Serious and cutaneous involvement was similar between groups. The presence of arthralgia was also similar (ns) but there were statistically significant differences with the presence of arthritis (p<0.008). Severe hematologic manifestations were also more frequent in Latin American patients but only statistically significant for autoimmune hemolytic anemia (AIHA). Lupus nephritis and end-stage renal disease (ESRD) were two-fold and four-fold more common in Latin American patients. Among the immunological findings: hypocomplementemia, Anti-Sm, and anti-histones were differential markers between the two groups. Anti-RNP was also more frequent in the Latin American group (ns).

Methods: There were also no disparities in outcomes measured by activity (SLEDAI), clinical history. Considering the progression of RF among patients with positive aPLs, the occurrence of flare was retrospectively reviewed from the date of SLE diagnosis to the date of last follow-up. Multivariable Cox regression analysis was conducted to estimate the hazard ratio (HR) and 95% confidence interval (CI) of SLE flare, according to the positivity of autoantibodies. Multivariable model was adjusted for sex, age at SLE diagnosis, positivity of other autoantibodies, SLEDAI-2K at diagnosis, use of immunosuppressants.

Results: Among the 228 patients, flare occurred in 179 (78.5 %) patients during 635.0 person-years of follow-up (incidence rate: 28.2/100 person-years). Of the 179 flares, 92 were severe flares (necessitating use of glucocorticoid dose >20mg of prednisolone or equivalent, and/or addition of immunosuppressants), whereas 87 were mild-to-moderate flares (necessitating use of glucocorticoid dose <20mg of prednisolone or equivalent, and no addition of immunosuppressants). In the multivariable Cox regression analysis, anti-dsDNA Ab positivity (adjusted HR 1.46, 95% CI 1.04–2.05, p = 0.031) and anti-Sm antibody positivity (adjusted HR 1.73, 95% CI 1.16–2.59, p = 0.007) were significantly associated with a higher risk of SLE flares.

Conclusion: Patients with SLE who are positive for anti-dsDNA Ab or anti-Sm Ab at diagnosis have a higher risk of SLE flare during the course of their disease. Careful monitoring of disease activity and prompt adjustment of therapy accordingly could be helpful in these patients.

AB0505 RISK OF SYSTEMIC LUPUS ERYTHEMATOSUS FLARES ACCORDING TO THE POSITIVITY OF AUTOANTIBODIES

O. C. Kwon1, 2, M. C. Park1, 2, 3

1Yonsei University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by excessive production of pathogenic autoantibodies. A variety of autoantibodies can be detected in patients with SLE. Presence of particular autoantibody is known to be associated with specific manifestations of SLE: anti-dsDNA antibody (dsDNA Ab) with renal involvement and overall disease activity, anti-Sm Ab with renal involvement, anti-Ro Ab with cutaneous lupus and neonatal lupus, anti-La Ab with cutaneous lupus and neonatal lupus, and anti-U1RNP Ab with Raynaud’s phenomenon and pulmonary hypertension. However, little is known about the association between positivity of each autoantibody and risk of SLE flare.

Objectives: To assess the risk of SLE flare according to the positivity of various autoantibodies.

Methods: A total of 228 patients with SLE who fulfilled the 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for SLE were included. SLE flare was defined as an increase of SLE disease activity index-2000 (SLEDAI-2K) of more than 4 points and/or hospitalization for SLE acute exacerbation in the same year. The occurrence of flare was retrospectively reviewed from the date of SLE diagnosis to the date of last follow-up. Multivariable Cox regression analysis was conducted to estimate the hazard ratio (HR) and 95% confidence interval (CI) of SLE flare, according to the positivity of autoantibodies. Multivariable model was adjusted for sex, age at SLE diagnosis, positivity of other autoantibodies, SLEDAI-2K at diagnosis, use of immunosuppressants.

Results: Among the 228 patients, flare occurred in 179 (78.5 %) patients during 635.0 person-years of follow-up (incidence rate: 28.2/100 person-years). Of the 179 flares, 92 were severe flares (necessitating use of glucocorticoid dose >20mg of prednisolone or equivalent, and/or addition of immunosuppressants), whereas 87 were mild-to-moderate flares (necessitating use of glucocorticoid dose <20mg of prednisolone or equivalent, and no addition of immunosuppressants). In the multivariable Cox regression analysis, anti-dsDNA Ab positivity (adjusted HR 1.46, 95% CI 1.04–2.05, p = 0.031) and anti-Sm antibody positivity (adjusted HR 1.73, 95% CI 1.16–2.59, p = 0.007) were significantly associated with a higher risk of SLE flares.

Conclusion: Patients with SLE who are positive for anti-dsDNA Ab or anti-Sm Ab at diagnosis have a higher risk of SLE flare during the course of their disease. Careful monitoring of disease activity and prompt adjustment of therapy accordingly could be helpful in these patients.

AB0506  PRELIMINARY STUDY ON IMBALANCE BETWEEN TH17 AND REGULATORY T CELLS IN ANTIPHOSPHOLIPID SYNDROME

H. Yan1, B. C. Li1, R. Su1, C. Wang1.1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

Background: Antiphospholipid syndrome (APS) is a typical autoimmune disease, which can be classified into primary antiphospholipid syndrome (PAPS) and secondary antiphospholipid syndrome (SAPS) based on the presence or not of other autoimmune diseases. Disorders of peripheral blood lymphocyte and CD4+T cell subsets, especially Th17 and Treg cell subsets, may be involved in the pathogenesis of APS.

Objectives: To investigate the differences of peripheral blood lymphocyte and CD4+T cell subsets between patients with primary and secondary antiphospholipid syndrome and healthy controls, and to evaluate the correlation of antiphospholipid antibody titers and Th17/Treg values in PAPS and SAPS groups, as well as the correlation of cytokines and clinical characteristics in APS patients.

Methods: A total of 67 APS patients (12 PAPS patients, 55 SAPS patients) and 40 healthy controls were enrolled in this study. Retrospectively collected clinical and laboratory data of these patients. The absolute numbers of peripheral blood lymphocyte subsets and CD4+T cell subsets were detected by flow cytometry, and serum cytokine levels were detected by flow cytometry bead array.

Results: Compared with healthy control group, the absolute values of T [689.26 vs. 1239.00, \( p < 0.001 \)], B (104.69 vs. 177.50, \( p < 0.001 \)), NK (98.97 vs. 300.00, \( p < 0.001 \)) and CD4+T (330.16 vs. 628.50, \( p < 0.001 \)) cells in SAPS group were decreased. While only the NK cells (151.30 vs. 300.00, \( p = 0.002 \)) in the PAPS group were lower than that in healthy control group. However, the absolute values of T (1295.41 vs. 689.26, \( p = 0.011 \)), B (184.44 vs. 104.69, \( p = 0.012 \)), NK (151.30 vs. 98.97, \( p = 0.023 \)) and CD4+T cells (698.34 vs. 330.16, \( p = 0.002 \)) in PAPS group were significantly higher than those in SAPS group. For CD4+T cell subsets, PAPS patients and SAPS patients showed the same trend compared with healthy controls, showing increased Th1 (111.50 vs. 23.47, \( p = 0.002 \) and 71.43 vs. 23.47, \( p = 0.001 \), respectively), decreased Th2 (6.97 vs. 12.43, \( p = 0.037 \) and 2.49 vs. 12.43, \( p < 0.001 \), respectively) and, more importantly, decreased Treg (18.77 vs. 29.53, \( p = 0.001 \), respectively), with increased Th17/Treg ratio (0.39 vs. 0.17, \( p = 0.001 \) and 0.42 vs. 0.17, \( p < 0.001 \), respectively). Meanwhile, Th2 (6.97 vs. 2.46, \( p = 0.006 \)), Th17 (8.42 vs. 4.00, \( p = 0.042 \)) and Treg (18.77 vs. 12.01, \( p = 0.020 \)) cells in PAPS group were higher than those in SAPS group. As for the correlation study, we concluded that both aCL (\( r = 0.6061, p = 0.0405 \)) and aβ2GPI (\( r = 0.6900, p = 0.0158 \)) were positively correlated to Th17/Treg ratio in PAPS group. In addition, for APS patients, IL-2 (\( r = 0.420, p = 0.010 \)), IL-4 (\( r = 0.392, p = 0.016 \)), IL-10 (\( r = 0.331, p = 0.046 \)), IL-17 (\( r = 0.479, p = 0.006 \)) and IFN-γ (\( r = 0.339, p = 0.040 \)) were negatively correlated with titers of aCL. And IL-6 is also associated with ESR (\( r = 0.469, p = 0.004 \)) and CRP (\( r = 0.670, p < 0.001 \)).

Conclusion: Whether PAPS or SAPS patients, detection and balancing of lymphocyte and CD4+T cell subsets, especially Th17 and Treg cell subsets, may help correct immune disorders. Of course, the immune function of primary and secondary APS patients is not completely consistent, at least in terms of immune cells. Also, the role of cytokines in the pathogenesis of APS should not be ignored.

AB0507  IMPACT OF CAFFEINE CONSUMPTION ON ENDOTHELIAL PROGENITOR CELLS SURVIVAL IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

V. Ortet1, F. Cecarelli2, C. Barbati2, E. Putro1, C. Pinone1, F. R. Spinelli3, C. Alessandrini1, F. Conti1.1Lupus Clinic, Rheumatology Unit, Sapienza University of Rome, Italy, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, 00161, Italy

Background: Circulating endothelial progenitor cells (EPCs) are widely demonstrated biomarkers of endothelial function. Their frequency and function varied in systemic lupus erythematosus (SLE) patients, with a significant association with subclinical atherosclerosis. Caffeine, one of the most widely consumed products in the world, seems to interact with multiple components of the immune system by acting as a non-specific phosphodiesterase inhibitor, and it seems to be able to activate autophagy. In terms of cardiovascular disease (CVD), data from the literature showed a U-shaped association between habitual coffee intake and CVD. In this view, Spyridopoulos et al. demonstrated a significant improvement in endothelial cells and EPCs migration after coffee consumption in coronary artery disease both in mouse models and in patients. Finally, we demonstrated the impact of caffeine on SLE disease activity, in terms of SLEDAI2k values and clinical characteristics of APS patients.
serum cytokine levels. Moreover, patients with a low caffeine intake seemed to have a more severe disease phenotype.

Objectives: The aim of this study was to evaluate the role of caffeine intake on endothelial function in SLE patients, by assessing its effect on number and function of EPCs both ex vivo in SLE patients and in vitro in healthy donors (HD) treated with SLE sera.

Methods: We performed a cross-sectional study enrolling consecutive SLE patients (revised 1997 ACR criteria), referring to the Sapienza Lupus Clinic. Patients with history of traditional CV risks factors were excluded. Caffeine intake was evaluated using a 7-day food frequency questionnaire. At the end of questionnaire filling circulating EPCs were detected by using a flow cytometry analysis defined as CD34+KDR+ cells. Subsequently, EPCs pooled from 6 HD were co-cultured with caffeine at 0.5 mM and 1 mM with and without SLE sera. After 7 days, we evaluated the cells morpholology and the ability to form colonies. Moreover, we analyzed for the percentage of annexin V-positive (AV) apoptotic cells by flow cytometry analysis and for levels of autophagy and apoptotic markers LC3-II, p62 and Bcl2 by western blot.

Results: We enrolled 31 SLE patients (F:M 30:1, median age 43 years, IQR 18; median disease duration 144 months, IQR 180). The median intake of caffeine was 166 mg/day (IQR 194). We found a EPCs median percentage of 0.03% (IQR 0.04) observing a positive correlation between caffeine intake and EPCs percentage (p=0.03, r=0.4). Moving on in vitro experiments, after 7 days of cell cultures, HD EPCs treated with SLE sera and caffeine showed an improvement in morphology and in number of EPCs-CFU in comparison with those incubated with SLE sera without caffeine (p<0.0003). Moreover, the colonies treated with SLE sera were poorly organized in comparison with HD; the addition of caffeine restored the colony structure. After treated HD-EPCs with SLE sera we observed an increase in AV positive cells and p62 and LC3-II values and a reduction of Bcl2 values; the addition of caffeine was able to significantly reduce AV positive cells and p62 and LC3-II values and to significantly increased Bcl2 values, without any significant differences between caffeine 0.5 mM and 1 mM treatment (Figure 1A-D).

Conclusion: Our data demonstrated the ability of caffeine in increasing the number of circulating EPCs in SLE patients. Moreover, in vitro experiments seem to suggest a protective role of caffeine on EPCs survival and vitality through the promotion of autophagy and the inhibition of apoptosis.

AB0508 RISK FACTORS FOR DEVELOPMENT OF Atherosclerosis IN SYSTEMIC Lupus erythematosus T. Panfilova1, T. Popkova1, L. Kondrateva1, Y. Gorbunova1, E. Nasonova2. 1V.A.Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moscow, Russian Federation; 2V.A.Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation

Background: Systemic lupus erythematosus (SLE) has been strongly linked to accelerated atherosclerosis and increased cardiovascular morbidity and mortality.

Objectives: The goal is to evaluate the traditional cardiovascular risk factors (TRF), intima-media wall thickness (IMT) and cardiovascular events (CVE) in SLE patients as compared to the same-nationality populations.

Methods: This cross-sectional study included 227pts (69% females, aged 35,6±0,7years) with SLE according to SLICC/ACR 2012 criteria, attending a routine visit at our Clinic between February 2018 and February 2020. Carotid plaques were assessed by ultrasound (US). Disease duration was 132,9±7,7months, SLDEDIAI 2K-9,4±0,5, SLICC/DI-1,89±0,13 score. Briefly, 90% had a history of joint involvement, 72%-hematological involvement, 70%-nephritis, 67%-serositis, 64%-skin lesions, 48%-neuropsychiatric involvement. Out of them 82%pts were on prednison therapy at 17,3±1,0mg/day. 41%-on QC, 22%-immuno-suppressants. Forty-one (18%) patients were diagnosed with SLE for the first time and were not receiving therapy at the time of enrollment. Concomitant antiphospholipid syndrome (APS) had 24% of SLEpts: 80% of SLE+APSpts had venous thrombosis, 43%-arterial, 56%-obstetric pathology. The control group (healthy donors) was matched by age and gender (n=99, 79% females, aged 36,2±0,8years).

Results: Patients with SLE compared to controls had a higher incidence of hypertension (52% and 21%,p<0,001), triglyceride concentrations (1,60±0,07 and 0,89±0,09mmol/l,p<0,001), lower levels of high-density lipoprotein (HDL) cholesterol (1,20±0,03 and 1,40±0,04mmol/l,p<0,01) and a higher number of TRF (2,40±0,08 and 2,01±0,13,p<0,05). Following carotid US assessment, atherosclerotic plaques (IMT≥1,5 mm) occurred in 24% of SLEpts versus 5% of controls,p<0,001. SLEpts had hazard ratio (HR) of carotid plaques of 5,22 (95%CI 1,95-13,99). Clinical manifestations of atherosclerosis (CVE) were reported in 19% of SLEpts vs 2% of controls, p<0,001. Out of them coronary artery disease (CAD) was in 13% vs 2%, p=0,002, myocardial infarction (MI)-in 5% vs 1%, p<0,05, stroke – 7% vs 1%, p<0,05. SLEpts had HR of CVE of 9,16 (95%CI 2,26-37,09), of CAD - 6,54 (95%CI 1,59-26,84). In SLEpts carotid plaques were more common than in controls at the age of 30-49 years, p<0,05; clinical manifestations of atherosclerosis occurred after 40 years: CAD - at 40-49 years, stroke - >50 years, p<0,05.

No differences were found in other age groups. Patients were found to correlate CVE with age (r=0,384,p<0,001), male gender (r=0,361,p<0,001), hypertension (r=0,227,p<0,001), body mass index (BMI) (r=0,180,p=0,007), number of TRF (r=0,247,p<0,001), SLE duration (r=0,317,p<0,001), SLICC/DI (r=0,273,p<0,001), steroid use duration (r=0,255,p<0,001) and cumulative prednisolone dose (r=0,163,p<0,05).

Conclusion: The frequency of CVE (CAD, MI) and carotid plaques is higher in patients with SLE than in controls. In patients, CAD and carotid plaques were detected more frequently at the age of 30-49 years than in controls. Hypertension, hypertriglyceridemia and low HDL are the most common TRF in young SLE patients. In SLE, not only TRF and their number are associated with CVE, but also SLE duration, SLICC/DI, steroid use duration and cumulative dose.

Disclosure of Interests: None declared

Background: Ultrasound is a promising non-invasive tool in the evaluation of the salivary glands for parenchymal changes related to Sjogren’s Syndrome (SS). The OMERACT Ultrasound Grey-scale (GS) Scoring System for SS has been shown to have good sensitivity and excellent specificity for fulfilling the SS classification criteria, when a GS ≥2 in at least 1 gland was considered indicative of SS (1), however others have suggested pathology in at least 2 glands is required (2). Systematic use of ultrasound might reduce the need for labial biopsies if US findings are in agreement with biopsies.

Objectives: To assess the agreement between labial biopsy results and salivary gland ultrasound findings in patients suspected of SS.

Methods: Patients referred to our department with a suspicion of SS from 2017-2021, scheduled for a diagnostic labial biopsy were recruited. All underwent GS ultrasound of the parotid and submandibular glands bilaterally prior to clinical exam, Schirmer’s test, unstimulated salivary flow, blood samples including autoantibody analysis. Still images of the four glands were scored 0-3 using a previously developed ultrasound atlas (1) of the OMERACT ultrasound scoring system for SS (2,3). All biopsies were evaluated by a pathologist and focus score ≥1 was considered indicative of SS. Two different ultrasound scores for SS were tested: US-score ≥2 in at least 1 gland and US-score ≥2 in at least 2 glands. Descriptive statistics were used. In these analyses, we used labial biopsy as reference standard.

