Katayama Orthopedic Rheumatology Clinic, Radiology, Asahikawa, Japan; 5Graduate School of Informative, Information and Communications, Nagoya, Japan;

Background: Rapid radiographic progression (RRP) was reported to be one of clinical symptom in difficult to treat RA(D2T RA) (1). Eular recommendation for imaging showed BME is strong and independent prognostic factor for bone destruction(2). We reported bone marrow edema (BME) in MRI image was most associated with RRP compared with bone erosion, synovitis in Adalimumab add-on therapy in MXT-IR RA patients(3). To rescue RRP, early detection of BME is important although cost of MRI is expensive and hard to repeat.

Objectives: To investigate the score of BME in hand X ray film by deep learning between X ray film and MRI BME information can discriminate the differences between BME and non-BME.

Methods: In this work, we use a neural network consisted of convolutional layers and fully connected layers to classify X-ray images (Figure 1) in this paper, the output is the score of BME which ranges from 0 to 1( threshold = 0.4). We also
Results: Regarding data split, 104 images including 79 non-BME images and 25 BME images are used as a hold-out test set. The rest of the images (473 images) are used as training data and validation data. Five fold cross-validation is used for these 473 images. For each fold, there are about 378 images including 297 non-BME images and 81 BME images in the training set. There are about 95 images including 74 non-BME images and 21 BME images in the validation set. In order to fully utilize every image and unify the distribution of the training set and the validation set, the ratio of non-BME and BME is controlled to be the same which is about 3.66:1. The five folds showed similar performance on the hold-out test set. AUC is the area under the ROC curve. As the result, AUC which indicates the general performance of this model, ranged from 0.88 to 0.91. The average precision was 63% and the average recall rate was 87%. In this experiment, the initialization seed will greatly influence the final result. For example, AUC can be reduced to 0.73 from 0.89 because of a different initialization seed. It perhaps results from the shortage of data, which can easily make the neural network drop into a local minimum. We also utilized Grad-cam to visualize the result. The result of Grad-cam shows the importance of each part to the final prediction (Figure 2).

Figure 2. Result of Grad-cam. Numbers in the parentheses are the possibilities of BME. The middle case is unexpected because red region is the surrounding of the hand. The left and right cases may indicate the evidence for prediction.

Conclusion: The preliminary result is much better than a random guess. According to this result, there should be a certain difference between BME and non-BME images. If it’s the characteristic of BME that domains this difference, our classification algorithm will be feasible for BME. Our future work is to justify the evidence of the predictions and improve performance.

Disclosure of Interests: None declared
Background: Quantitative computer tomography (QCT) has emerged as a screening tool for opportunistic measurements of volumetric bone mineral density (vBMD) from clinical CT scans, enabling early diagnosis of osteoporosis. However, intravenous contrast media administered during clinical CT examinations, calibration methods as well as different scan phases may influence vBMD and must be considered. Calibration methods include synchronous and asynchronous CT phantoms as well as phantom-less internal calibration.

Objectives: To investigate the effect of intravenous contrast media on QCT-measured vBMD. Furthermore, to review the effects of different calibration methods and scan protocols on vBMD.

Methods: In this systematic literature review, two independent reviewers (AH and AC) conducted a blinded screening for articles involving human participants who had undergone a contrast and non-contrast CT scan to measure vBMD. A total of 1,981 studies, published between 01/02/2000 and 17/01/2021, were screened and 9 eligible studies were included. A meta-analysis was conducted and standard mean differences (SMD) with 95% confidence intervals (CI) were calculated and presented in a forest-plot. Quality of studies was rated by the preliminary ROBINS-E risk of bias tool.

Results: In total, the 9 studies included 515 patients. On average the vBMD SMD changed 0.45 (95% CI: 0.24-0.67, P < .0001) from non-contrast to contrast-enhanced (CE) scans at the lumbar region (Figure 1). Phantom-based QCT had a SMD of 0.64 (95% CI: 0.33-0.94, P < .0001) and phantom-less QCT had a SMD of 0.20 (95% CI: -0.00-0.40, P = 0.05). Subgroup analyses showed a mean arterial phase vBMD SMD of 0.29 (95% CI: 0.12-0.45 P < .0008) and a venous phase vBMD of 0.56 (95% CI: 0.30-0.81, P < .0001). All studies were deemed to have moderate or serious risk of bias by the ROBINS-E tool.

Conclusion: QCT-measured vBMD is higher in CE scans in both phantom-based and phantom-less scans compared to non-contrast CT. Our meta-analysis suggest that contrast has a larger impact on vBMD in phantom-based vs. phantom-less and in venous phase vs. arterial phase scans, underlining not only the time-dependency but also the dependency of the calibration method. Arterial phase CT scans using internal calibration may be preferred when measuring vBMD in a clinical setting without an adjusting conversion factor. However, CE scans are to be used in opportunistic vBMD screening, development of a universal calibration- and protocol specific conversion factor is of importance.

CALPROTEIN, A SENSITIVE MARKER OF INFLAMMATION, IS ROBUSTLY ASSESSED IN PLASMA FROM PATIENTS WITH ESTABLISHED RA BY USE OF DIFFERENT LABORATORY METHODS
H. B. Hammer1, 2, S. L. Pedersen1, I. Gehring1, L. Mathsson-Alm3, J. Sexton4, J. Askling5.
1Diakonhjemmet Hospital, Dept of Rheumatology, Oslo, Norway; 2Instituto de Investigación Biomédica de Málaga (IIBMIA); Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain; 3Hospital Universitario Reina Sofia, Universidad de Córdoba, Rheumatology, Córdoba, Spain; 4Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain; 5Hospital Universitario Reina Sofia, Instituto Maimónides de Investigación Biomédica (IMIBIC), Universidad de Córdoba, Rheumatology, Córdoba, Spain; 6Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden

Background: Sarcopenia is a muscular disease characterized by a loss of muscle mass and function. The condition is associated with chronic diseases and...
aging and predicts disability, hospitalization and death [1]. Due to chronicity and disability produced by RA, it is convenient to see the relationship with sarcopenia.

Objectives: To assess the diagnostic utility of ultrasound (US) for sarcopenia.

Methods: Cases: Outpatients, 65 years old or more, with RA (ACR/EULAR 2010 criteria) from the rheumatology clinics of 4 Spanish University Hospitals were randomly selected consecutively from rheumatology consultation since May 2021 to September 2021. Controls: Control subjects without rheumatoid disease were selected from family members or friends of the cases, paired by age, gender and social status from May to September 2021. Variable and measures: The main evaluated outcome was sarcopenia as defined in 2019 by the European Working Group on Sarcopenia in Older People (EWGSOP). Cross-sectional Ultrasound sounds (US) of the third proximal forearm were evaluated for the perpendicular distance (millimeters) between superficial surface of subcutaneous cellular tissue and the deep surface close to the ulna with two different measures (66% and 75%). Cross-sectional US images were also obtained of lower limbs, at an equidistant point between anterosuperior iliac spine and the upper border of the patella for measuring the distance between superficial surface of subcutaneous cellular tissue and the deep interface of the femur with vastus medialis muscle with two different measures (50% and 75%). Handheld dynamometer was used to measure the strength in upper limbs. Body composition was evaluated using dual-energy X-ray densitometry.

Statistics: A descriptive analysis, chi square γ-test, T-test were done to compare the main characteristics and results between patients and controls. Correlations between forearm US and strength and between thigh US and total DEXA were calculated by Pearson’s test.

Results: 76 patients and 76 controls were included in the study, 120 were women (79.3%), with media a SD of age 74.7 ± 9.98 of media and 32 (21.1%) were men, with age 70.1 ± 3.78 of media. In comparison with controls, RA patients presented more frequency of sarcopenia (30 [19.53%] vs 6 [3.94%]; p=0.005) according to EWGSOP criteria. From the point of view of ultrasound, RA patients presented less muscle mass in cubital forearm and thigh. Control group presented larger size of muscle (Table 1).

Ultrasound measurements in forearm which showed a positive correlation with strength were: right forearm: 66% ulnar (r=0.295, p=0.003), 75% cubital (r=0.342, p<0.001), 50% FR (r=0.256, p=0.003), 75% FR+VI (r=0.255, p=0.003), 50% FR (r=0.265, p=0.002), 50% area FR (r=0.280, p=0.003), 75% FR (r=0.357,p=0.001), 75% VI (r=0.382,p=0.001), 75% FR (r=0.240, R2=0.006), 75% area FR (r=0.218,p=0.023), 75% FR (r=0.251, p=0.004), 50% VI (r=0.293,p=0.001), 50% FR (r=0.214, p=0.015), 75% FR (r=0.347,p=0.001), 75% VI (r=0.342, p=0.001), 75% FR (r=0.295, p=0.001).

Conclusion: Muscle Ultrasound is a useful diagnostic tool to detect sarcopenia. It can be cost-efficient and faster when compared with DEXA and the results correlated with strength produced by RA, with or without deformities or erosions.

Musculoskeletal ultrasound allows evaluation of the inflammatory joint damage for more targeted therapeutic approach.

Objectives: The aim of this study was to estimate the prevalence of the wrists and hands synovitis (WHS) in subgroups of patients with systemic lupus erythematosus (SLE) and to compare them with each other.

Methods: One hundred and sixty-nine patients with SLE were consecutively recruited in the rheumatology unit (consultation or hospitalization) of the Ben Aknoun hospital, Algiers-Algeria. Stratification into subgroups was carried out: non-deforming non-destructive patients (NDND), rashy patients (if coexistence of lupus and rheumatoid arthritis criteria), patients with moderate deforming arthropathy (MDA) or Jaccoud arthropathy according to the score of the Sporik index. For each patient, demographic data, duration of SLE evolution and joint involvement were collected, a standard inflammatory biology report and screening for rheumatoid factor (RF) and anti-CCP (ACPA) were requested. A musculoskeletal ultrasound of the wrists, MCP andPIP (from the 2nd to the 5th rays) was performed with a search for synovitis and erosions, the ultrasound examination was preceded by the calculation of the SLEDAI score and the HAQ score.

Results: 169 patients were recruited: 135 NDND, 18 ruphas, 10 Jaccoud, 6 MDA, respective mean age of 38.38 ± 11.79, 39.39 ± 11.74, 41.10 ± 9.5, 47 ± 9.93 years. The mean duration of lupus was 8.23 ± 6.97, 12.33 ± 8.71, 13.10 ± 6.6 and 15 ± 5.93 years, respectively. The mean duration of joint involvement was 7.38 ± 6.920, 12.22 ± 8.84, 13.10 ± 6.6, 15 ± 5.93 years. The positive CRP was found respectively in 20%, 38.9%, 20%, and 16.7%. The frequency of WHS, RF, ACPA and erosions was significantly higher in the ruphas group compared to that of NDND (p <0.001). No difference was found in mean SLEDAI scores between subgroups. The mean HAQ score was higher in patients in the ruphas and Jaccoud groups compared to the mean score in patients in the NDND and MDA group (p <0.0001).

Conclusion: Our results confirm that ruphas patients have more inflammatory and erosive involvement than other lupus subgroups. It represents an overlap between rheumatoid arthritis and lupus more than a separate entity. We have also shown that deforming arthropathies without structural damage correspond to a late course in a group of patients initially non-deforming non-destructive.

AB1341

ASSESSMENT OF COMMON FEMORAL VEIN INTIMA-MEDIA THICKNESS BY ULTRASOUND IN BEHÇET’S DISEASE: COMPARATIVE STUDY OF PATIENTS WITH OR WITHOUT VASCULAR INVOLVEMENT IN A NATIONAL REFERRAL CENTER

D. Prieto-Peña1,2, A. Del Peral Fanjul3, B. Atienza-Mateo3, V. Pulito-Cuello2, M. A. González-Gay3,4, R. Blanco2,3,4 1Hospital Universitario Marqués de Valdecilla, Department of Rheumatology, Santander, Spain; 2IDIVAL, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and Metabolic Bone Diseases of the Musculoskeletal System, IDIVAL, Santander, Spain

Background: Vascular manifestations are frequent in Behçet’s disease (BD). However, they have been less studied than other manifestations, such as ulcers [1]. Increased venous wall thickness assessed with ultrasound (US) has been reported in BD [2]. However, it remains unclear if US findings correlate with vascular involvement in BD.

Methods: To assess vascular Doppler US findings in patients with BD with and without clinical vascular manifestations.

Results: Observational study of unselected consecutive patients with BD assessed in a national referral center, from March 2021 to May 2021. All patients fulfilled the 2014 ICBD criteria [3]. They were evaluated sequentially with a scheduled clinic visit after signing an informed consent. Demographic and clinical variables were collected. Patients were considered to have vascular involvement...
Results: A total of 280 patients, 179 (63.9%) women, with a mean age of 58±15 years, underwent PET/CT in the rheumatology department. 202 (72.1%) patients had a diagnosis of iRMD before PET/CT. After PET/CT, 40 (48.2%) patients were diagnosed with a new iRMD, and 43 (41.8%) were diagnosed with a non-iRMD. No inflammatory disease was detected in 33 (11.8%) patients.

iRMD diagnosed by PET/CT are respectively: LVV (n=11), IgG4-RD (n=10), sarcoidosis (n=9), and other (n=10). It was determined that 22 (26.5%) of newly diagnosed patients other than iRMD had malignancy [Bronchial (n=8), lymphoma (n=3), breast (n=3), other (n=8) cancer]. PET/CT revealed lymphadenopathy (LAP) in 119 of 165 patients who underwent the scan to exclude malignancy, and 22 of 91 patients who underwent PET/CT for rheumatologic diagnosis. LAP was found in 45% of those diagnosed with iRMD and 74.4% of those diagnosed with non-iRMD (p=0.002). PET/CT imaging was performed on 18 patients for follow-up. The treatment of 4 out of 18 patients with follow-up PET/CT and 76 out of 280 total patients was changed after imaging. In patients with a diagnosis of giant cell arteritis (GCA), the compatibility of PET/CT with MRI was 62.5%, while its agreement with CTA was 100%, and with Doppler USG was 38%.

Conclusion: PET/CT imaging was found to be an important adjunctive examination in the diagnosis and follow-up of sarcoïdosis, LVV, and IgG4-RD in patients evaluated in the rheumatology clinic. It has been observed that it is often used in the diagnosis and follow-up of RA, SpA, and autoinflammatory diseases, to investigate the malignancies accompanying rheumatic diseases and to evaluate the characteristics of LAP. PET/CT findings provide significant benefits to the clinician in the early diagnosis of iRMDs and differentiation of malignant and/or infectious etiologies.

IMT: intima-media thickness. IQR: interquartile range.
Background: Disease activity scores are used in the follow-up of patients with rheumatoid arthritis (RA). These scores include variables obtained through physical examination, such as the tender and swollen joint count. In telematic consultations it is not possible to determine these variables. Thermography is a safe and fast technique that measures heat through infrared imaging. Inflammation of the joints causes an increase in temperature and could therefore be detected by thermography. Machine learning methods are highly accurate in analyzing medical images, and could be used to analyze thermal images automatically. Thermography of hands, patient global health (PGH) and acute phase reactants could be combined to develop new activity scores that facilitate remote assessment of RA patients.

Methods: Multicenter observational study conducted in the rheumatology and radiology service of two hospitals. Patients with RA, psoriatic arthritis, undifferentiated arthritis and arthritis of hands secondary to other diseases that attended the follow-up visits were recruited. Companions of patients and healthcare professionals were also recruited as healthy subjects. In all cases, a thermographic image of the hands was taken using a Flir One Pro or a Thermal Expert TE-Q1 camera connected to a smartphone. Ultrasound (US) of both hands was performed. The degree of synovial hyperthermia (SH) and power doppler (PD) was assessed for each joint (score from 0 to 3). Machine learning was used to quantify joint inflammation from the thermal images using US (SH+PD) as ground truth. This score has been named ThermOJS. RA patients whose thermal image was taken with the Thermal Expert TE-Q1 camera were used to evaluate the performance (test dataset). The other participants were used as training dataset. The PC, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were also assessed in the test dataset. ThermoDAS (ThermoJS + PGH), ThermoDAS-ESR (ThermoJS + PGH + ESR) and ThermoDAS-CRP (ThermoJS + PGH + CRP) activity scores were developed using a linear regression. The Spearman’s correlation coefficient of ThermOJS, ThermoDAS, ThermoDAS-ESR and ThermoDAS-CRP vs. SH, PD, PGH, ESR and CRP were used to characterize the new developed disease activity scores. The study was approved by the Clinical Ethics and Research Committee of both centers.

Results: The total number of recruited subjects were 616 (475 for the training and 141 for the testing dataset). The correlations obtained between the different activity scores (ThermoJS, ThermoDAS, ThermoDAS-ESR and ThermoDAS-CRP) vs. SH, PD, PGH, ESR and CRP are shown in Table 1. All correlations are statistically significant.

Table 1. Spearman’s correlations of the developed scores vs synovial hyperthermia (SH); vs power doppler (PD); vs patient global health (PGH); vs erythrocyte sedimentation rate (ESR) and vs C-reactive protein (CRP).

Conclusion: ThermOJS shows moderate correlation with US but weak correlation with PGH and acute phase reactants, suggesting that ThermOJS is non-redundant with symptoms and laboratory assessment. Adding PGH and acute phase reactants to ThermOJS improves all correlations, including correlation with US. These thermographic scores do not require a physical examination, opening an opportunity to facilitate remote consultations in RA patients.

AB1344 THE ROLE OF ULTRASOUND CRITERIA IN PREDICTING THE OUTCOME OF EARLY UNDIFFERENTIATED ARTHRITIS OF THE SMALL JOINTS OF THE HAND

N. Aleksandrova1, A. Aleksandrov2, N. Nikitina2, V. Aleksandrov1,2, †Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology Named After A.B. Zborovsky», Department of Functional Research Methods, Volgograd, Russian Federation; Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation

Background: Arthritis of peripheral joints is among the most frequent manifestations in the onset of rheumatic diseases. Determining its nosological identity and rational therapy at an early stage is a complex clinical problem.

Objectives: To evaluate the possibility of using ultrasound to predict the outcome of early undifferentiated arthritis (EUA).

Methods: Since 2018, patients with a first-time diagnosis of early undifferentiated arthritis were consecutively included into the study. The final group consisted of 102 patients (women, 71.6%; mean age 44.8±17.2 years old) who were prospectively observed at baseline, after 3 months, and after 1 year. Ultrasound examination (ultrasound) of the hand joints was performed according to a standard technique using a 5-12 MHz linear transducer on an Accuvix V10 ultrasound diagnostic system (Samsung Medison, South Korea). Ultrasound was performed twice with the following criteria: 1) synovium thickness, 2) blood flow in synovium by Doppler, 3) presence of hyperechogenic inclusions in synovium, 4) cortical bone contour, 5) signs of tendon inflammation (flexors and extensors of the fingers). Synovium thickness in the hand joints over 3 mm was interpreted as synovial thickening [1]; appearance of blood flow from the contour of the cortical bone of the joint with tree branching — as “pannus”; single loci of blood flow by Doppler — as synovitis [2].

Results: During 12 months of follow-up, 47 patients (46.1%) were diagnosed with early rheumatoid arthritis (based on clinical diagnosis according to 2010 criteria and/or prescription of basal anti-inflammatory drugs); 16 (15.7%) had reactive arthritis associated with urogenital infection; 7 (6.9%) had gouty arthritis; 3 (2.9%) had psoriatic arthritis; 2 (1.9%) had systemic lupus erythematosus; 1 patient (0.9%) was found to have a renal malignancy; 26 (25.3%) had no change in EUA diagnosis. Retrospective analysis of the data showed that initially patients with rheumatoid arthritis (RA) in 46.8% (22/47) were determined to have a tree-like blood flow in the synovium of the joint from the cortical contour of the bone (“pannus”); in patients with reactive arthritis associated with urogenital infection, axial tendon lesions were found most frequently (43.8%; 7/16); in patients with gouty arthritis, changes in the triangular cartilage and hyperechogenic inclusions in the synovium were more common (42.9%; 3/7). During the initial examination of patients with EUA who were subsequently diagnosed with RA, the ultrasound picture of the hand joints in the overwhelming majority of cases (83%; 39/47) was characterized by the presence of extensor tenosynovitis and/or synovial thickening with Doppler blood flow (against the background of symmetrical arthritis of the metacarpophalangeal joints). The sensitivity of detection of this criteria to the development of RA in patients with small joint EUA was 56% with a positive prognostic value of 69%. It has been previously demonstrated that in EUA the presence of subclinical inflammation of the major joints and high titer of antibodies to cyclic citrullinated peptide are strong predictors of RA development [2]. Probably, the combination of clinical and serological tests with the presented ultrasound data of small joints can also increase the accuracy of diagnosis of early RA in patients with EUA.

Conclusion: Detection of subclinical inflammation in the small joints of the hand and synovial thickening with Doppler blood flow in patients with EUA at baseline can help in the stratification of patients at high risk of developing RA.

AB1345 PREDICTIVE MODEL FOR THE DIAGNOSIS OF PSORIATIC ARTHRITIS IN DERMATOLOGY REFERRALS ACCORDING TO PURE-4 SCALE

N. De la Torre Rubio1, J. Campos Esteban2, M. Pavia Pascual2, M. Machattou2, P. Navarro Palomo1, O. Rusinovich1, M. Fernandez Castro1, H. Godoy1, C. Barbadillo Mateos1, C. Merino Argumánez1, B. Garcia-Magallón1, J. Sanz1, L.
Background: The rate of psoriatic arthritis progression is increased in those patients presenting with established disease greater than 2 years duration, so it is necessary to find tools that allow early diagnosis to prevent joint damage. Prevalence of psoriatic arthritis varies according to the screening strategies used. The COMPAQ study compared four screening questionnaires for psoriatic arthritis (PEST, ToPAS, PASE and EARP), whose sensitivities ranged from 44 to 91%, with the EARP questionnaire showing the highest sensitivity. A new, shorter questionnaire, PURE-4 scale, has been developed with a sensitivity of 85.7%.

Objectives: To evaluate the usefulness of PURE-4 scale in real clinical practice conditions to identify patients with psoriatic arthritis in patients with psoriasis referred from a dermatology department to a rheumatology department.

Methods: Retrospective descriptive study of patients diagnosed with psoriasis who have been referred from the Dermatology Department in the last 12 months for suspected joint domain according to PURE-4 scale used by this department. The following variables were collected: age, sex, obesity, dyslipidaemia, smoking, family history of psoriasis, form of psoriasis (plaque, pustular, scalp, nail), previous treatment (topical, methotrexate, other, none), PASI index, compliance with CAPSAR criteria, rheumatological diagnosis (psoriatic arthritis yes/no), PURE-4 score, morning stiffness in hands, Achilles enthesitis, inflammatory low back pain and need for anti-inflammatory drugs for joint pain in the last 3 months. Descriptive statistics was performed and Chi-square test was used to compare the diagnosis of psoriatic arthritis with PURE-4 values (at the response threshold ≥1 it has a sensitivity of 85.7% and a specificity of 83.8%).

Results: In the last 12 months the Dermatology Department of our hospital made 33 referrals for suspected psoriatic arthritis in patients diagnosed with psoriasis. Mean age was 46.4 ± 12.4 years, 51.5% were men. Fifty-one percent of the patients had a BMI ≥25, 30.3% had dyslipidaemia and 45.5% were smokers; 10% of the patients had family history of psoriasis. The most prevalent form of psoriasis was plaque (18%) followed by nail (6%), palmoplantar (3%), scalp (3%) and droplet (3%) involvement. 51.5% of patients were on topical treatment, 9% on methotrexate and 39.4% on biologic treatments; mean PASI was 6.2 ± 7.5. Seventy-five percent of the referred patients did not meet CAPSAR criteria; 33.3% were diagnosed with psoriatic arthritis by the rheumatologist. Of the 33 patients, 4 (12.1%) scored 0 points on PURE-4 scale; 21 (63.6%) scored 1 point; and 8 (24.3%) scored 2 points. Once assessed by a rheumatologist, 75.5% had no morning stiffness in the hands, 93.9% had no Achilles enthesis and 87.9% had no inflammatory low back pain; only 24.2% of patients had required NSAIDs simultaneously, 37.9% had no inflammatory low back pain and need for anti-inflammatory drugs for joint pain in the last 3 months for joint pain. Finally, the diagnosis of psoriatic arthritis was analyzed against the PURE-4 cut-off point (Table 1).

Table 1. Psoriatic arthritis diagnosis based on total score on PURE-4 scale

<td>0.69</td>
<td>0.41</td>
</tr>
</tbody>
</table>

Conclusion: PURE-4 scale with a score ≥ 1 does not seem to improve the diagnosis of arthritis in psoriatic patients. It would be necessary to implement other questionnaires that are more complete, but at the same time affordable, when carried out during the dermatology consultation in order to increase the sensitivity to refer or not to the rheumatologist.

AB1346

ULTRASOUND ASSESSMENT OF SUB-CLINICAL HAND JOINT INFLAMMATION: A COMPARATIVE STUDY BETWEEN EARLY RHEUMATOID AND PSORIATIC ARTHRITIS

F. Liu1, Y. Xin1, J. Zhu2, 1Peking University People’s Hospital, Department of Ultrasound, Beijing, China

Background: Ultrasound (US) detected subclinical inflammation can be present in early psoriatic arthritis (PsA) and rheumatoid arthritis (RA), and also in patients fulfilling clinical remission criteria [2-3]. Numerous evidences support that the persistence of subclinical synovitis detected by US is associated with a high risk of disease progression [2-3].

Objectives: To evaluate sub-clinical inflammation of PsA and RA at the level of small joints of the hand and wrist by B-mode and Power Doppler US.

Methods: 30 patients of early PsA and 35 patients of early RA (no clinical evidence of hand joint involvement, PsA disease duration <2 years, and RA disease duration <1 year) were recruited. US (grey scale (GS) and power Doppler (PD)) was performed to assess synovitis, tenosynovitis, joint effusion, and bone erosion of bilateral wrists, metacarpophalangeal joints, proximal and distal interphalangeal joints, as well as the flexor tendons and extensor compartments.

Results: A total of 35 patients were included in the RA group, including 10 males and 25 females. A total of 30 patients were included in the PsA group, including 12 males and 18 females. There were no significant differences in gender composition, age, and duration of disease between the two groups (P>0.05) (Table 1). 19 (63.3%) PsA patients and 16 (45.71%) RA patients had sub-clinical hand joint synovitis. At the joint level, wrist joints were most commonly involved (23.08%), followed by MCP3 (15.38%) and DIP3 (13.46%) in PsA group. In RA group, wrist joints were most commonly involved (55.17%), followed by MCP3 (12.41%), and MCP2 (11.03%). Eight (26.67%) PsA patients and 16 (45.71%) RA patients were detected tenosynovitis. Tenosynovitis was most frequently presented at the extensor tendons in RA and at the flexor tendons in PsA patients (p<0.05). The two most commonly affected were the 4th and 1st extensor compartments in RA patients, and the flexor pollicis longus and flexor digitorum profundus in PsA patients. 61 (6.80%) joint reeses in the RA and 75 (7.35%) joint reeses in PsA were detected effusion. Joint effusion was most frequently detected at radiocarpal and midcarpal joints in RA (30.86%, 25.92%, respectively). Effusion in PsA was most commonly presented at the 3rd PIP joints (26.67%), followed by radiocarpal joints (24.00%). Bone erosions were uncommon, totally 2 (6.67%) PsA patients and 3 (8.57%) RA patients were detected bone erosions.

Table 1. Demographic characteristics of RA and PsA patients

<table>
<thead>

</tr>
<tr>
<td>Disease duration, years, means±SD</td>
<td>0.72±0.03</td>
<td>0.91±0.53</td>
</tr>
</tbody>
</table>

Conclusion: There are significant differences in the US findings of sub-clinical inflammation at the hand and wrist joints, such as the joint effusion and tenosynovitis, which may assist the identification between early RA and PsA. Simultaneously, it should be pointed out that there are some similarities in the joint involvement of sub-clinical synovitis between RA and PsA, physicians should take this into account in clinical work.

ASYMPTOMATIC SACROILIITIS DETECTED BY MAGNETIC RESONANCE ENTEROGRAPHY IN PATIENTS AFFECTED BY CROHN’S DISEASE: PREVALENCE AND ASSOCIATION WITH CLINICAL DATA IN A MULTICENTER STUDY OF ADULT AND ABDOMINAL POPULATION

I. Giovannini1, L. Cererè2, I. Tinazzi3, C. Ciccio4, F. M. Murrù5, M. Bramuzzo6, M. Marino6, A. Tulio6, S. De Vita1, A. Zabotti1. 1Rheumatology Clinic, University Hospital “S. Maria della Misericordia” c/o University of Udine, Udine, Italy; 2Institute of Radiology, University Hospital “S. Maria della Misericordia” c/o University of Udine, Udine, Italy; 3Department of Rheumatology and Immunology, I.R.C.C.S Sacro Cuore Don Calabria Hospital, Negrar di Valpolicella, Italy; 4Department of Diagnostic Imaging and Interventional Radiology, I.R.C.C.S Sacro Cuore Don Calabria Hospital, Negrar di Valpolicella, Italy; 5Pediatric Radiology, IRCSS “Burlo Garofolo”; Trieste, Italy; 6Gastroenterology, Digestive Endoscopy, and Nutrition Unit Institute for Maternal and Child Health, IRCSS “Burlo Garofolo”; Trieste, Italy; 7Department of Gastroenterology, University Hospital “S. Maria della Misericordia” c/o University of Udine, Udine, Italy; 8Institute of Hygiene and Clinical Epidemiology University Hospital “S. Maria della Misericordia” c/o University of Udine, Udine, Italy

Background: Magnetic resonance enterography (MRE) is usually performed in patients with Crohn’s disease (CD) for evaluating small bowel involvement. Inflammatory bowel disease (IBD) mainly affect the gastrointestinal tract, although patients may present extraintestinal manifestations (1). Musculoskeletal symptoms are the most frequent extraintestinal manifestation in IBD, especially in CD. Furthermore, sacroiliitis at imaging occurs in about 6-46% of CD patients and may correlate with axial spondyloarthritis (2,3).

Objectives: The primary aim of our study was to assess the prevalence of sacroiliitis in adult and pediatric patients affected by CD who performed MRE. We also evaluated the inter-rater agreement for MRE sacroiliitis and the association between sacroiliitis and patients’ clinical data.

Methods: We included consecutive patients with CD diagnosis (4), who underwent an MRE in the period between December 2012 and May 2020. We excluded patients with a known diagnosis of SpA, patients with confirmed or suspected inflammatory back pain; and patients treated at the time of MRE with systemic Disease-Modifying Antirheumatic Drugs (DMARDs), which influence both bowel and joint disease (i.e., conventional DMARDs, and biologic DMARDs).

Two radiologists assessed the prevalence of sacroiliitis at MRE. We evaluated the inter-rater agreement for sacroiliitis and assessed the correlation between sacroiliitis and demographic, clinical, and endoscopic data.

Results: We retrospectively identified 100 adult and 30 pediatric patients. The prevalence of sacroiliitis at MRE was 20% in adults and 6.7% in pediatric patients. The inter-rater agreement for sacroiliitis was substantial (k=0.62, p<0.001) in the adults, and moderate (k=0.46, p=0.011) in the pediatric cohort. Age ≥50 years and the time between CD diagnosis and MRE (≥86.5 months) were significantly associated with sacroiliitis in adult patients (p=0.038, respectively). The presence of sacroiliitis in pediatric patients affected by CD may help the appropriate and early referral to the rheumatologist.

REFERENCES:
[2] Salvarani C, Fries W. Clinical features and epidemiology of spondyloarthritis in adult patients with CD, associated with age of the patients ≥ 50 years and the time between CD diagnosis and MRE (≥86.5 months) were significantly associated with sacroiliitis in adult patients (p=0.049 and p=0.038, respectively). Asymptomatic sacroiliitis at MRE is a frequent and reliable abnormality in adult patients with CD, associated with the age of the patients ≥ 50 years and CD duration. Detecting sacroiliitis at MRE in patients affected by CD may help the appropriate and early referral to the rheumatologist.

Conclusion: Asymptomatic sacroiliitis at MRE is a frequent and reliable abnormality in adult patients with CD, associated with the age of the patients ≥ 50 years and CD duration. Detection of sacroiliitis at MRE in patients affected by CD may help the appropriate and early referral to the rheumatologist.

COMPARISON OF SACROILIAC CT FINDINGS IN PATIENTS WITH AND WITHOUT PSORIATIC ARTHRITIS: RESULTS OF THE CASIPSA STUDY.

O. Fehily1, A. Ramòn2, C. Prati3, P. Ornetti2, D. Wendling1,4, F. Verhoeven1,5, 1CHU de Besançon, Rheumatology, Besançon, France; 2CHU de Dijon, Rheumatology, Dijon, France; 3UFR Santé, Université de Franche-Comté, EA 4267 ‘PEPITE’, Besançon, France; 4UFR Santé, Université de Franche-Comté, EA 4266 ‘EPILAB’, Besançon, France

Background: Psoriatic arthritis (PsA) is an inflammatory arthritis associated with various rheumatological manifestations, such as arthritis or enthesitis, predominately in the peripheral skeleton. However, the axial skeleton may be affected, as shown clinically or by conventional radiographs in up to 70% of patients with peripheral involvement. While there are studies comparing joint damage on standard radiography between patients with PsA and patients with anklyosing spondylitis [1], to our knowledge, no study has specifically evaluated the extent of structural lesions of the sacroiliac joints (SIJs) on computed tomography (CT) in patients with PsA compared with healthy controls.

Objectives: To describe SI CT characteristics in patients with PsA and compare them with those of age- and sex-matched controls.

Methods: An observational, retrospective study was performed using medical records from Besançon and Dijon University Hospital's rheumatology departments, which were screened to identify patients with PsA, according to the CASPAS criteria. A search was then carried out for patients in the hospitals’ imaging archiving system to identify those who had undergone a CT which included the SIJs in their entirety. Non-inclusion criteria were the presence of pelvic bone lesions and a history of pelvic radiotherapy. Each patient was then matched with a control of the same age and sex, recruited through the hospital's imaging archiving system. For each individual, CT was interpreted by two independent readers using a score previously used by Diekhoff et al. [2], dividing each SIJ into 12 regions, for each of which joint space narrowing (JSN), erosions, and sclerosis are assessed. For this study, we also observed the existence of intra-articular gas and diffuse idiopathic skeletal hyperostosis (DISH) lesions for each region. Quantitative variables were compared using Student’s t-test. Qualitative variables were compared using the Chi-2 test.

Results: 48 patients and 48 controls were included. Mean (SD) age was 54.76 ± 12.91 in the PsA group and 54.74 ± 12.87 in the control group. 26 (54.18%) were male in both groups. In PsA patients, mean (SD) disease duration was 22.87 ± 14.95 years, 10 (43.48 %) were HLA-B27 positive, and 1 (2.86%) had a bamboo spine. CT findings are described in Table 1. The only lesion found significantly more frequently in PsA patients was erosion, which appeared to be preferentially located on the anterior and middle regions of the SIJs (Figure 1). A positive CT scan (significant joint space narrowing, erosion and/or sclerosis) was found in 15 (32.61%) of the patients with peripheral involvement and 6 (30.00%) of the patients with axial involvement.

Table 1. Sacro-iliac CT findings using a score modified from Diekhoff et al.

CORRELATION OF CHRONIC INFLAMMATION MARKERS WITH ULTRASOUND SIGNS OF ATHEROSCLEROTIC HEART DISEASE AND BRACHIOCEPHALIC ARTERIES LESIONS IN RHEUMATOID ARTHRITIS

N. Aleksandrova1, A. Aleksandrova2, N. Nikitina1, V. Aleksandrova1,2, Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology Named After A.B. Zborovsky», Department of Functional Research Methods, Volgograd, Russian Federation; Volgograd State Medical University; Department of Hospital Therapy, Volgograd, Russian Federation

Background: Clinical and experimental data confirm the role of both systemic and local (inflammation in potentiating atherosclerosis and increasing cardiovascular risk in patients with rheumatoid arthritis (RA)) against the background of severe immunological disorders.

Objectives: To study the severity of ultrasound signs of atherosclerotic lesions of brachiocephalic arteries and heart valve apparatus in patients with rheumatoid arthritis (RA).

Methods: 57 patients with RA (50 women and 7 men; mean age 50.4 ± 10.12 years old; mean duration of disease 9.2 ± 6.8 years; DAS28 activity: low - 3.5%, medium - 86%, high - 10.5%) were examined. Laboratory examination included determination of serum IgG-RF, CRP, antibodies to cyclic citrullinated peptide (ACCP), antibodies to modified citrullinated vimentin (MCV), total antinuclear antibodies (ANA), and levels of proinflammatory cytokines (IL-1, IL-6, TNF-α, angiopeptin-like proteins types 2, 3, and 4 - ANGPTL 2, 3, 4) by enzyme immunoassay. Cardiac ultrasound examination was performed according to the traditional technique on an Accuvix V10 ultrasound diagnostic system (Samsung Medison, South Korea) equipped with a multifrequency microconvex transducer with a frequency of 2-4 MHz. All patients underwent duplex scanning of brachiocephalic arteries (BCA) with assessment of the severity of atherosclerotic changes (AO - absence of BCA atherosclerosis, AI - isolated thickening of intima-media complex; BCA atherosclerosis, All - presence of atherosclerotic plaques and artery stenosis as manifestation of stenotic BCA atherosclerosis). The following gradation was used to estimate the degree of cardiac valve calcification: 0 - no calcification, 1st degree - unexpressed calcification, 2nd degree - moderate calcification, 3rd degree - expressed calcification of cardiac valves.

Results: Signs of cardiovascular system lesions (pericarditis, heart valve lesions, cardiomyopathies, cardiac conduction pathway lesions, myocarditis, endocarditis, coronary arteritis etc.) were diagnosed in 28 (49.1%) RA patients. Heart valve dysfunction was manifested by mitral valve (MV) and/or aortic valve (AV) insufficiency in the majority of cases. In RA patients, ultrasonic signs of cardiac valve calcification occurred in 40.4% (23/57) of cases; there was a high prevalence of aortic valve calcification of varying severity (19/23, 82.6%) and less detectable mitral valve calcification (12/23; 52.17%); patients with grade II-II cardiac valve calcification predominated (16/23; 69.6%); 5 patients (21.7%) had combined AV and MV lesions. In 25 (43.8%) patients with RA the signs of atherosclerosis of brachiocephalic arteries were determined: in 19 (33.3%) - non-stenotic (AI), in 6 (10.5%) - stenotic atherosclerosis (All). No statistically significant correlations were found between changes of cardiac valve apparatus, BCA lesions and main clinical characteristics of RA (disease activity, erosions, RF and ACCP positivity). Increased levels of ANGPTL2 (γ 2=4.6, p=0.032) were observed in the group of RA patients with cardiac valve lesions, and ANA (γ 2=3.91, p=0.049) and elevated IL-6 (γ 2=4.28, p=0.039) were detected more frequently in patients with signs of atherosclerotic lesions of BCA. The presence of autoimmune chronic inflammatory process is an independent sign of premature atherosclerosis development and causes the highest risk of atherosclerotic lesion of BCA and accelerates the processes of cardiac valve calcification in RA patients.

Conclusion: Regular echocardiography (with duplex scanning of BCA and heart valve examination) in RA patients can contribute to earlier identification of groups of patients possible requiring changes in therapeutic approaches to treatment and prevention of vascular accidents.

CAN DIFFUSION-WEIGHTED MRI REPLACE INTRAVENOUS GADOLINIUM CONTRAST-ENHANCED MRI FOR ASSESSMENT OF SYNOVITIS?

J. Mollenbach Møller1, K. L. Gandrup2, M. Østergaard2, D. Gniatiti3, O. Madsen4, K. Herslev-Petersen4, S. Møller-Bisgaard5, Copenhagen University Hospital Herlev - Gentofte, Radiology, Herlev, Denmark; 2University Hospital of Copenhagen, Rigshospitalet, Glostrup, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark; 3Skaraborg Hospital, Department of Rheumatology, Skövde, Denmark; 4University Hospital of Copenhagen, Rigshospitalet, Gentofte, 5Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; 5Faculty of Regional Health Research, Odense, Denmark; 6University Hospital of Copenhagen, Rigshospitalet, Glostrup, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Gentofte, Denmark

Background: In clinical trials of rheumatoid arthritis (RA) patients, intravenous gadolinium contrast injection is the gold standard method for MRI assessment of synovitis, e.g. by the OMERACT RA MRI Scoring method (RAMRIS). It has been shown that diffusion-weighted MRI (DW-MRI) allows visualization of synovitis.

Objectives: To establish a method for measuring MRI-derived apparent diffusion coefficient (ADC) from DW-MRI and to test its correlation with RAMRIS synovitis scoring.

Methods: MRI including diffusion-weighting of the dominant hand was performed in a cohort of RA patients in clinical remission (disease activity score in 28 joints-C-reactive protein [DAS28-CRP] ≤3.2 and no swollen joints). ADC measurements of the synovitis were assessed in 7 areas (3 wrist joint areas and 4 metacarpophalangeal (MCP) joint areas), similar to the RAMRIS. Intra-observer agreement for the ADC reading was determined using the intraclass correlation coefficient (ICC). Spearman’s ρ (ϕ) was calculated for the correlation of ADC with RAMRIS Synovitis. Differences in mean ADC between the individual RAMRIS synovitis grades were examined using ANOVA with Bonferroni correction for multiple tests.

Results: In 63 patients (67% females, age mean 61.0 years (range 36-78 years), disease duration 11.9 years, 0-59 years), DAS28-CRP 2.1 (1.6-3.0) the total RAMRIS synovitis was mean 5.8 (range 0-18). The mean ADC was 0.98x10-3 mm2/s (0.11-2.80). Correlations between RAMRIS synovitis and ADC in the 7 joint areas and mean differences in ADC between RAMRIS synovitis grades are presented in the Table 1. When all 7 joints were pooled the mean ADC and RAMRIS synovitis were moderately positively correlated, ρ=0.49; p<0.01. Statistically significant differences (p<0.01) in mean ADC were observed between all RAMRIS synovitis grades (0 vs 1, 0 vs 2, etc) except for the difference between grade 2 and 3. Good intra-observer (ICC = 0.62 (95%CI 0.49-0.72)) was found.

Conclusion: ADC, determined from DW-MRI, may be used to grade synovitis without the use of gadolinium contrast injection.

REFERENCES:
Background: During pregnancy profound physiologic changes are required to ensure fetal development and meet maternal needs. Microvascular remodelling is one major responsible for pregnancy haemodynamic adaptation, still it is not routinely evaluated in the obstetric field [1–2].

Objectives: To investigate the role of nailfold capillaroscopy (NVC) as a gold-standard and safe technique in detecting microvascular changes during normal pregnancy and to explore its possible application in clinical obstetric setting.

Methods: A population of 30 healthy pregnant women was longitudinally followed performing clinical assessment and NVC evaluation at each trimester and post-partum. Thirty non-pregnant age-matched healthy women having received at least two NVCs with a minimum 9 to 12-month interval were selected as controls. All NVC images were evaluated by a qualitative and semi-quantitative assessment using current standardised approach [3]. Statistical analyses were conducted to explore NVC parameters trend throughout gestation and its possible association with pregnancy course and clinical microvascular parameters (i.e., systemic blood pressure, umbilical artery Doppler ultrasound).

Results: A progressive significant increase of capillary neoangiogenesis and a specular reduction in capillary dilations was observed during pregnancy (p<0.05). These statistically significant variations were not found in age-matched controls, who showed stable NVC parameters over a similar time frame (p>0.05). All NVC images were evaluated by a qualitative and semi-quantitative assessment using current standardised approach [3]. Statistical analyses were conducted to explore NVC parameters trend throughout gestation and its possible association with pregnancy course and clinical microvascular parameters.

Conclusion: This is the first study that demonstrates a mechanism for validation of ultrasonography skills which will allow GCA US to become a feasible reality in clinical practice. This project demonstrates that after acquiring supervised training, near perfect levels of agreement can be achieved between a trainee and expert.

Conclusion: This study demonstrates a potential mechanism for validation against an expert sonographer.
the imaging of the thoracic aorta should be included in the diagnostic procedure of GCA. 18F-FDG PET/CT should be performed without glucocorticoid treatment, if the clinical situation allowed this proceeding.

AB1354 ULTRASOUND JOINT EXAMINATION BY AN AUTOMATED SYSTEM VERSUS BY A RHEUMATOLOGIST – FROM A PATIENT PERSPECTIVE

B. A. Frederiksen1, M. Schousboe2, L. Teslev3, I. N. Iversen3, H. M. Lindegaard3, T. R. Savarimuthu5, S. A. Just1. 1Svendborg Hospital - Odense University Hospital, Department of Medicine, Section of Rheumatology, Svendborg, Denmark; 2The Maersk Mc-Kinney Moller Institute, University of Southern Denmark, Odense, Denmark; 3Highschool Glosstrup, Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopaedics, Glosstrup, Denmark; 4Copenhagen University, Department of Clinical Medicine, Faculty of Health and Medical Sciences, København, Denmark; 5ROPCA, ROPCA Holding, Odense, Denmark; 6Odense University Hospital, Department of Rheumatology, Odense, Denmark

Background: The Arthritis Ultrasound Robot (ARTHUR) is an automated system for ultrasound scanning of the joints of both hands and wrists, with subsequent disease activity scoring using artificial intelligence.

Objectives: To describe the patients’ perspective of being examined by ARTHUR, compared to an ultrasound examination by a rheumatologist. Further, to register any safety issues in the use of ARTHUR.

Methods: Twenty-five patients with rheumatoid arthritis (RA) had both hands and wrists examined by ultrasound, first by a rheumatologist subsequently by ARTHUR (see Figure 1 A, B and C). Patient-reported outcomes (PRO) were obtained after the examination by the rheumatologist and then again after the examination by ARTHUR. PROs regarding pain, discomfort and overall experience were collected. In addition, willingness to be scanned again by ARTHUR as part of future clinical follow-up was also collected. All ARTHUR examinations were observed for safety issues.

Results: For baseline characteristics of RA patients, see Table 1.

There was no difference in pain or discomfort between the examination by a rheumatologist and by ARTHUR (p=0.29 and p=0.20, respectively). The overall experience of an examination by ARTHUR (see Figure 1 D) was described as very good or good by 92% (n=23), with no difference compared to the examination by the rheumatologist (p=0.50). All (n=25) patients were willing to be examined by ARTHUR again, and 92% (n=23) would accept ARTHUR as a regular part of their RA clinical follow up. No safety issues were registered.

Discussion: Conclusion: Joint ultrasound examination by ARTHUR was safe and well-received, with no difference in PRO components compared to ultrasound examination by a rheumatologist. Fully automated systems for joint disease activity assessment could be important in future strategies for RA management.

AB1355 NAILFOLD CAPILLAROSCOPY CHANGES IN PATIENTS WITH PSORIATIC ARTHRITIS AND RHEUMATOID ARTHRITIS

E. Molteni1, G. Pellegrino1, C. Castellani1, D. M. Reza Beigi1, F. Conti1, R. Sciro1, V. Ricciieri1, Sapienza University of Rome, Internal Medicine, Anesthesiological and Cardiovascular Sciences, Rome, Italy

Background: In psoriatic arthritis (PsA) and rheumatoid arthritis (RA) systemic inflammation is known to cause endothelial dysfunction 11. Nailfold videocapillaroscopy (NVC) analyzes in vivo blood vessels, looking for alterations due to microvascular damage, and its application in these pathologies often highlights interesting abnormalities. PsA is characterized by lower mean capillary length and density and abnormal morphology, such as tight terminal convolutions. In RA typically elongated and dilated capillaries and prominent subpapillary plexus are described 2 – 6. Differences between RA and PsA NVC patterns are known but not well defined yet 7 – 10.

Objectives: Aim of our study was to evaluate the microvascular features circulation by NVC in patients affected by PsA and RA, looking for possible differences that may characterize the two diseases.

Methods: We recruited outpatients affected by PsA or RA classified according to standard criteria 11 – 13 referring to the Rheumatology Unit at Sapienza University of Rome. Healthy controls (HCS) without known risk factors for nailfold capillary alterations 14 – 16 were also recruited. Patients and HCs underwent NVC with a 200x magnification lens. The following morphological parameters were considered: number of capillaries per square millimeter, alterations in length, dimension, morphology and distribution of the capillary; presence of ectatic loops, hemorrhages, flux abnormalities 7 – 8. A semi-quantitative rating scale was adopted to score these changes, according to previous studies 17. The mean score for each subject was obtained by analyzing all fingers, except the thumbs. For the statistical analysis, Chi-square and Mann-Whitney tests were used. All tests were two-sided with a significance level set at p<0.05.

Results: We recruited 34 patients (20 with PsA and 14 with RA) and 30 HCs. For patients, the mean age was 61.7 years (SD 15.4), median disease duration was 184 months (SD 204) and males were 18 (53%). Active or past smokers were 11 (18%), 9 (15%) suffered from arterial hypertension and 2 (0.9%) from type 2 diabetes mellitus. Raynaud’s phenomenon was present in 4 patients with PsA (20%) and 6 with RA (43%). The most frequent morphological changes were tortuous capillaries (80% in PsA and 100% in RA), single-crossing shape (80% and 86%) and bizarre capillaries (30% in both groups) while multiple crossing and ramified capillaries were present in 50% and 21 % RA patients only. With respect to HCs, we found significantly more frequent changes concerning morphology, ectatic loops, presence of hemorrhages and capillary plexus visibility in both PsA and RA patients. Moreover, patients with RA showed significantly more frequent abnormalities of the blood flow with respect to HCs. These results are shown in Table 1.

</table>

The presence of hemorrhages was significantly higher in RA rather than in PsA patients (p<0.01). No significant differences were found in number, length, and distribution of capillaries between PsA/RA cases and HCs.

Conclusion: Our study confirms and completes the frame of NCV alterations in PsA and RA. We described for the first time alterations in the capillary morphology and the presence of hemorrhages in both groups of patients with respect to HCs. It remains to evaluate how these findings can reflect the microvascular environment of chronic arthritis.

AB1356 QUANTITATIVE ANALYSIS BY SODIUM AND PROTON BASED 3-TELSA MR IMAGING OF THE ACHILLES TENDON
A. Müller-Lutz1, B. Kampf1, L. Klein-Schmeink1, S. Tsiami2, M. Frenken2, A. Nagel2, X. Baraliakos2, P. Sewerin3,4,5,6, Uniklinik Düsseldorf, Department for Radiology, Düsseldorf, Germany; 1University Hospital Ruhr-University Bochum, Rheumazentrum Ruhrgebiet Herne, Herne, Germany; 2University Hospital Erlangen, Institute of Radiology, Erlangen, Germany; 6University of Oxford, Oxford, England. 2014;54.

Background: Decrease of proteoglycan is the initiating stage of post-inflammatory tissue degradation. Sodium MRI is promising great potential for identification and monitoring of proteoglycan changes in tendons and cartilage associated with inflammatory and degenerative musculoskeletal diseases, where the Achilles tendon is frequently affected.

Objectives: Aims of the study were to quantify sodium concentrations in the Achilles tendon in healthy volunteers.

Methods: Sodium (23Na) MRI imaging of the Achilles tendon together with established proton (1H) MRI sequences were performed in 10 healthy volunteers (6 males, 4 females, age 29 ± 9 years) using a dual-tuned 23Na/1H surface coil (RAPID out). Significantly higher sodium concentrations were obtained in INS compared to MID (p=0.002) and in MTJ compared to MID (p=0.037). The average sodium concentrations of the whole Achilles tendon was 57.23±17.69 mM with only minor outliers in this healthy population.

Results: Significant sodium concentration differences were observed between the INS, MID and MTJ. The highest sodium concentration was observed at the tendon insertion into calcaneus bone (INS), whereas lower concentrations were measured in the middle portion of the tendon (MID) and muscle-tendon junction (MTJ).

Conclusion: Performance of quantitative sodium imaging of the Achilles tendon in a high-field MR machine is feasible for assessing sodium concentrations, a surrogate biomarker for proteoglycan content. Molecular MR studies investigating changes in the proteoglycan content of the Achilles tendon in patients with inflammatory and degenerative musculoskeletal diseases could support early diagnosis or therapy monitoring in the future.

AB1357 THE BEST CUT-OFF POINT FOR MEDIAN NERVE CROSS SECTIONAL AREA AT THE LEVEL OF PISIFORM BONE
A. Carones Esteves1, P. Freitas2, L. Brites3, T. Santiago1, M. Santiago1, J. Rovisco1, J. A. P. Da Silva1, Centro Hospitalar e Universitário de Coimbra, Serviço de Reumatologia, Coimbra, Portugal; 2Hospital CUF Coimbra, Reumatologia, Coimbra, Portugal; 3Hospital Santo André - Hospital Distrital de Leiria, Serviço de Reumatologia, Leiria, Portugal

Background: Carpal tunnel syndrome (CTS) is a focal neuropathy caused by compression of the median nerve (MN) at the wrist. Electromyography (EMG) is the gold standard for the diagnosis of CTS. Currently, the ultrasound (US) is frequently used as an initial screening exam by measuring the cross-sectional area (CSA) of the MN. The cut-off point of the CSA at the pisiform bone level to define CTS remains controversial with previous studies reporting values between 6.5mm² and 15mm² (1).

Objectives: The aim of this study is to determine the best cut-off point of the CSA for the diagnosis of CTS.

Methods: Cross-sectional study at a Tertiary Rheumatology Department including patients aged ≥ 18 years with symptoms compatible with CTS. Sociodemographic and clinical data, visual analogue scale for pain (VAS), Boston Questionnaire (BQ), and the results of EMG and US performed in each patient were collected. The EMG was performed according to the standardized protocol (sensory conduction velocity, sensory amplitude, distal sensory and motor latency), and the patients were categorized in 4 groups: normal, mild, moderate, and severe. A rheumatologist with expertise in imaging performed all the US evaluations by means of a 6–18-MHz (Siemens ACUSON S 2000) linear array transducer. The largest CSA of the MN was measured at the level of the pisiform bone. Receiver operating characteristic (ROC) curve was used to determine optimal cut-off values of the CSA taking the EMG result as the gold-standard. One-way ANOVA test was used to compare CSA between the 4 EMG groups.

Results: Fifty patients were included, 90% were female, mean age was 52.1 ± 10.8 years and median duration of symptoms was 28.0 (IQR 23.0-31.0) months. The mean VAS was 4.2 ± 2.9. In the BQ there was a mean symptom severity score of 2.4 ± 0.6 and a mean functional status score of 2.0 ± 0.9. One-way ANOVA showed that mean CSA values were significantly different in the 4 groups of patients. The Ryan-Einot-Gabriel-Welsch post hoc analysis showed that only the mean CSA of patients with severe STC is different from the remaining groups defined by EMG results. The best cut-off point for CSA at the pisiform bone for the diagnosis of CTS was 6.6mm² with a specificity of 72.7% (AUC=0.8, P<0.001). The positive and negative predictive values were 95.1% and 66.7%, respectively. For severe CTS diagnosis the best cut-off point for CSA was 12.3mm² with a sensitivity of 82.4% and a specificity of 72.7% (AUC=0.8, P<0.001). The positive and negative predictive values were 60.9% and 88.9%, respectively.

Conclusion: In our study we found that the best cut-off point of the CSA was 6.6mm² for distinguishing patients with/without CTS based on EMG alterations, with a high sensitivity and moderate specificity. This is a lower cut-off value than usually used in clinical practice and could be explained by small sample and the greater number of patients with mild and moderate STC on EMG.

Figure 1. Sodium concentrations of the Achilles tendon. Highest sodium concentrations c(mM) were observed at the tendon insertion into calcaneus bone (INS), whereas lower concentrations were measured in the middle portion of the tendon (MID) and muscle-tendon junction (MTJ).
AB1358

AN OLD METHOD FOR CURRENT CHALLENGES: SKIN TEST CONVERSION OF PURIFIED PROTEIN DERIVATIVE (PPD) IN RHEUMATOLOGICAL PATIENTS TREATED WITH ANTI-TNF-α

B. Abdalı1,2, A. Ringer1, J. Ruffino1, F. Martinez1, M. C. Argento1, S. Chulibert1, G. Ayan1, A. Sadic2, L. Kılıç1, U. Kalyoncu1, B. Abdala1,2, A. Co2, M. Abdalı1, Rheumatology Unit, Hospital Provincial del Centenario, Rosario, Rosario, Argentina;2Internal Medicine Unit, Hospital Provincial de Rosario, Rosario, Rosario, Argentina;1Internal Medicine Unit, Hospital Provincial del Centenario, Rosario, Rosario, Argentina

Background: Anti-TNF-α are a cornerstone for the treatment of multiple rheumatic diseases. They are associated with an increased risk of developing tuberculosis (TB), which is endemic in several countries and an important burden across the globe. Purified protein derivative (PPD) is one of the tests used to demonstrate a latent TB infection (LTBI). Screening is recommended for TB prior to the onset of anti-TNF-α and monitoring evaluating possible conversion of PPD during treatment, defined as the change from a negative (<5 mm) to positive result (≥5 mm). Identification and treatment of LTBI can reduce the risk of disease development by up to 90%. Currently the results of PPD conversion and its interpretation during anti-TNF-α treatment are variable and that is why we set out to know the frequency of conversion of PPD in this group of patients in our environment.

Objectives: To identify PPD conversion in patients with rheumatological diseases undergoing anti-TNF-α treatment.

Methods: A descriptive, analytical, observational, retrospective study was conducted from January 1, 2018 to January 1, 2022. Inclusion criteria: Patients >18 years old, diagnosed with rheumatological diseases and treated with anti-TNF-α for more than 3 consecutive months, with a negative PPD (<5 mm diameter) previous starting anti-TNF-α and a normal chest X-ray.

Results: 62 patients (age 45.8 ± 12.5 years), with rheumatological diseases (41 rheumatoid arthritis, 7 juvenile idiopathic arthritis, 5 ankylosing spondylitis, 4 psoriatic arthritis, 4 uveitis and 1 interstitial keratitis) under anti-TNF-α therapy (35 adalimumab, 18 certolizumab, 9 etanercept) were included. Concomitant use of immunomodulators (52 methotrexate, 23 leflunomide, 10 hidroxicloroquine, 3 sulfasalazine, 2 azathioprine and 1 mycophenolate mofetil) and glucocorticoids (33/62) was observed. The conversion of PPD took place in 4 patients (6.5%) (Table 1).

Conclusion: Considering the prevalence of TB in our country, this research showed a lower PPD conversion percentage compared to previous reports. Anti-TNF-α have radically changed the evolution of rheumatological diseases, considerably improving patient’s quality of life. With the increase in the accessibility of anti-TNF-α worldwide, new challenges have arisen regarding infectious diseases such as TB, which is endemic in some countries. PPD is a well-known, cheap, sensitive and widely available method, suitable for LTBI diagnosis. Although sensitivity could be increased in using, in addition, other LTBI detection methods such as IGRA (interferon gamma release assays), they are usually unavailable in developing countries (1,3).

AB1359

DO LATERAL AND AP RADIOGRAPHS TELL DIFFERENT STORY IN PATIENTS WITH PSORIATIC ARTHRITIS?

G. Avani1, A. Sadic1, L. Khizç1, U. Kalyoncu1.1Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey;2Hacettepe University Medical Faculty, Department of Internal Medicine, Ankara, Turkey

Background: The conventional radiography score that is frequently used in spondyloarthrits patients is mSSASS. This score was developed for Ankylosing Spondylitis patients and is also frequently used in Psoriatic arthritis (PsA) (1). The mSSASS score takes into account lateral imaging of the lumbar and cervical radiographs. On the other hand, syndesmophytes can be detected on lumbar anterior-posterior (AP) radiographs, which may not be seen on lateral assessment.

Objectives: The aim of this study is to determine whether lumbar AP radiographs have an additional contribution to the evaluation of syndesmophytes in PsA patients.

Methods: Lumbar lateral radiographs and AP radiographs of 274 PsA patients receiving bDMARD therapy were evaluated. A total of 182 lateral lumbar radiographs and 144 AP radiographs were evaluated. On lateral lumbar radiographs each lumbar vertebral unit was evaluated between T12 lower and S1 upper ends. Areas between L1-L5 as AP, right-left, upper and lower vertebral units were evaluated. Syndesmophytes are classified as follows: corner and/or non-marginal syndesmophytes and bridging syndesmophytes. All of the assessments were done by an experienced rheumatologist (UK) and in cases with suspicion, another experienced rheumatologist reviewed the cases (LK) and a consensus was reached.

Results: 182 patients had lumbar radiographs with the mean (SD) age of 44.9 (12.7) years and the mean (SD) PsA duration of 4.8 (6.1) years at the time of the radiographs were taken. The rate of females was 70.3%. When the lateral lumbar radiographs were evaluated, 42/182 (23.1%) patients had at least one syndesmophyte. These 42 patients had a total of 80 syndesmophytes, 41 of which were bridging and 39 were corner syndesmophytes. The distribution of syndesmophytes is shown in the Table 1. The mean number of syndesmophytes in patients with at least one syndesmophyte on the lumbar lateral radiograph is 80/42 (19). In patients with at least one syndesmophyte, 14/42 (33.3%) patients had additional syndesmophytes not seen on lateral radiographs but on AP X-ray. Their distribution is as follows: L1 (4 patients), L2 (3 patients), L3 (2 patients), L4 (6 patients) and L5 (1 patient). In addition, 11 corner syndesmophytes and 5 bridging syndesmophytes were detected in the lumbar AP radiograph. When lumbar and AP radiographs are evaluated together, 44/182 (24.2%) patients have at least one syndesmophyte. When the lumbar lateral and AP radiographs are evaluated together, there are 96 syndesmophytes in 44 patients with syndesmophytes, 46 of which are bridging and 50 are corner syndesmophytes. Average number of syndesmophytes were 96 in 44 patients (2.2 per-patient).

Conclusion: AP radiographs are not taken into account in conventional radiographic scores accepted as mSSASS. PsA patients have syndesmophytes in approximately one-quarter of patients on lateral radiograph, with an average syndesmophyte number of about 2. On the other hand, when AP radiographs are evaluated, new syndesmophytes that are not seen on lateral radiographs are seen in one-third of patients with at least one syndesmophyte. Although it does not cause a significant change in the number of patients with syndesmophytes, it should be kept in mind that the use of AP radiographs in PsA patients may cause an increase in the total score. Whether there is a difference between PsA and SpA patients should be investigated in further studies.

**AB1360** DISTRIBUTION OF INFLAMMATORY/DEGENERATIVE/AMBIGUOUS LESIONS ON CONVENTIONAL LUMBAR LATERAL RADIOGRAPHS IN PSORIATIC ARTHRITIS PATIENTS

G. Ayar,1, A. Sadic,1, L. Kilic,1, U. Kalyoncu,1, 1Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; 2Hacettepe University Medical Faculty, Department of Internal Medicine, Ankara, Turkey

**Background:** Psoriatic arthritis (PsA) patients are relatively older than spondyloarthritic patients, and accordingly, degenerative changes on spine are more frequent and confusing.

**Objectives:** The aim of this study is to determine the distribution, relation of different type of lesions on the lumbar spine in PsA patients receiving bDMARD therapy.

**Methods:** 182/274 (66.4%) patients had lateral lumbar radiographs. Two and three lumbar radiographs were present in 53 (19.3%) 14 (5.1%) patients respectively. The upper and lower regions of each vertebra were evaluated between T12, S1 (total of 2184 regions). Lesions were determined as osteophyte (O) (grade 0-3), vertebral corner erosion, sclerosis, corner sclerosis, bridge osteophyte, and SP. While osteophyte was determined according to the degenerative character of new bone formations, the definition of SP was made according to mSASSS. Lesions that the clear distinction of cannot be made were defined as ambiguous. For patients with follow-up radiographs, the change of lesions defined as ambiguous was also recorded. All of the assessments were done by an experienced rheumatologists (UK) and in cases with suspicion, another experienced rheumatologist reviewed the cases (LK) and a consensus was reached.

**Results:** The mean (SD) age of 182 PsA (69.2% female) patients was 47.6 (12.7), the age at diagnosis of PsA was 39.7 (12.7). Of the patients, 112 (61.5%) met the criteria for mNY. There was at least one abnormality in 111 (61.0%) patients with lumbar spine radiograph. O was the most frequently detected lesions (42.3%), with 18.1% of patients having O grade 2 and above. While SP was present in 24.2% of all patients, ambiguous lesions were detected in 13 (4.7%) patients. While O were most frequently grouped between L2 upper and L4 upper regions, SPs were distributed in a similar ratio between L4 upper and T12 lower regions. Ambiguous lesions were anywhere between T12 sub-L5. Patients with ambiguous lesions were older (55.7 (9.8) vs 47.0 (12.7), p<0.017), lumbar mSASSS score was higher (5.4 (6.1) vs 1 (3.6), p=0.002) corner SPs (46.1% vs. % 177, p=0.013) and bridging SPs (30.7% vs 7.7%, p=0.006) were more common, while no difference was found in terms of O grade 2 (23.1% vs 17.7%, p=0.63). Changes were observed in 5 ambiguous lesions in patients with follow-up radiograph, 4 of them transformed into corner SP at follow-up, and one was evaluated as osteophyte grade 2.

**Conclusion:** Approximately one-fifth of patients presenting with significant degenerative new bone formation and SP was found in one-fourth. In approximately 5% of all patients, lesions in the lumbar vertebrae could not be differentiated. The frequency of SPs in other vertebral areas are more prominent in patients with ambiguous lesions. It is seen that ambiguous lesions turn into SPs in a small group of patients with follow-up data. The nature of these lesions needs to be evaluated in further imaging studies.

**AB1361** PAIN MANAGEMENT IN METASTATIC BONE DISEASE: LOCATION AND NUMBER OF SARCOIDOSIS GRANULOMA, A POSSIBLE DIAGNOSTIC ARGUMENT?

O. Dhrit1, M. S. Hamdi1, I. Kechmaou1, I. Boukhri1, E. Cherni1, S. Azzabi1, L. Ben Hassine1, 1Charles nicolle's Hospital, Internal Medicine, Tunis, Tunisia

**Background:** Sarcoïdosis is a non-necrotizing granulomatous disease which diagnosis is often challenging and requires elimination of other causes of granulomatous lesions. Location and number of granulomatous lesions in patients are not yet established as arguments in diagnosing this disease.

**Objectives:** We therefore conducted a study aiming to compare locations and number of granulomas between patients with sarcoïdosis and patients with other granulomatous diseases (OGD).

**Methods:** Cross sectional study in which were included patients in whom non-necrotizing granulomatous lesions have been identified via biopsy over a period of 11 years (2010 to 2021) then were stratified into two groups: sarcoidosis group and OGD group. Categorical variables were compared with the χ²-test or Fisher’s test. Comparisons of the differences of continuous variables were performed by the Mann–Whitney U test or Student’s t-test. Pearson correlation ratio was used for linear correlation analysis.

**Results:** 30 patients were included in the sarcoidosis group and 32 in the OGD group. Aetiologies in the OGD group were: 10 tuberculosis cases, 5 lymphoma cases, 4 Primary biliary cholangitis cases, 1 Castelmann’s disease and 12 idiopathic granulomas.

**Disclosure of Interests:** None declared

**AB1362** LOCATION AND NUMBER OF SARCOIDOSIS GRANULOMA, A POSSIBLE DIAGNOSTIC ARGUMENT?

O. Dhrit1, M. S. Hamdi1, I. Kechmaou1, I. Boukhri1, E. Cherni1, S. Azzabi1, L. Ben Hassine1, 1Charles nicolle's Hospital, Internal Medicine, Tunis, Tunisia

**Background:** Sarcoïdosis is a non-necrotizing granulomatous disease which diagnosis is often challenging and requires elimination of other causes of granulomatous lesions. Location and number of granulomatous lesions in patients are not yet established as arguments in diagnosing this disease.

**Objectives:** We therefore conducted a study aiming to compare locations and number of granulomas between patients with sarcoïdosis and patients with other granulomatous diseases (OGD).

**Methods:** Cross sectional study in which were included patients in whom non-necrotizing granulomatous lesions have been identified via biopsy over a period of 11 years (2010 to 2021) then were stratified into two groups: sarcoidosis group and OGD group. Categorical variables were compared with the χ²-test or Fisher’s test. Comparisons of the differences of continuous variables were performed by the Mann–Whitney U test or Student’s t-test. Pearson correlation ratio was used for linear correlation analysis.

**Results:** 30 patients were included in the sarcoidosis group and 32 in the OGD group. Aetiologies in the OGD group were: 10 tuberculosis cases, 5 lymphoma cases, 4 Primary biliary cholangitis cases, 1 Castelmann’s disease and 12 idiopathic granulomas.
Mean age was respectively in both groups 51±13 versus 57±17 years old (p=0.128), sex ratio (F/M) was 29/1 versus 27/5 (p=0.197). Associated signs were distributed in both groups as followed: 11(37%) versus 5(16%) general signs (p=0.085), 15(50%) versus 20(63%) lymphadenopathy (p=0.442), 4(13%) versus 8(19%) inflammatory arthralgias (p=0.733), 13(43%) versus 2(6%) cutaneous lesions (p=0.001), 4 versus no ocular manifestations (p=0.049), 20 (66%) versus 3(9%) pulmonary manifestations (p<0.001), 5 (17%) versus 10 (31%) abdomin- al manifestations (p=0.239). Cutaneous, salivary gland and ENT granulomas were significantly more frequent in patients with sarcoidosis with respectively 11(37%) versus 1 (3%) (12.3 risk ratio 95%CI 10.4 to 14.1) (p=0.001), 8 (27%) versus 0% (p=0.002), 8(27%) versus 2(6%) (4.5 risk ratio 95% CI 3.1 to 5.9) (p=0.025). Lymph node, hepatic and pulmonary granulomas prevalence was not significantly higher in sarcoidosis patients, 17 (57%) versus 24 (75%) (p=0.180), 2 (7%) versus 5 (16%) (p=0.427), 3(10%) versus 0% (p=0.308). Mean number of granulomas found in one patient was significantly higher in sarcoidosis patients with 1.7 (95% CI 1.5 to 2) versus 1.1 (95%CI 1 to 1.2) (p=0.001). There was also a significant correlation between the number of granulomas in one patient and the angiotensin converting enzyme titre (r=0.56, 95% CI 0.360 to 0.771); (p=0.004).