Results: 103 patients were included and 44 were clinically diagnosed with SS of which 42 (95%) fulfilled the 2016 ACR/EULAR classification criteria and 33 (75%) had positive labial biopsy. Demographics are shown in Table 1.

The agreement between labial biopsy and ultrasound for SS is shown Figure 1.

Figure 1

Conclusion: In patients with suspected SS, we found good agreement between US of salivary glands and subsequent labial biopsy. US of salivary glands seems useful in the diagnosis and classification of SS, but labial biopsies may still be necessary in select cases.

AB0512 COMPARISON OF SALIVARY GLAND ULTRASONOGRAPHY FINDINGS IN PRIMARY SJÖGREN'S SYNDROME VS TYPE 2 DIABETES MELLITUS

A. Kahveci1, A. Gümrüktepe1, Ş. Ataman2, 1Ankara University, Division of Rheumatology, Ankara, Turkey

Background: Primary Sjögren syndrome (pSS) is a chronic autoimmune disease that mainly affects the exocrine glands [1]. Type 2 diabetes mellitus (DM) is also an autoimmune disease involving not only the pancreas but also salivary glands. In both diseases, sicca symptoms due to different mechanisms were common [1, 2]. The use of salivary gland ultrasonography (SGUS) has become widespread in the diagnosis and follow-up of pSS [3, 4]. In DM, few US-based studies have shown abnormalities in the major salivary glands [2].

Objectives: This study aimed to compare the SGUS findings in patients with pSS and DM patients with sicca symptoms (not meet ACR/EULAR pSS criteria) were included. Demographic data and patient characteristics were obtained from medical records. Physical examination was assessed by a rheumatologist. In all patients, bilateral parotid and submandibular gland US was performed by a blinded another rheumatologist, using the Hocevar and the Outcome Measures in Rheumatology (OMERACT) scoring system. Clinic and ultrasonographic variables were compared between groups. The association between SGUS score and disease duration was analyzed by correlation analysis.

Results: Patients with pSS presented higher SGUS scores than patients with DM significantly (the Hocevar total score; 20.93(±9.65) vs 3.82(±3.71); p<0.05, the OMERACT total score; 5.96(±2.30) vs 2.07±1.65; p<0.05, respectively). In patients with pSS, the submandibular gland scores higher than the parotid gland scores while in patients with DM showed higher parotid gland scores. Other demographic data is shown in Table 1. In pSS patients, the Hocevar and the OMERACT total SGUS scores were significantly correlated with disease duration (r=0.584, p<0.01 vs r=0.518, p<0.01, respectively). This correlation was not found in patients with DM (Figure 1).

Figure 1. Correlation between SGUS scores and disease duration in two groups

Conclusion: This study demonstrated that the major salivary gland involvement was more severe, submandibular gland dominant and correlated with disease duration in pSS. Contrarily, in patients with DM, it was mild compared to pSS, parotid dominant and uncorrelated with disease duration.

AB0513

COVID-19 PREVENTION IN PATIENTS WITH MODERATE-TO-SEVERE LUPUS DURING THE PANDEMIC: RESULTS FROM THE BILAG-BILOGICS REGISTRY (BILAG-BR)

S. Dybá1, M. Rodziewicz2, E. Sutton1, B. Parker3, I. N. Bruce1,2,3

Methods: A cohort where total of 200 subjects (100SLE patients and 100 controls) were enrolled. All patients underwent a thorough medical history and clinical examination. Lupus activity was evaluated by SLEDAI-2K score. Two single-nucleotide polymorphisms (SNPs) (rs10065172 & rs4958846) were genotyped. Genotypes and Alleles analysis were conducted to compare between cases and controls as well as on the stratification analysis of presence or absence of lupus nephritis.

Results: Among selected SNPs of IRGM, no association was considered between both SNPs and SLE susceptibility. For rs10065172, the major expressed genotype was CC (61% and 71%) (Adj OR= 2.9, 95% CI=0.545-15.5) followed by TC (34 % and 27%) (Adj OR= 1.985, 95% CI=0.357-11.041) in cases and controls respectively. For rs4958847 AA and AG were comparably expressed in case (43% &39%) and control (41%&43%) with (Adj OR= 1.24, 95% CI=0.557-2.763) respectively. Additionally, no relation between both SNPs with gender, lupus nephritis, disease activity, or disease duration.

AB0515 CARDIOVASCULAR RISK FACTORS ASSESSMENT AND CONTROL IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. Torcato Cartaxo1, N. Carreira2,3, L. Duarte4,5, M. Terenas1, C. Mota3, P. Gaspar2,5

1Hospital Fernando Fonseca, Internal Medicine, Amadora, Portugal; 2Hospital de Santa Maria, Internal Medicine Department II, Lisboa, Portugal; 3Faculty of Medicine, University of Lisbon, Internal Medicine II University Clinic, Lisboa, Portugal; 4Hospital de Santa Maria, Emergency Department, Lisboa, Portugal; 5Instituto de Medicina Molecular (IMM), Cellular Immunology Lab, Lisboa, Portugal

Background: Systemic lupus erythematosus (SLE) is an independent risk factor for cardiovascular disease (1). Studies reporting how cardiovascular risk factors (CVRF) are assessed in clinical practice are scarce.

Objectives: To describe the prevalence of CVRF and characterize the assessment and control of dyslipidaemia and high blood pressure (HBP) in SLE patients.

Methods: Cross-sectional study of all adult SLE patients (SLICC 2012 criteria) followed in a dedicated clinic in 2019. Patients with less than one year of follow-up or less than three in-person visits were excluded. LDL-cholesterol control was defined as desirable (<115mg/dL), ideal (<100mg/dL), and according to the SCORE risk (2) (low, <115mg/dL; moderate, <115mg/dL; high, <100mg/dL; very high, <70mg/dL). Blood pressure (BP) control was defined as desirable (systolic BP [SBP] <130/90mmHg) and ideal (SBP/DBP<130/80mmHg). Data are shown as number (%) and median (interquartile range [IQR]) for categorical and continuous variables respectively. We used statistical tests as needed.

Results: Among 62 SLE patients followed in 2019, 65 met the inclusion criteria (89% female; median age, 52 years; median disease duration, 15 years; median follow-up, 8 years). The median SLEDAI-2K was 2 (0-4). Most patients were on hydroxychloroquine (88%), 43% were on steroids and 31% on other immunosuppressants. Dyslipidaemia was present in 62% of patients, followed by HBP (51%), obesity (n = 9, 14%), and diabetes mellitus (n = 4, 6%). Once-a-year CVRF assessment in the five years prior to the study was performed (CVRF) - 25% among all patients (33% of patients with dyslipidaemia); BP - 9% of all patients (15% of patients with HBP) (Table 1). In the study year, LP was assessed in 69% of all patients and in 85% (34/40) of patients with known dyslipidaemia, with a median LDL-cholesterol of 96 (128-74) mg/dL. Thirty-five (35/40, 88%) patients were under statins and the LP control was desirable, ideal and in line with the SCORE risk in 56%, 53% and 56% of patients, respectively; in the study year, BP was assessed in 32% of all patients and in 39% (13/33) of patients with known HBP, of whom 94% were under antihypertensive drugs. Among these patients (n=13), 69% had desirable and 23% ideal BP control. Steroid treatment regimen prevalence as well as dose (specific and age-specific standardised mortality ratios of patients with systemic lupus erythematosus in Ontario, Canada over 43 years (1971-2013). Ann Rheum Dis 2019;78:802-6.

AB0516 IN-HOSPITAL MORTALITY IN YOUNG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND ASSOCIATED CLINICAL FEATURES

S. Bowman1, S. Bruera2, S. Agarwal3, 1Baylor College of Medicine, Internal Medicine, Houston, United States of America; 2Baylor College of Medicine, Section of Immunology; Allergy and Rheumatology Houston, United States of America

Background: Patients with systemic lupus erythematosus (SLE) are three times more likely to die from any cause as compared to patients without SLE. This is largely driven by cardiovascular disease, malignancy, and an increased risk of infection. Alarmingly, recent studies have shown that younger patients with SLE are particularly vulnerable to all-cause mortality. However, there is a paucity in knowledge about patient characteristics and specific etiologies of mortality in this population that needs to be described in order to implement strategies to improve outcomes in younger patients with SLE.

Objectives: To identify disease characteristics and etiologies of mortality in young patients with SLE that died while hospitalized.

Methods: A retrospective chart review of a multi-institutional publicly funded health system in Texas, USA was performed. Deceased patients aged 18-49 with a 2019 EULAR/ACR diagnosis of SLE were identified from 2012 to 2021. Patients with mixed connective tissue disease, missing records, or cardiac arrest in the emergency room that did not have a clear etiology of death were excluded. Data was extracted from the electronic medical records by two independent reviewers to determine the most likely cause of death. If there was any discrepancy between the reviewers, this would be resolved by a third-party reviewer. Baseline demographics, disease activity by the SLE disease activity index (SLEDAI), medications, and reasons for prednisone administration were collected.

Results: Twenty-six patients with SLE (age range 22 to 48) that died in the hospital were identified. The most common cause of death was infection (58%) followed by lupus activity (15%). Of those that died of infection, all but one was on a two-month average dose of prednisone ≥10mg. Furthermore, the majority of patients (71%) that were on prednisone doses of ≥10mg had not undergone a prednisone taper within two months (i.e. were on a consistent dose). This was because of either persistent disease activity or poor follow-up.

Conclusion: To our knowledge, this is the first study to describe characteristics of young patients with SLE that died during hospitalization. Our findings show that young patients with SLE primarily die from infection while on increased doses of corticosteroids that have not been tapered. Further research is warranted to determine association and causality of these findings with mortality. Practitioners should remain vigilant and continue to taper steroids as able as this may be a potential source of mortality in young patients with SLE.

*Calculated from the clinical assessment number for each group.
Background: Systemic lupus erythematosus (SLE) is a multi-system autoimmune disease characterized by the secretion of normal autoantibodies that can form immune complexes and cause inflammation of multiple organs. Cardiovascular events and mortality are nearly twice as high in SLE patients as in the general population. (2) In SLE, cachexia plays an important role in rheumatoid arthritis (RA), due to its chronic inflammatory process characterized by decreased muscular mass with preservation or increase of fat that occurs in 1-13% of the RA population. A decreased BMI has a paradoxical relationship with disease activity, with an increase in disease activity and mortality (1). Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the production of nuclear autoantibodies that can form immune complexes and cause inflammation of multiple organs. Cardiovascular events and mortality are nearly twice as high in patients with SLE as in the general population. (2)

Objectives: To measure the expression of serum zonulin to assess and compare the function of intestinal mucosal barrier in patients with SLE and healthy adults, and to explore the role of intestinal mucosal barrier in the pathogenesis and development of SLE.

Methods: 20 patients with SLE who hospitalized at the Second Hospital of Shanxi Medical University and 10 age and gender-matched healthy adults were enrolled in this study. We collected the blood sample of the patients and healthy controls to examine the function of intestinal mucosal barrier and the absolute number of Th17 and Treg cells. The level of serum zonulin was measured by ELISA to assess the function of intestinal mucosal barrier. The absolute number of Th17 and Treg cells was detected by flow cytometry. Disease activity indicators of patients with SLE were collected from laboratory including erythrocyte sedimentation rate (ESR, mm/h), complement 3 (C3, g/l) and anti-dsDNA (IU/ml). Then we compared the expression of serum zonulin between the patients and healthy controls and analyzed the correlation of serum zonulin with Th17 cells, Treg cells and disease activity.

Results: The level of serum zonulin of SLE group were significantly higher than that of healthy control group (p<0.05). The expression of serum zonulin was positively correlated with the level of ESR (r=0.491, p=0.033) and anti-dsDNA, but was negatively correlated with C3 (r=-0.519, p=0.018). And the expression of serum zonulin was not correlated with the absolute number of Th17 cells and Treg cells (P>0.05), but Th17 cells showed a trend of increasing with the increase of zonulin, while Treg cells showed a trend of decreasing with the increase of zonulin.

Conclusion: The results here showed that the level of serum zonulin,a marker of the intestinal mucosal barrier function, was up-regulated in patients with SLE, and the higher level of serum zonulin was positively correlated with the disease activity of SLE, which indicated that impaired intestinal mucosal barrier function in SLE played an important role in the development of the disease.

Table 1. A summary of baseline demographics of all enrolled patients and healthy controls

Results are expressed as the mean ± standard error. Normally distributed continuous variables were analyzed by the independent-samples Student’s t-test.
Results: The mean age of SLE patients was 35.4 ± 12.11 years, rest of demographic characteristics in Table 1. Pearson’s test showed a correlation between BMI and disease activity (r = -0.304, p = 0.020) Image 1. Multivariate analysis found that a decrease in BMI is independently associated with an increase in disease activity assessed by SLEDAI (β = -0.411, 95% CI: -0.819 - -0.003, p = 0.049).

**CONCLUSION**: The results suggest that patients with SLE have increased QRS segment, increased heart rate and decreased QT segment duration, which may be related to disturbances of the conduction system.

**ASSOCIATION BETWEEN LEFT VENTRICULAR MASS INDEX AND BODY WEIGHT IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS**

A. N. Garza-Cisneros, D. Á. Galarza-Delgado, J. R. Azpiri-López, I. J. Colunga-Pedraza, M. A. Balderas-Palacios, A. García-Heredia, N. Guajardo-Jauregui, A. B. Rodríguez-Romero, A. Cárdenas. Universidad Autónoma de Nuevo León, Hospital “Dr. José Eleuterio González”; Rheumatology, Monterrey, Mexico; *Universidad Autónoma de Nuevo León, Hospital “Dr. José Eleuterio González”; Cardiology, Monterrey, Mexico*

**Background:** Rheumatoid cachexia is a clinical spectrum of rheumatoid arthritis in which individuals present increased inflammatory activity, more aggressive joint destruction, and worse cardiovascular prognosis (1). Systemic lupus erythematosus (SLE) is a chronic, inflammatory, autoimmune disease in which there is a high cardiovascular mortality rate (2). Currently, the cachexia phenomenon in SLE patients has not been studied.

**Objectives:** To correlate body weight with left ventricular (LV) indexed mass in SLE patients.

**Methods:** This was a cross-sectional study that included a total of 34 patients aged ≥18 years with a diagnosis of SLE according to EULAR/ACR 2019 criteria. Patients with a personal pathological history of cardiovascular disease (myocardial infarction, stroke, or peripheral arterial disease) and pregnancy were excluded. Three certified cardiologists performed a transthoracic echocardiogram in each patient, assessing relative wall thickness, and indexed LV mass. The distribution was assessed with Kolmogorov-Smirnov. Correlations between weight and echocardiographic parameters with Spearman-rho coefficient. A value of p<0.05 was considered statistically significant.

**Results:** Most patients were female (94.1%), with a mean age of 33.29±9.91. Of the total patients 2 (5.88%) had Type 2 Diabetes Mellitus, 2 (5.88%) hypertension, 1 (2.94%) dyslipidemia, 3 (8.82%) obesity, and 6 (17.64%) smoking. Spearman-rho coefficient showed a significant negative correlation between LV indexed mass and body weight of SLE patients (r=-0.411, p=0.016) (Figure 1).

**Figure 1.** Spearman rho correlation between weight and LV indexed mass.

ECG: electrocardiogram, SLE: systemic lupus erythematosus, NS: not significant, HR: heart rate, MS: milliseconds, BPM: beats per minute.
Conclusion: There is a negative correlation between body weight and LV indexed mass in SLE patients, this suggests that a lower body weight may be related to higher LV mass, which may result in LV hypertrophy and increased cardiovascular morbidity and mortality.

AB0521 PERICARDITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS: CHARACTERISTICS, MANAGEMENT, EVOLUTION AND PREDICTIVE FACTORS FOR RELAPSE. A MONOCENTRIC RETROSPECTIVE STUDY.

Background: Pericarditis is frequent in Systemic Lupus Erythematosus (SLE) and usually benign. Dedicated studies are scarce. However, recurrences can lead to repeated steroid prescriptions and further immunosuppression. The best management, including the potential benefit of colchicine, remains to be determined.

Objectives: The aim of this study was to describe management, evolution over time and risk factor for relapse in SLE pericarditis in our University Hospital Center.

Methods: Cases were retrospectively collected among hospital discharge data (coding code “SLE” and “pericarditis”), from January 1997 to December 2019. All SLE cases met the ACR/EULAR 2019 classification criteria. Pericarditis cases met ESC 2015 diagnosis criteria. Patients with conditions other than lupus known to cause pericarditis were excluded as well as patients with myocarditis. A minimal follow-up of one year after pericarditis diagnosis was mandatory. Relapse-free survival was described using an actuarial survival model.

Results: Among 103 patients identified in the database, 29 patients (women: n=25; mean age 30 +/- 13 years) were included. Median follow-up was 7 years (range: 1-22).

Description of first episodes: 31% (n=9) were inaugural of SLE; otherwise, median time elapsed since SLE diagnosis was 65 months (1-400). Fifty-five percent (n=16) of first episodes occurred during a multi-systemic lupus flare. Median SLEDAI-2K was 9 [range: 4-30]; clinical symptoms and signs were typical chest pain (93%, n=27), dyspnea (55%, n=16); pericardial rub (31%, n=9), fever (38%, n=11). EKG was abnormal in 59% of the cases (n=17). When present, 79% of effusions (n=17) were circumferential, 82% (n=18/22) were mild to moderate (<20mm), and 25% (n=7) were dry pericarditis. Two Cardiovascular Magnetic Resonance imaging were performed and were pathological.

Biological data showed always high CRP levels (65mg [range: 7-460]), high-titer anti-DNA (79%, n=19) but few patients had low complement levels (C3 21% (n=4/19), C4 26%(n=5/19)).

Prescribed drugs were non-steroidal anti-inflammatory drugs/ acetylsalicylic acid (NSAIDs/ASA) (41%, n=12), corticosteroids (66%, n=19; mean daily prednisone dose: 57±2mg +/- 13.9), colchicine 0.5 to 1mg/day (41%; n=12). There was a significant difference in SLEDAI-2K values at pericarditis onset between those treated with NSAIDs/ASA (7.5, [range: 0-16]) and those not (12, [range: 4-30]), (p=0.05). Only 41% (n=9) of colchicine prescriptions lasted at least 3 months; they were associated with a lower SLEDAI-2K at pericarditis onset compared to pericarditis not or insufficiently treated with colchicine (respectively, 7 [range: 4-9] and 11 [range: 4-30], p=0.04). Immunosuppressive drugs were prescribed in 17% (n=3) of the patients, always due to extra-pericardial involvements.

Recurrences were frequent (55%, 16 patients out of 29) and multiple (1 to 6, average 3 ± 1.26). Short and long-term relapse-free survival tended to be better in patients exposed to at least 3 months of colchicine (100% vs 75% at 1 year, p=0.09) (Figure 1). There was no statistical difference (p=0.25) in terms of short-term relapse-free survival in patients treated with NSAIDs/ASA compared to those who were not. Corticosteroid prescription and previous antimalarial treatment were not associated with a poorer or better outcome during the year following remission (p=0.78). No patient has progressed to constriction.

Conclusion: Our conclusions are limited due to the small number of patients and lack of multivariate analysis.

AB0522 EARLY DAMAGE AS MEASURED BY THE DAMAGE INDEX FOR ANTIPHOSPHOLIPID SYNDROME (DIAPS) IS NOT A PREDICTOR OF MORTALITY IN THROMBOTIC ANTIPHOSPHOLIPID SYNDROME

1Hospital de Santa Maria, Internal Medicine Department II, Lisboa, Portugal; 2Instituto de Medicina Molecular (IMM), Cellular Immunology Lab, Lisboa, Portugal; 3University College London, Centre for Rheumatology, London, United Kingdom; 4University College London Hospitals NHS Foundation Trust, Department of Haematology, London, United Kingdom; 5University College London, Haemostasis Research Unit, London, United Kingdom; 6University College London Hospitals Nhs Foundation Trust, Department of Rheumatology, London, United Kingdom

Background: Antiphospholipid syndrome (APS) patients experience damage accrual (1) but correlation with mortality is rarely reported. In systemic lupus erythematosus (SLE), early damage accrued in the first year of disease is a predictor of mortality (2).

Objectives: To determine whether damage accrued within the first year after APS onset as measured by the Damage Index for APS (DIAPS) predicts mortality.

Methods: Single-centre retrospective analysis of thrombotic APS patients (2006 Sydney criteria). The disease onset was determined as the first thrombotic event related to APS was diagnosed. Annual DIAPS assessments were determined for each patient. Early damage was considered to be a score ≥1 at the initial assessment (six months). DIAPS is shown as median (interquartile range [IQR]). Survival was analysed by the Kaplan-Meier method. Cox regression analysis was performed to investigate predictors of mortality.

Results: A total of 197 patients (71.1% female; 65.9% primary APS; 72.4% Caucasian) with a median age at APS onset of 40 years (IQR 51 - 28) were followed for up to 43 years (median 10 years). Cumulative damage developed
in 143 (73.6%) patients with a median DIAPS of 1 (IQR 2 – 0) at the last visit. Early damage was present in 69 (35.0%) patients. Patients with early damage had similar sex distribution (p=0.735), age at disease onset (p=0.526) and median time of follow-up (p=0.181) comparing to those without early damage. Secondary APS (SAPS) (odds ratio [OR] 1.89, 95% CI 1.03 – 3.48, p=0.041) and having a first arterial event (OR 7.24, 95% CI 3.74 - 14.03, p<0.001) were associated with early damage. Twenty-three patients (11.7%) died. SAPS (p=0.009), male sex (p=0.008) and age at onset ≥40years (p=0.001) were risk factors for death (Table 1). Early damage was not associated with death (hazard ratio [HR] 1.65, 95% CI 0.73 - 3.78, p=0.231; Figure 1: survival curve) even after adjusting individually for APS category (secondary, p=0.446), sex (male, p=0.374), age at onset ≥40years (p=0.115) and type of event (arterial, p=0.555).

† In this column, we present the Early Damage hazard ratio and 95% confidence intervals for death adjusted for the variable in each row. Statistically significant values are presented in bold. APS, antiphospholipid syndrome; CI, confidence interval; DIAPS, Damage Index for Antiphospholipid Syndrome; HR, hazard ratio.

Conclusion: Unlike SLE, early damage accrual accessed by DIAPS is not a predictor of mortality regardless of the nature of the thrombotic event, gender, APS category and age at APS onset.

AB0523 THE ENTEROTYPES OF THE GUT MICROBIOTA IN CHINESE POPULATION WITH AUTOIMMUNE DISEASE

M. J. Chang1,2,3, S. X. Zhang3,4, J. Qiao3,4, C. Wang2,3, H. R. Chen1, T. Huang1, Q. Yu1, P. F. He1,2,3,4,5. Shanxi Medical University, School of Management Shanxi Medical University, Key Laboratory of Cellular Physiology, Tai Yuan, China; 6Shanxi Medical University, Academy of Microbial Ecology, Tai Yuan, China; 7Shanxi Medical University, Department of Rheumatology, Tai Yuan, China; 8Shanxi Medical University, School of Basic Medical Sciences, Tai Yuan, China; 3Shanxi Medical University, Medical Data Sciences, Tai Yuan, China

Background: An increasing number of autoimmune disorders (AD) have been associated with microbial dysbiosis1,2. However, this dysbiosis is difficult to characterize for individual patients owing to the high heterogeneity of the gut microbiota. Thus, researchers must find an accurate method of characterizing the AD gut microbiota that is meaningful to clinical diagnosis.

Objectives: The aim of this study was to investigate the enterotype characters of intestinal flora in AD and their associations with peripheral lymphocyte subpopulations and cytokines.

Methods: A total of 339 AD patients and 339 age- and sex-matched healthy controls (HCs) were enrolled in this study. Mathematical modeling using Dirichlet multinomial mixtures (DMM) was applied to describe the variability in the microbiome data and cluster samples into enterotypes. The peripheral lymphocyte subsets were detected by flow cytometry and the cytokines were assessed by ELISA. Differential abundance analysis was carried out the STAMP software. R (version 4.1.0) was used for comparative statistics, and spearman’s correlation analysis was used to assess the correlations between the relative abundances of bacterial genera and clinical variables.

Results: Laplace approximation of DMM suggested gut microbiota of AD patients and HCs both can be divided into two distinct enterotypes (Figure 1 A-B), and AD E1 and HC E1 were primarily dominated by Prevotella while AD E2 and HC E2 by Bacteroides. Interestingly, the Prevotella-enriched enterotype (AD E1 and HC E1) had a higher alpha diversity than The Bacteroides-enriched enterotype (AD E2 and HC E2). Patients with AD always had a lower richness and diversity compared with those of HCs in each enterotype (p<0.001), suggesting gut microbiome was markedly less diverse in composition in AD. Bray curtis distance-based beta-diversity were also different (P<0.001, ANOSIM.R =-0.23, Figure 1 C-H). Significant differences in gut microbiota composition at the genus level between AD patients and HCs were found using the STAMP software in each enterotype. Compared with HCs, 37 species in AD E1 patients and 40 species in AD E2 patients of flora were discovered to be distinctly different. In the co-upregulated flora of both enterotypes, Lactobacillus was inversely associated with a variety of lymphocytes such as T, CD4+T, NK, Th2, Th17, Treg cells(P<0.05), and positive correlation with IL-10 and IFN-γ(P<0.05,Figure 1 J). However, in the co-downregulated flora of Coprococcus had a positive correlation with B, NK and Treg cells, and anaerostipes had a negative correlation with IL-2 and IL-4(P<0.05,Figure 1 J).

Conclusion: There were both two enterotypes in patients and HCs with autoimmune disease, E2 exhibited a loss of Prevotella but a growth of Bacteroides, with IL-2 and IL-4(P<0.05), and positive correlation with IL-10 and IFN-γ(P<0.05,Figure 1 J).

Methods: A cross sectional study was conducted recruiting consecutive patients with pSS without history of gout. SUA was measured upon recruitment alongside the assessment of disease activity (EULAR Sjögren’s syndrome disease activity index, ESSDAI and ClinESSDAI), patient reported symptoms (EULAR Sjögren’s syndrome patient reported symptoms, ESSPRI), CV risk factors including hypertension and diabetes among others, and previous CV events. Dietary habits were also explored with various food frequency questionnaires.

Results: One hundred and three patients with pSS were enrolled. SUA levels ranged between 2.9 and 6.8 mg/dL and, according to the cut-off values of the URRAH study, 16 (16%) patients had SUA levels >4.7 mg/dL while 5 (5%) had SUA levels >5.6 mg/dL. Patients with SUA levels >4.7 mg/dL were more likely males (20% vs 3%) with a higher number of CV risk factors compared to patients with SUA levels <4.7 mg/dL. No differences were observed regarding dietary habits across groups. Disease activity assessed with both ESSDAI and ClinESSDAI was significantly higher in patients with SUA levels >4.7 mg/dL compared to patients with SUA levels <4.7 mg/dL. The disease activity assessed with both ESSDAI and ClinESSDAI was significantly higher in patients with SUA levels >4.7 mg/dL compared to patients with SUA levels <4.7 mg/dL. Conversely, patient reported symptoms (total ESSPRI and individual VAS scales for total dryness, xerostomia, xerophthalmia, pain and fatigue) did not differ across groups. Logistic regression analysis confirmed the association of SUA values >4.7 mg/dL and a higher number of CV risk factors (OR 2.8; 95% CI: 1.2-6.5; p=0.016).

Conclusion: Accumulating evidence highlights the emerging role of hyperuricemia as an independent CV risk factor, but no data are available in pSS patients. This is the first study demonstrating that SUA levels >4.7 mg/dL correlate with both a higher number of CV risk factors and a higher disease activity in pSS patients. Large interventional studies are needed to clarify the possible benefits of urate-lowering treatments in pSS patients.

AB0524
RELATIONSHIP BETWEEN SERUM URIC ACID, CARDIOVASCULAR RISK AND INFLAMMATORY STATUS IN PRIMARY SJÖGREN’S SYNDROME
A. Alunno1, F. Carubbi1, F. M. Mariani1, M. Rossi1, J. Santilli1, C. Ferrì1. Internal Medicine and Nephrology Unit, University of U'quila, Department of Life, Health and Environmental Sciences, U'quila, Italy

Background: An unhealthy diet, with or without impaired renal urate excretion, is the most frequent cause of hyperuricemia. Despite its pivotal role in the pathogenesis of gout, the clinical relevance of serum uric acid (SUA) levels goes well beyond the simple association with gout and/or nephrolithiasis. Several studies pointed to hyperuricemia as cardiovascular (CV) risk factor in the general population therefore, the 2018 guidelines of the European Society of Cardiology and the European Society of Hypertension included the assessment of uricemia among the screening tests to be performed in hypertensive patients. Furthermore, in view of the association between hyperuricemia and mortality (both CV and all-cause) and CV events, it is conceivable that cardiovascular damage begins with much lower levels of uricemia. In this context, the first results of the URRAH (Uric Acid Right for Heart Health) study identified a uricemia threshold value of 4.7 mg/dL for all-cause mortality and 5.6 mg/dL for CV mortality.

Objectives: Since patients with primary Sjögren’s syndrome (pSS) have a higher risk of CV events compared to the general population, we aimed to explore how uricemia correlates with other CV risk factors and previous CV events in patients with pSS and without gout.

Methods: A cross sectional study was conducted recruiting consecutive patients with pSS without history of gout. SUA was measured upon recruitment alongside the assessment of disease activity (EULAR Sjögren’s syndrome disease activity index, ESSDAI and ClinESSDAI), patient reported symptoms (EULAR Sjögren’s syndrome patient reported symptoms, ESSPRI), CV risk factors including hypertension and diabetes among others, and previous CV events. Dietary habits were also explored with various food frequency questionnaires.

Results: One hundred and three patients with pSS were enrolled. SUA levels ranged between 2.9 and 6.8 mg/dL and, according to the cut-off values of the URRAH study, 16 (16%) patients had SUA levels >4.7 mg/dL while 5 (5%) had SUA levels >5.6 mg/dL. Patients with SUA levels >4.7 mg/dL were more likely males (20% vs 3%) with a higher number of CV risk factors compared to patients with SUA levels <4.7 mg/dL. No differences were observed regarding dietary habits across groups. Disease activity assessed with both ESSDAI and ClinESSDAI was significantly higher in patients with SUA levels >4.7 mg/dL compared to patients with SUA levels <4.7 mg/dL. Conversely, patient reported symptoms (total ESSPRI and individual VAS scales for total dryness, xerostomia, xerophthalmia, pain and fatigue) did not differ across groups. Logistic regression analysis confirmed the association of SUA values >4.7 mg/dL and a higher number of CV risk factors (OR 2.8; 95% CI: 1.2-6.5; p=0.016).

Conclusion: Accumulating evidence highlights the emerging role of hyperuricemia as an independent CV risk factor, but no data are available in pSS patients. This is the first study demonstrating that SUA levels >4.7 mg/dL correlate with both a higher number of CV risk factors and a higher disease activity in pSS patients. Large interventional studies are needed to clarify the possible benefits of urate-lowering treatments in pSS patients.

MODELS OF SYSTEMIC LUPUS ERYTHEMATOSUS ACTIVITY (A RESTROSPECTIVE-PROSPECTIVE STUDY)
A. Shumilova1, E. Travkina1, M. Cherkasova1, T. Reshetnyak2, A. Lila3-on behalf of The study was performed at the V.A.Nasonova Research Institute of Rheumatology within the framework of the fundamental topic FURS-2022-003. 1V.A.Nasonova Research Institute of Rheumatology, 4th Rheumatological Department, Moscow, Russian Federation; 2V.A.Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; 3Russian Medical Academy of Continuing Professional Education, Department of Rheumatology, Moscow, Russian Federation

Background: Systemic lupus erythematosus (SLE) is a heterogeneous chronic autoimmune rheumatic disease with a wide range of clinical manifestations, characterized by impaired activation of cellular and humoral links of immunity, uncontrolled hyperproduction of autoantibodies of a wide spectrum to nuclear antigens and the formation of immune complexes that cause immune-inflammatory damage to tissues and organs. This disease is characterized by periods of exacerbation and remission, over time, the activity of SLE may change, mainly in response to therapy. Despite this, patients can be classified according to the current or currently prevailing activity model.

Objectives: To study the activity patterns of patients with SLE.

Methods: The retrospective-prospective study was conducted from 2019 to 2021 based on the study of the history of the disease and annual visits of patients with an assessment of the activity of SLE by SLE Disease Activity Index-2000 (SLEDAI-2K). Depending on the level of SLEDAI-2k flare index, the models of SLE activity, the number of exacerbations during the observation period and the period of the disease, as well as the predominance of organs and systems involved in the process were analyzed. The study included 183 patients with SLE (163 women and 20 men). The average age was 37.5±12.8 y.o. The duration of the disease was Me=9.9 [2.0; 16.0] years.

Results: The clinical and immunological manifestations of SLE were evaluated in the study. The average number of exacerbations of SLE during the period of the disease was 2.9±1.9. The average number of exacerbations during the observation period was 1.1±0.78. The most frequent exacerbation was manifested by a lesion of the musculoskeletal system – 29.5% (54 patients), the skin-mucous system – 21.8% (40 patients) and lupus-nephritis – 21.8% (40 patients). The predominant activity model was relapsing-remitting disease (RDR) – 43.16% (79
23 patients with involvement of the skin-mucosal system had 1 exacerbation of SLE in 3 years of the study. 23 patients with involvement of the musculoskeletal system had 1 exacerbation and 19 patients had 2 exacerbation of the disease in observation period. Exacerbation of lupus nephritis 1 time during the follow-up period was noted in 26 patients, 2 times - in 8 patients.

Conclusion: The most frequent model of SLE activity is RRD, which characterizes periods of exacerbation and remission. The most frequent clinical manifestations of exacerbation of SLE are lesions of the skin-mucous and musculoskeletal systems, as well as lupus nephritis.

AB0527 DIFFUSE ALVEOLAR HEMORRHAGE IN LATIN AMERICAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A CASE-CONTROL STUDY

D. C. Quiñonez-González1, M. Muñoz-Urbano1, J. Sanchez-Bautista2, Y. Santamaría-Alza1, A. Ramírez3, C. Muñoz1,3, A. L. Vanegas-García1,3, G. Vásquez1, L. A. González1,1, Universidad de Antioquia, Rheumatology, Medellín, Colombia;2 Universidad de Antioquia, Internal Medicine, Medellín, Colombia;3 Hospital San Vicente Fundación, Rheumatology, Medellín, Colombia

Background: Diffuse alveolar hemorrhage (DAH) is an uncommon and life-threatening complication of systemic lupus erythematosus (SLE) with a high mortality rate (estimated average 50%). The presence of respiratory symptoms (dyspnea, cough, hemoptysis), a new drop in hemoglobin levels, and diffuse infiltrates on chest imaging should raise suspicion of this complication.