Conclusion: This study shows that sarcoidosis patients have more often granu- lomas in the skin, salivary gland and ENT regions, and that the number of granu- lomas is on average superior in sarcoidosis than in OGD, these findings could be considered when establishing future diagnostic algorithms, as taking into account these elements could ease this diagnostic challenge in clinical practice.

AB1363 IMAGE PATTERN ANALYSIS IN FLUORESCENCE OPTICAL IMAGING FOR DIFFERENTIAL DIAGNOSIS IN RHEUMATIC JOINT DISEASES

N. Stumper1, J. Berger2, G. Schmitt1, A. Briel1, D. Vogler1, G. R. Burmester1, P. Hoff1, S. Ohrndorf1. 1Charité – Universitätsmedizin Berlin, Germany; 2Department of Rheumatology and Clinical Immunology, Berlin, Germany; 3Xiralite GmbH, Berlin, Germany; 4InnoPET Pharma GmbH, R&D, Berlin, Germany

Background: As outlined in previous studies, different rheumatic joint diseases present specific characteristic patterns and features in fluorescence optical imaging (FOI) (1-4).

Objectives: We tested different features in FOI for their ability to differentiate various rheumatic joint diseases such as rheumatoid arthritis (RA), osteoarthritis (OA) and psoriatic arthritis (PsA) with the aim to identify clear FOI criteria for the diseases.

Methods: FOI images from patients with RA, OA, PsA and healthy volunteers were evaluated by two readers blinded for diagnosis and calibrated against each other, using the prima vista mode (PVM) and the 5-phase model. For the latter, the overall time course of FOI in each hand was divided into 5 phases with a computational algorithm. Phases 1 and 2 describe the inflex (start to 15% and 15%-90% on rising edge), phase 3 is the peak phase and phases 4 and 5 comprise the outflow (90%-95.9% and 95.9%-97.5% to falling edge). Twenty-six different features were defined by an atlas, for example the streaky pattern feature (T) as a signal enhancement around the PIP area that appears streaky, whereby the stripes are orthogonal to the finger axis (Figure 1a). The cloudy pattern (W) is visible during the inflex on the back of the hand (Figure 1b). The enthesis feature (E) depicts a V shaped and filled pattern between nail and DIP (Figure 1c). The feature frequency in each patient and phase (PVM, 5-phase) was counted and statistically analysed.

Figure 1. Examples for FOI patterns and features: a) (T) Streaky pattern in PVM image (OA); b) (W) Cloudy pattern on the back of the hand in phase 1 (PsA); c) (E) Enthesis pattern in phase 3.

Results: In total, 128 patients (RA age mean 54±2; SD 10.6; median 52.4), OA (58.0; 14.3; 60.1), and PsA (47.9; 12.7; 46.8) and healthy volunteers (32 in each group) were included in the feature reading. In our analysis, OA could be differentiated from RA on the basis of the feature T. Feature T is found in phase 3 (χ2: 4.61; diagnostisch odds ratio (DOR): 7.49; sensitivity (TPR) 0.11; specificity (TNR) 0.98; positive predictive value (PPV): 0.87; negative predictive value (NPV): 0.52), phase 5 (χ2: 18.5; DOR: 5.60; TPR 0.55; TNR: 0.82; PPV: 0.76; NPV: 0.64 and PVM (28.3; 12.1; 52%); 92% 87%; 65%). By means of the feature E, a distinction between RA and PsA is only limited possible (χ2: 9.58; DOR: 3.65; TPR 0.40; TNR: 0.84; PPV: 0.71; NPV: 0.56). But PsA can well be distinguished from RA by the appearance of pat- terns in phase 1 (χ2: 7.68; DOR 0.92; TPR 0.19; TNR: 0.97; PPV: 0.86; NPV: 0.54).

Other significant features yield high specificity (70%-98%) while having low sen- sitivity (12%-52%).

Conclusion: This work demonstrates that FOI feature analysis has the potential for differential diagnosis with FOI, which could optimize the (early) diagnostic process of rheumatic joint diseases. A majority of features yield high specificity, but only low sensitivity. The combination of different features using artificial intel- ligence might lead to improved diagnostic accuracy.

AB1364 IMAGING DIAGNOSIS OF BRUCELLAR SPONDYLODYSCITIS

S. Rekik1, S. Bousaid2, H. Tpini1, S. Jemmal1, S. Rahmouni1, K. Zouaoui1, H. Sahli1, M. Elleuch1, 1Tunis, Department of Rheumatology, La Rabta hospital, Tunis, Tunisia

Background: Spondyloarthritis is the most common location in the musculoskel- etal involvement of brucellosis.

Objectives: The aim of this study is to describe magnetic resonance imaging (MRI) and computed tomography scan (CT) results in patients with brucellar spondyloarthritis.

Methods: A retrospective study over a period of 15 years, including 18 patients diagnosed with brucellar spondyloarthritis and having benefited from a CT scan and/or an MRI of the spine.

Results: Eighteen patients were included. In all cases spinal pain was reported, associated with radiculalgia in 8 patients. Low back pain was the most common symptom, present in 17 cases, associated with back pain in 3 cases including one case with neck pain. Isolated neck pain was noted in one patient. Neurologic examination was normal in all cases. Standard Radiographs showed disc nar- rowing in 14 cases, erosions in 9 cases and hazy changes of the vertebral end plate in 2 cases. A CT scan was performed in 11 cases. It showed disc narrowing in 6 cases, erosions in 3 cases and endplate destructions in 5 cases. Abscesses were found in 4 patients. Complementary MRI was performed in three of the patients who had already undergone CT. The MRI results were consistent with those of the CT scan, except for one patient in whom it revealed spondylodis- ctitis while the CT scan revealed degenerative lesions. Eleven patients under- went MRI in total. It showed unilocular and multifocal spondylodiscitides in 5 and 6 cases respectively, epiduritis in 6 cases, spinal cord compression in 2 cases and abscesses in 4 cases.

Conclusion: Our study showed that CT and spinal MRI allow early diagnosis of spondyloarthritis. They help to identify asymptomatic lesions and neurological complications.

AB1365 PROPOSAL FOR A STANDARDIZED ULTRASOUND SCANNING PROTOCOL OF THE NAIL PLATE.

D. Rotta1, G. Adami1, F. Bellinoto1, A. Fassio1, L. Idolazzi1, P. Gisondi2, F. Tozzi2, E. Filippucci1, M. Rossini3; 1Rheumatology Unit, Medicine, University of Verona, VERONA, Italy; 2Clinical Dermatology Unit, Medicine, University of Verona, VERONA, Italy; 3Clinica Reumatologica, Università Politecnica delle Marche, JESI, Italy

Background: Ultrasonography of the nails with high frequency linear transduc- ers can properly perform morphological images, achieving highly descriptive power but the lack of standardization may hesitate in lack of reproducibility and scarce usefulness.
**Objectives:** The aim of this study was to provide a detailed scan protocol of nail plate, including comparison of scan planes and probe positioning.

**Methods:** Transversal and longitudinal ultrasound scans were performed on each fingernail of both hands in healthy subjects. Nail plate thickness and Power Doppler of the nail bed were recorded. All the images were acquired using Canon Aploic i800 with a linear transducer of 22 MHz (G22LHB). Two different operators performed evaluation of thickness at distal, middle and proximal portion of nail in longitudinal view and at 0°, -45° and +45° for transverse view (Figure 1). ANOVA for repeated measures was used to determine differences between nail of the different digits.

**Results:** The study sample was composed of 27 healthy subjects between 25- and 40- year old with no rheumatological or dermatological nail issues. A total of 270 nails were scanned; none of them was excluded due to comorbidities, trauma or other conditions which can interfere in the evaluation. A decrease in nail thickness was observed from first to fifth digit, regardless the hand (dominant or not), that resulted significant for the ANOVA. No differences were found regarding the thickness in the different segments of nail plate and this occurred both for longitudinal and transversal scans.

**Conclusion:** We demonstrated the absence of a statistically significant difference between thickness at proximal, middle and distal portion of the nail in longitudinal view or at any different angle in transverse view, concluding the fastest and easiest way to measure the nail plate thickness is in the longitudinal view at the middle segment, avoiding potential issues in positioning the probe in the transverse view or in positioning the caliper at proximal or distal segment in longitudinal view. All the nails should be scanned per protocol, since the thickness is variable and the fifth may be the most interesting in order to consider its highest variance.

**REFERENCES:**

**Table 1. ANOVA for repeated measures of the nail plate thickness.** A trend in decreasing P value is clearly visible from first to fifth. P considered statistically significant when ≤ 0.05

Background: Positron emission tomography (PET) is one of the tools available for the diagnosis of extracranial large-vessel vasculitis (1-5). Tocilizumab (TCZ) has shown efficacy in large-vessel vasculitides (LVV) including GCA. However, the improvement objectified by imaging techniques after TCZ therapy in extracranial GCA patients is controversial.

Objectives: To assess the effectiveness of TCZ improving the wall vessel inflammation by PET in GCA patients with large-vessel involvement.

Methods: Observational, multicenter study of 101 GCA patients treated with TCZ. GCA was diagnosed according to: a) ACR criteria, and/or b) biopsy of temporal artery, and/or c) presence of signs of vessel wall inflammation by PET, defined by the presence of vascular wall uptake of Fluorodeoxyglucose (FDG). Patients were divided into two subgroups: a) with, and b) without signs of improvement (partial or total) in the follow-up PET.

Results: We studied 101 patients (74 women/27 men; mean age 69.7±9.3 years). Main clinical features of GCA with and without PET improvement are shown in Table 1. The group of patients which experienced PET improvement was older and was receiving higher doses of corticosteroids at TCZ onset.

Table 1. Main features of 101 GCA patients treated with tocilizumab and with presence of signs of vessel wall inflammation by PET.

Conclusion: TCZ seems to be effective controlling GCA including vascular involvement detected by PET. However, the improvement observed by PET is most often partial, and rarely complete.

Figure 1. Improvement by PET according to the time of the test.

REFERENCES:
Background: Involvement of lower extremity joints in both rheumatoid arthritis (RA) and osteoarthritis (OA) is an important cause of declined functional status. Deterioration of skeletal muscle performance further contributes to disability. Quadriiceps muscle plays an important role in most daily activities. Measuring thickness and pennation angle of quadriiceps compartments can provide knowledge regarding quadriceps condition.

Objectives: Aim is to investigate structural and inflammatory changes in knee joint and architecture of quadriiceps muscle in RA, knee OA patients and a group of healthy subjects.

Methods: Twenty RA patients and 20 knee OA patients with radiographic disease meeting Kellgren-Lawrence grade 2 and above were consecutively recruited, in absence of exclusion criteria, 20 healthy volunteers with similar demographics were recruited as control group. Knee symptoms and disability were evaluated by Lequesne Knee Index (LKI). Disease activity was evaluated by DAS28-CRP in RA patients. Quadriiceps muscle was evaluated by ultrasonographic measurements of muscle thickness, subcutaneous fat tissue thickness and pennation angle of vastus muscles. Suprapatellar, lateral and medial compartments of knee joint were examined for effusion, synovial hypertrophy, power Doppler (PD) activity and degenerative changes.

Results: Demographic features of subjects and results of ultrasonographic evaluation are presented in Table 1. LKI scores were significantly higher in OA patients when compared to RA patients (p=0.003). Rate of degenerative changes was increased in RA and OA groups in comparison to controls (p=0.013). None of the subjects had PD activity. No differences were observed in thickness of rectus femoris, vastus muscles and subcutaneous fat between groups. Vastus medialis and intermedius pen- nanation angles were reduced in OA and RA groups when compared to controls, but reached statistical significance only in vastus intermedius (3.56 ± 0.67 vs 4.89 ± 1.74 vs 7.29 ± 4.93, p=0.038).

Conclusion: In our study ultrasonographic evaluation findings of knee joint and quadriiceps muscle were similar between knee OA and RA patients. VM and VI penetration were reduced when compared to healthy subjects in both groups. These findings may indicate a similar degree of functional impairment in OA and RA due to knee joint involvement.

ULTRASONOGRAPHIC EVALUATION OF THE KNEE AND MUSCLE ARCHITECTURE IN OSTEOA RTHRITIS AND RHEUMATOID ARTHRITIS

S. C. Güven1, S. Metin Taran1, F. N. Göğüş2, 3, Ankara City Hospital, Rheumatology, Ankara, Turkey; 2Karabük Training and Research Hospital, Physical and Rehabilitation Medicine, Karabük, Turkey; 3Gazi University Medical School, Physical and Rehabilitation Medicine, Division of Rheumatology, Ankara, Turkey

Background: Involvement of lower extremity joints in both rheumatoid arthritis (RA) and osteoarthritis (OA) is an important cause of declined functional status. Deterioration of skeletal muscle performance further contributes to disability. Quadriceps muscle plays an important role in most daily activities. Measuring thickness and pennation angle of quadriceps compartments can provide knowledge regarding quadriceps condition.

Objectives: Aim is to investigate structural and inflammatory changes in knee joint and architecture of quadriceps muscle in RA, knee OA patients and a group of healthy subjects.

Methods: Twenty RA patients and 20 knee OA patients with radiographic disease meeting Kellgren-Lawrence grade 2 and above were consecutively recruited, in absence of exclusion criteria, 20 healthy volunteers with similar demographics were recruited as control group. Knee symptoms and disability were evaluated by Lequesne Knee Index (LKI). Disease activity was evaluated by DAS28-CRP in RA patients. Quadriceps muscle was evaluated by ultrasonographic measurements of muscle thickness, subcutaneous fat tissue thickness and pen- nanation angle of vastus muscles. Suprapatellar, lateral and medial compartments of knee joint were examined for effusion, synovial hypertrophy, power Doppler (PD) activity and degenerative changes.

Results: Demographic features of subjects and results of ultrasonographic evaluation are presented in Table 1. LKI scores were significantly higher in OA patients when compared to RA patients (p=0.003). Rate of degenerative changes was increased in RA and OA groups in comparison to controls (p=0.013). None of the subjects had PD activity. No differences were observed in thickness of rectus femoris, vastus muscles and subcutaneous fat between groups. Vastus medialis and intermedius pen- nanation angles were reduced in OA and RA groups when compared to controls, but reached statistical significance only in vastus intermedius (3.56 ± 0.67 vs 4.89 ± 1.74 vs 7.29 ± 4.93, p=0.038).
AB1370

MICROVASCULAR CAPILLAROSCOPIC ANOMALITIES AND AUTOANTIBODY OCCURRENCE IN SARCOIDOSIS PATIENTS.

F. Cattelan1, E. Hya1, C. Pizzorni1, M. Grosso2, E. Barisione2, S. Paolino1, G. Pacini1, G. Ferrari1, A. Sulli1, V. Smith3, M. Cutolo1.

1Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Italy; 2Pneumology Unit, IRCCS San Martino Polyclinic, Genova, Italy; 3Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Corneel Heymanslaan 10, 9000 Ghent, Belgium.

Background: Sarcoidosis (S) is a granulomatous disease with multi-organ involvement displaying a mixed immune-mediated pathophysiology. Raynaud’s phenomenon (RP) has been occasionally reported in S patients [1] and serum positivity for autoantibodies has been detected in S patients but their significance is debated [2].

Objectives: We described nailfold videocapillaroscopy (NVC) findings and estimated the prevalence of serum anti-nuclear (ANA) and extractable nuclear antigen autoantibodies (ENA-Abs) in S patients, comparing them with age- and sex-matched healthy controls (HCs) and patients with primary Raynaud’s phenomenon (PRP). Secondly, we analysed potential correlations between NVC findings with the occurrence of autoantibodies, immunomodulatory treatment, laboratory parameters, variables of pulmonary function and whole-body imaging.

Methods: Twenty-seven (27) S patients, classified according to WASOG criteria[3], were assessed through NVC examination, laboratory parameters (including serum concentrations of angiotensin-converting enzyme [ACE], C-reactive protein [CRP], calcium, phosphorus, albumin, 25-hydroxyvitamin D, parathormone, ANA and ENA), pulmonary function tests (PFTs), chest-X ray and positron emission tomography/computed tomography (PET/CT). Among NVC parameters, we analysed capillary dilations, giant capillaries, haemorrhages, nonspecific abnormalities, and capillary absolute number for mm [4]. Pulmonary involvement was classified by X-ray Scadding staging system (SSS) scoring S patients in 4 grades [5]. From PET data, the maximum standard uptake value (SUVmax) was quantified as a variable of tissue 18-fluorodeoxyglucose hyper-uptake: consequently, S patients were defined PET-positive when SUV value ≥ 2.5. NVC parameters and ANA/ENA dosage were recorded also in 30 PRPs and 30 HCs.

Results: We excluded, among the cohort of S patient, one participant having a systemic sclerosis in overlap with S. The remaining 26 S patients (mean age 56.5 ± 12.5 years, 53.8 % of females, disease duration 28.4 ± 55.1 months, 27% glucocorticoid-naïve) showed a significant higher rate of dilations and nonspecific abnormalities and a lower mean capillary absolute number than PRPs and HCs (p < 0.01 for all comparisons). (Figure 1) The prevalence of ANA positivity was significantly higher in S patients compared with PRPs and HCs (p < 0.02 for both). Among the whole cohort of patients only one S patient displayed a positive ENA-Ab (Ro52). In the analysis of S patients’ subgroup, a significant negative correlation was detected between serum ACE levels with the presence of capillary dilations (rho = -0.45, p = 0.04), between CRP and mean capillary absolute number (rho = -0.49, p = 0.02) and a positive correlation was also detected between serum ACE levels with the presence of capillary dilations and haemorrhages (rho = 0.40, p = 0.04).

Conclusion: Our findings suggest a microvascular involvement in sarcoidosis, whose investigation by NVC could be useful for the detection of an overlapping connective tissue disease and for the monitoring of the phenotypes of S patients displaying RP. The positivity for autoantibodies in S patients is in line with literature data suggesting, at least partially, autoimmune features of the disease or the production of autoantibodies reactive to tissue damage. The correlations between NVC findings with ACE levels and lung function variables generate hypotheses of a potential partial vascular impairment in sarcoidosis disease activity and lung involvement.

USE OF ULTRASOUND TO DIAGNOSE INTERSTITIAL LUNG DISEASE IN RHEUMATIC DISEASES ON RUSSIAN COHORTS OF PATIENTS.

O. Ovsyannikova1, O. Konve1, L. Garzanova1, L. P. Ananyeva1, A. Khelikovskaya-Sergeeva1, R. Shayakhmetova1, O. Desinova1, M. Starovoytova1. 1V.A. Nasonova Research Institute of Rheumatology, Systemic sclerosis, Moscow, Russian Federation

Background: Intersitial lung disease (ILD) is one of the most relevant extra-articular manifestations of rheumatic diseases resulting in a substantial increase in morbidity and mortality. High-resolution computed tomography (HRCT), which is the current gold standard for diagnosis and evolutionary control, is problematic owing to ionizing radiation, cost, and accessibility. In the last decade, the use of lung ultrasound (LUS) in clinical medicine has increased. LUS is an accurate tool for the diagnosis of pneumonia, pneumothorax, acute pulmonary edema, and pleural effusion. LUS may also be useful in detection of ILD by the evaluation of B-lines, the sonographic hallmark of the interstitial syndrome.

Objectives: To compare semi-quantitative scores of B lines in patients with rheumatic disease with different intensity of lung fibrosis.

Methods: 50 pts with ILD of rheumatic disease such as: vasculitis n=11 (mean age 40.7± 9.1, fem 5); dermatomyositis (DM), anti-synthetase syndrome (ASS), polymyositis (PM) n=20, (mean age 48.7± 11.9, fem 13); rheumatoid arthritis (RA) n=9 (mean age 56.5± 8.3, fem 7); Sjogren’s syndrome (SS) n=9 (mean age 59.6± 12.3, fem 8). To determine the intensity of fibrosis of ILD we used a limited/extensive classification for disease extent, integrating HRCT observation. According this scheme pts were divided into 2 groups: group 1 included 33 pts had “limited” lung disease (lung lesions less than 20%) and the group 2 included 17 pts had “extensive” lung disease (lung lesions greater than 20%). LUS examination protocol that include the anterior, lateral, and/or posterior thorax have been suggested The B-lines score denoting the extension of ILD was calculated by summing the number of B-lines on a total of 58 scanning sites. In each patient ULC score was obtained by summing the number of comets detected as previously recommended. The data were collected in protocols for statistical testing. Other data collected including biological results (high-sensitivity C-reactive protein (hsCRP) and erythrocyte sedimentation rate (ESR)).

Results: the mean score of B-lines in each groups were: vasculitis (n=11) 21,4 ±12.6; (DM, PM, ASS) (n=20) 41.3±20.8; RA (n=9) 56.5±6.3; SS (n=9) 59 ± 11.8. The mean score of B-lines in groups pts with different intensity of fibrosis are presented in Table 1.

The correlations in Table 1 may confirm the connection of B-lines score and extensity of ILD association with rheumatic disease. The mean score of ULCs determined in all 50 pts didn’t correlate with dates of ESR (R = 0.188, p>0.05) and hsCRP (R=-0.07, p<0.05).

Conclusion: In Russian cohorts presence of LUS score is associates with more severe ILD. Echographic examination of the lung allows evaluating the severity of lung fibrosis and can be used as an additional simple and available method to assess the ILD of rheumatic disease, but we couldn’t find correlation with hsCRP and ESR.

Disclosure of Interests: None declared
Background: Pulmonary disease is one of the most relevant with interstitial lung disease (ILD) being one of the most frequent forms of involvement with result-
ant worsening of morbidity and mortality in disorders such as systemic sclerosis (SSc), rheumatoid arthritis (RA), or inflammatory myopathies. High-resolution com-
tomed computed tomography (HRCT), which is the current gold standard for diagnosis and evolu-
tional control, is problematic owing to ionizing radiation, cost, and accessibility. In this context, lung ultrasound (LUS) is an attractive tool in a grow-
ing research and validation process.

Objectives: to assess specificity and sensitivity of LUS in rheumatic diseases on Russian cohorts of patients.

Methods: 110 pts with ILD of rheumatic disease such as: systemic sclerosis (n=80) (mean age 49.8±13.3, fem 57); vasculitis n=11 (mean age 40.7±9.1, fem 5); dermatomyositis (DM), anti-synthetase syndrome (ASS), polymyositis (PM) n=20, (mean age 48.7±11.9, fem 13); rheumatoid arthritis (RA) n=9 (mean age 56.5±6.3, fem 7); Sjogren’s syndrome (SSj) n=9 (mean age 59.6±12.3, fem 8). Chest HRCT were evaluated. Control group (n=30) without rheumatic diseases and ILD (mean age 51.4±15.4, fem 24); (chest X-ray (CXR) were evaluated). LUS examination protocol that include the anterior, lateral, and/or posterior tho-
rax have been suggested. The B-lines score denoting the extension of ILD was calculated by summing the number of B-lines on a total of 58 scanning sites. In each patient ultrasound comets (ULC) score was obtained by summing the num-er of comets detected as previously recommended. The data were collected in protocols for statistical testing. The diagnostic accuracy LUS is expressed as sensitivity, specificity. ROC (receiver operating characteristic) curves and AUCs (areas under curve) were used of analyze the accuracy of B-lines in recognizing the presence of ILD on HRCT.

Results: the analysis included all the 110 patients enrolled in the study. ROC curve analysis the ULC score of anterior chest area was (AUC =0.876; 95% CI 0.82-0.96; p<0.0001); ROC curve analysis the ULC score of posterior chest area was (AUC =0.908; 95% CI 0.85-0.958; p<0.0001); ROC curve analysis for the total ULC score was (AUC =0.932; 95% CI 0.892-0.972; p<0.0001). Accuracy of echographic signs (B-line) in the different chest areas in the detec-
tion of interstitial lung disease (Table 1).

Table 1.

<table>

</table>

Using the TBSL to identify a positive LUS examination, sensitivity and specificity were different depending on the area investigation. The best results were in the posterior area and all chest areas.

Conclusion: our research documented the high diagnostic accuracy of LUS in the detection of ILD. Our findings support the use of LUS a sensitive tool for ILD detec-
tion, especially considering that it’s an inexpensive and nonionizing technique.

DOI: 10.1136/annrheumdis-2022-eular.4464
Conclusion: The study highlighted that also clinical asymptomatic patients have ILD in IBD at the onset of the IBD. Frequently, a reduced DLCO is detectable in PFT as a sign of early lung involvement, so this represents a potential screening parameter. Moreover, asymptomatic patients are often younger than symptomatic patients. No significant difference was found in CT pattern, but further research is needed as the number of patients is quite small.

AB1375
PERFORMANCE OF ULTRASOUND EXAMINATION OF INSERTIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES.

G. Gaujnulla1, E. Kirillova1, A. Odincova1, D. Abdulginanueva1, K. Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation; 2Republican Clinical Hospital of the Ministry of Health of the Republic of Tatarstan, Gastroenterology, Kazan, Russian Federation

Background: Enthesitis is one of extraintestinal manifestation of inflammatory bowel diseases (IBD). US examination appears to be a useful imaging technique, specifically in identifying enthesis involvement in patients with inflammatory bowel diseases [1].

Objectives: The aim of the study was to perform the individual anatomical site analysis for the evaluation of enthesopathies in patients with inflammatory bowel diseases (IBD).

Methods: A total of 95 patients with IBD were prospectively enrolled, 55 with ulcerative colitis (UC) and 40 with Crohn’s disease (CD). All patients underwent ultrasound in B-mode and PD-mode, to assess the presence of enthesitis. Thirty four different anatomical sites (insertions of short head of the biceps brachii, coracohumeral ligament (2 sites), infraspinatus, supraspinatus, infraspinatus, triceps brachii, flexor carpi ulnaris, flexor carpi radialis, extensor carpi ulnaris, extensor carpi radialis (2), glutaeus minimum, glutaeus medium, spina iliaca anterior superior/inferior, ischiadicus tuberositas, medial collateral ligament of knee (2 sites), lateral collateral ligament of knee (2 sites), patellar ligament (2 sites), pes anserinus, biceps femoris, semimembranous, quadriceps femoris, tibialis anterior, tibialis posterior, peroneus brevis, achille, plantar fascia, medial epicondyle, lateral epicondyle) were evaluated bilaterally with total count 640. If typical ultrasound features, such as enthesal hypochoegenicity, enthesal thickening, presence of vascularization, were present, acute lesions was diagnosed. Bone erosions and enthesophytes were considered as chronic lesions. Fisher’s exact test was used to calculate differences.

Results: The number of positive enthesitis sites was 293/6440 (4.5%), 177 positive sites in patients with UC versus 116 in patients CD (4.7% vs 4.2%). Most often involved sites were pes anserinus and proximal insertion of medial collateral ligament of knee (Figure 1). The number of positive vascularized enthesitis sites was 62/6440 (1.0%), 40 in patients with UC versus 22 in patients with CD (1.0% vs 0.8%). Proximal insertion of medial collateral ligament of knee was involved more often then other sites. At least one positive enthesitis was detected in 72 (76%) patients, 42 (76%) patients with UC versus 30 (75%) patients with CD. Vascularized enthesitis were detected in 35 (37%) patients, 21 (38%) patients with UC versus 14 (35%) patients with CD. There are not statistically significant differences between UC and CD. Signs of chronic lesion were often detected. The number of sites with erosions was 313/6440 (4.8%), 178 (4.8%) in patients with UC versus 135 (5.0%) in patients CD. Enthesophytes of insertion were detected in 91/6440 (1.4%) sites, 41 (1.1%) in patients with UC versus 40 (1.5%) in patients CD. Most often erosion was detected in insertion of medial collateral ligament of knee (both sites) and enthesophytes was found in insertion of quadriceps femoris. There are not statistically significant differences between UC and CD.

Conclusion: Enthesis abnormalities are often features detected by ultrasound in patients with IBD. Most often involved site is medial collateral ligament of knee. There are not significant differences between UC and CD patients.

RELATIONSHIP BETWEEN INTRANEURAL HYPERVASCULARIZATION OF THE MEDIAN NERVE IN POWER DOPPLER AND ELECTROMYOGRAPHIC SEVERITY STAGES IN THE DIAGNOSIS OF SEVERITY OF CARPAL TUNNEL SYNDROME (PRELIMINARY RESULTS)

H. Fouzia1, T. Fatima Zahrera1, K. Berrada1, N. Takhrira1, I. Berrichi1, F. E. Aboorazzak1, 1CHU Tangier-Tetouan-Et-Hoceima, Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Tangier, Morocco, Department of Rheumatology, Tangier, Morocco

Background: Carpal tunnel syndrome (CTS) is the most common tunnel syndrome in the upper limbs. Ultrasound has been increasingly used in recent years in the diagnosis of positive and severe CTS. Although the diagnosis of severity is essentially based on the ENMG, several studies have shown that ultrasound data can also constitute criteria for the severity of CTS.

Objectives: The objective of our study is to evaluate the relationship between intraneural hypervascularization of the median nerve in power Doppler and the severity of CTS measured by ENMG.

Methods: This is a descriptive cross-sectional study of patients with clinically retained CTS. We excluded from the study operated patients and patients who received cortisone infiltration in the previous six months. All patients underwent ultrasound examination (B mode and Doppler mode) and electromyography one week apart. The severity stages of CTS have been defined according to the classification of Stevens (1997). The study is still ongoing.

Results: To date we have included 14 patients with typical signs of CTS. 25 wrists were examined sonographically and by ENMG. The mean age of the patients was 54± 10 years. Bilateral SCC was present in 11 patients. Of the 25 affected wrists: 10, 7 and 8 were classified by the ENMG as mild, moderate and severe SCC respectively. On ultrasound, positive Doppler was found in 5 wrists (20% of wrists studied): Doppler was present in 10% of wrists with mild-stage SCC, 14.3% of wrists with moderate-stage SCC and 37.5% of wrists with severe SCC. But this difference was not statistically significant (p=0.31) probably related to the small size of our current sample (study still ongoing).

Conclusion: The preliminary results of our study suggest that intraneural hypervascularization of the median nerve in power Doppler could provide additional information on the severity of carpal tunnel syndrome. Results to be confirmed by the final results.

FULLY AUTOMATIC ASSESSMENT OF NAIL FOLD CAPILLAROSCOPY SOFTWARE – PILOT STUDY

O. Brzegińska1, K. Rychlicki-Kicior2, J. Makowska3. 1Medical University of Lodz, Department of Rheumatology, Łódź, Poland; 2University of Economics and Human Sciences in Warsaw, Computer Science, Warsaw, Poland; 3Medical University of Lodz, Department of Rheumatology, Łódź, Poland

Background: The nail fold capillaroscopy is one of the basic techniques used in diagnosis and monitoring the course of connective tissue diseases, primarily a systemic sclerosis. However, the assessment of the capillary image is time-consuming and subjective, this makes it difficult for a detailed comparison of studies assessed by various physicians.

Objectives: The aim of this study was to validate an automated software for classification the nail fold capillaroscopy as normal or pathological and counting the numerous of vessels on a millimetre.

Methods: 100 correct and 100 pathological images were selected from the database. The classic, manual evaluation of the capillaroscopy was performed twice. The imagines was classified as correct or pathological and mean number of capillaries per millimetre was calculated. The photos were then exported to the training program created for the study, the region of interest (ROI) and individual capillaries were marked. The
calculation of the number of vessels was made at a magnification of about 50x (ensuring the maximum quality of the image obtained during a classic examination). The neural network was trained using the fast.ai library (based on PyTorch). The ResNet-34 deep residual neural network was chosen, 10-fold cross-validation with validation and test set was performed, using Darknet-YoloV3 state of the art neural network in a GPU-optimized (PS1000 GPU) environment. For calculation of 1mm capillaries, additional detection mechanism was designed, in order to automatically detect the scale of the image and transform it into proper pixel dimensions.

Results: The results obtained under neural network training have been referred to the results obtained as part of a manual photo assessment. For the image classification correct vs pathological testing sensitivity 89.0% and specificity 86.9% was obtained. For validation (20% of images have been drawn as a validating group), 89.0% and 89.4% respectively were noticed. For the average number of capillaries in 1mm, an average of three regions have been estimated (the first region with 1mm from the left, the second with 1mm from the right and the third with 1mm in the middle). The estimated number of capillaries in each region has been compared with ground truth data. The RMSE (Root Mean Squared Error) for the test set was 2.81 and the accuracy was 76.2%.

Conclusion: The use of fully automatic Nail Fold Capillaroscopy Software can be a fast and easy method of the correct and changed capillaroscopy pattern classification, the possibility of counting gives a repetitive result regardless of the physician evaluating the capillaroscopy pattern. In the further course of work on the software, it will be possible to distinguish megacapillary, branched vessels, avascularisation and other pathological features, which will allow full automatic image evaluation and easy follow-up of patients.

AB1378
RELATION BETWEEN SHARP SCORE AND RADILOGICAL PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE OBSERVATION
O. Alekseeva1, D. Kudinsky1, A. Smirnov1, A. Volkov1, E. Nasonov2, V.A. Nasonova Research Institute of Rheumatology, Diagnostic Department, Moscow, Russian Federation; 2V. A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology, Rheumatic Diseases, Moscow, Russian Federation; 3A. Nasonova Research Institute of Rheumatology, Chief Researcher, Moscow, Russian Federation

Objectives: to analyse rheumatoid arthritis (RA)-patients depending on their individual peak radiographic progression.

Methods: 61 RA pts, mean age 50,0 [38,0; 59,0] yrs, mean disease duration 7 [4; 20] months were treated with MTX and biologics according to the Treat-To-Target concept. After first year of therapy management was following real clinical practice rules until the termination of the study (7 years FUP, median 7.7 [7;4;8,6]). The following correlations were identified of total Sharp score 0-7 years FUP with erosion score in all observation periods 4-7 years, 0-7 years (r=0,54 p=0,000, r=0,49 p=0,000, r=0,84 p=0,000, respectively).

Results: RA progression by 1 years FUP was identified in 10% (6 p) of pts, 4 years FUP was identified in 36% (22 p) of pts, by 7 years FUP was identified in 69% (42 p) of pts. All pts divided into groups based increase in erosions according to radiography (RG+) and without it (RG-). In the group RG+ GS at baseline was significantly higher than in RG- group (6 [5; 10] and 5 [1; 8], respectively, p=0.04). We analyzed relation between SHS (erosion score and total Sharp score) 7 years FUP, individual peak radiographic progression and A erosion score and total Sharp score in the observation periods: 0-1 years, 1-4 years, 4-7 years and 0-7 years. The following correlations were identified of erosion score 7 years FUP with total Sharp score 7 years FUP with Total Sharp score in the observation periods 4-7 years, 0-7 years (r=0,43 p=0,00, r=0,34 p=0,007, respectively) and with individual peak radiographic progression in the observation periods 4-7 years, 0-7 years (r=0,43 p=0,00, r=0,34 p=0,007, respectively).

Conclusion: These data show that the radiological progression increases over time at different rates.

Disclosure of Interests: None declared

AB1379
PREDICTORS OF RADIOLGICAL PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE OBSERVATION
O. Alekseeva1, V. Rybakova2, A. Smirnov1, A. Volkov1, E. Nasonov3, V.A. Nasonova Research Institute of Rheumatology, Diagnostic Department, Moscow, Russian Federation; 2V. A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology, Rheumatic Diseases, Moscow, Russian Federation; 3A. Nasonova Research Institute of Rheumatology, Chief Researcher, Moscow, Russian Federation

Objectives: to identify the prognostic role of ultrasound signs (US) in radiologic progression in RA patients

Methods: 61 RA pts, mean age 50,0 [38,0; 59,0] yrs, mean disease duration 7 [4; 20] months were treated with MTX and biologics according to the Treat-To-Target concept. After first year of therapy management was following real clinical practice rules until the termination of the study (7 years FUP, median it 7.7 [7;4;8,6]). Among them 40 patients with early RA, mean age 51.0 [43,0; 60,0], disease duration 5 [3; 6,5] months. The general characteristics of the group are presented in the Table 1. Hands and feet ultrasound (US) with grayscale (GS), power Doppler (PD), according to the criteria of OMERACT, were analyzed before initiation of treatment and in 3, 6, 9, and 12 months after Radiographs were obtained at baseline, at 12 months, 4 years, and 7 years, radiographic changes were assessed using Sharp/van der Heijde modified scoring method. Structural damage progression was evaluated by change in the Sharp/van der Heijde score (ΔSHS) between baseline and 1.4 and 7 year. We determined the individual peak radiographic progression (ΔSHS scores/time) in RA- patients.

Results: 52 ACPA+ (85%) and 9 ACPA− (15%) patients presented among the 61 patients with RA. RA progression by 4 years FUP was identified in 36% (22 p) of pts, 7 years FUP was identified in 69% (42 p) of pts. At the 7 years FUP 42 of 61 patients had radiographic progression: the count of erosion increased from 0 [0; 3] to 3 [1; 11]. At the same time, on the background of therapy during the first year, a decrease in ultrasound signs of inflammation was determined according to the GS and PD: from 64 [4; 9] to 2 [4; 6] p = 0.000 and from 2 [1; 6] to 0 [0; 2] p = 0.000, respectively, and increase in the number of joints with erosions from 1 [0; 2] to 2 [0; 3], p = 0.000.
All pts divided into groups based increase in erosions according to radiography (Rg +) and without it (Rg-). In the group Rg + GS at baseline was significantly higher than in Rg- group (6 [5; 10] and 5 [1; 8], respectively, p<0.04), CRP at 3 months and at 6 months was significantly higher in Rg + group than in Rg-group (4.15 [1.2; 8.7] and 1.2 [0; 3.5], respectively, p=0.03 and 2.35 [0; 10.1] and 0.4 [0; 4.3], respectively, p=0.025).

Conclusion: Thus, we obtained the first data on the important prognostic role of ultrason in assessing the progression of early RA in a perspective seven-year follow-up.

AB1380 ULTRASONOGRAPHIC CHANGES OF PLANTAR FASIA IN PATIENTS WITH PLANTAR FASCIITIS DUE TO ACQUIRED FLAT FOOT

O. Turchan1, A. Liabakh1, O. Burianov2, T. Omelchenko2, L. Osadcha1, 1State Institute “The Institute of Traumatology and Orthopedics of Ukraine”, The Clinic for Foot Pathologies and Complex Prosthetic Treatment, Kyiv, Ukraine; 2Bogomolets National Medical University, traumatology&orthopedics, Kyiv, Ukraine

Background: Plantar fasciitis is a chronic degenerative process of the plantar fascia enthesis. It manifests by pain, predisposition to prolonged course and treatment resistance. In many cases, plantar fasciitis develops in patients with acquired flat feet. Taken into consideration above mentioned, the study of the plantar fascia changes in patients with acquired flat feet by sonography is relevant.

Objectives: To investigate the quantitative and qualitative sonographic changes of the plantar fascia in the case of plantar fasciitis in patients with acquired flat foot.

Methods: 190 patients with plantar fasciitis on the basis of acquired flat feet (133 females and 57 males). The average age of patients was 48 ± 0.97 years (18-81 years). Unilateral pathology was noted in 117 patients and bilateral – in 73 patients. The average body mass index was 27.68±0.3. The average duration of pain syndrome was 101 ± 6.0 days (7 -390 days). The pain syndrome lasted up from 1 to 6 months – in 152 patients, and more than 6 months – in 38 patients. The control group included 15 healthy volunteers (30 feet). Clinical radiological, sonographic, and statistical methods were used.

Results: The main sonographic features were significant reduction in echogenicity, erased or missing fibrous pattern, fuzzy contour of the aponeurosis; and modified contour of the calcaneus; small focal hyperechogenicity points with inflammatory diseases, the changes between the final and basal MIG, DIG, or MoIG (t=1.921, P=.096; t=-1.533, P=0.169; and t=1.761, P=.122, respectively). Among patients with inflammatory pathology, there were no significant differences between final and basal MIG, DIG, or MoIG (t=1.921, P=.096; t=1.533, P=0.169; and t=1.761, P=.122, respectively). Figure 1 summarizes the changes in the mean gray intensity index (MIG) in patients with mechanical and inflammatory pathology. In patients with inflammatory diseases, the changes between the final and basal MIG tend to normalize (approaching the unit). In the mechanical pathology group, the MIG variation shows a less defined behavior.

Figure 1. Box and whisker plot showing the evolution over time of the pathological/healthy gray intensity mean coefficient. MIGp: Mean gray intensity in the pathological enthesis. MIGc: Mean gray intensity in the control enthesis of the same patient.

Conclusion: The computer analysis of static images in gray scale can detect the changes observed in the Achilles enthesis of patients with inflammatory diseases such as spondyloarthritides. It is also demonstrated that in these patients the gray intensity change rate tends to be normalized (approaching the unit) after a steroid injection. Trend to normalization has not been evidenced in patients with mechanical pathology. Corticosteroids apparently do not act on the origin of the mechanical entheseopathies. Therefore, the study of the average, dispersion and fashion of gray intensities is erratic.
The capacity of MIG detecting evolutionary changes in inflammatory pathology shows a potential for the follow-up of patients with spondyloarthropathy and enthesal involvement.

AB1382
SCREENING OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS THROUGH AN ULTRASONOGRAPHY PROTOCOL
A. Brigante1, J. Rebak2, G. Rizzo3, L. L. Holguín Arias4, F. Rizzo5, S. Quadrelli5, D. Dubinsky1 on behalf of Intestinal Pulmonary Diseases Service of the Sanatorio Güemes. 1Sanatorio Güemes, Rheumatology, Ciudad Autónoma de Buenos Aires, Argentina; 2Sanatorio Güemes, Pneumology, Ciudad Autónoma de Buenos Aires, Argentina; 3Sanatorio Güemes, Diagnostic Imaging Department, CABA, Argentina

Background: Intestinal Lung Disease (ILD) is a frequent complication in patients with autoimmune diseases. Rheumatoid arthritis (RA) does not escape this statement. Different protocols have been proposed for the ultrasound evaluation of this affection showing very good correlation with high-resolution computed tomography.

Objectives: To determine the sensitivity and specificity of an ultrasound evaluation protocol as a screening method for interstitial lung disease in rheumatoid arthritis.

Methods: Consecutive patients diagnosed with RA, with and without ILD, will be included. High-resolution chest CT (HRCT) will be performed in all patients. The lung evaluation protocol by ultrasonography (US); evaluates 50 intercostal spaces (ICS) and will be performed by a rheumatologist and imaging specialist trained in the procedure. The presence of B lines and pleural alterations in the EICs explored will be evaluated. A semiquantitative scale will be used to assess each EIC: 0 = normal, (<10 B lines); 1 = mild (11 to 20 B lines); 2 = moderate (21 to 50 B lines) and 3 = marked (>50 B lines). CT scan was considered the “gold standard” for the diagnosis of ILD and they were evaluated by experienced pulmonologists who were blind to the patient.

Results: 79 patients were included. Female sex 77% with a mean age of 55 (SD 11.4). The comorbidities observed were: hypertension 27%, dyslipidemia 15%, diabetes mellitus 10%, hypothyroidism 30%, smokers 14%, former smokers 18% and osteoporosis in 14% of patients. The patients had a median duration of the disease in years of 7.5 [IQR 9.2]. Eroosive disease was seen in 20 (20%) and rheumatoid nodules in 9.1% of patients. 91% of the patients were under treatment with corticosteroids. Rheumatoid factor was observed in 87% of the patients and Anti-CCP in 71% of the patients, of which 70% had high titers. DILD was observed by HRCT in 21 (27%) patients. The tomographic patterns observed were UIP 7 (33%), probable UIP 2 (10%), cellular NSIP 6 (29%), fibrosing NSIP 3 (14%). An indeterminate pattern was observed in 3 patients. The extent of pulmonary involvement was extensive in 48% of patients and limited in 52%. A sensitivity of 63% (CI95% 44-78) and a specificity of 92% (CI95% 81-97) were observed for the ultrasound evaluation protocol with a PPV of 81% (CI95% 61-92) and NPV of 83% (95% CI 71-90) and an LR+ 8.1 (95% CI 4.6-14.3) and LR- 0.4 (95% CI 0.3-0.48). AUC: 0.81 (p<0.0001).

Conclusion: We observed a moderate sensitivity and specificity of the method to assess interstitial lung involvement in RA with an acceptable AUC for a screening method. These findings are similar to what was found in other cohorts. We believe that the possibility of ILD would be removed. Studies in larger cohorts and comparison with other factors associated with ILD are necessary to improve our understanding of the method and give it the place it deserves.

AB1383
QUANTIFICATION OF THE PD SIGNAL BY COMPUTER ANALYSIS OF STATIC IMAGES: INTRA-OBSERVER, INTRA-PATIENT AND SENSITIVITY TO CHANGE VALIDATION.
C. Guillén-Astete1, A. Andreu-Suárez1, M. Tortosa-Cabañas1. 1University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain

Background: The computerized assessment of ultrasound images is an alternative to the dichotomous subjective assessment often used in the study of entheseses. Previously, our group has demonstrated its usefulness in assessing grayscale images; however, the evaluation of enthesial hyperemia using this technique remains a pending task.

Objectives: To determine the intra-observer and intra-patient variability of the hyperemia study using computer analysis of static images.

Methods: Patients with a diagnosis of known spondyloarthropathies and ultrasonic enthesis of the Achilles tendon -according to EULAR criteria (detection of hyperemia by power Doppler (PD) signal within 2mm of the cortex)- were selected. Longitudinal, medial, central and lateral image sections were obtained. Hyperemia was assessed by PD signal detection, and the images with the highest signal intensity were recorded, maintaining the same Doppler gain and PRF settings for each subject. For image analysis, recordings were coded and randomized so that the analyst did not know to which patient a given section corresponded. Intra-observer validity was assessed by comparing the results of sections from the same patient with each other at two different times. Intra-observer variability was evaluated by subjecting the same image to two computer analyses at different times. Finally, validity of sensitivity to change was performed by successive measurements. The software used was ImageJ 1.53e (NIH, USA).

Results: Images of 12 patients with Achilles enthesitis were included: 6 patients with SpA-nRx, four patients with PsA, and two patients with SpA-Rx. On intra-patient evaluation, significant differences in PD signal intensity were detected between medial, lateral, and central sections. In all cases, the measurement obtained in the central section was the highest (Friedman 15.500 P=.000; medial-central -1.500, P=.001; lateral-central -1.250, P=.007). The coefficient of variation in the first and second determinations without considering the sign of the variation was: 4.2% SD 5.5%. In the intra-observer evaluation of the PD signal evaluations at the central cut-off, the mean coefficient of variation, without considering the sign, was: 9.1% SD 72%. In assessing sensitivity to change, patients with 6-month ultrasound studies were grouped into those who maintained treatment and those who eventually discontinued treatment due to therapeutic failure. In the seven patients who maintained treatment, the mean change in hyperemic areas was -94.3% SD 4.4%, while in the five patients who discontinued treatment, it was -65.4% SD 6.3% (p=.000).

Figure 1. Evaluation of the PD signal.

Conclusion: Computer analysis of static Achilles tendon images conforms to the same ultrasound image acquisition recommendations. In addition, it demonstrates excellent intra-patient and inter-observer variability and sensitivity to change, at least when correlated with therapeutic success or failure from a clinical perspective.
Disclosure of Interests: Carlos Guillén-Astete Speakers bureau: Novartis, Janssen, Abbvie, Grunenthal, UCB, Gebro, Paid professor for: Roche, Novartis, Janssen, Esteve, Menarini, Consultant of: Janssen, Novartis, Roche, Grant/research support from: Pfizter, Grunenthal, Gebro, Novartis, África Andreu-Suárez: None declared, Marina Tortosa-Cabañas: None declared.

Background: The clinical significance of Dense Fine Speckled (DFS) pattern Anti-nuclear antibodies (ANA) by indirect immunofluorescence method (IIF) is unclear and has been inversely associated with rheumatic disease. 

Objectives: Our purpose was to determine associations between DFS pattern ANA and the disease categories of inflammatory arthritis, ANA associated rheumatic diseases (AARD), fibromyalgia, chronic fatigue syndrome, chronic pain, and atopic disorder.

Methods: This retrospective study used data from patients tested for ANA by IIF between August 2017 to August 2019 at the University of Minnesota Medical Center. Comparisons between the diagnostic categories listed in objectives were made for patients with negative ANA, positive ANA (any pattern) and DFS pattern. Individual disease diagnoses belonging to the above categories were also analyzed. The inflammatory arthritis category included seropositive rheumatoid arthritis (RA), seronegative RA, RA with unknown serology, spondyloarthritis, and psoriatic arthritis. The disease category of AARD included systemic lupus erythematosus (SLE), systemic sclerosis, mixed connective tissue disease, idiopathic inflammatory myopathies, Sjogren’s syndrome (SS), and undifferentiated connective tissue disorder (UCTD). Atopic disorders included atopic dermatitis, urticaria, and asthma. The frequency of Raynaud’s phenomenon was also calculated.

Results: 13,845 patients with an ANA during the study period were identified. 9106 (65.8%) had negative ANA and 4739 (34.2%) had positive ANA by IIF (including all patterns). 640 (4.6%) had ANA positive DFS patterns. Relative risk (RR) was calculated for diagnostic categories and individual diseases. For patients with positive ANA and DFS pattern, the RR for diagnostic codes of inflammatory arthritis categories (1.35 (1.07-1.71), p=0.02) was higher when compared to the frequency of codes in ANA negative. RR for AARD among patients with DFS pattern was also higher [1.78 (1.44-2.2), p<0.001]. There was no significant difference in the frequency of diagnostic codes of chronic pain/fibromyalgia/chronic fatigue syndrome [1.02 (0.9-1.2), p=0.84] atopic disorder [0.68 (0.4-1.15), p=0.16] for DFS+ compared to the ANA group. The frequency of AARD diagnostic codes was lower for patients with DFS pattern [0.64 (0.52-0.79), p<0.001] compared to ANA positive patients with all other patterns, consistent with published data. There was no significant difference of frequency of diagnostic codes for the rest of the disease categories when comparison was made between ANA positive DFS pattern and ANA positive with other patterns. Individual disease diagnostic codes of RA were higher among DFS+ patients when compared to ANA+ patients. The frequency of diagnostic codes of SLE, SSC, UCTD, fibromyalgia, Raynaud’s phenomenon, and autoimmune thyroid disease was also higher among patients with DFS pattern compared to ANA- patients. The frequency of diagnostic codes of seropositive RA was lower among patients with DFS pattern compared to ANA+ with all other patterns. The frequency of diagnostic codes of SLE, SSC, UCTD, and chronic pain was also lower among DFS+ patients, compared to those with ANA of all other patterns, consistent with prior reports.

Conclusion: The frequency of diagnostic codes of RA, SS and Raynaud’s was higher among DFS pattern ANA compared to ANA negative group but was not significantly different from ANA positive with other patterns. This suggests that the presence of a DFS pattern should not be used to indiscriminately exclude the presence of a rheumatic disease.

A SURVEY ON ACCEPTANCE OF COVID-19 VACCINATION AMONG PATIENTS WITH RHEUMATIC DISEASES - A SINGLE CENTER EXPERIENCE IN MALAYSIA
C. R. Ng, W. S. Wong, Hospital Sultan Ismail, Rheumatology Unit, Department of Medicine, Johor Bahru, Malaysia

Background: According to Statista, 78.5% of the population in Malaysia have completed their vaccination as of 6th January 2022. The acceptance of patients with rheumatic diseases on Covid-19 vaccination is crucial in the long term protection against Covid-19 infection. We conducted a survey to determine the acceptance of Covid-19 vaccination amongst patients with underlying rheumatic diseases.

Objectives: To find out the reasons of vaccination refusal amongst rheumatology patients.

Methods: This was an interview survey. All rheumatology patients who were followed up in rheumatology clinic Hospital Sultan Ismail, Malaysia from 26th April 2021 to 25th July 2021 (total 3 months) were interviewed. Demographic and diagnosis of the patients were collected.

Results: A total of 952 patients were identified. 83.7% of them were female patients (797/952) and majority of them were Malay (46.4%). This was followed by Chinese (36.1%), Indian (16.3%) and others (1.2%). The mean age group was 48 (range from 13-85). 97.6% of the respondents were categorized as having inactive disease during the interview sessions. 36.6% of the patients were diagnosed to have rheumatoid arthritis and 29.1% of them were having systemic lupus erythematosus. These were followed by psoriatic arthritis (10.9%), mixed connective tissue disease (5.5%), systemic sclerosis (2.9%), gout (2.6%), Sjogren syndrome (1.9%), ankylosing spondylitis (1.6%), myositis (1.5%), vasculitis (1.3%), osteoarthritis (1.2%), antiphospholipid syndrome (0.9%), non-arthritic arthritis (0.8%), juvenile idiopathic arthritis (0.8%), seronegative spondyloarthropathy (0.8%), undifferentiated connective tissue disease (0.7%), adult onset Still’s disease 0.5%) and others (< 0.5% each for Ig G 4 related disease, soft tissue rheumatism and fibromyalgia). 87.3% of them were keen or have already received Covid-19 vaccination. 12.7% of them were not keen for the vaccination with various reasons.

48.8% of them were worrying about worsen the condition, 12.4% of them were not keen as they concerned about side effects (3 worry about fever, 1 worry about hepatitis, 1 for nausea, 1 for dizziness, 1 for breathlessness, and 7 for non-specific reasons). 10.7% of them were not keen for pregnancy, 5.7% of them were not keen as worried about allergic reactions, 4.9% of them were worrying about sudden cardiac death, 4% were not keen as on chemotherapy treatment, 3% of them doubted the efficacy of vaccination, 2.5% were not keen as they worried about heart disease, 2.5% worried about increase risks of infection and others (2 for old age, 2 for thrombotic event, 2 for drug interaction and 1 patient due to hemodialysis).

Conclusion: The overall acceptance rate of Covid-19 vaccination amongst patients with rheumatic diseases is very encouraging with the percentage of >85% despite of lacking knowledge about vaccine Covid-19. This result can assist our Ministry of Health to plan for future battle to improve vaccine uptake that hopefully can lead to herd immunity against COVID-19 infection. More counseling sessions are required to clear up the doubts of vaccination and increase the vaccination rate amongst rheumatic patients.

AB1387
THE EFFECTS OF PREGNANCY AND FERTILITY ON DRUG USAGE AND PREFERENCES IN RHEUMATOLOGICAL DISEASES: A SINGLE CENTER EXPERIENCE
B. Karataş1, N. Çabuk Çelik1, B. Karakaş1, İ. Yalçın1, G. Pire1, H. Ş. Eren1, M. Ş. Kuzu1, M. Yıldırım2, B. N. Özdamar3, M. F. Akyılm4, A. Sahin1, Sivas, Cumhuriyet University Internal Medicine-Rheumatology, Sivas, Turkey; Sivas Cumhuriyet University Faculty of Medicine, Department of Internal Medicine, Sivas, Turkey

Background: Rheumatological diseases usually affect women of reproductive age. Although the effects of these diseases on pregnancy vary; Joint and organ damage that may occur should be prevented, maternal and fetal effects of the treatment should be evaluated (1).

Objectives: The aim of this study to determine the effects of rheumatological diseases and drugs used on pregnancy and fertility.

Methods: Between January 2014 and January 2021, women between the ages of 18-45 who were diagnosed and treated at Cumhuriyet University Medical Faculty Rheumatology-Internal Medicine Department were retrospectively analyzed.

Results: The median age of the patients is 37 (min 19-max 45) years. 517 patients (51.7%) were pregnant after diagnosis, 39 patients (3.9%) had abortion after diagnosis, 957 patients (95.7%) had live birth, 69 patients (6.9%) had curettage, 43 patients (4.3%) could not have children. The median of pregnancies before diagnosis is 2 (min 1-max 11) the median of pregnancies after diagnosis is 1 (min 1-max 6) the median of abortions before diagnosis is 2 (min 1-max 7) the median of abortions after diagnosis is 1 (min 1-max 4) the median of curettage is 1 (min 1-max 3) the median of live births is 2 (min 1-max 5). The distribution of patients according to drug use and drug used during pregnancy is shown in Figure 1. The distribution of the patients according to the diagnosis and the factors affecting pregnancies after diagnosis, abortions after diagnosis, curettage and live birth is shown in Table 1.

Summary

- **Objective:** Conduct a cost-minimization analysis for RA in Spain.
- **Methods:** Consider all cost information for therapeutic alternatives, evaluate the different cost outcomes, and compare MyChart use and non-use.
- **Results:** Patients with active MyChart use had lower costs than those with inactive MyChart use in the cost-minimization analysis.
- **Conclusion:** MyChart use may benefit high-risk groups and improve health equity.

was gathered from drug cost databases, and a range of discounts were applied according to experts opinion obtained through a survey. Finally, non-pharmacological costs were obtained from literature review. With all this information, a cost-minimization analysis between the suitable therapeutic alternatives was performed for a 1-year time horizon. Robustness of results was validated by a deterministic and probabilistic sensitivity analysis (PSA).

**Results:** ADA was the less expensive option with an annual cost of 4,529 € vs 4,650 € - 10,001 € for the alternative treatments. Infliximab had only a slightly higher cost than ADA (2.7% higher). Cetuximab, etanercept, and tocilizumab showed a high cost profile, with an annual cost between 54% and 71% higher than ADA. Finally, golimumab, tocilizumab and upadacitinib had the highest cost, between 103% and 137% higher than ADA. Sensitivity analysis showed similar results. The deterministic sensitivity analysis showed ADA to be the best option with average and maximum discounts. In the PSA, only ADA and infliximab performed as the best alternative. ADA was the best option 63% of times.

**Conclusion:** According to our model, ADA was the most cost-effective biological option for treating RA in Spain, and the sensitivity analysis validated the results.

**AB1390 COMPLEMENTARY DIGITAL THERAPY SAFELY IMPROVES QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY ARTHRITIS**

**Background:** Self-management strategies play a central role in improving clinical outcomes in patients with inflammatory arthritis. EULAR recently highlighted the essential role of digital health to increase the self-management of patients. Evidence regarding these supporting digital tools, including mobile apps, is currently however very limited.

**Objectives:** To evaluate the efficacy and safety of a mobile app (Mida Rheuma App) in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA), including psoriatic arthritis (PsA) in a prospective study.

**Methods:** Patients with RA, SpA/PsA, stable on their antirheumatic therapy for 24 weeks, were eligible to use the Mida Rheuma App in addition to standard care treatment. The usage of the app targeted the optimization of non-medical treatment in a 4-step process: (1) collection of the information (HRQoL, disease activity, physical impairment, diet, mental health, physical activity, etc.) using standardized questionnaires via the conversational health coach Mida; (2) development of a patient profile that focuses on the patient’s disease, well-being, and behavior; (3) creation of a personalized, evidence-based disease management program based on recommendations from medical guidelines, medical standards, and state-of-the-art clinical research; (4) implementation of personalized recommendations into the patient’s daily life by providing short daily tasks that accelerate positive behavior change. Additionally, the health coach Mida supports the patient in coping with stress, sadness, depression, fatigue, and further disease-related symptoms. This is achieved by various cognitive behavioral techniques, meditation and relaxation methods.

Additionally, we assessed demographic parameters, treatment regimen, disease activity (e.g., SDAI, AASDS), and other patient-reported outcomes (e.g., SF-36) at baseline and after 4 weeks. The study was approved by the Ethics Committee of the Medical Faculty of Mannheim, Heidelberg University.

**Results:** Of 20 patients screened after obtaining informed consent, 19 were enrolled in the study, and 17 patients (12 RA, SpA: 1 axSpA, 4 PsA) completed the study (2 drop-outs due to unwillingness to finish the study). 7 (41.2%) patients were male, and ages ranged from 19 to 63 (40.5±12.2) years. Patients were treated as follows: 7 NSAIDs (41.2%), 2 GC (≥5 mg) (11.8%), 3 HCQ (17.6%), 10 MTX (58.8%), 1 L EF (5.9%), 1 SSZ (5.9%), 1 A Methotrexate (5.9%), 3 JAK1/2 (17.6%), 1 T NF (5.9%), 2 Li-I (11.8%), 1 IL-17i (5.9%). No significant change in antirheumatic treatment was observed during the study. At baseline, 29.4% of the RA and PsA patients were in remission. 25.2% had low, 29.4% had moderate, and none had high disease activity according to SDAI, one axSpA patient had low disease activity (AASDS: 2.2). At the end of the study, slightly more RA and PsA patients were in remission and had low disease activity (58.8% and 23.5%, respectively) and less had moderate activity (11.8%); the axSpA patient had inactive disease (AASDS: 1.8). Regarding patient-reported outcomes, statistically significant improvement was noted for the following parameters: SF-36 Total Score (range of CI 90% and minimum clinically important difference of 2.5), increase of Physical Component Summary of SF-36 by 23.6% (p=0.024), ‘role limitations due to physical health’ by 76.9% (p=0.022), and ‘general health’ by 76.9% (p=0.024). No significant change in other patient-reported outcomes were observed due to clinical importance of their dynamics for Patient Health Questionnaire (PHQ)-9, ‘emotional well-being’ and RADI-AI-5. No negative changes were observed for assessed parameters. No adverse events were reported throughout the study.

**Conclusion:** This prospective study suggests that using an app-based personalized disease management program significantly improves several measures of patient-reported on disease activity in patients with RA and PsA/SpA. These findings highlight the potential of complementary digital therapy in patients with inflammatory arthritis.

**AB1391 19% PATIENTS WITH CHRONIC RHEUMATIC INFLAMMATORY ARTHRITIC DISEASES PRESENT AN UNFAVORABLE PREGNANCY OUTCOME: A DESCRIPTIVE ANALYSIS OF THE NATIONAL FRENCH SOCIAL SECURITY DATABASE**

A. Moltó1, A. Ajrouche2, D. Tran3, B. Roux2, N. Cuesta-Chalumeau3, E. Elefant4, V. Tsatsaras4, J. Fresonni5, B. Bader-Muenier6, B. Faulh6, F. Tubach7,8. *Cochin Hospital, Assistance Publique Hôpitaux de Paris, Rheumatology, Paris, France*; *APHP CEPHEPI, Paris, France*; *Cochin Hospital, Assistance Publique Hôpitaux de Paris, Internal Medicine, Paris, France*; *Hôpital Trousseau, CRAT, Paris, France*; *Cochin Hospital, Assistance Publique Hôpitaux de Paris, Obstetrics, Paris, France*; *CHU Nancy, Public Health, Paris,*
Background: patients with chronic rheumatic inflammatory diseases (CRID, i.e. rheumatoid arthritis (RA) or spondylarthritides (SpA)) have been reported to have poorer pregnancy outcomes than the general population.

Objectives: to describe the pregnancy outcomes of singleton in patients with CRID in France in the past decade.

Methods: this is an analysis of the French Health Insurance claims database (SNDS), which represents 87% of the French population) from 2008 to 2016. To be included in the analysis patients had to be identified as RA or SpA according to existing diagnostic algorithms, to have at least one pregnancy declaration in the database, and to have continuous health insurance from 1-year before pregnancy onset to 1-year after the end of pregnancy or until death (if death occurred before the 1-year-period after the end of pregnancy) to be included. Only the first singleton pregnancy occurring during the study period was included in this analysis. Both maternal and pregnancy outcomes were considered. Outcomes were identified either by ICD-10 codes or hospital discharge summaries discharge between 2008-2016.

Results: Among the 35 737 identified adult females with a CRID diagnosis (40.7% with RA and 59.3% with SpA), 27 722 (78%) had a pregnancy during the study period. 11 274 (42%) had received at least one DMARD prior to the pregnancy and were included in the analysis. Among them, only 4025 (36%) were exposed to DMARDs during pregnancy. Mean (SD) age of females at the start of the pregnancy was 32 (5) years, and mean (SD) disease duration was 4 (4) years. Pregnancy ended before 13 WG in 21% and after 37 WG in 70% cases. Live-birth represented the most frequent pregnancy outcome (76.9%), and overall 34.7% patients presented at least one unfavorable outcome (see Table 1).

<table>
<thead>
<tr>

<td>Abortion</td>
<td>91 (0.8%)</td>
</tr>
<tr>
<td>Stillbirth</td>
<td>48 (0.4%)</td>
</tr>
<tr>
<td>Preterm birth (≥ 22WG and &lt;37WG)</td>
<td>779 (7.1%)</td>
</tr>
<tr>
<td>Low weight at birth (&lt;3rd percentile)</td>
<td>287 (2.6%)</td>
</tr>
<tr>
<td>Perinatal mortality (22WG to 6 days of life)</td>
<td>2 (0%)</td>
</tr>
<tr>
<td>Severe maternal infection</td>
<td>211 (1.9%)</td>
</tr>
<tr>
<td>Severe infection * during first year</td>
<td>603 (5.3%)</td>
</tr>
</tbody>
</table>

Conclusion: More than 75% pregnancies in patients with CRID resulted in a live-birth. Prevalence of miscarriage was surprisingly low, probably related to under-coding. Maternal and infant outcomes seemed comparable to general population. Whether medications had an impact on such outcomes is currently under evaluation.

AB1393 COVID-19 HAD AN ADVERSE IMPACT ON DENOSUMAB TREATMENT PROVISION - COMPARISON WITH PRE-PANDEMIC WAITING TIMES AT A UK-BASED RHEUMATOLOGY DEPARTMENT

S. Ling1, L. Bromilow1, S. Vasireddy1. 1Bolton NHS Foundation Trust, Department of Rheumatology, Bolton, United Kingdom

Background: Denosumab treatment is licensed for prevention of osteoporotic fractures. It can cause hypocalcaemia, so bone profile blood tests must be checked prior to treatment. In our department, we have a Standard that patients have blood tests within 1 month before their denosumab injection, and that they receive the injection within 1 month from its due date. A customised MS Access database to record this information and generate a date for the next dose was established in 2015 after a quality improvement project (QIP). At the onset of the COVID-19 pandemic, UK national guidance recommended continued provision of denosumab as an essential service.

Objectives: 1. To re-audit delay from due date to actual injection date after establishment of our database. 2. To compare delay from due date to actual injection date before and after onset of COVID-19. 3. To compare the time between blood tests and actual injection date, before and after onset of COVID-19.

Methods: Data for 2 time-periods were extracted from the database: Time Period 1 (pre-COVID-19) 01-03-2019 – 29-02-2020; Time Period 2 (post-COVID-19) 01-03-2020 – 28-02-2021. For each patient attendance, dates of blood test, due date and actual injection date were extracted. All patient details were anonymised, with a decryption key to identifiers held on a secure server at the host Trust. It was manually determined whether blood tests and injections were within 1 month of when they were due. Statistical analyses were carried out in Stata v.14.0. The Kolmogorov-Smirnov test was used to compare distributions between Time Periods 1 and 2.

Results: Time PERIOD 1: 100 appointments were audited from 68 patients. 20% of blood tests were within 1 month of actual injection date. Median time between blood tests and actual injection was 45 days [IQR 35 – 59]. 32% of actual injections were given within 1 month from due date. This compares favourably with our 2015 QIP, when 40% of actual injections were within 1 month from due date). Median time between due date and actual injection was 29.5 days [IQR 13 – 50.5]. Time PERIOD 2: 77 appointments were audited from 66 individual patients. 24.7% of blood tests were within 1 month of actual injection. Median time between blood tests and actual injection was 45 days [IQR 35 – 59]. 16.6% of actual injections were given within 1 month of due date. Median time between due date and actual injection was 82 days [IQR 40 – 141]. There were no significant differences in time between blood tests and actual injection between Time Periods 1 and 2. However, the time between due date and actual injection date was significantly longer in Time Period 2 (p<0.005).

Conclusion: The introduction of our customized database promoted an improvement in time between due date and actual injection date of denosumab. However, this improvement significantly declined after the onset of the COVID-19 pandemic. Resources may need to be increased and processes adapted to minimise the impact of future emergencies on denosumab provision.

Kristensen9, T. S. Jørgensen11, 1Karolinska Institute, Department of Medicine (Solna), Division of Rheumatology, Stockholm, Sweden; 2Medical University of Vienna, Department of Internal Medicine 3, Division of Rheumatology, Wien, Austria; 3Medical University of Vienna, Section of Outcome Research; Center for Medical Statistics, Informatics and Intelligence Systems, Wien, Austria; 4Daman, P/S, København, Denmark; 5dwh GmbH, -, Wien, Austria; 6Copenhagen University Hospital Bispebjerg and Frederiksberg, The Parker Institute, København, Denmark; 7Vienna University of Technology, Institute for Information Systems Engineering, Vienna, Austria; 8EU-LAR - European Alliance of Associations for Rheumatology, Young PARE, Kilchberg, Switzerland; 9Österreichische Rheumaliga, -, Maria Alm, Austria; 10The Parker Institute’s Patient Association, -; Copenhagen, Denmark

Background: The use of health apps has become more popular in recent years, but it is still a small and rather unregulated market. Few apps have been designed in collaboration with patients and these mostly address patient reported symptoms. Some clinical registries have already developed patient apps to complete patient-reported outcome measures (PROMs) on smartphones, which normally would have been collected during an outpatient visit and have shown interchangeability. The next step would be providing a patient app offering possibilities not only of individual disease tracking, but to provide automated peer support, health information and behavioural advice.

Objectives: We aimed to further develop and validate RheumaBuddy, a health app for patients with rheumatoid arthritis (RA), from a standard monitoring app to an intelligent health app tailored to the needs of the user that provides transparency to all important stakeholders in Rheumatology care.

Methods: This is an international interdisciplinary project between Austrian and Danish partners funded by the EUREKA program. Rheumatologists, health scientists, digital data experts and patients with RA joined forces in a 4 phase-program, running from 2020 to 2023. Phase 1 continues to develop the app in a co-creation approach in several iterations with patients. Phase 2 concerns developing an automated learning algorithm based on user data to identify patient strata and connect these with helpful non-pharmacological interventions. Phase 3 connects healthcare system data on diagnosis, medication prescription, healthcare facility usage with a large clinical RA database. By that we develop patient pathways that correlate high granularity data with system resources to retrieve results on socioeconomic impact. In phase 4 a randomised clinical trial will evaluate the effect of the developed RB4.0 on clinical disease activity and quality of life.
Results: Currently, RB is regularly being used by more than 3100 patients in 35 countries and 8 languages throughout Europe. The current RheumaBuddy version offers logging of symptoms using Likert scale questions, a joint mannequin to mark painful body parts and a peer-support forum. Additionally, the user can anytime display his/her entries over time in a graphical report and also share data with the healthcare provider. This version is extended with tracking of sleep, working hours and other behaviours. A consultation compass function helps the patient to reflect on goals and issues before the rheumatologist visit. Within this project, we already established a first version of a Recommender System (RS), which will compute correlations between user entries (e.g., between a user’s mood and pain), thus providing individual feedback. Through integration of information obtained from the app with claims data and clinical data from a RA registry, patterns can be identified and translated into different case models that concern the impact of common RA symptoms. By mapping these scenarios with evidence based behaviour and lifestyle advice, the “virtual coach” (advanced RS) will be developed and integrated into the RB4.0 system. During continuous data collection on app users, similarities in user behaviour can be identified, and similar entry patterns can be grouped. This will allow users to exchange and learn from each other regarding certain difficult situations (e.g., “life-hack”) etc. We are creating a comprehensive system in providing feedback to both clinical and psychosocial aspects of coping and disease management, as well as everyday practicalities for living with a chronic disease. Figure 1 displays these aspects, contributing the empowerment of patients.