Objectives: Our aim was to describe DAH-SLE patients and compare them with non-DAH SLE patients.

Methods: We conducted a single-center, case-control study that enrolled hospitalized patients between 2012 and 2020 in Colombia. Twenty-three DAH-SLE patients (cases) were matched by age and sex with 23 non-DAH-SLE patients (controls). Descriptive, comparative, and logistic regression analyses were performed.

Results: In seven (30.4%) patients, DAH was the initial manifestation of SLE; 69.5% of DAH-SLE patients were females with a mean age of 35 years. Lupus nephritis was present in 65% of cases, mean hemoglobin decrease was 2.22 g/dl [standard deviation (SD) 0.92 g/dL], and 78% had hemosiderophages in bronchoalveolar lavage. All patients received intravenous (IV) pulses of methylprednisolone followed by high-dose steroids, 87.0% IV cyclophosphamide pulses, 60.8% plasmapheresis, 21.7% IV immunoglobulin, and 8.7% rituximab. Comparisons between DAH and non-DAH groups are shown in Table 1. Bivariate logistic regression analysis showed that male sex (OR 9.625 CI95% 1.07 - 86.17; p=0.043), higher SLEDAI-2K score (OR 1.28 CI95% 1.10 - 1.48; p=0.001), and higher C-reactive protein (CRP) levels (OR 1.09 CI95% 1.01 - 1.18; p=0.016) were independently associated with the occurrence of DAH, whereas prior use of corticosteroids (OR 0.029 CI95% 0.003 - 0.25; p=0.001) and antimalarials (OR 0.121 CI95% 0.03 - 0.45; p=0.002), higher hemoglobin levels (OR 0.457 CI95% 0.29 - 0.71; p=0.001), higher C3 (OR 0.94 CI95% 0.91 - 0.97; p<0.0001) and higher C4 levels (OR 0.87 CI95% 0.80 - 0.95; p=0.002) were negatively associated with DAH occurrence (Graph).

Disclosure of Interests: None declared

*P value < 0.05

Conclusion: In about one-third of patients diagnosed with DAH, this life-threatening complication was the initial presentation of SLE. Male sex, higher SLEDAI-2K scores, and higher CRP levels were associated with increased occurrence, whereas higher hemoglobin levels, elevated complement levels, prior use of glucocorticoids, and antimalarial treatment were negatively associated with the occurrence of DAH.

Background: Neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) have been reported as useful inflammatory biomarkers associated with the disease activity of systemic lupus erythematosus (SLE). Recently, the albumin to globulin ratio (AGR) has demonstrated potential indicator to predict the prognosis of some cancers. However, whether AGR can predict the disease activity of SLE has been rarely investigated.

Disclosure of Interests: None declared

Methods: This retrospective study enrolled 101 SLE patients and 75 age- and gender-matched healthy individuals. According to the SLEDAI-2K score, SLE patients were classified into Group 1 with a score of 9 or lower (patients with mild disease activity, N = 60) and Group 2 with a score > 9 (patients with moderate to severe disease activity, N = 41). Albumin, globulin, NLR, PLR, monocyte to lymphocyte ratio (MLR), AGR, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), complement 3 (C3), complement 4 (C4), SLEDAI-2K and other clinical data were collected. Receiver operation characteristic (ROC) curves were conducted to discriminate SLE patients from healthy controls and SLE patients with different disease activity. Correlations between the inflammatory markers and SLEDAI-2K were checked.

Results: Albumin and AGR in SLE patients were lower compared to those of the healthy controls (P < 0.05), while NLR, PLR, MLR, globulin and CRP were higher (P < 0.05). Patiens in Group 2 had lower levels of albumin, AGR, C3 and C4 than those in Group 1 (P < 0.05), NLR and PLR were higher (P < 0.05), while MLR (P = 0.198), globulin (P = 0.704), CRP (P = 0.224) and ESR (P = 0.135) displayed no significant differences. The ROC curves for differentiating SLE patients from healthy individuals showed that the area under curve (AUC) of AGR (0.812, 95%CI: 0.750 - 0.874) and albumin (0.840, 95%CI: 0.782 - 0.898) were higher than NLR (0.786, 95%CI: 0.719 - 0.853), PLR (0.708, 95%CI: 0.629 - 0.786), MLR (0.776, 95%CI: 0.708 - 0.845) and globulin (0.630, 95%CI: 0.548 - 0.713). Similarly, the ROC curves for predicting the disease activity of SLE patients displayed that the AUC of AGR (0.779, 95%CI: 0.689 - 0.870) and albumin (0.827, 95%CI: 0.746 - 0.929) were also higher than NLR (0.644, 95%CI: 0.534 - 0.753), PLR (0.672, 95%CI: 0.565 - 0.780), MLR (0.583, 95%CI: 0.466 - 0.701), globulin (0.521, 95%CI: 0.403 - 0.639), CRP (0.567, 95%CI: 0.452 - 0.683), ESR (0.589, 95%CI: 0.475 - 0.703), C3 (0.709, 95%CI: 0.603 - 0.815) and C4 (0.655, 95%CI: 0.542 - 0.768); AGR was negatively correlated with SLEDAI-2K (r = -0.543, P < 0.001) in SLE patients. Logistic regression analyses showed that AGR (OR = 13.047, 95%CI: 3.407 - 49.966, P < 0.001) was an inverse predictor for SLE disease activity, yielding a highest hazard than other inflammatory parameters.

Conclusion: AGR was significantly decreased in SLE patients compared with healthy subjects and negatively associated with the disease activity of SLE. AGR might be a potential indicator for evaluating inflammation in patients with SLE.

AB0529 PULMONARY HYPERTENSION (PAH) IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IS NOT DEFINED BY AUTO-ANTIBODY AND CLINICAL VARIABLES.

R. Baiya1, M. G. S. R2, P. K. Devarasetti1, A. Aggarwal3, V. Shobha4, L. Rajasekhar1on behalf of INSPIRE. 1Nizam’s Institute of Medical Sciences, Clinical Immunology & Rheumatology, Hyderabad, Telangana, India; 2Indian Statistical Institute, Statistical Quality Control and Operational Research Division, Hyderabad, India; 3Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India; 4St John’s Medical College Hospital, Clinical Immunology and Rheumatology, Bangalore, India

Background: PAH is a well-recognized but infrequent manifestation of SLE. Often insidious in onset, PAH may have progressed for a while, before symptoms manifest. Prediction of clinical risk of PAH may have clinical benefit during the follow-up of a patient with SLE.

Objectives: The aim of the study was to develop a prediction algorithm for PAH in patients with SLE using clinical and auto-antibody variables.

Methods: The study included patients from the INSPIRE cohort which is, a national multi-center study enrolling patients with disease duration of less than three years. Lupus patients with symptomatic PAH confirmed by a transthoracic
2D ECHO right ventricular systolic pressure of more than 40 mm Hg were enrolled as cases. Controls were age, sex and date of enrolment matched patients from the same cohort without any clinical evidence of PAH. We excluded patients with a known cause of PAH and critical illness. The clinical variables and antibody data was retrieved from records. Outcome of death if any was noted. Using supervised learning, a logistic regression model was built for the prediction of SLE-PAH. The final Prediction model included one clinical variable (RP), sixteen autoantibodies (Sm-RNP, Smith, SS-A, Ro-52, SS-B, SCL-70, PM-SCL, Centromere, Jo1, PCNA, Nucleosome, dsDNA, histone, Ribosomal P and AMA, anti-cardiolipin antibody) and complement level, to ensure accuracy of the model, a confusion matrix using python was performed. The proportion of right predictions ($\mu$) is a measure of accuracy of the model. If the model is good, $\mu$ must be close to 1.

**Results:** A total of 69 patients with symptomatic PAH, confirmed by 2D echo-cardiography were enrolled as cases. Raynaud phenomenon (RP), Interstitial lung disease (ILD) and ischemic stroke were significantly higher in cases than control (p = 0.026, 0.001, 0.05 respectively). There was no difference in the prevalence of individual auto-antibodies between the groups except high prevalence of anti-cardiolipin antibody in cases (39% vs 23% p = 0.048). Mortality rate was higher in cases (17% vs 0.06%, p = 0.003) during a follow up of 3 years with all the deaths occurring within one year of PAH diagnosis. Ten repetitions of the confusion matrix analysis using Python for this prediction model (both derivation and validation) yielded the following $\mu$ scores 0.60, 0.47, 0.57, 0.63, 0.50, 0.60, 0.57, 0.43, 0.50, 0.57, which exhibited wide variability.

**Conclusion:** A prediction model using RP and commonly assayed autoantibodies failed to be informative for PAH in Indian lupus patients.

**CARDIOVASCULAR RISK STATUS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: WHICH ALGORITHMS IS THE BEST?**

T. Panafidina1, T. Popkova1, L. Kondrateva1, Y. Gorbunova1, E. Nasonov2, V.A.Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moscow, Russian Federation; V.A.Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation

**Background:** Systemic lupus erythematosus (SLE) has been strongly linked to accelerated atherosclerosis and increased cardiovascular morbidity and mortality. Rheumatological guidelines recommend evaluating the cardiovascular (CV) risk status in SLE patients, for an early identification of patients at high risk to preventive strategies.

**Objectives:** The aim of our study is to describe for the first time individual patient GC toxicity in SLE patients using the Glucocorticoid Toxicity Index (GTI).

**Methods:** A total of 37 patients SLE (30 (81%) women and 7 (19%) men) were enrolled in this study. The mean age was 36±11.9 years and the median disease duration was 36 [12; 128] months. At the first visit, all patients were assessed for SLE activity by the SLEDAI 2k index, irreversible organ damage by SLICC Damage Index (DAI), GTI1, and current treatment.

**Results:** The mean disease activity index SLEDAI2k was 11.3±6.2, DAI SLICC = 1 (20 (54%), 14 (46%) patients had not any irreversible organ damage during the period of illness the maximum GC dose was 33.7 mg ± 19.9 mg, the median of cumulative dose of GC administered intravenously was 15653 mg [293; 6478] mg, median duration of GC treatment was 22 months [8; 112]. 30 (81%) of patients had GTI with median 19 [14; 21] points: 2 (5%) patients had zero GTI, but there were severe organs’ injuries from the TGI Specific List. In 3 out of 5 patients, the duration of GC treatment did not exceed 6 months, in 2 out of 5 patients, the maximum dose of GC during the period of the disease did not exceed 5 mg/day. In 1 out of 5 patients, the duration of treatment was 13 months, and the maximum dose of GC was 15 mg during the period of treatment. The most frequent changes occurred in 5 of 9 main domains: an increase in body mass index was detected in 10 (27%) patients, an increase in blood pressure was detected in 15 (41%) patients, hyperlipidemia was detected in 9 (24%) patients, a decrease bone mineral density was detected in 6 (16%) patients and the development of infectious complications in 5 (14%) patients; The less frequent changes occurred in 5 of 9 main domains: 3 (8%) patients had impaired glucose tolerance, 2 (5%) patients had steroid myopathy; neuropsychiatric intoxication was detected in 2 (5%) patients. Severe organs’ injuries were identified, included in a Special list and not scored in points: cataracts were detected in 7 (19%) patients, avascular necrosis was detected in 3 (8%) patients, osteoporotic fractures - in 2 (5%) patients. GTI correlated with disease duration (r = 0.33); the maximum dose of GC per os (r = 0.43); duration of GC therapy (r = 0.37); DAI SLICC (r = 0.39), p<0.05 in all cases.

**Conclusion:** GTI was detected in a significant number of patients with SLE (81%). ITG correlates with the duration of the disease, the maximum dose of GC during the period of illness, the duration of GC therapy, and the SLICC DAI. GTI should be used to evaluate the safety of GC therapy in patients with SLE who receive GC therapy for more than 6 months, together with the SLICC DAI.

The GTI includes Composite Index and Specific List. Composite Index, consists of 9 domains and 31 elements, each of which is assigned a certain number of points. It contains information on the most common complications of GC therapy: BMI, glucose tolerance, BP, lipids, myopathy, bone mineral density, skin lesions, neuropsychiatric lesions, infections.

Severe organ damages, which is less common but contributes significantly to GC toxicity, are included in a special list. The specific list includes 11 domains.
LACTATE DEHYDROGENASE AS A PREDICTOR OF FATIGUE IN PRIMARY SJOGREN'S SYNDROME: A POOLED ANALYSIS

L. Rajaïaoppal1, S. Jude Tan1, W. F. Ng1, J. Tarn1. 1Translational and Clinical Research Institute, Newcastle University; Newcastle upon Tyne, UK, Department of Rheumatology; Freeman Hospital, Newcastle upon Tyne NHS Trust, United Kingdom; Newcastle upon Tyne, United Kingdom

Background: Fatigue is one of the most disabling symptoms in primary Sjögren's syndrome (pSS) and it significantly impacts patients' quality of life[1]. However, the cause of this symptom remains unclear. Lactate dehydrogenase (LDH), is an enzyme of the anaerobic respiratory pathway. High lactate levels are a marker of inflammation and create a pro-inflammatory microenvironment[2]. LDH levels can be raised in myositis, haemolysis and lymphoma. For this reason, serum LDH is routinely monitored in patients with pSS. However given its role in metabolic pathways, we hypothesise that serum levels of LDH may also be a biomarker of fatigue in pSS.

Objectives: 1. To investigate the bivariate relationship between LDH and fatigue severity, hypothesising a positive correlation between them.
2. To incorporate factors such as depression, anxiety, serum creatinine and haemoglobin levels as covariates, as these factors may also contribute to fatigue.

Methods: We used routinely collected clinical and laboratory data from 512 pSS patients from the Newcastle Sjögren’s syndrome cohort. The participants consented for their linked anonymised data to be used in pSS-related research. Severity of fatigue was measured using fatigue subscale of EULAR Sjogren’s Syndrome Reported Patient Index (ESSPRI) - a Likert scale of 0-10. Fatigue severity was also categorised into 4 categories: 0-2 being minimal, 3-5 mild, 6-7 moderate and 8-10 severe. Hospital Anxiety and Depression Score was used to measure patients’ anxiety and depression levels. Blood parameters including haemoglobin, full blood count, ESR, CRP, serum creatinine, alanine aminotransferase (ALT), alkaline phosphatase (ALP) and LDH were checked during each visit. Dryness was measured using ESSPRI dryness subscale. Statistical analysis of the relationship between the continuous blood parameters and categorical fatigue groups was performed using Kruskal-Wallis for categorical fatigue groups and linear regression for continuous fatigue measures.

Results: The majority of the patients were female (87%) and Caucasian. Baseline measurements of pain, anxiety, depression, abnormal fatigue, mental fatigue and overall ESSPRI score increased with increasing fatigue severity. This is seen most prominently in serum LDH levels. LDH levels increased with increasing fatigue scores. We identified significant differences in baseline LDH levels across the four fatigue groups (p = 0.002). Within groups comparisons showed significant differences between mild and minimal, severe and minimal and moderate and minimal fatigue groups only (p-values: 0.026, 0.019 and 0.032 respectively). A baseline linear regression model for fatigue using LDH, CRP, and gender was performed and showed LDH has a significant relationship with fatigue p=0.007. Findings were also determined using ANOVA where significant difference (p= 0.0023) of LDH between fatigue groups were identified using a Tukey-Kramer test. A supplementary Tukey-Kramer test was carried out to determine if LDH was significant between two-groups of fatigue severity score, where significant difference was seen between three different sets of fatigue categories: mild-minimal, severe-minimal and moderate-minimal. The test ensured that a relationship between the enzyme and fatigue was present especially between the groups of fatigue severity stated above. The actual-by-predicted and leverage plot further supports our finding by showing the unique effect of LDH in the models.

Conclusion: The study concludes that a relationship between enzyme lactate dehydrogenase and fatigue exist; however, further study will be required to examine its role as a predictor of fatigue severity in pSS. The complex interconnection between inflammation, disease activity, psychological factors and LDH will have to be further investigated to advance the current understanding of chronic fatigue in Sjogren syndrome.

THE ASSESSMENT OF CLINICAL CHARACTERISTICS OF MALE SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

M. Canbas1, S. Colak1, E. Tekgoz2, M. Cinár1, S. Yılmaz1. 1University of Health Sciences Turkey; Guzeliye Faculty of Medicine, Guzeliye Education And Research Hospital; Division of Rheumatology, Ankara, Turkey

Background: Systemic lupus erythematosus (SLE) is a multisystemic chronic autoimmune disease that is nine times more frequent among females. Due to a female dominance, the data regarding male patients is limited.

Objectives: This study aimed to evaluate the clinical characteristics of male patients with SLE.

Methods: This retrospective study included male SLE patients who followed up in a tertiary rheumatology outpatient clinic between October 2016 and December 2021. Those who met the Systemic Lupus International Collaborating Clinics (SLICC) criteria were included. The data of the patients and SLE Disease Activity Index-2000 (SLEDAI-2K) values were obtained from files.