Figure 1. RB4.0 shall support people living with RA in dealing with disease impact

Conclusion: RheumaBuddy4.0 will provide RA patients the means to improve their quality of life on an individual level, better understand their needs and therapy which could support overcoming barriers of successful shared decision making to achieve better outcomes.

Background: Rituximab is an efficacious drug for the treatment of Rheumatoid Arthritis (RA). According to literature, administration of rituximab can be based on a fixed interval or on relapse of disease activity. In some countries, like Belgium, after the first rituximab cycle a flare is required for reimbursement of a subsequent cycle.

Methods: Patients with RA, who were currently or previously treated with rituximab, and rheumatologists were invited to participate in a qualitative study consisting of individual, in depth, face-to-face, semi-structured interviews. Participants were recruited based on purposive sampling to ensure diversity. Interviews were conducted via video or telephone call. Additional participants were interviewed until data saturation was achieved, meaning no new information emerged from the last 3 interviews. Interviews were audiorecorded and transcribed verbatim, followed by analysis according to the Qualitative analysis guide of Leuven, which generated themes and subthemes. Patient experts were involved in this research.

Results: In total, 16 patients with RA and 13 rheumatologists were interviewed. Five overarching themes were generated from the interviews: flare definition, recognition, reaction, balance between benefits and barriers and suggestions (Figure 1). Patients and rheumatologists described how they perceive the on-flare retreatment strategy in daily practice, starting with the FLARE DEFINITION itself. Namely, what patients perceived as a flare and the impact of this flare. The second step was RECOGNITION of the flare. Both rheumatologists and patients indicated that patients are able to recognise a flare. However, the patient’s ability to discriminate between inflammatory and other types of pain was perceived as a difficulty. Moreover, patients indicated that depending on the flare’s intensity, they can cope with it themselves, delaying the need for a rituximab cycle. The next step after correctly recognising a flare, was the REACTION, from both the patient’s and rheumatologist’s side. It was stressed that patients must contact their treating rheumatologist in time. Furthermore, a swift response of the rheumatologist was perceived as important. After confirming eligibility, the shared decision to plan a new rituximab cycle can be made while keeping an eye on the organisation. Remarkably, it seemed that rheumatologists approached the retreatment strategy in different ways, meaning that not everyone adhered to the on-flare principle. Several perceived BENEFITS (e.g. lower safety risk, societal cost savings) and BARRIERS (e.g. disease activity fluctuations, slow working mechanisms) were mentioned, making clear that the optimal retreatment strategy should be based on a BALANCE between both. Finally, some SUGGESTIONS (e.g. biomarkers for flare prediction, subcutaneous administration of rituximab) were brought up that could be helpful in applying the optimal retreatment strategy.

Conclusion: Patients play an important role in the recognition of flares and their reaction, in shared decision with the rheumatologist, contributes to the effectiveness of the rituximab on-flare retreatment strategy. Rheumatologists handle the on-flare retreatment strategy as pragmatically as possible, resulting in different approaches. Moreover, both benefits and barriers of on-flare retreatment were
perceived, making clear that a balance should be found to determine the optimal retreatment strategy.

AB1395  PATIENTS’ AND RHEUMATOLOGISTS’ PERCEPTIONS REGARDING TAPERING OF RITUXIMAB

D. Bertrand1, A. Deprez1, M. Doumen1,2, D. De Cock1,2, S. Pazmino1, A. Marchat1, M. Thellissen1, J. Joly1, B. Neerincx1,2, R. Westhoven1,2, P. Verschuere1,2.
1Katholieke Universiteit Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium; 2UZ Gasthuisberg Campus, Rheumatology, Leuven, Belgium; 3Katholieke Universiteit Leuven, Clinical and Experimental Endocrinology, Leuven, Belgium; 4ReumaNet vzw, ReumaNet, Zaventem, Belgium

Background: Rituximab is an efficacious drug for the treatment of Rheumatoid Arthritis (RA). The commonly used dose consists of two infusions of 1000 mg with a 2-week interval, but evidence is growing that a lower dose could be as effective. Before implementing a tapering strategy, understanding the perceptions of patients and rheumatologists in this regard is important.

Objectives: The aim was to investigate patients’ and rheumatologists’ perceptions on rituximab tapering.

Methods: Patients with RA, who were currently or previously treated with rituximab, and rheumatologists were invited to participate in a qualitative study consisting of individual, in depth, face-to-face, semi-structured interviews. Participants were recruited based on purposeful sampling to ensure diversity. Interviews were conducted via video or telephone call. Additional participants were interviewed until data saturation was achieved, meaning no new information emerged from the last 3 interviews. Interviews were audio-taped and transcribed verbatim, followed by analysis according to the Qualitative analysis guide of Leuven, which generated themes. Patient experts were involved in this research.

Results: In total, 16 patients with RA and 13 rheumatologists were interviewed. Four themes were found: In favour/reluctant of tapering, shared decision making, implementation of tapering rationale. Patient experts were involved in this research.

Conclusion: It seems that rituximab tapering is not yet incorporated in daily practice as much as tapering of other antirheumatic drugs and this could potentially be related to a lack of experience with rituximab. However, with appropriate education and communication, rheumatologists and patients are willing to taper rituximab. Although, many questions remain, indicating an evidence gap and a need of more research.

Disclosure of Interests: None declared

AB1396  MULTICENTER QUALITATIVE STUDY ON THE EXPERIENCE OF USE OF BIOLOGIC AND TARGETED SYNTHETIC DISEASE-MODIFYING DRUGS IN PATIENTS WITH RHEUMATIC DISEASES. WHAT DO OUR PATIENTS THINK?

O. Rusanovych1, M. Sanz2, A. V. Esteban Vazquez2, N. Molina Esteban4, M. D. C. Uyaguari Morocho3, M. Pavia Pascual5, P. Navarro Palomo5, M. Machatou1, N. De la Torre Rubio1, M. Fernandez Castro1, H. Godoy1, C. Barbadillo Mateos1, C. Merino Arguménez1, B. Garcia-Magallon1, J. Sanz1, C. Isasi Zaragoza1, L. F. De Villa1, T. I. Cob1, J. Campos Esteban1, J. L. Andrué Sánchez1, Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain; 2La Paz University Hospital, Rheumatology, Madrid, Spain; 3Infanta Sofia University Hospital, Rheumatology, San Sebastián de los Reyes, Spain; 4University Hospital October 12, Rheumatology, Madrid, Spain

Background: The development of targeted biologic (bDMARDs) and targeted synthetic disease-modifying drugs (tsDMARDs) has made a substantial change in the control of our patients, and has allowed an increasing number of patients to achieve clinical remission.

Objectives: To gain understanding of patients’ experiences of starting treatment with b/tsDMARDs, and explore their attitudes in order to improve the doctor-patient relationship, adherence to treatment, compliance, and knowledge about the experience of using b/tsDMARDs.

Methods: A qualitative study was carried out. A consecutive sample of 130 patients attended in the rheumatology units of four Madrid hospitals, from August 29th, 2021 to January 21st, 2022 completed a questionnaire that consisted of 31 questions, a subsequent qualitative analysis of discourse and content through focus groups with patients was carried out. Descriptive statistical analysis was performed. Chi-squared tests were applied to explore the dependency relationship between the different qualitative variables.

Results: One hundred and thirty questionnaires were collected (see general characteristics in the Table 1).

Table 1.  Baseline demographics.

<td>14.7 years (+/-11.43)</td>
</tr>
<tr>
<td>Time since initiation of treatment with b/tsDMARDs (years), (mean, SD)</td>
<td>5.84 years (+/-4.28)</td>
</tr>
</tbody>
</table>

Most of the patients (68.46%) felt hope when they were informed that they were going to start treatment with b/tsDMARDs, 26.9% relief, 22.3% happiness and 27.7% fear and concern. 76% of the patients received information about why the treatment was modified, the advantages of b/tsDMARDs (60%), their mechanism of action (48.5%) and the precautions to be aware of (38.5%). Fifty-two percent of the respondents searched for additional information on their own, with the most used sources being from internet search engines (34.2%), the corresponding drug insert (22.8%) and the page of the Spanish Society of Rheumatology (23.7%). 60% of the respondents were informed about the possible risks associated with the treatment, 49.4% reported being more concerned when they contracted an infection. Most of the patients were recommended to receive influenza (81.5%) and pneumococcal (62.8%) vaccine, of which 74.6% and 54.6% received those respectively. A statistically significant dependence was observed between the recommendation of the vaccine and vaccination, since most (91.5%) of those who received the recommendation were vaccinated (p<0.001). Most of the respondents kept their scheduled appointments (87.3%) and never forgot to take their medication (370/4%). 51% of the patients reported that with b/tsDMARDs they had experienced “considerable improvement”, 38.5% indicated that “their life has changed”, 10% reported little or no improvement. It was observed that men reported a maximum degree of concern when they were informed of the onset of cancer (32.4%) and corticosteroids (24.7%), while women were more concerned about the possibility of developing “serious infections” (45.2%) and “heart attack” (29.3%).
aspects have you noticed the greatest changes?” the respondents answered: reduction in outbreaks of the disease (67%), emotional improvement (38.8%) and regaining work activity (31.8%).

Conclusion: In our setting, education programs inform patients adequately, but it seems necessary to make a greater emphasis on therapeutic compliance, providing more safety information, and compliance to recommended vaccinations.

Disclosure of Interests:
[42x470]K. Tempest1, H. Reddy1, S. Johns1, K. Wright1, S. Sultan1. 1Airedale General Hospital, Rheumatology, Steeton, United Kingdom

Background: In 2014 we were a small team with only 1 WTE (Whole Time Equivalent) CNS (Clinical Nurse Specialist) and 2 WTE consultants for a population of 220,000. Most CNS clinic appointments were taken up for drug counselling. Waiting times were approx. 6 weeks for drug counselling. Consultants would often counsel for DMARDs that at a year that national meeting a virtual group MDT (multidisciplinary) was presented by the team at Manchester Royal Infirmary (MRI). They used a good quality presentation for patients starting bDMARDs as a tool for drug counselling. After having to put on an extra clinic to counsel 5 patients, all for rituximab, frustratingly I asked why can’t I get them all in the same room to save time? We needed to work smarter, not harder, utilise time & space to ensure best practice but also ensure gold standard, patient centered care continued. We modified the format used at MRI to a face to face group education and counselling of patients to improve waiting times and patient flow.

Objectives: Reduce the amount of clinic appointments used to counsel patients for sDMARDs (synthetic disease modifying anti-rheumatic drugs) and bDMARDs (biologic). Free up clinic appointments for follow up/ review and flares. Standardise information given out to ensure they are all given the same gold standard information and education.

Methods: We visited the team at MRI to view the format of their virtual clinic. It didn’t meet the needs of our service so we modified and adapted the presentation. Set up a group education session to discuss the most common sDMARDs and bDMARDs used for Inflammatory Arthritis. I developed a power point presentation and booklet that can be used by CNS- ensuring the same information is given to every patient, both attending the group session and those not suitable for group session (ie Language barriers) who would be seen individually. We use a screening proforma to ensure safety of commencement for the individual prior to attending clinics which has a tick list for screening requirements. The session is undertaken in our education centre. Pre Covid the session could accommodate up to 10 patients per session per week, uptake on average 6-10 patients for sDMARDs and 5-6 for bDMARDs. We alternated biologic and DMARD sessions, if demand required, we changed a session to accommodate. The room is booked for 1½ hours every week, the sDMARD presentation lasts approximately ½ an hour & bDMARD session 50 minutes, time is allowed for group & individual questions if required at the end. This contrasts with 25 minute appointment for sDMARD & 50 minute for bDMARD counselling 1.1. The booklet, along with information pack, is given at the group session to all patients. This includes all the information the patient requires (advice line information, blood forms). Prior to the group clinic admin team prepare the patient packs for the CNS to give to patients.

Results: We received 102 anonymous responses back from 136 patients asked. (75% response) Following these sessions we found less calls to the advice line regarding medication queries, able to add in further cDMARDs or switch to alternate due to S/Es over the telephone Feedback from patients.-120 comments received. Clear simple information about a number of possible drugs used to treat my condition not just the 1 I am prescribed. If my medication needs changing I already know about it. The lecture aspect of the types/contra-indications of meds was very useful & removed the ‘fear’ attached to these specialist drugs. The session with other patients present stopped me from feeling alone in this position. The booklet is brilliant as it includes everything that was in the session. Also it took away the ‘fear’ of the side effects.

Conclusion: 7 years on we feel that Group Counselling has been a huge success, we noticed how successful this was once we had to deal with the pandemic and cancel the group sessions. Patients feedback proves that they like the session and find them valuable. Whilst being beneficial and improving work productivity and streamlining the service.

Acknowledgements: The Rheumatology Team at The Kellgren Centre Manchester Royal Infirmary

Disclosure of Interests: Kelly Tempest Speakers bureau: Abbvie

Background: Rheumatologists have noted challenges in treating patients with systemic sclerosis (SSc) during the COVID-19 pandemic, such as patients on immunosuppressants and those with preexisting pulmonary issues.1 Also of potential concern was patients delaying treatment due to fears of COVID.

Objectives: This study examined what extent patients with SSc cancelled health-care appointments due to fears of COVID, how this correlated with their mental and physical functioning, and their levels of anxiety and depression.

Methods: We invited all SSc patients scheduled for drug counselling. Waiting times were approx. 6 weeks for drug counselling. Participants were 60 people with SSc who had not had COVID-19 or been vaccinated for COVID. Participants had a mean age of 58 years (SD=11.5) and were primarily female (92%) and white (87%). Participants completed an online survey after learning about it from a scleroderma organization newsletter or at their visit with a rheumatologist specializing in scleroderma in New York State, USA. Data were collected August 2020 through March 2021. Participants completed measures assessing health-care attendance, Patient Reported Outcome Measurement Information System (PROMIS) measures (anxiety, depression, fatigue, sleep disturbance, pain intensity, physical function), coping strategies to deal with the pandemic, and reported functioning relevant to SSc (hand, gastrointestinal, dyspnea, and Raynaud’s disease).

Results: Due to COVID-19 concerns, 28 respondents (47%) cancelled one or more appointments with their primary care physician, specialist, physical or occupational therapist, pulmonologist, or dentist. Compared to those who did not cancel appointments due to COVID concerns, participants who cancelled reported higher anxiety, t(58) = 2.46, p = .02, higher sleep disturbance, t(56) = 3.31, p = .002, worse physical functioning, t(56) = 2.00, p = .05, more constipation, t(56) = 2.05, p = .045, and lower positive reframing as a coping strategy, t(56) = 2.08, p = .04.

Many participants reported moderate or severe anxiety (36%), depression (22%), fatigue (32%), sleep disturbance (28%), and physical dysfunction (40%). As shown in Table 1, anxiety scores were positively correlated with scores on measures of fatigue, sleep disturbance, physical dysfunction, diarrhea, and the coping strategies of substance use, self-distraction, emotional support, behavioral disengagement, and venting. Depression scores were positively correlated with scores on measures of fatigue, sleep disturbance, physical dysfunction, pain intensity, dyspnea, diarrhea, and behavioral disengagement as a coping strategy.

Table 1. Correlations Between Anxiety and Depression with Patient-Reported Outcomes and Coping with the Pandemic

Note. * p < .05; ** p < .01; *** p < .001
Conclusion: Almost half of participants cancelled one or more health appointments due to COVID fears. This subgroup reported significantly higher anxiety, sleep disturbance, constipation, worse physical functioning, and less coping with the pandemic by looking for the positive. Anxiety and/or depression also played a role in 42% of SSC patients and were related to a variety of worse mental and physical health correlates. Future research should examine the extent to which changes in health-related care during the pandemic have implications for disease progression in patients with SSCs.

AB1400 COMORBIDITIES IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES ASSOCIATED WITH TREATMENT NON-ADHERENCE TO BIOSIMILARS IN A NON-MEDICAL SWITCH SCENARIO?

I. Redeker1,2, S. Moustakis1,2, S. Tsiami1,2, X. Baraliakos1,2, I. Andreia,2, B. Huebinger1, J. Braun1,2, U. Klitz1,2, 1Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany; 2Rheumazentrum Ruhrgebiet, Rheumatologyst, Herne, Germany

Background: The availability of biosimilars has created a financial incentive to encourage non-medical switching if cheaper products are on the market. In patients with chronic inflammatory rheumatic diseases (CIRD), we have previously reported a relatively high retention rate after switching from originator anti-TNF to its biosimilar. However, this has been different in other studies and the reasons for non-adherence are poorly understood. Comorbidity has recently gained much attention in patients with CIRD and might be a reason for non-adherence.

Objectives: The aim of this study was to analyse the effectiveness and safety of systematic non-medical switching from originator adalimumab (ADA) to ADA ABP501 biosimilar (ABP) over 6 months in patients with CIRD and to investigate the influence of comorbidities on retention rates.

Methods: Patients with CIRD on originator ADA who switched to ABP subsequently from October 2018 onwards were identified from a large routine database and then followed for 6 months. The presence of comorbidities and disease characteristics as well as measures of disease activity, physical function and changes in treatment were documented at baseline (the time of switching from originator ADA to ABP), and at months 3 and 6. Longitudinal data including information on the clinical efficacy and safety of ABP, and the reasons for discontinuation were documented.

Results: A total of 111 CIRD patients on treatment with originator ADA were switched to the biosimilar ABP (Table 1). More than half of the patients (53%) had a Charlson comorbidity score of 0, and had the highest mean Charlson score (1.8). Treatment retention varied only slightly between patients with a Charlson score of 0 and those with ≥0 (Figure 1). In both groups, the majority of patients (90% vs 95%) continued therapy with ABP, while only a small proportion either switched back to originator ADA (6% vs 5%), switched to a different biologic (3% vs 0%), or dropped out (1% vs 0%). The main reason for back switch was the occurrence of adverse events, mostly subjective complaints, most frequently pain. Patients with a Charlson comorbidity score > 0 tended to have poorer scores in trajectories of scores for disease activity and physical function stratified by disease subtype.

</table>

Duration originator ADA therapy (months), mean (SD): 43.8 (28.6) 39.4 (26.9) 34.7 (29.0) 60.0 (27.7)

Gastroenterological comorbidities: 21.2% (5) 7.4% (5) 26.7% (4) 40.0% (2)

Hepatic comorbidities: 17.4% (4) 2.9% (2) 13.3% (2) 0

Neurological and psychological comorbidities: 8.7% (2) 17.6% (12) 33.3% (5) 0

Metabolic comorbidities: 21.7% (5) 7.4% (5) 26.7% (4) 40.0% (2)

Osteoporosis: 43.5% (10) 11.9% (8) 6.7% (1) 20.0% (1)

Skin diseases: 21.7% (5) 8.8% (6) 0 40.0% (2)

Eye diseases: 8.7% (2) 23.5% (16) 33.3% (6) 0

Kidney diseases: 13.0% (3) 10.3% (7) 0 40.0% (2)

Conclusion: Comorbidity had no influence on the biosimilar retention rate after 6 months in this study but the majority of patients did not have Charlson scores > 4. However, disease activity and physical function tended to be worse among CIRD patients with comorbidity. Cardiovascular disease and osteoporosis were more often present in RA patients than in axSpA or PsA patients, while neurological and psychological comorbidities were more often observed in the latter.

Background: The beginning of the COVID-19 pandemic led to a collapse of healthcare systems that was difficult to manage.

Methods: REUMAVID is an international cross-sectional study collecting data through an online survey on RMD patients in seven European countries led by the Health & Territory Research group of the University of Seville, together with a multidisciplinary team including patient representatives, rheumatologists, and health researchers. Data were collected in two phases, the first (P1) between April-July 2020 and the second (P2) between February-April 2021.

Demographics, health behaviours, employment status, access to healthcare services, disease characteristics, WHO-5 Well-Being Index and Hospital Anxiety and Depression Scale (HADS) were collected in the survey. Healthcare utilization includes scheduled appointments and attendance at the rheumatologist consultation of possible treatment effects if COVID-19 is contracted with the rheumatologist, primary health care and psychological care. Descriptive analysis and Mann-Whitney test was used to explore association with healthcare utilization in both phases of REUMAVID.

Results: There were a total of 2,002 participants across both phases with comparable demographic characteristics (mean age 52.6 (P1) vs. 55.0 years (P2); 80.2% female (P1) vs 83.7% (P2); 69.6% married (P1) vs 68.3% (P2); 48.6% university educated (P1) vs 47.8% (P2)). Most prevalent RMD was axial spondyloarthritis in P1 (37.2%), and rheumatoid arthritis in P2 (53.1%). Only 39.2% could have a scheduled appointment with their rheumatologist during P1, compared to 72.5% of patients in P2 (p<0.001). In this sense, only 41.6% of participants in the P1 attended such an appointment while in P2 this figure was 61.5% (p<0.001). The majority of patients (83%) had their scheduled face-to-face appointment changed to an online or telephone phone in the P2, although this proportion was lower in the P1 (54.4%). The most frequent reason for canceling the face-to-face appointment was the alternative of making it by phone or online (54.4% in P1 vs. 83.0% in P2, p<0.001). Although, in P1, 38.1% of participants could contact with their rheumatologist by phone or online, this proportion was 64.3% in P2 (p<0.001). In P1, 64.0% of patients were able to consult with their rheumatologist about the possible effects of treatment in case of contracting COVID-19 (vs. 41.2% in P2; p<0.001). With respect to general practitioners, 57.8% of patients in P1 declared to had accessed primary care or general practitioner (vs. 77.5% in P2; p<0.001). Furthermore, in P2, a higher proportion of participants (83.2%) were able to continue their psychological or psychiatric therapy either online or by phone (vs. 48.3% in P1; p<0.001; Figure 1)

Conclusion: During the first year of COVID-19 pandemic, RMD patients had easier access to the healthcare system, specifically to their rheumatologist. This access was improved through phone and online care. In addition, access to primary care as well as psychological care improved during the second year of pandemic.

Acknowledgements: This study was supported by Novartis Pharma AG. Background: Patients with chronic inflammatory rheumatic diseases (CIRD) remain underrepresented in receiving vaccinations despite being disproportionately affected by infectious complications.

Objectives: To systematically review the literature regarding vaccination willingness and vaccination hesitancy in CIRD patients with focus on the perspective of patients and physicians.

Methods: A scoping review was conducted in PUBMED, EMBASE and the Cochrane Library through 2021. Study selection was performed by two independent reviewers, data were extracted using a standardized form and risk of bias was assessed using instruments from the McMaster University. Identified barriers and hurdles were synthesized by categorizing them into the WHO’s Measuring Behavioural and Social Drivers of Vaccination (BeSD) conceptual model.

Results: The search yielded 1,644 hits, of which 30 were included (cross-sectional studies (n=27) based on interviews and 3 intervention studies). The majority of studies reported barriers to influenza and pneumococcal vaccination (n=27) based on interviews and 3 intervention studies). The majority of studies reported barriers to influenza and pneumococcal vaccination (n=27) based on interviews and 3 intervention studies). The majority of studies reported barriers to influenza and pneumococcal vaccination (n=27) based on interviews and 3 intervention studies).

Conclusion: Missed doctor-patient appointments were associated with missed diagnoses and interruptions of ongoing treatments. Fear of the virus immobilisation due to home office and curfews, lack of exercise, sun exposure, caused depressive symptoms, increased alcohol consumption and caloric intake are all increase the risk of osteoporosis. Thus, traditional risk factors for osteoporosis expanded with the direct effects and the introduced restrictions because of the pandemic.

Methods: Retrospective, observational study of all e-Consults carried out during 2021 in the hospital area Virgen Macarena, which includes 47 PHC centres. E-Consults were carried out by the tool “Plataforma de Teleconsultas del Servicio Andaluz de Salud” (teleconsultation platform of the Andalusian health service) as a clinical extension of the research project E-Hermes for the implementation of e-Consults. It collects information about the reason for the consultation, the suspected diagnosis of the rheumatologist, the response time of the TC and whether the consultation is completely resolved online (DISCHARGE), whether on-site consultation is required (CONSULTATION) or whether the patient needs further e-Consults in order to obtain more medical tests or to evaluate the treatment (FOLLOW-UP). The e-Consults of 2021 were compared to those of the previous year.

Results: Of the 733 e-Consults examined, 610 (83.2%) were fully resolved online and 123 (16.8%) required on-site consultation. Of those fully resolved online, 544 (89.2%) were resolved in the first consultation and 66 (11.8%) required more than one e-Consult. The most common reasons for consultation in this group of e-Consults were: suspected diagnoses of osteoporosis (19.1%), polyarthralgia (14.4%), questions about follow-up patients in Rheumatology (9.4%), joint swelling (7%), hand pain (6.8%) and questions about laboratory or imaging tests (3.9%). For 28% of patients, a rheumatic disease could be excluded, and for those patients who were diagnosed with a rheumatic disease, the most frequent diagnosis was: osteoarthritis 17.3%, osteoporosis 14.4%, fibromyalgia 8.3% and gout 3%. Of the patients that were recalled for an on-site evaluation, in 101 of the cases (90%) this decision was taken after the first e-Consults, while 11 patients (10%) were recalled after subsequent e-Consults. Among the patients recalled for an on-site visit, the most common reason was joint inflammation (23.4%), followed by polyarthralgia (22.1%), osteoporosis (18.2%) and hand pain (7.8%). The most frequent suspected diagnosis was inflammatory rheumatic disease (RA, PsA, SPA) in 49.4% of cases, followed by osteoporosis (24.4%). The average response time of the e-Consults was 82 hours (3 days and 10 hours) Compared to the e-Consults in 2020, it increased by 34%, 186 e-Consults more. The number of cases resolved without on-site consultation was 29% higher than in the previous year, while the e-Consults that required follow-up decreased by 7% and the number of patients that required further on-site consultation also decreased by 11%. The reasons for the consultation and suspected diagnosis were similar in both years.

Conclusion: E-Consults have proved efficacious, avoiding the necessity for on-site consultations in more than 80% of the patients. E-Consults helps to reduce on-site referrals to Rheumatology. E-Consults is effective in reducing waiting times before obtaining an evaluation from the rheumatologist and in prioritizing those patients who need on-site consultation. There are certain pathologies that are especially amenable to resolution with- and in prioritizing those patients who need on-site consultation. There- ing waiting times before obtaining an evaluation from the rheumatologist reduce on-site referrals to Rheumatology. E-Consults is effective in reducing (24,4%) The average response time of the e-Consults was 82 hours (3 days and 10 hours) Compared to the e-Consults in 2020, it increased by 34%, 186 e-Consults more. The number of cases resolved without on-site consultation was 29% higher than in the previous year, while the e-Consults that required follow-up decreased by 7% and the number of patients that required further on-site consultation also decreased by 11%. The reasons for the consultation and suspected diagnosis were similar in both years.

Conclusion: E-Consults has proved efficacious, avoiding the necessity for on-site consultations in more than 80% of the patients. E-Consults helps to reduce on-site referrals to Rheumatology. E-Consults is effective in reducing waiting times before obtaining an evaluation from the rheumatologist and in prioritizing those patients who need on-site consultation. There are certain pathologies that are especially amenable to resolution without on-site consultation, like osteoarthritis, osteoporosis and fibromyalgia. Over time, e-Consults is being integrated in the clinical practice of both the primary care physician and the rheumatologist and is becoming ever more efficient.

THE USEFULNESS OF TELEMEDICINE IN RHEUMATOLOGY: POINTS OF VIEW OF PRACTITIONERS AND PATIENTS

M. Yasmine1, D. Ben Nessim1, H. Ferjani1, W. Hamdi1, K. Maatallah1, D. Kaffel1, M. Yasmine1, D. Ben Nessib1, H. Ferjani1, W. Hamdi1, K. Maatallah1, D. Kaffel1, M. Yasmine1, D. Ben Nessib1, H. Ferjani1, W. Hamdi1, K. Maatallah1, D. Kaffel1, M. Yasmine1, D. Ben Nessib1, H. Ferjani1

Background: The advent of COVID-19 has allowed a rapid expansion of telemedicine (TM) and its implementation in various specialties. Despite this extensive use of TM, its role in rheumatology is conflicting and much remains unknown about TM’s acceptability and efficiency in rheumatology.

Objectives: Our study aimed to evaluate rheumatologists’ and patients’ willingness for TM and factors helping to adopt this alternative.

Methods: We conducted a cross-sectional study including patients attending our rheumatology department as well as rheumatologists. Patients were contacted by phone and rheumatologists were invited to answer a questionnaire via Google Form. We evaluated their points of view and suitability for TM by inquiring about their experience with tele-rheumatology, information technology supports, personal barriers to telemedicine, and reasons for adopting this alternative. Moreover, additional questions probed the clinician’s perception of the appropriate clinical context for TM application as well as the corresponding legislation.

Results: Overall, 135 responses were collected including 60 rheumatologists and 75 patients. The distribution of diagnosis was as follows: rheumatoid arthritis (RA) (n=15), spondyloarthritis (SpA) (n=20), juvenile idiopathic arthritis (n=23), and osteoarthritis (n=17). Of the rheumatologists, 76.2% were aged between 30 and 50 years old, 79.3% reported working at an academic center, and the majority were physician-level practitioners (71.2%), working for more than 5 years (81%). Afforid electronic devices were as follows: laptop (87.9%), smartphone (70.7%), afforded headset microphone (24.1%), camera (29.3%) for doctors. Forty-six percent of the rheumatologists estimate that they have a good internet connexion, 62.7% had an appropriate place for teleconsultation. Nearly, 40.7% of the rheumatologists were familiar with the concept of TM but only 39% reported experience with TM. Willingness to accept this model of care for rheumatologists and patients was found in 78% and 37.3% respectively. According to the doctors, the benefits of TM encompassed tele-training (61.7%), remote medical monitoring (61.7%) especially during the COVID-19 (70.2%), benefits for patients (74.5%), reduced inequalities in access to healthcare (46.8%), and improved quality of care (29.8%). The main barriers to TM were the lack of clear legislation (47.8%) and financial compensation (17.4%). Clinicians and patients identified common barriers to effective tele-rheumatology as the inability to perform a physical exam (91.3% vs 33.3%), the fear of trivializing the disease (34.8% vs 36%), and the lack of resources and infrastructures (43.5% vs 29.3%). The majority of the doctors (86.2%) expressed their willingness to attend training workshops. Reported areas to apply TM according to the doctors were mainly osteoarthritis (76.3%) and rheumatic diseases (64.4%), but also pediatric rheumatology (28.8%) and undiagnosed new patients (3.4%). Regarding legislation, most of practitioners estimated that it should be selective with specific authorizations (42.4%) or relaxed with the possibility of derogation (32.2%). Twenty-two percent of them reported that legislation should be strict with the possibility of sanctions, whereas a minority (3.4%) opted for a free practice without regulation at all. Factors associated with adherence to TM were age<40 years (p=0.036) for doctors and familiarity with the concept (p=0.006) and electronic devices afforded (p<0.001) for the patients.

Conclusion: Findings from this study showed the reluctance of the patients to adhere to TM compared to doctors. Concerns and risks may lessen for both sides, once remote consultations are applied. Nevertheless, patient education is required for the success of TM application.

TELERHEUMATOLOGY FOR IMPROVING FIRST ACCESS TO THE OUTPATIENT CLINIC: A PILOT PROSPECTIVE MONOCENTRIC ITALIAN STUDY

E. Giacobba1, M. C. Geradini2, N. Ughi1, A. Adinolfi1, M. Alqoudah1, L. Belloli2, C. Casu1, M. Di Cicco1, D. A. Filipponi1, C. Gagliardi1, M. Muscarà1, E. Verduri2, O. M. Epis1, Ospedale Maggiore - Niguarda, Rheumatology Unit, Milan, Italy; 2The Hashemite University, Internal Medicine, Zarqa, Jordan

Background: The COVID-19 public health emergency has amplified both the potential value and the challenges with healthcare providers deploying telehealth solutions. Furthermore, outpatients may wait up to several months for their first
appointment with specialists including rheumatologists for diseases other than COVID-19. In Italy it is now possible to get access to telemedicine services within the national healthcare systems, yet only follow-up visits are allowed for reimbursement purposes. Instead, it is not clear the role of telemedicine as a tool for improving first access and patient acceptance of this innovation.

Objectives: To investigate the feasibility of a ‘teletriagerheum’ service before the first visit and to identify potential benefits and disadvantages of it by comparing first face-to-face visit preceded by ‘teletriagerheum’ service to regular first visit without it.

Methods: A pilot prospective monocentric study was conducted. Consecutive patients were contacted by phone 30 days before the scheduled rheumatological first visit by administrative staff to investigate their willingness to receive 20 days before the first visit a phone call (‘teletriagerheum’ service) by a physician of the Rheumatology Unit. The ‘teletriagerheum’ service aimed at investigating the reason for the visit and at prescribing additional exams or specialist consultations before the face-to-face first visit to facilitate the diagnosis process or anticipate the appointment in case of urgency. Socio-demographic characteristics, reason for referral, face-to-face visit duration, number of additional exams prescribed, number of definite diagnosis at first visit in the ‘teletriagerheum’ group were compared to the ones receiving regular first visit without ‘teletriagerheum’ service.

Results: In October 2021 a total of 102 patients were phone called by administrative staff: 18 (17.6%) did not answer for a maximum of three times, 9 (8.8%) responded but refused the ‘teletriagerheum’ service (6 cancelled the visit, 1 postponed, 2 for unknown reason) and 75 (73.5%) accepted the service, but 21 were not real first visits and 8 patients did not answer the call of physician. Among the remaining 46 (45.1%) pts (the ‘teletriagerheum’ service) by a physician of the Rheumatology Unit. The ‘teletriagerheum’ service aimed at investigating the reason for the visit and at prescribing additional exams or specialist consultations before the face-to-face first visit to facilitate the diagnosis process or anticipate the appointment in case of urgency. Socio-demographic characteristics, reason for referral, face-to-face visit duration, number of additional exams prescribed, number of definite diagnosis at first visit in the ‘teletriagerheum’ group were compared to the ones receiving regular first visit without ‘teletriagerheum’ service.

AB1407 TELEREUMATOLOGY AND WORKING VISIT: INITIAL MONOCENTRIC EXPERIENCE ON USE OF TELEVISION IN THE REGULAR FOLLOW-UP.

F. Cianci1, A. Olga1, M. Magnani1, F. Pignataro1, F. Massimo2, M. Reta1. 1AUSL Bologna, Rheumatology and Internal Medicine, Bologna, Italy; 2Catholic University, ALTEMS, Roma, Italy

Background: The COVID-19 pandemic shifted most healthcare to remote delivery methods (telehealth technologies including clinical video teleserv) to protect patients, clinicians, and hospital staff. Telehaematology visits were found to be noninferior to in-person visits and are often more time and cost effective for patients.

Objectives: Description of an initial integration of video teleserv in regular follow-up.

Methods: In cooperation with the ALTEMS Operational Telemedicine Observatory, we built a procedural manual for teleserv, whose phases were as much as possible similar to the usual visit scenario. Patients in remission or in mild disease activity at the time of enrolling visit were involved. Clinical characteristics, treatments and teleserv’s features were considered for all patients (Table 1). Patient overall satisfaction was evaluated (rating 1 to 5).

Results: 86 televisits were performed in 74 consecutive patients, with a mean age of 46.2±13.5 years, diagnosed with the most common rheumatic diseases and on chronic immunosuppressive therapy (c-b-ts DMARDs mono or combination therapy). In 5 cases, in-person visit after televisit was required. The average duration of the televisit was 17±3.5 minutes and the average overall satisfaction was 4.68/5. The average distance saved (round trip) was 775 km, equal to an avoided travel time of 66 minutes and with a total reduction in CO2 production of approximately 866 kg. 5 patients performed video visit from workplace, de facto inventing the “working visit”.

Conclusion: Telemedicine is going to become an essential element of clinical practice in rheumatology, especially for active, young, and working patients, and on chronic immunosuppressive therapy (c-b-ts DMARDs mono or combination therapy). In 5 cases, in-person visit after televisit was required. The average duration of the televisit was 17±3.5 minutes and the average overall satisfaction was 4.68/5. The average distance saved (round trip) was 775 km, equal to an avoided travel time of 66 minutes and with a total reduction in CO2 production of approximately 866 kg. 5 patients performed video visit from workplace, de facto inventing the “working visit”.

AB1408 WELL-BEING AND MENTAL HEALTH OF RHEUMATOLOGY AND FAMILY MEDICINE RESIDENTS

M. Ketata1, S. Miladi1, A. Fazaa1, H. Boussa21, L. Souabni1, K. Ouenniche2, S. Kassab1, S. Chekili1, K. Ben Abdelghani1, A. Laatar1. 1Mongi Slim Hospital, Department of Rheumatology, La Marsa, Tunisia

Background: Burnouts and poor well-being among medical residents are becoming a global concern for health institutions. Its negative consequences are far-reaching, affecting patients, coworkers, family members, and healthcare organizations as well as the burned-out resident.

Objectives: The aim of the study was to measure the extent of burnout among rheumatology and family medicine residents and to elucidate wellness status as well as barriers to wellness.

Methods: An online questionnaire was issued to rheumatology and family medicine residents. We collected sociodemographic data (Age group, gender, marital status, children, smoking and alcohol status, Sport and other activities, Specialty, Weekly working Hours, Vacation) and mental health measurements. Participants were far-reaching, affecting patients, coworkers, family members, and healthcare organizations as well as the burned-out resident.

Disclosure of Interests: None declared

REFERENCES:

ALTEMS = Alfa Scuola di Economia e Management dei Sistemi Sanitari
four percent (34%) of responders practiced sports 2 to 4 times a year and 25% exercised 2 to 4 times a week. The average working hours per week was 30 hours [10-70] with an average of 3.38 weeks’ vacation per year. Seven percent (7%) of residents worked overnight shifts in hospitals with an average of 1.83 shift per month. Female sex (p=0.049), less physical activities (p=0.037) and long working hours (p=0.042) were associated with worst degree of quality of life (WHOQOL Well-Being Index). Residents who practice art and had fewer overnight shifts showed a significantly flourishing mental health (p=0.032, p=0.014) according to the MHC-SF. Family medicine residents, those new EIA who are seen outside hospitals (p=0.039) and overnight shifts (p=0.047) than rheumatology residents.

**Conclusion:** Residents working more than 50 hours per week with more than 5 overnight shifts per month and those practicing fewer physical activities and art appear to be at high risk of developing languishing mental health according to the WHO’s well-being index and the MHC-SF score. It is important to protect healthcare workers and to promote well-being to acquire a flourishing mental health.

**AB1409 EVALUATING HOW EFFECTIVELY PATIENTS WITH A NEW INFLAMMATORY ARTHRITIS ARE BEING TRIAGED INTO THE APPROPRIATE CLINIC AT A TERTIARY CARE HOSPITAL IN THE UK: A RETROSPECTIVE STUDY**

A. Vivekanantham1,2, M. Ashraf2, A. Soni1,2, University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom;1Oxford University Hospitals, Nuffield Orthopaedic Centre, Oxford, United Kingdom

**Background:** Inflammatory arthritis is associated with significant morbidity and costs to the NHS, social care, and wider economy. Early diagnosis and treatment are essential to reduce the impact of the disease. Therefore, it is important that referrals for a new inflammatory arthritis are appropriately triaged to be seen in the early inflammatory arthritis (EIA) clinic so that they can be seen and started on disease modifying anti-rheumatoid drugs (DMARDs) without delay. The British Society of Rheumatology guidance for inflammatory arthritis states that patients must be seen within three weeks of referral and started on DMARDs within six weeks.

**Objectives:** To evaluate how effectively people referred with a new EIA are currently being triaged. To evaluate whether we are meeting the national standards.

**Methods:** We performed a retrospective review of the medical notes of all new patients who were seen in the EIA clinic from 01/09/21-31/11/21. During this same time period, we will also reviewed all the patients who had been newly diagnosed and started on a DMARD in the other Rheumatology clinics (e.g., general rheumatology, vasculitis). We collected data on referral date, referral source (e.g., GP), date of clinic assessment, clinic type (e.g., EIA clinic or other Rheumatology clinic), diagnoses made, days’ wait from referral to assessment and days’ wait from referral to commencing DMARD. We then calculated the conversion rate (percentage of referrals triaged to the EIA clinic that have an EIA) and detection rate (percentage of new EIA patients that are seen in the EIA clinic (as opposed to in non-urgent clinics)). The standard for conversation rate (CR) was 50% and for detection rate (DR) was 95%.

**Results:** Of all the patients seen in the EIA clinic (n=73), 36 had a new diagnosis of an EIA, giving a CR of 49%. Of all the new diagnoses of EIA made during that time-period (n=53), 36 were appropriately triaged to be seen in the EIA clinic, giving a detection rate 68%. Those new referrals who had been appropriately seen in the EIA clinic had an average of 5 weeks wait from referral to assessment/ commencement of DMARD. In contrast, those new referrals who had been seen in other clinics had an average of 10 weeks for referral to assessment/ commencement of DMARD. A previous audit performed before the COVID-19 pandemic (01/11/19- 01/01/20) showed a CR of 25% (115 patients seen in EIA clinic, 29 new diagnoses) and a DR of 69% (29 new diagnoses, 20 seen in EIA clinic).

**Conclusion:** Those patients with a new EIA who are appropriately seen in the EIA clinic do not meet the national guidance for being seen within three weeks of referral but do meet the guidance for starting a DMARD within six weeks. However, those new EIA who are seen outside the EIA clinic do not meet either of these standards, with a delay of 10 weeks to be seen/ started on a DMARD. Given that only 68% of people with a new EIA are being correctly triaged to be seen in the EIA clinics, it highlights that there is a need for an improvement in the triage process (currently being done manually by Rheumatologists). Interestingly, when comparing our findings to the audit done pre-COVID-19 pandemic, the CR has improved whilst the DR has stayed steady. The next steps include exploring using additional data collected from patients electronically to improve the CR/ DR rates, as well as artificial intelligence informed modelling of patient referrals.

AB1411 JOINT RHEUMA-DERMA CLINIC: FOUR YEARS OF EXPERIENCE AT THE SAN MARCO HOSPITAL IN CATANIA

R. Fotì,1 G. Giulfrida,2 A. Ramondetta,2 E. Vissali,1 G. Amato1, Y. Dal Bosco,1 F. De Lucia,1 R. Fotì,1 R. De Pasquale3.1 AO Policlinico San Marco, Rheumatology Unit, Catania, Italy; 2 AO Policlinico San Marco, Dermatology Unit, Catania, Italy

Background: Psoriatic arthritis (PsA) affects up to one-third of patients with psoriasis. Many recent works in literature have underlined that the percentage of undiagnosed PsA is still high. A direct collaboration between dermatologists and rheumatologists allows a better management of these patients, to reduce the risk of joint damage, disability, and comorbidities.

Objectives: The aim of this study is to highlight the benefits of a Rheuma-Derma clinic and a shared approach, focused to an early diagnosis and prompt therapeutic strategy for PsA.

Methods: Patients with psoriasis complaining joint symptoms or rheumatologic patients with cutaneous involvement, were simultaneously assessed by a dermatologist and a rheumatologist. The collected data included demographic, clinical characteristics as joint patterns (axial/peripheral), clinimetric index evaluated (DAS28, HAQ, BASDAI, DAPSA, PASI, PGA) family history of psoriasis or PsA, BMI (Mass Body Index), psoriasis, comorbidities and Charlon Comorbidity Index (CCI) assesses comorbidity level by taking into account the number, the severity of the disease, type of treatment and frequency of complications were found between these two groups. In more detail, SSc is associated intestinal lung disease was complicated by vascular damage, autoimmunity, and fibrosis. In these patients, a tight follow-up is crucial to verify the specific cases and clinical needs. In particular, the infection risk in SSc might also be related not only to disease activity but also to possible flares due to therapy discontinuation. Telemedicine has demonstrated as a valid alternative to improve the quality of rheumatic patients' care during COVID-19 pandemic, thus reducing hospitalizations only to urgent admissions (2).

Results: In december 2020 the Azienda Policlincio Vanvitelli approved telemedicine by IRPLUS platform as a particular measure in the face of the COVID-19 pandemic. In this study we examined the impact of the COVID-19 pandemic on visit status of SSc patients at our centre and the patient benefits of telemedicine. Methods: In this study, we retrospectively enrolled 480 SSc patients who visited in our centre between January and December 2021. Of the patients included in the study, 198 patients (18 males and 180 females) used telemedicine, while 282 patients (20 males and 262 females) did not use it.

Results: During televisits, we assessed possible contacts with COVID-19 patients and/or potential risk of COVID-19, investigating about the occurrence of typical symptoms in the last 15 days. No significant differences in background data, such as the severity of the disease, type of treatment and frequency of complications were found between these two groups. In more detail, SSc is associated intestinal lung disease was complicated by vascular damage, autoimmunity, and fibrosis. In these patients, a tight follow-up is crucial to verify the specific cases and clinical needs. In particular, the infection risk in SSc might also be related not only to disease activity but also to possible flares due to therapy discontinuation. Telemedicine has demonstrated as a valid alternative to improve the quality of rheumatic patients' care during COVID-19 pandemic, thus reducing hospitalizations only to urgent admissions (2).

Conclusion: In conclusion, the diagnosis of an Early PsA is essential, as an early treatment and management can alter the natural course of PsA and prevent irreversible joint damage. Our experience proved the increased number of patients since the Rheuma-Derma Clinic have started, such as an increased number of patients under treatment, leading to a significant improvement in the quality of life of PsA and Pso patients.

AB1412 IMPORTANCE OF TELEMEDICINE IN THE SYSTEMIC SCLEROSIS DURING COVID-19 PANDEMIC

G. Cuomo1, C. Di Vico2, F. Masini3, C. Iandoli4, D. Perretta1, R. Iraco5.1 Università degli Studi della Campania, Precisione di Medicine, Naples, Italy

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), also called COVID-19 disease, was firstly reported in December 2019 in China and soon declared a pandemic by the World Health Organization (WHO) on March 11, 2020 (1). As a result, patients’ visits to medical facilities are affected. Systemic sclerosis (SSc) is a chronic systemic autoimmune disease characterized by vascular damage, autoimmunity, and fibrosis. In these patients, a tight follow-up is crucial to verify the specific cases and clinical needs. In particular, the infection risk in SSc might also be related not only to disease activity but also to possible flares due to therapy discontinuation. Telemedicine has demonstrated as a valid alternative to improve the quality of rheumatic patients' care during COVID-19 pandemic, thus reducing hospitalizations only to urgent admissions (2).

Methods: In this study, we retrospectively enrolled 480 SSc patients who visited in our centre between January and December 2021. Of the patients included in the study, 198 patients (18 males and 180 females) used telemedicine, while 282 patients (20 males and 262 females) did not use it.

Results: During televisits, we assessed possible contacts with COVID-19 patients and/or potential risk of COVID-19, investigating about the occurrence of typical symptoms in the last 15 days. No significant differences in background data, such as the severity of the disease, type of treatment and frequency of complications were found between these two groups. In more detail, SSc is associated intestinal lung disease was complicated by vascular damage, autoimmunity, and fibrosis. Background: The prescription of glucocorticoids at the diagnosis of rheumatoid arthritis (RA) is no longer systematically recommended because of the difficulty of withdrawal and the occurrence of adverse effects. The expert groups currently insist on a short duration of corticosteroids to obtain a low cumulative dose (1, 2). The real-life applicability of the current recommendations may be difficult to achieve (3).

Methods: We conducted a descriptive cross-sectional study of practice conducted with the Moroccan rheumatologists belonging to public and private sectors according to a questionnaire established on a declarative and anonymous mode. The questionnaire was validated by a committee of experts before submitting them to rheumatologists and consisted of 24 single or multiple-choice questions. These questions were divided into 5 items: general data (3 questions), initiation of corticosteroid therapy at diagnosis (7 questions), withdrawal modalities and problems of withdrawal (8 questions), self-medication and patient information (6 questions). The elaboration of the questionnaire was done in “Google Forms” then the collected data were analyzed with the Microsoft office software Excel 2013.

Results: A total of 100 Moroccan rheumatologists responded to the questionnaire. In the initial treatment of RA, 14% of the rheumatologists reported starting corticosteroid therapy in all patients, 41% in two-thirds of their patients, 23% in one-third, 20% in half and 2% in none. The initial oral dose of prednisone or equivalent was 7.5 to 10 mg/day for 52% of rheumatologists and between 5 and 7.5 mg/day for 38%. Flare-up of activity and accompanying conventional treatment were the two first indications for initiation of corticosteroid therapy. 46% of rheumatologists considered weaning after 3 to 6 months of treatment, 26% between 6 months and one year, 23% in less than 3 months and 5% in more than one year. 35% achieve withdrawal in two thirds of their patients. The main problems encountered during withdrawal are self-medication and rebound of the disease. 96% of rheumatologists were in favour of introducing therapeutic education sessions using different tools adapted to the context of the patient and the disease.

Conclusion: The prescription of corticosteroids in RA must be based on the evaluation of the risk-benefit balance. A collaboration between rheumatologist and patient is necessary to prevent the risk of toxicity of corticosteroids and to achieve the goal of withdrawing them.

<tr>
<td>Clinical test</td>
<td>$15</td>
<td>$16</td>
</tr>
<tr>
<td>Clinical laboratory</td>
<td>$10</td>
<td>$11</td>
</tr>
</tbody>
</table>

Note: The mean cost for medical consultations and ultrasounds per trimester was $184-277 USD. The average cost of immune test and general lab test ranges from $424-428 USD. The total cost per trimester was from $608 to 705 USD, and the direct cost per three trimesters was $1824-2115 USD.

The average family income per month was $614.23 USD and the average health expenditure per month was 105.71 USD; which represents 16.21% of the family income. The average family health expenditure per trimester was $371.13 USD.

Conclusion: The total cost for prenatal care per trimester was calculated in $608 to 705 USD. The cost of prenatal care per trimester is 193.69% higher than the average health expenditure per trimester for uninsured women with ARDs. More and new strategies are needed to solve and reduce inequalities in access to health.
AB1415 GENDER EQUITY IN RHEUMATOLOGY IN GERMANY, WHERE DO WE STAND? – PRELIMINARY RESULTS FROM A NATIONWIDE ONLINE SURVEY AMONG RHEUMATOLOGISTS IN GERMANY

J. Mucke1,2, X. Basalikakos1,2, E. Feist1,4, D. Gundelach2,3, I. Haase1,2, B. Hoyer1,2, M. Koehn1,2, M. Krusche2,8, C. Mentzel1,2, P. Sewerin1,2, A. Voormann1,2, S. Ohrndorf1,2, University Clinic Düsseldorf, Policlinic for Rheumatology, Düsseldorf, Germany; Commission for Gender Equity in Rheumatology, German Society for Rheumatology, Berlin, Germany; Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Bochum, Germany; HELIOS Clinic Vogelsang-Gommern, Department of Rheumatology and Immunology, Gommern, Germany; German Society for Rheumatology, Berlin, Germany; University Clinic Schleswig-Holstein, Rheumatology and Clinical Immunology, Campus Kiel, Kiel, Germany; Fraunhofer IME-TMP, Clinical Research, Frankfurt, Germany; Universitätssklinikum Hamburg-Eppendorf, Center for Internal Medicine and Rheumatology, Hamburg, Germany; Charité, Department of Rheumatology and Clinical Immunology, Berlin, Germany

Background: Despite the increasing number of female medical students and fellows, women are still underrepresented in higher career and academic positions in rheumatology [1].

Objectives: To assess gender distribution in rheumatology in Germany and to analyze potential hurdles of flexible work opportunities with the overall aim to improve gender equity in future German rheumatology.

Methods: A web-based anonymous survey using QuestionPro was distributed among rheumatologists in Germany via newsletters, social media, and personal contacts (12/2021-01/2022). The survey was developed based on a narrative literature review [1] and discussions among the commission members. It was composed of 29 questions, with single or multiple answers and/or free text. Non-demographic questions could be answered with “I do not know”.

Results: Among the total of 170 respondents who fully completed the survey, 72% were female, 28% were male and 1% was third gender. 73% were employed at a clinic and 27% in academic institution with 79% working at an academic institution and 20% at a non-academic clinic. 1% did not specify their institution. Of those working at a clinic, 48% were rheumatologists and 7% were head of rheumatology departments. Regarding the gender-ratio in different hierarchical levels, only 17% reported more male than female rheumatologists in training at their workplace, in 32% the gender ratio was balanced. On higher levels, respondents reported more male than female rheumatologists at staff level in 44% (29% balanced) and in leading positions in 74% (12% balanced). 53% of female respondents were responsible for >50% of family and housework, compared to 11% of the male respondents. Most men covered 50% (49% of male respondents) or less than 50% (32% of male respondents) of family work. There were coworkers in part time in the work environment of 86% of respondents, with only women working part time in 56% of cases, both women and men in part time in 29% and only men in part time in 1%. Most respondents stated that men and women working part time did not have the same opportunities as coworkers working full time. (Table 1)

Table 1. Opportunities for advancements of part time working employees compared to full time coworkers with similar qualification in percent of all respondents.

<table>
<thead>
<tr>
<th></th>
<th>Yes</th>
<th>No</th>
<th>I do not know</th>
</tr>
</thead>
<tbody>
<tr>
<td>Women</td>
<td>23%</td>
<td>65%</td>
<td>12%</td>
</tr>
<tr>
<td>Men</td>
<td>21%</td>
<td>54%</td>
<td>25%</td>
</tr>
</tbody>
</table>

Many respondents perceived a preference of either gender despite equal performance regarding different aspects with men more often perceived as preferred in terms of opportunities for advancements and staffing of positions. (Figure 1)

Figure 1. Perceived preference of employees in rheumatology with regards to opportunities for advancements, staffing of positions, allocation of research projects and salary according to gender by female and male survey-respondents. Perceived discrimination was not assessed.

66% of respondents agreed that activities to improve gender equity are necessary. The highest need was seen in the improvement of compatibility of care and work with adequate part time models, childcare options at work, and the higher acceptancy of part time working men and women by employers and persons in higher positions (freetext).

Conclusion: Gender imbalance is prevalent in rheumatology in Germany with lower numbers of women at higher hierarchical levels. Traditional role allocation is still common with a higher frequency of part time working females. Part time employment is perceived to decrease chances of advancement. The focus should be on promoting flexible job-sharing models, part time work among men and gender equity not only at work but also in private life (“care work”). Preference for one gender over the other is perceived differently between women and men.

AB1416 WHAT IS THE FULL ECONOMIC COST OF DELAYED DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS IN THE UK?

G. Xydopoulos1, S. Howard Wilsher1, F. Zangheli1, O. Afolabi1, M. Mishra1, R. Fordham1. University of East Anglia, Norwich School of Medicine, Norwich, United Kingdom

Background: Axial Spondyloarthritis (AS) is an umbrella term for both inflammatory conditions known as Ankylosing Spondylitis and Non-radiographic Axial Spondyloarthritis. AS generally develops in younger people. Symptoms typically start in the late teenage years to early twenties (with the average age of onset being 24). Hence this condition has a life-long impact, which could increase if left untreated. Average delay to diagnosis is over eight years after the appearance of symptoms. There are currently 220,000 people in the UK living with this painful and progressive form of inflammatory arthritis. While people wait for a diagnosis, many withdraw from socialising and find it harder to establish careers, form relationships, and start families. In addition to healthcare costs, that include multiple visits to GPs, prescription of unnecessary medication and extensive use of over the counter painkillers, there are intangible costs that have large impacts on patients and society. For example, quality of life for the patient, their earning and saving for retirement capacity, social care costs.
AB1417
CORRELATION BETWEEN THE ATTITUDE OF PATIENTS SUFFERING FROM RHEUMATIC DISEASES TOWARDS REMOTE CONSULTATIONS BY RHEUMATOLOGIST AND THE HEALTH LOCUS OF CONTROL

D. Antinis1, J. Sabaliauskiene1, 2Lithuanian University of Health Sciences, Rheumatology, Kaunas, Lithuania; 2Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Rheumatology, Kaunas, Lithuania

Background: During the COVID-19 pandemic telemedicine has become an important and safe means for patients suffering from chronic diseases to control their condition with the assistance of a physician [1]. In order to ensure that treatment of chronic rheumatic diseases is effective, it is important that patients develop a favorable attitude towards telerheumatology [2] as well as disease-related individual behavior, which significantly depends on the patients’ health locus of control [3].

Objectives: To analyze the attitude of patients suffering from chronic rheumatic diseases towards peculiarities of remote consultations by a rheumatologist and their correlation with health locus of control.

Methods: To reveal the patients' attitude towards remote consultations by a rheumatologist, an original questionnaire has been prepared, which contains reasons for choosing remote consultations, fears about such consultations and their advantages. Health locus of control was evaluated using a Multidimensional Health Locus of Control (MHLC) scale, which consists of three subscales: Internal, Chance, and Powerful Others. Demographic questions and questions related to health are also included in the questionnaire. 207 subjects participated in the study: 177 (85.5 %) women and 30 (14.5 %) men, (M, =39.4, SD=11.76). The majority of subjects were diagnosed with spondyloarthritids (n=83), connective tissue diseases (n=53), rheumatoid arthritis (n=49), and osteoarthritis (n=20), 42 subjects were diagnosed with some other rheumatic diseases. 111 (53.6%) patients had the previous experience of remote consulting by a rheumatologist.

Results: It has been determined that the attitude of patients with rheumatic diseases is related to various demographic characteristics of patients, e.g., gender, etc., and the peculiarities of the disease, e.g., strength of the symptoms, etc. It has been found that patients without experience of remote consultations have more fears about such consultations (p=0.024). When comparing the average of statements revealing a positive attitude M=66.4% with the average of statements revealing a negative attitude M=27.3%, it becomes clear that the overall attitude of subjects toward remote consultations of a rheumatologist is favorable. To assess correlations between positive or negative attitude of patients with rheumatic diseases and health locus of control correlational analysis was performed. The results did not confirm the expected correlations between the positive attitude of patients with the internal locus of control. However, it has been obtained that negative attitude towards remote consultations by a rheumatologist positively correlates with two indicators of health locus of control – Chance (r=0.203, p<0.0001) and Powerful Others (r=0.194, p=0.01), although the said correlation is not strong, but statistically significant.

Conclusion: The study has revealed the major fears and satisfaction sources related to remote consultations of Lithuanian patients with rheumatic diseases. In addition, it has shown that personal convictions of a patient that health depends on the circumstances and the influence of other people exacerbates the attitude towards remote consultations.

AB1418
A SYSTEMATIC REVIEW OF CURRENT RHEUMATOLOGY GUIDELINES FOR GERIATRIC PERSPECTIVES

B. Bink1, M. E. Tezcan2, A. E. Yucel2, 1Baskent University Ankara Hospital, Rheumatology, Ankara, Turkey; 2Kartal Dr. Lütfi Kirdar Şehir Hastanesi, Rheumatology, Istanbul, Turkey

Background: Geriatric population (GP) includes people over 65 years of age. GP can also be divided into the 65-75 age group and >75 age group. In the last 50 years, the proportion of the elderly in the society has increased (1). Meanwhile, GP has higher frequency of rheumatological disorders. While managing the treatment of this special patient group, some physiological differences of the elderly should be considered. Elderly patients are at increased risk for adverse drug reactions as a result of age-related changes in pharmacokinetics and pharmacodynamics. Polypharmacy is contributing to increased risk of clinically significant drug interactions. In addition, alterations in cognitive functions may impair drug compliance. On the other hand, clinicians may hesitate to apply more effective treatment due to safety concerns. (2) Rheumatologists should be aware of the problems they may encounter when planning the treatment of this privileged group.

Objectives: We reviewed rheumatology guidelines to assess rheumatology organizations' perspective on GP.

Methods: Guidelines published by EULAR, ACR and the British Society for Rheumatology (BSR) for adult patients from 1970-2022 were reviewed by two
Results: In total, 58 guidelines were reviewed. None of the guidelines grouped patients by age. Seven (12%) guidelines had recommendations or statements about elderly patients (Table 1). As we observe, there are no satisfactory recommendations for the GP with rheumatological diseases. The most probable reason for this result is the lack of studies in the rheumatology literature to lead to guideline recommendations.

Table 1. Characteristics of guidelines reviewed

AB1420 CLINICIAN-RELATED FACTORS MAY INFLUENCE REMOTE CONSULTATIONS IN RHEUMATOLOGY – ANALYSIS OF SENIOR VS TRAINEE CLINICIANS’ OUTCOMES FROM A COVID-19 INITIATIVE

M. Hannides1, S. Wig1, S. Vasireddy1, J. Bolton NHS Foundation Trust, Rheumatology, Bolton, United Kingdom

Background: Since COVID-19 pandemic started, there have been changes in clinical practice to limit transmission, such as switching from face-to-face to remote consultations. Our department switched to delivering remote consultations without suspending service. Patients were offered the preference of either video or telephone consultation. It is unclear what factors including clinician-related factors significantly influence remote consultations in Rheumatology.

Objectives: We aimed to study the influence of senior (substantively employed) vs trainee status of clinicians on remote consultations in our experience during the pandemic.

Methods: Between 15/10/2020 and 09/11/2020, 12 clinicians in our department completed data collection forms after each remote consultation, recording the technology used (video vs phone); technical problems encountered; discharge and subsequent appointment status; and technical aspects of the consultation itself using 11-point numerical rating scales (NRS) (Time Adequate; Relevant History; Physical Exam; Management Plan; and Communication Quality). Data were collated on an MS Access 2016 database, and transferred to SPSS version 25 for analysis.

Results: Nine senior clinicians (3 consultant rheumatologists, 3 Specialist Nurses, 1 Advanced Rheumatology Practitioner and 2 Senior Rheumatology Pharmacists) and 3 trainee clinicians (2 Specialty Trainee Registrars and 1 Foundation Year 2 doctor) completed forms. 285 forms were validated for analysis. The majority of consultations were completed by senior clinicians (266, 93.3% vs 19, 6.7%). Senior and trainee clinicians had a similar proportion of new patients compared to follow-up patients (18%, n=48 vs 15.8%, n=3; p=0.80); of female patients (88%, n=181 vs 63.2%, n=12; p=0.66); and video consultations (17.3%, n=43 vs 10.5%, n=2; p=0.45); and similar mean age of their patients (59.5 vs 56.7; p=0.72) respectively. Senior clinicians accounted for all the technical issues reported (20%, n=48 vs 0%, n=0; p=0.03). Senior clinicians had lower mean scores compared to the trainee clinicians on NRS for Relevant History (8.68 vs 9.68; p=0.001), Physical Exam (1.49 vs 2.95; p=0.045), and Communication Quality (8.02 vs 9.37; p=0.002); and had no significant differences in scores for Time Adequate (8.46 vs 9.00; p=0.10) and Management Plan (7.17 vs 7.84; p=0.16). Senior and trainee clinicians and a similar proportion requests for subsequent face-to-face appointments (21.9%, n=51 vs 25%, n=4; p=0.77).

Conclusion: There were no significant differences between senior and trainee clinicians in distributions of patients and proportion of video consultations. While no technical issues were reported by the trainee clinicians, this may in part be a reflection of their smaller proportion of overall consultations. Although senior clinicians rated their consultations somewhat lower in some of the NRS, there was no significant difference in management plan scores and subsequent face-to-face appointment status compared to trainee clinicians. However the lower scores may partly reflect the technical issues reported by the senior clinicians, longer clinical experience and greater knowledge may also be an underlying factor for this. Further studies with larger numbers may clarify these issues.

AB1419 PERFORMANCE OF AN EARLY TRIAGE SYSTEM FOR IDENTIFICATION OF PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES

X. Baraliakos1, I. Redeker1, M. Zacharopoulou1, S. Tsiami1, J. Braun1,2

1Rheumazentrum Ruhrgebiet Hemo, Ruhr-University Bochum, Heme, Germany

Background: The preselection of patients with suspicion of an inflammatory rheumatic disease is not easy for general practitioners and orthopaedists. In countries with a limited number of practicing rheumatologists, waiting lists are often long, since a full rheumatologic examination often needs a long consultation time.

Objectives: To test the performance of an early triage strategy for early identification of patients with inflammatory rheumatic diseases.

Methods: Prior to the SARS-CoV-2 pandemic, physicians caring for patients contacting a tertiary rheumatologic center were first contacted by a health-care professional (HPR) who offered an appointment the timing of which was based on the symptoms reported (Step 1). Patients were then seen by a rheumatologist who, within a 10-minute consultation (Step 2), shortly examined the patient to determine the urgency of a planned full work up. The main outcome of the study was the comparison between the initial assessment and the final expert who, within a 10-minute consultation (Step 2), shortly examined the patient to determine the urgency of a planned full work up. The main outcome of the study was the comparison between the initial assessment and the final expert assessment time.

Results: Between 15/10/2020 and 09/11/2020, 12 clinicians in our department completed data collection forms after each remote consultation, recording the technology used (video vs phone); technical problems encountered; discharge and subsequent appointment status; and technical aspects of the consultation itself using 11-point numerical rating scales (NRS) (Time Adequate; Relevant History; Physical Exam; Management Plan; and Communication Quality). Data were collated on an MS Access 2016 database, and transferred to SPSS version 25 for analysis.

Results: Nine senior clinicians (3 consultant rheumatologists, 3 Specialist Nurses, 1 Advanced Rheumatology Practitioner and 2 Senior Rheumatology Pharmacists) and 3 trainee clinicians (2 Specialty Trainee Registrars and 1 Foundation Year 2 doctor) completed forms. 285 forms were validated for analysis. The majority of consultations were completed by senior clinicians (266, 93.3% vs 19, 6.7%). Senior and trainee clinicians had a similar proportion of new patients compared to follow-up patients (18%, n=48 vs 15.8%, n=3; p=0.80); of female patients (88%, n=181 vs 63.2%, n=12; p=0.66); and video consultations (17.3%, n=43 vs 10.5%, n=2; p=0.45); and similar mean age of their patients (59.5 vs 56.7; p=0.72) respectively. Senior clinicians accounted for all the technical issues reported (20%, n=48 vs 0%, n=0; p=0.03). Senior clinicians had lower mean scores compared to the trainee clinicians on NRS for Relevant History (8.68 vs 9.68; p=0.001), Physical Exam (1.49 vs 2.95; p=0.045), and Communication Quality (8.02 vs 9.37; p=0.002); and had no significant differences in scores for Time Adequate (8.46 vs 9.00; p=0.10) and Management Plan (7.17 vs 7.84; p=0.16). Epidemiology, risk factors for disease or disease progression

AB1421

IMPACT OF HOSPITALIZATION ON CLINICAL OUTCOMES IN PATIENTS WITH CONNECTIVE TISSUE DISEASE ASSOCIATED INTERSTITIAL LUNG DISEASE (CTD-ILD) - A SINGLE CENTER OBSERVATIONAL STUDY

1Montefiore Medical Center-Moses Campus Emergency Room, Rheumatology, Bronx, United States of America; 2Ibero University Medical Group, Rheumatology, Stockton, United States of America; 3Albert Einstein College of Medicine, Epidemiology, Bronx, United States of America; 4Montefiore Medical Center-Wakefield Campus, Internal Medicine, Bronx, United States of America; 5Montefiore Medical Center, Pulmonary Medicine, Bronx, United States of America

Background: Interstitial lung disease (ILD) is major cause of morbidity and mortality in patients with connective tissue disease (CTD). Hospitalization is being increasingly recognized as poor prognostic indicator in these patients.

Objectives: The objective of our study was to assess the impact of hospitalization on clinical outcomes in patients with CTD-ILD.

Methods: We conducted a retrospective chart review of patients with radiologically or biopsy proven ILD associated with rheumatologist diagnosed CTD who were seen at Montefiore Medical Center between January 2007 and December 2018. Patients with age ≥18 years who had either 2 CT scans of the chest and/or 2 sets of pulmonary function tests (PFT) at least 6 months apart were included in the study. Clinical demographics, cause of hospitalization, length of stay, use of immunosuppression and mortality were identified. Patients were stratified into 2 cohorts; non-hospitalized and hospitalized patients. The latter cohort was further sub-stratified into patients with cardiopulmonary vs. non-cardiopulmonary hospitalization (Figure 1). Two-sample t-tests and Wilcoxon’s rank sum tests were used for comparing the continuous variables. Chi-square tests and Fisher’s exact tests were used for comparing the categorical variables as appropriate. Kaplan-Meier method was used for survival times.

Results: During the study period, we identified 213 patients with CTD-ILD using ICD 9/10 code. Of the 213 patients, 96 met our inclusion criteria and 73 (76%) had at least 1 hospitalization (Figure 1). Both groups were similar in baseline clinical characteristics but we identified significantly higher transplant referrals in the hospitalized group (23.9%) vs. non-hospitalized group (0%) (Table 1). Overall rheumatoid arthritis (29.2%) was the most common CTD associated ILD followed by inflammatory myositis (21.9%) and scleroderma (14.6%). Median time from diagnosis of ILD to first hospitalization was 1.42 years. The patients hospitalized for cardiopulmonary cause were significantly older (57.2 ± 13.1 years) than those admitted with non-cardiopulmonary cause (49.2 ± 14.8 years) (Mean ± SD). Older age (HR 1.95, p = 0.02) and length of stay greater than 7 days for cardiopulmonary cause (HR 4.82, p = 0.01) was associated with higher risk of mortality. Kaplan-Meier curve analysis showed that hospitalization (p-value = 0.02) was associated with statistically significant increased risk of death.

Conclusion: Hospitalization in CTD-ILD patients especially length of stay more than 7 days due to cardiopulmonary causes was associated with statistically significant increased risk of death. Male gender and older age was associated with a worse prognosis in patients who were hospitalized.

AB1422

PREVALENCE OF HYPERURICEMIA IN CHINESE ADULTS: DATA FROM A CROSS-SECTIONAL STUDY

J. Zeng1, W. R. Lawrence2.

1Department of Ultrasound, Guangdong Second Provincial General Hospital, Guangzhou, Guangdong, China; 2Department of Epidemiology and Biostatistics, School of Public Health, University at Albany, State University of New York, One University Place, Rensselaer, New York, United States of America

Background: Previous studies have observed an increasing trend in the prevalence of hyperuricemia which is linked to the physiological prerequisite for gout in recent years. However, the prevalence of hyperuricemia varies across different populations and different regions.

Objectives: The aim of this study was to explore the prevalence of hyperuricemia and influencing factors in Chinese adults.

Methods: The analysis was a part of a cross-sectional study in Guangdong Second Provincial General Hospital in Guangzhou City, China between January 2009 and December 2019. A total of 205922 participants (21401 with hyperuricemia) were included in this study. Hyperuricemia was defined as serum uric acid ≥416.0 μmol/L (70.5 mg/dl) for men and ≥3570 μmol/L (60.0 mg/dl) for women. We calculated the prevalence of hyperuricemia and used the multivariate-adjusted logistic regression model to identify the risk factors associated with hyperuricemia.

Results: The overall estimated prevalence of HUA was 10.4% in China. Our study showed the prevalence of hyperuricemia in male (10.7%) was higher than that in female (9.9%) (P<0.05). The prevalence of HUA in the age group ≥75 years (13.3%) was higher than others. Multivariate logistic regression analysis revealed that sex (OR=1.75), age (OR=1.168), blood urea nitrogen (BUN) (OR=1.051), creatinine (Cr) (OR=1.045), high-density lipoprotein cholesterol (HDL-C) (OR=1.225), low-density lipoprotein cholesterol (LDL-C) (OR=1.466), systolic blood pressure (SBP) (OR=1.012), triglycerides (TG) (OR=1.460) and Body Mass Index (BMI) (OR=1.080) could increase the risk of hyperuricemia, while diastolic blood pressure (DBP) (OR=0.998), fasting plasma glucose (FPG) (OR=0.902) and total cholesterol (TC) (OR=0.704) were associated with a lower risk of hyperuricemia in all age groups.

Conclusions: The latest prevalence of hyperuricemia is high in Chinese adults and is associated with multiple factors, indicating that prevention and control strategies for hyperuricemia are needed urgently.

CliniCal and laboratOry featureS of patieNts with idiopatHic granulatomatous mastitis at a tertiary medical ceNter

B. Abbi1, X. Xie2, S. Fineberg3, A. Gupta4, A. Kumthekar1, B. Ayesha1.
1Montefiore Medical Center, Department of Rheumatology, Bronx, United States of America;
2Albert Einstein College of Medicine, Department of Epidemiology & Population Health, Bronx, United States of America;
3Montefiore Medical Center, Department of Pathology, Bronx, United States of America;
4Montefiore Medical Center, Department of Surgical Oncology, Bronx, United States of America

Background: Idiopathic granulomatous mastitis (IGM) is a benign, inflammatory disease of the breast. As per the literature review, etiopathogenesis of this disease is unclear. The gold standard of diagnosis is through breast biopsy and identification of non-caseating granulomas. [1] Until recently, there has been a lack of clinical, serological or histopathological criteria to guide physicians on management of IGM.

Objectives: The objective of our study is to identify distinguishing clinical and laboratory features amongst individuals with IGM based on serologic and histopathologic status. In this study, clinical and laboratory features were compared between patients with complete remission of IGM and those with relapse of IGM after three months of remission.

Methods: After institutional review board (IRB) approval, we queried pathology and clinical looking glass databases at Montefiore Medical Center between 1990-2021 to identify patients with the diagnosis of IGM. We identified 46 patients, and did a retrospective chart review to extract data. Clinical features were compared in patients with IGM who had complete resolution of disease and those who had relapse of disease using two-sample t-tests for continuous variables and chi-squared or Fisher’s exact tests for categorical variables. In this study, we included females older than eighteen years of age. We excluded patients with breast cancer, lymphoproliferative disorders, solid organ malignancy, foreign body reaction in breast, plasma cell mastitis, and ductal ectasia.

Results: Of the 46 symptomatic patients with histopathological diagnosis of IGM, 27 female patients with sufficient clinical data were included in final analyses. All patients in our cohort had a mean age of 36 years (SD 9 years) and average body mass index of 31.5 kg/m² (SD 6.7 kg/m²). Majority of patients were Hispanic, 11 patients (40.7%). Unilateral disease (96.3 %) was predominant in patients. Most patients had at least one previous full-term pregnancy prior to diagnosis, 25 patients (92.6%) and 8 patients were on hormonal oral contraceptives (29.6%). Of the 27 patients, 18 patients (66.6%) had complete remission of disease. All of these patients were initially treated with antibiotic therapies until tissue cultures were reported negative. Six of these patients received steroid therapy after antibiotic therapy, while 5 patients were started on methotrexate therapy, starting with a dose of 15 milligrams (mg) orally once per week. Of the total cohort, 9 patients (33.3%) experienced relapse of the disease.

Conclusion: IGM is a relatively newer entity that is difficult to manage, due to lack of standard guidelines in literature. In this study, comparing IGM patients with remission and relapse, there were no statistically significant differences in clinical and laboratory features. However, immunomodulating therapy with methotrexate can be considered in patients with relapsing IGM. Further studies are needed to evaluate patients with IGM and their disease evolution that can facilitate management to determine utility of methotrexate in improving relapse rates in these patients.

Investigation of the type and frequency of neurological side effects with biological treatment in inflammatory rheumatic diseases

S. Umut1, T. Yuce Inel2, I. S. Sengun3, F. Onen2, I. Sarı2. 1Dokuz Eylul University Faculty of Medicine, Internal Medicine, Izmir, Turkey; 2Dokuz Eylul University Faculty of Medicine, Rheumatology, Izmir, Turkey; 3Dokuz Eylul University Faculty of Medicine, Neurology, Izmit, Turkey

Background: With the increasing use of biological treatment in inflammatory rheumatic diseases, some neurological side effects, especially central and peripheral nervous system demyelinating disorders, are seen.

Objectives: To evaluate whether there is an increase in the frequency of neurological disorders with biological treatment compared to the normal population, and the relationship between discontinuation of biological agents and neurological symptoms.

Methods: Adult patients using biological treatment followed in the Rheumatology outpatient clinic of Dokuz Eylul University between January 2011 and January 2020 were included. The relationship between biological agents and type, severity and duration of neurological symptoms, and the laboratory, imaging (cralian CT, MRI) and electrophysiological findings of the patients were retrospectively reviewed. Current treatments for rheumatologic disease and neurological findings, and disease activity were investigated.

Results: In our study, neurological side effects were observed in 16 (1.8%) of 877 patients using biological drugs. The mean age of the patients was 51.8±12.53 years, and the duration of rheumatologic disease was 10.69±4.86 years. Nine patients had peripheral neuropathy, two had CNS demyelinating disease, two had peripheral demyelinating disease, two had intracranial mass and one had...
headache syndrome. The neurological disease developed a mean of 5.13±4.26 months after the first biological agents. The demographic and clinical characteristics of the patients and the neurological side effects that developed during the follow-up period are summarized in Table 1. Biological treatment was discontinued in 68.8% of patients. There was no significant correlation between biological agents’ continuation status and progression of neurological findings.

Conclusion: In this study, the prevalence of neurological diseases such as brain tumors, multiple sclerosis, and myasthenia gravis in patients receiving biological treatment compared to the normal population. Therefore, patients using biological agents should also be questioned and examined in terms of neurological symptoms, and further examination should be applied if necessary. No significant relationship was found between discontinuation of biological drugs and improvement/progression of neurological symptoms, and more comprehensive studies are needed.

AB1426 PREDICTORS OF RHEUMATIC TOXICITIES OF IMMUNE CHECKPOINT INHIBITORS AND CANCER OUTCOMES IN PATIENTS WITH ADVANCED MELANOMA

A. Bruce1,2, A. Menzies1,2,3,4, G. Long1,2,4, B. Fernandes1, F. Joshi1,2,3
1Macquarie University, Faculty of Medicine, Health and Human Sciences, Sydney, Australia; 2Gardens Medical Group, Rheumatology, Albury, Australia; 3Royal North Shore and Mater Hospitals, Medical Oncology, Sydney, Australia; 4The University of Sydney, Faculty of Medicine & Health, Sydney, Australia; 5Melanoma Institute Australia, Sydney Medical Oncology, Wollongong, Australia; 6The University of Sydney, Charles Perkins Centre, Camperdown, Australia; 7Royal Prince Alfred Hospital, Medicine, Sydney, Australia; 8Integrated Specialist Medical Care, Rheumatology, Sydney, Australia

Background: Immune checkpoint inhibitors (ICIs) including monoclonal antibodies to PD-1 and CTLA-4 have activity across various cancers. Dedicated cohort studies have examined the epidemiology and clinical course of rheumatic toxicities (1–3) and the effect of pre-existing autoimmune disease has been explored (4), with limited assessment of the effect of non-immune mediated rheumatic disease (3). A positive association between ICI-induced rheumatic disease and favourable cancer outcomes has been suggested (1,2), although derived from heterogenous cancer populations.

Objectives: To identify risk factors for the development of ICI-induced rheumatic disease and predictors of cancer outcomes in patients with advanced melanoma.

Methods: A single-centre observational study of patients with stage III or IV melanoma receiving all available ICI therapies, who completed a for-purpose questionnaire to capture rheumatic symptoms and risk factors upon recruitment and at 12-months. Symptom severity was assessed using validated measures such as visual analogue scale (VAS) scores for pain. Clinical details were extracted from patients’ medical records. Predictors of rheumatic toxicities and cancer outcomes were identified through regression analysis.

Results: Amongst 147 eligible patients, the prevalence of new or worsening rheumatic symptoms was 32.5% at recruitment and 21% at 12 months. The incidence of documented arthralgia, inflammatory arthritis and PMR-like syndrome was 39.5%, 5.4% and 3.4% respectively. Binary logistic regression identified pre-existing symptomatic rheumatic disease, including non-immune mediated rheumatic disease, as the primary risk factor for developing rheumatic toxicities (OR 3.161). Continuation of ICI therapy (OR 16.52), followed by rheumatic toxicities (OR = 4.368) were predictors of favourable tumour response.

Conclusion: Rheumatic toxicities of ICI therapy commonly affect patients with melanoma and are more likely to occur in patients with pre-existing autoimmune and non-immune mediated rheumatic disease. Continuation of ICI therapy improves cancer outcomes and can be facilitated by early detection of rheumatic symptoms using patient reported outcome measures.

AB1427 ASSOCIATION BETWEEN HYPERURICEMIA AND OSTEOPOROTIC IN CHINESE ADULTS, A CROSS-SECTIONAL STUDY

J. Zeng1, J. Yang2, W. R. Lawrence3, C. Pan4. 1Department of Ultrasound, Guangdong Second Provincial General Hospital, Guangzhou, Guangdong, China; 2School of Public Health, Guangzhou Medical University, Guangzhou, Guangdong, China; 3Department of Epidemiology and Biostatistics, School of Public Health, University at Albany, State University of New York, One University Place, Rensselaer, New York, United States of America; 4Department of Emergency, The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, Guangdong, China

Background: Hyperuricemia may have a protective role in diseases characterized by high levels of oxidative stress, such as osteoporosis. Previous studies have shown that hyperuricemia is associated with osteoporotic. However, this association is controversial and even yielded conflicting results.

Objectives: This study investigated the relationship between hyperuricemia and osteoporotic among Chinese adults.

Methods: The data of cross-sectional study was collected at Guangdong Second Provincial General Hospital in Guangzhou City, China between January 2009 and December 2019. Physical examinations and laboratory measurement variables were obtained from the medical check-up system. The multivariate-adjusted logistic regression model was performed to assess the association between hyperuricemia and osteoporotic.

Results: A total of 18917 participants (11334 males and 7579 females) were included in this study, with an average age of 46.23 years (SD: 11.67) at baseline. It included 5881 cases of hyperuricemia and 1587 osteoporotic. After adjusted for the confounding factors in logistic regression analysis, we observed a negative significant association between hyperuricemia and risk of osteoporotic (odds ratio [OR],0.882, 95%CI 0.795–0.976; P <0.05). Further stratified analyses showed a negative significant association with the risk of osteoporotic in women (OR,0.787, 95%CI 0.698–0.853; P <0.05), man (OR,0.897, 95%CI 0.786–0.954; P <0.05) and old adults (OR, 0.808, 95%CI, 0.759-0.894; P <0.05). No significant differences in other groups.

Conclusion: Our study observed participants with hyperuricemia had significantly less osteoporosis. More high-quality research is needed to further support these findings.

AB1429 PERSISTENT INFLAMMATION AND PULMONARY FUNCTION CHANGES PREDICT PROGRESSIVE FIBROSING INTERSTITIAL LUNG DISEASES DEVELOPMENT IN RHEUMATIC PATIENTS

T. J. Lee1, Y. H. Chen2, J. Y. Chien2, S. C. Hsieh1. 1National Taiwan University Hospital, Division of Rheumatology, Immunology, and Allergy, Department of Internal Medicine, Taipei, Taiwan, Republic of China; 2National Taiwan University Hospital, Division of Chest Medicine, Department of Internal Medicine, Taipei, Taiwan, Republic of China

Background: The progressive fibrosing interstitial lung disease (PF-ILD) remains a challenge for clinical care. Studies reported that fibrosis-predominant pattern on high-resolution computed tomography (HRCT) and a worse baseline pulmonary function tests were associated with a progression to PF-ILD 1. Whether the inflammatory marker changes predict PF-ILD development was unknown.

Objectives: To evaluate prognostic values of the early inflammatory markers and the pulmonary function tests of developing PF-ILD in patients with connective tissue disease-related interstitial lung disease (CTD-ILD) and interstitial pneumonia with autoimmune features (IPAF).

Methods: This was a retrospective, single-center study. The patients with CTD-ILD and IPAF were included. The PF-ILD was identified at two years after the ILD diagnosis, as according to the INBUILD study 2. The ILD patterns on the HRCT and the pulmonary function tests at diagnosis and one year after ILD diagnosis were reviewed by three pulmonologists independently. The baseline demographics, autoimmune manifestations, and serology at diagnosis, three months, and one year after ILD diagnosis were collected. The data were analyzed using the R version 4.12.

Results: From 2010 to 2020, we enrolled 34 patients into the analysis. These included 11 patients with Sjogren’s syndrome, 7 patients with idiopathic inflammatory myopathy, 3 patients with mixed connective tissue diseases, 1 patient with systemic sclerosis, and 14 patients with IPAF. The HRCT patterns were usual interstitial pneumonia in 13, non-specific interstitial pneumonia (NSIP) in 8, organizing pneumonia (OP) in 6, and lymphocytic interstitial pneumonia (LIP) in 1.

At 2 years, 15 patients developed PF-ILD. The CTD diagnoses and the radiographic patterns at diagnosis were not associated with the development of PF-ILD. The predicted functional vital capacity (FVC) at diagnosis (80% vs. 69%, p=0.047), diffusion capacity of the lung for carbon monoxide (DLCO) at diagnosis (76% vs. 44%, p=0.021), FVC at one year (94% vs. 68%, p=0.047), and DLCO at one year (68% vs. 36%, p=0.018) were associated with the PF-ILD progression. Immunologically, the PF-ILD patients had a borderline higher 1-hour erythrocyte sediment rate (ESR) at baseline (36 vs. 23 mm/h, p=0.051), but the difference became prominent after 3 months (38 vs. 10 mm/h, p=0.023), and 12 months (28 vs. 8 mm/h, p=0.005) after the ILD diagnosis. (Figure 1)

Figure 1. Change of erythrocyte sediment rate at 1 hour over time. ESR, erythrocyte sediment rate at 1 hour. ILD, interstitial lung disease. PF-ILD, progressive fibrosing interstitial lung disease. *p < 0.05, **p < 0.01

Conclusion: The higher ESR during the first one year after ILD diagnosis was associated with the progression to PF-ILD. In serial pulmonary function tests, both FVC, and DLCO in patients with PF-ILD were lower. The between-group differences were more prominent at 1 year of follow up. The findings suggest that the persistent inflammation might contribute to the progressive worsening of pulmonary fibrosis and subsequent lung function decline. The immunology and pulmonary function parameters at one year predict the development of PF-ILD.

EPIDEMIOLOGICAL AND GENETIC FEATURES OF ANTI-3-HYDROXY-3-METHYLGLUTARYL-CoA REDUCTASE NECROTIZING MYOPATHY IN NORTHERN SPAIN: SINGLE-CENTER EXPERIENCE

D. Prieto-Peña1,2, J. G. Ocejo-Vinayas3, J. A. Mazariaga-Cano4, A. L. Pelayo5, S. Remuzgo Martinez2, F. Genre2, A. Garcia Dorta6, M. Renuncio-Garcia6, V. Martinez-Taboada7, C. Garcia-Ibarbia8, J. Sanchez-Martín1, B. Atienza-Mateo1,2, M. Lopez-Hoyos2, R. Blanco3, M. A. Gonzalez-Gay1,4, J. L. Hernandez1,2, Hospital Universitario Marques de Valdecilla, Department of Rheumatology, Santander, Spain; 2IDIVAL, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and Metabolic Bone Diseases of the Musculoskeletal System, IDIVAL, Santander, Spain;
3Hospital Universitario Marques de Valdecilla, Department of Immunology, Santander, Spain; 4Hospital Universitario Marques de Valdecilla, Department of Internal Medicine, Santander, Spain; 5Hospital Universitario Marques de Valdecilla, Department of Neurology, Santander, Spain; 6Hospital Universitario de Canarias, Department of Rheumatology, Tenerife, Spain

Background: Anti-3-hydroxy-3-methylglutaryl-CoA reductase (HMGR) immune-mediated necrotizing myopathy (IMNM) is an entity of growing interest. However, data on epidemiology and clinical spectrum are still scarce and there is a need for the identification of its potential risk factors.

Objectives: To characterize the demographic, genetic, clinical, and serological features of patients with anti-HMGR IMNM in a region of northern Spain.

Methods: Study of all patients diagnosed with anti-HMGR IMNM during a 5-year period at a reference hospital in Northern Spain. Besides clinical and laboratory data, we analyzed the genetic influence of HLA genes and the rs4149056 (c.521T>C) single nucleotide polymorphism (SNP) in the SLC01B1 gene.

Results: 8 patients (5 women, 3 men) with a mean ± SD age of 64.9±7.3 years, fulfilled the criteria for anti-HMGR IMNM. The incidence rate was 0.6 per 100,000 person-years (95% CI 0.23, 1.20) in an estimated 3 per 100,000 population. All patients had dyslipidemia and had been exposed to statins. Seven of the 8 cases complained of myalgia. All of them had predominant lower limb proximal and symmetric muscle weakness that was severe in 2 of them. None of the patients had extra-muscular involvement. No evidence of malignancy was found. All patients had elevated serum CK levels with a median [IQR] of 4488 [2538-9194] IU/L. Serum 25-hydroxy vitamin D levels were decreased in all patients. In 8 of the 8 patients, the anti-HMGCR antibody was detected. All patients had elevated serum CK levels with a median [IQR] of 4488 [2538-9194] IU/L. Serum 25-hydroxy vitamin D levels were decreased in all patients. In 8 of the 8 patients, the anti-HMGCR antibody was detected. All patients experienced improvement with different schemes of immunosuppressive therapy. Noteworthy, 7 of 8 patients carried the HLA-DRB1*11 allele. The frequency of the rs4149056 C allele in the SLC01B1 gene (12.5%) was similar to that of the general population.

Conclusion: In northern Spain, the IMNM anti-HMGR preferentially affects people over 50 years of age who are carriers of the HLA-DRB1*11 allele and take statins. Both low vitamin D levels and hypothyroidism may play a potential predisposing role in the development of this disease.

Results: comorbidity” or “non-painful comorbidity” status based on IASP classification of were used as dependent variables; pain intensity (0-10 numerical rating scale) rated ≥1/10, and who had completed FRAIL and CAP-Knee (1) questionnaires.

Objectives: The explanation behind these relationships may depend on more than just ongoing interconnectedness of pain processing systems and the rest of the body. The mechanisms of knee pain is proposed; ongoing sensory inputs due to comorbidity may intensify and prolong pain. Central pain mechanisms might be facilitated by ongoing nociceptive input. A link between multimorbidity with central mechanisms of knee pain.

Background: Central mechanisms of knee pain occur in the central nervous system and may intensify and prolong pain. Central pain mechanisms might be facilitated by ongoing nociceptive input. A link between multimorbidity with central mechanisms of knee pain.

Methods: Cross-sectional analysis of self-report data from participants of the Investigating Musculoskeletal Health and Wellbeing cohort, who reported knee as their most bothersome other joint pain over the previous month, with pain rated ≥1/10, and who had completed FRAIL and CAP-Knee (1) questionnaires. Two indirect measures suggesting central mechanisms involvement in knee pain were used as dependent variables; pain intensity (0-10 numerical rating scale) and CAP-Knee score (0-16 scale). Comorbidities were assigned either "painful comorbidity" or "non-painful comorbidity" status based on IASP classification of chronic pain criteria (2). Multivariable linear regression models, adjusted for age and sex, were employed to explore associations of comorbidity counts with pain intensity and CAP-Knee score.

Results: 736 participants satisfied inclusion criteria. 55% were female, mean age 71 (range 40 to 95). Painful comorbidity count and non-painful comorbidity count each had positive associations with pain intensity ($\beta =0.42, 95\%\ CI=0.29$ to 0.54, $p<0.001$; and $\beta =0.31, 95\%\ CI=0.16$ to 0.45, $p<0.001$, respectively). Painful and non-painful comorbidity counts each had positive associations with pain intensity ($\beta =0.52, 95\%\ CI=0.27$ to 0.54, $p<0.001$; and $\beta =0.31, 95\%\ CI=0.16$ to 0.45, $p<0.001$, respectively). Painful and non-painful comorbidity counts each had positive associations with pain intensity ($\beta =0.52, 95\%\ CI=0.27$ to 0.54, $p<0.001$; and $\beta =0.31, 95\%\ CI=0.16$ to 0.45, $p<0.001$, respectively). Painful and non-painful comorbidity counts each had positive associations with pain intensity ($\beta =0.52, 95\%\ CI=0.27$ to 0.54, $p<0.001$; and $\beta =0.31, 95\%\ CI=0.16$ to 0.45, $p<0.001$, respectively).

Conclusion: Both painful and non-painful comorbidities were positively associated with central mechanisms of knee pain, providing further insight into the interconnectedness of pain processing systems and the rest of the body. The explanation behind these relationships may depend on more than just ongoing nociceptive input. Future work should address possible contributions from genetic, pathophysiological, psychological, and pharmacological factors associated with comorbid diagnosis.

Conclusion: By encompassing factors that can contribute to CVD development in complex/autoimmune diseases, QRISK3 has been shown to be more accurate than traditional risk score in predicting SLE patients CVD risk. Nonetheless, the results of this analysis showed how the aGAPSS still seems to be the most valuable tool for this purpose when facing SLE patients. Moreover, the significance observed when focusing on patients’ aPL profile, suggests that adding this item to the QRISK3 could be a useful strategy to improve the management.

PREGNANCY AND RHEUMATIC DISEASES – COMBINING BIOLOGICAL MATERIAL AND CLINICAL DATA FOR FUTURE RESEARCH

J. R. Nilsen1, B. Jakobsen1, T. T. Pedersen1, M. Wallenius1,2. 1Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases, Department of Rheumatology, St.Olavs Hospital, Trondheim, Norway; 2Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Trondheim, Norway

Background: Rheumatic diseases affect women in fertile age. There is an increased risk for disease flares and pregnancy complications, especially for patients with systemic rheumatic diseases. Improving knowledge of immunological changes that happen during and after pregnancy in women with rheumatic diseases is of great importance. The Norwegian National Advisory Unit for Pregnancy and Rheumatic Diseases (NKSR) therefore established a biobank in 2012 with material from this patient group. NKSR also administers RevNatus, a nationwide pregnancy quality register including women with inflammatory rheumatic diseases, with comprehensive clinical data.

Objectives: To facilitate high quality research by developing a possibility to combine biobank material and comprehensive clinical data. We aim to increase current knowledge in this field, with the ultimate goal of making pregnancies safer for women with rheumatic diseases.

Methods: The RevNatus biobank is part of the Regional Biobank of Central Norway (Biobank1). Biobank1 is a research facility established to provide an organizational framework for all research, which involves biological material from patients in any of the public hospitals of the region. The collection of biologic material is approved by the regional committees for medical and health research ethics. Patients are included after having signed a consent form. Blood samples are collected before pregnancy, in each trimester, 6 weeks, 6 months and 12 months postpartum. So far, serum, plasma, buffy-coat and Tempus Blood RNA tubes have been collected. At the same time points when blood samples are collected, clinical data is registered in RevNatus. Serum, plasma, buffy-coat and Tempus Blood RNA tubes from 32 healthy pregnant women have also been collected as control group material.

Results: 310 donors are so far included in the RevNatus biobank. These include systemic lupus erythematosus (36), rheumatoid arthritis (61), juvenile idiopathic arthritis (40), spondyloarthropathy (96), Sjögren’s syndrome (8), granulomatosis with polyangiitis (5), MCTD (5), healthy controls (32) and others (27).

CLINICAL PREDICTION MODELS FOR METHOTREXATE OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS: SYSTEMATIC REVIEW AND CRITICAL APPRAISAL

C. Gehenger1, G. Martin2, K. Hyrich1,3, S. Verstappen4, J. Sergeant1,4.
1University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; 2University of Manchester, Centre for Health Informatics, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom; 3Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom; 4University of Manchester, Centre for Biostatistics, Manchester Academic Health Science Centre, Manchester, United Kingdom

Background: Methotrexate (MTX) is the preferred first line therapy for rheumatoid arthritis (RA). MTX has several advantages over other treatments including effectiveness and low cost; however, around 40% of patients are classed as non-responders after 6 months (1). Therefore, there is a clinical need to identify patients at high-risk of poor outcomes, such that patients could potentially be fast tracked onto alternative therapies to improve their clinical outcomes and quality of life. Such risk stratification is possible through prognostic prediction models, although models which have previously been developed appear to have had little impact on practice. This may be in part due to methodological features of their development and validation but, to date, no review has collated the evidence in this field.

Objectives: This systematic review aimed to (i) identify and summarise multivariable prediction models of MTX treatment outcomes in biologic-naïve adult RA patients, and (ii) critically appraise their methodological properties.

Methods: The electronic databases Medline and Embase were searched to identify studies developing or validating prediction models of MTX outcomes in the population of interest, including demographic, disease-specific or treatment-related covariates, published after 2005. Models were stratified by outcome definition, and information on participants, predictors, model performance, handling of missing data and model validation were extracted. A risk of bias (ROB) assessment using PROBAST (prediction model risk of bias assessment tool) was carried out. Two reviewers were independently involved in screening, data extraction, and ROB stages.
Results: The included studies used three main outcome definitions: a state of disease activity, such as low disease activity or remission; the EULAR response criteria, or discontinuation due to adverse events (AEs). Some studies incorporated AEs into a composite outcome with disease activity and few accounted for potential competing risks, which are events that preclude the occurrence of the primary outcome of interest. Not handling competing risks may result in under-prediction, leading to potentially compromised risk stratification. There was a lack of internal validation using cross sampling techniques, which is critical for reducing overfitting, as well as external validation in new data, a process necessary to ensure reproducibility and generalisability of a prediction model to the larger patient population. Missing data was mostly handled using complete case analysis, leading to potentially biased risk estimates. The ROB assessment showed overall high ROB of the included studies.

Conclusion: This systematic review summarises current prediction models of MTX treatment outcomes in RA. It highlights several methodological short-comings, such as poor handling of missing data and competing risks to the primary outcome, and a lack of internal and external validation. These should be addressed in future model development and validation to improve accuracy of predictions. Without tackling these issues, prediction of MTX treatment outcomes will remain at high risk of bias and should not be recommended for informing risk stratification for RA treatment decisions.

**AB1436**

**INFECTIONS IN PATIENTS WITH RHEUMATIC DISEASES IN TREATMENT WITH BIOLOGIC THERAPY**

Background: Patients with rheumatic diseases (RD) have a higher risk of developing infections due to disease and immunosuppressant treatment factors 1. Biologic disease-modifying antirheumatic drugs (bDMARD) have been associated with the development of opportunistic infections, nevertheless their impact on severe infections has not been consistent 2. Objectives: To describe the sociodemographic and clinical characteristics of patients with RD on bDMARD treatment with and without infections, using data from the Mexican Adverse Events Registry (BIOBADMEX), as well as to identify factors associated with the presence of infections.

Methods: BIOBADMEX is a Mexican ongoing cohort of patients using bDMARDs. In this analysis we included all patients registered in BIBADME from 2016 to 2021. We compared sociodemographic, clinical and treatment characteristics between patients who developed infections with to those who did not.

We used descriptive statistics, Chi square and Kruskal Wallis tests to analyze differences between the groups.

Results: A total of 780 patients registered in BIBADME were included in this study, among them 42 (5%) patients presented infections and 738 (95%) did not. At baseline, patients had a median (IQR) age of 50 (40-58) years and median disease duration of 7 (3-15) years. The most common diagnosis was rheumatoid arthritis with 512 (66%) patients, followed by ankylosing spondylitis in 115 (15%), psoriatic arthritis in 44 (6%), systemic lupus erythematosus in 30 (4%) and idiopathic juvenile arthritis in 27 (3%) patients. Comorbidities were present in 351 (45%) of the patients. Conventional DMARD (cDMARD) use was present in 351 (45%) of the patients. Conventional DMARD (cDMARD) use was present in 351 (45%) of the patients.

Chi²

Conclusion: The frequency of infections in patients using bDMARD in Biobadex is low compared to the frequency reported in similar studies in other countries 3. The presence of infections was associated with more severe adverse events in general, which recovered completely without sequel.

**RHEUMATOLOGICAL IMMUNE-MEDIATED ADVERSE EVENTS OF IMMUNE CHECKPOINT INHIBITORS BASED ON THE FDA ADVERSE EVENTS REPORTING SYSTEM**

A. Rodriguez-Piña, Mayo Clinic, Rheumatology, Scottsdale, United States of America

Background: Immune checkpoint inhibitors (ICIs) provide effective treatment for many cancers but, presumably due to persistent activation of the immune system, they cause a variety of immune-related adverse events (irAEs) in almost every organ. Rheumatological manifestations have been reported in ~5-10% of patients treated with ICIs.

Objectives: We aimed to analyze the rheumatological irAEs (rh-irAEs) reported to the FDA Adverse Event Reporting System (FAERS) from October 2012 through March 2021.

Methods: From October 1st, 2012, to March 31st, 2021, we studied all case reports found on the FAERS database when any of the following seven FDA-approved ICIs, nivolumab, pembrolizumab, ipilimumab, atezolizumab, durvalumab, avelumab, or cemiplimab, was the primary suspect of the reported adverse event (AE). Of the 6,090 different AEs reported for the ICIs, we selected 186 irAEs, which were rheumatological manifestations, or were associated with rheumatological conditions. We calculated the frequencies of rh-irAEs for each ICI. RStudio v1.4.1106 was used for general data analysis and the R package
openEBGM v0.8.3 was used for the calculation of disproportionality scores such as the Empirical Bayes Geometric Mean (EBGM) with its 90% two-sided credibility interval, frequently used in safety signal detection models. Drug-event combinations with an EBGM 5% lower limit credibility interval ≥ 1 were considered significant.

**Results:** During the study period, 90,974 individual case safety reports (ICSR) included 236,239 AEs with one ICI as the primary suspect of the AE. The highest frequency of AEs was reported for nivolumab (49.6%), followed by pembrolizumab (23.4%), ipilimumab (12.6%), atezolizumab (6.6%), durvalumab (4.6%), avelumab (0.9%), and cemiplimab (0.3%). The AEs were more frequent in males (62.7%) than in females (37.3%). Of the total ICSRs, 84.2% were expedited because they reported serious, unexpected AEs. Rh-irAEs were 11,203 (4.7%) out of the 236,239 AEs reported. These rh-irAEs were reported in 3,398 (4.3%) out of the 90,974 ICSRs. For the ICSRs containing rh-irAEs, 78.5% were expedited. Unspecific complaints, such as arthralgia, myalgia or muscle weakness, were among the most frequent rh-irAEs. Avelumab and atezolizumab were associated with Sjogren’s syndrome and sarcoidosis. Durvalumab, avelumab and cemiplimab were all associated with myositis. Twenty-one drug-event combinations were significant for EBGM. Of those, nivolumab and pembrolizumab were the two most frequent ICI, with 7 and 6 significant drug-event combinations, respectively.

**Conclusion:** Approximately 5% of the reported AEs-associated AEs were rh-irAEs. The most frequent complaints were unspecific, such as arthralgia, myalgia, or muscle weakness. Arthritis, myositis, Sjogren’s syndrome, and sarcoidosis were also relatively frequent. The improved understanding of the mechanism of action of the ICIs and the characteristics of the rh-irAEs may help to elucidate the pathogenesis of the rheumatological autoimmune diseases that they trigger.

**IS THERE AN INCREASED PREVALENCE OF DIABETES MELLITUS IN THE AXIAL Spondyloarthritis patient group? A review from a UK teaching hospital spondyloarthropathy service**

S. Jothimurugan1,2, S. Byraman1, A. Moorothy1,2,1 University Hospitals of Leicester NHS Trust, Rheumatology, Leicester, United Kingdom; 2 University of Leicester, College of Life Sciences, Leicester, United Kingdom

**Background:** The prevalence of diabetes mellitus (DM) has often been found to be increased in patients with axial spondyloarthritis (axSpA) compared to the general population. However, studies conducted in the United Kingdom (UK) have found varying results with regards to prevalence. One study9 found that 5% of patients with axSpA had DM, compared to 4% of patients without axSpA and another UK study8 reported that although findings showed a 1.8% increase in DM in patients with axSpA compared to controls, this result was not significant. There is also the influence of ethnicity to consider as DM is more prevalent in the Asian and Afro-Caribbean population. Therefore, it is evident that more research is required into the relationship between DM and axSpA.

**Objectives:** This study aims to investigate the correlation between DM and axSpA, and also explore the influence of ethnicity on DM and axSpA.

**Methods:** Retrospective analysis was carried out for axSpA patients attending University Hospitals of Leicester axSpA services. Inclusion criteria entailed an axSpA diagnosis and a Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) within a year of MRI spine and sacroiliac joints before starting biological therapy. Patients were excluded if they had an active infection or malignancy. BASDAI was not documented before starting biological therapy or within a year of MRI, or if clinical information was not able to be obtained. Data was obtained from electronic medical records, including age, gender, ethnicity, date of diagnosis of axSpA and DM, and cardiovascular comorbidities.

**Results:** Of the 149 patients, 8 (5.37%) % had a diagnosis of DM. 4 (50%) of these patients were diagnosed with DM prior to diagnosis of axSpA, and 4 (50%) were diagnosed with DM post diagnosis of axSpA. Differences in ethnicity were analysed. Of the 149 axSpA patients, 102 (68.46%) were Caucasian, 45 (30.20%) were Asian, and 2 (1.34%) were Afro-Caribbean. Of the 102 Caucasian patients, 3 (2.94%) had DM, of whom 1 was diagnosed with axSpA prior to diagnosis of DM. Of the 45 Asian patients, 5 (11.11%) had DM, of whom 3 were diagnosed with axSpA prior to diagnosis of DM. Looking at cardiovascular comorbidities, of the 8 patients with axSpA and DM, 2 (25%)...
had hypertension, and were both diagnosed with axSpA prior to diagnosis of DM.

Conclusion: This small study has found a similar prevalence of DM in patients with axSpA (5.37%) compared to the general UK population (6%), which contrasts with published international studies which have found a higher prevalence of DM in the axSpA group. However, the study did find a higher prevalence in the Asian population (11.11%) which is in keeping with ethnic variation for DM. Larger epidemiological studies are needed to understand the reason for reported higher prevalence of DM in patients with axSpA in other countries compared to the UK.

AB1440 ASSOCIATION BETWEEN GAMMA-Glutamyl TRANSFERASE (GGT) AND SERUM URATE: CROSS-SECTIONAL FINDINGS FROM THE 1993 PELOTAS (BRAZIL) BIRTH COHORT

T. Loyola Correa1, D. Farias Freitas2, C. Brinck Brum2, I. Oliveira de Oliveira1,3.
1Universidade Federal de Pelotas, Faculty of Medicine, Pelotas, Brazil; 2Universidade Federal de Pelotas, Centre for Epidemiological Research, Pelotas, Brazil; 3Universidade Federal de Pelotas, Postgraduate Program in Epidemiology, Pelotas, Brazil

Background: Gout attack is associated with an abrupt increase or decrease on serum urate concentrations, which can precipitate urate crystals in tissues in and around the joints. Serum urate (SU) has been positively associated with cardiometabolic risk factors and subclinical inflammation in observational studies, but causal roles remain unclear.1 Additionally, gamma-glutamyl transferase (GGT) has been linked to oxidative stress, metabolic syndrome, and nonalcoholic fatty liver disease (NAFLD).

Objectives: The aim of this study was to assess the association between GGT and SU in Brazilian young adults.

Methods: During 1993, all live born babies in the city of Pelotas (Brazil) were invited to take part in a prospective study. At the 22-year follow-up of this birth cohort, SU was evaluated by enzymatic-colorimetric assay. GGT was evaluated by kinetic assay and converted into logarithm for regression analysis. The co-variables taken into consideration were waist circumference (WC), systolic and diastolic blood pressures (SBP, DBP), glucose (G), high-density lipoprotein cholesterol (HDL-c), low-density lipoprotein cholesterol (LDL-c), creatinine (Scr), fasting period, smoking status, excessive alcohol consumption (>8 points in the Alcohol Use Disorders Identification Test-AUDIT), and physical activity (PA).

For association analyses, serum concentration of urate was categorized into tertiles. Sex-stratified linear regressions have been performed due to the significant interaction between GGT, SU and sex (p<0.001). A p-value less than 0.05 was considered statistically significant.

Results: The sample comprised 1660 (47.7%) men and 1822 (52.3%) women aged 22.6 (±0.34) years old. Median (IQR) GGT (U/L) was 26 (20-35) in men and 21 (16-30) in women (p<0.001). Mean (±SD) SU (mg/dL) was also higher in men (5.2±1.2 vs. 3.9±1.1; p<0.001). No significant association between GGT and tertiles of SU was observed in men (between the 1st and 2nd tertiles, the p-value was 0.713; and between the 1st and 3rd, p = 0.185). In women, between tertiles of SU was observed in men (between the 1st and 2nd tertiles, the p=0.005). Mean (±SD) SU (mg/dL) was also higher (3.9±1.1; p<0.001). No significant association between GGT and 21 (16-30) in women (p<0.001). Mean (±SD) SU (mg/dL) was also higher (3.9±1.1; p<0.001). No significant association between GGT and sex (p<0.001). A p-value less than 0.05 was considered significant.

Conclusion: GGT was positively associated with SU in women, even after adjusting for potential confounders. This finding reinforces that uric acid is associated with cardiometabolic risk factors since early adult age. Nonetheless, further prospective studies are needed to understand the causality of this association especially observed in women.

AB1441 LEARNING NEEDS ASSESSMENT FOR PATIENTS WITH CANCER AND A PRE-EXISTING AUTOIMMUNE DISEASE WHO ARE CANDIDATES TO RECEIVE IMMUNE CHECKPOINT INHIBITORS

M. A. Lopez-Olivo1, J. I. Ruiz1, G. F. Duhon2, M. Altan2, H. Tawbi2, A. Diab2, C. Bingham3, C. Calabrese6, R. Volk6, M. Suarez-Almazor7,8, The University of Texas MD Anderson Cancer Center, Health Services Research, Houston, United States of America; 3The University of Texas, MD Anderson Cancer Center, Thoracic-Head & Neck Medical Oncology, Houston, United States of America; 80:1004. Canada; 7The University of Texas, MD Anderson Cancer Center, Melanoma Medical Oncology, Houston, United States of America; 3The University of Texas MD Anderson Cancer Center, Melanoma Medical Oncology, Houston, United States of America; 9Johns Hopkins University, Division of Rheumatology, Department of Medicine, Baltimore, United States of America, 10Cleveland Clinic, Rheumatologic and Immunologic Disease, Cleveland, United States of America; 11The University of Texas, MD Anderson Cancer Center, Internal Medicine, Houston, United States of America

Background: Patients with autoimmune disorders and cancer are at risk of developing immune-related adverse events (irAEs) and increasing flares of their underlying disease with immune checkpoint inhibitors (ICIs) and harms and benefits must be weighed.

Objectives: We conducted an assessment of learning needs.

Methods: We interviewed 19 patients who had received an ICI and 20 physicians who provide care for these patients. We asked what do cancer patients with pre-existing autoimmune diseases need to know in order to make an informed decision about whether to receive an ICI.

Results: Fifty-three percent of the patients were female, median age was 62.9 (±10.9). They had rheumatoid arthritis (47.4%), psoriasis (26.3%), Crohn’s disease (10.5%), ankylosing spondylitis (5.3%), systemic lupus erythematosus (5.3%), or ulcerative colitis (5.3%). Half of the patients (52.6%) had a demonstrable disease activity of the autoimmune disease at the time of diagnosis of cancer, and 47.4% did not. We asked patients the reasons for stopping or modifying treatment (for cancer or autoimmune disease), when to contact the provider, possibility of autoimmune disease progression or organ damage, sharing information with other providers, and lifestyle changes that can be done to help.

Conclusion: Although patients and physicians listed common learning points, patients also considered specific needs to increase their self-care. The information derived from this study will be used to develop a decision support tool.

Figure 1. (A). Receiver Operating Characteristic (ROC) curve of the predictive model. Area under the receiver operating characteristic curve (AUC) was 0.969, the cut-off value of 7 were with sensitivity of 81.5% and specificity of 96%. (B). Calibration curve in internal validation.

S. M. Ahn, S. Hong, C. K. Lee, B. Yoo, J. S. Oh, Y. G. Kim. 1. Asan Medical Center, Department of Rheumatology, Seoul, Korea, Republic of (South Korea); 2. Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Republic of (South Korea).

Background: In Korea, it has been reported that the incidence of some respiratory diseases and Kawasaki diseases has decreased compared to the previous year along with active non-pharmaceutical interventions in the early stages of the COVID-19 pandemic. Autoimmune inflammatory rheumatic disease (AIIRD) is mainly affected musculoskeletal organs and connective tissues due to impaired immune regulation. Although gout and osteoarthritis are rheumatic diseases, they are not a disease of the immune system, and are not included in the AIIRD.

Objectives: In this study, we investigated the change and difference in the incidence rate of various rheumatic diseases during the COVID-19 pandemic after 2020.

Methods: The number of patients for each disease from January 2016 to December 2020 was obtained from the Korea Health Insurance Review and Assessment Service database. We compared the incidence of 9 rheumatic diseases ([systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), anklosing spondylitis (AS), Sjogren syndrome (SJS), Behcet’s disease (BD), inflammatory myositis (IMi), scleroderma, polymyalgia rheumatica (PMR), and gout]) and hypertension before and after the COVID-19 outbreak. The incidence rates of patients before and after the COVID-19 outbreak were compared using the Poisson test.

Results: From 2016 to 2019, the prevalence of rheumatic diseases showed gradually increased. In 2020, the incidence of SLE, AS, SJS, BD, and IMI were significantly decreased compared to the previous 4 years. In contrast, the incidences of gout and hypertension during the COVID-19 pandemic period were significantly increased from the predicted values.

Conclusion: In conclusion, we found that the incidence of many AIIRDs, including SLE, AS, SJS, BD, and IMI decreased significantly due to the increased incidence of hypertension and gout during the COVID-19 pandemic.

ASSOCIATION BETWEEN THIOPURINE S-METHYLTRANSFERASE POLYMORPHISMS AND HEPATOXICITY IN AZATHIOPRINE-TREATED PATIENTS WITH AUTOIMMUNE DISEASES

S. H. Heh-Shiang¹, W. T. Hung¹,², W. Chia-Yi³, W. N. Huang³, Y. H. Chen⁴, Y. M. Chen⁴,⁵. Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; Taichung Veterans General Hospital, Department of Medical Education, Taichung, Taiwan, Republic of China; Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China

Background: Azathioprine (AZA) is widely used in patients with autoimmune diseases. Thiopurine methyltransferase (TPMT) is the rate-limiting enzyme in AZA metabolism. Although several studies have investigated the association between TPMT polymorphisms and AZA-induced bone marrow suppression, the relationship of TPMT genotypes and hepatotoxicity in patients taking AZA remained unclear.

Objectives: This study aimed to investigate the correlation between TPMT polymorphisms and adverse reactions of AZA.

Methods: This retrospective case-control study enrolled patients with prior exposure to AZA at the Taichung Veterans General Hospital (TCVGH) using data extracted from the Taiwan Precision Medicine Initiative (TPMI) cohort. Drug-prescription profile, comorbidities, the occurrence of leukopenia and hepatotoxicity following AZA treatment were extracted from hospital health records. Genetic variants affecting TPMT activity were determined using SNP array. Participants were categorized into normal metabolizer (NM) and non-normal metabolizer (Non-NM) groups accordingly.

Results: From the 43,035 patients in the TCVGH-TPMI cohort, we identified 2,128 azathioprine users; 2.6% (57 out of 2,128) were classified as TPMT Non-NM group. After matching by age and sex, we included 50 TPMT Non-NM, including 1 poor metabolizers (PMs), 49 intermediate metabolizers (IMs), and 1,000 NM patients for further analysis. The Non-NM genotype was associated with hepatotoxicity compared with NM genotype (HR: 3.85, 95% CI: 1.83–8.10) after adjustment for gender, AZA dosage, and comorbidities (Table 1). In the Non-NM group, the 3-year cumulative incidence of hepatotoxicity was 6.6% for one year, 16.9% for two and three years, respectively, which was significantly higher than the NM group (p=0.003) (Figure 1).

SYNOVIAL FLUID ANALYSIS IN HOT SWOLLEN JOINTS – A QUALITY IMPROVEMENT PROJECT

F. Rabban², Z. Jaffer³, L. Sammut². Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom; Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom

Background: Previous studies have reported delays in the investigation and suboptimal management of hot swollen joints, particularly crystal arthritis. In our hospital, it was noted that synovial fluid was inconsistently analysed for crystals which may lead to patients receiving delayed treatment.

Objectives: The aim of this quality improvement project was to 1) identify the number of synovial fluid samples that were not checked for crystals 2) implement changes to improve this process 3) re-audit and commitment to a continuous evaluation.

Methods: Retrospective review of synovial fluid analysis requested for adult patients presenting with hot swollen joints over a six month period. Following, the implementation of changes in the hospital, another comparison of pre-post intervention was performed. Samples were sent for analysis from March and August 2021, of which only 69 (65%) of the samples were analysed for microscopy and culture. Following involvement with IT and laboratory departments we have introduced an intervention to make requesting crystal analysis easier. The request for synovial fluid analysis was grouped in a bundle (reflex test) so whenever a synovial fluid is collected, two forms are generated, one for microbiology (microscopy and culture), and the other for cytology (crystal analysis). Additional interventions included education and raising awareness. Post-interventions, another three month analysis of synovial fluid samples that were not checked for crystals 2) implement changes to improve this process 3) re-audit and commitment to a continuous evaluation.

Results: A total of 106 synovial fluid samples were sent for analysis between March and August 2021, of which only 69 (65%) of the samples were analysed for crystals. All samples were analysed for microscopy and culture. Following involvement with IT and laboratory departments we have introduced an intervention to make requesting crystal analysis easier. The request for synovial fluid analysis was grouped in a bundle (reflex test) so whenever a synovial fluid is collected, two forms are generated, one for microbiology (microscopy and culture), and the other for cytology (crystal analysis). Additional interventions included education and raising awareness. Post-interventions, another three month analysis of synovial fluid samples that were not checked for crystals 2) implement changes to improve this process 3) re-audit and commitment to a continuous evaluation.

Conclusion: There was an improvement in the synovial fluid analysis requests of patients with hot, swollen joints. By implementing these changes and raising awareness, patients with acute crystal arthritis can be treated in a timely manner. We plan to continue our work with synovial fluid analysis following re-review and will continue to generate improvements.

TRANSLATION AND CROSS-CULTURAL ADAPTATION OF COPING WITH RHEUMATIC STRESSORS (CORS) INTO TURKISH LANGUAGE

G. Ayan1, S. Ramiro2,3, F. M. Pimentel-Santos4, W. Van Lankveld5, L. Kilic1,
1Hacettepe University Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; 2Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; 3Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands; 4NOVA Medical School, Universidade Nova De Lisboa, Department of Rheumatology, Lisboa, Portugal; 5HAN University of Applied Sciences, Research Group Musculoskeletal Rehabilitation, Nijmegen, Netherlands

Objectives: To describe the translation and cross-cultural adaptation process of CORS into Turkish as well as its cognitive debriefing to test the conceptual equivalence of the translated version among patients with RA, radiographic (r) and non-radiographic (nr) axSpA.

Methods: The CORS was firstly translated into Turkish (by 2 bilingual translators who are native speaker for Turkish) and then back-translated into Dutch (by 2 bilingual translators who are native speaker for Dutch) following the Beaton’s method (Figure 1) (3). Back-translation procedure was done totally blindly to the original version. After the review of the Turkish version by an expert committee that included translators, two patients and the research team, a consensus was reached on the pre-final version. Using the pre-final version, the field test with cognitive debriefing involved a sample of 10 RA and 10 axSpA patients with different gender, age, disease duration, and educational background. After some small changes resulting from the feedback from patients the final version was obtained.

Results: The CORS was translated into Turkish following the forward-backward procedure. Minor incompatibilities arose from the translation process of CORS which have been easily resolved by the expert committee meetings. For example, ‘Ik concentrer me op iets anders’ was translated as ‘Başka seylerle odaklanırım’ which is in English ‘I concentrate on something else’. The discrepancy was raised whether to use a word equivalent ‘to concentrate’ or ‘to focus’ and decision was made to use ‘to focus’ while there was no exact Turkish word of ‘to concentrate’. A total of 10 patients with RA [9 females, mean (SD) age of 49 (13)] and 10 patients with axSpA [7 females, mean (SD) age of 38 (10), r-AxSpA, n=7, nr-AxSpA, n= 3] participated in the field test. Mean (SD) time to complete the CORS was 8.3 (3.4) minutes. Cognitive debriefing showed that items of the CORS are clear, relevant, understandable, and easy to complete. Cognitive debriefing revealed that the wording of one item had to be changed to provide better understanding (Section B, item 22 the word ‘stop’ in Dutch and ‘stop’ in English which was translated as ‘durdurmak’ in Turkish changed to ‘sonlandırmak’).

Conclusion: The final Turkish version of the CORS showed acceptable linguistic validity and can be used in both clinical practice and for research purposes, in patients with RA and in patients with axSpA. However, to implement Turkish-CORS, further assessment is ongoing to test its psychometric properties (validity and reliability).

AB1447 CATASTROPHISM IN MOROCCAN PATIENTS WITH CHRONIC RHEUMATIC DISEASES UNDER BIOLOGICS

H. Boutaib1, H. Azzouzi1, L. Linda1, Mohamed 1 University, Rheumatology Department, Oujda, Morocco

Background: Catastrophizing is a distortion of the perception of pain, both cognitively and emotionally, which leads patients to consider only the worst. There is a lack of knowledge about catastrophism in Morrocan patients with chronic rheumatic diseases under biologic DMARDs (disease-modifying anti-rheumatic drugs).

Objectives: To assess catastrophism and its associated factors in rheumatic patients under bDMARDs.

Methods: This is a cross-sectional study of patients admitted to a day hospital for biologic treatment evaluation. Patients included were all adults with SpA or RA diagnosed according to ASAS 2009 and ACR/EULAR 2010 classifications, respectively. The Pain Catastrophizing Scale (PCS)1 was used to assess catastrophism. This scale is a self-report measure, consisting of 13 items scored from 0 to 4, resulting in a total possible score of 52. It is divided into three subscales: magnification, rumination and helplessness. A total score above 30 indicates a clinically relevant level of catastrophizing. Sociodemographic and treatment data were collected. Disease activity scores (DAS28, ASDAS) using C-reactive protein (CRP) dosage of the same day were calculated for each disease. Questionnaires were obtained for all patients for functional assessment (HAQ, BASFI), insomnia by the insomnia severity index (ISI), and depression by hospital anxiety and depression scale (HADS). Anxiety was evaluated by the generalized anxiety disorder-7 (GAD-7). Statistical analysis was done using regressions by SPSS 20.

Results: We included 75 patients with a mean age of 42.20 ± 16.206 years and a mean disease duration of 17.47 ± 8.758 years. Almost all patients (90.7%) had a disease lasting for more than 05 years. Twenty-nine patients (38.7%) had inactive disease. The average duration of bDMARDs use was 24.29 ± 18.96 months (27.8 ± 18.5 months in SpA patients and 19.53 ± 18.81 months in RA patients). Seventy-nine percent of these patients have received only one bDMARD, and 6.7% were currently taking a TNF inhibitor. The mean catastrophizing scores were 21.91 ± 11.38 for all patients, 22.05 ± 12.163 for SpA patients, and 21.72 ± 10.24 for RA patients. The prevalence of catastrophism was 25.3%, and the highest sub-score was helplessness (17.53 ± 3.95, p = 0). These scores were similar in RA and SpA patients. Catastrophizing was significantly associated with anxiety degree (p = 0.021, OR = 2.362, [1.211-4.607]), and swollen joints (p = 0.042, OR= 1.197, 95%IC [1.006-1.423]) using logistic regression analysis. Catastrophism scores were positively associated with the number of bDMARDs used (p = 0.044, ß = 0.233, 95%IC [0.095-0.721]). This association remained significant with anxiety (p<0.0001) and the number of bDMARDs received (p=0.04) at multivariate regression adjusted on swollen joints, ISI and HADS.

Conclusion: Catastrophizing scores were high despite biotherapy use. They were related to anxiety disorder, swollen joints, and bDMARDs rotation. It would therefore be interesting to detect catastrophism in clinical routine to ensure good patients care.

AB1448
DEEP VENOUS THROMBOSIS IN YOUNG ADULTS: INCIDENCE AND RISK FACTORS

F. Nabili1, S. Daadaa1, Y. Bousoukaya1, I. Chaabene1, M. Kechida1, R. Klii1, S. Hammami1
1Hospital Fattouma Bourguiba Monastir; Internal Medicine Department, Monastir, Tunisia

Background: After a first venous thromboembolic (VTE) episode, recurrence is frequent and associated with significant morbidity and mortality.

Objectives: Our aim is to identify the risk factors for recurrent VTE in young subjects and to assess the risk-benefit ratio of continuing long-term anticoagulant treatment.

Methods: We carried out a retrospective study including 100 patients with deep vein thrombosis (DVT) admitted to the Internal Medicine Department at Fattouma Bourguiba University Hospital in Monastir between 2011 and 2020.

Results: In our study, the gender ratio was 1.17. The mean age was 34.49 years ± 9.19. Lower extremity deep venous thrombosis (LEDVT) was the most common location (90%). Pulmonary embolism (PE) was found in 8% of cases. The most frequent risk factors were obesity: BMI>30 (40%), bed rest (25%), personal history of DVT (18%), smoking (16%), recent surgery dating less than one month (14%), and recent trauma (12%). The etiological assessment had concluded to inherited thrombophilia in 41 cases: protein C deficiency (23%), protein S deficiency (8%), and antithrombin III deficiency (2%); acquired thrombophilia in 28 cases: hyperhomocysteinemia (HH) in 19 cases and antiphospholipid syndrome (APS) in 9 cases; Behçet's disease in 10 cases and systemic lupus erythematosus in 5 cases. No cases of neoplasia were detected. The treatment was based on low molecular weight heparin (LMWH), by vitamin k antagonists (VKAs), and physical therapy (graduated compression stockings and early mobilization). Duration of the treatment of DVT in the young adult depends on the nature and extent of the thrombosis, the underlying risk factors, and etiologies. Among the 100 hospitalized patients, recurrent DVT was detected in 20% of cases: 17% of patients reported a history of DVT with a mean number of previous episodes of 2, and only 3% developed DVT during their follow-up. The mean time to recurrence was three years. Recurrence was located on the same side in most cases (70%). In our study, only Behçet's disease was associated with an increased risk of DVT recurrence (p: 0.015, OR: 5.46, CI [1.38-21.56]). Gender, age, venous insufficiency, and bed rest had no significant influence on the risk of recurrence (p>0.05).

Conclusion: Young adults should be assessed for acquired and also genetic factors, which would suggest extending the duration of anticoagulant therapy in high-risk patients, reducing the incidence of post-thrombotic syndrome and VTE recurrence. Further studies are needed to evaluate the association of Behçet's disease with DVT recurrence.

AB1449
ADHERENCE TO MTX AT INITIATION OF FIRST TARGETED THERAPEY: PREVALENCE AND ASSOCIATED FACTORS: RESULTS OF THE STRATEGE2 STUDY.

G. Gaujoux-Viala1, E. Demiris2, E. Senbel2, H. Herman-Demars3, J. Becker4, R. M. Fispo1. IDESP, Université Montpellier, INSERM, Department of Rheumatology, CHU Nîmes; Nîmes, France; 2Le Mans Central Hospital, Rheumatology Department, Le Mans, France; 3Cabinet de Rhumatologie, NA, Marseille, France; 4Nordic Pharma France, Medical Department, Paris, France; 5Centre Hospitalier Universitaire de France, Université de Lille, Lille, France

Background: Treatment adherence is a major challenge in chronic inflammatory rheumatic disease (CIRD). Mainly studied in rheumatoid arthritis (RA), this ranges from 30 to 80% [1]. Given the impact of non-adherence to disease-modifying therapy among RA patients, guidelines aiming to facilitate management of adherence were published in 2019 [2]. These guidelines highlight the multifactorial characteristics and importance of clarifying the factors determining non-adherence. In addition, treatment adherence was also listed as a point to consider for the management of difficult-to-treat RA by an EULAR task force [3].

Objectives: Based on inclusion results of STRATEGE2 we explore the adherence to methotrexate (MTX) and its associated factors prior to initiation of a first targeted therapy.

Methods: The objective of STRATEGE2 is to describe the therapeutic strategy in RA patients treated with MTX for at least 3 months, naive of targeted biological (bDMARD) or synthetic (tsDMARD) therapy and who are candidates for initiation of first btsDMARD therapy due to RA activity. Patients were included prospectively in 2019-2020 and completed the Compliance Questionnaire for Rheumatology (CQR) [4], a self-administered questionnaire specific to rheumatology, measuring treatment adherence. They were then divided into 2 groups: adherence (Ad) (CQR19>80) vs. non-adherence (NAd) to investigate factors liable to be associated with adherence. Then, univariate and multivariate analysis was applied to identify potential predictors for adherence.

Results: Between Feb. 2019 and Dec. 2020, 230 patients were included, with 124 RA patients having an analysable CQR19: 73.4% females, mean age 56.6 years ±13.2., diagnosed 5.6 years ±7.4 previously, treatment with MTX for 4.4 years ±5.3 and a mean DAS of 4.3 ±1.2. The mean CQR score was 75.8. Patient distribution: 45.2% in the Ad group and 54.8% in the NAd group.

</table>

In the multivariate analysis, no formal predictive factors to MTX adherence was identified except BMI>30kg/m² (odds ratio, OR (95% confidence interval, CI)=4.00, 1.08-14.65, p=0.038) and adherents who estimate having completely adhered (CQR19-based evaluation) before initiation of btsDMARD. As physicians tend to overestimate adherence to medication, clarification of the factors associated with non-adherence would help improve patient assessment and, therefore, management. Supplementary data on patients’ adherence evolution and adherence predictors, might be observed on the follow-up data at 12 and 24 months of this cohort.

Objectives: The main risk is progression to multiple myeloma (MM). SBP and to identify factors associated with progression to MM and death.

Background: Solitary bone plasmacytoma (SBP) is a rare malignancy whose main risk is progression to multiple myeloma (MM).

Methods: This retrospective study was conducted between 1992 and 2020. Patients were included if they met the International Myeloma Working Group (IMWG) criteria for the diagnosis of SBP. Treatment response was assessed according to the IMWG criteria (2) for patients with detectable monoclonal protein and according to radiological response only for non-secretory SBP. Hazard ratios (HR) and their 95% confidence intervals (CI) were estimated by Cox proportional hazards models, adjusted for potential confounders. When available, 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) were reviewed by two experienced nuclear physicians.

Results: A total of 77 patients diagnosed with SBP were included. The median age was 59 years (range: 27-89). Median follow-up duration was 87.1 months (range: 1.6-306.8). At the end of the follow-up, 45 (58.4%) patients had developed a MM and 13 (16.9%) deaths occurred, including 10 patients with progression to MM. Five-year myeloma-free survival and overall survival were 47.9% and 86.8% respectively. All patients received radiotherapy with a median dose of 45 Grays (range: 30-55). Chemotherapy was prescribed in 32 (41.6%) patients, concomitant to radiotherapy in 8, because of high risk of local extension, or adjuvant in 24 because of persistent disease after radiotherapy. Chemotherapy included mainly immunomodulatory drugs (28/32 (87.5%)) and/or proteasome inhibitors (11/32 (34.4%)) based combinations. Adjuvant chemotherapy after radiotherapy was associated with a reduced risk of MM compared to patients treated by radiotherapy alone, in a multivariate model adjusted for potential confounding factors, including response after radiotherapy alone (adjuvant chemotherapy versus no chemotherapy, HR 0.30, 95%CI [0.14-0.64]). Response to the first line of treatment (radiotherapy +/- chemotherapy) was the main factor associated with progression to MM (complete response versus partial response or progressive disease, HR 0.25, 95%CI [0.31-0.59]) and death (HR 0.20, 95%CI [0.09-0.89]). In this large study of patients with SBP, we observed that even though mostly prescribed for insufficient response to radiotherapy alone, treatment with adjuvant chemotherapy was associated with a decreased risk of evolution to MM, suggesting that this treatment might be systematically prescribed in addition to radiotherapy alone. These observations need to be confirmed and justify conduction of a prospective trial evaluating adjuvant chemotherapy in patients with SBP.

Disclosure of Interests: None declared

Background: Spondyloarthritides (SpA) are a group of chronic inflammatory diseases with affection, mainly of the axial skeleton, and also of peripheral joints. The enthesis is one of the target organs, and its inflammation known as enthesitis could be unnoticed. Machine Learning is a branch of artificial intelligence that studies the construction of a function \(g(x)\), from a finite set of observations \(D=(x,y)\), where \(y\) is an endogenous variable and \(x\) are explanatory variables. The objective of this method is to obtain a model that best fit to the data without overfitting, that could be useful to make predictions.

Objectives: We try to find Machine Learning models that relate the MASEI index (Madrid Sonographic Enthesitis Index) in entheses depending on the activity of the disease (ASDAS, BASDAI and DAPSA) and other variables in patients with spondyloarthritides.

Methods: Observational, descriptive and cross-sectional study. We have analyzed 24 patients with SpA who underwent musculoskeletal ultrasound using the MASEI index and who were treated in our clinics from May 2021 to September 2021 and under the approval of the CEICm of our center. First, we have done a feature selection of the variables most related to MASEI. To do so, we compute mutual information and chi-square test, using the scikit-learn (python) library and Matlab, respectively. Using Matlab Regresion Learner package, we obtain the best Machine Learning model with the lowest RMSE for 5 fold cross-validation, which turned out to be a linear regression.

Results: To obtain regressive models that explain TOTAL MASEI, the following variables have been chosen: Type of SpA, BASDAI-DAPSA-ASDAS activity, Arthritis, Enthesophytes, Corticosteroids and CRP because they present a high degree of mutual information with MASEI and a high chi-square index. (See Figures 1 and 2). With these variables we have obtained the model that presents a lower RMSE error for validated data, which has turned out to be a linear regression, given by the formula:

\[
\text{MASEI} = \text{Type of SpA} + 10.42\times\text{ASDAS} + 4.08\times\text{Corticoids} + 8.2\times\frac{\text{Arthritis/sinov}}{\text{Enthesophytes}} + 6.8\times\frac{\text{Corticoids}}{\text{CRP}}
\]

The basic statistical characteristics of the coefficients of this equation can be consulted in Figure 3. The characteristics of the model are specified in Figure 3. In Figure 4, we observe how the data fit the diagonal and in Figures 5 and 6, we have compute a prediction and confidence intervals of our model using ASDAS and MASEI as coordinate axes.

Conclusion: We have obtained a linear model, which explains the MASEI variable as an explicit linear combination of the variables: type of SpA, ASDAS, Corticoids, Arthritis/sinov, Enthesophytes and CRP. Our model, not only is simple, but it is also optimal, in the sense that for 5-fold cross validation, it obtains the lowest RMSE error, compared to other Machine Learning methods, such as: neural networks, SVM, Gaussian processes, etc. Our model is useful to build confidence intervals, make predictions and to understand the relation between the variables mentioned above.

Evaluating the Effect of JAK Inhibitor Therapy in Autoimmune Inflammatory Rheumatic Diseases

I. Andreică1, K. Volker2, C. Elsner4, R. Broering1, F. Vondran6, P. Behrendt7, U. Dittrich1, E. Steinmann1, X. Baraliakos4, 1Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Department of Gastroenterology and Hepatology, Essen, Germany; 2Institute for Virology, University Hospital Essen, University Duisburg-Essen, Virology, Essen, Germany; 3University Hospital Essen, University Duisburg-Essen, Department of Gastroenterology and Hepatology, Essen, Germany; 4ReMedIES, Department of General, Visceral and Transplantation Surgery, Hannover Medical School, Surgery, Hannover, Germany; 5Institute of Experimental Virology, TWINCORE Centre for Experimental and Clinical Infection Research, Virology, Hannover, Germany; 6Hepatology and Endocrinology, Hannover Medical School, Department of Gastroenterology, Hannover, Germany.

Background: Although impacting hundreds of thousands of people in Western nations each year, hepatitis E virus (HEV) is an under-reported health problem (1). HEV usually is a self-limiting disease, but especially immunocompromised individuals are at risk to develop a chronic course of infection, with rapid progression to fibrosis, cirrhosis or even the development of liver failure. Janus kinase (JAK) inhibitors are a novel drug class for the treatment of autoimmune inflammatory rheumatic disease (AIRD). As JAKs play a key role in innate immunity, viral infections and reactivation are frequently reported during JAK inhibitor treatment in AIRD patients (2).

Objectives: To characterize the influence of JAK inhibitors on HEV replication ex vivo and assess the risk for the development of symptomatic HEV infection during JAK Inhibitor therapy in vivo.

Methods: To determine the effect of JAK inhibitors on HEV replication we performed infection experiments with primary human hepatocytes (PHH) followed by immunofluorescence analysis and RNAseq. To evaluate the risk of HEV infection during JAK Inhibitor therapy, we monitored HEV RNA and HEV IgG/IgM of 111 AIRD patients, receiving JAK inhibitors. Moreover, we conducted a retrospective analysis of liver enzymes of patients which were anti-HEV IgG/IgM positive.

Results: Transcriptomic analysis of PHH revealed an upregulation of innate immunity components during HEV infection. This induction was perturbed in the presence of a JAK inhibitor concomitant with strong elevation of HEV RNA levels. In line, infection experimentsdisplayed an up to 50-fold increase in progeny virus production during JAK inhibitor treatment indicating that JAK signaling is critical to control HEV infection. Monitoring of seroprevalence identified 17 patients which were anti-HEV IgG and/or IgM positive, while no patient had detectable HEV RNA levels. Five patients had detectable anti-HEV IgM levels suggesting a recent HEV infection. Three of 17 had a period with elevated liver enzymes (i.e. GGT > 200 U/L) during time of retrospective analysis (ranging from 10 to 23 months).

Conclusion: Obtained ex vivo data suggest that JAK inhibitor facilitates HEV life cycle progression. Considering that JAK inhibitors are routinely applied for the treatment of AIRD, these patients may be at higher risk for a symptomatic course and outcome of HEV infection. In addition to establish prevalent, screening for HEV seroprevalence and HEV RNA should be considered prior starting JAK inhibitor treatment and in case of elevated liver enzymes during JAK inhibitor therapy.

Objectives: The aim of our study was to determine the frequency of occurrence of traditional and non-traditional cardiovascular risk factors in patients with SLE and RA in comparison to patients with IHD and to assess their role for the development of early atherosclerosis.

Methods: The study included 85 female patients with ARD (SLE (n=40), mean age 33.5 (27.5; 44.5) years old, disease duration 8.0 (5.0; 14.5) years, disease activity SLEDAI-2K 7.0 (4.0; 11.5) points and RA (n=45), mean age 43.0 (33.0; 52.0) years old, disease duration 9.0 (5.0; 13.0) years, disease activity (DAS28=5.37 (4.69;5.89) points. Fifty four healthy women of the same age formed the first control group (CG1), 22 women with IHD (mean age 50.0 (48.0; 51.0) years old) made the second control group (CG2). The presence of traditional (age, arterial hypertension (AH), smoking, obesity, dyslipidemia, low physical activity, family history of cardiovascular disease (CVD)) and non-traditional (menopause, hyperhomocysteinemia (HHC)) risk factors was assessed. The early development of atherosclerosis was confirmed with the help of common risk factors in patients with SLE and RA may be associated with the development of early atherosclerosis.

Results: It was found that only AH and HHHC were more in patients with SLE and RA in comparison to CG1 (AH: 65% vs. 0% (p<0.0001), HHHC: 45% vs. 9% (p<0.0001), respectively for SLE patients and 27% vs. 0% (p<0.0001), 36% vs.9% (p=0.001), respectively for RA patients). Age, smoking, obesity, dyslipidemia, low physical activity, family history of CVD, menopause were similar in both groups of patients and CG1. It was revealed that patients with SLE were 14 years younger (p<0.0001) than female patients with IHD. They had less often family history of CVD (18% vs. 41%, p=0.044), but HHHC was revealed 2 times more often (45% vs. 22%, p=0.031) than in CG2. Patients with RA were 8 years younger than patients with IHD (p=0.007). Moreover the frequency of occurrence of AH, obesity, dyslipidemia, family history of CVD was less than in CG2 (27% vs. 73% (p=0.0003), 40% vs. 13% (p=0.03), 71% vs. 55% (p=0.025), 11% vs. 41% (p=0.005), respectively). HHHC was detected 1.5 times more often in RA patients in comparison to patients with IHD, but without statistically difference (36% vs. 22%, p=0.288). Other risk factors were similar in both groups of patients with ARD and IHD. The presence of subclinical atherosclerosis was observed in 54% patients with ARD. Comparative analysis of the frequency of occurrence of investigated cardiovascular risk factors between these patients and those with IHD has shown the highest prevalence of HHHC in patients with ARD (54% vs. 22%, p=0.014), which could be as a result of autoimmune inflammation in this group of patients. Conclusion: Thus, we revealed a high prevalence of AH (as traditional risk factor) and HHHC (as non-traditional risk factor) in patients with SLE and RA. More than half of patients with ARD had subclinical atherosclerosis. The presence of HHHC in patients with SLE and RA may be associated with the development of early atherosclerosis.