Results: There were 40 male SLE patients with a mean age of 42.7 ± 17.3 years. The median age of diagnosis was 30 years, and the median disease duration was 63.5 months (ranges between 5-444). The mean value of the SLICC score was 4.7 ± 0.8. The most frequent initial clinical manifestations were thrombocytopenia and photosensitivity, which were seen in 8 (20.0%) patients each (Table 1). Six (15.0%) patients had secondary antiphospholipid antibody syndrome. Thirty-five (87.5%) patients achieved remission, but 14 (35%) patients had at least one relapse in the follow-up period. The most frequent manifestation after relapse was nephritis in 9 (22.5%) patients that had no renal involvement at the time of diagnosis. The median SLEDAI score was 2 (ranges between 0-12). The most commonly preferred drug for the treatment was hydroxychloroquine and corticosteroids (92.5% for each). Nineteen (47.5%) patients received pulse steroids. Besides, the most frequently prescribed immunosuppressive drug was mycophenolate mofetil (37.5%). The rates of azathioprine, cyclophosphamide, methotrexate, cyclosporine A, rituximab, intravenous immunoglobulin, and lefunomide usage were 30%, 27.5%, 17.5%, 10%, 75%, 5%, respectively. Antinuclear antibody (ANA) was positive in 35 (87.5%) patients, and anti-dsDNA was positive in 9 (22.5%). The median level of anti-dsDNA titer was 40 IU/ml (ranges between 23-200). Other autoantibody positive rates were; 12 (30%) for anti-Sm, 6 (15%) for anti-histone, 4 (10%) for anti-RO and 4 (10%) for anti-nucleosome. Ten (25.0%) patients had low C3 levels, and 11 (27.5%) patients had low C4 levels. The hospitalisation rate was 55%, and no death was seen during follow-up.

Conclusion: Since SLE is more prevalent among females, it may occur in male patients with mild or life-threatening manifestations. In the current study, the sero-positivity was less than in the literature, which may indicate male patients should be cautiously evaluated. Although renal involvement is not an initial manifestation, it may develop during the follow-up.

PROSPECTIVE STUDY OF 24 MONTHS OF EVOLUTION OF A COHORT OF PATIENTS WITH RHUPUS

I. Martínez Costellá1, C. Pávez Perelles1, S. Leal Rodriguez2, A. V. Huaylla Quipe1, C. Riesco Barcena1, L. Mas Sanchez2, P. Muñoz Martínez1, I. Cánovas Olmos1, M. De la Rubia Navarro1, J. J. Fragil Gió1, L. González Puig2, E. Grau García1, J. Ivorra Cortés1, C. Nájera Herranz1, R. Negueroles Albuixech2, E. Vicens Bernabeu1, J. E. Oller Rodríguez1, F. Ortiz-Sanjulián1, J. A. Román Ivorra1. 1La Fe University and Polytechnic Hospital, Rheumatology, Valencia, Spain

Background: Rhupus syndrome (RhS) is a rare combination of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Different studies describe cases of RhS with more frequent initial clinical manifestations in the form of erosive arthritis and the presence of rheumatoid factor (RF) and/or anti-CCP, with later manifestations of SLE appearing.

RhS has a low prevalence and it is useful to know the clinical characteristics of the patients and their evolution over time, since their treatment and clinical management differ from those who present RA or SLE in isolation.

Objectives: Our objective was to study the clinical, analytical and therapeutic evolution of our cohort of patients with Rhupus.
Methods: Prospective study of a cohort of patients with Rhus during 2020-2021 with systematic review of electronic records for the analysis of clinical, analytical and therapeutic parameters throughout follow-up.

Results: Nine patients with RNS (88.9% women) who met SLICC 2012 criteria for SLE and ACR 2010 for RA were included. The mean age was 62.7 (45-86) years. During follow-up, the death of one case due to metastatic pulmonary neoplasia was verified, as well as the incorporation of a new patient in the study population. In 4 cases, RA was the first diagnosis, with a mean evolution of 6.25 years until the diagnosis of SLE. On the contrary, in 5 cases SLE was the first diagnosis with a mean evolution of 7.2 years until the diagnosis of RA. Photosensitivity and arthritides were the predominant clinical manifestations. One patient presented rheumatoid nodules in both elbows and 2 patients presented symptoms of seborrhoea in the form of pleuropericarditis. No cases of renal or neurological involvement were recorded.

Clinically, the patients have remained stable, presenting joint manifestations as the predominant clinic. Regarding the serological evolution, 8 patients presented positive RF at the beginning of the study, 3 of them becoming negative during follow-up. Likewise, the presence of ACRA was positive in 6 patients, maintaining this percentage at the present time. On the other hand, the ANA were positive at the beginning in all the patients, with ANA becoming negative in 5 of them. Antiphospholipid antibodies were positive in 2 patients, however none of them developed antiphospholipid syndrome.

4 patients were treated with biological drugs/JAK inhibitors (1 abatacept, 1 rituximab, 1 brecitinib and 1 tofacitinib) with a favorable response.

Conclusion: The analysis of our cohort continues to show that, unlike other series, 44.4% of RhS cases begin with seropositive polyarticular arthritis. 55.6% of these start with manifestations compatible with SLE, in the form of hematological, cutaneous and serological alterations, and these show a more prolonged progression to develop polyarticular involvement. Therefore, a diagnosis of RhS continues to be reached earlier in patients who present with symptoms of RA.

37.5% of patients had a negative RF, maintaining ACRA in all of them. ANA were negative in 55%. Neither of the 2 patients with anti PL Ab developed APS.

Clinically, joint manifestations in the form of arthralgia of small joints were the predominant clinic. In general, the evolution has been favorable. Four patients were refractory to treatment with cDMARDs, requiring the use of biological drugs/JAK inhibitors with good response.

LEPTIN LEVELS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS, CONNECTION WITH COURSE OF THE DISEASE AND Atherosclerotic VASCULAR LESIONS

O. Shikina1, S. Shevchuk1. National Pirogov Memorial Medical University, Vinnytsya, Internal Medicine Chair №2, Vinnytsya, Ukraine

Background: Atherosclerosis and its complications remain the leading causes of death in patients with systemic lupus erythematosus (SLE). Along with the known pathogenic factors that significantly accelerate the development of cardiovascular events in patients with SLE (hyperinsulinemia, hypertension, atherogenic dyslipidemia, disease activity, etc.), in recent years the role of dysadipokinemia has been intensively studied. In patients with SLE serum leptin increases, but how its concentration changes under the conditions of the inflammatory process and how it is associated with other factors that aggravate the course, have not been studied enough. Its role in the formation of atherosclerotic vascular lesions in patients with SLE is also unknown.

Objectives: The aim of the study was to assess leptin levels in patients with SLE and to analyze its relationship with the course of the disease, lipid spectrum and atherosclerotic vascular lesions.

Methods: We examined patients with SLE (31 women and 4 men), mean age = 46.23 ± 1.36 years). The average duration of the disease was 9.97 ± 0.82 years. SLE was confirmed on the basis of ACR / EULAR criteria (2019) and formulated according to the classification recommended by the Association of Rheumatologists of Ukraine (2020). The control group included 20 healthy individuals of the appropriate age and sex.

The content of leptin in the serum was determined by enzyme-linked immunoassay according to the instructions of the manufacturer. The SLEDAI index was used to assess activity. Assessment of endothelial function was determined by the Celemayer method.

Results: The level of leptin in the serum in apparently healthy individuals and patients with SLE differed significantly. In particular, the average hormone content in patients with SLE was 39.4 ± 3.4 ng / ml, while in the control group - 24.4 ± 3.8 ng / ml, ie was higher by 38.1% (P < 0.01). The patient’s age and disease duration were weakly related to leptin levels (r = 0.25, r = 0.34, respectively).

It was found out that in patients with SLE serum leptin levels were directly proportional to the disease activity. In particular, a close associative relationship was established between the activity of the disease determined by the SLEDAI index and ESR (r = 0.81, r = 0.42, respectively). The study found a close association between serum leptin concentrations and blood lipid spectrum in patients with SLE. In particular, it was the highest with LDL/low density lipoprotein (r = 0.54) and probable with total cholesterol and triglycerides (r = 0.32, r = 0.28, respectively).

In patients with SLE with a high (≥42.2 ng / ml) leptin level, the endothelium-dependent vasodilation brachial artery (EDV BA) was 52.3% higher and the CCA IMT (common carotid artery intima-media thickness) was 32% higher than in patients with relatively normal leptin levels. In addition, the proportion of patients with a decrease in EDV BA and an increase in the area of CCA IMT among patients with high leptin levels was 12–25% higher than among patients with relatively normal levels of the enzyme under study. The presence of atherosclerotic plaques, their area and the severity of atherosclerotic lesions of the carotid arteries also determined the tendency to increase in proportion to the increase in serum leptin levels. Thus, hyperleptinemia in patients with SLE is associated with deterioration of vascular function of the carotid artery and the severity of atherosclerotic vascular lesions.

Conclusion: Significantly higher levels of serum leptin were found in patients with SLE, which were associated with inflammatory activity and dyslipidemia, as well as with structural and functional reorganization of blood vessels, which should be considered as an important risk factor for vascular lesions.

RELATIONSHIP OF EXERTIONAL ACTIVITY AND MENTAL WELLBEING IN SYSTEMIC LUPUS ERYTHEMATOSUS

S. Beider1, T. Witte1, D. Ernst1. Medical School Hanover, Department of Rheumatology and Immunology, Hanover, Germany

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with a variety of clinical manifestations [1] and has a profound effect on physical health [2]. Anxiety and depression are common symptoms of SLE which can have a significant impact on the quality of life [3].

Objectives: To study whether or not the physical state of health relates to the extent of anxiety and depression in SLE patients.

Methods: The Physical Component Summary Score (PCS) was determined using the 36-Item Short Form Survey (SF-36) in a cohort of 146 SLE patients consecutively visiting our outpatient clinic. Two groups were compared: one group with low PCS (<50 %) (LPCS) and the comparison group with high PCS ≥50% (HPCS). Patients with SLE who visited our Rheumatology clinic between March 2019 and December 2020 as part of a monocentric cross-sectional study completed additional standardized questionnaires: Hospital Anxiety and Depression Scale (HADS), Beck’s Depression Inventory (BDI II), Multidimensional Assessment of Fatigue (MAF), Functional questionnaire Hannover (FbH) and the international questionnaire on physical activity in short form (IPAQ-SF). The data was analyzed with SPSS 27 (IBM, Armonk, NY, USA). The tables include bivariate and partial correlations. Significance tests were performed using non-parametric tests.

Results: In total, 146 patients participated in the study. 14.4 % (n = 21) were men, the mean age was 50.4 ± 12.2 years. The mean state of physical health according to SF36 was 54.9 ± 25.6 % in the cohort examined.

There were 62 (42.5 %) patients with LPCS, of average age 50.4 ± 10.3 years and 84 (57.5 %) with HPCS, of average age 47.2 ± 13.3 years. The majority of patients in both groups were female (55/7, 88.7 % and 70/14, 83.3 %).

A SLEDAI score > 2 was confirmed in 33.9 % (n = 21) of the patients with LPCS and in 25 % (n = 21) of patients with HPCS, the mean SLEDAI score did not significantly differ between LPCS and HPCS patients (2.4 versus 1.9, p = 0.261). Among patients with LPCS, 54.8 % (n = 34) presented low physical activity and 64.5 % reported functional impairment (FFbH < 80). More than half of LPCS-patients (53.2 %, n = 33) showed a low Mental Health summary score (MCS < 50 %) and over a third of them had moderate to severe depression (BDI II > 19, 38.7 %, n = 24) and indicated pathological anxiety (HADS > 10, 37.1 %, n = 23).

Compared to the LPCS group, a smaller number of patients with HPCS had low physical activity (36.9 %, n = 31, p = 0.031) and the difference in mean weekly MET between the two groups was 2730 counts (p = 0.003). There was no impairment of functional capacity in patients with HPCS (FFbH mean Score 90.9 %, p < 0.001). In contrast to the LPCS group, only 17 % (n = 15) of the patients with HPCS showed MCS < 50 % (p < 0.001). Completely free of depressive symptoms were 65.5 % (n = 55) of the patients with HPCS and only 4 patients (4.8 %) reported moderate to severe depression (p < 0.001).

Patients with LPCS reported fatigue (GFI > 20) more often than patients with HPCS (98.4 % versus 54.8, p < 0.001).

Conclusion: SLE patients with low physical health conditions have highly significant mental health impairment, particularly anxiety and depression. Physical functioning and limitations due to physical health should be considered and physical activity needs to be improved. Measurement of the PCS should be a routine tool in the overall assessment of the health conditions of SLE patients.

L. Moro1,2, G. Ferrari3,4, F. Bonelli5, V. Batani6,7, M. Bellone1,2, M. Matucci-Cerinic8, L. Dagna1,2,11, IRCCS Ospedale San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; 2Vita-Salute San Raffaele University, Milan, Italy; 3IRCCS Ospedale San Raffaele, Cornea and Ocular Surface Unit, Milan, Italy; 4IRCCS Ospedale San Raffaele, Eye Repair Lab, Milan, Italy; 5University of Verona, Department of Medicine, Verona, Italy; 6University of Florence, Department of Clinical and Experimental Medicine, Florence, Italy

Background: Ocular involvement in primary Sjögren’s Syndrome (pSS) has been traditionally assessed by Schirmer’s test, Tear Break Up Time (TBUT) and Ocular Staining Score (OSS).

The role of Ocular Surface Disease Index (OSDI), Visual Function Questionnaire-25 (VFQ-25) and Numerical Rating Scale (NRS) in measuring ocular pain and discomfort in pSS have not yet been investigated in detail.

Objectives: To explore the prevalence of ocular pain in patients with pSS, and to investigate the potential correlations between dry eye, ocular pain, extraocular patient-reported outcomes and disease activity.

Methods: In this ongoing cross-sectional study, OSDI, VFQ-25 and NRS for ocular pain were administered to 19 consecutive patients with a definite diagnosis of pSS at our outpatient clinic. All patients signed an informed consent for the study. Pearson coefficients were obtained to assess correlation among EULAR Sjögren’s Syndrome (SS) disease activity index (ESSDAI), EULAR SS Patient Reported Index (ESSPRI), erythrocyte sedimentation rate (ESR), TBUT, OSDI, VFQ-25 and NRS.

Results: In the study, 19 consecutive patients have been enrolled so far. The sample demographics and disease-related features are representative of a typical pSS population (10% male sex, median age at diagnosis of 49 [IQR 24], median age 50.5 (10.3) years and disease duration 10.3 (7.0) years, were enrolled. Baseline SLEDAI-2K was 6.0 (2.0) driven predominantly from the musculoskeletal and mucocutaneous domains. The prevalence of anxiety (HADS-A >11) and depression (HADS-D >8) were 42.5% and 45.0%, respectively. During follow-up, disease activity was significantly reduced (average [SD] reduction in SLEDAI-2K, PGA), use of medications, and treatment adherence (Morisky Medication Adherence Scale-4 items scale) were monitored during the observation period.

Results: Forty SLE patients (39 females) with an average [standard deviation] age 50.5 (10.3) years and disease duration 10.3 (7.0) years, were enrolled. Baseline SLEDAI-2K was 6.0 (2.0) driven predominantly from the musculoskeletal and mucocutaneous domains. The prevalence of anxiety (HADS-A >11) and depression (HADS-D >8) were 42.5% and 45.0%, respectively. During follow-up, disease activity was significantly reduced (average [SD] reduction in SLEDAI-2K, 1.90 [2.80], p<0.001), however, anxiety and depression levels remained unchanged (average [SD] change in HADS-A -0.05 [3.76] and HADS-D 0.53 [3.25], respectively, p=0.300 for both). Accordingly, Spearman’s non-parametric test showed that longitudinal changes in SLEDAI-2K were not significantly correlated with the corresponding changes in the HADS-A (rho = 0.13, p=0.417) and HADS-D (rho = -0.05, p=0.781) scores. Treatment non-adherence was found in 19 patients (47.5%) but did not correlate with anxiety and depression (p>0.500 for both). Notably, mental disorders were not significantly associated with comorbidities (including fibromyalgia) but unemployment status predicted the presence of anxiety (odds ratio 7.73, p-value 0.018).

Conclusion: Anxiety and depression are frequent comorbidities in active SLE and do not correlate with short-term disease improvement, thus underscoring the need for adjunct treatment. Physician awareness in the detection of treatment adherence is necessary. Larger studies in early disease and with longer follow-up will be required to further explore the possible interaction between mental disorder and lupus disease course.

DEPRESSION, SELF-ESTEEM AND QUALITY OF LIFE IN SJÖGREN'S SYNDROME

T. Ramia¹, S. Daada², I. Chaabane³, R. Kissi⁴, S. Hammami⁵, K. Ines⁶, M. Kechida⁷, ¹Fattouma Bourguiba University Hospital, Internal Medicine Department, Monastir, Tunisia

Background: Sjögren's syndrome (SS) is a connective tissue disease characterized by a triad of fatigue, pain and dryness. SS is a chronic condition with important repercussions on functioning and a source of significant suffering. Therefore, the assessment of depressive symptoms, self-esteem and quality of life (QOL) is important in the clinical and research context.

Objectives: We aimed to describe the clinical picture, depression, QOL and self-esteem of patients followed for SS and to study their association with disease activity.

Methods: This is a descriptive and analytical cross-sectional study including 42 patients with SS diagnosed based on the criteria of the American European Consensus Group of 2002 (AECG). Depression was evaluated by the Beck 13 scale, QOL by the SF-36 and self-esteem by the Rosenberg scale. Disease activity was assessed by EULAR Sjögren Syndrome Disease Activity Index (ESSDAI).