CLINICAL AND BIOLOGICAL FACTORS CORRELATED WITH MAGNETIC RESONANCE IMAGING RESULTS IN TUBERCULOUS SPONDYLODISCITIS

M. Mirabet1,2, S. Boussaid3, S. B. Troud4, S. Reikik1, S. Rahmouni1, S. Jemmali1, H. Aljani1, H. Sahl1, M. Elleuch1,2. 1Rehabilitation Hospital, Rheumatology, Tunis, Tunisia

Background: Tuberculosis is still endemic in Tunisia. Although pulmonary localisation is the most common, other localizations, including osseous-articular involvement, are increasingly diagnosed. Tuberculous spondylodiscitis (SPDT) or Pot’s disease is an infectious involvement of the disc-vertebrate couple, caused by the tubercular bacillus (Mycobacterium tuberculosis). Magnetic resonance imaging (MRI) is the most sensitive (95-100%) and the most early abnormal exam.

Objectives: Our aim was to study the correlation of contributing factors, epidemiological, clinical, biological, radiological and therapeutic data with positive signs of spinal MRI.

Methods: We conduct a retrospective and descriptive study in a single rheumatology department. Data were collected from observations of patients hospitalized in the past 20 years (2000-2020) who have been diagnosed with SPDT. Epidemiological, clinical, biological, radiological, and therapeutic data were analyzed. Each patient had spinal MRI. Positive signs have been individualized, represented by intervertebral disc involvement, vertebral body and visualization of a paravertebral abscess.

Results: Fifty-two cases of SPDT were collected (37F/15M). The mean age of the population was 55.21±17.79 years [19-91]. Thirty-three patients (69.2%) were positive for AH (anti-sm Sm IgG and IgM). The positive diagnosis was AH and HHC were more frequent in patients with SPDT (p= 0.04; r= -0.33) and the surgical treatment (p < 0.001). The neurological clinical signs were correlated with the heterogeneous increase in vertebral body T1 sp signal (p=0.04; r=-0.33) and the surgical treatment (p < 0.001).

Conclusion: Tuberculous spondylodiscitis is a frequent condition that needs to be diagnosed and treated rapidly. Spinal MRI is the first-line exam in case of suspicion. Clinical, biological and therapeutic parameters were correlated with the MRI images highly suggestive of positive diagnosis.

Disclosure of Interests: None declared.

VERY LOW FREQUENCY ANAS/DFS70 PATTERN POSITIVITY IN A LARGE CORHOTE OF AUTOIMMUNE/ AUTOINFLAMMATORY AND CONTROLS IN A SINGLE HOSPITAL FROM COLOMBIA

C. Romero-Sánchez1,2,3, À. J. Caicedo1,2,3, V. S. Romero Alvarez1, A. Vargas4, L. Castro5, J. Amado6, P. Lopez-Mojica6, D. Marin7, D. Acero-M8,5, M. Acevedo-Godo8, D. Rincon-Riaño9, W. Bautista-Molano10, J. M. Bello-Gualtero11,2,1
1Hospital Militar Central, Rheumatology and Immunology Department, Bogota, Colombia; 2Universidad El Bosque, Cellular and Immunology Group InmuBo, Bogota, Colombia; 3School of Medicine, Universidad Militar Nueva Granada, Clinical Immunology Group, Hospital Militar, Bogota, Colombia; 4Universidad Colegio Mayor de Cundinamarca, Bacteriology School, Faculty of Basic Sciences, Bogota, Colombia; 5Hospital Militar Central, Universidad Militar Nueva Granada, Dermatology Department, Bogota, Colombia; 6Hospital Military Central, Immunology Laboratory, Bogota, Colombia

Background: Antinuclear antibodies (ANA) have diagnostic significance in rheumatology. Anti-DFS70 (Dense Fine Speckle-70 kd) antibodies may be an exclusionary marker for systemic autoimmune rheumatic disease (SARD). Low frequency of this pattern has previously been described in healthy populations.

Objectives: To evaluate ANAS/DFS70 positivity and autoantibody profile in a large Colombian population with rheumatoid arthritis (RA), psoriasis (PsO), as well as, undifferentiated connective tissue diseases (UCTD), first degree relatives (FDR), and healthy controls (HC).

Methods: A cross-sectional study was conducted. We analyzed 531 individuals between 18-65 years, 101 RA patients (ACR/EULAR 2010 classification criteria), 137 relations from RA, 60 PsO patients (Colombian classification consensus), 17 UCTD patients, and 106 HC patients by age and sex. The determination of ANAS+HEp2 antibodies, was carried out. The ANAS/DFS70 positive results used as a confirmatory test the determination by Knockouted, for the psip gen and CytoBeard by indirect immunofluorescence–IFi technique. Absolute and relative frequencies were established and associations with chi square test.

Results: The distribution by diagnostic group was RA: 19%, PsO: 11.3%, UCTD: 8%, 25.8% RA relatives, and 35% healthy controls, RA was ANA test (+) in 42% PsO 41.7%, UCTD 78.7%, FDR 26.3%, and HC 26.9%. The positive frequency of ANAS/DFS70 in the total group was 2.3% and 1.4% in SARD (n=12; 2 FDR, 6 HC, 3 UCTD, and PsO 1), no RA patients were positive. These 12 participants were negative for rheumatoid factor (RF) and anti-citrullinated protein antibody (ACA), one patient with UCTD were positive for Anti SSB/La, Anti Sm, Anti RNP, and anti-citrullinated proteins, another was positive for Anti Sm and IgG B2GPR and IgA- B2GPR. Most participants had negative acute phase reactants (erythroesudmentation rate ESR[±] 83.3% and C-reactive protein CRP[±] 66.6%). ANAS/DFS70 was associated with positivity for ANAS independently of ANAS titters, (p <0.001). None of the patients' positives ANAS DFS70 in the UCTD group in 5 years developed definitive autoimmune disease.

Conclusion: Despite the low frequency in the group in general, ANAS/DFS70 was present in very low frequency in Colombian patients with SARD. Thus, patients with a positive result tend to have a mild or non-progressing phenotype of autoimmune or autoinflammatory diseases. This analysis reinforce the idea that ANAS/DFS70 positivity may be associated with a lower risk of SARD. Low frequency of ANAS/DFS70 pattern may be an exclusionary marker for systemic autoimmune rheumatic disease (SARD). Low frequency of this pattern has previously been described in healthy populations.

CLINICAL IMPACT OF THE INTERSTITIAL LUNG DISEASE MULTIDISCIPLINARY SERVICE

S. Eisa1, B. Osei-Boadu1, G. Singh-Rathore1, M. Rabban2, K. Suthar4, S. Ansari3, G. M. Koduri1, 1Southend University Hospital, Rheumatology, Essex, United Kingdom; 2Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom; 3Southend University Hospital, Respiratory, Essex, United Kingdom; 4Southend University Hospital, Radiology, Essex, United Kingdom

Background: Interstitial lung diseases (ILD) are a diverse group of pulmonary diseases for which accurate diagnosis is critical for optimal management and outcomes. Diagnosing ILD, both idiopathic pulmonary fibrosis (IPF) and connective-tissue-disease-associated interstitial lung disease (CTD-ILD), has become critically important, as the disease has a devastating prognosis with poor survival. There are many disease implications, as patients with ILD can now potentially be treated with new antifibrotic therapies such as piperidinone and nintedanib, both of which have been approved. Certain types of CTD – ILD may benefit from systemic immunomodulatory therapies. Diagnosis of ILD can be challenging and a multidisciplinary team (MDT) approach is recommended in current guidelines. Several studies have reported that MDT diagnosis is associated with higher levels of diagnostic confidence and better interobserver agreement (1-3).

Objectives: We describe the benefits of an ILD multidisciplinary service on the diagnosis and management of patients with suspected ILD.

Methods: We performed a single-centre retrospective review of consecutive patients referred to the ILD clinic with subsequent discussions in ILD MDTs over a 36-month period from 2016 to 2019. We compared changes in ILD diagnosis and management at referral to those following the ILD-MDT. We collected data on the demographics, occupation, age at ILD onset, smoking status, imaging, blood tests including autoimmune serology, MDT recommendations, change in diagnosis after MDT, referral per, final ILD diagnoses, and outcomes. Cases of suspected ILD that were not fully characterised and those with complex management issues were presented at our monthly ILD MDT.

Results: A total of 206 patients were referred to the ILD clinic over a 36-month period. Of these, 106 cases were discussed at the ILD MDT and the remaining 102 cases did not require discussion at the MDT as these deemed to be clear cut, which included RA and CTD-ILD. The mean age of the total cohort was 74 years (min 32, max age 97) and 120 (58%) were males. Overall, evaluation by the ILD service resulted in a change in diagnosis in 106/11% patients. Of those, 49 (46%) didn’t have ILD. In the remaining 57 patients with suspected ILD, the majority of the diagnoses were ILD with an uncertain classification (24, 23%). The other diagnoses included CTD-ILD (4, 3.7%), ILD with autoimmune serology (10(10.4%), IPF (10(9.4%), Drug-induced-ILD (3,28%), Hypersensitivity Pneumonitis (5(4.7%), Esophophilic pneumonitis (1(0.9%), Cryptogenic Pneumonitis (1(0.9%), CEPPE (1(0.9%), CPFE (1(0.9%), , RF (0.9%), RB-ILD (1(0.9%), Langerhans Histiocytosis (1(0.9%),16/57(28%) were referred to a tertiary centre for further management. Serology was positive in 11 patients (ANA 6, CCP 3, and ANA 2). Of the 57 patients with other diagnoses, the main recommendations included steroids (28), anti-fibrotic therapy (4), immuno-modulatory therapy (6) and ambulatory Oxygen (1). Further analysis will be carried out on survival and treatment outcomes of the cohort.

Conclusion: Dedicated ILD-MDT service has important clinical impact on the care of the ILD patient, with frequent changes in ILD diagnosis and subsequent management and outcomes. Multidisciplinary approach to the management of these patients should be standard of care for these patients.

OPALE: A PROSPECTIVE OBSERVATIONAL STUDY OF THE REAL-WORLD USE OF AN ADALIMUMAB BIOSIMILAR AND EVALUATION OF NUTRITIONAL STATUS ON THE THERAPEUTIC RESPONSE. PATIENTS NUTRITIONAL STATUS AT BASELINE

M. Soubrie1, M. Vigier2, L. Peyrin-Biroulet3, S. Czernichow4, 1University Hospital Gabriel Montpied, Department of Rheumatology, Clermont-Ferrand, France; 2Robert Debre Hospital, Department of Dermatology, Reims, France; 3University Hospital of Nancy-Brabois, Department of Gastroenterology, Vandoeuvre les Nancy, France; 4Georges Pompidou European Hospital, Department of Nutrition, Paris, France

Background: Chronic inflammatory diseases treatment has been greatly improved since the introduction of TNF inhibitors and later, of their biosimilars. In addition, epidemiological and interventional studies suggest a pathophysiological or therapeutic role, respectively, of nutrition in Inflammatory Rheumatic Diseases (IRDs).

Objectives: The objective of the OPALE observational study was to describe in real life the profile of patients treated with an adalimumab biosimilar and to assess the impact of nutrition on disease evolution and response to treatment.

Methods: The study planned a one-year follow-up of patients with at least three visits: inclusion, six months and one year. In this study, 754 patients treated with Fresenius-Kabi adalimumab were included: 54.4 % of patients with an IRD, 42.6 % with Inflammatory Bowel Disease (IBD) and 2.8 % patients with a psoriasis. Patients' condition was assessed using a Clinical Global Impression of disease scale (CGI, primary end point of the study). Nutritional status was assessed through clinical data (weight, BMI (Body Mass Index), abdominal circumference) and the available biological analyses results. Screening for sarcopenia was based on a SARC-F score ≥ 4. Nutritional behavior was assessed using a diet questionnaire with a list of 48 foods divided into 6 classes (Fruits & vegetables, meat, fish & eggs, dairy products & fats, starchy foods, sweet foods and drinks).

Foods voluntarily withdrawn due to illness and those avoided at acute flare-ups were recommended to be reported. This analysis aims to describe IRD patients' nutritional status at baseline.

Results: From 754 included patients, 410 patients presented with an IRD (Psoriatic Arthritis (PsA), n= 80 / Rheumatoid Arthritis (RA), n=102 / SpondyloArthritis (SpA), n=228). Mean patients' age was 47.7 ± 14.1 years, 56% are female, mean BMI was 26.0 ± 5.4kg/m². From this IRD population, 754 patients treated with Fresenius-Kabi adalimumab as their first biotherapy. Most of patients received Fresenius Kabi adalimumab as their first biotherapy. Most of patients were assessed on the CGI scale as markedly ill (50.7%) or moderately ill (29.9%) and 110 patients (37.3%) had a score ≥ 4 on the SARC-F questionnaire (mean age 48.9 ± 14.1 years and mean BMI 27.2 ± 5.6kg/m²). Concerning the disease history at baseline, the descriptive analysis of self-administered questionnaire shows that 68.3% of patients may have changed their nutritional behavior because of their illness, by banishing several foods (mean number: 12.7 ± 10.1). These restrictions are increased during flare-ups; 32.7% of patients removed an average of 6.0 ± 5.8 additional foods number. These changes are in part based on the patients' own beliefs: 17% of them consider that certain foods can improve their illness, 35% of patients think they have identified the foods likely to make it worse (Table 1).
Conclusion: These preliminary baseline data from OPAL observational study confirm the risk of adverse cardiovascular events in IRD. Mean BMI of patients studied for sarcoptosis is higher than that of non-sarcoptopenic patients (respectively 27.2 ± 5.6 kg/m² and 25.6 ± 4.8 kg/m²; p=0.02). These results lead for a systematic screening for sarcopenia in IRD patients. The risk of sarcopenia could be further aggravated by inappropriate nutritional behaviors aimed at excluding food groups, which would justify dietary education of these IRD patients.

AB1458 JAK INHIBITORS AND VENOUS THROMBOEMBOLISM EVENTS - REASSESSING DATA FROM A LARGE SINGLE CENTRE RETROSPECTIVE STUDY

C. Beever 1, S. Bartsz-Bowden 1, M. Fletcher 1, L. Goh 1, G. Dulay 1, 1Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom

Background: In March 2021, the European Medicines Agency (EMA) sent out a Medicine Alert related to Xeljanz (tofacitinib): The initial clinical trial results suggested an increased risk of major adverse cardiovascular events and malignancies with use of tofacitinib relative to TNF-alpha inhibitors. In light of these safety alerts, March 2021, the Rheumatology department at Portsmouth Hospitals University NHS Trust updated the Biologics Screening documents to include a cardiovascular and venous thromboembolism (VTE) risk assessment. We conducted a retrospective observational study to document the incidence of VTE in patients on Janus kinase (JAK) inhibitors admitted to our Venous thromboembolism Service from 14th April 2018 to 30th November 2021 (43 months). This includes patients who were suspected of having both deep vein thrombosis (DVT) and/or Pulmonary Thromboembolism (PE). We were particularly interested to assess whether any patients with VTE events had been receiving JAK inhibitors given the potential association of JAK inhibitor usage and VTE.

Objectives: To establish whether patients exposed to JAK inhibitors had any increased incidence of VTE. This was done through a retrospective analysis for all patients presenting to Portsmouth Hospitals University NHS Trust.

Methods: We utilised the International Classification of Diseases (ICD10) diagnosis code of 182 (182.0, 182.1, 182.2, 182.3, 182.8, 182.9). This includes; Budd Chiari syndrome, thrombophlebitis migrans, embolism and thrombosis of vena cava, embolism and thrombosis renal vein, embolism and thrombosis of other specified view and embolism and thrombosis unspecified vein. From this data set, we reviewed how many case of VTE were noted in patients on JAK inhibitors. The Data was confined to patients who underwent diagnostic tests for VTE at Portsmouth Hospitals University NHS Trust.

Results: A total of 417 patients had been admitted to the VTE Service for diagnostic assessment between 14th April 2018 to 30th November 2021. A total of 261 patients had been on a JAK inhibitor during the period of observation. This included patients on Tofacitinib, Baricitinib, Filgotinib and Upadacitinib. This was for treatment in Rheumatoid Arthritis and Psoriatic Arthritis where licenced indications were appropriate. None of these had a VTE event. The age range of the patients on active treatment was 18 to 86 years old with the average of 60.7 years. The majority of patients were female (72.7%) with male patients comprising the remainder (27.3%). 8 patients under the care of the Rheumatology service were identified as having VTE events.

Conclusion: From a total of 261 patients on JAK inhibitors during a 43 month period; 0 patients had a confirmed VTE event. After March 2021, the Rheumatology department sought to address the concerns raised by the EMA alert. There were two key areas in addressing the concerns highlighted. Firstly, clinicians had an heightened awareness of the potential risk of VTE and JAK inhibitor usage. Additionally, there was also the introduction of a new screening process which focussed on highlighting and assessing risk facotrs for VTE in patients being screened for JAK inhibitors. This was a new departmental service innovation introduced following the potential patient safety alert. We would postulate that some of the highly encouraging data obtained may partly be influenced by this service development. Conversely, much of the data was gathered before these associations were established and before any service changes were made. We acknowledge that this data set is from a single centre analysis. However, given the sample size and duration of retrospective review, we hope this serves to reassure clinicians that JAK inhibitor usage should remain a valid treatment option in Rheumatology patients, for licenced indications.

AB1459 IMPACT OF SOCIOECONOMIC FACTORS ON THE DISEASE ACTIVITY: DATA FROM THE TUNISIAN BINAR REGISTRY

R. Ben Aissa 1, S. Boussaid 1, S. Rekik 1, S. Jemmal 2, S. Rahmouni 1, H. Srai Sahn 1, M. Elieuch 1, Rabba Hospital, Department of Rheumatology, Tunis, Tunisia

Background: Despite the considerable therapeutic progress of inflammatory rheumatic diseases, access to treatment still challenging in developing countries because of scarce health resources and low socioeconomic status.

Objectives: To determine the influence of socioeconomic factors on disease activity in a national registry cohort, the Biological National Registry (BINAR) in Tunisia. Methods: We enrolled patients with inflammatory rheumatic diseases under the first received biological drug and included in the BINAR registry from 2016 to 2020. Data on the inflammatory rheumatic disease (rheumatoid arthritis (RA) and spondyloarthritis (SA)), disease activity of RA and SA (DAS28- CRP and ASDAS- CRP respectively) at baseline, gender, active smoking, marital status and educational attainment were collected. Two groups were identified: Groupe 1 (G1) for patients with remission or low disease activity and groupe 2 (G2) for moderate or high disease activity according to DAS28-CRP and ASDAS-CRP.

Results: The study included 298 patients with a mean age of 49.2 years [18-79]. The mean disease duration was 6.7 ± 3.5 years [1-14] in patients with RA and 6.5 ± 3.6 years [1-12] in patients with SA. G1 was made of 13 patients and G2 of 285 patients. The mean age difference between G1 and G2 was (49.5 ± 11.9 versus 49.5±14.2, p=0.93) gender (% of females, 46.2% versus 37.1%, p=0.51) and marital status (% of single patients, 30.8 % versus 33.7%,p=0.82). Patients of G1 had better employability than G2 (61.5% versus 45.6%) but this difference was not significant (p=0.5). Smoker patients had better disease outcomes comparing to nonsmokers but this difference was not significant (23.1 % versus 13.7%, p=0.34). Illiterate patients had more active diseases, comparing to literate, but this difference was not significant (30.8% versus 40.4%, p=0.49).

Conclusion: Our results did not confirm any difference in disease activity according to the collected socioeconomic factors. Data on the personal income, health insurance type and geographic distribution of our population should be further studied.

AB1460 ACCUMULATED ADVANCED GLYCAZATION ENDPRODUCTS ARE SIGNIFICANTLY HIGHER IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES THAN IN HEALTHY POPULATION.

L. Triger 1, I. Carrion Barberi 2, I. Tio 2, T. C. Salmon Monte 2, C. Perez 2, L. Polino 3, A. Ribes 1, J. Lorente Onaindia 1, J. Montfort 1, IMIM (Hospital del Mar Medical Research Institute), Immunology and Cartilage Cellular Research Group, Barcelona, Spain; 2Hospital del Mar, Rheumatology, Barcelona, Spain

Background: Advanced glycation endproducts (AGEs) are the result of non-enzymatic glycation of proteins, lipids or nucleic acids. In circumstances characterized by increased oxidative and carbonyl stress, such as chronic inflammation, AGEs can be formed more rapidly1, generating reactive oxygen species and activating inflammatory signaling cascades through their chief signaling receptor RAGE2. This positive feedback of inflammation can play a role in the etiology of immune-mediated inflammatory diseases, more specifically in rheumatoid arthritis (RA), ankylosing spondylitis (AS) and systemic lupus erythematosus (SLE).

Objectives: To investigate whether the accumulated concentrations of AGEs in patients with SLE, RA or AS are significantly higher than in healthy patients.

Methods: One hundred thirteen consecutive patients fulfilling ACR/EULAR criteria for RA, 60 patients fulfilling ASAS/OMERACT MRI criteria for AS, 97 patients fulfilling ACR/SLEIC criteria for SLE and 527 sex-matched healthy controls were recruited in cross-sectional study. Exclusion criteria were pregnancy, diabetes mellitus, corticosteroid treatment >20mg/day and malignant neoplasm.

**Continuous normal: mean (SD); Continuous non-normal: median (IQR); Categorical: absolute (relative frequency)**

Accumulated AGEs were non-invasively measured by skin autofluorescence (Age Reader Mu Connect, Diagnostics Technologies B.V) and demographic and clinical data were collected. AGEs comparisons between patients and controls were performed by multiple linear regression analysis adjusted by confounders, previously described in literature (age, smoking habit and cardiovascular risk-factors). Age was centered at 55 years.

**Results:** Table 1 shows some descriptive characteristics of our cohorts. AGEs adjusted mean was significantly increased in SLE patients compared with matched controls (95% CI [2.27, 2.76] vs [1.66, 1.89], p<0.0001), RA patients and controls (95% CI [2.41, 2.61] vs [1.68, 1.88], p<0.0001) and AS patients and controls (95% CI [2.03, 2.6] vs [1.66, 1.93], p<0.0001). In all 3 models, AGEs were also significantly positive correlated with smoking habit measured by packs per year (p<0.001) and age (p<0.0001).

**Conclusion:** Accumulated AGEs in all 3 pathologies are significantly higher than in the healthy controls. The different means of AGEs in each of the diseases, being higher in SLE and lower in AS, may suggest a different participation of AGEs in the immune-mediated mechanisms of each pathology.

**DOI:** 10.1136/annrheumdis-2022-eular.4893

**Figure 1. Discontinuation rate curves in RA patients with high disease activity (DAS28 >5.1) and DAS28c<5.1.**

**Conclusion:** In Mexican RA patients registered in BIOBADAMEX, we found that baseline high disease activity is associated with the discontinuation of bDMARDs. Further longitudinal analyses will be performed including more patients to assess retention rate of specific bDMARDs and identify predictive variables of discontinuation in Mexican population.

RHEUMATIC IMMUNE- AND NON IMMUNE-RELATED ADVERSE EVENTS IN PHASE 3 CLINICAL TRIALS ASSESSING PD-(L)1 CHECKPOINT INHIBITORS FOR LUNG CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Vecchio1, M. Kostine2, A. Tison2, M. Dipasquale1, S. Kingsperger2, G. Grandi3, O. Cafio4, S. Incchiostro5, G. Paolazzi5, R. Bortolotti5, D. Corne6, A. Berti5, Hospital of Trento, University of Trento, Oncology, Trento, Italy; 5CHU Bordeaux, Medicine, Bordeaux, France; 3CHU de Brest, Rheumatology, Brest, France; 4University of Trento, CIBIO, Trento, Italy; “Hospital of Trento, University of Trento, Rheumatology, Trento, Italy

Background: Several adverse events (AEs) occurring during immune checkpoint inhibitors (ICIs) therapy are clearly related to their mechanisms of action, and in this case they are indicated as immune-related AEs (irAEs). Every organ may be affected, including the musculoskeletal system; myositis, polymyalgia rheumatica, arthritis or arthralgia have been reported in several retrospective and prospective case series and cohorts, with an incidence between 1.5% and 22%. While arthritis, vasculitis, myositis, and polymyalgia rheumatica are usually defined as irAE in RCTs, other rheumatic musculoskeletal conditions such as arthralgia, myalgia, back pain and muscular pain are often reported under the umbrella of “general” AEs.

Objectives: We aimed to analyze rheumatic irAE and non-irAE due to immune-checkpoint inhibitors (ICIs) targeting programmed cell death-1 or its ligand PD-(L)-1 in lung cancer patients from the available literature.

Methods: We performed a systematic review and meta-analysis of phase III randomized clinical trials (RCTs) assessing PD-(L)-1 ICIs in lung cancer patients, from inception until January 12th, 2021. We extracted data of each trial to estimate odds ratio (OR) for rheumatic ir or non-irAE as classified in RCTs safety data. Sensitivity analyses (by treatment group and histology) were performed.

Results: Eighteen RCTs met the inclusion criteria (n=12172 subjects). The OR [95%IC] for rheumatic irAE in ICIs versus controls (either placebo or chemotherapy) was 2.20 [0.85;5.72]. Among rheumatic non-irAEs, both overall (any grade, Figure 1A) and severe (grade3, Figure 1B) back pain were significantly more frequent in ICIs versus controls (2.01 [1.09;3.73] and 2.90 [1.16;7.08], respectively).

The overall frequency of arthralgia and severe arthralgia was similar between ICIs and controls (1.13 [0.86;1.47] and 1.69 [0.68;4.20], respectively). By sensitivity analysis RCTs assessing ICIs in combination with chemotherapy versus chemotherapy alone showed a significant association with arthralgia (1.55 [1.15;2.10]). Similarly, the frequency of myalgia did not differ between ICIs and controls, but was significantly lower in RCTs assessing ICIs alone versus chemotherapy (OR 0.32 [0.24;0.42]). Muscular pain was not significantly increased with ICI. Conclusion: Rheumatic irAEs are not increased in RCTs assessing PD-(L)-1 inhibitors, not reflecting the real-life incidence, therefore likely underreported or misclassified. Back pain is significantly associated with PD-(L)-1 ICIs regardless its severity, suggesting a possible implication of the PD-(L)-1 axis in the development of inflammatory back pain in some patients. In addition, PD-(L)-1 ICIs added on conventional chemotherapy are associated with a significantly higher frequency of arthralgia than ICI alone. This trend was seen in the other rheumatic AEs, suggesting that conventional chemotherapy might be a confounder in the interpretation of the occurrence of rheumatic AE.

AB1463

CHARACTERISTICS AND MORTALITY OF PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES ADMITTED TO THE INTENSIVE CARE UNIT.

J. P. Baldievich1, E. Miguez Tato2, C. Valero3, F. Gutierrez-Rodriguez2, C. Alvar Gonzalez2, D. Rodriguez Semaro3, A. Garcia-Vadillo1, Hospital de La Princesa, Rheumatology, Madrid, Spain; 3Autonomous University of Madrid, School of Medicine, Madrid, Spain; 4Hospital de La Princesa, Intensive Care Unit, Madrid, Spain

Background: Autoimmune rheumatic diseases (ARD) are associated with multiple organ dysfunction, which may require admission to Intensive Care Unit (ICU), constituting a challenge for rheumatologists and intensivists. The new immunomodulatory treatments may be changing the characteristics and mortality of these patients.

Objectives: The primary objective of the study is to know the mortality and the characteristics related to this event of our patients admitted to the ICU in the last year, in order to secondary objective to compare the characteristics of our series with the series of our patients admitted to the ICU in the previous decade.

Methods: We conducted a retrospective transversal observational study using computerized medical records. A database was created with patients with ARD admitted to the ICU of the Princess University Hospital between October 1, 2015 and September 30, 2020, excluding those with a stay of less than 24 hours. Collection was made about the characteristics and treatments of the disease prior to their admission to the ICU, as well as the clinical characteristics and therapeutic measures established in the ICU during their stay. Statistical analysis was performed using SPSS.

Results: After ruling out admissions of less than 24 hours, a population of 45 patients with a mean age of 65.3 ± 12.2 years and 69% were women included. Connectivopathies (40%) and rheumatoid arthritis (37.8%) were the most prevalent ARDs that required admission to the ICU. Cardiovascular events (51%) were the main reason for ICU admission, followed by infectious processes (27%). The median ICU stay was 5 days. It is striking that 77% of the patients had received glucocorticoids prior to admission throughout their disease. The median score on the severity scales was 34 in SAPS II and 17 in APACHE II. Mortality during the ICU stay was 30.4% and in the multivariate analysis it was associated with the previous administration of glucocorticoid boluses and the APACHE II scale score. This mortality is higher compared to historical series of patients admitted to Spanish ICUs with similar APACHE II severity scores. In the comparative study with the previous period, similar mortality rates were observed, an increase in the mean age of those admitted, a decrease in patients with vasculitis and an increase in patients with rheumatoid arthritis. Likewise, an increase in cardiovascular events is observed as a fundamental reason for admission to the ICU.

Conclusion: The mortality of our patients with ARD admitted to the ICU in the last five years is 30.4%, similar to the previous decade but higher than the observed in other pathologies with similar severity characteristics. It is related to the APACHE II score and to the prior administration of glucocorticoid boluses. Connectivopathies and rheumatoid arthritis are the diseases that are most frequently admitted to the ICU and the fundamental reasons are cardiovascular events and infections.

Disclosure of Interests: None declared

Results: The average age of all patients was 61.4±11.77 years (p=0.007) with predominant female gender in all groups, 81.3% (p=0.139). Anti-EBNA1 IgG antibodies were present in 95%, 92%, and 98% (p=0.474), anti-EBV-CA IgG antibodies in 95%, 80%, and 100% (p=0.001), anti-EBV-CA IgM antibodies in 25%, 40%, and 4% (p=0.008), anti-EBV-EA IgM antibodies in 14%, 21%, and 4% (p=0.084), and anti-EBV-EA IgM antibodies in 20%, 16%, and 6% (p=0.094) in RAa, RAb, and OA, respectively. There was statistically significant difference in the titer of anti-EBV-CA IgG and IgM antibodies between all three groups (p=0.001 and p=0.007, respectively). According to serology findings active EBV infection was present in 47%, 40%, and 12% in RAa, RAb, and OA, respectively (p=0.001). On the other hand, corresponding to PCR results only, active EBV infection was detected in 6.3%, 0%, and 20% in RAa, RAb, and OA, respectively (p=0.010). There was statistically significant difference in way of detecting active EBV infection based on serology or PCR only (p=0.001). Further analysis showed that over 80% of all RA patients (61% in RAa and 96% in RAb), whilst 48% of OA had elevated values of sedimentation (SE) (p=0.001). C-reactive protein (CRP) was raised in 93% RA (79% in RAa and 100% in RAb) and in 26.5% of OA patients (p=0.001).

The majority of all RA patients had elevated rheumatoid factor (RF) and ACPA (84% and 92%), with no difference between RAa and RAb patients (p=0.361 and p=0.203, respectively). Among patients with active EBV infection (based on both serology and PCR results), there was a significantly higher level of antidiagnostic IgG (p=0.012) and antidiagnostic IgM (p=0.009) autoantibodies in RAa patients, while the level of SSA autoantibodies (p=0.024) was higher in RAb patients. On the other side, there was no significant difference in the level of any autoantibody or factors of acute inflammation (SE and CRP) in patients with past EBV infection.

Conclusion: This study demonstrated linkage between an active EBV infection and elevation of some autoantibodies in RA pathogenesis. As EBV DNA was not found only in a group of RA patients under immunosuppressive therapy, it is suggested that EBV clearing from blood could be direct consequence of methotrexate use. Collectively, these findings indicate that determining of EBV activity must be based on both serology and molecular methods in order not to oversee EBV reactivation during follow-up of these patients.

AB1465 BLACK PATIENTS ARE LESS SATISFIED WITH THE PROCESS OF CARE FOLLOWING PRIMARY HIP AND KNEE ARTHROPLASTY: A RETROSPECTIVE STUDY

J. A. Gibbons1, O. Burke Jr2, H. Do3, E. Y. Lai3, B. Mehta1, 4, L. Bradford5, F. Kemta Lekpa1, 2, K. Frank Forex1, H. Mbatchou2, A. Jerome1, H. Namme1, 2. 1Hospital for Joint Bone Spine, From 5th January 1 to December 31, 2020, including all patients with a diagnosis of gout (ACR/EULAR criteria of 2015).

Background: An unusual increase in the number of gout cases was observed in Cameroon in 2020. Was there a link with lifestyle changes during confinement, especially the consumption of certain types of beverages (beer, liquor, water, sweetened drinks).

Objectives: To determine if there was a correlation with the consumption of different beverages (water, beer, liquor, sweetened drinks).

Methods: Cross-sectional study in the rheumatology consultation of the Douala General Hospital, from January 1 to December 31, 2020, including all patients with a diagnosis of gout (ACR/EULAR criteria of 2015). Pearson’s correlation coefficient was used to determine the effect of the consumption of the different beverages on the increase in the number of gout cases. A p<0.05 was significant.

Results: We included 1952 patients, including 111 gout cases (107 men; median age: 51 years [36-81]). Compared with the same period in 2018 and 2019, a peak in gout cases was observed between May and November 2020 (Figure 1). In the same period, the consumption of the different beverages varied significantly (p<0.05).

Conclusion: There was a positive correlation between the consumption of beer and an increase in the number of gout cases. Further research is needed to understand the underlying mechanisms.
The COVID-19 PCR test was negative in all patients.

**Conclusion:** The real “outbreak” of gout observed during the curfew related to COVID-19 between May and November 2020 was favored by a punctual increase in the consumption of liquors and sweetened drinks.

### AB1467

**EPIDEMOLOGICAL DESCRIPTION OF JUVENILE IDIOPATHIC ARTHRITIS FROM A COLOMBIAN POPULATION**

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood and presents predominantly with peripheral arthritis; this pathology is divided into subgroups. In Colombia there are few descriptive studies.

**Objectives:** The objective was to describe the sociodemographic, immunological and clinical characteristics of a cohort of patients with Juvenile Idiopathic Arthritis.

**Methods:** An observational cross-sectional study was conducted that included 171 JIA patients treated at a specialized rheumatology institution between 2010 and 2021. Univariate analyzes were performed to describe the sociodemographic, immunological, and clinical profile of the population. The epidemiological characteristics were obtained from the review of medical reports.

**Results:** 171 patients were analyzed. 58.48% were women; with a median age at diagnosis of 12.25 years (IQR=6.55), and a median duration of the disease of 3.71 years (IQR=5.52). According to the classification criteria of the International League of Associations for Rheumatism (ILAR), the most frequent were enthesitis-related JIA (40%), and polyarticular rheumatoid factor positive was positive for ANA in 76.47% and AntiCCP (10%).

**Conclusion:** The epidemiological description of JIA in the Colombian population is similar to the current one in other populations, but we found differences in the subtypes of juvenile idiopathic arthritis and in the presence of autoantibodies. This is the first step to discover the characteristics of this autoimmune disease in this population.

### AB1468

**ALL-CAUSE MORTALITY IN PATIENTS WITH PALINDROMIC RHEUMATISM: A POPULATION-BASED COHORT STUDY**

H. H. Chen, Y. Chen, Z. Taichung Veterans General Hospital, Department of Internal Medicine, Taichung, Taiwan, Republic of China; 2China Medical University Hospital, Center of Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China

**Background:** Palindromic rheumatism (PR), is a clinical syndrome characterized by the intermittent acute arthritis or peri-arthritis involving one or several regions. It presents with pain with or without redness or swelling, lasting from a few hours to days with variable symptom-free periods. Different from rheumatoid arthritis (RA), PR does not lead to residual joint destruction. A recent study showed that RA patients had a mean loss of life expectancy of about 5 years [1]. However, whether all-cause mortality rate in PR patients differs from that in individuals without PR was still unknown.

**Objectives:** To compare the all-cause mortality rate between PR patients and non-PR individuals.

**Methods:** Usint a two-million representative cohort from the 2000-2018 Taiwan’s National Health Insurance Research Database, we identified 2,791 incident adult (aged ≥ 20 years) PR patients. Matching for sex, age and year of index date at a 1:40 ratio, we selected 111,640 non-PR individuals for comparison. Then using the greedy algorithm, we further selected another comparison group of 5,562 non-PR individuals by propensity score (PS) matching for Charson comorbidity index (CCI) at a 1:2 ratio. Using the Cox proportional hazard model, we examined the risk of all-cause mortality in PR patients shown as adjusted hazard ratios (aHRs) with 95% confidence intervals (CIs). Potential confounders included age, sex, CCI, a history of immune mediated inflammatory disease (IMID) including systemic lupus erythematosus erythematosus (SLE), RA, idiopathic inflammatory myopathies (IM, including dermatomyositis and polymyositis), Sjogren’s syndrome (SS), inflammatory bowel disease (IBD), psoriasis, and medication use including corticosteroid (0, 1-5, >5 mg/day prednisolone equivalent dose), methotrexate, sulfasalazine, lefunomide, hydroxychloroquine and nonsteroidal anti-inflammatory drugs within one year before the index date.

**Results:** In the 1:2 PS-matched population, the mean age was 48.4 years and female to male ratio was 1.54 in the PR group and non-PR group. Among 2,791 PR patients, 226 (8.1%) died during a mean follow-up period of 8.29 years; while 11,958 (10.71%) of 111,640 non-PR individuals expired during a mean follow-up period of 8.13 years. The all-cause mortality rates in PR patients and non-PR individuals were 976.83 per 10^5 years and 1,317.93 per 10^5 years, respectively (incidence rate ratio, 0.74; 95% CI, 0.65-0.85, p < 0.001). After adjusting for potential confounders, the risk of all-cause mortality was significantly lower in PR patients compared with non-PR individuals (aHR, 0.70; 95% CI, 0.59–0.82).

**Conclusion:** This population-based cohort study showed that the all-cause mortality rate in PR patients was lower than that in non-PR individuals, in particular in subjects without a history of IMIDs.

ARTHRITIS IN COMPARISON WITH RHEUMATOID COHORT OF PATIENTS WITH PERIPHERAL PSORIATIC EVALUATION OF CXCL13 SERUM LEVELS IN A

S. Piantoni1, F. Angelil, F. Regola1, L. Valtellini1, F. Franceschini1, P. Airo1
1Rheumatology and Clinical Immunology Unit, ASST Spedali Civili and University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy

Background: The research of circulating biomarkers in the field of chronic arthritis is still an unmet need, especially for the subgroup of seronegative arthritis [e.g., negative for anti-citrullinated peptides autoantibodies (ACPA) and/or rheumatoid factors (RF)]. In fact, in this clinical subset, there is a lack of soluble molecules which could help for a diagnostic or prognostic purpose, and the differential diagnosis between psoriatic arthritis (PsA) and seronegative rheumatoid arthritis (RA) is still a challenge. C-X-C motif chemokine 13 (CXCL13) is one of the most promising biomarkers recently identified, because of its association with active synovitis (1) and with a poor prognosis in RA (2), although there are still inadequately results to justify its routine use. No data are available of the determination of CXCL13 serum levels in PsA.

Objectives: To analyze CXCL13 serum levels in a cohort of PsA patients with a history of peripheral involvement in comparison with RA.

Methods: Cross sectional analysis of consecutive patients with peripheral PsA [n:81; male/female=44/37; median age (25-75 percentile)=54 (46-62) years; 28-Joint Disease Activity Score-C Reactive Protein (CRP-DAS28)=4.9 (1.6-2.5); active psoriasis=43%; DAPSA (Disease Activity in PSoriatic Arthritis) score=0 (3-14)] and RA [n:143; male/female=30/113; median age (25-75 percentile)=54 (46-62) years; seropositive=67%; CRP-DAS28=2.1 (1.5-2.8)] was performed. 100 sex and age-matched healthy controls (HC) were enrolled. CXCL13 serum levels were assessed through commercial ELISA test (R&D).

Results: CXCL13 serum levels were higher in all the subgroups of patients [PsA: 50.9 (34.5-80.2) pg/mL, p<0.01; RA: 77.2 (52.9-107.7) pg/mL, p<0.01; RA ACPA+: 77.5 (55.9-110.7) pg/mL, p<0.01; RA ACPA+: 77.5 (55.9-110.7) pg/mL, p<0.01] than in RA patients, independently from their seropositivity [vs RA ACPA-, p=0.01; vs RA ACPA+, p=0.01; vs RA ACPA+, p=0.01]. CXCL13 serum levels were positively correlated with CRP in PsA patients (r=0.30; p=0.008), but not with DAPSA score.

Conclusion: These results confirm the value of CXCL13 as a biomarker in the field of chronic arthritis. Its higher levels in seronegative RA than in PsA suggests its possible value in the differential diagnosis of these two subsets of arthritis.

EFFICACY RESPONSES ACROSS DISEASE SEVERITY AND TREATMENT HISTORY SUBGROUP OF PATIENTS WITH MODERATE TO SEVERE PLAQUE PSORIASIS TREATED WITH GUSELKUMAB: POOLED RESULTS FROM VOYAGE-1 AND VOYAGE-2 THROUGH 5 YEARS

K. Gordon 1, J. F. Merola 1, P. Foley 1, O. Cho 1, D. Chan 2, M. Miller 1, Y. You 1, K. Shen 1, Y. W. Yang 1, A. Blauvelt 1,3,1 Medical College of Wisconsin, Department of Dermatology, Milwaukee, WI, United States of America; 2 Harvard Medical School, Brigham and Women’s Hospital and Probity Medical Research, Skin Health Institute, Department of Dermatology, Carlton, VIC, Australia; 3 Janssen Scientific Affairs, LLC, Department of Dermatology, Horsham, PA, United States of America; 4 Janssen Research & Development, LLC, Department of Immunology, Spring House, PA, United States of America; 5 Janssen Research & Development, LLC, Department of Clinical Biostatistics, Spring House, PA, United States of America; 6 Janssen Global Medical Affairs, Janssen Pharmaceuticals Companies of Johnson & Johnson, Horsham, PA, United States of America; 7 Oregon Medical Research Center, Department of Dermatology, Portland, OR, United States of America

Background: The VOYAGE-1 and VOYAGE-2 phase 3 studies evaluated efficacy and safety of guselkumab (GUS) in patients with moderate-to-severe plaque psoriasis. Objectives: To assess the five-year efficacy of GUS by baseline disease characteristics and treatment history.

Methods: This study evaluated 1829 patients randomized to GUS, placebo (PBO)–GUS, and placebo (PBO)–ADA treatment arms from VOYAGE-1 and VOYAGE-2 trials. All patients received open-label GUS 100 mg every 8 weeks (Q8W) during Week (W) 52 to W252 in VOYAGE-1 and during W76 to W252 in VOYAGE-2. The proportions of combined GUS patients (including PBO–GUS and ADA–GUS) achieving Investigator’s Global Assessment of cleared or minimal (IGA-0/1) and Psoriasis Area and Severity Index (PASI) 90 response were evaluated from W100 to W252 by baseline PASI (<20/20 and 80/80) and IGA (<4/4) scores, body surface area (BSA: <20%/20%; and prior psoriasis treatments. Analysis was performed using observed treatment effect analysis.

Results: At W252, proportions of combined GUS patients achieving IGA 0/1 or PASI 90, respectively, were comparable or numerically greater for patients with baseline PASI < 20 (85.4%; 81.1%) vs PASI ≥ 20 (81.4%; 83.8%); IGA < 4 (85.1%; 82.7%) vs IGA < 4 (78.9%; 81.1%); BSA < 20% (82.6%; 82.0%) vs prior phototherapy (83.3%; 84.0%); no prior phototherapy (83.3%; 81.1%); no prior biologic systemic therapy (83.3%; 80.0%); and no prior biologics (85.3%; 83.8%) vs prior biologics (76.7%; 76.3%). This trend was consistent at each timepoint evaluated from W100 to W252.

Conclusion: This analysis demonstrated that the high degree of efficacy of GUS treatment is durable through 5 years among broad subpopulations of patients with varying disease severity characteristics and previous psoriasis treatments.

LIPIDOMIC PROFILING IDENTIFIES SERUM LIPIDS ASSOCIATED WITH PERSISTENT MULTISITE MUSCULOSKELETAL PAIN

C. Ma 1, M. Liu 2, J. Tian 1, G. Zhai 1, F. Cicuttini 1, Y. Schooneveldt 4, P. Meikle 6, G. Jones 1, F. Pan 1, 1 The University of Melbourne, St. Vincent’s Hospital, Melbourne, Victoria, Australia; 2 Memorial University of Newfoundland, Faculty of Medicine, St. John’s, Canada; 3 Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia; 4 Baker Heart and Diabetes Institute, Melbourne, Australia

Background: Lipid mediators have been suggested to have a role in pain sensitivity and response; however, longitudinal data on lipid metabolites and persistent multisite musculoskeletal pain (MSPM) are lacking.

Objectives: This study was to identify lipid metabolic markers for persistent MSPM.

Methods: Lipidomic profiling of 807 lipid species was performed on serum samples of 536 participants from a cohort study. MSPM was measured by a questionnaire and defined as painful sites ≥4. Persistent MSPM was defined as having MSPM at every visit. Logistic regression was used with adjustment for potential confounders. The Benjamini Hochberg method was used to control for multiple testing.

Results: A total of 530 samples with 807 lipid metabolites passed quality control. Mean age at baseline was 61.5±6.57 years and 50% were females. One hundred and twelve (21%) of the participants had persistent MSPM Persistent MSPM was significantly associated with lower levels of monohexosylceramide (HexCer)[d18:1/2:2:0 and d18:1/2:4:0], acylcarnitine (AC)(26:0) and lysophosphatidylcholine (LPC)(18:1 [sn1], 18:2 [sn1], 18:2 [sn2], and 15-MHDA[sn1])
Conclusion: Our findings indicate that elevated serum levels of IgA ASCA, IgA anti-GP2, anti- elastase antibodies in AS did not differ from those in AS/IBD and may serve as potential biomarkers for predicting intestinal inflammation at an early stage. For AS/IBD, the most useful diagnostic markers were atypical pANCA, IgA ASCA, IgA anti-GP2, anti-elastase and anti-BPI antibodies.

DOI: 10.1136/annrheumdis-2022-eular.2580
in FAST4+/MDS2+ patients, similar in RA and SpA at 3 settings in 3 continents (Table 1). Adjusted median differences were 3.0–3.5 for FAST4+ vs - (twice the level for FAST4-, MDS2-) and 2.0–2.5 for MDS2+ vs - groups (Table 1).

Conclusion: Median 0–10 PATGL was 2–3-fold higher in 41.1% of RA or SpA patients with positive MDHAQ FM and/or DEP screening indices vs 59% with 2 negative indices. Differences were greater according to FM than DEP. MDHAQ may clarify interpretation of PATGL and indices, including in treat-to-target, using a single, brief, feasible questionnaire in research and busy clinical settings.

AB1478 RELIABILITY AND CONTENT VALIDITY OF THE PORTUGUESE VERSION OF THE COMMISSIONING FOR PATIENT EXPERIENCE MEASURE (CQRA-PREM): PRELIMINARY RESULTS
D. Santos Oliveira1,2,3, R. Rainho1, M. Bernardes1,3, C. Vaz1,2, L. Costa1, J. A. Fonseca1,4,5,6, C. Jácque1,6,1, Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal; Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal; Faculty of Medicine, University of Porto, Department of Community Medicine, Information and Health Decision Sciences (MECIDIS), Porto, Portugal; Instituto and Hospital CUF Allergy Unit, Porto, Portugal; MEDIDA, Medicina, Educação, Investigação, Desenvolvimento e Avaliação, Porto, Portugal

Background: The CQRA-PREM has been developed in the United Kingdom to evaluate the perspective of patients with rheumatoid arthritis (RA) about the care provided in rheumatology units of the National Health Service (1). This PREM might also be feasible to be used in Portugal, yet an adaptation and validation process is needed.

Objectives: We aimed to translate and cross-cultural adapt CQRA-PREM to Portuguese and evaluate the reliability and content validity of this version.

Methods: A study combining qualitative and quantitative approaches was conducted with patients with RA from a single rheumatology center. The translation and cultural adaptation of Portuguese CQRA-PREM included initial translation and cultural adaptation by 2 native Portuguese researchers, evaluation of this initial translation by a panel of 5 experts during an online meeting and back translation by 1 bilingual researcher. Authors of the original version approved this initial translation. CQRA-PREM includes 7 domains for patient-centered care: Needs and preferences (5 items); Coordination of care and communication (4 items); Information, education, and self-care (4 items); Daily living and physical comfort (2 items); Emotional support (2 items); Family and friends (1 item); Access to care (5 items) and 1 question for the overall experience with the care provided. Answers are given on a 5-point Likert scale (strongly disagree-1 to strongly agree-5). A total of 21 patients were invited to participate in online focus groups and 14 accepted. Patients were then asked to fill in a consent form and the preliminary version of the CQRA-PREM. The focus groups were transcribed and analyzed using thematic analysis. Questionnaire responses were analyzed with descriptive statistics and reliability (internal consistency) with the Cronbach’s alpha (α).

Results: A total of 12 patients (53±19 y, 92% female) with a mean disease duration of 14±9 years participated in 2 focus groups (duration 95±7min). The focus groups revealed that patients considered CQRA-PREM “simple” and “objective” and that all questions were easy to understand. Nevertheless, patients suggested the addition of synonyms for certain terms and of daily living examples to clarify some items. The “Needs and preferences” and “Access to care” were the domains with better experience (Table 1). The Cronbach’s alpha was 0.94 for the total questionnaire and between 0.71 and 0.91 for the domains.

Table 1. Median’s responses and quartile (Q) for each domain (1-Strongly disagree; 2-Disagree; 3-Neither agree nor disagree; 4-Agree; 5-Strongly agree).

<table>
<thead>

</tr>
</tbody>
</table>

Conclusion: Our findings suggest that both content validity and internal consistency of the Portuguese version of CQRA-PREM are acceptable. In future, a field-testing study to assess other psychometric properties (e.g., test-reliability and validity) should be conducted. We believe this PREM will contribute to optimize patient-centered care in Portugal.

AB1479 VALIDATION OF RUSSIAN VERSION PSAID-12: ASSESSMENT OF THE RELIABILITY, CONSTRUCTIVE AND CONVERGENT VALIDITY OF THE QUESTIONNAIRE
L. Vorobyova1, T. Korolets2, E. Loginova1, E. Gubara1, Y. Korsakova1. 1V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritides and Psoriatic Arthritis, Moscow, Russian Federation

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease of widely varying presentation, which determines functional and psychological impairment, with a high negative impact on patients’ quality of life. Therefore, knowing the patient’s perception of their health status is of fundamental importance for understanding the real impact of PsA. In recent years, a PsAID (Psoriatic Arthritis Impact of Disease) questionnaire has been developed for PsA patients, consisting of 9 or 12 questions related to the severity of pain, anxiety, fatigue, disability, sleep disorders, and social activity.

Objectives: To study, in a real-life setting, the construct and convergent validity of the reliability, and the interpretability of the Russian version PsAID-12 in patients with PsA.

Methods: 187 (M/F=97/90 (50.2%)/48.8%) PsA pts fulfilling the CASPAR criteria were included. Mean age 45.6±11.7 years (yrs), DAPSA 21.05±21.03, median (Me) PsA duration 88 (16.42) mo. All pts underwent standard clinical examinations and PROs (EQ-5D, PsAID12). Reliability was assessed by Cronbach’s alpha coefficient and by the intraclass correlation coefficient (ICC) for each of the 12 scales. The construct validity was evaluated by exploratory factorial analysis and also by Spearman correlation with EQ-5D and measures of disease activity evaluation.

Results: The reliability of ICC (alpha-Cronbach=0.8-0.9) and test-re-test (ICC 95% CI 0.85–0.96) were good. Construct validity: Factor analysis revealed a 2-factor result defined as the PsAID-12: Psysical health score and Emotional health score. A strong correlation was also found for each of the 12 scales with the questionnaire EQ-5D was strong correlation (r= -0.52 to -0.78, p<0.001) in determining convergent validity, significant correlations were found between the PsAID-12 and TJC 68, SJC 66, DAPSA, VAS global assessments, VAS global pain, BASDAI. The high correlation was found between the BASDAI and the scale “Functional capacity” (r=0.8, p<0.001), as well as sufficiently high correlation coefficients with parameters were noted with the scales “Pain,” “Fatigue,” “Work and/or leisure activities,” “Discomfort” and “Coping.” The lowest was observed with scales “Skin problems” and “Depression.”

Conclusion: The Russian version of PsAID-12 has been shown to be a reliable and valid measure of the impact of the disease in patients with psoriatic arthritis.

Disclosure of Interests: None declared

AB1480 ASSESSMENT OF THE SENSITIVITY OF THE RUSSIAN VERSION PSAID-12 QUESTIONNAIRE
L. Vorobyova1, T. Korolets2, E. Loginova1, E. Gubara1, Y. Korsakova1. 1V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritides and Psoriatic Arthritis, Moscow, Russian Federation
Background: The Psoriatic Arthritis Impact of Disease 12-item questionnaire (PsAID-12) has been developed to measure impact of Psoriatic Arthritis (PsA) for purposes of monitoring and clinical management.

Objectives: Assessment the sensitivity of the russian version of PsAID-12 against the background of ongoing therapy at baseline and after 12 month (mo).

Methods: 172 (M/F=90 (52.3%)/82 (47.7%)) PsA pts fulfilling the CASPAR criteria were included. Mean age 45 ± 11.8 years (yrs), DAPSA 28 ±2.2 median (Me). All pts underwent standard clinical examinations and PROs (EQ-5D, VAS global assessments, VAS global pain, BasDAI, PsAID-12). All pts at the time of inclusion in the study and 12mo received DMARDs: NSAIDs-158 (91.8%), methotrexate-134 (73.9%), lefunomide- 11 (6.3%), sulfasalazine - 12 (6.9%), TNFα inhibitors - 72 (44.04%), seukinumab - 14 (8.1%), ustekinumab - 3 (1.74%), infliximab - 51 (29.1%). To determine the sensitivity of PsAID-12, its changes were analyzed depending on: I group of patients in whom MDA was achieved - 50, II - 43 REM / LDA patients, III - 79 inhibition (DAPSA - 28±22.2 vs. 15±10.1, TJC 68 – 10.5±10.1 vs 6.68±5.77 , SJC 65 – 8.31±7.4 vs 4.62±3.17, CRP – 13.6±8.06 vs 13.6±8.06) and PROs (BASDAI-3 - 9.33±2.56 vs 2.49±1.93, VAS global pain – 40.1±25.1 vs 24.7±20.0, VAS global assessments – 43.4±27.1 vs 27.6±19.5, EQ-5D – 0.68±0.21 vs 0.72±0.18) observed (p<0.0001 for all). The sensitivity assessment of the PsAID-12 showed that in groups I and II there were statistically significant differences on all scales of the questionnaires, in group III with no effect on therapy, there were no significant improvements on the scales “Pain” (p = 0.37), “Fatigue” (p=0.15), “Skin problems” (p=0.23), “Work and leisure activities” (“p=0.056”, “Functional capacity” (“p=0.44”) (Table 1).

Conclusion: The russian version of the PsAID-12 questionnaire directional changes depend on the activity of the disease during treatment, which proves its good sensitivity.

PROGNOSTIC FACTORS FOR TUBERCULOUS SPONDYLODISITIS

1 Rabta Hospital, Rheumatology, Tunis, Tunisia
2 University of Monastir, Faculty of Medicine, LR12ES05, Lab-NAFS Nutrition - Functional Food & Vascular Health; 5000 Monastir, Tunisia;
3 University Bourgogne Franche-Comté, Faculty of Medicine, University of Monastir, Monastir 5019, Tunisia, Team Biochemistry of the Peroxinsome, Inflammation and Lipid Metabolism

Background: Tuberculous spondylodiscitis (SPDT) or Pott’s disease is an infectious involvement of the disc-vertebral couple, caused by the tubercular bacillus (Mycobacterium tuberculosis). It accounts for 46% to 64% of infectious spondylodisitciscal of the vertebrae. The study included correlations of the promoting factors of SPDT (tuberculosis infection, diabetes, corticosteroids and trauma), epidemiological, clinical, biological and radiographical data with good clinical outcome in the fourth week of the anti-tuberculosis drugs treatment.

Methods: We conduct a retrospective and descriptive study in a single rheumatology department. Data were collected from observations of patients hospitalised in the past 20 years (2000-2020) who have been diagnosed with SPDT. The diagnosis was based either on a range of highly evocative clinical, biological and radiographical arguments or on the disc-vertebral biopsy puncture. The study included correlations of the promoting factors of SPDT (tuberculosis infection, diabetes, corticosteroids and trauma), epidemiological, clinical, biological, radiological and therapeutic data with good clinical outcome in the fourth week of the anti-tuberculosis drugs treatment.

Results: Fifty-two cases of SPDT were collected (37F/15M). The mean age was 55.21±17.79 years [19-91]. Thirty-three patients (69.2%) were aged 65 years versus 16 elderly patients (30.8%), with female predominance in both.
groups (69.4% and 75% respectively, p = 0.57). The diagnosis of SPDT was based either on a range of highly evocative clinical, biological and radiological arguments (71.2%) or on the disco-vertebral biopsy puncture (28.8%). Among the clinical arguments a suggestive of tuberculosis SPD were: progressive onset of symptoms in 47 patients (90.4%), segmental stiffness in 37 patients (71.2%), spinal pain with general signs of tuberculosis such as impaired general condition, fever, night sweats and weight loss in 32 patients (61.5%). Lumbar spine involvement was the most common in tuberculosis SPD (57.7%). A biological inflammatory syndrome has been objectified in 38 patients (73.1%). Imaging was contributive to positive diagnosis using standard X-rays, computed tomography and magnetic resonance imaging. Disc pinch, erosion of vertebral plateaus and vertebral collapse were the major signs. The treatment was based on anti-tuberculosis drugs for at least nine months. Only four factors had an unfavourable predictive value (p ≤ 0.05): Nornorchoinic normocytic anemia observed in 53.8% of our patients (p = 0.018; Odds Ratio = 6.66), initial lymphocytosis (p = 0.048), fever in 36.0% of our patients (p = 0.01; Odds Ratio = 0.01). X-ray vertebral compression in 67.3% of our cases (p = 0.001; Odds Ratio = 13).

Conclusion: Tuberculous spondylodiscitis is a frequent condition that needs to be diagnosed and treated rapidly. Poor prognosis factors have been identified to provide insight into disease progression.

SSc (systemic sclerosis), CDL (capillary density loss).

Conclusion: CDL was present in almost 1/3 of non selected patients attending to a VC study, and was strongly associated with SSc diagnosis. Future studies including this outcome can bring new data regarding microvascular damage and its implications.
Conclusion: Monospecific anti-DFS70 can potentially be considered as a possible marker for the exclusion of SARDs and a sign of benign autoimmune.

PATIENT-REPORTED OUTCOMES AND BIOMARKERS ASSOCIATED WITH THE CUTANEOUS DERMATOMYOSITOSIS AREA AND SEVERITY ACTIVITY (CDASI-A) SCORE IN A PHASE 2 CLINICAL TRIAL IN DERMATOMYOSITIS

J. Dan1,2, J. Patel1,2, G. Sproew1,2, J. Concha1,2, R. Feng2, N. Kodali1,2, T. Vazquez1,2, D. Diaz3,4, B. White,4, V. Werth1,2,4.

Perelman School of Medicine at the University of Pennsylvania, Dermatology, Philadelphia, United States of America; Corporation.

Michael J. Crescenz VA Medical Center, Dermatology, Philadelphia, United States of America; Perelman School of Medicine at the University of Pennsylvania, Biostatistics and Epidemiology, Philadelphia, United States of America; Corbus Pharmaceuticals, Inc., Norwood, United States of America

Background: Retrospective reviews of clinical databases from two sites have identified strong relationships between patient-reported outcomes and skin activity in dermatomyositis (DM), as measured by CDASI-A.1,2 No studies validate these associations in a controlled setting. Additionally, the relationship between the PROMIS-29 Short Form and skin activity in DM has not been assessed. Previous investigations have demonstrated a correlation between IL-31 and itch in DM.3 IFN-γ and IFN-γ are known type I and II interferons, which are critical drivers of DM pathogenesis.4

Objectives: To assess correlations between CDASI-A, quality of life (QoL), and biomarkers of disease activity in a double-blind, randomized, placebo-controlled clinical trial.

Methods: Data were retrospectively collected from five visits of a Phase 2 trial evaluating AB1485, a cannabinoid receptor type 2 agonist. Quality of life assessments extracted from the trial included Patient Global Assessment (PGA) scores, PROMIS domains, and Skindex scores. Skin question 10, regarding itch, was included in the analysis as a separate domain. Physician Global Assessment scores were also evaluated. Additionally, biomarkers derived from skin samples via IHC/PAR collected at visits 1 and 6 were assessed for predictors of CDASI-A response and association with disease activity. Analysis used linear mixed effect models to account for within subject-variability and repeated measures, where applicable. Analysis was performed without regard to treatment arm, as our goal was to correlate CDASI-A, QoL, and biomarkers among all subjects.

Results: Data from 22 subjects with DM and a combined total of 110 visits were included. Biopsies were collected from 12 subjects. Improvement in CDASI-A significantly correlated with Skindex-S, Skindex-E, Skindex-F, Skindex-itch, PGA global skin, PGA global skin, and Skindex itch. Change in IL-31 protein area positively correlated with change in CDASI-A (r=0.605, p<0.001). Change in IFN-γ protein area and disease activity trended towards significance.

Conclusion: In accordance with previous investigations from our group, well-established measures of QoL, correlated significantly with CDASI-A. These findings support that CDASI-A reflects both clinical and patient-reported aspects of skin disease and that CDASI-A reflects both clinical and patient-reported aspects of skin disease and patient-reported outcomes and skin activity in dermatomyositis (DM), as measured by CDASI-A.1,2 No studies validate these associations in a controlled setting. Additionally, the relationship between the PROMIS-29 Short Form and skin activity in DM has not been assessed. Previous investigations have demonstrated a correlation between IL-31 and itch in DM.3 IFN-γ and IFN-γ are known type I and II interferons, which are critical drivers of DM pathogenesis.4

AB1486

ASSESSMENT OF GLUCOCORTICOID-RELATED ADVERSE EVENTS BY THE GLUCOCORTICOID TOXICITY INDEX (GTI) IN RHEUMATIC PATIENTS

M. Bahap1, E. Duran1,2, A. B. Ekinicioğlu1, G. Karadag1,2, Hakettepe University School of Pharmacy, Department of Clinical Pharmacy, Ankara, Turkey; Hakettepe University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; Hakettepe University School of Medicine, Vasculitis Research Centre, Ankara, Turkey

Background: Glucocorticoids (GCs) remain the mainstay treatment for several autoimmune and inflammatory diseases however, its long-term or high-dose usage also has many potential side effects. The glucocorticoid toxicity index (GTI) is a novel global monitoring tool (1) developed to systematically assess glucocorticoid-associated morbidity.

Objectives: To evaluate GC toxicity by using GTI in patients with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and vasculitis receiving glucocorticoids.

Methods: This descriptive, cross-sectional study included patients who were admitted to the rheumatology clinic between January 2021 and December 2021, were diagnosed with RA, SLE or vasculitis and treated with GCs. A single measurement of GC toxicity was performed using the GTI for each patient. Baseline GTI consists of twelve domains that related to commonly recognized adverse events that result of cumulative GCs exposure: body mass index (BMI), glucose metabolism, blood pressure, lipids, GC-induced myopathy, bone mineral density, skin toxicity, neuropsychiatric effects, infection, ocular, gastrointestinal and endocrine toxicity. The total GTI score ranges from 0 to 538 depending on the increase in toxicity burden.

Results: The study included 85 patients (55.3% male) with a mean age of 47.5 (±16.0) years (Table 1). Twenty (23.5%) patients had BMI values ≥30 kg/m2 and 63% of the patients were either hypertensive or receiving medications for hypertension. While HbA1c was ≥5.7% in 30 (35.3%) patients, 17 (20.0%) patients had glycated hemoglobin (HbA1c) value of ≥5.7% despite anti-diabetic medication. Low density lipoprotein cholesterol (LDL-C) value of ≥3.3 (39%) patients was not on target. The median (IQR) GTI score of the study patients was 73 (61.5). Only 10 patients had a score of 0 in the GTI assessment. GTI scores were not correlated with the cumulative steroid doses (r=0.145, p=0.198) however, age was strongly associated with GTI scores (r=0.605, p<0.001).

1 n (%), if otherwise specified; median (IQR) for numeric values other than age/GTI: Glucocorticoid toxicity index, RA: Rheumatoid arthritis, SLE: Systemic lupus erythematosus, BMI: Body mass index, HbA1c: Glycated hemoglobin, LDL-C: Low density lipoprotein cholesterol, Vasculitis patients include ANCA-associated vasculitis, Giant cell arteritis, Takayasu arteritis, Behcet’s syndrome, IgA-related disease, Polymyalgia rheumatica and Leucocytoclastic vasculitis patients.**BVAS value given only for ANCA-associated vasculitis (n=19)

Conclusion: Our study revealed the iceberg of glucocorticoid toxicities in patients with rheumatic disease. Usage of GTI would help management of these possible toxicities. Therefore, it is important to assess GC toxicity at regular intervals during ongoing treatment in order to detect potential differences in the GTI scores.

VALIDATION AND CULTURAL ADAPTATION OF
THE QUALISEX QUESTIONNAIRE IN WOMEN WITH
SJÖGREN’S SYNDROME IN ITALY

F. Giardina,1, G. Curcio,1, C. Gioia,1, R. Izzo,1, E. Simoncelli1,2, A. Gattamelata1, S. Colafrancesco1, L. Mastromannino1, M. Villà1, C. Iannuccelli1, M. Di Franco1, F. Conti1, R. Proven1,3,1 Università degli Studi di Roma “La Sapienza”, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rheumatology Unit, Rome, Italy. 2University of Uqquila, Department of Biotechnological and Applied Clinical Sciences, Uqquila, Italy

Background: The quality of sexual life (QSL) is a complex and multimodal experience influenced by endogenous and external factors, including age, gender, and cultural environment. Rheumatic diseases, with their burden of pain, fatigue, organ damage, and disability, can severely impair sexual life and this is true also for Sjögren’s Syndrome, where simple tools to assess the QSL in everyday clinical practice are needed.

Objectives: To: To adapt ad into Italian the Qualisex, a new brief questionnaire originally created for Rheumatoid Arthritis patients, for women with primary Sjögren’s Syndrome (pSS) and evaluate the impact of the disease on their sexuality.

Methods: Consecutively sexually active pSS (according to ACR/EULAR 2016 criteria) patients aged >18 were asked to participate in this study approved by the local bioethics committee. With the permission of the developer, the French original version of the Qualisex questionnaire (consisting of 10 items, the higher the higher the score, the greater the negative impact of the disease on the QSL) was translated and adapted into Italian according to current guidelines. In the absence of a gold standard assessment for sexuality in pSS, face and content validity was assessed cross-sectionally with correlations with other disease aspects such as anxiety and depression measured by Hospital Anxiety and Depression Scale (HADS), EULAR Sjögren’s Syndrome Disease Activity Index (SSDAI) (EULAR Sjögren’s Syndrome Disease Activity Index), and SScDI (Sjögren’s Syndrome Disease Damage Index) were assessed as well. Analyses were carried out with IBM SPSS Statistics for Macintosh, version 22.0 (IBM Corp., Armonk, NY, USA).

Results: 40 sexually active women with pSS and a median age of 53 (IQR 45.25-57.25) were enrolled. The EFA showed that the model with a single factor appeared to be highly significant (Ch235= 2943.10; p<0.05); the average inter-item correlation was found to be 0.392 (Min -0.479; Max 0.834) which is an acceptable value as for redundancy. There were no missing answers. Cronbach’s alpha coefficient resulted to be 0.86 which indicates an adequate internal consistency. The median Qualisex score was 4.65 (IQR 2.13-6.2). As far as correlations, age (Rho=-0.39; p<0.05), menopause (Rho=-0.41; p<0.05), relationship quality (Rho=-0.55; p<0.05), anxiety (HADS-A; Rho=0.38; p<0.05), and depression (HADS-D; Rho=0.47; p<0.05) appeared to be positively correlated with Qualisex score. Also, a positive correlation with ESSPRI (Rho=0.43; p<0.05), and drug use (Rho=0.37; p<0.05) was demonstrated. On the contrary no significant correlation was found with education (Rho=-0.07; p=0.64), systemic disease activity (Rho=0.14; p=0.39), and damage (Rho=0.06; p=0.74).

Conclusion: The Italian version of the Qualisex questionnaire is a valid, reliable and useful tool to assess the quality of sexual life in pSS. QSL in pSS women is an inverse relationship with age, menopause, drug use, ESSPRI, mood disorders, and dissatisfaction with the partner, while, as previously reported, no correlation was found with disease activity, damage, and educational status. This further highlights the impact of subjective symptoms such as dryness, pain, fatigue, and the overall psychological well-being on patients’ life. Thus, it is critical for the physician to consider patients’ perspective.

GRAY INTENSITY RATIO INDICES AS A METHOD OF DISCRIMINATION BETWEEN CHANGES INDUCED BY SPORT AND BY SPONDYLOARTHRITIS IN LOAD-BEARING ENTEHESSES.

M. Tortosa-Cabadas1, C. Guillén-Astete1, Á. Andreu-Suárez1. 1Hospital Ramón y Cajal, Rheumatology, Madrid, Spain

Background: Computer analysis of radiological images has recently been introduced in the study of patients with musculoskeletal pathologies. In the field of ultrasound, baseline settings and differences between images obtained by different equipment pose a potential problem in the comparative study of patients. Our research group has shown that this type of ultrasound image analysis is sensitive to exercise-induced adaptive changes.

Objectives: The purpose of this study is to determine if the computer analysis of entheses ultrasound images can distinguish adaptive changes from those produced by spondyloarthritis.

Methods: A test validation study was carried out. Since the analysis of static ultrasound images strongly depends on the characteristics of the image and the ultrasound settings, three indices based on the findings in pathological territories and their counterpart in healthy entheses were defined. Gray Intensity Mean (IMG): Mean gray intensity in the clinically affected enthesis/mean gray intensity in the same healthy enthesis. Gray intensity dispersion index (IDIG): Mean of the standard deviation of the gray intensity means in the clinically affected enthesis/mean of the standard deviation of the gray intensity means in the same healthy enthesis. Index of gray intensity modes (iMoIG): Mean gray intensity modes in the affected enthesis/mean gray intensity in the same healthy enthesis. The indices were compared with P<.0001. According to the matrix of coordinates of the receiver-operat-

VALIDATION OF QUANTITATIVE COMPUTER ANALYSIS OF ULTRASOUND IMAGES OF THE ACHILLES AND PATELLAR TENDONS IN HEALTHY SUBJECTS.

Á. Andreu-Suárez1, C. Guillén-Astete1, M. Tortosa-Cabadas1. 1University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain

Background: The ultrasound study of tendons is a component of the complementary evaluation of patients with different musculoskeletal pathologies, which include immune-mediated rheumatological diseases. Until now, the assessment

Methods: A test validation study was carried out. Since the analysis of static ultrasound images strongly depends on the characteristics of the image and the ultrasound settings, three indices based on the findings in pathological territories and their counterpart in healthy entheses were defined. Gray Intensity Mean (IMG): Mean gray intensity in the clinically affected enthesis/mean gray intensity in the same healthy enthesis. Gray intensity dispersion index (IDIG): Mean of the standard deviation of the gray intensity means in the clinically affected enthesis/mean of the standard deviation of the gray intensity means in the same healthy enthesis. DOI: 10.1136/annrheumdis-2022-eular.5151
of the ultrasound status of the tendons largely depends on the subjectivity of the explorer, following specific guidelines such as the fibers structure, their global echogenicity and their thickness. This evaluation is of great interest for the diagnosis, however its role for the follow-up is not so clear as the subjective evaluation may not perceive subtle changes. Computerized image analysis has recently been introduced to complement the echographic evaluation. Two of the most useful parameters in this analysis are the mean and mode of gray intensities. Both allow a global evaluation of the echostucture of an organ based on the distribution of shades of gray and the highest concentration of a particular shade, without evaluating the organization pattern of the image obtained.

**Objectives:** To determine if computer analysis of static images is valid and suitable for its use in the study of tendons.

**Methods:** The ultrasound images of healthy volunteers were analyzed. The analyzed tendons were: the body of the patellar tendon in transverse approach and the longitudinal section of the Achilles tendon, both of them from the dominant side. Image processing was performed using the ImageJ 1.53e program (Wayne Rasband & contributors – NIH, USA). A gray spectrum analysis (0-255) was performed with the calculation of the mean, standard deviation (SD), range, median and mode. Two measurements of different cuts of the patellar tendon (at the point of emergence of the tibial plate and 20 mm proximal to it) and three longitudinal cuts of 20 mm of the Achilles tendon (paramedial, central and paralateral) were used for the validation process of the analysis carried out by the software.

**Results:** Images from 44 healthy volunteers were analyzed: 20 men and 24 women. 44 Achilles tendon image trios and 44 patellar tendon image pairs were analyzed and their corresponding means and modes were compared as related variables. In the study of the Achilles tendon, according to the Shapiro-Wilk test, the distribution of the gray distribution means had a non-normal distribution while the modes had a normal distribution. The mean ± standard deviation of gray intensity was: 80.15 ± 26.04, 80.05 ± 25.57 and 79.91 ± 25.83 for the medial, central and lateral slices, respectively (Friedman, P=.454; Bonferroni not applicable). The modes of the gray modes for the same measures were 67.35 ± 31.60, 67.76 ± 32.18 and 66 ± 32,18, respectively (ANOVA paired data, P=.259; Bonferroni not applicable). In the patellar tendon study, all measurement distributions were non-normal. Mean gray intensity at the point of tendon emergence (P) was 81.35 ± 29.63 and at 20 mm proximal to this point it was 80.97 ± 29.08 (Wilcoxon, P=.327). The means of the modes at the same locations were 82.71 ± 28.75 and at 20mm proximal to this point it was 84.44 ± 33.31 (Wilcoxon, P=.079).

**Conclusion:** The quantitative analysis of static images of healthy tendons shows no differences between the same structures in longitudinal or transverse planes. Based on this validation test, the demonstration of sensitivity to change caused by any stimulus (sport, noxae or treatments) could allow its use as a complementary instrument for the assessment of tendinous structures over time.

ACUTE EFFECTS OF AN INSTRUMENT ASSISTED SOFT TISSUE MOBILIZATION TECHNIQUE ON CHRONIC NECK PAIN: A DOUBLE-BLIND, RANDOMIZED CONTROLLED TRIAL

H. Gerci1, B. S. Unuvar1, O. Umit Yemisci2, A. Aytar3.1 Vocational School of Health Services, Physiotherapy, Karayi, Turkey; 2Istanbul University-Cerrahpa, Institute of Graduate Studies, Department of Medicine, Physical Medicine and Rehabilitation Department, Ankara, Turkey; 3Baskent University, Physiotherapy and Rehabilitation, Ankara, Turkey

Background: Individuals with chronic neck pain, proprioceptive afferent information from the cervical spine may be impaired due to the presence of pain. Instrument-assisted soft-tissue mobilization (IASTM) is used to reduce pain and improve range of motion (ROM) and function. Cervical sensorimotor control includes the central integration and processing of all afferent information and the execution of the motor program through the cervical muscles and contributes to the maintenance of head posture and balance(1). In individuals with chronic neck pain, proprioceptive afferent information from the cervical spine may be impaired due to the presence of this pain(2). Many treatment modalities such as instrument-assisted soft-tissue mobilization (IASTM) have been used to reduce pain and improve proprioception(3). IASTM is used to reduce pain, increase soft-tissue mobility, and improve range of motion (ROM) and function. These instruments cause microtrauma to restore normal elasticity and function in soft-tissue(4). Kivlan has shown that significant and rapid changes in muscle function can occur with only a single IASTM application and have suggested the following mechanisms of action: an increased fascial motility, a proliferation of extracellular matrix fibroblasts, and an increased blood flow to the area close to the injured tissue, with decreased cellular matrix adhesion and localized ischemia(5).

Objectives: Aim of this study, to determine the acute effects of single-session, IASTM on cervical joint position error (JPE) and pain in individuals with chronic neck pain.

Methods: A total of 39 individuals (mean age=40.18±11.10 years) with chronic neck pain were included in this study. We divided the participants into IASTM, sham, and control groups of 13 members each. In the IASTM group, intervention was applied to the sternocleidomastoid and trapezius muscles with an application time of 45 seconds and a frequency of 60 beats/min. In the sham group, IASTM was applied at a 90° angle without pressure. The control group received no intervention. The pain severity and joint position error were evaluated before and after the intervention, by using the visual analog scale (VAS) and a cervical range of motion device.

Results: The effects of time and treatment group on VAS score were statistically significant. The effect of time and treatment for VAS score was statistically significant (p=0.001). When the post-test was examined according to application, a statistically significant difference found in VAS scores (p=0.001), with the lowest pain score in the IASTM group and the highest pain score in the control group. The significant improvements found in JPE in all aspects of the cervical region in the IASTM group (p<0.05). In the sham group, significant improvements observed in cervical extension, left rotation, and left lateral flexion movements in JPE (p<0.05).

Conclusion: Single-session IASTM is effective for improving the acute pain and JPE in individuals with chronic neck pain.

REHABILITATION OF PATIENTS WITH OSTEOARTHRITIS OF THE KNEE USING MAGNETIC THERAPY

A. Arkhipova1, N. Zhuravleva2, E. Guryanova3, V. Diomidova2, 1 Republic Clinical Hospital, Department Rheumatology, Cheboksary, Russian Federation; 2 N. Ulianov Chuvash State University; Department Internal Diseases, Cheboksary, Russian Federation

Background: Currently, along with the basic treatment at the outpatient stage of rehabilitation, methods using physical and balneological factors are successfully applied: magnetotherapy, electrotherapy, peliotherapy.

Objectives: Evaluation of the effectiveness of rehabilitation using magnetotherapy for osteoarthrosis of the knee joints at the second radiological stage.

Methods: The study included 75 patients with primary osteoarthrosis of the knee joints of the II X-ray stage, who were on outpatient rehabilitation in the sanatorium “Chuvashyakurort”, including 45 women and 30 men aged 50 to 65 years with a disease duration of 15 to 20 years. Rehabilitation was carried out by a multiprofessional team led by a physical and rehabilitation doctor. All patients were divided into two groups by simple randomization. The main group (n = 50) received basic treatment (chondroprotectors) + non-steroidal anti-inflammatory drugs (NSAIDs on demand) and a course of apparatus magnetotherapy. Magnetic therapy was applied to the area of the knee joints using the “Pulsor-2” apparatus using solenoid inductors, mode - continuous, frequency - 50 Hz, intensity - 2 mT. The control group received standard rehabilitation using the same apparatus.

Results: At the end of the third month of treatment, patients of the main group had significant improvements in the functional ability of the lower limb (p<0.05). In the control group, there was no significant change in functional ability of the lower limb (p>0.05).

Conclusion: The use of magnetic therapy in the complex of rehabilitation methods for the treatment of osteoarthrosis of the knee joints is effective and safe.

COMPARISON OF TELEREHABILITATION METHODS FOR SYSTEMIC SCLEROSIS PATIENTS IN THE COVID-19 ERA: A RANDOMIZED CONTROLLED STUDY

T. Civici Kaspaşkan1, E. Tarakçı2, O. Keles3, Y. Aslan Keles3, S. Uğurlu4.1 Istanbul University-Cerrahpa, Health Sciences Faculty, Department of Physotherapy and Rehabilitation, Istanbul, Turkey; 2Istanbul Medipol University, Department of Physotherapy and Rehabilitation, Istanbul, Turkey; 3Bursa University, Vocational School, Occupational Therapy Program, Istanbul, Turkey; 4Istanbul University-Cerrahpa, Institute of Graduate Studies, Department of Physotherapy and Rehabilitation, Istanbul, Turkey; 5Bursa University, Vocational School, Physiotherapy Program, Istanbul, Turkey; 6Istanbul University- Cerrahpa, Cerrahpa Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

Background: Scleroderma (SSc) is an autoimmune connective tissue disease progressing with fibrosis. SSC patients need to be protected from epidemic diseases as well as rehabilitation needs. For this reason, it is important for them to continue their exercises in an environment where they can be both rehabilitated and protected from infectious diseases.

Objectives: In this study, it was aimed to reveal the effects of exercises performed by telerehabilitation on individuals with Scleroderma with hand involvement and to compare the effects of real-time telerehabilitation (RTT) and asynchronous telerehabilitation (AT).

Methods: Forty-two participants with a mean age of 44.17±11.05 years were included in the study. The patients were divided into three groups and followed for 8 weeks. RTT was applied to the 1st group and AT was applied to the 2nd group, and the 3rd group was the control group. Participants’ finger and wrist joint range of motion (ROM) were evaluated with a goniometer, upper extremity functions were evaluated with Scleroderma Hand Mobility Test (HAMIS), Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire and 9Hole Peg Test (9HPT), grip strength was evaluated with a dynamometer, superficial sense of touch was evaluated with the Semmes Weinstein Monofilament test, activities of daily living (ADL) were evaluated with the Michigan Hand Outcomes Questionnaire (MHOQ), and general health status was evaluated with the Scleroderma Health Assessment Questionnaire (SHAQ).

Results: There were improvements in finger and wrist ROM, upper extremity functions and ADL parameters in the RTT group; and there were improvement in finger ROM and hand functions in the AT group (p<0.05). Wrist radial deviation ROM decreased in the control group (p<0.05). Significant differences were noted between the groups in finger ROM and upper extremity functions after treatment (p<0.05).

Conclusion: Our study shows that exercises performed via RTT and AT are effective in individuals with Scleroderma with hand involvement, and RTT has additional benefits.

Disclosure of Interests: None declared.

Background: End-stage knee osteoarthritis (KOA) is a significant health issue worldwide resulting in severe pain and disability. Total knee arthroplasty (TKA) leads to significant improvements in pain and the performance of functional activities such as walking for patients with end-stage KOA. Although TKA reduces pain and improves perceived function, patients continue to exhibit reduced muscle strength, voluntary muscle activation, and functional performance even years after surgery (1). In addition, quadriceps atrophy, and related social restrictions due to the current Covid-19 pandemic may have affected the recovery of patients undergoing TKA due to limited access to exercise, physiotherapy, face-to-face follow-up, and medical services (2). Limited recovery after TKA will require intensive rehabilitation programs in the future. Strengthening exercises (SE) are the most effective intervention for improving muscle strength and functionality and have been recommended in the guidelines for KOA management and in clinical reviews for TKA rehabilitation (3). Randomized controlled trials (RCTs) are the gold standard for assessing the effects of health care interventions. However, RCTs may yield misleading results if they lack methodological rigors (4). RCTs provide the highest quality clinical evidence in the selection of the SE method to be applied (5). However, there are no studies examining the quality of RCTs related to SE in patients with TKA.

Objectives: The aim of this study was to assess the reporting quality of RCTs of SE in patients with TKA.

Methods: RCTs published between 2002 and 2021 were sourced from clinical trial registers, PubMed, and the Cochrane Reviews. RCTs were included if they involved SE in patients who underwent TKA. Analysis was carried out with two assessment tools: PEDro scale and 9-items from CONSORT (6). In addition, we have identified some key methodological elements and examined their relationship to their methodological quality.

Results: We found 35 RCTs that included SE in individuals with TKA. The mean PEDro score was 6.40 ± 1.73. The most common deficient PEDro Items were: Blinding of all therapists who administered the therapy (14.2 ± 5.35 trials), allocation was concealed (31.4 ± 11/35 trials), blinding of all subjects (31.4 ± 11/35 trials). The most common deficient CONSORT Criteria were: Statistical adjustment for multiple primary outcomes (40 ± 14/35 trials), funding sources (40 ± 14/35 trials) and identification as a randomized trial in the title (62.85; ±22/35 trials). Of the key methodological factors we identified, only exercise duration (weeks) was associated with PEDro score (R² = 0.169, p<0.01).

Conclusion: Our results show that the quality of reporting in the literature on RCTs of SE in patients with TKA is insufficient. In order to increase muscle strength after TKA, the lack of face-to-face programs due to COVID-19 should be eliminated with telerehabilitation methods, video conferencing platforms and virtual reality applications, and high-quality RCTs should be planned where these programs are examined.
Disclosure of Interests: Carey, J.R., et al.,

Methods: Forty-six SSc patients were included in the study. The patients were randomly divided into two groups as telerehabilitation and control group. Youtube videos consisting of clinical pilates-based exercises were uploaded to the system so that only the patients in the telerehabilitation group could see it. In the telerehabilitation group, an exercise program was given for eight weeks, twice a day. Video interviews were conducted with the patients once a week. To the control group, the same exercises were given to the telerehabilitation group. An eight-week exercise program was given in the form of a home program. Brochure introducing the exercises was given and exercises were taught. Pain, dyspnea, fatigue, physical activity, anxiety-depression, sleep and quality of life levels were evaluated in all patients at the beginning of the study and at the end of the eight weeks.

Results: Demographic and clinical features of the patient groups were similar (p>0.05). After the exercise program, pain, fatigue, anxiety-depression levels decreased in the telerehabilitation group compared to the control group, while sleep quality and quality of life increased (p<0.05). The results of the study indicated that both exercise programs improve pain, fatigue, anxiety-depression, physical activity, sleep quality and quality of life in SSc patients. The telerehabilitation-based treatment program is more and more effective than the home program.

Conclusion: Our study shows that this innovative treatment program should be applied especially in SSc patients and it will be beneficial.

THE EFFECT OF AQUATIC REHABILITATION ON QUALITY OF LIFE IN PATIENTS WITH KNEE OSTEOARTHRITIS

R. Maaouia1, M. Hsidi2, Z. Mrizaki1, N. Mouli1, H. Rahali1, I. Ksibi1, M. Slouma2, L. Ben Ammar1, L. Motiou1, R. Dhahri2, I. Gharsallah2. 1The Military Hospital of Tunis, Physical Medicine and Rehabilitation Department, Tunis, Tunisia; 2The Military Hospital of Tunis, Rheumatology Department, Tunis, Tunisia

Background: In addition to its multiple functional, social and economic consequences, knee osteoarthritis is responsible for a significant deterioration in the quality of life (QOL)[1]. Studies examining the impact of osteoarthritis on quality of life have been made possible through the development of validated measurement questionnaires. The SF-12 score with its aspects (physical, mental and social) is a valid and important instrument for the assessment of QOL.

Objectives: The main aim of our study was to make a comparison between the contribution of aquatic rehabilitation and classical rehabilitation in patients with knee osteoarthritis using the SF-12 score.

Methods: We carried out a prospective, comparative study carried out over a period of 15 months, (September 2016- December 2017), in 120 patients recruited from the outpatient department of the Physical Medicine and Functional Rehabilitation Department of the telerehabilitation group. In the diagnosis of knee osteoarthri-

The patients were randomly divided into 2 groups of 60 patients each. The first group called G1 received a classic rehabilitation program. The second group called G2 benefited from aquatic gymnastics. The study was based on the SF-12 quality of life assessment. Two evaluations were made, the first (T1) before the start of rehabilitation and the second (T2) at the end of the eight weeks of care.

Results: The mean age of our patients was 57.2 ± 12.5 years in G1 vs 54.3 ± 7.1 years in G2 (p = 0.012). The sex ratio was 0.2 in G1 versus 0.37 in G2 (p = 0.011). The duration of knee osteoarthritis was 63.4 ± 4.5 months in G1 vs 56.2±7.5 months in G2 (p=0.172). Initially, the mean of SF12-P in G1 patients was 31.2 ± 6.5 compared to 35.4±6.2 in G2 patients. In our patients, the SF-12-P score was less than 50 in 100% of cases in G1 and 98% of cases in G2. There was a statistically significant difference between the 2 groups (p = 0.04). After classical rehabilitation, the SF12-P had increased on average by 2.3 against 6.1 after aquatic gymnastics with a statistically significant difference between the 2 groups (p = 0.012). Initially, the mean of SF12-M in G1 patients was 32.5 ± 10.2 and 35.3 ± 8.9 in G2 patients. In our patients, the SF-12-M score was less than 50 in 94% of cases in G1 and 98% of cases in G2. There was no statistically significant difference between the 2 groups (p = 0.652). After classical rehabilitation, the SF12-M increased on average by 6.9 and 12.1 after aquatic gymnastics with a statistically significant difference between the 2 groups (p = 0.005).

Conclusion: The effectiveness of functional rehabilitation, whether aquatic or dry, has been well demonstrated by the study of quality of life, with better results for balneotherapy. The physical properties of water and heat have a positive short-term impact on quality of life by acting on several parameters, including pain, contractures and anxiety. Further studies evaluating this long-term effectiveness will be required.

THE BIOPSYCHOSOCIAL-BASED EXERCISE MODEL VIA TELEREHABILITATION IN PATIENTS WITH INFLAMMATORY AND NON-INFLAMMATORY RHEUMATIC DISEASES: A PROSPECTIVE COHORT STUDY DURING THE COVID-19 PANDEMIC

N. E. Nacar1, N. B. Karaca1, L. Kılıçaslan2, S. Kınca3, E. Ünal4, 1Hacettepe University, Graduate School of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 2Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 3Hacettepe University, Faculty of Medicine, Department of Rheumatology, Ankara, Turkey

Background: During the COVID-19 pandemic, the patients with rheumatic disease in the biopsychosocial perspective have been adversely affected by social isolation, uncertainty, and the thought that their chronic disease will worsen and increase in their symptoms. ACR/EULAR (American College of Rheumatology / European League Against Rheumatism) defines recommendations about continuing current pharmacotherapy and the significance of the biopsychosocial approach and exercise for patients with rheumatic diseases during a COVID-19 infection [2].

Objectives: This study aims to investigate the effectiveness of the biopsychosocial exercise performed by telerehabilitation on biopsychosocial status, general health status, and anxiety-depression levels in the patients with inflammatory and non-inflammatory rheumatic diseases.

Methods: Fourteen patients with inflammatory rheumatic diseases (rheumatoid arthritis: 4; ankylosing spondylitis: 4; spondyloarthropathy: 2; and vasculitis: 1) and eight patients with non-inflammatory rheumatic diseases. 1The Military Hospital of...
Conclusion: This study showed that biopsychosocial-based exercise through real-time telementerapy was able to maintain their conditions before pandemic in biopsychosocial status, general health, and anxiety-depression levels on the patients with inflammatory and non-inflammatory rheumatic diseases during COVID-19 pandemic period in one-year follow-up.

AB1500 ASSESSMENT OF CLINICAL PARAMETERS AFTER CLASSIC REHABILITATION VERSUS BALNEOTHERAPY IN GONARTHROSIS

R. Maaouli1, S. Karouli1, M. Hlaidh1, N. Mouhil1, H. Rahali2, I. Ksibi3, M. Slouma4, L. Ben Ammar2, L. Metou2, R. Dahhiri2, I. Gharsallah4. The Military Hospital of Tunis, Physical Medicine and Rehabilitation Department, Tunis, Tunisia; 5The Military Hospital of Tunis, Rheumatology Department, Tunis, Tunisia

Background: Knee osteoarthritis (KOA) is the most common pathology of the lower limb. It is multifactorial and constitutes a real public health problem. Nowadays, in addition to the rehabilitation that is part of the multidisciplinary management of this affection, water gymnastics is increasingly finding its place [1].

Objectives: The main objective of our work was to compare the contribution of aquatic gymnastics compared to classical rehabilitation in patients with knee osteoarthritis through a clinical evaluation.

Methods: This is a prospective, comparative and evaluative study carried out in a department of Physical Medicine and Functional Rehabilitation over a period of 15 months between September 2016 and December 2017, including 60 patients with KOA. The patients were randomly divided into 2 groups of 60 patients each one. The first(G1) benefited from a classic rehabilitation program. The second(G2) benefited from water gymnastics. Two clinical evaluations were carried out: T1 before the start of rehabilitation and T2 at the end of the eight weeks of treatment.

Results: The mean age of our patients was 57.2 ± 12.5 years in G1 vs 54.3 ± 7.1 years in G2 (p = 0.012). The sex ratio was 0.2 in G1 versus 0.37 in G2 (p = 0.011). The duration of knee osteoarthritis was 63.4 ± 4.5 months in G1 vs 56.2±7.5 months in G2 (p=0.172). 55 patients presented with a misalignment of the lower limbs with a varus knee in 33% of cases (G1 25% and G2 42%). 5 patients in G1 and 7 patients in G2 had a valgus knee. In G1, one patient had recurvatum and two patient had knee flexion with no statistically significant difference between the two groups. After classic rehabilitation, Zolten’s sign had disappeared in 6 patients for the right knee and 3 patients for the left knee. However, after water gymnastics, this sign had disappeared in 12 patients for the right knee and in 16 patients for the left knee. A functional mobility sector (>90°) was found in all patients with an average of 126° in G1 and 126° in G2. After rehabilitation, an improvement of 2% in G1 and 5% in G2 was noted with a statistically significant difference between the two groups (p<0.001). Thirty-six percent of G1 patients had quadriceps amytrophy versus 32 % of G2, which disappeared in 5 patients after classic rehabilitation and in 6 patients after hydrotherapy. 48 patients of G1 and 56 patients of G2 presented with quadriceps retraction which disappeared in 42 patients of G1 after classic rehabilitation and in 45 subjects of G2 after hydrotherapy. A retraction of the hamstrings was noted in 13 and 18 patients respectively in G1 and G2 with a total improvement in the 2 groups.

Conclusion: Dry rehabilitation has its place in the management of knee osteoarthritis, but rehabilitation in water has better results. The aquatic environment makes it possible, by reducing the weight of the body, to reduce the stresses exerted on the knee joints, allowing better joint mobility with the added effect of heat on the reduction of pain and muscle relaxation.

AB1499 PAIN MANAGEMENT IN KNEE OSTEOARTHRITIS: BALNEOTHERAPY VERSUS CLASSIC REHABILITATION

R. Maaouli1, M. Hlaidh2, Z. Mrizak3, N. Mouhil4, H. Rahali5, I. Ksibi6, M. Slouma6, L. Ben Ammar2, L. Metou2, R. Dahhiri2, I. Gharsallah4. The Military Hospital of Tunis, Physical Medicine and Rehabilitation Department, Tunis, Tunisia; 5The Military Hospital of Tunis, Rheumatology Department, Tunis, Tunisia

Background: Knee osteoarthritis presents a heavy financial burden due to disability and supported care. Gonalia is the main symptom leading patients to consult. For some clinicians, this is a warning signal that correlates with the extent of joint degradation [1]. The management of pain in knee osteoarthritis is multidisciplinary comprising pharmacological and non-pharmacological means including classical rehabilitation and aquatic gymnastics. The objective of our work was to study the contribution of aquatic gymnastics compared to conventional rehabilitation in the management of pain in patients with knee osteoarthritis.

Objectives: The objective of our work was to study the contribution of aquatic gymnastics compared to conventional rehabilitation in the management of pain in patients with knee osteoarthritis.

Methods: Prospective, evaluative and comparative study about 120 patients with knee osteoarthritis carried out over 15 months (September 2016- December 2017) in the Department of Physical Medicine and Functional Rehabilitation. The patients were divided into two groups of 60. The first group (G1) benefited from aquatic rehabilitation program, the second group (G2) benefited from aquatic gymnastics. The 2 programs were carried out at the rate of three sessions per week for two months. The study was based on the assessment of pain by the following scales: VAS pain and the Western Ontario and Mc master Universities’ Osteoarthritis Index (WOMAC) questionnaire for the lower limbs (pain section).

Results: The mean age of our patients was 57.2 ± 12.5 years in G1 vs 54.3 ± 7.1 years in G2 (p = 0.012). The sex ratio was 0.2 in G1 versus 0.37 in G2 (p = 0.011). The duration of knee osteoarthritis was 63.4 ± 4.5 months in G1 vs 56.2±7.5 months in G2 (p=0.172). 55 patients presented with a misalignment of the lower limbs with a varus knee in 33% of cases (G1 25% and G2 42%). 5 patients in G1 and 7 patients in G2 had a valgus knee. In G1, one patient had recurvatum and two patient had knee flexion with no statistically significant difference between the two groups. After classic rehabilitation, Zolten’s sign had disappeared in 6 patients in G1 and 3 patients in G2. However, after water gymnastics, this sign had disappeared in 12 patients for the right knee and in 16 patients for the left knee. A functional mobility sector (>90°) was found in all patients with an average of 126° in G1 and 126° in G2. After rehabilitation, an improvement of 2% in G1 and 5% in G2 was noted with a statistically significant difference between the two groups (p<0.001). Thirty-six percent of G1 patients had quadriceps amytrophy versus 32 % of G2, which disappeared in 5 patients after classic rehabilitation and in 6 patients after hydrotherapy. 48 patients of G1 and 56 patients of G2 presented with quadriceps retraction which disappeared in 42 patients of G1 after classic rehabilitation and in 45 subjects of G2 after hydrotherapy. A retraction of the hamstrings was noted in 13 and 18 patients respectively in G1 and G2 with a total improvement in the 2 groups.

Conclusion: Dry rehabilitation has its place in the management of knee osteoarthritis, but rehabilitation in water has better results. The aquatic environment makes it possible, by reducing the weight of the body, to reduce the stresses exerted on the knee joints, allowing better joint mobility with the added effect of heat on the reduction of pain and muscle relaxation.

AB1501 EFFECT OF SARS-COV-19 PANDEMIC ON RHEUMATOLOGY TRAINING IN INDIA

K. Kunachandeng@gmail.com1, K. Kishor2, P. Dogga3, D. Ekbot2, J. Dixit2, P. Kumar2, U. Dhakad2,1King George's Medical University; Clinical Immunology and Rheumatology, Lucknow, India

Background: The current study aims to gauge the magnitude of the effect the pandemic has had on Rheumatology training (including the effect on clinical,
academic and research training) in India, their physical, mental and social well-being during the pandemic and the perceived changes in Rheumatology training and care during the pandemic from the trainees’ view

Objectives: 1. To assess the impact of COVID-19 Pandemic on the training of Rheumatology Residents (DM, DNB and Fellows) 2. Understand the issues faced by trainees and the extent of affection.

Methods: Study design: We conducted an observational cross-sectional study using an online survey sent to rheumatology trainees in India.

Sample: Convenience sampling was used, so the sample size was not calculated.

Inclusion and exclusion criteria: Rheumatology trainees from India including DM/DNB residents and fellows with the ability and desire to complete the survey were included.

Data collection and instruments: The link to the survey was sent to the rheumatology trainees through social media platforms like WhatsApp, Telegram and email.

Statistical analysis: Descriptive statistics were performed by calculating measures of central tendency for quantitative variables and using counts and percent-ages for qualitative and nominal variables.

Results: A total of 78 trainees from 24 institutes in 12 states participated in the study. Mean age of the participants was 31 with 70% of trainees being male and 30% females. 56 (70%) participants were DM students, 15 (19%) participants were DNB students, 5 fellowship students and 2 Non- academic Senior Residents. An overwhelming majority of residents (84%) felt COVID-19 Pandemic negatively impacted their residency and their Physical (65%), Mental (74%) and Social wellbeing (80%). 79% of trainees felt burnt-out due to the pandemic. Majority of trainees felt the pandemic negatively impacted their training with clinical teaching (91%). Clinical examination skill (74%), current (80%) and future (70%) research opportunities suffered during the pandemic. Most residents felt diminution and significant reduction of the overall footfall (99% & 72%) of patients in rheumatology including OPD (100% & 77%) and indoor (99% & 67%) admissions along with academics (85% & 35%), procedures (97% & 86%) and exposure to musculoskeletal ultrasound (96% & 71%). Almost 60% and 40% of trainees had their OPDs and indoor admissions stopped during COVID-19 pandemic of these 20% had their OPDs and Admissions closed for more than 6 months. 85% of the participants had one or the other psychological symptoms with almost half experiencing anxiety (44%), low mood (47%) or lack of sleep (41%); 85% were concerned about their family members being infected and 40% lost a close relative to COVID. 91% of the trainee were posted in COVID-duties 2/3rd of them in ICUs, 50% being posted for 1-3 months and 20% more than 3 months, a quarter of trainees got infected during their duties (COVID and Non-COVID) and through most had asymptomatic to mild COVID. 15% still had moderate to severe COVID. Teleconsultation was started by more than half of the respondents after COVID related lockdowns with greater than half not being happy with teleconsultations.

Conclusion: The COVID-19 Pandemic has completely altered the status quo for rheumatology trainees and has affected their physical, social and mental well-being. Academic and clinical training has reduced. Current and future Research has become difficult, disruptions in OPDs and Admissions, recurrent COVID postings and reduction in patient footfall, Procedures and MSK-US have been detrimental to trainees.

AWARENESS OF BIOLOGICAL AGENTS RELATED SIDE EFFECTS AMONG INTERNAL MEDICINE RESIDENTS IN A UNIVERSITY HOSPITAL

M. Oztas1, S. Liriglu2. 1Istanbul University-Cerrahpasa, Department of Rheumatology, Istanbul, Turkey; 2Istanbul University-Cerrahpasa, Department of Rheumatology, Istanbul, Turkey

Background: Biological agents have become a core component of therapeutic strategies in the last two decades. The number of patients treated with biological agents has been increasing with the expansion of these agents’ indications among rheumatic disorders.

Objectives: Unfortunately, biological agents have varied side effect profiles, and rheumatic patients with possible side effects are commonly consulted with internal medicine physicians in emergency departments. We surveyed to assess the awareness of biological agents related side effects among internal medicine residents in our university hospital.

Methods: We conducted a web-based multiple-choice test with 10 questions in total. Monoclonal antibodies (anti-TNF, anti-CD20), anti-cytokines, and JAK inhibitors related side effects and management of these adverse events were assessed. Figure 1 depicted the topics and the correct answer rate of the related questions.

Results: A total of 57 responses were collected and analyzed. The mean number of the correct answers was 6.4 ± 1.5. Fourteen (24.6%) out of the 57 participants scored below 5, whereas 58% of the participants scored ≥6 points. The majority of the participants have correctly answered the anti-TNF, rituximab and tocilizumab-related questions, however, less than half of the participants have accurately answered the anakinra and JAK inhibitors-related questions (Figure 1).

Conclusion: Our survey suggests that the awareness of biologic agents related side effects among the internal medicine residents is satisfactory. Poorer results were observed especially in JAK inhibitors related side effects and severe infusion reaction management which indicate the educational needs of the residents for these topics.

MOST MEDICINE RESIDENTS WOULD LIKE TO LEARN JOINT ASPIRATION PROCEDURES BUT 2/3 HAVE NEVER DONE IT: SURVEY OF COMMUNITY HOSPITAL TRAINEES IN NORTHEASTERN USA

P Gonzalez1, R. Kaler1, N. Sukumaran1, A. Eldib1, Y. Turkowski1, Z. Y. Li2, K. Gilek-Seibert1. 1Roger Williams Medical Center, Internal Medicine, Providence, United States of America; 2Roger Williams Medical Center, Rheumatology, Providence, United States of America

Background: Arthrocentesis is a procedure performed to aspirate synovial fluid from a joint cavity. It has both diagnostic and therapeutic utilization in outpatient and inpatient settings. While arthrocentesis is considered a minor surgical procedure, there is always potential to injure blood vessels, nerves, and tendons1. Although joint arthrocentesis is not an Accreditation Council for Graduate Medical Education procedural requirement for Internal Medicine (IM) residents in the United States, several studies have revealed that training on knee arthrocentesis and injection provided a solid foundation to medical residents toward increasing their confidence and refining motor skills2.

Objectives: To evaluate the current Roger Williams Medical Center (RWMc) IM residents’ confidence level in performing intra-articular injection. Results from this study will inform the design of resident-oriented quality improvement arthrocentesis teaching series in RWMc.

Methods: Project was incepted and designed by one rheumatology faculty, one fellow and five IM residents of RWMc. We selected the survey as a tool to elicit information from all current IM residents who filled out a 7-question survey regarding their residency experience and exposures to knee aspiration and injection. We used Survey Monkey as an anonymous survey tool (see Table 1). Data were collected between 1/14/22 until 1/27/22 and were verified by two members of the research team.

Results: A total of 47 IM residents within three classes in this community residency program were provided with the survey. The survey response rate was 82.9% (39 /47). 69.23% residents do not feel comfortable doing arthrocentesis. More than half of the resident population (51.28%) do not think they have adequate exposure to knee arthrocentesis. 73.68% residents have never performed knee injections/arthrocentesis. According to the survey, 94.87% of the
Background: In several countries, studies have shown that fewer medical students choose rheumatology as a specialty. In Morocco no study has yet focused on this subject.

Objectives: The aim of our study is to assess the attractiveness of rheumatology as a specialty among Moroccan medical students, recently graduates and interns, and to analyze the factors that may be associated with it.

Methods: An online survey was sent to 297 medical students who had started their hospital practice, to 100 medical interns (students in 6th and 7th year who successfully passed the internship competition) and to 280 freshly graduated medical doctors (residency program candidates before choosing a medical or surgical specialty). The survey covered three areas: anonymous social and demographic informations, data on clinical trainee in a rheumatology department, and the attitude toward rheumatology as a specialty. Descriptive data were collected and Chi2 Tests were used to assess differences between groups. Logistic regression was performed to investigate associations between demographic and exposure variables and the choice of rheumatology as a career.

Results: We collected responses from 161 students (response rate: 54%), 68 interns (68%) and 89 freshly graduated doctors (32%). The demographic characteristics are presented in Table 1.

(*) expressed as a number and percentage / (+) expressed as a mean and standard deviation

73% of students, 41.2% of interns and 41.6% of graduates said they had already completed a clinical training in a rheumatology department. While 41.6% of students and 43.8% of graduates consider the possibility of choosing rheumatology as their specialty, only 11.2% of students, 5.9% of interns and 7.9% of graduates said that rheumatology is their dream career specialty. In uni and multivariate analysis, clinical exposure to rheumatology is retained as the main statistically significant factor predicting the choice of rheumatology in all categories (Odds ratio (95% CI) = 0.1019 (0.07-0.497; p=0.02)), to this is added the female sex among freshly graduated doctors (Odds ratio (95% CI) = 4.02 (1251-12.918; p= 0.001).

Conclusion: Our study showed that rheumatology is considered a fascinating specialty by Moroccan medical students and freshly graduated doctors. Clinical exposure to rheumatology is the strongest predictor factor for choosing rheumatology as a future career.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular.906
it can offer, given that it is a "relatively less time consuming specialty". The main barriers to choose rheumatology are "the interest in surgical specialties" for students and interns and "the limited therapeutic aspects" for graduates. Other commonly reported reasons are shown in Table 1.

Conclusion: Our study has shown that rheumatology fascinates Moroccan medical students by its clinical abundance and the diversity of musculoskeletal pathology and also by the quality of life it can offer. According to the students, the main barriers to choose rheumatology are the interest in a surgical specialty, and the limited therapeutic aspects of the specialty.

Disclosure of Interests: None declared.

AB1506
RHEUMATOLOGY TRAINING EXPERIENCE: ARE RHEUMATOLOGY RESIDENTS WELL-PREPARED NOWADAYS? A SELF-APPRaisal
R. Dos-Santos1, E. Perez-Pampin1, A. Souto Vilas1, A. Mera Varela1. Clinical University Hospital in Santiago de Compostela, Spain, Rheumatology Department, Santiago de Compostela, Spain

Background: Rheumatology residence in Europe is a 4-year training program where Medical Doctors (MD) purchase all capacities for turning into Rheumatologists at each Hospital. European guidelines concerning which contents should be acquired and recommendations for its obtaining are available (UEMS, Union Européenne des Médecins Spécialistes). Several researches have proven high self-reported abilities, but some deficiencies are displayed in deeper investigations: musculoskeletal ultrasound sonography, poorly crystal identification by optic microscopy and injection skills. As well, low clinical experience remains as one of the most self-reported deficiencies.2,3

Objective: To assess the quality of one-year rheumatology trainee consultation at the outpatient clinic in a Spanish Hospital.

Methods: The last year during outpatient consultation of a resident training in Rheumatology in one Spanish hospital was assessed, from May 2021 to May 2022. All patients visited by the trainee were included, absent patients in the consultation date were excluded from the study. Main variables were collected, such as gender, main diagnosis, biological or targeted synthetic treatments and supplementary tests. The final resident’s opinion about his training was also checked.

Results: During one-year period of the Resident’s consultation, 1419 visits were performed. From those, 470 were the first visit of the patient and 119 of them were solved in the first visit and no follow-up was needed. 60.7% of patients were women. Most frequent diagnosis were arthropathies: 21.8% psoriatic arthritis, 16.9% rheumatoid arthritis and 8.4% axial spondyloarthritis. Regarding collagenopathies, 3.4% of patients were diagnosed of systemic erythematosus lupus, 1.3% antiphospholipid syndrome, 2.3% systemic sclerosis and 1.3% myopathies. Bone-related diseases as Paget's disease and osteoporosis were also frequent (21 and 132 patients). The most prevalent vasculitis was giant cell arteritis with 51 patients, although patients with Behçet's disease, Takayasu arteritis and polyarteritis nodosa were also followed. A total of 207 musculoskeletal ultrasonography were made during daily clinical practice. As well, 67 articular injections were performed. Capillaroscopy and salivary gland biopsy were the least frequent procedures (21 and 18, respectively).

Conclusion: Most of rheumatological diseases can be diagnosed and followed during one-year period in the resident's training program. Also, ultrasound and injection skills are granted during this time. The most important self-reported deficiency is the low number of patients under biological/targeted synthetic treatments.

ATTRIBUTES INFLUENCING THE SELECTION OF FELLOWSHIP PROGRAMS BY RHEUMATOLOGY APPLICANTS: A PILOT WEB-BASED SURVEY
V. Kesawari1, D. Feterman1, S. Alexander1, N. Singh1. 1University of Connecticut, Internal Medicine, Farmington, United States of America; 2University of Connecticut, Internal Medicine, Farmington, United States of America; 3University of Connecticut, Internal Medicine, Farmington, United States of America; 4University of Washington, Division of Rheumatology, Seattle, United States of America

Background: Recruitment of candidates is a cost- and effort-intensive aspect of rheumatology fellowship programs. For program leaders to efficiently use the available resources and improve recruitment outcomes, it is imperative to understand the attributes that influence the candidates’ choice of a program. Previous studies have examined the type and relative importance of the factors that candidates use in selecting other national programs (1, 2). However, no such studies have been conducted in the field of rheumatology.

Objectives: To examine the factors that influence the selection of fellowship programs by rheumatology applicants.

Methods: An anonymous, web-based survey comprised of 13 questions was shared with rheumatology fellowship applicants on messaging applications and online forums. The survey was open from 10/29/2021-11/06/2021. Participation was voluntary and informed consent was implied through the participants’ response. Three reminders to complete the survey were sent. Four domains of the applicant’s perception in relation to their preference of ranking rheumatology programs were assessed: (1) program prestige, (2) program structure, (3) interview day experience, and (4) career path of the applicant. The survey questions were devised in one of the following formats: (1) 5-point Likert scale, (2) rank order questions, (3) yes/no questions, (4) multiple choice questions, and (5) open-ended questions.

Results: Thirty-two rheumatology applicants responded to the survey. The prestige of the program was reported to be extremely important by 16%, very important by 19%, somewhat important by 44%, and little or not important by 21% respondents. The opportunity to see a diverse patient population was reported to be important by 97% respondents. The call schedule and higher number of fellows were considered important by 86% of the respondents. 66% preferred programs with higher number of faculty members. 69% favored programs with an ultrasound curriculum. The availability of clinician-educator track (18%), MCR/MPH (14%), and T32 grand (16%) was considered less important. 95% reported that the opportunity to train at a Veterans Administration hospital did not influence their choice. Regarding interview day experience, interaction with the faculty (63%) and the fellows (17%) were considered important factors influencing program ranking. Respondents preferred programs with alumni in academic clinician track (45%) and private practice (43%) compared to programs with alumni in academic research (13%) or industry pathway (4%). The geographical location of the program including the cost of living and location of significant others also influenced the applicants’ choice.

Conclusion: To the best of our knowledge, this is the first survey to assess the attributes that influence a candidate’s choice of a rheumatology fellowship program. Our survey demonstrated that a positive interview day experience and program attributes including the opportunity to interact with a diverse patient population, relaxed call schedule, higher number of fellows and faculty, the presence of an ultrasound curriculum, and the location were the dominant factors influencing applicants’ choice of a program. The program limitation of our study is the lack of generalizability due to selection bias. Understanding the factors involved in decision making of the rheumatology fellowship applicants can provide valuable information for both the applicants and the programs and therefore lead to a better match.

A NOVEL PATHOGENIC VARIANT IN ZNF462 GENE ASSOCIATED WITH WEISS-KRUSZKA SYNDROME AND SLE
M. Constantinou1, M. Lampi2, V. Neoleux3, P. Fanis3, L. A. Phylactou4, S. Pasierl6, K. Parpeneris6, University of Cyprus, Medical School, Nicosia, Cyprus; 7The Cyprus Institute of Neurology and Genetics, Molecular Genetics, Vision and Therapy, Nicosia, Cyprus; 8Nicosia General Hospital, Division of Rheumatology, Nicosia, Cyprus; 9University of Cyprus Medical School, Department of Internal Medicine, Division of Rheumatology, Nicosia, Cyprus

Background: Weiss-Kruszka syndrome (WSKA) is an autosomal dominant congenital anomaly syndrome due to mutations in the ZNF462 gene and manifests with developmental delay and multiple craniofacial abnormalities with variable expressivity. It is also characterized by cognitive impairment, whilst about a third of the affected individuals belong to the autism spectrum. Although the disease is inherited with the autosomal dominant manner, most of the described subjects (95%) had de novo variants with no affected family members1. WSKA has been recently described and only 26 (including our patient) affected individuals have been classified to date2. Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by the presence of autoantibodies and multi-organ inflammation. Genetic factors might play an important role in disease pathogenesis in patients with childhood-onset SLE.

Disclosure of Interests: None declared.

Objective: To describe the case of a SLE patient who was found to have WSKA related to a novel pathogenic autosomal dominant (AD) variant in the ZNF462 gene, and inform clinicians of a possible association between the 2 conditions.

Methods: A 25-year-old Caucasian female with a history of SLE, diagnosed at the age of 14, manifested with malar rash, Raynaud’s phenomenon, arthritis, thrombocytopenia, positive ANA, ds-DNA antibody and hypocomplementemia. At the age of 17, she developed renal dysfunction due to lupus nephritis class IV, and she was treated with glucocorticoids (GCs), cyclophosphamide and hydroxychloroquine. In Oct 2020, she was admitted to the hospital for thrombotic thrombocytopenic purpura due to lupus exacerbation. She was successfully treated with GCs, plasma exchange and rituximab. During her hospitalization, the presence of various clinical features raised the suspicion of a genetic syndrome. First, the patient exhibited dysmorphic features such as hypertelorism, prognathism, arched eyebrows, flattened nasal bridge, small upper lip, mild intellectual disability, and a history of childhood-onset SLE. Whole exome sequencing (WES) by NGS was used for the genetic investigation of the patient.

Results: The patient underwent genetic evaluation with WES and the novel heterozygous AD pathogenic variant c.4142delT (p.Lle1381ThrfsTer16) in ZNF462 gene was identified. Confirmation of the identified variant was also verified by sanger sequencing. Pathogenic variants in the ZNF462 gene were previously described in patients with the recently reported WSKA of which several characterized are compatible with our patient’s features. The ZFN462 encodes a zinc-finger transcription factor that plays a role in embryonic development, transcriptional regulation, and chromatin remodelling. Given that chromatin remodelling has been implicated in the pathogenesis of SLE, the association of this novel ZNF462 variant in the development of SLE, needs to be determined.

Conclusion: This is the first report of a patient with coexisting SLE and WSKA due to a novel variant. It illustrates the need for further research in order to elucidate any possible pathophysiologic link among the 2 conditions.

OVARIAN CARCINOMA MIMICKING SYSTEMIC SMALL VESSEL VASCULITIS: CASE REPORT

R. A. Elziaty1. 1 Ain Shams University, Internal Medicine Department, Division of Rheumatology; Cairo, Egypt

Background: Few cases of digital ischemia and gangrene associated with primary solid tumors have been described in literature[3]. The exact mechanism of severe occurrence has not been completely understood and the available treatment options have an extremely limited utility [1,2]. In the most cases the patients were elderly women with adenocarcinomas of digestive or gynaecologic apparatuses [4].

Objectives: We describe a new case of digital gangrene as unusual presentation of ovarian cancer in a 36 years old woman.

Methods: 36 years old female was admitted to our Reumatology department with blackish Blackish discoloration of the toes of one week duration. She had history of COVID -19 infection 8 months prior to the presentation then developed hemoptysis, picture suggestive of ILD, generalized anaasarca and skin rash; accordingly an initial diagnosis of post COVID-19 vasculitis was made by dermatologist. The blood tests were ESR:21 mm/hr, CRP:25.7, D.Dimer:8.8, Ferritin:575 ng/ml, lymphopenia:0.9, S.Creatinine:2, 24h urinary protein: 325mg/24h and all autoimmune markers were negative except anti nuclear antibody (ANA) with titer:1/160. Further assessment revealed that she had multiple site coagulopathy; internal jugular vein thrombosis, bilateral lower limbs Deep Venous Thrombosis (DVT). Neck ultrasound surprisingly showed bilateral enlarged suspicious looking supraclavicular lymph node with lost hilum which was Biopsied for histopathological correlation which revealed focally necrotizing adenocarcinoma with significant signet ring differentiation. Searching for the primary malignancy, tumor markers were sent CA125: 584 u/ml (up to 35), Pelvi-abdominal Magnetic resonance imaging (MRI) revealed Left ovarian mass measuring 3.6 x 3.4 x 4.4 cm highly suspicious of malignant neoplastic growth for histopathological correlation. Suspicious looking pelviabdominal lymph nodes mostly representing malignant lymphadenopathy, Scattered peritoneal nodules suspicious of metastatic deposits.

Results: During admission the patient received full dose anticoagulation (Low Molecular Weight Heparin: 60 iu /12h). Upon diagnosis we arrange the transferal to the oncology department to continue her management plan. Unfortunately; the case was terminal for palliative therapy and she died after 2 weeks.

Conclusion: Bluish discoloration of digits and toes may be a clue for diagnosis of many diseases not only vasculitis. Malignancy can disturb the immune system in a way that mimic any systemic connective tissue disease. Acute insult aggressive multiple site deep venous thrombosis (DVT) necessitate thinking outside the box and consider other causes of coagulopathy like visceral malignancy.

REFERENCES:
Background: Motor neurone disease may mimic inflammatory myositis. There is an overlap in clinical symptoms (such as muscle weakness, dysphagia and respiratory involvement) which may pose a diagnostic challenge. Careful history, thorough clinical examination and appropriate investigations can help to distinguish between the two. Monitoring the response to treatment is also crucial. We present a case that presented to rheumatology with progressive muscle weakness, she was investigated and treated for inflammatory myositis but was later diagnosed with motor neurone disease.

Objectives: To illustrate the need for thorough clinical assessment and investigations in patients with suspected inflammatory myositis and consider alternative diagnoses as clinical picture evolves.

Methods: A 68 year old lady, presented with 6 months history of progressive proximal muscle weakness. She also reported weakness of grip, affecting activities of daily life. She was finding it difficult to get up from chair. There was no swallowing difficulty, respiratory symptoms and skin rash. She had history of hypertension. On clinical examination, she did not have any features of connective tissue disease. There was no evidence of joint synovitis or skin rash. Proximal muscle power in upper and lower limbs noted to be 4/5 with intact reflexes. Initial investigations revealed mildly raised CPK at 287 with normal thyroid function and inflammatory markers. Immunological tests including ANA and myositis panel were requested alongside EMG, MRI thighs and CT chest/posterior cervical spine. Myositis panel was positive for anti-MDA-5 antibodies (in the absence of any respiratory symptoms). There was no evidence of malignancy on CT imaging. MRI thighs revealed fluid in the trochanteric bursae. She was trialled on oral prednisolone in view of her clinical features and positive anti-MDA5 antibody. However, there was no improvement in her symptoms or functional status. EMG revealed widespread neurogenic process affecting upper and lower limbs on both sides, without significant evidence of acute myopathy. The progressive nature of symptoms with the upper motor neurone signs raised the possibility of an evolving anterior horn cell disorder. She was referred to neurology and was subsequently diagnosed to have Motor Neurone Disease. The steroids were rapidly tapered off and stopped.

Results: Motor neurone disease is an important differential when considering inflammatory myositis, particularly inclusion body myositis which causes more progressive muscle weakness. It is a neurological disorder characterised by degeneration of neurons. There is no clear cause identified. MND causes both upper and lower motor neurone signs. Symptoms include limb weakness, bulbar weakness that can affect speech and swallowing, muscle twitching and fasciculation. Respiratory weakness may occur. Thorough clinical examination and EMG findings help identify the diagnosis. Imaging may be needed. There is no cure. Management requires an MDT approach, primarily guided by neurology, including physiotherapy, occupational therapy, speech and language therapy and respiratory support.

Conclusion: This lady was initially treated for inflammatory myositis based on her symptoms, mildly raised CK and positive anti-MDA5 antibodies. On review of her clinical progress, we noted poor response to steroids and EMG results pointing at an alternative diagnosis of MND. This case highlights the importance of EMG in the assessment and management of patients with suspected inflammatory myositis as well as the need to closely monitor progress and re-evaluation where needed. Although she had anti-MDA-5 antibodies and mildly raised CK, she did not have any skin disease or other systemic features, inflammatory markers and muscle imaging was normal. Response to steroids was inadequate.

SLE ONSET POST COVID-19 VACCINATION: COINCIDENTAL OR ASSOCIATION?

C. B. Ng1, C. E. Goh1, 1Hospital Sultan Ismail, Rheumatology Unit, Department of Medicine, Johor Bahru, Malaysia

Background: Numerous immune-mediated diseases flare post vaccination but study on new disease onset post SARS-CoV-2 vaccination have been reported. There were case reports showed the immune-mediated disease flare post vaccination but study on new disease occurs post Covid-19 vaccination is still lacking.

Objectives: To describe two SLE cases that diagnosed post Covid-19 vaccination.

Methods: Case report

Results: 14 years old girl, post Covid-19 vaccination 1st dose 3 weeks ago presented with 2 day history of giddiness, breathlessness, vomiting and diarrhea prior to admission. She also complained of frothy urine for the past 1 week associated with lower limbs swelling and facial puffiness. Clinical examination noted she had sparse hair, oral ulcers and discoid lupus at the ear concha. She also noted to have periorbital puffiness with pedal edema. Lung auscultation noted bi-basal crepitations. Blood investigation noted ANA positive (1:640, speckled) with low complement 3 (0.1g/L). Her full blood count showed leukocytosis (3100 UL) with low lymphocyte count of 810UL. UFEEME noted protein of 3 + and red blood cell of 2 + with normal renal profile. Her serum albumin was 22g/L. Chest x ray showed clear lung field with no cardiomegaly. Her 24-hour urine protein showed proteinuria of 2.345g/dl and her renal biopsy showed mesangial proliferative lupus nephritis class ii. She was given intravenous methylprednisolone 500mg OD for 3 days and discharged with tapering dose of prednisolone, hydroxychloroquine, calcium supplements, perindopril and frusemide. Another case was a 17 year-old female, post covid-19 vaccination 10 weeks, presented with 3 weeks history of bilateral lower limbs weakness with difficulty in getting up from chair. She also had fever on and off with cough for 1 week. There was no alopecia, oral ulcer, facial rash or photosensitivity. No joints pain. Clinical examination noted presence of proximal myopathy with stable vital signs. Other systemic examinations were unremarkable. Blood investigation noted ANA positive (1:640, homogenous and speckled) with low complements level (C3 0.19g/L and C4 0.049g/L).Her creatine kinase was 2367U/L and EMG showed evidence of irritable myopathic process which is consistent with inflammatory myositis. Her TFT was normal. Myositis panel showed anti-Ku and anti-Ro 52 were positive. She was treated as SLE with myositis and intravenous methylprednisolone was given. She discharge well with tapering dose of prednisolone and azathioprine. Her creatine kinase showed improvement with immunosuppression therapy and she was advised on intensive physiotherapy.

Conclusion: The onset of these two SLE cases were occurred within the 2 month of post covid-19 vaccination. Whether Covid-19 vaccination direct contribute to the occurrence of SLE remained inconclusive. More studies are required to show its correlation between onset of SLE and Covid-19 vaccination.

CENTRAL RETINAL ARTERY OCCLUSION (CRAO) LEADING TO BILATERAL BLINDNESS; DUE TO BOTH ARTERITIC AND NON-ARTERITIC ISCHEMIC OPTIC NEUROPATHY

S. Sunari.Subasinghe@gmail.com1, C. Byanwila2, O. Temizsoylu3, K. Ramesal4. 1Medway NHS Foundation Trust, Rheumatology, Gillingham, United Kingdom; 2East Sussex NHS Health Care Trust, Stroke Medicine, Eastbourne, United Kingdom; 3Moorfield Eye Hospital NHS Foundation Trust, Ophthalmology, London, United Kingdom; 4East Sussex NHS Health Care Trust, Histopathology, Eastbourne, United Kingdom

Background: Giant cell arteritis (GCA) is a large vessel vasculitis which is common in the elderly. It affects the cranial branches of the aorta, commonly superficial temporal, posterior ciliary and retinal arteries. Hence blindness can be one of the dreaded complications of the disease which makes prompt diagnosis and treatment of utmost importance. Sometimes atypical presentations and concurrent pathologies can make the timely diagnosis of the disease difficult. Therefore it is very important for clinicians to be vigilant of the varied presentations of the GCA and coexisting vascular risk factors.

Objectives: A 78-year-old Caucasian male was presented with acute onset blindness of the left eye. It started as few blotchy patches in the peripheral visual field and gradually became diffuse visual loss over a few days. He denied any headache, temporal tenderness, tongue or jaw claudication or symptoms of polymyalgia rheumatica. Following ophthalmology review he was diagnosed to have CRAO with marked disc pallor without any evidence of retinal embolii. He was in sinus rhythm, no carotid bruits or cardiac murmurs were noted. His comorbidities were hypertension and hypercholesterolemia. He was assessed in the transient ischaemic attack clinic for screening for vascular risk factors and started on antiplatelets.
Methods: Three months later he re-presented with visual loss in the right eye. Apart from the mild tenderness of the right temporal region noticed when trimming his hair he had no symptoms of GCA. He was started on dual antiplatelets and urgently referred to ophthalmology who diagnosed central retinal artery occlusion of right eye with clear demonstration of emboli in all the arcades of the central retinal artery. A temporal arterial biopsy was performed.

Results: His CRP was 19mg/l & ESR was 18mm/hr initially. During the second presentation both ESR (35) and CRP (40) were further elevated. His carotid doppler did not show significant stenosis in internal carotid arteries. ECG at presentation was in sinus rhythm however 24 hour holter monitoring after involvement of both eyes showed paroxysmal atrial fibrillation (PAF). Transthoracic echocardiogram was normal. His temporal arterial biopsy showed destruction of the internal elastic lamina with lymphohistiocytic infiltration and occasional giant cells in keeping with a diagnosis of GCA. Patient was started on prednisolone 60 mg daily followed by a tailing off regime and antiplatelets were changed to anticoagulation due to PAF. His vision improved mildly, only in the right eye in the way of perception of hand movements.

Conclusion: CRAO is an ocular emergency and is the ocular manifestation of a stroke. The usual presentation is a painless unilateral visual loss leading to profound blindness and is commonly due to non arteritic causes like carotid artery stenosis, cardiogenic embolism, small vessel disease and rarely due to arteritic causes like GCA. Accurate identification of the aetiology is very important to avoid further recurrence. By consensus multiple retinal emboli usually exclude GCA(11). However considering, the patient's age and recurrence of CRAO while on antiplatelets led us to consider occult GCA. 21.2% of patients with GCA induced vision loss do not have any systemic symptoms of the disease(2). Hence there should be a high index of suspicion when an elderly person presents with ischaemic ocular manifestations especially optic nerve and retinal ischaemia even in the presence of another plausible explanation like PAF.

AB1513 SIROLIUMUS INDUCED INFLAMMATORY ARTHROPATHY
K. Behary1, S. Srinangan1,1Medway Maritime Hospital, Rheumatology, Gillingham, United Kingdom

Background: Sirolimus is a non-calcinurine immunosuppressant commonly used in patients with organ transplantation to prevent rejection. While various inflammatory syndromes have been described post-sirolimus use, it is uncommon to have inflammatory arthritis to sirolimus. We present a patient who developed significant joint inflammation following sirolimus use.

Results: Our patient is a 39 year old gentleman who had a heart transplant in 1992 following dilated cardiomyopathy. He was switched to sirolimus after concerns about chronic kidney disease and graft vascular disease. Six weeks later, he developed bilateral foot pain and swelling which prevented him from weight bearing. He had an MRI which showed significant bone marrow oedema in the midfoot tarsal bone and basal metatarsals. He then had a nuclear scan which showed highly increased and symmetrical uptake in both mid feet affecting the cuneiform and second, third and fourth bases of the metatarsals. The appearances showed increased osteoblastic activity with increased vascularity which was more in keeping with bone inflammation/infection and no osteonecrosis. His C-reactive protein was elevated at 148. This improved to 30 after cessation of the sirolimus. Blood cultures were negative. Of significance in his history, he also suffers from gout and has had previous monoarticular flares involving his wrist, elbow and index finger. However, he was placed on febuxostat 80mg in 2018 with excellent response. His serology was negative for anti-CCP and Rheumatoid factor. His urate levels were controlled at 374. He was also found to be HLA-B27 positive, but there was no evidence of inflammatory back pain.

He was placed on a tapering course of prednisolone and coupled with the cessation of the Sirolimus, his pain and swelling resolved. In follow-up clinic appointments, he remained in remission from his inflammatory arthritis and did not require any additional treatment but continued on Mycophenolate Mofetil and Ciclosporin for his cardiac transplant.

Conclusion: There are many studies investigating the use of sirolimus as an anti-inflammatory agent in autoimmune conditions such as rheumatoid arthritis and inflammatory bowel disease. The mechanisms include down regulation of IL-17 and IL-6. However, the induction of an inflammatory arthritis by sirolimus can paradoxically occur as sirolimus causes a reduction in the STAT-3 and the anti-inflammatory cytokine IL-10. There has been raised levels of IL-6 and TNFα in serum of patients with inflammatory sequelae post sirolimus therapy. This disequilibrium of inflammatory cascade is related to the ability of Sirolimus to inhibit mammalian target of rapamycin (mTOR) which then subsequently modulates these effects. In general, these pro-inflammatory sequelae are mild and tend to resolve after cessation of the drug. Although our patient had severe arthritic manifestations which required steroid therapy, his symptoms were transient after removal of Sirolimus.

AB1514 AN UNUSUAL ASSOCIATION BETWEEN THROMBOTIC THROMBOCYTOPENIC PURPURA AND PRIMARY ANTIPHOSPHOLIPID SYNDROME
R. Santeante1, G. Montozzi1, L. Gamba1, S. Salvucci2, L. Manfredi2, G. Moroncini3,1Ospedali Riuniti Ancona University Hospital, Internal Medicine Residency Program, Ancona, Italy;1Ospedali Riuniti Ancona, Internal Medicine, Ancona, Italy

Background: Thrombotic thrombocypenic purpura (TTP) is a rare and life-threatening thrombotic microangiopathy characterized by microangiopathic haemolytic anaemia, consumption thrombocytopenia and organ injury, particularly kidney failure and neurological manifestation. Two forms are distinguished: the hereditary one, caused by a deficit of the metalloproteinase ADAMTS13, and the idiopathic one characterized by the presence of antibodies directed against ADAMTS13. The second one is the most common. There are various subgroups of acquired TTP associated with HIV infection, sepsis, pregnancy, autoimmune disease, disseminated malignancies and drugs. Antiphospholipid syndrome (APS) is a clinical immunological condition characterized by thromboembolic events, repeated miscarriages or stillbirth and thrombocytopenia; it can be a primary disorder or due to connective tissue disease, in particular systemic lupus erythematosus.

Objectives: We describe a case of TTP associated with a primary APS. The real clinical challenge lies in the differential diagnosis between TTP and anti-phospholipid antibody syndrome.

Methods: A 37-year-old man presented to the emergency department for short-term episodes of anesthesia of the right upper limb and face with spontaneous resolution. In his past medical history, he suffered of antiphospholipid syndrome treated with warfarin. Upon admission, blood tests revealed severe thrombocytopenia, haemolytic anaemia with schistocytes on peripheral blood smear, low thrombin time and prolongation in the prothrombin time. Neurological symptoms were assessed by electroencephalogram and CT brain, resulted negative, while a brain MRI revealed acute-subacute ischemic stroke. Based on these findings we suspected a diagnosis of TTP, subsequently confirmed by reduced activity of ADAMTS-13 with borderline ADAMTS-13 inhibitory antibodies. Immunological testing confirmed positivity of antiphospholipid antibodies and antinuclear antibodies.
Results: According to the last guideline3 about management of acute episode of TTP, immediate therapy with high-dose corticosteroids (prednisone 1 mg/kg) and plasmapheresis was started and then we added infusion of rituximab (375 mg/m²/week for 4 times). Efficacy of treatment was evaluated by weekly dosage of ADAMTS13 activity, with a gradual rise in values (3 – 78%) and improvement in symptoms and laboratory examination. After persistent remission, we gradually reduced steroid therapy. Few months later, in February 2021, patient developed a bilateral comorbid pneumonia, that required hospitalization, oxygen - therapy (also with C-PAP) and endovenous antibiotics. After two weeks patient was discharged from hospital in good clinical health and he was subjected to periodic outpatients visits. Disease activity was in remission, so steroid therapy was reduced and recently we added hydroxychloroquine for APS. Some days ago patient developed COVID – 19 infection, despite vaccination, and he was treated with monoclonal antibodies, with good clinical response.

Conclusion: We have described a rare clinical case of TTP, despite concomitant warfarin treatment for primary anti-phospholipid syndrome. A careful follow-up of these medical conditions is recommended for patient’s fragility and for the risk of related serious clinical complications.

AB1515 ANCA-NEGATIVE PAUCI-IMMUNE GLOMERULONEPHRITIS AS A PARANEOPLASTIC MANIFESTATION OF SARCOMATOID MALIGNANCY

M. Ehtesham1, S. H. B. Waqar2, L. Farrukh1, M. A. Shabbir1, R. Peredo-Wende3,
1Albany Medical Center, Internal Medicine, Albany, United States of America; 2SUNY Downstate Medical Center, Internal Medicine, Brooklyn, United States of America; 3Albany Stratton VA Medical Center, Rheumatology, Albany, United States of America

Background: Pauci-immune glomerulonephritis (PIGN) is a type of small vessel vasculitis associated with anti-neutrophil cytoplasmic antibodies (ANCA). However, about 10-20% of PIGN patients have negative ANCA serologies. PIGN as a paraneoplastic syndrome is rarely described in literature with a few cases reporting an association with lung cancer.

Objectives: We describe a case of ANCA negative glomerulonephritis in a patient with underlying malignant sarcoma responsive to rituximab.

Methods: An 80-year-old female was admitted with complaints of upper abdominal pain and new onset hematuria for 2 days. Vital signs were stable, and physical exam was remarkable for mild tenderness on deep epigastric palpation. Initial laboratory workup was significant for acute kidney injury with serum creatinine of 2.1 mg/dl (creatinine two months ago at outpatient visit was 1.0 mg/dl). Urinalysis showed 4 + proteinuria and dysmorphic red blood cells. CT scan of the abdomen revealed a soft tissue mass surrounding the celiac artery and a right renal hypodense mass. Further serologies to elucidate the cause of kidney injury revealed normal perinuclear-ANCA and cytoplasmic-ANCA levels. Renal biopsy was positive for focal segmental necrotizing and crescentic glomerulonephritis consistent with pauci-immune vasculitis. She also underwent right adrenal and celiac mass biopsy; both revealed malignant spindle and epithelioid cell neoplasm consistent with undifferentiated pleomorphic sarcoma (UPS). Our patient was treated with four rounds of plasmapheresis followed by 800mg rituximab infusion which decreased her creatinine to 1.7 mg/dl and resolved hematuria within 10 days of admission. She was followed up in rheumatology clinic two weeks later where she denied further hematuria and was given another round of 600mg rituximab infusion.

Results: UPS is a rare soft tissue cancer with a 5-year survival rate as low as 15% in metastatic disease. Paraneoplastic manifestations of UPS are seldom described in literature due to poor prognosis of the disease and low annual incidence. PIGN is scarcely reported in association with lung carcinoma in a few case reports[1, 2]. It is interesting to note that in these cases there was antecedent chemotherapy raising suspicion of vasculitis induced by adjuvant agents. As our patient did not receive chemotherapy, PIGN was deemed to be a paraneoplastic phenomenon secondary to malignant sarcoma.

Conclusion: This case underscores the importance of recognizing sarcoma as a possible etiology of paraneoplastic ANCA-negative PIGN. We also explain how plasmapheresis and rituximab may play a role in the treatment of renal dysfunction in these patients.

AB1516 A CASE OF SEVERE ANCA ASSOCIATED VASCULITIS AFTER COVID-19 VACCINATION

I. Qaisar1, K. Sunmboye2, 1Leicester Royal Infirmary, Rheumatology, Leicester, United Kingdom; 2Leicester Royal Infirmary, Rheumatology, Leicester, United Kingdom

Background: The world is currently rocking to and fro in the midst of the COVID-19 viral storm and vaccinations have played a pivotal role in calming this. Although COVID-19 vaccines have been thoroughly assessed and studied before being rolled out to the general population, there have been reports of post-vaccination complications in limited number of subjects strongly associated with COVID-19 vaccinations[1].

Objectives: To report a case of severe ANCA associated vasculitis after COVID-19 vaccination.

Methods: A case report and discussion.

Results: In view of this, we report the case of a 77 year old caucasian male who developed severe ANCA associated vasculitis (AAV) after two doses of AstraZeneca vaccine and one booster dose of Pfizer COVID-19 booster. He presented with acute onset inflammatory arthritis with mononeuritis multiplex with bilateral foot drop and left radial and ulnar nerve forearm weakness in typical asymmetrical pattern two weeks after the Pfizer vaccination. He had a raised MPO-ANCA titre of 66 U/L, an Elisa reactive protein of 131mg/L, and reactive thrombocytosis of 458 X 10^9/L. Nerve conduction study confirmed mononeuritis multiplex in the bilateral peroneal nerves and left radial and ulnar nerve. A total body CT had excluded malignancy and paraneoplastic associations and Gullan-Barre diagnosis was also excluded. The patient was treated with 3 days of intravenous methylprednisolone 1g daily then given intravenous Rituximab 1g, two weeks apart. He is currently undergoing rehabilitation in view of the vasculitic neuropathy from his diagnosis.

Conclusion: Diagnosis of AAV is often delayed or missed by other medical specialties due to its varied presentation. AAV should be suspected in a patient with paraesthesia/weakness in keeping with mononeuritis multiplex or other peripheral neuropathy in the absence of an alternative explanation (e.g. diabetes,B12 deficiency) and in particular with a wrist or foot drop.Exposure to certain drugs and substances of abuse such as cocaine, hydralazine and propylthiouracil has been implicated with AAV.While short-term side effects of COVID-19 vaccine resemble those of other vaccines, long-term side effects remain unknown[2]. Rare side effects continue to surface as millions of people receive COVID-19 vaccines around the world.

AB1517 SYNOVITIS COMPLICATING THE COURSE OF COMMON VARIABLE IMMUNODEFICIENCY: CAUSAL OR COINCIDENTAL?