Results: The average age was 54.5 ± 15.67 years and the sex ratio was 0.2. Assessment of disease activity of these patients showed an average activity score of 8.23 ± 6.39 with low activity in 16 patients (38.1%), moderate activity in 18 patients (42.9%) and severe activity in 8 patients (19%). The QOL measured by SF-36 was impaired in all areas with average ranges from 39.76 for physical limit to 66.28 for emotional limit. Depression score evaluated by the Beck scale was 8.42 ± 7.05 average with 59.5% of the patients having depression. The self-esteem score evaluated by Rosenberg scale was 32.8 ± 5.70 average. Self-esteem was rated as low to very low in 30.95% of patients.

Conclusion: The antidepressant and depression were correlated to disease activity, taking into account these aspects in SS can improve the overall management of the disease.

SD - standard deviation

Conclusion: Raised serum uric acid levels in SLE patients are associated with a higher incidence of hypertension, hypercholesterolemia, obesity, diabetes mellitus, decreased glomerular filtration rate, with a higher Charlson comorbidity index, but not with disease activity.

MANAGEMENT AND ASSOCIATED FACTORS

SYSTEMIC LUPUS ERYTHEMATOSUS: PREVALENCE, NEUROPSYCHIATRIC MANIFESTATIONS IN SLE, WITH GOUT, ACTIVE INFECTIONS, ONCOLOGICAL DISEASES, WITH GLOMERULAR REPORTS (≤360 µmol/l) – group 1 and of 106 SLE pts with normal uric acid level in 3 laboratory reports (>360 µmol/l) – group 2. Pts with rheumatological diseases other than SLE, with gout, active infections, oncological diseases, with glomerular filtration rate <30ml/min*1.73 m2 and other secondary reasons of HP were excluded. The clinical and laboratory data, presence of comorbidities, Charlson Comorbidity Index, SELENA-SLEDAI were analyzed. SPSS2020 was used to Statistics. Local ethics committee approved the study.

RESULTS: SLE pts with and without HP were matched in age, sex and disease activity characteristics, Table 1 (p<0.05). Uric acids' level did not correlate with activity of SLE (SELENA-SLEDAI), Spearman r=0.06, p<0.05. Hypertension, obesity, hypercholesterolemia, diabetes mellitus, lower renal function were more common in SLE patients with HP than in SLE patients without HP, Table 1. Charlson comorbidity index was higher in SLE pts than in SLE pts without HP (p<0.05).

Background: Comorbidities play an important role in the course and prognosis of systemic lupus erythematosus (SLE) [1]. Hyperuricemia (HP) could cause an increased burden of comorbidities in SLE patients (pts).

Objectives: To evaluate the interrelation between HP and comorbidities in pts with SLE.

Methods: We performed retrospective analysis of the data from 191 SLE pts that were collected in electronic Saint-Petersburg rheumatological register in a period from 01 Jan 2009 until 31 Dec 2020. In analysis were involved data of 85 SLE patients with hyperuricemia (serum uric acid level >360 µmol/l in 3 reports) (group 1) and of 106 SLE pts with normal uric acid level in 3 laboratory reports (≤360 µmol/l) – group 2. Pts with rheumatological diseases other then SLE, with gout, active infections, oncological diseases, with glomerular filtration rate <30ml/min*1.73 m2 and other secondary reasons of HP were excluded. The clinical and laboratory data, presence of comorbidities, Charlson Comorbidity Index, SELENA-SLEDAI were analyzed. SPSS2020 was used to Statistics. Local ethics committee approved the study.

RESULTS: SLE pts with and without HP were matched in age, sex and disease activity characteristics, Table 1 (p<0.05). Uric acids' level did not correlate with activity of SLE (SELENA-SLEDAI), Spearman r=0.06, p<0.05. Hypertension, obesity, hypercholesterolemia, diabetes mellitus, lower renal function were more common in SLE patients with HP than in SLE patients without HP, Table 1. Charlson comorbidity index was higher in SLE pts than in SLE pts without HP (p<0.05).

Table 1. Characteristics and occurrence of comorbidities in SLE pts.
AB0542 ANTIPHOSPHOLIPID ANTIDIES CARRIERS WITH THROMBOCYTOPENIA COULD BE AN INDEPENDENT PHENOTYPE OF PRIMARY ANTIPHOSPHOLIPID SYNDROME

Y. Shi1, J. Zhao1, X. Zeng1. Chinese Academy of Medical Sciences, Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China

Background: Among patients with immune thrombocytopenic (ITP), 10–20% of them were found with positive antiphospholipid antibodies (aPLs) but without typical clinical manifestations of antiphospholipid syndrome (APS), especially thrombotic events.

Objectives: To compare the clinical characteristics and prognosis between aPLs carriers and patients with APS.

Methods: This is a single center prospective cohort study consecutively enrolling thrombocytopenic patients with continuous positive aPLs. Patients developing thrombotic events are classified as the APS group. The exclusion criteria are other underlying connective tissue diseases such as lupus and other causes that might manifest as thrombocytopenia, such as virus infection, hypersplenism, etc.

Results: This cohort included 47 thrombocytopenic patients with continuous positive aPLs and 55 with diagnosed primary APS. The proportion of thrombotic high risk demographic characteristics including smoking, hypertension, and higher level of homocysteine are higher in the APS group (p = 0.03, 0.04, respectively). The prevalence of nephropathy was significantly higher in APS patients (13.8%) than APS patients (4.1%). The mean sedimentation rate (ESR) was 53.7 ± 34.4 mm [2–130]. The mean C-reactive Protein was 13.6 ± 27.8 mg/dL [0–130]. Anti-nuclear antibodies and anti-DNA were positive in 100% and 41.4% of cases, respectively. Anti-Sm antibodies were positive in 13.5%, anti-SSA in 24.1% and anti-SSB in 13.8% of cases. Antiphospholipid was positive in 8 patients.

Discussion: The platelet count of aPLs carriers and patients with APS [0 vs 7 (12.7%), p = 0.01]. Laboratory results and antibody profiles are presented in Table 1.

Disclosure of Interests: None declared

AB0543 HIGHER LEFT VENTRICULAR MASS INDEX IN PATIENTS WITH LUPUS NERPHRITIS

N. Guajardo-Jauregui1, J. R. Azpiri-López2, J. I. Colunga-Pedraza1, D. A. Galarza-Delgado1, A. Cárdenas1, A. N. Garza-Cisneros1, A. Garcia-Heredia1, M. A. Balderas-Palacios1, A. B. Rodríguez-Romero1. Hospital Universitario “Dr. José Eleuterio González”, Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico; Hospital Universitario “Dr. José Eleuterio González”, Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico

Background: Systemic lupus erythematosus (SLE) patients have a worse cardiovascular prognosis than the general population. It is estimated that approximately 40% of SLE patients develop lupus nephritis (LN) throughout the evolution of the disease (1). Patients with LN had 8 times more risk of myocardial infarction and 4 times more risk of cardiovascular mortality than SLE patients without LN (2).

Objectives: To compare the echocardiographic parameters between SLE patients with and without LN.

Methods: This was a cross-sectional study nested of a SLE cohort. We recruited patients with SLE diagnosis, according to the 2019 EULAR/ACR

Results: A total of 48 SLE patients, 24 with LN and 24 without LN were included. Mean age of patients with LN was 36.9 ± 10.4 years, compared to 36.5 ± 9.3 years in patients without LN, \( p = 0.873 \). There were no significant differences in demographic characteristics between groups (Figure 1). When evaluating echocardiographic parameters we found a significant difference in the left ventricular mass index, higher in LN patients (66.9 g/m² vs 54.8 g/m², \( p = 0.035 \)) (Table 1).

SLE: systemic lupus erythematosus; LN: lupus nephritis; NS: not significant; LV: left ventricular; RVT: relative wall thickness; LAESVI, left atrial end-systolic volume index; LVEF, left ventricular ejection fraction; LVEF, left ventricular end-systolic volume; LVESVI, left ventricular end-diastolic volume.

Conclusion: SLE patients with LN had higher left ventricular mass index than SLE patients without LN. An increased left ventricular mass could lead to the development of ventricular hypertrophy, which is associated to a higher risk of cardiovascular mortality. A transthoracic echocardiogram should be considered as part of the cardiovascular evaluation of SLE patients, especially those with LN.

Disclosure of Interests: None declared

Background: Systemic lupus erythematosus (SLE) is an autoimmune inflammatory disease. Patients with SLE have higher risk of developing a cardiovascular event than the general population (1), with multiple factors contributing to this increased risk, including systemic inflammation (2).

Objectives: To compare the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and other disease characteristics of SLE patients with and without left ventricular (LV) geometry abnormalities.

Methods: This was a cross-sectional study nested of a SLE cohort. We recruited patients with SLE diagnosis, according to the 2019 EULAR/ACR classification criteria, aged ≥ 18 years. Patients with a previous cardiovascular event, another connective tissue disease or pregnancy were excluded. A transthoracic echocardiogram was performed by two certified echocardiographers blinded to clinical information. Disease activity was assessed with SLEDAI. SLE patients with LV geometry abnormalities were included in this study and matched by age and gender to SLE patients with normal LV geometry by a certified rheumatologist blinded to clinical information. Comparisons were done with Chi-square test or Fisher’s exact test for qualitative variables, and Student’s T test or Mann-Whitney’s U test for quantitative variables. A \( p \)-value < 0.05 was considered statistically significant.

Results: A total of 44 SLE patients were included, 22 patients with LV geometry abnormalities and 22 patients with normal LV geometry. Mean age of SLE patients with LV geometry abnormalities was 35.1 ± 12.2 years, compared to 35.4 ± 9.4 years of SLE patients with normal LV geometry, \( p = 0.923 \). The rest of demographic characteristics are shown in Figure 1. When evaluating disease characteristics, the SLEDAI score was significantly higher in SLE patients with LV geometry abnormalities (26.45 vs 17.33, \( p = 0.016 \)) (Table 1).

Table 1. Comparison of disease characteristics of SLE patients with and without LV geometry abnormalities.

SLE: systemic lupus erythematosus; LV: left ventricular; NS: not significant; SLEDAI: Systemic Lupus Erythematosus Disease Activity Index; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; ANA: antinuclear antibodies; anti-dsDNA, anti-double stranded DNA.

Conclusion: SLE patients with LV geometry abnormalities had higher SLEDAI score than patients with normal LV geometry. A transthoracic echocardiogram may be useful detect early cardiovascular abnormalities in SLE patients with high disease activity, and therefore should be considered as part of the cardiovascular evaluation of these patients.

Disclosure of Interests: None declared

REFERENCES:
The thymus, a primary lymphoid organ, plays a crucial role in immune system homeostasis. In systemic lupus erythematosus (SLE), the thymus is a target organ for autoimmunity, and thymic abnormalities are frequently observed in SLE. Recent studies have suggested that thymic abnormalities are associated with the disease activity and damage in SLE. In this study, we investigated the association between radiographic thymus variants and clinical and immunological features in patients with SLE and PM/DM, and clarified its significance.

Methods: In this retrospective study, we examined 144 SLE patients (9.1% and 9.1%, respectively) and 15 PM/DM patients (9.1% and 9.1%, respectively). Thymic enlargement was found in 16 (22.2%) and 14 (28.8%) patients with SLE and PM/DM, respectively. Thymus attenuation (score ≥ 2) was found in 11 (15.3%) and 9 (19.1%) patients with SLE and PM/DM, respectively. These findings were more frequent than in non- connective tissue diseases patients (9.1% and 9.1%, respectively). In SLE patients, radiographic thymus variants, both thymic enlargement and the thymus attenuation score, were significantly positively associated with body weight, and the thymic attenuation score was negatively associated with the ratio of serum IgG and significantly negatively associated with the ratio of serum RF. In these high-risk pregnancies, maternal serum concentration of antiphospholipid antibody positivity was high (69.2% vs. 42.9%, p=0.052) in vasculitis group. In multivariate logistic regression analysis, higher SLEDAI score was positively associated with lupus nephritis and anti-DNA positivity (87.5% vs. 62.5%, p=0.008) but negatively associated with lupus nephritis.

Conclusion: In SLE, vasculitis presentation is common. Higher the SLEDAI score the more chance of lupus vasculitis.

the anti-angiogenic factor soluble Fms-like tyrosine kinase-1 (sFlt-1) and the pro-angiogenic factor placental growth factor (PIGF) can predict fetal growth restriction and preeclampsia (1-3).

Methods: Patients with SLE and APS that followed in our outpatient clinic were retrospectively analysed for their pregnancy course and outcomes. In these high-risk pregnancies, the sFlt-1/PIGF ratio was measured in the context of screening for preeclampsia and a ratio below 38 was applied to exclude preeclampsia. We compared the sFlt-1/PIGF ratio between patients with and without adverse pregnancy outcome. Adverse pregnancy outcome (APO) was defined as preeclampsia, preterm delivery and small for gestational age newborns.

Results: We analysed sFlt-1/PIGF ratios of 13 singleton pregnancies in 12 patients with SLE and/or APS (4 SLE, 6 SLE with APS or aPL, 2 obstetric APS). Low-dose aspirin was used in all but one pregnancy with de-novo obstetric APS. Low-molecular weight heparin was given in seven pregnancies. Adverse pregnancy outcome occurred in five pregnancies thereof two with preeclampsia. The median sFlt-1/PIGF ratio measured between gestational week 22 and 37 was higher in patients with APO (median 173, range 4-1904) than in patients without APO (median 7.5, range 50) (P=0.03). The sFlt-1/PIGF ratio > 38 was found in 6 pregnancies including two with preeclampsia. Highest sFlt-1/PIGF ratios were found in a case with severe intrauterine growth restriction without signs of preeclampsia (sFlt-1/PIGF=1940) and in a case with early preeclampsia (< week 34 (sFlt-1/PIGF=1187). In pregnancies with a sFlt-1/PIGF ratio < 38 there were no signs of preeclampsia or intrauterine growth restriction.

Conclusion: The detection of a dysbalanced sFlt-1/PIGF ratio is clinically useful as it differentiates between pregnancies with adverse outcome and those with normal outcome. More data are needed to further evaluate the predictive potential of these placental biomarkers in the first trimester and their usefulness for treatment adjustments in order to improve pregnancy outcome.

Figure 1. Distribution of adult-onset and childhood-onset NPSLE patients

AB0548 A COMPARATIVE STUDY BETWEEN THE NEUROPSYCHIATRIC INVOLVEMENTS IN ADULT-ONSET AND CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

1Hacettepe University Faculty of Medicine, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey; 2Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey; 3Hacettepe University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey; 4Hacettepe University Faculty of Medicine, Department of Neurology, Ankara, Turkey; 5Hacettepe University Faculty of Medicine, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey; 6Hacettepe University Faculty of Medicine, Department of Pediatric Neurology, Ankara, Turkey; 7Hacettepe University Faculty of Medicine, Department of Radiology, Ankara, Turkey

Background: Neuropsychiatric(NP) manifestations in systemic lupus erythematosus(SLE) encompass a wide spectrum of neurologic and psychiatric features. The nervous system is frequently affected by adult-onset and childhood-onset SLE patients, but disease course and clinical features may differ between both groups.

Objectives: The aim of this study is to evaluate and compare NP manifestations in adult-onset and childhood-onset SLE patients.

Methods: The study included a retrospective analysis of medical records of adult-onset SLE patients and childhood-onset SLE patients following at Hacettepe University from Jan 2015 to Jan 2021. The ACR established case definitions seen in SLE. Additionally, posterior reversible encephalopathy syndrome, cerebral venous thrombosis, small fiber neuropathy and pseudotumor cerebri were evaluated as having NPSLE in this study.
AB0549

OBESITY AND TOBACCO SMOKING ARE INDEPENDENTLY ASSOCIATED WITH POOR PATIENT-REPORTED OUTCOMES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS FROM A SWEDISH TERTIARY REFERRAL CENTRE

A. Gomez,1,2 I. Parodi,1,2 C. Siowja,1 Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden;3 Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden; Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection, Linköping, Sweden

Background: Patients with systemic lupus erythematosus (SLE) experience impaired health-related quality of life (HRQoL), pain, fatigue and functional disability. The effect of pharmacotherapy on these aspects has been inconclusive in literature. In light of this, the investigation of the impact of lifestyle facets is needed to support complementary non-pharmacological interventions such as weight control strategies and tobacco smoking cessation.

Objectives: To evaluate associations of obesity and tobacco smoking with SLE patients’ HRQoL, pain, fatigue and functional disability.

Methods: Patients from the Linköping University Hospital with an SLE diagnosis according to the 1982 American College of Rheumatology (ACR) and/or the 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria were included in the present cross-sectional analysis of data captured at visits between January 2008 and September 2021. Among consecutive visits, the first visit with complete demographic, clinical and patient-reported data was selected for the present analysis.

Body mass index (BMI) categories were based on the World Health Organization classification: underweight (BMI <18.5 kg/m²), normal weight (18.5 ≤ BMI <25 kg/m²), pre-obesity (25 ≤ BMI <30 kg/m²) and obesity (BMI ≥30 kg/m²). Smoking status was self-reported and categorised into never, prior and current smoking. HRQoL was self-reported using the 3-level EuroQoL 5-Dimension (EQ-5D-3L) index scores. Visual analogue scales (VAS; 0–100) were used to self-report fatigue, pain and well-being within the preceding 7 days. Functional disability was evaluated using the Swedish version of the Health Assessment Questionnaires Disability Index (HAQ-DI). Disease activity was evaluated using the clinical (c) SLEDAI-2K (serology excluded). Comparisons of continuous data between different BMI and smoking categories were performed using the Mann-Whitney U test and Kruskal-Wallis test. Multivariable linear regression analysis was employed to assess independence and priority of contributors to HRQoL and functional impairment.

Results: Compared with normal weight, obese individuals reported lower VAS fatigue [50.0 (27.0–72.5) versus 32.0 (6.5–89.5); P=0.008], VAS pain [40.0 (11.0–67.0) versus 20.5 (5.3–46.5); P=0.011], VAS well-being [50.0 (27.0–72.5) versus 32.0 (6.5–59.5); P=0.008] and HAQ scores [0.73 (0.36–0.80) versus 0.78 (0.68–0.85); P=0.014], as well as higher VAS fatigue [β =0.12; P=0.021] and VAS pain [β =0.27; P<0.001] and HAQ scores [β =0.30; P=0.001] in obese patients compared with normal weight.

Conclusion: Obesity is independently associated with lower EQ-5D-3L index scores (β =0.12; P=0.021), but not with cSLEDAI-2K (β =0.05; P=0.27), in patients with SLE. Smoking was independently associated with lower VAS fatigue (β =-0.12; P=0.021) and VAS pain (β =-0.30; P=0.001) and HAQ scores (β =-0.30; P=0.001) and HAQ scores (β =-0.30; P=0.001) in patients who were never exposed to regular tobacco smoking. There were no differences across groups regarding cSLEDAI-2K scores.

CUTANEOUS LUPUS AREA AND SEVERITY INDEX (CLASI) CORRELATES WITH SELF-IMAGE SCORE BUT NOT QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. H. Malee2,3,1, D. Maikap2, P. Padhan2, R. Misra2, S. C. Ch, S. Ahmed,1 Kalinga Institute of Medical Sciences, Dermatology, Bhubaneshwar, India; 2Kalinga Institute of Medical Sciences, Clinical Immunology and Rheumatology, Bhubaneshwar, India

Background: Systemic lupus erythematosus (SLE) has multi-system involvement including skin. We explored how skin involvement influenced with the quality of life of patients with SLE.

Objectives: To correlate the domains of SLE QoL with skin involvement and total lupus disease activity.

Methods: A cross-sectional survey of patients with SLE who were carried out to assess Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) and SLE-QoL. Lupus disease activity and damage were quantified using MexSLEDAI (Mexican SLE Disease Activity Index) and SLICC (Systemic Lupus International Collaborating Clinics) Damage Index respectively. Data is expressed as median (IQR).

Disclosure of Interests: None declared

AB0550

CLINICAL AND PROGNOSTIC SIGNIFICANCE OF ANTINUCLEAR ANTIBODIES IN PRIMARY ANTIPHOSPHOLIPID SYNDROME: FRENCH MULTICENTER RETROSPECTIVE STUDY

L. Ricard,1 L. Charlotte,1 M. Papo,1 A. Meikinian,1 Saint Antoine, Internal Medicine, Paris, France;2 Pitié, Internal Medicine, Paris, France

Background: The antiphospholipid syndrome (APS) is defined by the development of vascular thrombosis, or pregnancy morbidity in the presence of persistent antiphospholipid antibodies (APL). Antinuclear antibodies (ANA) can be detected in primary APS patients without any clinical systemic autoimmune disease. The presence of ANA antibodies could confer a specific phenotype in primary APS.

Objectives: To evaluate the characteristics of APS patients with antinuclear antibodies without other autoimmune disease (ANA-positive APS patients) in comparison with primary APS without ANA (ANA-negative APS) or secondary APS patients with associated systemic lupus erythematosus (SLE-APS).

Methods: Clinical and biologic data from 195 APS were retrospectively collected. ANA test was considered to be positive when titers were superior or equal to the 1/80 dilution. ANA-positive APS patients did not fulfilled SLE ACR/EULAR classification criteria.

Results: 40 patients (21%) with ANA-positive APS were included, 77 patients (39%) with primary APS without ANA autoantibodies (ANA-negative APS) and 78 patients (40%) with SLE-APS (SLE-APS). Patients with ANA-positive APS presented arterial thrombosis in 20 cases (51%) and venous thrombosis in 14 cases (41%), adverse obstetrical in 19 cases (51%), non-criteria APS features were noted in 19 cases (51%). ANA-positive APS patients had more non criteria manifestations than ANA-negative APS (48% versus 25%; p<0.01). ANA-positive APS patients had more triple APL positivity and more thrombosis recurrences in comparison with ANA-negative APS patients, respectively (59% versus 18%; p<0.001) and (63% versus 36%; p<0.01). ANA-positive APS and SLE-APS patients had similar clinical manifestations and recurrences. Despite a limited follow-up (28 months (11-50)) none of the ANA-positive APS patients develop SLE. Antplatelet and anticoagulant therapies were similar for the three groups. SLE-APS patients received more immunomodulatory therapies.

Conclusion: ANA positivity in patients with APS enables to individualize a subset of patients with a more severe phenotype. Whereas the ANA positivity does not seem to be associated with the risk to develop SLE, prospective studies with a longer follow-up are necessary, in particular to evaluate the effect of additional therapies in this subset of APS.

Results: In the cohort of 35 patients with SLE, with an age of 26(IQR:17-32) years and including eight (22.9%) males, the CLASI score was 3(1-11.5) with an activity score of 3(1-15) and a chronicity score of 1(0-4). The disease duration was 4years (IQR: 2-3) while SLE-QoL was 73(62-86). Overall, most of the patients had active disease at inclusion with a mex-SLEDAI of 8(6.5-11.5). SLICC was 1(0-4).

The correlation matrix of different domains of the SLE-QoL with CLASI, and Mex-SLEDAI is presented in Table 1. Correlation with SLICC was not analysed since it was zero in the majority of participants. Multivariate analyses were not done since there was lack of association on univariate analysis.

Conclusion: In this cohort of patients with active SLE, the SLE-QoL did not correlate with either the overall disease activity score nor the skin specific score. Only the Self-image domain correlated with the skin score. This implies that in active disease, the skin involvement may have only a minor effect on the quality of life.

AB0552 ELEVATED KYNURENINE LEVELS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME
1Ministry of Health Ankara City Hospital, Department of Rheumatology, Ankara, Turkey; 2Ankara Yildirim Beyazit University, Ankara City Hospital, Biochemistry, Ankara, Turkey; 3Ankara City Hospital, Biochemistry, Ankara, Turkey; 4Acibadem University, Biochemistry, Istanbul, Turkey; 5Ankara Yildirim Beyazit University, Ankara City Hospital, Rheumatology, Ankara, Turkey

Background: Sjögren’s syndrome (SS) is a chronic autoimmune inflammatory disease of unknown origin that predominantly affects the exocrine glands (mainly salivary and lacrimal glands). Primary Sjögren’s syndrome (pSS) is a disease whose etiology is not yet fully understood, as in most autoimmune diseases, where genetic, epigenetic and environmental factors are hypothesized to play to the pathogenesis of the disease. Metabolism of tryptophan (Trp) via the kynurenine (Kyn) pathway has been proposed to act a substantial role in inflammatory processes.

Objectives: In the present study, we investigated levels of Trp and its metabolites in the Kyn pathway in patients with pSS and in healthy controls. Also, the relationship between Trp metabolites and laboratory parameters, disease activity was evaluated in patients with pSS.

Methods: The study included 34 pSS patients and 42 healthy individuals, and serum Trp and Kyn concentrations were measured by liquid chromatography with tandem mass spectrometry (LC-MS/MS). Trp degradation was predicted using the ratio of Kyn and Trp concentrations (Kyn/Trp). The EULAR Sjögren’s syndrome disease activity index (ESSDAI) and the EULAR Sjögren’s Syndrome Patient Reported Index (ESSPRI) were used to evaluate pSS activity.

Results: In our study, the mean serum Trp concentration was found to be considerably lower in the pSS group compared to the control group (p=0.001). The lev-
els of Kyn (p=0.019) and Kyn/Trp ratio (p<0.001) were significantly higher in the pSS group compared to the control group (Table 1). Trp concentration was negatively correlated with physician global assessment (r=-0.568, p<0.001), positively correlated with albumin (r=0.384, p=0.026) and hemoglobin (r=-0.396, p=0.032). The Kyn/Trp ratio was negatively correlated with CRP (r=-0.369, p=0.032). There was no correlation between the Trp pathway and disease activity parameters ESSDAI and ESSPRI.

AB0553 KIDNEY BIOPSY IN FIRST RENAL FLARE OF SLE – WHAT DOES IT TELL US?
L. Karlsön1, A. Zickert1, E. Svennungsson1, I. Gunnansson2, J. Olofsson1, 2Karolinska Institutet, Department of Medicine, Division of Rheumatology, Solna, Sweden; 1Karolinska University Hospital, Rheumatology, Solna, Sweden

Background: Lupus Nephritis (LN) is an immune-complex mediated glomerulonephritis affecting up to 60% of all SLE patients during the disease course. A kidney biopsy is indicated in SLE patients presenting with signs of renal involvement, such as persistent proteinuria, and is generally recommended to evaluate the inflammatory findings but also to rule out other etiologies of renal involvement and to guide the need of immunosuppressive therapy.

Objectives: To investigate the histopathological findings in first-time renal biopsies from a large cohort of SLE patients. We especially evaluated the type and occurrence of histopathological findings other than LN as these may lead to a risk of inadequate therapeutic interventions.

Methods: Patients from the Karolinska SLE cohort who had a first-time onset of renal involvement from 1995 to 2021 and subsequent renal biopsy were included in the study. All patients fulfilled the American College of Rheumatology (ACR) and/or Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) disease classification criteria (1, 2) for SLE and were biopsied on clinical indication, i.e., proteinuria > 0.5g/day or active SLE in combination with a rise in plasma creatinine, decrease in glomerular function or new onset proteinuria with concurrent active urea sediment.

Results: In total, 141 patients with first time presentation of renal involvement who had been subject to renal biopsy were included. Of these 107 patients (75.9%) were female. The median age at the time of biopsy was 34.5 years (range 15.5 - 86.4). For more patient baseline characteristics, see Table 1. One-hundred twenty-five patients (88.7 %) had findings consistent with LN according to ISN/ RPS classification system. Twenty-five patients (18.4 %) had class I - II, 43 (30.5 %) class III ± V, 31 (22.0 %) class IV ± V and 26 (18.4 %) class V. Sixteen patients (15.5 %) did not have histological changes in accordance with LN. Of these, 3 had membranous nephropathy, 2 had antiphospholipid associated nephropathy, 1 had IgA nephropathy, 1 had tubulointerstitial nephritis and 7 had evidence of systemic vasculitis. Of these, 5 were later found to be ANCA-positive and were re-diagnosed with concomitant ANCA-associated vasculitis. Two patients did not
show any classifiable histological changes. Of the 16 non-LN patients, 6 had proteinuria > 0.5 g/day, 2 had new-onset low-grade proteinuria and concurrent active urine sediment, 2 had new-onset low-grade proteinuria with concurrent SLE disease activity, and 5 patients had isolated persistent low-grade proteinuria. In one case data was missing.

### Table 1. Baseline characteristics, 141 patients

| Age at SLE diagnosis (years); M (IQR) | 32.2 (22.0 – 44.9) |
| SLE duration at biopsy (years); M (IQR) | 0.6 (0.2 – 5.3) |
| Systolic blood pressure (mm Hg); Mean (SD) | 127.5 (20.8) |
| Erythema | 119 (84.4) |
| Asian; n (%) | 9 (6.4) |
| African; n (%) | 7 (5.0) |
| Hispanic; n (%) | 6 (4.3) |
| Prednisone equivalent dose (mg/day); M (IQR) | 10.0 (0.0 – 20.0) |

**Diagnosis according to ISN/RPS**

- Class I-II 25 (17.7)
- Class III ± V 43 (30.5)
- Class IV ± V 31 (22.0)
- Class V ± II 26 (18.4)
- TMA/antiphospholipid syndrome 2 (1.4)
- Vascuities 7 (5.0)
- Hypertensive nephrosclerosis 3 (2.1)
- IgA nephropathy 1 (0.7)
- Tubulointerstitial nephritis 1 (0.7)
- Nonspecific changes 2 (1.4)

**Conclusion:** We demonstrate that renal histopathology confirmed other causes than LN in a significant proportion (11.3%) of SLE patients with signs of renal involvement. Since these patients may need other therapeutic interventions than patients with classic LN, we can conclude that the renal biopsy is important in order to guide the choice of therapeutics.

49% of SLE patients were categorized as SLEDAI 7-12 or >12. Among the SLEDAI 7-12 (moderate) patients, 75.7% were subjectively categorized by their physician as having mild SLE. Of the SLEDAI >12 patients (severe), 73.4% were categorized as having mild SLE. Joint symptoms and flaring in the last 12 months were not significantly different across SLEDAI groups.

Patients with greater SLEDAI reported lower EQ5D and greater FACIT-Fatigue scores. There was no statistical difference in WPAI between the SLEDAI groups.
emphysema, Chronic Obstructive Lung Disease, bronchial asthma etc.) were excluded. The following data were collected from clinical charts: demographics, smoke exposure, comorbidities, respiratory symptoms, disease duration and disease activity (SELENA-SLEDAI) at the onset of lung involvement, immunological profile, treatment, CT and spirometry parameters.

**Results:** Over 450 SLE patients in regular follow-up, we found 11 female patients with a history of clinically relevant non-serositis lung involvement: 7 interstitial lung disease (ILD), 2 acute lupic pneumonitis (ALP), 1 diffuse alveolar hemorrhage (DAH) and 1 shrinking lung syndrome. 45.4% of patients had a history of smoke exposure and had stopped smoking on average 9 years before the onset of lung manifestations. For the 2 patients with ALP, this was the first manifestation of SLE. Among the other 9 patients, lung involvement was diagnosed after a mean disease duration of 14 ± 15 years. At the diagnosis of pulmonary involvement, 10/11 patients presented respiratory symptoms and an overall active disease, with a median SLEDAI of 9 (IQR 6-13). Clinical characteristics are summarized in Table 1. All patients were hospitalized and 2 of them (1 ALP and 1 DAH) were admitted in intensive care unit.

As for the immunologic profile, SSA/Ro50 were positive in 72% of patients and SSA/Ro52, SSB, U1-RNP in 36%; 36% had Sjögren Syndrome (SS) in overlap.

Spirometry was available in 6/11 patients: a restrictive pattern and a moderately severe reduction of diffusing capacity of the lung for carbon monoxide was found in 5 patients.

In the ILD subgroup, the most prevalent CT pattern was the Non-specific interstitial pneumonia (NSIP) (5/7), 2 patients presented a Bronchiolitis obliterans/organizing pneumonia (BOOP) pattern.

Lung involvement was the driving manifestation in the treatment choice for 6/11 patients: 1 DAH, 2 ALP, 1 Shrinkling lung and 2 ILD. All received pulse steroids and in 3 cases (2 ILD and 1 DAH) cyclophosphamide was added for the induction treatment; the patient with Shrinkling lung had an overlap SS and was treated with Rituximab.

At last visit (mean follow-up of 8 ± 8.7 years since lung disease onset), 7/11 patients presented no respiratory symptoms and a complete resolution of CT alterations. 3/11 presented a residual exertional dyspnea and mild spirometry alterations. No patients developed respiratory insufficiency; only 1 patient died for cardiovascular complications.

**Conclusion:** In our large cohort of SLE patients, non-serositis lung involvement seems to be overall rare; the most frequent type of lung manifestation is ILD which appears to be associated with anti-SSA/SSB and anti-U1RNP positivity. The low prevalence of lung involvement (2.4%) in our cohort could be due to the presence of patients with a subclinical involvement. Further studies are needed to assess the real prevalence of subclinical lung manifestations in SLE and to identify the clinical phenotype of patients more prone to develop pulmonary disease.

**AB0556 CHARACTERISTICS OF PATIENTS DIAGNOSED WITH UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE**

**G. Siegel, B. Stamm, J. Vega, E. Sevim, M. Lockshin, L. Sammaritano, M. Barbhaiya, C. Siegel, Hospital for Special Surgery, Medicine, New York, United States of America; 2Hospital for Special Surgery, Barbara Volcker Center for Women and Rheumatic Diseases, New York, United States of America; 3Montefiore Medical Center, Medicine, Bronx, United States of America; 4Albert Einstein College of Medicine, Medicine, Bronx, United States of America; 5Weill Cornell Medicine, Medicine, New York, United States of America

**Background:** Patients with undifferentiated connective tissue disease (UCTD) struggle with physical symptoms as well as diagnostic uncertainty. 1 UCTD diagnosis requires exclusion of other connective tissue diseases (CTD). Prior studies use variable definitions of UCTD that do not account for updated classification criteria thus limiting generalizability.

**Objectives:** We identified characteristics associated with rheumatologist-diagnosed UCTD, applied stringent exclusion criteria, and compared UCTD patients to those with criteria-defined CTD.

**Methods:** We recruited patients ≥18 years old seen between 2018-2022 who had rheumatologist-diagnosed UCTD with positive ANA and ≥1 sign/symptom of a CTD. We reviewed medical records to identify those who fulfilled ACR/EULAR-endorsed classification criteria for SLE, RA, SSc. Primary Sjögren’s, Idiopathic Inflammatory Myopathies, and 2006 Revised Sapporo Criteria for APS. We compared sociodemographic, clinical, serologic, and treatment variables between UCTD and CTD using chi-square, Fisher’s exact, and t-tests.