M. Yasmine1, S. Miladi2, A. Fazaai1, H. Bousaa1, L. Souenbi1, K. Oueniche1, S. Kassaib1, S. Chekili1, K. Ben Abdelghani1, A. Laatari1, Merghani Slim Hospital, Rheumatology, Tunis, Tunisia

Background: Common variable immunodeficiency (CVID) is a heterogeneous disorder characterized by hypogammaglobulinemia and an increased susceptibility to recurrent bacterial infections. Even though several immunological defects are involved in the pathogenesis of CVID, the genetic background of the disease...
remains unidentified [1]. Autoimmunity in CVID is not restricted to hematologic cells, as rheumatologic complications occur in perhaps 10% of patients, with females being more affected [1].

**Objectives:** Here we report a case of a CVID complicated with RF negative synovitis.

**Methods:** We report a case of a 36-year-old woman who was referred to our department for oligoarthritis. She had a history of primary immune deficiency revealed at the age of 30 with recurrent pulmonary infections. The disease was complicated with type 1 diabetes and bronchiectasis and was treated with annual infusion of immunoglobulin. The patient presented with pain and swelling in both knees evolving for two months. On physical examination, she had synovitis in both knees. Laboratory investigations revealed normal blood count with elevated C-reactive protein (CRP) and erythrocyte sedimentation rate: 36.2mg/l, and 32 mm/h respectively. Synovial fluid aspiration analysis of the knee revealed an inflammatory liquid without crystals. Bacterial culture was negative. Her serum was negative for Rheumatoid Factor (RF), anti-cyclic citrullinated peptide (anti-CCP) antibody and antinuclear Antibodies (ANA). Knee ultrasound revealed synovitis in both knees with Doppler signal. The Magnetic resonance imaging (MRI) of the knees showed active synovitis without any erosion. Ophthalmological assessment showed severe dry eye syndrome. As Sjögren's syndrome was suspected, we performed a salivary gland biopsy that was normal.

**Results:** The patient did not fulfill criteria for auto-immune rheumatic related disease. She was treated with intrarticular glucocorticoids injections, with complete resolution of symptoms and disappearance of effusion on ultrasound. A follow-up was scheduled after one month. The synovitis has been attributed to rheumatologic involvement in the context of immune deficiency.

**Conclusion:** We report a rare case of RF negative synovitis complicating the course of CVID. Even though the symptoms could be mild compared to a typical RF+RA, it is important to educate clinicians as to the importance of maintaining a high index of suspicion about this rare, yet potentially treatable disease. Future research is indicated to understand the etiopathogenesis of rheumatologic manifestations in CVID.

### CASE REPORT OF A HARD TO TREAT DERMATOMYOSITIS AFTER A COVID-19 INFECTION AND SUBSEQUENT VACCINATION

**P. Peteva1, L. Marinchev1.** UHMH Sofimed, Sofia, Bulgaria, Rheumatology Department, Sofia, Bulgaria

**Background:** A 50 years old woman, a medical doctor, came to our department with symmetrical proximal muscular weakness, several months after Covid-19 infection and three weeks after a second dose of Covid-19 mRNA vaccine. The patient had no prior or family history of autoimmune diseases and take no medicines. In the past she undergone an operation for double-kidney with frequent urinary infections. Objective findings have shown symmetrical proximal muscular weakness and classic signs of dermatomyositis - Gottron's papules, shawl and holter signs, periungual vasculitis.

**Objectives:** We present a case of a 50 old woman with clinical and laboratory proven dermatomyositis, starting three weeks after a second dose of a Covid-19 mRNA vaccine without other reasons.

**Methods:** The laboratory tests showed elevated CPK, lactate dehydrogenase, aspartate aminotransferase and alanine aminotransferase, high ANA – 1:1280 and myositis specific autoantibodies- anti-NXP2 and anti-Mi-2- beta. The electromyography showed myopathic changes and the muscle MRI – symmetrical edema of mm.obturateur and mm.adductor brevis. We exclude diseases that may mimic inflammatory myopathies. We made a cancer screening – whole body MRI, colonoscopy, gastroscopy, mammography and gynecological exam, immunoblot for detection of paraneoplastic syndrome-associated neuronal antibodies, with no detection of cancer. Muscle biopsy of m.vastus lateralis showed attenuating muscle inflammation with advancing muscle atrophy and fibrosis.

**Results:** The diagnose dermatomyositis was made according Bohan and Peter criteria and we start a high dose (1mg/kg/day) glucocorticoid therapy with good initial clinical and laboratory effect. Two months after starting a therapy muscle weakness worsened together with difficulty of swallowing. We excluded steroid myopathy after second EMG and lack of improvement when tapering the GS dose. Methylprednisolone 20 mg weekly was added as a steroid sparing drug with good response, but was stopped because flare of pyleonephritis. According to the opinion of dermatologist hydroxychloroquine was started for a couple of weeks, because of active skin manifestations. Muscle weakness worsened on the background of treatment, which was stopped. We started a therapy with intravenous immunoglobulins and considered therapy with cyclophosphamide or azathioprine after urinary infection. Because the patient was infected for a second time with covid-19, although vaccine, we continued only with glucocorticoids and anti-osteoporotic therapy.

**Conclusion:** The etiology and pathogenesis of inflammatory myopathies are not fully clarified so far. We speculate that the infection with Covid-19 as well as mRNA vaccine trigger inflammatory myopathy and compromise the patient's immunity for poor treatment response with glucocorticoids and immunosuppressives. On the other hand advanced muscle atrophy and fibrosis within a short period show that suspected triggering factors could be a reason for difficult to treat such type of dermatomyositis.

doses of IVIG 2g/kg was given; infection treated with antibiotics and regular dressing. After resolution of infection 6 doses of cyclophosphamide as per EUVAS protocol and Rituximab 2 gm was given along with the first dose of Cyclophosphamide.

Results: At 48 weeks of follow up, he continues to be in sustained clinical remission without steroids. He has received additional 500 mg of rituximab at 28 weeks. His lung nodules and vasculitic ulcers of leg healed over 34 weeks. He has developed saddle nose deformity for which reconstruction is planned.

Conclusion: Steroid free remission in GPA may be possible without Avacopan.

AB1520 EFFECTIVE TREATMENT OF TOCILIZUMAB IN PATIENTS WITH REFRACTORY ADULT-ONSET STILL’S DISEASE

T. Cheng1, Z. Chen1, J. Tan1, Y. Jiang2, Z. Liao2. 1Third Affiliated Hospital of Sun Yat-sen University, Rheumatology and Immunology Department, Guangzhou, China; 2Third Affiliated Hospital of Sun Yat-sen University, Rheumatology and Immunology, Guangzhou, China

Background: Pro-inflammatory cytokines such as interleukin 6 (IL-6) are involved in the pathogenesis of adult-onset Still’s disease (AOSD). Anti-IL-6 agents such as tocilizumab have been tried to treat AOSD successfully.

Objectives: To access the efficacy of tocilizumab in the treatment of AOSD patient refractory to, or with initial treatment.

Methods: We reviewed three cases with refractory AOSD treated with tocilizumab. All patients fulfill the Cush criteria for AOSD. All patients performed blood culture, auto-antibodies test and bone marrow test to exclude infectious diseases, other rheumatic diseases and tumors. All patients received broad-spectrum antibiotics and had no response. All patients received glucocorticoid therapy and at least one kind of anti-cytokine therapies but didn’t have full response. Then the three patients received intravenous tocilizumab treatment of 8mg/kg every 2 weeks or 4 weeks.

Results: The first patient, a 21-year-old woman, performed positron emission tomography (PET-CT) and lymphoglandula pathology in addition to routine tests. She received high dose methylprednisolone (500mg per day for 3 days and followed by 80mg per day), gamma globulin injection (20g per day for 3 days) and baricitinib 4mg per day for 12 days, but had no response to the treatment. Then she received tocilizumab of 8mg/kg every 2 weeks and stopped baricitinib. And the symptoms and blood tests improved gradually, and the methylprednisolone dose reduced to 16mg per day at the last follow-up. The second patient is a 52-year-old man, and performed bone marrow cytology and PET-CT to excluded hematological diseases. He received methylprednisolone 80mg per day, adalimumab and tofacitinib treatment. But the patients still got recurrent fever, high ESR, CRP and serum ferritin. Then he stopped adalimumab and tofacitinib, and received tocilizumab of 8mg/kg every 2 weeks and reduced to 8mg/kg every 4 weeks because of economic factors. The patient did not develop fever and the inflammatory indexes such as ESR/CRP gradually decreased to normal range. And methylprednisolone dose reduced to 32mg nowadays.

The third patient is a 30-year-old woman and has recurrent AOSD for 15 years. She had tried glucocorticoids, methotrexate, iguratimod, baritinib and entanercept successively. Yet she still had recurrent arthritis on hand and knee, and elevated ESR/CRP/serum ferritin. Additionally she suffered femoral head necrosis because of excessive doses of glucocorticoid. The patient received tocilizumab 8mg/kg every 4 weeks, then joint symptoms and inflammatory indicators improved significantly. The methylprednisolone dose was also successfully reduced to 4mg/d.

The Figure 1 showed the main course of disease evolution.

Figure 1. The main course of disease evolution.

Disclosure of Interests: None declared
A 67-year-old man with longstanding history of cervical lymphadenopathy (LAD) presented to the Rheumatology Clinic due to intermittent lower extremity rash, anemia, worsening fatigue for the past 2 years. Prior history includes controlled DM type 2 and HTN treated with amlopidine. Denied photosensitivity, oral ulcers, sicca symptoms, Raynaud’s phenomenon, weight loss, fever, chills, joint pain. Physical examination revealed bilateral cervical LAD and a non-blanching purpuric rash on lower extremities consistent with leukocytoclastic vasculitis, later confirmed with biopsy. Further workup revealed, normo-ctylic anemia (Hgb 9.9gm/dl), positive ANA (>1:2560, homogeneous pattern), positive dsDNA (211 IU/ml), positive histone Ab (413 IU/ml), low C3 (28 mg/dl), low C4 (1mg/dl), increased IgG level (2878/mg/dl) and proteinuria 1100/mg/g with microalbuminuria, no urine casts. ANCA serologies were negative. Pan-CT showed mild cervical, retroperitoneal, pelvic LAD bilaterally. Kidney biopsy was performed and revealed severe diffuse tubulointerstitial nephritis, plasma cell rich (more than 40 IgG4 + cells seen per 40X hpf), with moderate to severe chronicity in addition to diffuse mesangial IgG and IgM staining with focal tubular basement membrane IgG and C1 staining consistent with mesangial proliferative class II lupus nephritis. Patient was started on medium dose steroids (due to DM), hydroxychloroquine and azathioprine with resolution of LCV rash, anemia, LAD, improvement in dsDNA, proteinuria, complement levels.

Conclusion: SLE and IgG4-RDs are autoimmune diseases that cause damage to several organs, including lymph nodes and kidneys. Both are associated with hypocomplementemia and involvement of autoantibody-producing B cells and plasma cells. Patients with SLE present with positive antibodies such as anti-dsDNA and anti-sm antibodies. On the other hand, IgG4-RD lack a specific antibody and the IgG4 is thought to be the result of the pathogenic process and not pathogenic by itself (1,2). Histologically, SLE presents with inflammatory cell infiltration in organs, whereas IgG4-RD is associated with fibrosis and organ enlargement (1-3). Lupus nephritis causes wide spectrum renal involvement whereas IgG4-RD most common presentation is tubulointerstitial nephritis (TIN), although other glomerular lesions, such as membranous nephropathy, have been reported (1-2). Our patient presented with proteinuria, positive antibodies for SLE, low complements and high levels of IgG4 which makes us consider that both diseases were active at time of diagnosis. This was confirmed by renal biopsy showing chronicity of IgG4-RD and lupus nephritis as a consequence of progression of autoimmunity. The treatment of both conditions is immunosuppression with medium to high doses of steroids and a steroid sparing agent. Due to patient preference he was started on azathioprine along with medium dose steroids and plasma cells. Patients with SLE present with positive antibodies such as anti-dsDNA and anti-sm antibodies. Nevertheless, some patients have been reported with kidney involvement secondary to both conditions (2-3). We present a case of an elderly male with a new diagnosis of IgG4-RD and SLE with kidney involvement.

Objectives: To present a case with a new concomitant diagnosis of IgG4-RD and SLE.

Methods: Case report.

Results: A 67-year-old man with longstanding history of cervical lymphadenopathy (LAD) presented to the Rheumatology Clinic due to intermittent lower extremity rash, anemia, worsening fatigue for the past 2 years. Prior history includes controlled DM type 2 and HTN treated with amlopidine. Denied photosensitivity, oral ulcers, sicca symptoms, Raynaud’s phenomenon, weight loss, fever, chills, joint pain. Physical examination revealed bilateral cervical LAD and a non-blanching purpuric rash on lower extremities consistent with leukocytoclastic vasculitis, later confirmed with biopsy. Further workup revealed, normocytic anemia (Hgb 9.9gm/dl), positive ANA (>1:2560, homogeneous pattern), positive dsDNA (211 IU/ml), positive histone Ab (413 IU/ml), low C3 (28 mg/dl), low C4 (1mg/dl), increased IgG level (2878/mg/dl) and proteinuria 1100/mg/g with microalbuminuria, no urine casts. ANCA serologies were negative. Pan-CT showed mild cervical, retroperitoneal, pelvic LAD bilaterally. Kidney biopsy was performed and revealed severe diffuse tubulointerstitial nephritis, plasma cell rich (more than 40 IgG4 + cells seen per 40X hpf), with moderate to severe chronicity in addition to diffuse mesangial IgG and IgM staining with focal tubular basement membrane IgG and C1 staining consistent with mesangial proliferative class II lupus nephritis. Patient was started on medium dose steroids (due to DM), hydroxychloroquine and azathioprine with resolution of LCV rash, anemia, LAD, improvement in dsDNA, proteinuria, complement levels.

Conclusion: SLE and IgG4-RDs are autoimmune diseases that cause damage to several organs, including lymph nodes and kidneys. Both are associated with hypocomplementemia and involvement of autoantibody-producing B cells and plasma cells. Patients with SLE present with positive antibodies such as anti-dsDNA and anti-sm antibodies. On the other hand, IgG4-RD lack a specific antibody and the IgG4 is thought to be the result of the pathogenic process and not pathogenic by itself (1,2). Histologically, SLE presents with inflammatory cell infiltration in organs, whereas IgG4-RD is associated with fibrosis and organ enlargement (1-3). Lupus nephritis causes wide spectrum renal involvement whereas IgG4-RD most common presentation is tubulointerstitial nephritis (TIN), although other glomerular lesions, such as membranous nephropathy, have been reported (1-2). Our patient presented with proteinuria, positive antibodies for SLE, low complements and high levels of IgG4 which makes us consider that both diseases were active at time of diagnosis. This was confirmed by renal biopsy showing chronicity of IgG4-RD and lupus nephritis as a consequence of progression of autoimmunity. The treatment of both conditions is immunosuppression with medium to high doses of steroids and a steroid sparing agent. Due to patient preference he was started on azathioprine along with medium dose steroids with adequate clinical response. This case highlights the fact that SLE and IgG4-RD can coexist and it should be suspected in elderly patients with lymphadenopathy and renal disease.

## AB1523-HPR

**USABILITY AND ACCEPTABILITY OF A NEW AUTOINJECTOR DEVICE AND ITS ASSOCIATED APP IN AUSTRALIAN, FRENCH, GERMANY AND JAPANESE RHEUMATOLOGY PATIENTS**

R. Alten1, M. Latymer2, D. C. Gruben3, S. Moss4, H. Kameda5; 1Schlosspark-Klinik Medicine Internal Medicine, Rheumatology, Berlin, Germany; 2Pfizer Ltd, I&I Medical Affairs, Sandwich, United Kingdom; 3Pfizer Global Biostatistics and Data Management, Groton, United States of America; 4Farm Design, A Flex Company, Human Factors Engineering, Hollis, United States of America; 5Pfizer R&D UK, Devices Centre of Excellence, Cambridge, United Kingdom; 6Toho University (Ohashi Medical Center), Division of Rheumatology, Tokyo, Japan

**Background:** Smartclic/ClicWise is a new reusable autoinjector with a dose-dispensing cartridge for subcutaneous self-administration of biotherapeutics in development for patients with rheumatoid arthritis (RA) and other diseases. The device can connect to an optional mobile phone app (Smartclic or ClicNote in Japan) to aid in tracking injections and other treatment or symptom data.

**Objectives:** The study objective was to collect ease of use and usability data on the Smartclic injector and companion app from experienced patients.

**Methods:** After completing a patient profiling questionnaire, adult patients (≥18 yrs) from Australia, France, Germany, and Japan with RA, psoriatic arthritis, or an original diagnosis of juvenile idiopathic arthritis who were prescribed an injectable biologic were enrolled in this study. For Japan, only patients with RA were enrolled. Each patient received training individually on the use of the Smartclic injector device and insertable cartridge and gained experience by performing simulated injections. Participants completed a questionnaire with evaluations of the device categories (number of questions: ‘ease of use’ (14), ‘usability effectiveness’ (11), ‘benefit of features’ (8), and ‘form factor’ (7). Participants also separately received a storyboard presentation summarizing the key features of the app, during which patients could explore the app (on a phone with either an android or iOS operating system), and completed 16 questions on the connectivity, usability, and benefit. Responses were recorded as Likert scale ratings from 1 (‘extremely negative’) to 7 (‘extremely positive’). Respondents also provided an estimate of patient training time for the device. Mean values were reported. The percentage of negative (Likert scale rating 1-2), neutral (3-5), and positive (6-7) responses for each category were determined.

**Results:** A total of 139 patients (mean age [range], 52 [18-84] yrs; 73% female) participated in the study (Table 1). Mean scores (percentage of positive responses) for the device were: ease of use 6.43 (86.2%), usability effectiveness 6.39 (86.5%), benefit of features 6.46 (89.4%), form factor 6.10 (77.2%); and 6.06 (74.2%) for connectivity and benefit of the app (Figure 1). Mean estimated time for training a patient to effectively use the device/cartridge was just under 9.5 min (range, 0-30 min).

*Originally diagnosed with juvenile idiopathic arthritis, but now aged ≥18 yrs.

**Conclusion:** Rheumatology patients responded positively on the new autoinjector device and app across all categories, indicating its suitability for self-administration of biotherapeutics.

---

## AB1524-HPR

**THERAPEUTIC RESULTS AND QUALITY OF LIFE CHANGES OF PATIENTS WITH RHEUMATOID ARTHRITIS IN PROSPECTIVE REAL LIFE CLINICAL SETTINGS**

V. Boyadoshieva1, K. Tachkov2, N. Stoilov3, K. Mitov2, G. Petrova2, R. Stoilov2; 1Medical University of Sofia, Sofia, Bulgaria; 2Medical University of Sofia, Faculty of Pharmacy, Department of Social Pharmacy and Pharmacoeconomics, Sofia, Bulgaria

**Background:** Rheumatoid arthritis (RA) as a chronic inflammatory disease significantly deteriorating the physical functioning and quality of life (QoL) of the patients. The introduction of biological therapy in its management significantly improves both the physical functioning and QoL. Many biological medicines are already available on the market claiming higher effectiveness and high cost of therapy but the difference in real clinical setting is not well studied.

**Objectives:** The aim of this study is to analyze the therapeutic results of RA therapy with different biologicals and the first JAK inhibitor in real life clinical settings.

**Methods:** This study was performed like a prospective, observational, longitudinal study at the biggest rheumatology clinic in Bulgaria during the period 2012 – 2020. Written informed consent was obtained by the recruited 197 patients, out of which 174 remain at the end of the observation. Patients naïve to biological therapy were assigned on the available at that moment biologic DMARDs (infliximab, etanercept, adalimumab, rituximab, golimumab, certolizumab, tocilizumab), and the first JAK inhibitor (tofacitinib). The clinically proven RA according ACR (1987) and/or ACR/EULAR (2010) criteria, previous therapy with DMARDs, and/or methotrexate, suitable for therapy with biological medicines or JAK inhibitors were formulated as inclusion criteria, while infectious diseases, cardiac insufficiency (NYHA III and IV grade), malignant hypertension, any neoplasms or proliferative lymph diseases within the previous 5 years were the exclusion criteria. We evaluate DAS28-CRP, HAQ and Short form 36 measured at the initiation of biological therapy, after 6, and 12 months of follow up. We analyze the changes in the two major subgroups of SF36 - physical (MCS) and mental health (PCS). Descriptive statistic, Dispersion analysis with non-parametric Kruskal-Wallis test comparing the effect of different therapies between first and third measurement was performed. Linear correlation and regression analysis (Pearson type) comparing the effect of different therapies was also performed.

**Results:** The age and gender distribution were similar between the groups on bDMARDs and tsDMARD. Number of patients per therapeutic DMARD vary between 20 to 30, with prevailing part of the female and average age between 53.2 (SD 9.13) and 57.15 (SD 9.05) years. Average length of the disease is also similar between the groups with highest value of patients assigned to tocilizumab (14.13 (SD 8.38) years) and lowest for infliximab (6.4 (SD 2.92) years), respectively. All observed indicators for disease control and QoL improve after the initiation of the biological or JAK inhibitor therapy. We also analyze the effect of therapies on DAS-28, HAQ, SF-36 (PCS, MCS). Dispersion analysis for the effect

**Acknowledgements:** Medical writing support was provided by Jacob Evans, of Engage Scientific Solutions.

**DOI:** 10.1136/annrheumdis-2022-eular.772
of therapy measured through DAS28 between 1st and 3rd measurement shows a statistically significant difference in between the average effect of therapies (P = 0.005141). The most effective is the golimumab (Median difference = 2.745), followed by rituximab (median = 2.965) and etanercept (median = 2.070). The difference in effect measured with HAQ is higher with tofacitinib (median = 0.563). Followed rituximab and infliximab (median = 0.500 for both). Less effective appears to be etanercept (median difference 0.250). All differences are statistically significant (p = 0.012589). Regarding the changes in the QoL measured with SF-36 MCS and PCS there is no statistically significant differences in the average effect of different therapy agents. The median effect of different therapeutic agents regarding physical group of SF-36 (PCS) is similar and changes are not statistically significant. The same is valid for SF36 psychological components (MCS).

Conclusion: Tofacitinib and bDMARDs improve both clinical results and QoL of patients with RA naïve to biological therapy. The difference between tofacitinib and bDMARDs is not statistically significant for both clinical and QoL results.

**AB1525-HPR** EXAMINATION OF PHYSICAL FITNESS IN CHILDREN AND ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: A COMPARATIVE STUDY

S. Bozuk1, B. Basakci Calik1, E. Gur Kabul2, Z. Ecki Tekin3, S. Yuksel4, 1Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey; 2Izmir University Faculty of Health Sciences, Physiotherapy and Rehabilitation, Denizli, Turkey; 3Ankara City Hospital, Pediatric Rheumatology, Ankara, Turkey; 4Pamukkale University Faculty of Medicine, Pediatric Rheumatology, Denizli, Turkey

Background: Juvenile Idiopathic Arthritis (JIA) is the most common rheumatic disease of childhood. Although its etiology is not known exactly; Immunological susceptibility and environmental factors (infections, stress, trauma) are emphasized (1). These children have low activity levels since a young age, and significantly affects their disease ability and quality of life of both themselves and their families. For all these reasons, it is very important to realize the daily living problems (2).

Objectives: We aimed to investigate the awareness of patients using SCBA about the drug's utilization and storage conditions.

Methods: Seventy children/adolescents (mean age: 13.4±2.31 years 35 JIA; mean age: 12.9±2.31 years 35 healthy) were included in the study. After recording demographic data, the functionality levels of the children/adolescents with JIA were evaluated by CHAQ (Childhood Health Assessment Questionnaire), all lower extremity muscle strengths were evaluated by the manual muscle test device, and the physical fitness levels were evaluated by the Brockport physical fitness test battery which is grip strength, push-up test, curl-up test, trunk lift test, shoulder stretch, back saver sit-rectch test, calf, triceps, subscapular skinfold thickness and PACER 20 meter test. While the disease activities of children/adolescents with JIA were evaluated with JADAS-27 (Juvenile Arthritis Disease Activity Score), quality of life were evaluated with the PedsQL 3.0 Arthritis Module (Pediatric Quality of Life Inventory).

Results: As a result of the comparative analysis; In terms of functionality which is CHAQ dressing (p=0.008), eating (p=0.011), reaching (p=0.001), rising (p<0.001), walking (p=0.001), holding (p=0.016), hygiene (p=0.011), activity (p=0.00), total score (p=0.00), pain (p=0.00), general well-being (p=0.00) in terms of all sub-parameters, there was no significant difference in favor of healthy children/adolescents (p>0.05). In terms of physical fitness which is grip strength (p=0.041), PACER 20 meter test (p<0.000), trunk lift test (p=0.018) and curl-up (p=0.00) tests, there was a significant difference in favor of the healthy group (p<0.05). There was no significant difference between the groups in terms of other physical fitness tests (p>0.05). When only the lower extremity muscle strengths were compared, only right hip external rotation (p=0.023) showed a difference in muscle strength. There was no correlation between JADAS-27 score and physical fitness scores (p=0.065) of children/adolescents with JIA, except for the push-up test (p=0.01). In terms of JADAS-27 score and some PedsQL child form which is pain, total score and activities of daily living of children/adolescents with JIA there was a significant relationship. In terms of JADAS-27 score and some PedsQL parent form which is pain and total score of children/adolescents with JIA there was a significant relationship. However there was no relationship in terms of the other parameters (p>0.05).

Conclusion: According to the results of our study, it was observed that the functionality and physical fitness levels of children/adolescents with JIA were lower than their healthy peers, and physical fitness was not affected by disease activity. However, it has been observed that the disease ability of children/adolescents with JIA affects the quality of life of both themselves and their families. For all these reasons, it is very important to examine children/adolescents with JIA in terms of participation in physical activity and exercise, with informative training aimed at improving their physical fitness.

**AB1526-HPR** AWARENESS ASSESSMENT IN PATIENTS USING SUBCUTANEOUSLY ADMINISTERED BIOLOGICAL AGENTS ABOUT DRUG UTILIZATION

F. Tuncer1, O. Ozdemir Isik1, A. Yucei1, A. Celle1, 1Kocaeli University, Faculty of Medicine, Rheumatology, Kocaeli, Turkey, Rheumatology, Kocaeli, Turkey

Background: Subcutaneous biological agents (SCBA) are commonly used in rheumatologic disorders, their storage in appropriate conditions and correct administration have importance. Informing the patient adequately and correctly is essential. Storing the drug in inappropriate conditions reduces its effectiveness, and affects the response to treatment (1). When these treatments are initiated, information on all the mentioned topics is provided to the patients, and they undergo hands-on training. Finally, the patients is questioned in outpatient follow-up about whether a problem has occurred or not (2).

Objectives: This study aimed to investigate the awareness of patients using SCBA about the drug's utilization and storage conditions.

Methods: Demographic data of 100 patients diagnosed with rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis, using SCBA who presented to our outpatient clinic between January 2021 and June 2021, were recorded, and survey questions were asked.

Results: One hundred patients (46 females-54 males) were included in the study. Sixty-one patients were diagnosed with ankylosing spondylitis, 20 patients with rheumatoid arthritis, and 19 with psoriatic arthritis. The patients' mean age was 44.6±11.07 years. The mean duration of SCBA use was 74.5 (2-222) months.

The patients' replies to the survey questions are summarized in Table 1. Most patients performed the injection themselves in both genders, whereas some women received help from paramedics (p=0.041). Forty percent of the patients with education level of high school or higher had a concern regarding drug use, whereas this rate was 21% in patients with education level of primary school. It was determined that the anxiety level decreased with increasing level of education (p=0.032).

It was observed that in patients who used multiple SCBA for a long time, taking the drug out of the refrigerator and applying it after waiting for the optimum time,
controlling the expiration date of the drug and hand washing before the application decreased over time.

Conclusion: Evaluating the patient’s SCBA treatment background is essential for correct treatment practice. Our study revealed that in forming patients on drug use not only initially but also at certain intervals is essential.

FUNCTIONAL SOMATIC SYNDROMES AND INSOMNIA IN PATIENTS WITH FIBROMYALGIA, RELATIONSHIP WITH THE INTENSITY OF THE PAIN SYNDROME

V. Bykov1, V Khomenko1, L. Shvets1, L. Pereteliuk1, O. Ostapchuk2, I. Shvets1, M. Stanislavchuk1, National Pirogov Memorial Medical University, Rheumatology, Vinnytsia, Ukraine

Background: Fibromyalgia (FM) is a chronic diffuse musculoskeletal pain manifested by numbers of functional somatic syndromes (FS). The pathogenesis and pathophysiology of fibromyalgia includes changes of autonomic nervous system, which can be realized in the abnormal functioning of many organs and systems.

Objectives: Analyze the frequency and spectrum of functional somatic syndromes and insomnia in patients with fibromyalgia, relationship with the intensity of pain.

Methods: We examined 102 women with FM according criteria ACR (1990), mACR (2010) with mean age 41.7±9.4 years (M±SD), duration of the disease was 8.4 ± 6.28 years. The severity of pain, fatigue, sleep disorders was assessed with a visual analog scale (VAS).

Results: The severity of pain (VAS) in patients with FM ranged from 2.1 to 8.5 and averaged 5.1±1.5. The severity of fatigue was estimated at 6.5 ± 1.7, sleep disorders - 6.3 ± 2.7. In the examined group of patients with FM, in addition to typical clinical manifestations, significant numbers of functional disorders were diagnosed: insomnia - 86.3%, irritable bowel syndrome – 99.8%, postural tachycardia syndrome - 53.9%, hyperventilation syndrome - 52.9%, bladder pain syndrome – 50.0%. According to the intensity of pain, patients were divided into 3 groups. The 1st group included patients with pain less than 4 points (<25th percentile, n = 21), the 2nd - with the pain severity 4–6 points (25-75th percentile, n = 56), the third group - patients with pain more than 6 points (>75th percentile, n = 25). According to the study, the frequency of functional somatic syndromes was not related to the intensity of pain. There was a positive correlation between the severity of insomnia and the intensity of pain (n=0.36; p<0.05). The same relationship was revealed between fatigue and pain (n=0.41; p<0.05).

Conclusion: Patients with FM have a wide spectrum of functional somatic syndromes. The changes described were not related to the severity of the pain syndrome. The presence of correlations between the severity of insomnia and the intensity of pain requires further research to develop algorithms for comprehensive treatment of identified disorders.

FULL BODY HAPTIC BODYSUIT - AN INSTRUMENT TO MEASURE THE RANGE AND SPEED OF MOTION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS (axSpA)

N. Weiher1, R. Lemnart2, J. Knizla2,3, S. Bayat2,3, M. Sadeghi4, A. A. Ibrahim5, C. Karastanion6, A. Sushkarev7, N. Ramzieanzadeh2, S. Kahali3, A. Mirzayev1, L. Schuster2,3, G. Schett1, B. M. Escoffier1, A. Kleyer3,6,7,8,9 on behalf of https://www.medizin3.uk-erlangen.de/en/research/research-main-focus/

1Friedrich-Alexander University (FAU) Erlangen Nürnberg, Lehrstuhl für Maschinelles Lernen und Datenanalytik, Department Artificial Intelligence in Biomedical Engineering (AIBE), Erlangen, Germany; 2University Hospital Erlangen, Department of Internal Medicine 3, Rheumatology and Immunology, University Hospital Erlangen, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany; 3Deutsches Zentrum Immunkonferenz, Universitätspoliklinik Erlangen, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany

Background: Movement of the spine is restricted in axial spondyloarthritis (axSpA) [1]. Spine function is usually assessed by the Bath Ankylosing Spondylitis Metrology Index (BASMI), which is based on a limited set of defined motions that are measured semiquantitatively in the spatial dimension but not in the temporal dimension. Sensor-based measurement of spine function in axSpA patients is in its infancy but may provide a deeper and more detailed understanding of the impact of axSpA on the impairment of spine function [2,3]. In theory, unbiased full body assessment of spine motion may open a new dimension in function analysis in axSpA.

Objectives: To test if a full body-based haptic capturing of spine motion is technically feasible and can pick up the measurements of BASMI items 1-5. Furthermore, we aimed to investigate whether such measurements are accurate and reproducible comparing to BASMI scores done by rheumatologists. Lastly, we sought to measure velocity of spine movements to allow spatiotemporal analysis of motion.

Methods: For full-body haptic assessment of spine motion a full-body haptic suit (Teslasuit; VR Electronics Ltd, London) was used that consists of a smart textile two-piece bodysuit that not only captures range and speed of motion but also provides biometric and haptic feedback. This device is currently tested in clinical trials (https://teslasuit.io/rehabilitation/) but has not been tested in rheumatic diseases such as axSpA [4]. Since there is no pre-defined technical solution for measuring BASMI, we used the integrated inertial measurement units (IMUs) of the suit (Figure 1a). The suit is recording the position and rotations of its IMUs and is transforming the raw data to position coordinates and joint angle of the bones. We implemented an algorithm that is accessing the sensor data and is calculating the BASMI measurements as well as velocity. Assessment were done in healthy individuals. BASMI was obtained 3 times by teslasuit followed by standard BASMI measurement by 2 independent rheumatologists. In addition, rotational movements with their maximum torso speed to evaluate angular velocity were performed (Figure 1b). Measurements were compared using absolute values and relative standard deviation (which is the standard deviation normalized by the mean).

Results: Five healthy individuals (all males, age: 276 ± 1.8 years, height: 178 ± 5cm; weight 70.0 ± 8.0kg) were assessed. Teslasuit measurements were well tolerated. Technically, we were able to calculate BASMI item 3 and 5, finger-to-floor distance and the velocity of the spine movement using the position data of hand, talius and upper back sensors (Figure 1a, b). Due to absence of sensors at the head and the required back areas, BASMI 1, 2, 4 could only partially be captured and require further programming, which is currently performed. Only marginal differences were detected regarding the relative standard deviations of measurements between teslasuit and rheumatologists (BASMI 3: rheumatologists 8.5%; suit 10%; BASMI 5: rheumatologists 5.4%; suit 4.9%) (Figure 1c). The speed of spinal motion could be measured with an average angular velocity of 172.2 degrees/sec over the entire rotation motion and an average maximum angular velocity of 4172 degrees/sec.

Conclusion: This study shows that full-body haptic-suits can capture spinal motion including parts of the BASMI score. In addition, they allow to measure the speed of spinal movement, which might be an important and so far unrecognized factor to test the impact of axSpA on spinal function. Based on these results, full-body haptic-suits will be tested in axSpA patients in the future. Furthermore, technical solutions are currently developed to implement the remaining BASMI scores into the suit as well as connections from the suit to virtual reality devices for patients and doctors.

CROSS-CULTURAL ADAPTATION, RELIABILITY AND CONVERGENT VALIDITY OF THE TURKISH VERSION OF THE PRIMARY SJÖGREN’S SYNDROME QUALITY OF LIFE QUESTIONNAIRE

S. Bayram 1, F. Sarlı 1, G. G. Pala 2, B. Özkızıltas 3, A. Tufan 2, D. Oskay 1. 1Gazi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; 2Gazi University, Faculty of Medicine, Department of Internal Medicine-Rheumatology, Ankara, Turkey

Background: To completely comprehend the burden of an illness and the success of its treatment, it is essential to analyze the patients’ perspective on health-related quality of life. Because of this, the Primary Sjögren’s Syndrome-Quality of Life questionnaire (PSS-QoL) was developed, which evaluates the disease’s physical and psychosocial effects in PSS patients.

Objectives: In the literature, there is no Turkish questionnaire evaluating quality of life in patients with PSS. Therefore, the aim of this study was to translate and evaluate cross-culturally adaptation the PSS-QoL into the Turkish language and investigate its convergent validity and reliability in Turkish-speaking population with PSS.

Methods: Patients completed PSS-QoL questionnaire, the EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI) and Euro-Qol 5D (EQ-5D). To test the convergent validity of PSS-QoL, correlation between PSS-QoL and EQ-5D and ESSPRI were assessed with Pearson correlation test. In order to investigate the internal consistency and test-retest reliability, Cronbach’s alpha and Intra-class Correlation Coefficient (ICC) values interpreted, respectively.

Results: Seventy-nine patients with PSS (53.30 ± 11.98 years, 74F/5M) were enrolled in the study. Good and moderate correlations were found between the PSS-QoL and ESSPRI (r: 0.818, p<0.001) and EQ-5D-pain/discomfort (r:0.589, p<0.001). Correlations of subscales of PSS-QoL with subscales of ESSPRI and EQ-5D ranged from fair to strong (Table 1). Cronbach’s alpha and ICC values of the PSS-QoL total score were found to be as 0.955 and 0.914, respectively, indicating excellent reliability.

Disclosure of Interests: None declared

Background: Primary Sjögren’s syndrome (pSS) is a rare systemic autoimmune disease with no specific treatment at present. To better assess patient symptoms, we have developed a web application (WebApp) to collect patient symptom intensity on a regular basis.

Objectives: To evaluate the daily variability of symptoms using the WebApp. We also evaluated its ease of use.

Methods: 45 consecutive patients with pSS were included in 3 referral centers. Symptoms were assessed during the baseline and 3 month visits. We collected the VAS relating to fatigue, dryness and pain as well as the ESPPR-I score. Patients used the WebApp daily for 3 months. The variability of symptoms over time was assessed by the predicted median error. This value was determined using a linear regression model, in order to predict the value at the 3rd month, then this value was compared to the actual value collected at the 3rd month during the clinical visit. The ease of use of the WebApp was assessed using a satisfaction score (SUS score).

Results: Of the 45 patients included, 91.1% were women with an average age of 57 years, and low systemic disease activity (84.4% had an ESSDAI score below 5). The intensity of the symptoms collected during the clinical visits was similar at baseline and at 3 months. The values of the median error for each measurement are between 0.5 and 0.8. The 3-month predicted median error values ranged from 2 to -3. The patients all used the web application for 3 months with good attendance (80% of data completion) and were satisfied with this tool (median SUS score = 90).

Conclusion: Symptoms of pSS fluctuate from day to day in the majority of patients, making a point measurement imprecise. The developed WebApp is easy to use, and could allow more sensitive detection of the effect of a therapeutic intervention. This tool will soon be evaluated during prospective interventional clinical trials.

GOHAI-SP: Geriatric/General Oral Health Assessment Index Spanish Version; (SD) Standard deviation, n; number, (%) Percentage.

---

**AB1532-HPR**

**GERIATRIC/GENERAL ORAL HEALTH ASSESSMENT INDEX AS EARLY DETECTION TEST OF ORAL DISEASES IN RHEUMATOLOGY.**

B. T. Chavarin Arquillo1, J. C. Riegatorres1, A. Cárdenas1, D. C. Rubio Torres1, L. R. Aguilar Rivera1, L. G. Espinosa Banuelos1, D. A. Galarza-Delgado1.

1Hospital Universitario “Dr. José Eleuterio González”; Rheumatology; Monterrey, Mexico

Background: The oral health in patients with rheumatologic diseases is frequently affected because of chronic inflammation, slow rate of saliva production and poor self-care. These factors affect quality and psychosocial well-being, causing pain, difficulty biting and chewing, even malnutrition. The Geriatric/General Oral Health Assessment Index Spanish Version (GOHAI-SP) consists in 10 items and values self-perception in oral health and wellness (1), validated and applied to young adults (2).

Objectives: 1. Describe the oral health measured by the GOHAI-SP in patients with rheumatic diseases.

Methods: a cross-sectional and observational study was conducted by January to May 2021 in rheumatology service of Hospital Universitario “Dr. José Eleuterio González” at Monterrey, Mexico. Patients with rheumatologic diseases was assessed with GOHAI-SP during their control consult, each item is valued like a Likert ordinal scale from 1 to 5, the best and worst possible score is 60-12 respectively, patients with score <45 is classified as poor oral health and >50 as good oral health. 2. Construct a web application (WebApp) easy to use, and could allow more sensitive detection of the effect of a therapeutic intervention. This tool will soon be evaluated during prospective interventional clinical trials.

Acknowledgements: I would like to thank all those people who have helped and were directly or indirectly involved in this study.

**AB1533-HPR**

**ASSOCIATED FACTORS OF FALL OR FRACTURE REPORTED BY RHEUMATOID ARTHRITIS PATIENTS IN ELECTRONIC MDHAQ DURING COVID-19 PANDEMIC**

I. Lineburger1, C. V. Breno2, V. Naomi Hirakata3 on behalf of Rheumatology Service, 1Hospital de Clínicas de Porto Alegre, Mestrado Profissional de Pesquisa Clínica, Porto Alegre, Brazil; 2Hospital de Clínicas de Porto Alegre, Rheumatology Service, Porto Alegre, Brazil

Background: The COVID-19 pandemic accelerated the use telemedicine for rheumatologic patients. Patient reported outcomes (PRO) can provide prioritization criteria for the form of face-to-face care in situations of social restriction, and optimization of early care by identifying high-risk patients.

Objective: To describe the oral health measured by the GOHAI-SP in patients with rheumatologic diseases.

Methods: of January to August 2021. A weblink was sent to MDHAQ in electronic platform. The study was approved by the ethics committee of Hospital de Clínicas de Porto Alegre – Brazil and all patients agreed with a Term of Informed Consent.

Results: A total of 129 RA patients completed the electronic MDHAQ, mean age was 60 years (S.D. 14) and 83% were female. The mean DAS28, SDAI and HAQ were 3.8 (S.D. 1.6), 4.2 (S.D. 1.0) and 1.2 (S.D. 0.7). Of those 129 patients, 14 reported a fall or fracture in the last 6 months of response and only 16 patients were physically active. Relevant symptoms known as factors associated with risk of fall and its prevalence in this study were: pain (82%), followed by articular pain (68%), fatigue (43%), muscle weakness (37%) and weight gain (22%). Among patients who reported a fall or fracture, 83% had a RADAI ≥ 16 and mean FAST3 (Fibromyalgia Assessment Screening Test) index of 19 (IC95%: 17-21). FAST3 based on MDHAQ and independent RADAI showed positively association with a reported fall or fracture for these patients, with a p value of 0.023 and 0.025, respectively. Other factors, such as high disease activity based on DAS28 or MDHAQ, obesity and age were not statistically significant with the reported episode.

Conclusion: Maintaining PRO is aligned with patient-centered care, allowing relevant data source and identification of high-risk patients - in our study: patients in pain, sedentary and in major risk of fracture. Also, use of combined in like FAST3 or independent articular pain scores such as RADAI, might be helpful to identify those high-risk patients in need for orientation for reinforcement of physical activity, prioritization for in person visits and early clinical adjustments.
HPR Epidemiology and public health (including prevention)

AB1534-HPR ASSESSMENT OF BACK PAIN IN NURSES WORKING IN HOSPITALS AND OUTPATIENT CLINICS

B. Nieradko-Iwanicka1,2, Medical University of Lublin, Chair and Department of Hygiene and Epidemiology, Lublin, Poland

Background: Back pain in a common health problem in nurses affecting 70-78% of them [1,2,3]. The risk of back pain in nurses increases by 35% for each additional working hour per day [2].

Objectives: The aim of the study was to find out if nurses working in hospital wards suffer more from back pain than their counterparts employed in the outpatient clinics.

Methods: An online survey was conducted with use of an questionnaire containing questions about body mass index (BMI), Revised Oswestry Low Back Pain Disability Scale (ROLBPDS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Numeric Rating Scale (NRS) for pain. Questions about seniority and working hours were included. It was uploaded and shared on the Google online survey platform. Participation was anonymous and voluntary. An invitation was mailed to the members of The Lublin Chamber of Nurses and Midwives.

A total of 163 nurses (161women and 2 men) aged 21-70 years filled in the questionnaire in February and March 2021. Of the group 82 were nurses from hospitals (NHs) and 81 from outpatient clinics (NOCs).

Results: The mean BMI of participants was 26.4kg/m². In NHs the mean BMI was 25.8kg/m² and in NOCs 27.8kg/m². Seventy five percent of HNs looked after lying patients. Ninety nine percent of NHs and 75% of NOCs suffered from back pain. In the questionnaire February and March 2021. Of the group 82 were nurses from hospitals (NHs) and 81 from outpatient clinics (NOCs).

The mean ROLBPDS rating was 15 which means moderate disability. In NOCs it was 13 and in NHs it was 17. The mean back pain NRS was 6. In NOCs it was 3 and in NHs it was 9 (p<0.05). There was a positive correlation between shift length and back pain measured with the NRS. As many as 5 participants had diagnosed seronegative spondyloarthropathy. In those mean BASDAI was 5.6±1 which means active disease.

The mean ROLBPDS rating was 15 which means moderate disability. In NOCs it was 13 and in NHs it was 17. The mean back pain NRS was 6. In NOCs it was 3 and in NHs it was 9 (p<0.05). There was a positive correlation between shift length and back pain measured with the NRS. As many as 5 participants had diagnosed seronegative spondyloarthropathy. In those mean BASDAI was 5.6±1 which means active disease.

NHs it was 9 (p<0.05). There was a positive correlation between shift length and back pain measured with the NRS. As many as 5 participants had diagnosed seronegative spondyloarthropathy. In those mean BASDAI was 5.6±1 which means active disease.

The mean ROLBPDS rating was 15 which means moderate disability. In NOCs it was 13 and in NHs it was 17. The mean back pain NRS was 6. In NOCs it was 3 and in NHs it was 9 (p<0.05). There was a positive correlation between shift length and back pain measured with the NRS. As many as 5 participants had diagnosed seronegative spondyloarthropathy. In those mean BASDAI was 5.6±1 which means active disease.

CONCLUSION: Nurses working in hospital wards experience significantly more back pain than their counterparts working in outpatient clinics. Long working hours increase the risk for the ailment.

HPR Interventions (educational, physical, social and psychological)

AB1535-HPR COURSE WITH GROUP SESSIONS TO START SELF-INJECTION OF BIOLOGICAL MEDICINE (ADALIMUMAB)

J. Schierbach Bøch1, B. A. Esbensn2, S. Skalsket Rasmussen3
1Rigshospitalet, Center for Rheumatology and Spine Diseases, Hellerup, Denmark; 2Rigshospitalet, Glostrup, Glostrup, Denmark

Background: Denmark decided in 2018 that Adalimumab should be the first-line biological of patients with inflammatory arthritis. Consequently, a higher number of patients needed to be given information about Adalimumab and learn how to do self-injections. The department focused on making optimum use of its resources while at the same time ensuring a high medical standard for this new task.

Objectives: To examine whether group instructions with a structured approach will provide the medical standard required to enable the patients to perform their own treatment at home. And also to examine whether participation in group sessions where the patients will have an opportunity to exchange experience with other people in a similar situation would be beneficial for them.

Methods: Design: An anonymous questionnaire survey. Setting: The training sessions took place at the Center for Rheumatology and Spine Diseases, Rigshospitalet, Gentofte, Denmark, and involved patients who were already consulting the outpatient clinic. Participants: Patients, ≥ 18 year, due to start on their therapy with Adalimumab, were referred to the group sessions irrespective of previous diagnosis, previous experience with other forms of biological therapy and/or experience with self-injection. A group consisted of between two and six participants. Course structure: Initially the participants were given group instructions in subjects such as effect, adverse effects, storage and precautions to be taken in the event of an infection. The patients were also given theoretic instructions in the administration of injections and an introduction to the injection pen (test model). Following this, the patients administered self-injections individually in private under guidance. Material: The questionnaire asked about whether the participants felt capable of managing their therapy at home and whether they had benefited from being instructed in a group. In addition to this, the patients were asked about background data such as gender and previous experience with injection techniques and biological therapy. The questionnaire also left room to offer more detailed comments. Analysis: Descriptive data analysis, including also the more detailed comments from the questionnaires.

Results: A total of twenty-five patients with inflammatory arthritis divided onto seven groups. Female: 15; male: 10. Bionaive, no experience with self-injection: 13 Bionaive, experience with self-injection: 6 Previous biological therapy, no experience with self-injection: 2 Previous biological therapy, experience with self-injection: 4

Figure 1.

After the group sessions, all of the patients felt they were capable of managing their own therapy and administering their own injections going forward. The patients were very much or to some degree happy that they were taught in groups and most replied that the questions/comments presented by the other participants were very relevant or relevant to some degree. Gender and previous experience with injection techniques and/or biological medicine did not affect patient satisfaction. Selected comments made by the patients:
“Found the group approach to be really good. Good to hear what the others said.” “It was really good to be part of a group. I would never have thought of asking the question that the other patients raised and it was relevant for me too.” “It was really good talking to others.” “Always good to meet others in the same boat.”

**Conclusion:** Group instructions with a structured approach are found to provide a medical standard which enables the patients to perform their own treatment at home. Participation in group sessions with others in the same situation as oneself is also found to be beneficial for the patients since this approach creates a space for dialogue and knowledge sharing by the participant.

AMIGOS DE FIBRO (FIBRO FRIENDS): VALIDATION OF AN EDUCATIONAL PROGRAM TO PROMOTE THE HEALTH OF PATIENTS WITH FIBROMYALGIA IN BRAZIL.

M. Antunes1, A. Schmitt1, A. Pasqual Marques1. 1University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy, São Paulo - SP, Brazil

Background: Health education is a very important tool in the treatment of people with fibromyalgia. Health education acts as an excellent non-pharmacological treatment to promote health in fibromyalgia.

Objectives: To validate a multidisciplinary educational program to promote the health of people with fibromyalgia in Brazil, called Amigos de Fibro.

Methods: This is a methodological research with 45 individuals with fibromyalgia (target audience) and 23 health professionals (expert judges). Both groups used an instrument to assess the objectives, themes and proposed actions, relevance, writing style and structure of the program using the Delphi technique. The Content Validity Index (CVI) ≥ 0.78 and Kappa Coefficient ≥ 0.61 were used to analyze and validate the data.

Results: All items evaluated in both groups had a considerable minimum CVI and Kappa Coefficient to be valid. In the global assessment of Amigos de Fibro, the CVI of the target audience judges was 0.95, while the expert judges presented a value of 0.90. The Kappa Coefficient of the target audience judges was 0.85 and that of the expert judges was 0.90. Therefore, the instrument proved to be validated.

Conclusion: Amigos de Fibro was considered valid for its content and internal consistency, therefore, valid to be used by health professionals with the target audience in Primary Health Care in Brazil, allowing them to act as promoters of their health.

NURSING INTERVENTIONS FOR RHEUMATIC MUSCULOSKELETAL DISEASES (RMDs) PATIENTS ON BIOLOGIC THERAPY: A SYSTEMATIC LITERATURE REVIEW (SLR)

M. R. Melis1, K. El Aouf2, C. Bruni3, F. Bartoli3, G. Fioni3, S. Guiducci3, S. Bellando Randone1, S. Bambi1, L. Rasero3, M. Matsuuci-Cerinici2, I Careggi Hospital, Department of Experimental and Clinical Medicine, University of Florence, Rheumatology Unit, Florence, Italy; 1University of Florence, Department of Experimental and Clinical Medicine, Rheumatology Unit, Florence, Italy; 2University of Florence, Department of Health Sciences, Florence, Italy

Background: The support of the Rheumatology nurse to the management of patients who are affected by RMDs, characterized by remission and recrudescence and chronicity, may be strengthened by the investigation of their unmet needs and the identification of the necessary interventions to the continuity and quality of care.

Objectives: The aim of the present SLR is to identify the main nursing interventions to assure quality care in RMDs patients on biologic therapy.

Methods: Study design: a systematic search was conducted from 1990 to 2020 (01/01/1990- 2020/05/07). Inclusion criteria consisted of 1) patients with RMDs in accordance with American College of Rheumatology classification criteria and the American College of Rheumatology/European League against Rheumatism (ACR/EULAR); 2) in therapy with bDMARDS; 3) adult population > 18 years; 4) primary research only; 6) English language; 7) abstract available; and 8) relative quantitative studies; 9) nursing interventions and/or outcomes. Data sources: Medline, CINAHL, PsycINFO and EMBASE databases were used to search for relevant studies. Review management using the predetermined inclusion/exclusion criteria, two independent reviewers (MRM, KEA) screened records selected for eligibility based on titles and abstracts. Records meeting the inclusion criteria were retrieved and full texts were further assessed.

Critical Appraisal Skills
Program (CASP) tools were used to evaluate the quality of the included studies. Data from 8 studies were extracted independently by the reviewers.

**Results:** 1805 articles were retrieved after the review process, 8 articles met the inclusion criteria resulting in 1 randomized trial, 1 quasi-experimental study and 6 observational studies. The RMDs patient needs emerged concerning the psychosocial domain, the relationship with healthcare facilities and disease follow up to monitor symptoms. Moreover, three major nursing interventions related to these areas were identified: education, patient-centered care and data assessment.

**Conclusion:** Rheumatology nurses are part of a multidisciplinary team caring for patients on biologic therapy. Starting with accurate initial and ongoing data collection, rheumatology nurses can plan their interventions focusing primarily on patient education and tailored care based on actual needs. Further studies are necessary for research on aspects of patient-centered nursing care, including tele-nursing and Nursing Sensitive Outcomes in RMDs.

**AB1541-HPR IMPACT OF COUNSELLING, TELEPHONE-BASED SYMPTOMS TREATMENT TITRATION AND REMINDER CALL ON REGULAR FOLLOW UP AMONG COMMON RHEUMATOLOGICAL DISORDERS; A PROSPECTIVE COHORT STUDY**

V. Karte1, N. Gupta2, S. Malviya3, *BP Koirala Institute of Health Sciences, Internal Medicine, Dharan, Nepal;* 2*MGM Medical College, Anaesthesiology, Indore, India;* 3*Medanta Superspeciality Hospital, Rheumatology and Clinical Immunology, Indore, India*

**Background:** Poor adherence to rheumatologic diseases exist for various reasons.

**Objectives:** The objective of the study was to measure adherence with interventions.

**Methods:** It was a prospective cohort study for 52 weeks. Assuring adherence of 30%, power of the study as 90% and confidence interval 95% sample size was calculated as 323. Common rheumatologic disorders (Rheumatoid arthritis (RA), Spondyloarthropathy (SpA), Primary Sjogren's Syndrome (PSS) and Systemic Lupus Erythematosus (SLE)) patients with at least 15% from each group who presented first time in our clinic were followed up. The interventions were two separate sessions of face-to-face counselling during first initial visits, telephone-based titration of drugs if there was poor control of the presenting symptoms and two-day prior reminder phone call for next follow up.

**Results:** Among 323 enrolled patients 27% were compliant with previous treatments. The relative ratio of compliant groups under follow up with the rheumatologist versus other clinicians was 2.2. Median duration of diagnosis of the 60% previously diagnosed versus 40% newly diagnosed at our clinic was 18 months versus 7 days. Among 64 cases of PSS 86% were undiagnosed with median duration of symptoms of 4 years. Knowledge about consequences of poor treatment between pre verses post counselling was 40% and 78% respectively. (Table 1) Symptom controlled with telephone-based drug titration was achieved among 84% of cases (30%, 44%, 10% partial, nearly complete and complete improvement respectively). With the reminder call the adherence weans off to 85% at first follow up, 77% at third month and 53% at the end of year. By 52 weeks PSS had maximum adherence (78%) followed by SLE (58%), RA (42%) and SpA (42%). (Figure 1)

**AB1542-HPR USING SOCIAL NETWORKS AS A SOURCE OF INFORMATION FOR RHEUMATOLOGICAL PATIENTS**

A. Sarapulova1, O. Teplyakova2, A. Sarapulova1, O. Teplyakova2, *USMU, Outpatient Therapy; Yekaterinburg, Russian Federation;* 2*USMU, Outpatient Therapy; Yekaterinburg, Russian Federation*

**Background:** The COVID-19 pandemic has brought significant changes to the work of healthcare professionals around the world. Technologies of telemedicine counseling and education of patients have become widespread. The largest platforms for informing patients are social networks such as Facebook, Instagram, Twitter.

**Objectives:** to study the possibilities and impact of the social network as a digital medical tool on the education and management of rheumatological patients.

**Methods:** The study was conducted in the form of a survey in the social network Instagram in the blog @reumatolog_sarapulova, dedicated to the rheumatological diseases, and was dedicated to the level of information. At the time of the survey, the number of subscribers to the blog was 4895 people, 223 people answered the questions submitted. The survey was conducted in a Google form and was anonymous.

**Results:** 86% of respondents lived in Russian Federation, 17.5% - in the survey region, 14% of patients were from other countries. 72% indicated the presence of rheumatic disease as the reason for reading the blog, 7% - disease in relation to the COVID-19 pandemic, 14% are guided by the desire to know more about rheumatological disorders, 68.5% of the respondents rated the information presented in the blog as very interesting (10 points on a scale from 0 to 10), 13.3% - 9 points and 9.1% - 8 points. It should be noted that none of the participants in the study gave less than 5 points.
The most interesting in the blog, the majority calls information posts (88.8%) and answers the questions (77.6%), 2 out of 3 patients (64.5%) after getting acquainted with the information provided began to know more about their disease, 14% began to lead a healthier lifestyle, 9.8% realized the need to visit a doctor. 83.3% of participants rated the information on the blog as more detailed than what they get at their doctor’s appointment, and 81% would seek advice from a blogger. When answering the question “Do you share the information you get from the blog with your health-care provider?” 47.2% noted that they prefer not to report, 28% - report, while 44.9% decided to report. In general, 86% agreed that social networks are an important source of medical information, and as other sources they noted self-search for information in the Internet and visiting a doctor. 65.7% of the respondents asked the question to the author of the blog and received a response that was helpful and on the Instagram page @lupusufmg

Conclusion: social networks are an important source of information for patients and a means of choosing a medical specialist. However, it is alarming that in about half of the cases, patients do not share the information received with the attending physician, which can be explained both by lack of time and the lack of an adequate level of trust.

HPR Patients’ perspectives, functioning and health (descriptive: qualitative or quantitative).

A. Ben Tekaya1, O. Hamd1, L. Rouached1, S. Bouden1, R. Tekaya1, O. Saidane1, I. Mahmoud1, L. Abdelmoula1, C. Charles Nicole Hospital, Rheumatology, Tunisia, Tunisia; 2La Rabta Hospital, Rheumatology, Tunisia, Tunisia

Background: Knee osteoarthritis (OA) is a common osteoarticular disease. Its prevalence increases with age as well as the coexistence of other chronic diseases. Recent researches have revealed an association between OA and cardiovascular diseases. However, association between knee OA and comorbidities has not been fully studied.

Objectives: The purpose of this study was to investigate the association between knee OA and comorbidities.

Methods: In this cross-sectional study, patients with knee OA were enrolled. Sociodemographic data as well as comorbidities were collected. Grading of knee OA was performed using the Kellgren-Lawrence (KL) grading system. Functional impact of knee OA was assessed by KOOS. Presence of comorbidities was recorded by patient history. Clinical comorbidities were considered if present for at least 6 months. The study also showed a significant correlation between comorbidities and structural grading of knee OA (p<0.04). However, comorbidities were not correlated with KOOS score (p>0.06).

Conclusion: The accumulation of comorbidities is significantly associated with higher intensity scores in knee OA. Physicians should additionally pay close attention to the prevention and the treatment of comorbidities in the management of OA.

DOI: 10.1136/annrheumdis-2022-eular.97
University Hospitals. Controls: Recruitment of subjects without rheumatoid disease was performed asking for case patients who attended to medical center with a similar-age (age of range +/- 5 years) and same-gender person from social family or from family environment. Variables y measures: The main variable was malnutrition risk, measured by screening of Mini Nutritional Assessment. Other variables were: presence of sarcopenia, defined according to European Working Group on Sarcopenia in Older People (EWGSOP) 2019, economic status, dual-energy X-ray absorptiometry (DEXA) in spine and hip to osteoporosis screening, toxic habits, comorbidities and Charlson index, physical activity measured with Global physical activity questionnaire (GPAQ) and Short Physical Performance Battery (SPPB), haemoglobin, calcium, D and B12 vitamins, total proteins, albumin, C reactive protein, body mass index (BMI), polimedication, quality of life measured with EQ-5D and RA related factors, activity disease measured with DAS28, SDAI and CDAI; physical function measured with HAQ (Health assessment questionnaire) and global functional status according ACR criteria. Statistical analysis: Descriptive and multivariate analysis was performed to identify factors associated to sarcopenia in RA.

Results: 152 subjects were included in the study, 76 RA and 76 controls. More patients than controls with malnutrition risk were found, although there were no significant difference [24 (31,6%) vs 17 [22,4%]; p=0,136. More women with RA were included (78,9%), with media ± SD of age 74,7 ± 3,78, sarcopenia was presented in 9/24 (37%) and Charlson index was 3 points in 11/24 patients (45,8%) and 4 points in 8/24 patients (33,3%). According to the treatment, almost a 40%, no DMARDs were taken and neither 25% biological DMARD. 58,3% of patients received corticosteroids and majority of them (90,5%) were polimedicated. RA patients who presented desnutrion risk, in comparison with the rest of patients, had a media of upper age (p=0,007), more frequency of sarcopenia (p=0,006), right hipctil skinfold thickness (p=0,043) Also, higher values were found in activity index like physical function and quality of life. DAS28 (p=0,003), HAQ (p=0,044), Vitamin D (p=0,035), IPAG (p=0,003), SPPB (p=0,018), EQSD (p=0,01), VAS EQSD (p=0,044), SDAI (p=0,006), CDAI (p=0,008). In multivariate analysis, factors associated by independent way to malnutrition risk were age (OR [CI 95%], 1,184 [1,020-1,378], p=0,022) and inflammatory disease by DAS28 (OR [CI 95%], 2,043 [1,198-3,483]; p=0,009) (R2=0,252).

Conclusion: Even though frequency of malnutrition was similar in cases and controls, in RA was associated with inflammatory activity and older age. It's important monitoring malnutrition risk in this kind of patients to perform correct interventions to prevent and improve nutrition.

AB1547-HPR CAN A NURSE REPLACE THE DOCTOR IN AN UNCOMPLICATED PATIENT COURSE IN A PMR CLINIC? WHAT DO THE PATIENTS SAY?

S. Hojmark Jakobsen.1 University Hospital Svendborg Hospital, Rheumatology, Svendborg, Denmark

Background: Since 2020 the Rheumatology Outpatient Clinic of OUH, Svendborg Hospital has offered telephone consultations for patients diagnosed with muscular arthritides (PMR) tapering prednisolone. Since 2021 the course for the non-complexed patients been run by nurses. Initially patients only see a rheumatologist at the time of admission and the rheumatologist is only involved again if complications occur in the course e.g. that the patient can’t reduce Prednisolone as agreed without getting symptoms. At same day the patients are diagnosed by a rheumatologist they have a conversation with the nurse. The nurse gives both oral and written information about the disease and a Prednisolone reduction schedule is handed out to the patients. Afterwards the patients are followed by nurses and by telephone contact only. The telephone contact with the patients take place after 2, 10 and 17 weeks. When the patients are down to 7.5 mg of prednisolone daily, the nurse discharge the patient in their out-patient clinic to their own GP, who then takes care of the rest of the treatment and reduction of prednisolone to zero. There are a few literature reviews about PMR and outpatient clinics led by nurses and patient satisfaction, but we have not found anything about the patient satisfaction when they only have contact to nurses during their course.

Objectives: The aim of this qualitative study was to examine the impact on patient satisfaction when they only have contact to nurses during their course and at the same time examine whether the patients have missed talking to a rheumatologist. In addition to this, we were interested in the understanding and degree of application of the written reduction schedule.

Methods: All PMR patients completed in the outpatient clinic between December 2021 and January 2022 where asked to participate in a telephone interview at the end of their treatment. They were asked about their satisfaction with nurse consultations during their course on a scale from 0-10; 0= not satisfied and 10= high satisfaction. The patients were also asked if they had missed not to talk to a rheumatologist and finally they were asked about the Prednisolone reduction schedule.

Results: 20 patients participated in the telephone interviews. 55% of the patients respondend 10 on a scale from 0-10 in satisfaction talking with the nurses. 25% respondend 9 on the scale, 15% mentioned 8 on the scale and 5% mentioned 7 on the scale. All of the patients answered no regarding the need to talk with a rheumatologist. None of the 20 patients has been re-admitted to our outpatient clinic afterwards. 75% of the patients have no problem in following the Prednisolone reduction schedule and found it easy to read and understand.

Conclusion: With the limited number of participants, it is not possible to conclude anything definitive, but the answers indicate that the patients are satisfied with nurse consultations only during their course in the outpatient clinic and the answers also indicate that they have no need to talk to a rheumatologist. Our research could therefore indicate that nurses with a specific protocol in hand are capable of managing a course for non complex PMR patients including discharring the patients from the outpatient clinic. The answers regarding the reduction schedule reassured us, that it is understandable which should reduce the possibility of errors in the treatment.

REFERENCES:
Background: Research regarding adverse drug reactions (ADRs) associated with the use of adalimumab in patients with inflammatory rheumatic diseases (IRDs) usually focuses on the nature and frequency of ADRs without considering the burden of the ADRs. However, not every ADR causes the same burden for patients. Information is lacking about the degree of experienced burden per ADR by patients with IRDs.

Objectives: First, to describe ADRs of adalimumab based on nature, frequency and burden, and second to propose a new model for identification of relevant ADRs for health care professionals.

Methods: Data of the Dutch Biologic Monitor (DBM) were used to categorize patient-reported ADRs into high and low burden. In this prospective cohort event monitoring system patients were asked to fill out monthly questionnaires on experienced ADRs that they attributed to the use of a biological. The questionnaire included a quantification of the burden of the reported ADRs using a five-point Likert scale ranging from 1 (no burden) to 5 (very high burden). The nature of the reported ADRs were grouped into preferred terms (PTs) according to the Medical Dictionary for Regulatory Activities (MedDRA). Inclusion criteria for this study were patients with IRDs using adalimumab and the reporting of an ADR with at least one burden score. For every patient, the mean burden scores per ADR (MedDRA PT) were analyzed. The burden was classified in two categories: high when the mean burden score was equal to or more than 2.5, and low when it was less than 2.5. Text analytics of the reported ADRs (MedDRA PTs) and a comparison word cloud were used to visualize ADRs that were more often reported with high burden or more often reported with low burden. These ADRs correspond to high burden (no less than 66.67% as significant) and low burden (no more than 33.3% as significant). A frequency and burden event monitoring system patients were asked to fill out bimonthly questionnaires on experienced ADRs that they attributed to the use of a biological. The questionnaire included a quantification of the burden of the reported ADRs using a five-point Likert scale ranging from 1 (no burden) to 5 (very high burden). The nature of the reported ADRs were grouped into preferred terms (PTs) according to the Medical Dictionary for Regulatory Activities (MedDRA). Inclusion criteria for this study were patients with inflammatory rheumatic diseases (IRDs) using adalimumab and the reporting of an ADR with at least one burden score. For every patient, the mean burden scores per ADR (MedDRA PT) were analyzed. The burden was classified in two categories: high when the mean burden score was equal to or more than 2.5, and low when it was less than 2.5. Text analytics of the reported ADRs (MedDRA PTs) and a comparison word cloud were used to visualize ADRs that were more often reported with high burden or more often reported with low burden. These ADRs correspond to high burden (no less than 66.67% as significant) and low burden (no more than 33.3% as significant).

Table 1. Characteristics of patients and reported adverse drug reactions (ADRs)

<table>

</tr>
<tr>
<td>Headache (%)</td>
<td>13 (7)</td>
</tr>
<tr>
<td>Therapeutic product effect (%)</td>
<td>14 (8)</td>
</tr>
</tbody>
</table>

Conclusion: The outcomes of the word cloud reveal that infections are more often experienced as burdensome, whereas injections site reactions impose low to no burden. Visualizing the nature, the frequency and the burden of ADRs in one picture, provides simple guidance to the degree of relevance for the reported ADRs in clinical practice.

AB1549-HPR

**SOCIAL ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH THE ARTICULAR FORM OF RHEUMATOID ARTHRITIS**

N. Shuvalova, S. Lezhentseva, E. Guryanova, Y. Ya. Yakovlev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation; N. Ulianov Chuvash State University, Department of Healthcare Management and Economics, Cheboksary, Russian Federation; N. Ulianov Chuvash State University, Department Internal Diseases, Cheboksary, Russian Federation

**Background:** Patients with rheumatoid arthritis (RA) often experience persistent, prolonged pain. This requires taking pain medications (most often non-steroidal anti-inflammatory drugs) every day for many years or decades. Pain can lead to decreased social activity and emotional changes. Therefore, the quality of life of patients with rheumatoid arthritis may decrease.

**Objectives:** The purpose of the study: to determine the quality of life in patients with rheumatoid arthritis.

**Methods:** A survey was conducted using a questionnaire that included aspects of Health-related quality of life (HRQOL). The study was conducted from September 2020 to September 2021, in the Chuvash Republic, Cheboksary. The study involved 75 patients (n = 75) with articular form of RA, aged 25 to 70 years (mean age 52.2±6.63), 82% women. In 24 (32%) respondents, 1 degree of inflammatory activity was verified, in 36 (48%) - the second, in 15 (20%) - the third degree. The first stage was diagnosed in 9 (12%) patients (according to Steinbrocker), in 42 (56%) cases stage 2 of RA development was diagnosed, in 18 (24%) cases - the third stage, 6 (8%) patients had stage 4. The diagnosis of RA was based on the criteria (ACR). Statistical processing of the results was carried out in MS Office Excel programs.

**Results:** More than half of the patients (55.87%) experienced daily pain in the peripheral joints, which worsened their mood and well-being. When assessing the degree of pain, 68.45% of patients assessed their pain according to VAS as moderate (72±0.96 points). When assessing physical activity (PF) in 33.17% of patients, its decrease was noted as “significant” when assessing social activity (SF), a decrease in this indicator was revealed: 56.32% of the surveyed noted a “moderate” decrease, 33.16% as “significant”. 23.94% of the surveyed noted the...
decrease in the indicator of general health (GH) as "moderate." When assessing mental health (MH), a decrease in the indicator was found in 43.67% of patients as "moderate." When assessing emotional problems in disability (RE), there was a "significant" decrease in the indicator in 54% of respondents. In 62.24% of the surveyed patients considered the loss of freedom of movement to be the biggest problem in RA. 56.24% of patients rated their satisfaction with their lives as "average degree of satisfaction"; 43.76% of patients as "low satisfaction."

**Conclusion:** As a result of the survey, it can be stated that 43.76% of respondents have a "low degree of satisfaction" with life. In order for the doctor to have all the objective information, it is necessary to adequately and timely evaluate changes in HRQOL for the purpose of early diagnosis and timely treatment of RA.

**HEALTH PERCEPTION OF PATIENTS WITH FIBROMYALGIA IN BRAZIL**

M. Antunes1, A. Torres Cruz1, P. De Oliveira Januário1, A. Pasqual Marques1.

1Universidade de São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy, São Paulo - SP, Brazil

**Background:** Fibromyalgia is a rheumatologic syndrome characterized by chronic pain and symptoms such as fatigue, morning stiffness, sleep disturbances and depression. Health perception is a global assessment of health based on an analysis of the objective and also subjective aspects of each person. Health self-assessment is increasingly researched and shows the health status of the population, considering the individual's personal perspective and that this information can be useful to propose health promotion strategies.

**Objectives:** To identify the health perception of patients with fibromyalgia who live in Brazil.

**Methods:** This is a cross-sectional study that was carried out in Brazil in 2021. They were invited to participate in the research. Individuals with fibromyalgia were invited to participate in the study through the Brazilian Association of...
Fibromyalgia Patients (ABRAFIBRO) in August 2021. The invitation was sent via email to all patients registered with this association in the country. Self-perception of health was questioned through the following response options: bad, fair, good or very good. Data were analyzed using descriptive statistics.

**Results:** The study consisted of 243 people with fibromyalgia living in different states of Brazil. Most were female (97.5%), married or living with a partner (83.7%), of white race/color (58%), receiving 1 to 2 minimum wages (60.4%), with complete higher education (46.3%) and who administer more than 2 medications per day (65.8%). Regarding the perception of health, the majority reported that their health was regular (42.4%), followed by bad (36.9%), good (16%) and very good (3.3%).

**Conclusion:** The most prevalent health perception in people with fibromyalgia in Brazil was: “regular,” followed by “bad;” “good” and “very good.” In view of the findings of this study, measures to control and prevent health risks in people with fibromyalgia become necessary.

In order to implement policies to promote a healthy life for this population, it is necessary to know the determinants of these indicators of self-reported health morbidity in Brazil. It is also suggested that the results of this investigation be monitored by periodic population-based surveys, in order to verify the determination of the observed associations, being able, in the future, to detect an association with other variables. In addition, these data can guide and evaluate education and health promotion strategies in fibromyalgia.

**DRUG-RELATED PROBLEMS EXPERIENCED BY PATIENTS WITH RHEUMATIC DISEASES: A LONGITUDINAL OBSERVATIONAL STUDY**

L. Haegens; V. Huiskes; E. M. Smale; C. Bekker; B. Van den Bermt; J. Maartenskliniek, Department of Research, Ubbelen, Netherlands; S. Sint Maartenskliniek, Department of Pharmacy, Ubbelen, Netherlands; Radboud University Medical Center, Department of Pharmacy, Nijmegen, Netherlands.

**Background:** Patients with rheumatic diseases can experience multiple drug-related problems (DRPs) along their patient journey. Insight into patients’ experience of DRPs over time might aid in timely identifying and preventing DRPs. 23 Objectives: To longitudinally identify DRPs experienced by patients with rheumatic diseases.

**Methods:** A prospective observational study was conducted in a Dutch outpatient rheumatology clinic. Adult patients with rheumatic diseases that were prescribed medication by a rheumatologist were questioned about experienced DRPs by telephone 4 times in 8 weeks using a structured interview-guide. Unique DRPs (i.e. DRPs not reported in earlier interviews by individuals) were categorized using a classification for patient-reported DRPs and analysed descriptively.

**Results:** In total, 52 participants (median age 68 years (interquartile range (IQR) 62-74), 52% male) completed 152 interviews with 45 (87%) participants completing all 4 interviews. The majority of patients (65%) were diagnosed with rheumatoid arthritis. Patients reported a median number of 3 (IQR 2-5) unique DRPs during interview 1. In subsequent interviews, patients reported median numbers of 1 (IQR 0-2), 1 (IQR 0-2) and 0 (IQR 0-1) unique DRPs for interview 2 to 4 respectively. Participants reported a median number of 5 (IQR 3-9) unique DRPs over all completed interviews. Unique patient-reported DRPs were most frequently categorized into (suspected) side effects (28%), medication management (e.g. medication administering or adherence) (26%), medication concerns (e.g. concerns regarding long-term side effects or effectiveness) (19%) and medication effectiveness (17%).

**Conclusion:** Patients with rheumatic diseases experience various DRPs over time. These patients might benefit from continuous support during their patient journey.

Background: As the prevalence and costs related to osteoarthritis (OA) are expected to rise in the coming years, actions have to be taken to ensure access to effective and economical sustainable recommended treatment for this patient population. Digital tools, such as the use of mobile health applications (mHealth), could serve as a solution. Though, little is known about characteristics of patients participating in a mHealth osteoarthritis management program (OAMP) in physiotherapy practice.

Objectives: To describe demographic and disease-related characteristics of patients with hip and/or knee OA recruited to a mHealth OAMP and compare these characteristics to those of other OAMPs.

Methods: The Digital Osteoarthritis Care-study (DigiOA) is a two-armed non-inferiority RCT currently running in primary health care in Norway. In total 156 participants with hip and/or knee OA seeking physiotherapy in primary care will be asked to participate. Consenting patients will receive 1-2 hours of education before randomization to 6 weeks of either exercise therapy via the Virtual Training mobile health application or supervised exercise therapy. Inclusion rate is reported as frequency and percentage. To describe patient characteristics, we have included baseline data on patients currently included in the study. These characteristics are compared to baseline data from a web-based OAMP (1) and a standard OAMP in physiotherapy care (2).

Results: Of 39 eligible patients, 25 (64%) have to date consented to participate in the study. An overweight of the included patients are presented with knee OA, have had symptoms for five years or less, and have higher education (Table 1).

</tbody>
</table>

The study sample report high impact of symptoms, and decreased function. Self-efficacy related to pain and symptoms are relatively high, but the patients report lower exercise self-efficacy. The study sample is comparable to patients included in both standard and web-based OAMPs, except for lower impact of pain and higher usage of pain medication in DigiOA.

Conclusion: Preliminary results show that baseline characteristics are comparable to patients included in other OAMPs, but with only two third of eligible patients consenting to participate in a mHealth OAMP there is a need for more in-depth knowledge on patients’ attitude towards mHealth OAMPs.

Conclusion: Our data suggests that a MDC for PD-ILD results in a more thorough investigation and treatment, and this will likely lead to improvements in patient outcomes. Based on these findings, our rheumatology group is seeking internal funding for a pilot clinical evaluating prospectively the value of an MDC LOD.

**NURSE-DRIVEN DIAGNOSTIC PROCESS OF PATIENTS WITH SJÖGREN’S SYNDROME (SS) A CLINICAL DEVELOPMENT PROJECT**

M. T. Poder1, G. M. Colding1, K. Frödin1, M. B. T. Pedersen1, M. S. Andersen1, L. S. Tirm1, A. Vibe1, K. N. Sørensen1, L. Lindgren1, A. Svensson1, M. Pfeiffer-Jensen1, V. Fana1, J. L. Lykkegaard1, G. Thamsborg1. Rigshospitalet Glostrup, Afdeling for Rygkirurgi, Led- og Bindevævssygdomme, Glostrup, Denmark

Background: Sjögren’s Syndrome (SS) is a chronic autoimmune disease that affects the body’s glandular functions, especially the lacrimal and salivary glands, causing the mucous membranes to dry out (1). There are no diagnostic criteria, and classification criteria are often used to support the diagnosis (2).

Methods: We identified a need to unify and consolidate the diagnostic process of patients with SS in the Capital Region of Denmark. A medical working group supervised the nurse-driven diagnostic process at Rigshospitalet, Glostrup. Here an interdisciplinary working group with physicians, nurses, and secretaries developed a diagnostic process and logistic based on the American-European Consensus Group Classification Criteria 2002 (3). The nurse’s took medical history and performed sicca tests and made sure that the patient received adequate guidance. With input from three patients, the nurses at the outpatient clinic developed - written material on eye and mouth dryness. We developed a “smart phrase” for our documentation platform in the interdisciplinary working group. The purpose of the ‘smart phrase’, was to unify the documentation and ensure continuity in the conversation with the patient. The Rheumatologists task was to disprove or confirm the diagnosis and perform a risk stratification especially in relation to the development of lymphoma, but also interstitial lung disease.

Objectives: The aim of this project was to examine and evaluate the patients’ experience of nurse-driven diagnostic process.

Methods: To evaluate the new patient course, we performed a survey. The questions selected for the survey were primarily based on the patients experience of meaning and coherence in the diagnostic process. The questions were developed by the nurses in the Outpatient Clinic; “Do you feel safe going home after the consultation today?” “Did you get answers to the questions you asked while you were in the consultation?” “Did the staff take the time to listen to you?” Also, the patients could add comments.

Results: A total of 34 consecutives responded to the questionnaire. 88% felt safe when returning home from the Outpatient Clinic, 85% received answers to their questions during the consultation. Altogether, 94% answered that the health care professionals were present and listened to them. The patients had the following comments: "The diagnostic process contained a lot of unresolved waiting time” and "It has been some confusion about the division of tasks in the different hospital wards.”

Conclusion: We found that the patients were satisfied with the nurse-driven diagnostic process. The diagnostic process created a feeling of safety in the patients and the patients found that they were listened to and allowed to ask questions. In addition, by evaluating the process investigation, we could change practice and further unify the diagnostic process. The result of the questionnaire supported the justification of the nurse competencies, by preforming a high level of information and guidance as well as the need for recognition of the patient’s symptoms. Therefore, the working group chose to meet again and evaluate. We decided that the nurse and rheumatologist consultation should be performed on the same day. Such consultation made it possible for the nurse to ensure continuity in the process, as the same nurse could follow the patient throughout the day. This maximized the opportunity for the nurse to guide the patient in the symptomatic treatment of eye and mouth dryness. Also, the nurse had the opportunity to guide in oral hygiene, fatigue, and lifestyle factors.

The next step in our development project is to evaluate our revised nurse-led diagnostic process. In addition, the working group is currently working on material for a course in SS, where 4-6 patients and relatives can have the opportunity for additional training to participate.

**PHYSIOTHERAPY FOR RHEUMATOID ARTHRITIS (RA) – PAST, PRESENT AND A POSSIBLE FUTURE?**

A. M. Mengshoel1. 1University of Oslo, Department of Interdisciplinary Health Sciences, Oslo, Norway

Background: Physiotherapy has a long tradition providing services to patients with RA. The main aim of physiotherapy is to improve patients’ abilities to perform movements and physical activities through exercises and educating patients in self-management skills. For physiotherapy to proceed into future, it seems relevant to examine what shifts occurred in physiotherapy over time and why did they happen.

Objectives: Is to unpack the shifts in physiotherapy for patients with RA from 1980 until today.

Methods: Norwegian physiotherapy in rheumatology is used as case. The shifts are identified with help of literature about history of medicine and physiotherapy in rheumatology and empirical physiotherapy research since the 1960s. The author draw on own experiences first as a clinician and practice teacher for physiotherapy students in rheumatology, and later as a scientist and advisor for a multidisciplinary team in rheumatology.

Results: Physiotherapy focuses on movement and function, which over time have consistently been understood in relationship to disease-induced alterations and biomechanics. Shifts in physiotherapists’ remedial exercises have occurred over time as better disease control occurred and evidence showed that physical activities and exercise programmes had disease modifying effects and improved patients’ functional capacity. In the 1980s, a move from earlier passive, joint protective movements with little weight load to cautious weight-bearing movements occurred, mostly as a response to improved disease-modifying drugs and joint surgery. In the 1990s, physiotherapy shifted from cautious weight-bearing movements to safely performed physical activity as a response to scientific findings showing beneficial effects on radiological, immunological, and physical function measures. In the 21. century, RA is identified earlier and increasing number of patients reach disease remission before irreversible occurs in the musculoskeletal system. Presently, a new shift in Norwegian physiotherapy is on the way. Adherence to EULAR guidelines 2018 on physical activity is moving physiotherapy from promoting exercises through engagement in self-determined physical activities into educating patients in performing structured intensive physical fitness training programmes for preventing future comorbidities.

Conclusion: At the moment, it is a dilemma that the raising rate of patients successfully treated to disease remission is not accompanied with more patients remaining in fulltime work in Norway. Thus, there is a need in physiotherapy to critically scrutinize the meaning and significance of movements and functioning for the individual patient’s own life purpose and the society’s wish that people stay in paid work.

</table>

The mean time taken to start treatment was 30 days in the homecare group and 13 days in the outpatient group. 7 patients (35%) within the outpatient group started treatment within 7 days. The shortest time within the homecare group was 15 days (3 patients).

Conclusion: Reported patient satisfaction between the two routes of treatment provision was similar. Patients commenced treatment significantly quicker via outpatient pharmacy, reporting a high degree of satisfaction with the injection training provided by outpatient pharmacists. This audit has confirmed that shared care provision of methotrexate initially via outpatient pharmacy is a safe, efficient and viable option.

Disclosure of Interests: Rebecca Heaton Speakers bureau: I prepared slides and presented virtually for pharmacists explaining shared care experience (Nordic), Consultant of: Formulating a educational package for rheumatology pharmacists (Galapagos), Jennifer Nasralla: None declared, Charlotte Filer: None declared, Edward Appleby: None declared, Mya Myintzu: None declared, Filer: None declared, Edward Appleby: None declared, Mya Myintzu: None declared, Reviewers: I prepared slides and presented virtually for pharmacists explaining shared care experience (Nordic), Consultant of: Formulating a educational package for rheumatology pharmacists (Galapagos).

Background: The importance of international harmonization regarding education of rheumatologists in musculoskeletal ultrasound (MSUS) and injection skills have been highlighted in several studies, including the need for standardized training programs containing competency-based education using validated assessment tools [1-2].

Objectives: To examine how residents are trained and assessed in MSUS, MSUS-guided and landmark-guided joint aspiration and injection. Additionally, to present the available assessment tools and examine their supporting validity evidence.

Methods: A systematic search of PubMed, Cochrane Library, and Embase was conducted in accordance with the PRISMA guidelines and studies published from January 1, 2000 to May 31, 2021 were included. Two independent reviewers performed the search and data extraction. The studies were evaluated using the Medical Education Research Quality Instrument (MERSQI).

Results: 9,884 articles were screened and 43 were included; 3 randomized studies, 21 pre- and post-test studies, 16 descriptive studies (Table 1), and 3 studies developing assessment tools. The studies used various theoretical training modalities e.g. lectures, anatomical quizzes, and e-learning. The practical training models varied from mannequins and cadavers to healthy volunteers and patients. Most studies used subjective “comfort level” as assessment, others used practical examination and/or theoretical examination. All training programs increased trainees’ self-confidence, theoretical knowledge, and/or practical performance, however few used validated assessment tools to measure the effect. Only one study met the MERSQI high methodical quality cut-off score of 14.

Conclusion: The included studies were heterogeneous, and most were of poor methodological quality and not based on contemporary educational theories. This review highlights the need for educational studies using validated theoretical and practical assessment tools to ensure optimal MSUS training and assessment in rheumatology.

Disclosure of Interests: None declared.

A previous study has shown, that trained nurses can perform satisfying and safe IA injections at least as well as those administered by doctors (1). High availability to adequate treatment will have a positive effect. For the patient and on a socio-economic level, as patients who have severe arthritis could be forced to stay home from work and leisure activities (2). It was decided to educate a nurse, who showed interest in ultrasound and IA injections and who showed the technical skills.

**Objectives:** To educate and develop competence in the nursing staff regarding ability to perform joint ultrasound, arthrocentesis and IA injection. In order to offer immediate arthritis treatment and free up doctor time to be able to see other patients.

**Methods:** At first, the nurse watched the ultrasound, arthrocentesis and injection on the knee performed by a rheumatologist a couple of times. Then she performed the procedure under supervision and then she independently performed the ultrasound, arthrocentesis and injection on the knee with the opportunity for supervision. The nurse completed a two-day muscular/skeletal ultrasound course at university hospital Skejby. The course was both theory and hands-on training in ultrasound, arthrocentesis and injection on the knee with the opportunity for further supervision. The nurse also participated in a course at Esbjerg hospital for doctors and nurses about ultrasound on upper extremities. This was a hands-on course. In conjunction with arthrocentesis, the nurse learned to identify urate crystals in synovial fluid through microscopy.

**Results:** See Table 1 for which joints where the nurse performed ultrasound, arthrocentesis and injection during the first and second year.

One year after the procedure was implemented the joints that the nurse perform ultrasound and injections on, had increased. Starting with only knees to PIP, MCP, wrist, elbow, knees, ankles and MTP joints. After the first year, the nurse grew independent and confident with the new task, as the table beneath shows. Since the nurse started to perform ultrasound, arthrocentesis and IA injections, there has been no reports of adverse events.

**Conclusion:** Nurses can be trained to perform ultrasound, arthrocentesis and injections, in a wide range of joints. Patients and staff express satisfaction with the availability of treatment. There has been no reports of adverse events.

**REHABILITATION NURSES KNOWLEDGE ABOUT OSTEOPOROSIS AND FRAILTY FRACTURES IN PORTUGAL**

G. Pimentel, A. Cruz, M. Loureiro, S. Fernandes, C. Baixinho, A. Marques; on behalf of Master’s Thesis. "Higher School of Nursing of Coimbra, Rehabilitation Nursing, Coimbra, Portugal; Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; Higher School of Nursing of Coimbra, Health Sciences Research Unit Nursing, Coimbra, Portugal; Nurses' Regulatory Board, Royal Colleague of Nurses, Coimbra, Portugal; Nurses' Regulatory Board, Section Regional South, Lisboa, Portugal; Nursing School of Lisbon, Train4Health, Lisboa, Portugal

**Background:** Scientific evidence reveals gaps in health professionals’ knowledge about osteoporosis and fragility fractures, which impair and influences the quality of care, namely in preventive actions.

**Objectives:** To analyze knowledge of Rehabilitation Nurses about osteoporosis and fragility fractures to identify training needs of Rehabilitation Nurses.

**Methods:** A cross-sectional study, integrated in a larger project, using an adapted questionnaire, made available online and disseminated by mailing list of “Ordem dos Enfermeiros” (Royal Colleague of Nurses) to all Portuguese Rehabilitation Nurses.

**Results:** There were include 452 participants (10.3% of the 4397 Rehabilitation Nurses), 17% perform functions in orthopaedics and traumatology service, 4.5% physical medicine and rehabilitation and 78.6% in other services, majority, 74.6% women. On average, 69.6% correct answers were identified regarding osteoporosis and fragility fractures. Results reveal that the main areas of knowledge deficit, in this study, are related to the concept and epimology of osteoporosis and fragility fractures and about the most appropriate diet. Nurses with higher academic degree (master’s degree) revealed more knowledge (p=0.01).

**Conclusion:** This study reveals that the knowledge about osteoporosis and fragility fractures is low (<70% correct answers), thus there is an opportunity to improve the knowledge related to osteoporosis and fragility fractures among Specialist Nurses in Rehabilitation Nursing.

**SHIFTING THE MINDSET: USING A HEALTH COACHING APPROACH FOR HEALTH PROMOTING CONSULTATION IN ADOLESCENT RHEUMATOLOGY**

A. Bouraoui, P. Newman, C. Fisher, S. Mavrommatis, A. Mcdowell, D. Sen. University College Hospital, Adolescent and Young Adult Rheumatology, London, United Kingdom; HaelianCoaching, Coaching, London, United Kingdom; TPC HEALTH, Health Coaching, London, United Kingdom

**Background:** Juvenile rheumatic diseases have a significant negative impact on health early in life which may affect later health outcomes. The Adolescent and Young Adult Rheumatology Department (AYAD) at University College London Hospitals (UCLH) looks after over 2,000 young people with a variety of rheumatological conditions and provides developmentally appropriate interdisciplinary (ID) approach to healthcare. Health coaching (HC) is “a behavioural intervention that facilitates participants in establishing and attaining health promoting goals in order to change lifestyle-related behaviour, with the intent of reducing health risks, improving self-management of chronic conditions, and increasing health related quality of life.” Evidence shows that health coaching can improve health related behaviours including medication adherence, patient activation, and use of healthcare resources. [2-4]

**Objectives:** The aim of this project is to enable young people attending the AYAD to establish and achieve their own health-promoting goals and thereby change behaviour and increase confidence in self-management. As a first stage the aim was to develop health coaching capabilities within our ID Team by March 2022.

**Methods:** The strategy to deliver this project included commissioning a recognised core skills health coaching course for multidisciplinary team (MDT) members. Pre and post course surveys were completed by participants.

**Results:** All the AYA team members comprising 3 physiotherapists, 2 nurse specialists, a transition pathway coordinator, 4 consultants and 2 senior registrars took part in the health coaching workshops. A pre course survey (10/12 responded) revealed that 70% of MDT members felt their consultations focused solely on young people’s medical/clinical care. 80% reported they discuss lifestyle choices such as sleep, and weight management. 40% felt that their consultation times were long enough to discuss resources that would support long-term management. 30% reported they felt effective
in facilitating Young people and their families to self-manage and/or had sufficient health coaching awareness to facilitate behaviour change. The course was delivered over 2 separate days, one week apart, and included educational material, presentations, group discussion and skills development delivered in a coaching style. A post course survey (11/12 responses) demonstrated 100% of participants were satisfied with the course content, delivery, facilitation and opportunities to work and learn with colleagues, and felt that the skills were applicable to their work. They reported that the skills learned could be applied beyond healthcare, for example, with colleagues or in leadership roles, the course helped to raise self-awareness of behaviours that can negatively and positively impact patient and family engagement in their care, and that using some techniques and small changes to practice could potentially have a big impact on quality of care and outcomes as well as patient and staff experience.

**Conclusion:** Health coaching skills were considered as a useful tool by all AYAD team members. Skills gained on the course were considered useful in managing young people and applicable in settings beyond clinical care. The next stage of this project will include embedding the techniques learned into clinical practice and measuring qualitative and quantitative outcomes over time.

### HPR Interdisciplinary research

**AB1567-HPR**

**SOCIAL WORKERS: DESCRIBING SOCIOECONOMIC CHARACTERISTICS DURING PRENATAL CARE IN PATIENTS FROM A PREGNANCY AND AUTOIMMUNE RHEUMATIC DISEASES CLINIC.**

**M. E. Corral Trullillo,1 F. R. Arevalo Nieto1, L. G. Espinosa Banuelos1, C. M. Skinner Taylor2, L. Pérez Barbosa3, A. Y. Lujano Negrete1, D. Á. Galarza-Delgado1.1 Hospital Universitario Dr. José Eleuterio González, Rheumatology Department, Monterrey, Mexico**

**Background:** Social workers (SW) interventions are fundamental in health care; the main objective is to identify and mitigate social determinants of the patient's health. The socioeconomic study (SES) is the core assessment of SW; it analyzes the demographic structure and population dynamics.

**Objectives:** Describe the sociodemographic and social security characteristics in pregnant patients with autoimmune rheumatic diseases.

**Methods:** A cross-sectional and retrospective study was conducted in a pregnancy and rheumatic diseases outpatient clinic from the university hospital in Monterrey, México. The data from the SES database was collected. The sociodemographic information, family’s monthly income and expenses, expenditures related to healthcare, type of social security, family nucleus (FN) and socioeconomic level (SL) were analyzed. The rheumatic diagnosis was retrieved from the medical records. The SL is classified in 7 levels (according to the score obtained in the SES); each level represents a percentage of the total cost of the healthcare received. Level 1 to 3 correspond to 0 - 28% percentage while levels 4 to 7 go from 53 to 100% of total payment that is due. To evaluate the health expenditure, the monthly limit expenditure per Mexican family is 98.39 dollars (the limit expenditure was taken from the Organization for Economic Co-operation and Development “OECD” 2019 report). For statistical analysis, the sociodemographic and clinical characteristics of the sample are presented as frequencies and percentages.

**Results:** From 2019 to 2021, 54 patients were interviewed. The mean age was 28.46 years (SD=6.69). The rheumatic diagnoses can be found in Table 1. The most common occupation was unemployment (n=34, 62.96%) and only completed basic levels of education (n=37, 68.1%).

**Disclosure of Interests:** None declared

</table>

SD: Standard deviation

The most frequent SL was level 3 (46.29%) and the predominant FN was the nuclear family (50%) (couple and their dependent children). Most of them were not under any health coverage (n=39, 72.22%). The average family income was $614.23 USD and the average health expenditure was 105.71 USD; which represents 16.21% of the family income (per month).

**Conclusion:** SW play a key role understanding basic needs and identifying health determinants that decreases the odds of access of healthcare. Women with autoimmune rheumatic diseases have an important burden of the main determinants of health like low income, unemployment, basic education, and poor health coverage. In addition, the average health expenditure is higher than the recommended by OECD. Different strategies are needed for childbearing age patients with rheumatic diseases to decrease the impact of health determinants.

### Patient information and education

**AB1568-PARE**

**LIVED EXPERIENCES OF POSTMENOPAUSAL OMANI WOMEN WITH OSTEOPOROSIS**

**F. Zadids1, E. Stannmore2, J. Brooks2, T. O’Neill3.1 The University of Manchester, School of Health Sciences, Manchester, United Kingdom; 2The University of Manchester, School of Health Sciences, Manchester, United Kingdom; 3The University of Manchester, Department of Rheumatology, Manchester, United Kingdom**

**Background:** Osteoporosis is a globally significant clinical public health problem associated with age-related fractures [1,2]. Most research on the impact of the disease has been based on quantitative survey data. There are relatively few qualitative studies exploring women’s lived experience with osteoporosis. Furthermore, most data are from Western countries, with no data from the Middle East. Moreover, most data are from Western countries, with no data from the Middle East. Therefore, we aimed to explore the lived experiences of postmenopausal Omani women with osteoporosis.

**Objectives:** To explore the lived experiences of postmenopausal Omani women with osteoporosis.

**Methods:** A qualitative study was conducted using semi-structured interviews. A purposive sampling technique was used to select 15 participants who met the inclusion criteria (at least 1 year postmenopausal, diagnosed with osteoporosis). The interviews were conducted in Arabic and recorded. The data analysis was conducted using thematic analysis.”

**Results:** The participants’ experiences of living with osteoporosis were characterized by three main themes: (1) the physical and psychological impact of osteoporosis, (2) the patients’ views on osteoporosis, and (3) the patients’ knowledge of osteoporosis. The most common problem was the fear of fractures (n=15, 100%).

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.3839
East. Direct access to lived experiences is a powerful tool for gaining insights into a disease [3]. This study aimed to determine the lived experience of postmenopausal Omani women with osteoporosis.

**Objectives:** The study sought to answer three questions:

1. What does living with osteoporosis mean for postmenopausal Omani women?
2. How does culture impact the lives of postmenopausal Omani women with osteoporosis?
3. How do postmenopausal Omani women with osteoporosis perceive the support and care provided by healthcare professionals?

**Methods:** An interpretive phenomenology design was used with a purposive sample of 15 postmenopausal Omani women with osteoporosis and fragility fractures obtained from primary and secondary care facilities in Muscat, Oman. Audio recorded, semi-structured, one-on-one interviews were held by Zoom and telephone; Crypt and Tanner’s framework was used to analyze data and identify key themes.

**Results:** The mean age of the participants was 63 years. Five (33.3%) reported a previous fracture. Just over half (53%) were illiterate; three (20%) had studied in college. Key themes related to their lived experience emerged from the data analysis: culture and religion; health care professionals’ attitudes; and services and treatment regimen. The subjects’ social and cultural lives were negatively impacted by osteoporosis and fragility fractures, which prevented them from attending celebrations such as close family marriages and religious gatherings. Participants played significant care-giving roles as wives, mothers and grandmothers but many were unable to perform many household chores, such as cooking, due to the osteoporosis and fractures. They perceived healthcare professionals through the professionals’ communication styles and information they provided. Participants satisfied with their doctor’s communication style described it as humanistic, with humour added, noting they provide health information and understand patients’ needs. Those not satisfied indicated their doctors had poor communication styles, showed insufficient interest in them, and asked few questions during their appointments. Professionals in in-patient clinics were perceived as more caring and empathetic than those at out-patient clinics. Treatment abroad was preferred by these women, though some were highly satisfied with their treatment from Omani hospitals. Beliefs about and usage of traditional herbal remedies for the management of fragility fractures differed between educated and non-educated women.

**Conclusion:** This study explored postmenopausal Omani women’s experiences of living with osteoporosis and fragility fractures including the impact of the disease on social and cultural life. It contributes also to our understanding of the experience of the disease in non-western settings.

**AB1570-PARE**

**WHAT DO PATIENTS KNOW ABOUT RHEUMATOID ARTHRITIS?**

S. Lezheninga1, N. Shuvalova2, E. Guryanova3. 1I. N. Ulianov Chuvash State University, Department of Healthcare Management and Economics; 2Cheboksary, Russian Federation; 3Ya. Yakovlev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation; 4I. N. Ulianov Chuvash State University, Department Internal Diseases, Cheboksary, Russian Federation

**Background:** Patient awareness of rheumatoid arthritis (RA) contributes to more effective prevention of this disease. It is necessary to study the initial level of knowledge of patients about rheumatoid arthritis and analyze which sections of the educational program need to be studied carefully.

**Objectives:** To analyze what patients know about rheumatoid arthritis, and determine with this nosology want to be trained in various educational programs?

**Methods:** A survey of 86 patients with RA of varying severity was conducted. The diagnosis of RA was established according to the (EULAR)/ACR criteria. Patients were divided into 2 groups by age: group 1 - 18-44 years old (young patients, N=43), group 2 - 45-65 years old (middle-aged patients, N= 43. The study was conducted in the General Hospital of the city of Kanash. Questioning was conducted from January to December 2021. The questionnaire consisted of 2 parts: the first part (part A) included 20 questions (2 points were awarded for each correct answer). Questions related to the relationship between the onset of the disease and hypothermia, infection, stress, injuries of the musculoskeletal the presence of rheumatoid arthritis in close relatives. The knowledge of one's own role in the process of treatment and prevention of RA was assessed. The second part of the questionnaire (part B) consisted of 6 questions. The need for obtaining information about RA and the desire of patients to be trained in various educational programs was studied. It was studied in what format they would like to study (remote or full-time) Survey data was processed in Statistical Analysis Software 15.0. Statistical significance was handled using Analysis of Variance analysis of variance.

**Results:** 43.7% of group 1 and 56.8% of group 2 correctly classified rheumatoid arthritis as a disease that occurs predominantly in women. 14.6% of young respondents knew about the role of infection in the occurrence of RA, 32.8% - middle-aged. 52.2% of middle-aged patients, 22.8% of young patients knew about the influence of heredity in the occurrence of the disease. 28.0% of young respondents knew about the negative impact of stress on the onset and course of RA, middle-aged respondents - 58.2%. 21.6% of young respondents were aware of the impact of injuries of the musculoskeletal system on the occurrence of RA compared to 55.3% of middle-aged respondents. The awareness of patients about their own role in the treatment process in group 1 was 4.2%, in group 2 - 5.4%. 10.6% of young respondents and 14.8% of middle-aged respondents consider it possible to prevent RA exacerbations. A positive factor was that 90.6% of the respondents report a need to obtain additional information about the disease.

**Conclusion:** It is necessary to actively implement various educational programs, in which more attention should be paid to the prevention of RA and the participation of the patient himself in the treatment process. Training for patients is preferable to be carried out in a distance learning format.

Conclusion: The relationship between RA and fertility seems to be misunderstood in young women with RA. Clinicians must routinely discuss this issue with these young patients to preserve their fertility by learning them the mechanisms by which RA may affect their fertility: the disease itself and medication. Appropriate information about fertility can help women in productive age reach and carry a healthy pregnancy.

AB1573-PARE | WHAT DO OSTEOPOROTIC PATIENTS KNOW ABOUT THEIR DISEASE?

P. Idrissi Zakl, H. Araibi, A. Mougui, I. El Bouchtel, 1Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Rheumatology, Marrakech, Morocco.

Background: Osteoporosis (OP) is a systemic skeletal disorder characterized by low bone mass responsible of fracture. It is a major public health problem. Knowledge assessment is an essential step in therapeutic education which could improve the management of osteoporosis.

Objectives: The objective of this study is to assess the degree of knowledge of osteoporotic patients regarding their disease as part of therapeutic education in order to improve management and develop a shared decision with the patient.

Methods: This is a cross-sectional epidemiological study conducted on osteoporotic patients at the rheumatology department of the university hospital center Mohammed VI Marrakech. Descriptive data, knowledge evaluation, patient expectations and therapeutic adherence were collected and analysed by SPSS 20. The comparison was made by the Chi-square test for qualitative variables.

Results: 137 patients were included with an average age of 63.7 years, with a female predominance (94.9% female vs 5.1% male). 70% were illiterate. 58.4% had postmenopausal OP, 36.5% secondary OP and 5.1% (n=7) male OP. 14.6% of the patients had diabetes, 9.5% had arterial hypertension, 5.8% had breast cancer under aromatase-inhibitors. 13.9% had rheumatoid arthritis and 9.5% had other chronic diseases, 16.1% were on long-term corticosteroids. 98.5% were on oral bisphosphonate and only 2 patients were on Intravenous zoledronate. 51.1% had osteoporosis for less than 2 years, 9.5% had a history of fracture with 2.9% major fractures. 9.5% of patients answered that osteoporosis was linked to bone fragility. 29.2% thought it was age-related, 26.3% had a confusion between osteoporosis and osteoarthrosis. 16.8% believed it was an inflammatory rheumatism. 81% supposed it was a silent disease. 95.6% assumed that physical activity is harmful and 32.1% had made environmental modifications. 52.6% were linked to osteoporosis, 58.4% didn’t know OP’s risk factors, 14.6% and 61.3% didn’t know any fall nor fracture related factors respectively. 8.8% had recognized aging and menopause as OP’s risk factors respectively. 9.5% had a history of fracture with 2.9% major fractures. 9.5% of patients

AB1574-PARE | "ABITARE" PROJECT – HOME FOR PATIENTS WITH RHEUMATIC DISEASES

L. S. Martin1, S. Middei2, R. Convertino2, A. Celano2. 1ASL ROMA 6 (Operative Unit of Internal Medicine and Rheumatology), Rome, Italy; 2APMARR APS - Italian National Association of People With Rheumatological and Rare Diseases, Rheumatology, Lecce, Italy

Background: Talking about home means talking about ourselves. Our home represents the "movie set" where the film of our lives is shot, and we can choose whether to be simple actors or the directors of it. The house expresses our personality, it identifies us in a unique way, like a fingerprint. Talking about our home means understanding how the way we relate to it can create well-being or discomfort.

Objectives: The objective of this project is to promote the empowerment of people with disabilities and chronic diseases. We aim to do that starting from a greater awareness of their living needs and the quality of life and self-esteem enhancements that derives from a tailor-made home.

Methods: 308 people participated in the survey and were distributed anonymous questionnaires regarding their experience at home.

Disclosure of Interests: None declared.

AB1575-PARE | DIETS AND JOINT SYMPTOMS: SURVEY OF MOROCCAN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM

N. Takhra1, T. Fatima Zahrae1, I. Berriche1, A. Anassa, K. Berrada1, F. Abourazzak2. 1Tangier, Department of Rheumatology, Tangier, Morocco

Background: The role of diet in triggering or aggravating chronic diseases, in particular chronic inflammatory rheumatism (CIR), is a question frequently asked by patients.

Objectives: The objective of our study is to investigate whether Moroccan patients report a relationship between certain diets or foods and the symptoms of the disease and also to study whether patients adopt specific eating behaviors in order to relieve their symptoms.

Methods: This is a survey based on a questionnaire that included any patient followed by CIR who presents to the rheumatology department. The questionnaire...
RHEUMATOID ARTHRITIS ASSESSMENT KNOWLEDGE QUESTIONNAIRE (RAKE) IN TUNISIAN POPULATION

S. Rekik1, Z. Zeineb1, S. Jemmali1, S. Boussaid1, S. Rahmouni1, K. Ksibi1
H. Sahli1, M. Elieuch1
1Rabta University Hospital, Rheumatology, Tunisia, Tunisia

Background: Rheumatoid arthritis (RA) is a chronic, systemic, inflammatory disease that has a very high burden on patients their families, and society. So that it is important that RA patients receive education about their disease. The knowledge of RA patients in Tunisia regarding their disease has not yet been assessed.

Objectives: The purpose of the study was to evaluate disease-specific knowledge of patients with rheumatoid arthritis by using the RAKE questionnaire (Rheumatoid Arthritis assessment Knowledge Questionnaire).

Methods: This was a cross-sectional study. Adults with RA fulfilling the ACR/EULAR criteria were asked to participate by responding to RAKE Questionnaire in the short version.

Results: A total of 28 RA patients were included: 23 females (82%) and 5 men (18%). The mean age was 58.5 years with a range of 31 to 79 years. The mean disease duration was 9.8 years. The disease duration was 0-5 years in 5 (17.8%) patients, more than 5 years in 23 (82.2%) cases. Twenty patients were housewives. Thirteen (46.4%) patients were from rural areas. Most of the patients didn't follow education programs for their RA. Twenty-two (78.5%) patients obtained information about RA from their rheumatologist. Six patients (21.5%) from other sources (neighbors, nurses, other RA patients, social media). The mean time for answering the questionnaire was 11.6 min (9-15 min). The RAKE total score was 118.832 [3-22]. For the initial part of the questionnaire, related to the general aspects of RA, the mean score was 4.38 [0-6]. The mean score of the second component of the questionnaire concerning medications and non-pharmacological management, was respectively 4.31 [0-7] and 2.35 [0-4]. For comorbidities, the mean score was 0.61. The last component includes auto-management, pain, and tiredness, the mean score was 1.43 [0-3]. The last component covers psychosocial, occupational, and health system coping skills. Its mean score was 2.14. The mean score of unknown answers was 6.732 [4-16].

Conclusion: In our study, the knowledge of patients of RA was low in all domains of RAKE questionnaire at various degrees. These findings can be used for improving current patient education programs and better disease control.

ADJACENT ANATOMIC ASPECTS OF THE ACROMEGALIC GLAND

C. Abdennour1, N. Bentahila1, B. Abdesselem1, F. Mhenni1
1IRCC, Departement of Endocrinologie, France

Background: The acromegalic gland is an anatomically and functionally different entity within the pituitary gland. The aims of this study were to investigate the clinical and anatomical aspects of the acromegalic gland and identify the potential clinical implications.

Methods: The study included 100 consecutive patients with acromegaly who underwent pituitary surgery over a 10-year period. Radiological evaluation was performed using preoperative magnetic resonance imaging (MRI) scans. The surgical approach was determined based on the anatomical considerations and clinical presentation.

Results: The mean age of the patients was 47 years (range: 20-70 years). The majority of patients (84%) presented with typical clinical features of acromegaly, including acral overgrowth, coarse facial features, and gigantism. The acromegalic gland was identified in all patients, with an average size of 3.2 cm x 2.1 cm x 1.8 cm. The gland distribution was anterior in 70% of cases, posterior in 20%, and bilateral in 10%. The surgical approach varied based on the gland's location and size, with transsphenoidal microsurgery being the most common (60%). Postoperative MRI showed complete resection in 90% of cases, with minimal residual disease in the remaining 10%.

Conclusion: This study highlights the anatomical variations of the acromegalic gland and suggests that these variations may influence surgical approaches and outcomes. Further research is needed to investigate the long-term clinical implications of these findings.

Disclosure of Interests: None declared.

DO MOROCCAN PATIENTS DISCUSS WITH THEIR RHEUMATOLOGISTS ABOUT DIET AS PART OF THE MANAGEMENT OF THEIR OSTEARTHRITIS?

N. El Mansouri1, T. Fatima Zahrae1, R. Bensaid1, N. Tahri1, H. Fouzia1, B. Khadj1, F. Abourazzak1
1Tangier, Department of Rheumatology CHU Tangier Tetouan Al Hoceima, Tangier, Morocco

Background: The question of diet is frequently asked by patients with osteoarthritis. Beyond the effect of weight on the worsening of their symptoms, patients often ask whether certain foods, labelled as inflammatory or anti-inflammatory, can improve or worsen their disease.

Objectives: The aim of our study is to find out whether patients with osteoarthritis discuss diet during their medical visits and to investigate the association between patients’ reported dietary beliefs and practices and their willingness to discuss them.

Methods: This is a survey based on a questionnaire that included all patients followed for osteoarthritis who presented to the rheumatology department. The questionnaire consists of 3 parts:

1. Socio-demographic data, co-morbidities, and information on osteoarthritis (location, duration of evolution, functional impact and treatments)
2. Patients’ beliefs and attitudes about diet in relation to osteoarthritis
3. Discussions about diet during medical visits and whether there is any patient interest in such discussions.

Results: In total, we included 120 patients. The average age was 57.1 ± 11.8. 88.3% of the patients were women, 41.2% had comorbidities, 62.5% were illiterate. The median duration of evolution of osteoarthritis was 4 years [2; 7]. 64.2% of the patients were followed for Gonarthrosis, 25% for Discarthrosis and 10.8% for Digital osteoarthritis. The average BMI was 27.8 ± 5.2. 83.3% of the patients thought that diet influenced their osteoarthritis. 9.5% of the subjects stated that food had an effect on their symptoms, with 9.2% reporting an improvement and 8.3% an aggravation. 6.7% of patients reported food avoidance behaviours, while 10.8% adopted certain diets in order to relieve joint symptoms. Only 2.5% of the patients reported having ever had discussions about diet with their rheumatologists while 99.2% showed interest in such discussions. For those who had never done so, the main reason was that the rheumatologist had never broached the subject. In uni and multi-variate analysis, the experience of a food that improves symptoms (OR: 13; 95% CI [1,258-134,333]; p=0.019) and the adoption of dietary practices (OR: 13; 95% CI [1,258-134,333]; p=0.019) were associated with discussing diet.

Conclusion: Discussions about diet are reported by a minority of osteoarthritis patients and seem to be mainly related to patients’ experiences with certain foods that improve their symptomatology and also to patients’ adoption of certain diets. This situation needs to be improved as nutritional advice should be an integral part of the management of our patients.

Disclosure of Interests: None declared.

A PATIENT-REPORTED OUTCOME SCALE: RASQ FOR MEASURING SYMPTOMS OF RHEUMATOID ARTHRITIS

S. Rekik1, Z. Zeineb1, S. Boussaid1, S. Rahmouni1, J. Jemmali1, K. Ksibi1, H. Sahli1, M. Elieuch1
1Rabta University Hospital, Rheumatology, Tunisia, Tunisia

Background: Patient-reported outcome (PRO) instruments are used to assess the patient experience of rheumatoid arthritis (RA) symptoms and impacts and can capture RA treatments effects. Also, there are often discrepancies between patient reported and physician perspectives.

Objectives: The objective of our study was to proceed with a psychometric evaluation of patients with RA using the Rheumatoid Arthritis Symptom Questionnaire (RASQ).

Methods: Adults with clinically confirmed RA, as defined by the ACR/EULAR criteria, were recruited for this cross-sectional study, and then completed the RASQ. Medical records were reviewed, clinical features, studies, and outcomes were analyzed.

Results: In total 28 subjects (82% females) with RA were included. The mean age was 58.5 years (31-79 years). Comorbidities were present in 46.4%, diabetes (25%), thyroid disease (3.7%), and depression (7%). The mean duration of RA diagnosis was 9.8 years. Almost all the patients had at least one of the disease severity criteria, high level of CRP (76%), radiographic erosion (96%), C1-C2 involvement (18%), or hip involvement (14.2%). All of the patients received CsDMARDs and biological therapy. Disease activity evaluated by the DAS28 score was in remission or very low disease activity in 38%, moderate (46%), and high (16%). Functional impact evaluated by the Health Assessment Questionnaire (HAQ) was an average of 1.1 (0.2-3). The RASQ total symptom score was 2 (0-10). The mean of each item was joint pain (5.4), joint warmth (4.3), joint stiffness (4.1), joint tenderness (4.1), joint warmth (4.3), muscle pain (5), joint tenderness (4.5), joint stiffness (6), joint swelling (5.5), joint pain (5.3). The RASQ total symptom score was statistically significantly different (p<0.01) across the DAS28 severity rankings but only the first two single items of the RASQ were not statistically significantly different (p=0.9 and p=1.6). A medium positive correlation was found between subjects’ HAQ score and the total symptom score of the RASQ (r=0.38).

Conclusion: The primary goal of treating patients with RA is to maximize the long-term health-related quality of life. In this order, measurement of all of the signs and symptoms of RA that are significant and relevant to patients living with the disease is important to achieve this main objective.
The effects of a health education programme on patients’ symptoms and lifestyle changes in patients with knee osteoarthritis attending a tertiary care clinic in Sri Lanka

S. Janagan1, R. M. Wickramarachchi2, M. De Silva1. 1National Hospital of Sri Lanka, Rheumatology, Colombo, Sri Lanka

Background: Osteoarthritis is the major cause of joint pain and disability among middle aged and elderly with no disease specific treatment. Management includes analgesics, lifestyle changes and physical therapy.

Objectives: We aimed to study the demographics of the patients and knowledge regarding osteoarthritis among those who attended our clinic with mechanical knee pain and the effects of a health education programme.

Methods: Patients complaining of mechanical knee pain who were found to have examination findings suggestive of knee joint osteoarthritis were enrolled in this study (N=150). Where available diagnosis was confirmed by radiography. Data was collected when they attended a health education programme which focused on lifestyle changes in osteoarthritis including diet and exercise (n=76). An inter-viewer administered questionnaire regarding disease, dietary changes for reduction of weight and exercise was used to obtain data before and 3 months after the health education programme. Anthropometric measurements were taken using validated instruments. Data was analyzed using SPSS software.

Results: Response rate was 50.67 %.The average age of the study population was 54.8 years and constituted of 92.1 % females. About one fifth of them had received only primary school and 50 percent were unemployed. The average BMI was 29.68 (SD-5) and average WOMAC score was 44.1 (SD -19.4). Their knowledge of healthy dietary habits, primarily to lose weight and exercises for knees were assessed before the health education programme and 3 months later.

Table 1.

</table>

There was no statistically significant correlation between WOMAC score and age, educational level or BMI. Though the knowledge regarding disease and lifestyle changes improved significantly (p< 0.05) following the health education program, there was no significant difference in the WOMAC score.

Conclusion: Health education was seen to improve the knowledge regarding disease and lifestyle measures despite no significant improvement in the pain or disability scores. Further studies are needed to see the long term effects of health education.

Attitudes towards medications and commonly reported side effects to DMARDs in rheumatoid arthritis patients attending a tertiary care hospital in Sri Lanka

S. Janagan1, M. De Silva1. 1National Hospital of Sri Lanka, Rheumatology, Colombo, Sri Lanka

Background: Rheumatoid arthritis (RA) is a chronic multisystem disease which can be controlled with disease modifying anti-rheumatic drugs (DMARDs). Compliance to treatment can be affected by attitudes to medicines and side effects of drugs.

Objectives: To identify attitudes towards medicines in patients with rheumatoid arthritis and its relationship to disease characteristics and identify the side effect profile of commonly used DMARDs in a Sri lankan population.

Methods: A cross sectional study was carried out on patients attending a rheumatology clinic at National hospital of Sri Lanka between August to November 2018. Patients diagnosed with RA based on standard criteria and on DMARDS for more than 3 months were administered an interviewer administered questionnaire regarding sociodemographic and beliefs about medicines questionnaire (BMQ) assessing patients’ attitudes to the necessity of prescribed medication for controlling their disease and their concerns about potential adverse consequences of taking it. Further questions about commonly reported side effects were also asked. Data was analysed using SPSS software.

Results: 160 patients fulfilled our inclusion criteria and the response rate was 75%. The study population consisted of 84% females with an average age of 52 years. They were predominantly Sinhalese (82 %) with a median duration of disease of 10 years (Interquartile range 1-6-18.4 years). Three fourths of them were seropositive. The mean disease activity (DAS-28) was 4.03 (SD-1.29). Respondents indicated their degree of agreement with each statement in the BMQ on a five-point Likert scale, ranging from 1 = strongly disagree to 5 = strongly agree.

The first ten questions specifically asked regarding arthritis medication.

The overall necessity scale score (mean 19.2, S.D. 3.21) was higher than the concerns scale score (mean 14.86, S.D. 3.89; P<0.01) but was not statistically significant. The overall necessity scale score was found to be significantly correlated with duration of disease (p<0.05) but not with age, sex, seropositivity or disease activity. 59.2 %, 13.4 %, 8.2 %, 6.1 % of the patients were on monotherapy with Methotrexate. Leflunomide, Sulphasalazine, HCO respectively, 12.8 % were on combination methotrexate and leflunomide and remainder were on biologics. The commonest side effects noted on methotrexate were leucopenia, loss of appetite, raised liver enzymes, oral ulcers, hair loss which were 30 %, 21 %, 8 %, 7 % and 11 % respectively. Patients on leflunomide reported raised BP, raised liver enzymes, loss of appetite and leucopenia in 30 %, 14 %, 8 % and 6 % respectively. Patients on both reported raised liver enzymes, leucopenia, loss of appetite in 78 %, 60 %,11 % respectively. Sulphasalazine caused anaemia, leucopenia and insomnia in 23 %, 17 %, 8 % respectively. HCO caused pigmentation and maculopathy at 17 % and 9 % respectively.

**Conclusion:** Though a positive attitude towards their medication was seen in most patients with rheumatoid arthritis, they had concerns regarding potential long-term effects and dependency. This was found to be significantly correlated to duration of disease. Educating patients about their medication and clarifying misconceptions will improve compliance and disease outcomes. Side effects noted were similar to western population but GI side effects were notably less.

### Building patient led organisations

**AB1582-PARE**

**ASSIGNING A VALUE TO THE ‘PASS’ CONCEPT IN PSORIATIC ARTHRITIS PATIENTS: A SINGLE CENTER DATA.**

R. Reji1, S. K. C.1, S. Joemo C.1, R. R.1, P. Shenoy1, A. J. Mathew2. 1Centre for Arthritis & Rheumatism Excellence, Rheumatology, Ernakulam, India; 2Christian Medical College, Department of Clinical Immunology and Rheumatology, Vellore, India

**Background:** Psoriatic arthritis (PsA), a chronic, heterogeneous disease, needs long-term management. The concept of Patient acceptable symptom state (PASS), evaluated with a dichotomized question on patients' overall satisfaction with their current state of symptoms, represents the overall health state at which patients consider themselves well. Therapeutic compliance improves when the patient's perspective of wellness is recognized while modifying treatment.

**Objectives:** To identify cut-off points for composite disease activity scores (DAS) and patient reported outcomes (PROs) that can reciprocate the PASS status of a patient with PsA.

**Methods:** A cross sectional study was conducted in patients with PsA attending a rheumatology centre in Kerala between March 2020 and Aug 2021. Baseline demographics, clinical characteristics, composite DAS (disease activity index for PsA (DAPSA), clinical (c) DAPSA) and PROs (PsA impact of disease (PsAI), patient pain visual analogue scale (VAS), patient global assessment (PGA), 12-item short-form survey (SF-12)) were compared in patients who responded ‘yes’ and ‘no’ to the ‘PASS’ question. Cut-off values for PASS in composite DAS and PROs were quantified using the Receiver Operator characteristic curve (ROC) curve. Regression models assessed the impact of different variables on the PASS status.

**Results:** From a total of 314 patients, 302 who fulfilled the inclusion, exclusion criteria were chosen for analysis. Of them, 171 (56.62%) patients were males. Mean age (S.D.) and median disease duration (range) were found to be 50.50 ±11.77 years and 8 (4-14) years respectively. Among the study patients, 215 (70.46%) had acceptable PASS status. Median values for composite scores and patient reported characters in patients who accepted their symptoms and in patients who did not accept their symptoms, are represented in Table 1. Cut-off values for patient pain VAS, Pat GA, DAPSA, cDAPSA and PsAI, with the best trade-offs between sensitivity and specificity, were found to be 175, 25, 10.95, 4.75 and 1.95, respectively (Figure 1A and B). Patients with active psoriatic lesions indicated by higher PASS score, presence of nail involvement, and moderate to high disease activity DAPSA value tended not to attain PASS (OR: 0.793; 95% CI: 0.67-0.93, OR: 0.438; 95% CI: 0.22-0.87, OR:0.168; 95% CI: 0.081-0.349).

**Conclusion:** The determined cut-off values for PASS lay in the low disease activity range. A significant number of patients who did not attain PASS, received treatment intensification. Patients with increased PASI, presence of nail dystrophy, and moderate to high disease activity DAPSA value tended to not accept their state.

QUALITATIVE INTERVIEWS OF SYMPTOMS, IMPACTS AND SELECTED PROMIS SHORT FORMS: A STUDY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

A. Findley1, J. Middlehurst1, C. Howse1, M. Clifford, W. Neill1, S. Tatlock1, W. H. Chen2, M. Bracher3, D. Patel4, Adelphi Values, Patient-Centred Outcomes, Bollington, United Kingdom; GxalxoSmithKline, Specialty Care, General Medicines & Vaccines, Collegeville, United States of America; "GxalxoSmithKline, Global Value Evidence & Outcomes, Stevenage, United Kingdom; "GxalxoSmithKline, Global Value Evidence & Outcomes, Collegeville, United States of America

Background: Axial spondyloarthritis (axSpA) is characterised by inflammation of the sacroiliac joints and spine. Sleep disturbance, pain and fatigue are reported in the literature to be key symptoms and impacts of axSpA. Three customised Patient-Reported Outcomes Measurement Information System (PROMIS) Short Forms (Sleep Disturbance, Pain Interference and Fatigue) have been developed for use in patients with axSpA to assess the key concepts.

Objectives: To conduct in-depth qualitative interviews to further understand the patient experience of axSpA and evaluate the content validity of the three PROMIS Short Forms to support their use as endpoints in axSpA clinical trials.

Methods: A non-interventional, cross-sectional qualitative (concept elicitation [CE] and cognitive debriefing [CD]) study was conducted in 28 adult patients with diagnosed axSpA. The radio-graphics were conducted as anykylosing spondylitis (AS, n=12), and non-radiographic axSpA (nr-axSpA, n=16). Patients took part in 90-minute telephone interviews. A semi-structured interview guide was used to assist discussions. The CE section used broad, open-ended questions to elicit information about symptoms and impact experienced by patients. The CD section involved a ‘think-aloud’ exercise in which patients read out each instruction, item and response option for the three PROMIS Short Forms and shared their feedback. Patients were also asked detailed questions about the relevance of the items, response options and recall period. Verbatim interview transcripts were subject to thematic and content analysis.

Results: Patients were from the United States (n=20) and Germany (n=8), mean age was 52.8 years, and 57% (n=16) were male; mean time since diagnosis of axSpA was 9.5 years (range 0.3–31.3 years). The CE section identified 12 distinct signs and symptoms that characterised patients’ experience of axSpA: pain, sleep problems, fatigue/tiredness, stiffness, swelling, vision/eye issues, restricted body movements, headache/migraine, spasms, change in posture/stature, balance/coordination problems and numbness. Pain, sleep problems and fatigue/tiredness were all reported to be experienced by ≥90% of patients, occurring simultaneously and exacerbating one another. 78% (n=21/27) of patients reported pain to be the most bothersome symptom, and 88% (n=23/26) described it as the symptom they would most like treatment to improve. Patients reported axSpA to impact their lives across six health-related quality of life (HRQoL) domains: physical functioning (100%), emotional wellbeing (88%), work/volunteering (79%), social functioning (75%), activities of daily living (61%) and cognitive functioning (54%). Impacts were most frequently described as being associated with pain, stiffness and fatigue. The experiences of symptoms and impacts were consistent between the AS and nr-axSpA patients. CD showed all three PROMIS instruments are conceptually comprehensive and well understood by patients with axSpA. No patients reported misunderstanding of instructions and/or items of the sleep disturbance instrument, and only one and four items had a small number of instances of misunderstanding for the fatigue and pain interference instruments, respectively. Across each instrument, all items were relevant to at least half of patients, and almost all patients reported the instruments to be appropriate for measuring their experience of sleep problems, pain and fatigue due to axSpA. Both AS and nr-axSpA patients confirmed the three PROMIS Short Forms to be relevant and appropriate for assessing their disease experience.

Conclusion: Pain, sleep problems and fatigue are pivotal symptoms of axSpA and associated with HRQoL impacts. Interpretability and content validity of the PROMIS customised Short Forms have been confirmed, with each deemed to adequately assess key impacts associated with axSpA, making them suitable for use in clinical trials of patients with axSpA.

UNDERSTANDING HETEROGENEITY IN PATIENTS’ CONCEPTUALIZATION OF TREATMENT FOR RHEUMATOID ARTHRITIS: A CLUSTER ANALYSIS

B. Hsiao1, J. Downs2, M. Langoy3, J. R. Curtis4, S. Blaoc5, C. Wiedmeyer6, S. Venkatachalam5, W. B. Nowell5, L. Fraenkel6,7, Yale-New Haven Medical Center, Rheumatology, New Haven, United States of America; 1University of Alabama at Birmingham, Division of Clinical Immunology & Rheumatology, Birmingham, United States of America; 2University of North Carolina, Chapel Hill, Division of Pharmaceutical Outcomes and Policy, Chapel Hill, United States of America; 3Global Healthy Living Foundation, Patient-Centered Research, Upper Nyack, United States of America; 4Berkshire Medical Center, Rheumatology, Lenox, United States of America; 5Yale University, School of Medicine, New Haven, United States of America

Background: Uptake of treat to target strategies for the management of rheumatoid arthritis (RA) is low. System-related barriers to accessing treatment are known, but poor adherence to starting and continuing treatment are prevalent causes of suboptimal care.

Objectives: To better understand heterogeneity in patients’ conceptualization of RA treatment to inform interventions aimed at improving appropriate utilization of disease modifying antirheumatic drugs (DMARDs).

Methods: Participants (pts) were recruited from the ArthritisPower US online research registry. Pts who met eligibility criteria [physician diagnosed RA currently being treated with DMARD(s)] rated 56 items (coded on 5-point scales) reflecting concepts raised during in-depth patient interviews. To combine similar items for ease of analysis and interpretation, we conducted a principal component analysis using Varimax rotation. We then entered mean scores, weighted by how heavily each item loaded on a cluster, into a k-means cluster analysis. We examined whether demographic characteristics differed across clusters using ANOVA for continuous and chi-square for categorical variables.

Results: Pts (N=621) ranged in age from 22 to 93, with a mean of 57 years (SD=11.5). Most (89%) were female and reported as non-Hispanic white (89%); 27% reported having a post-graduate degree. A score plot revealed that a 4-factor solution explaining 36.8% of the variance would provide desirable interpretability, with a discontinuous drop in eigenvalues for additional factors slowly tapering and adding little discriminability between later solutions. The four factors (% variance explained, number of items) were: 1) Access to high quality care and support (12.10%, n=21); 2) Comfortable adding/switching DMARDs (9.73%, n=14); 3) Perceived favorable DMARD risk/benefit ratio (8.74%, n=15); and 4) Confidence that testing reflects disease activity (6.20%, n=6). A 5-cluster solution showed the most stable convergence of cluster centers after 10 iterations. Figure 1 shows the weighted mean scores for each factor across clusters. The largest group (31.7%) is characterized by mean scores on each of the four factors toward the high end of mean responses for the sample, reflecting positive experiences; we labeled this group “Successfully Engaged in Care” to indicate a positive rheumatologist relationship, feeling well-informed and active participation in care. The next group (24.3%) also had high scores for Factor 1 (access to high quality care/support) and Factor 3 (perceived favorable DMARD risk/benefit ratio), but were less comfortable adding/switching DMARDs (Factor 2) and had less confidence in testing their disease activity (Factor 4); we labeled this group “Worried About Medication” . The three remaining clusters are smaller. The third cluster (16.4%), labeled “Skeptical of Testing,” had a favorable view of DMARDs (Factor 3) despite lower scores related to access and quality of care (Factor 1) and confidence in testing (Factor 4). The fourth cluster (14.3%) expressed low perceived value of DMARDs as well as reduced scores for DMARD risk/benefit and confidence in testing; we labeled this group “Resistant to DMARDs.” The last cluster (13.2%) scored lowest on their rating of access to high quality care and support, indicating less access to, and satisfaction with, information needed to...
about treating to target specific to RA. The survey was made available on tablet devices in 4 rheumatology clinics in the U.S. and Puerto Rico. Clinic staff obtained patient consent and gathered demographic information to generate a unique confidential identifier code for each visit, which was inputted into surveys on tablet devices. After the visit ended the patient and rheumatologist were each given the PPQ coded for that visit to complete independently of one another. The PPQs were submitted electronically to a secure database in which the visit code was the only identifier recorded.

**Results:** Across 114 clinical visits, 96.75% of possible answers were recorded and were almost invariably positive with scores of 5 (strongly agree; 88%), 4 (agree; 12%), or 3 (neither agree nor disagree; 0.09%).Physicians responded with 4 (agree) more often than patients (18% vs 6% of responses). Responses from both patient and physician were available for (96.64%) of answered questions. Within these paired answers, 80.67% were concordant (same answer from both patient and physician). Physicians answered 4 when patients answered 5 in 76.5% of discordant responses (different ratings from patient and physician). Most physician ratings of 4 came from 1 of the 4 physicians involved and only 12.5% of patients were responsible for 75% of the patient responses of 4.

**Conclusion:** Hispanic/Latinx patients with RA and their rheumatologist rated their communication, goal setting, and relationships extremely positively, making it difficult to evaluate true concordance and not possible to use rheumatologist-completed PPQs as proxy for patient assessments. Notably, ratings were substantially different from what is typically seen on Likert scales, which normally skew positively but with a normal distribution. This finding may reflect social determinants of health or cultural differences such as a social-desirability bias toward positive statements about physician-patient interactions. Heterogeneity within the participants is also a plausible explanation, considering that a distinct subset of respondents account for almost all responses below the 5 rating. Further research is needed to identify best practices for measuring treatment to target and patient-rheumatologist interactions in the Hispanic/Latinx population with RA.

**AB1585-PARE**

**DO PATIENT AND PHYSICIAN ASSESSMENTS OF A HEALTH CARE VISIT MATCH FOR HISPANIC/LATINX PATIENTS WITH RHEUMATOID ARTHRITIS IN THE UNITED STATES AND PUERTO RICO?**

**D. Hernandez1, J. Bravo2, J. J. Maya3, O. Soto-Raíces4, A. Tapia5,**

G. Valenzuela5, W. B. Nowell5, S. Venkatachalam5, Global Healthy Living Foundation, Medical Affairs and Hispanic Outreach, Nyack, United States of America; 6Novartis Health Westbrook, Rheumatology & Arthritis, Winston-Salem, United States of America; 7Rheumatology Center of Palm Beach, PLLC, Lake Worth, United States of America; 8Shilpa Venkat-chalam Mindful Rheumaxtix and Medical Research Group, Rheumatology, San Juan, Puerto Rico; 9Integral Rheumatology and Immunology Specialists, Rheumatology, Plantation, United States of America

**Background:** Nonlinear associations in rheumatoid arthritis (RA) prevalence and sociodemographic indices suggest social determinants of health affect RA.1 RA screening tools have lower sensitivity and specificity for Hispanic/Latinx individuals compared with white individuals (77% vs 85% sensitivity and 45% vs 87% specificity).2 Hispanic/Latinx people also present to physicians later and with more severe RA.3 There is little research in this population to explain these differences or how they can be addressed. Because it is known the Hispanic/Latinx population has lower English-language proficiency, we hypothesized this is in part because of the lack of validated Spanish-language educational materials and research tools for RA.

**Objectives:** To validate a Spanish-language patient-provider questionnaire (PPQ) for Hispanic/Latinx patients with RA that had previously been validated as concordant for primary care visits in Sweden.4 To understand if rheumatologist and patient assessments for Hispanic/Latinx people with RA are concordant when using a Spanish-language digital PPQ. To determine if a Spanish-language rheumatologist-completed PPQ could be a proxy for patient impressions in a prospective clinical study.

**Methods:** A Spanish-language PPQ for RA was created by translating 9 of 13 questions previously validated in the Swedish study,5 and adding a question

**Results:** When using a Spanish-language digital PPQ, determinants of health affect RA.1 Match for Hispanic/Latinx patients with RA and their rheumatologist rated their communication, goal setting, and relationships extremely positively, making it difficult to evaluate true concordance and not possible to use rheumatologist-completed PPQs as proxy for patient assessments. Notably, ratings were substantially different from what is typically seen on Likert scales, which normally skew positively but with a normal distribution. This finding may reflect social determinants of health or cultural differences such as a social-desirability bias toward positive statements about physician-patient interactions. Heterogeneity within the participants is also a plausible explanation, considering that a distinct subset of respondents account for almost all responses below the 5 rating. **Innovations in arthritis health care.**
Background: AVT02 is an investigational biosimilar to adalimumab. It is approved in Europe, Canada, and the UK. It is not approved by the US Food and Drug Administration (FDA).

Methods: This was a Phase 1, randomized, open-label, parallel-group study in which 207 healthy adult subjects were randomized in a 1:1 ratio to receive 100 mg/mL AVT02 either via a pre-filled syringe, or with an autoinjector, stratified by body weight. Subjects received a single subcutaneous 40 mg dose on Day 1. Pharmacokinetics, immunogenicity, local injection site reactions, and adverse events were assessed prior to, and up to 64 days after, study drug administration.

Results: The results observed supported the assessment of pharmacokinetic similarity of investigational AVT02 administered by pre-filled syringe or with an autoinjector. The 90% CIs for the ratios of geometric least square means for the primary pharmacokinetic parameters $C_{\text{max}}$, $AUC_0^\text{inf}$, and $AUC_0^\infty$ were contained within prespecified margins 80% and 125%, based on an analysis of variance model with treatment as a fixed effect. The mean serum concentration-time profile of adalimumab by treatment group is shown in Figure 1.

Figure 1. Mean Serum Concentration-Time Profile of Adalimumab by Treatment Group on Semilogarithmic Scale (Pharmacokinetic Population)

Binding anti-drug antibodies were detectable at the end of study visit on Day 64 in 100% and 97.0% of subjects in the pre-filled syringe administration and the autoinjector groups, respectively. Of those subjects positive for anti-drug antibodies, 85.7% and 86.5% further tested positive for neutralizing antibodies in the pre-filled syringe administration and autoinjector groups, respectively. The frequency of local administration site reactions was 11.8% overall and similar between treatment groups. The most frequently reported treatment-emergent adverse events in both treatment groups were under the SOC: Infections and infestations (56.0% in the AVT02-pre-filled syringe group and 45.2% in the AVT02-autoinjector group). The safety profiles were generally similar between treatment groups.

Conclusion: The results observed supported the assessment of pharmacokinetic similarity between the pre-filled syringe and autoinjector delivery systems after a single subcutaneous 40 mg dose. The autoinjector delivery system was generally well tolerated in healthy subjects, with a safety and immunogenicity profile similar to that observed with 100 mg/mL AVT02 administered using a pre-filled syringe. ClinicalTrials.gov Identifier: NCT03983876

Disclosure of Interests: To evaluate the pharmacokinetic similarity of 100 mg/mL AVT02, an investigational biosimilar of adalimumab, when administered either via a pre-filled syringe, or with a newly developed autoinjector in healthy adult subjects.

Disclosure of Interests: None declared.

Work and rehabilitation

INFLUENCE OF COMPLEX KINESIOThERAPy ON METABOLISM IN CASES OF SARCOPENIC OBESITY

V. Vasileva, L. Marchenkova. National Medical Research Center of Rehabilitation and Balneology, Department of Somatic Rehabilitation, Reproductive Health and Active Longevity, Moscow, Russian Federation

Background: exercise is one of the main factors for the successful treatment of obesity. It is known that with increasing age, muscle strength (sarcopenic obesity) decreases in an obese patient, which can lead to early disability. Regular exercise therapy increases the functional capacity of the metabolism, prevention of obesity among the population, as well as treatment for persons with sarcopenia and obesity. Therefore, it is relevant to study in metabolism obese patients while using kinesiotherapy.

Objectives: aim of the study was to estimate the effect of complex 3-week treatment with 4 kinesiotherapy methods on body weight loss and carbohydrate metabolism in patients with obesity.

Methods: 80 people were enrolled in the study. 40 people in the first group (G1) - 26-69 years old with alimentary obesity (mean age 53.7 ± 11 years, weight 106.8 ± 25 kg, BMI 38.3 ± 7.4 kg/m², waist circumference WC 110.6 ± 16 cm, hip circumference HC 121 ± 15.3 cm). 40 people in the second group (G2) - 21-68 years old with alimentary obesity (mean age 51.3 ± 11 years, weight 112.7 ± 25 kg, BMI 41.8 ± 8.2 kg/m², WC 113.6 ± 16 cm, HC 126.3 ± 15.1 cm). Complex kinesiotherapy administered daily for 3 weeks and included interactive sensorimotor training on double platform, a special complex of physical exercises in the gym and ergocycle trainings. In addition, in 2 gr. patients additionally included kinesiohydrotherapy in a pool. Weight, WC, HC, carbohydrate tolerance test (TT HC), insulin last 3 weeks was measured at baseline and after the treatment was completed. Evaluation of the results were performed at baseline and in 3 weeks.

Results: there was a significant improve in body weight in two groups (110 ± 24 kg at baseline vs 107 ± 22.5 kg in 3 weeks; p = 0.000), BMI (40 ± 8 vs 39 ± 7.6 kg/m²; p = 0.000), WC (112 ± 15.9 vs 108.1 ± 15 cm; p = 0.000), HC (124.3 ± 15.4 vs 119 ± 14 cm; p = 0.000) in treated obese patients. After 3 weeks, we registered statistically significant elevation in insulin levels of G2 vs to G1. With Z = 2.63 in G1, p = 0.003 and Z = 1.96, p = 0.002 in G2, and Z = 2.87 when assessing the significance elevation between G1 and G2, p = 0.023. Significantly improved performance of TT HC in 1 g, Z = 2.02, p = 0.04, in 2 g, Z = 3.004, p = 0.002. When assessing the significance of differences between G1 and G2 after treatment, Z = 2.3, p = 0.017.

Conclusion: Complex treatment with 4 methods of kinesiotherapy helps to reduce body weight, reduce WC, HC, insulin, TT HC in obesity. However, patients who additionally received kinesiohydrotherapy in a pool showed more significant improvements in metabolism.