**Results:** Of 89 patients with rheumatologist-diagnosed UCTD (mean age 49.0 ± 13.7 years, 97.8% female, 66.3% White), 59 (66.3%) had UCTD and 30 (33.7%) had criteria-defined CTD (27 SLE, 3 SLE and RA, 1 RA, and 1 APS). Patients in both groups had similar non-criteria manifestations, most commonly arthralgia (89.8% UCTD vs. 83.3% CTD, p=0.50) and fatigue (59.5% UCTD vs. 73.3% CTD, p=0.17). Compared to patients with CTD, those with UCTD were less likely to have nonerosive arthritis (27.1% vs. 56.7%, p=0.01) (Table 1).

1. Do not fulfill ACR/EULAR classification criteria for SLE, RA, SSc, PSS, IMF, APS
2. Diagnosed with UCTD and fulfill ≥1 set of listed CTD classification criteria.
3. Defined per listed classification criteria.
4. Criteria with n≤5: fever, proteinuria/cellular casts, pulmonary hypertension, intestinal lung disease, dysphagia/oesophageal dysmotility

**Patients with UCTD were less likely than those with CTD to have any hematological manifestation (lymphopenia, leukopenia, thrombocytopenia, or hemolytic anemia) (p=0.02), anti-dsDNA or anti-Smith antibodies (p<0.01), or hypocomplementemia (p<0.01). The frequency of RA, Sjögren’s, and APS-related serologies did not differ between groups (Table 1). Compared to those with CTD, UCTD patients were less likely to have ever received systemic corticosteroids (71.2% vs. 96.7%, p<0.01); ever use of any disease-modifying antirheumatic drug (DMARD) was similar (35.6% vs. 46.7%, p=0.36).

**Conclusion:** Among patients diagnosed with UCTD, 66.3% met a stringent definition. Compared to those with criteria-defined CTD, UCTD patients had lower frequency of arthritis, hematologic abnormalities, SLE-specific antibodies, and hypocomplementemia. Use of DMARDs did not differ, UCTD patients were less likely to use systemic corticosteroids. Rheumatologists diagnose UCTD even when criteria are met for other CTDs. Our findings suggest UCTD is nonetheless a distinct clinical entity; more rigorous characterization will enable generalizable prognostic and therapy trials.

Registry (KAPRI) registry offers a unique opportunity to pioneer and spearhead a systematic and organized format in collecting pertinent clinical information that will offer information on current clinical scenarios and offer a platform to conduct other research projects to improve pediatric lupus healthcare in sub-Saharan Africa.

Objectives: Our objective was to determine the clinico-epidemiological profile of paediatric lupus patients by describing their baseline patient characteristics and clinical features at the Aga Khan University Medical College East Africa who were enrolled into the KAPRI registry from inception in March 2019 to December 2021.

Methods: All patient records were selected from the KAPRI registry database using the ICD 10 code M32 that denotes Systemic Lupus Erythematosus (SLE). Age, gender, laboratory, clinical features at diagnosis, treatment options offered at time of diagnosis were extracted from the database.

Results: Among the 207 patients enrolled thus far in the registry, 7 had a diagnosis of cSLE (3.4%). The commonest symptom among the patients were joint pain, fever and rash. Other clinical features and outcomes are highlighted in the Table 1.

Conclusion: Over a 2 year period, 57% of our cSLE patients (4 of 7) achieved remission while 43% (3 of 7) were lost to follow up. Further studies are required to elucidate predictors of good clinical response and reasons for loss to follow up among our cSLE patients.

AB0560 CLINICAL, SEROLOGICAL AND IMAGING CHARACTERISTICS OF LATIN AMERICAN PATIENTS WITH LUPUS MYOCARDITIS: A CASE-CONTROL STUDY

D. C. Quintero-González 1, J. Sanchez-Bautista 2, C. Agudelo 1, A. L. Vanegas-García 3, M. Muñoz 3 1, Y. Santamaria-Alza 1, A. Cardona-Cardona 1, M. Muñoz 1, G. Vásquez 1, L. A. González 1,3, Y. S. Antigliiero 1, M. García 1, C. Muñoz 1,2, Y. Santamaria-Alza 1, A. Cardona-Cardona 1, M. Muñoz 1, G. Vásquez 1, L. A. González 1, 1Universidad de Antioquia, Rheumatology; Medellín, Colombia; 2Universidad de Antioquia, Internal Medicine, Medellín, Colombia; 3Hospital Universitario San Vicente Fundación, Rheumatology; Medellín, Colombia

Background: Lupus myocarditis (LM) is an uncommon manifestation of systemic lupus erythematosus (SLE), with a prevalence of 9% that tends to be lower in recent studies; it can range from subclinical to life-threatening manifestations (1). The clinical and immunological characteristics of LM have not been established in Latin American patients.

Objectives: To determine the clinical, serological, and imaging characteristics of patients with LM.

Methods: We conducted a single-center, case-control study that enrolled hospitalized patients between 2012 and 2020 in Colombia. Fifteen LM patients (cases) were matched by age and sex with thirty non-LM patients (controls). Descriptive, comparative, and logistic regression analyses were performed.

Results: Patients with LM were mostly females (93.3%) with a mean age of 28.2 years. The major affected clinical domains was renal (80%) and articular (53.3%). The most common valvulopathy was mild mitral regurgitation. Nineteen LM patients underwent cardiac magnetic resonance. In this modality, mean LVEF was 54%, increased regional intensity on T2-weighted images, increased myocardial perfusion ratio on T1- and non-ischemic enhancement (mainly epicardial) was presented in 85.7%, 50%, and 57.1%, respectively. All patients received glucocorticoids and cyclophosphamide. Comparisons of the demographic, clinical, serological between LM and non-LM groups are shown in Table 1.

AB0562 LIVER ENZYME ABNORMALITIES IN HOSPITALIZED LUPUS PATIENTS – A RETROSPECTIVE STUDY

Our data indicate that patients with SLE have a high level of alexithymia. Indeed, patients suffering from this disease experience difficulties in understanding and verbalizing feelings, persistently strive to draw the doctor’s attention to their physical sensations, without attaching importance to or denying trouble in the emotional sphere.

Conclusion: The results of the study indicate a certain role of the phenomenon of alexithymia in the pathogenesis of psychosomatic disorders in SLE, and the level of alexithymia does not depend on gender, age, and the main clinical characteristics of the disease, but correlates with general neuroticism. It is possible that the high level of alexithymia in SLE patients leads to an increase in depression and anxiety, and generates psychological distress. Thus, the study of alexithymia, among other risk factors of a biological and psychosocial nature, is important for a better understanding of the role of psychological mechanisms in the pathogenesis of psychosomatic diseases, the organization of preventive measures aimed at correcting alexithymic features, carried out in individual and group forms of psychotherapy.

ALEXITHYMIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

R. Grekhov1,2, V. Zborovsky2 Research Institute for Clinical and Experimental Rheumatology, Rehabilitation Dept, Volgograd, Russian Federation; 2Volgograd State Medical University, Chair of General and Clinical Psychology, Volgograd, Russian Federation

Background: The growth of psychosomatic disorders is the most important medical and social problem of modern healthcare. Particular attention of researchers is attracted by the alexithymic radical in the structure of the patient’s premorbid personality, as one of the possible psychological risk factors for the development of psychosomatic disorders. Alexithymia is a psychological phenomenon that described as difficulty in definition one’s own feelings, difficulty in distinguishing between feelings and bodily sensations, a decrease in the ability to symbolize, and a focus on external events rather than internal experiences.

Objectives: The aim of this work was to study the level of alexithymia in patients with systemic lupus erythematosus (SLE).

Methods: There were 87 patients under observation, the majority were women (82.8%), of 35.33 ± 1.77 years old in average. The average duration of the disease was 7.09 ± 0.89 years.

The Toronto Alexithymia Scale (TAS) [1] was used to measure alexithymia.

Results: It should be noted that in healthy people [1] the level of alexithymia is 59.3 ± 1.3 points. The mean value of alexithymia in SLE patients was 74.05 ± 2.62 points. The high and medium rates of alexithymia were established in 54 cases from 78 patients, and there were low levels in 24 cases indicating the absence of alexithymia. It was not possible to identify the dependence of alexithymia on gender and age. There was also no significant dependence of the level of alexithymia on the duration of the disease, the course and the activity of the pathological process. However, a significant direct correlation between the severity of alexithymia and depression and anxiety was revealed (see Table 1).

Table 1. Dependence of the level of alexithymia on some characteristics of SLE patients

PROGNOSTIC ROLE OF PRE-CONCEPTIONAL COMPLEMENT CONSUMPTION ON PREGNANCY OUTCOMES IN ANTI-PHOSPHOLIPID ANTIBODY SYNDROME, POLYARTERITIS AND RECURRENT IMPLANTATION FAILURE

V. Cantu1, B. De Lorenzo2, C. Gerbin0, G. Adorno0, F. Fusi3, M. T. Castiglioni3, P. Rovere-Querini1, 1San Raffaele Hospital, Internal Medicine, Milan, Italy; 2San Raffaele University, San Raffaele University, Milan, Italy; 3San Raffaele Hospital, Obstetrics and Gynecology, Milan, Italy

Background: In anti-phospholipid antibody syndrome (APS), complement C3/C4 activation favours the development of adverse pregnancy events. The prognostic role of complement in recurrent pregnancy loss (RPL) and recurrent implantation failure (RIF) has never been clinically studied. Additionally, the influence of hydroxychloroquine and heparin on complement modulation at the molecular level has already been accepted, while few clinical studies on these drugs have been published up to date.

Objectives: The aim of the study was to investigate whether C3/C4 levels represent a risk factor for pregnancy outcomes in a population of patients with APS, patients with RPL and patients with RIF. Moreover, the study investigated the...
Effects of therapies during pregnancy (low dose aspirin, low molecular weight heparin and hydroxychloroquine and their combinations).

Methods: We collected data of 136 patients (33 APS, 69 RPL, 34 RIF) prospectively after low dose aspirin in the past. 106/136 (78%) patients had normal pre-conceptional level of 8/106 (7%) had anamnestic history of adverse pregnancy outcomes and 91/106 (86%) had at least one abortion in the past. 64/136 pregnancies prospectively followed in our centre, 17/64 (26%) had pre-conceptional level of 8/106 (7%) had anamnestic history of adverse pregnancy outcomes and 91/106 (86%) had at least one abortion in the past. In 64/136 pregnancies prospectively followed in our centre, 17/64 (26%) had pre-conceptional level of 8/106 (7%) had anamnestic history of adverse pregnancy outcomes.

Results: 30/136 (22%) patients had pre-conceptional level of 8/106 (7%) had anamnestic history of adverse pregnancy outcomes. The presence of consumed pre-conceptional level of 8/106 (7%) had anamnestic history of adverse pregnancy outcomes.

Conclusion: Measurement of pre-conceptional level of 8/106 (7%) had anamnestic history of adverse pregnancy outcomes. The presence of consumed pre-conceptional level of 8/106 (7%) had anamnestic history of adverse pregnancy outcomes.
Five patients presented with ANCA associated vasculitis, which represents and exceedingly rare and severe manifestation in this context. Patients with SS may present a wide range of vasculitis, ranging from the most common leucocytoclastic vasculitis to the more severe systemic vasculitides, such as: AAV and cryoglobulinemic vasculitis. The association of SS with vasculitis is more common in patients with anti-Ro, anti-La and/or RF, hypocomplementemia, cryoglobulins and hypergammaglobulinemia.

AB0567
SHORT AND LONG-TERM RENAL OUTCOMES OF PATIENTS WITH PROLIFERATIVE LUPUS NEPHRITIS: DATA FROM A SINGLE INSTITUTE INCEPTION COHORT.

E. Kapia1, S. Marinka1, I. Michelakis2, G. Liapis3, P. Stltakis4, J. N. Boletis5, M. Tektonidou6, 1Medical School National & Kapodistrian University of Athens, Laiko Hospital, Department of Nephrology and Renal Transplantation, Athens, Greece; 2Medical School National & Kapodistrian University of Athens, Department of Medicine, Athens, Greece; 3Medical School National & Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Athens, Greece; 4Medical School National & Kapodistrian University of Athens, Laiko Hospital, Department of Pathology, Athens, Greece; 5Medical School National & Kapodistrian University of Athens, Laiko Hospital, Rheumatology Unit, First Department of Paedopaedic Internal Medicine, Athens, Greece

Background: Renal involvement in SLE is associated with high risk of morbidity with proliferative lupus nephritis (PLN) having the worst prognosis. Although advances in immunosuppressive treatment led to better renal survival rates, response to treatment and short- and long-term outcomes differ among cohorts.

Objectives: To evaluate short and long term renal outcomes in an inception cohort of patients with PLN. We also aimed to define clinical, laboratory, histological and treatment determinants of partial (PR) or complete response (CR), flare, and long-term renal and patient survival.

Methods: An inception cohort of 83 patients with biopsy-proven PLN (class III, IV, or III/IV-V) (diagnosed between 1992 and 2019) was retrospectively studied. Data collected included histologic characteristics at baseline, demographic, clinical, laboratory, and therapeutic parameters at baseline. E-9-12-18-24-36-72 months after PLN diagnosis, time of renal flare and last follow-up visit.

Univariate logistic and Cox regression analyses were performed to estimate response to treatment, flare and long-term renal survival. Variables found to be significant in the univariate analyses were included in the multivariate models.

Results: Mean age of the patients was 43±12 years, 78% were women, 96% were Caucasians and median duration of SLE before PLN diagnosis was 12 months (IQR 6). Mean SLEDAI score at PLN diagnosis was 12.8±4.5 and mean proteinuria was 3.69±3.9 g/dL. At baseline, 73.5% (61/83) had eGFR>60mL/min/1.73m², 15.5% (13/83) eGFR 30-60 and 11% (9/83) eGFR<30. 32% (27/83) of the patients had class III LN, 46% (38/83) IV, and 22% (18/83) III/IV-V. Median follow-up time was 107 months (IQR 94). Induction immunosuppressive treatment consisted of cyclophosphamide (CYC) in 71% (59/83) of patients (12/59 in combination with rituximab (RTX)), mycophenolic acid (MPA) in 25% (21/83) (2/21 in combination with RTX) and RTX alone in 2 patients. 1 patient did not receive any immunosuppressive treatment due to ESRD. Patients treated with CYC had a higher baseline SLEDAI score, lower C3 and C4 levels, higher biopsy activity index and higher proteinuria levels than those treated with MPA. 76% (63/83) received MPA as maintenance treatment. 8% (7/83) azathioprine, 7% (6/83) CYC and 8% (7/83) did not receive any maintenance regimen (3/7 due to ESRD, 2/7 received RTX as induction and continued with steroids only, 1/7 due to non-compliance, 1/7 lost to follow-up after 6 months). Median duration of treatment was 43.6 months (IQR 44.6).

66% of patients had response (CR or PR) at 6 months (43% CR, 23% PR), 73% at 9 months (46% CR, 27% PR), 77% at 12 months (61% CR, 16% PR) and 91% at the end of follow-up (80% CR, 11% PR) (Figure 1). Median time to complete remission was 9 months (IQR 14) and median time to partial remission was 4 months (IQR 7). In multivariate analysis, baseline eGFR>60mL/min correlated with shorter time to remission (HR 1.7, p<0.05). No clinical, laboratory or histological (PLN class, activity/chronicity index, number of crescents) parameters or any of induction immunosuppressives could predict time to remission.

Conclusion: In our inception cohort of patients with PLN, 86% of patients achieved response at 6 months, 77% at 12 months and 91% at the end of follow-up. Proteinuria >1g/dL at 12 months emerged as an important risk factor of renal flare and CKD, while MPA treatment was associated with lower risk of renal flare.

CHRITIDHA LUCILAE IMMUNOFLUORESCENCE PRESENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS ASSOCIATION WITH POSITIVE CHAGAS TESTS

E. Picco1, B. Cariazeres2, R. Rojas Tessein3, E. Buschiazzo1, M. Aciar4, N. Cucchiaro1, L. N. Belbruno1, M. B. Lecumberri1, A. C. Raile1, V. Juarez1, M. E. Crespo Espindola1, 1Hospital Sr del Milagro, Rheumatology, Salta, Argentina; 2Hospital Sr del Milagro, Biochemistry, Salta, Argentina

Background: Systemic lupus erythematosus (SLE) is characterized by the presence of auto-antibodies, including anti-double stranded DNA (dsDNA), which are highly specific for the disease diagnosis and its follow up. Direct immunofluorescence (IF) using chrigida luciiae (CL) as the antigenic substrate, is the most widely used method to detect it, and its positivity is defined with the staining of the kinetoplast and/or the nucleus. CL is a flagellated parasite, included in trypansomatisidae family, which also includes trypanosoma cruzi, the cause of Chagas Disease (CD). Some studies suggest that membrane and flagellum fluorescence (considered ‘atypical’ staining) could be associated with positive CD serology.

Objectives: Describe the prevalence of positive IF-CL images and its association with positive CD test in SLE patients.

Methods: A cross sectional study was designed including consecutive outpatients with SLE diagnosis (SLICC criteria), in which anti-dsDNA antibodies was requested to monitor disease activity. At the same time, two serologic CD tests were performed, since they improve sensibility to detect the disease.

Anti-dsDNA by IF were performed by an experienced laboratory biochemistry blinded to patients clinical data. Pregnant patients and those ≤ 18 years old were excluded from this analysis.

Standard descriptive analysis was performed, data was compared by exact fisher test or chi2, student's T test or Mann Whitney. A p value < 0.05 was considered as significant.

Results: Thirty five patients were included, 33 (94.3) female, median age 38 (IQR 31-48), with 20 (57.1) patients being from middle-low socioeconomic status (measured by Grafar score). Twenty-six (74.3) patients were receiving glucocorticoids, 28 (80) hydroxychloroquine, 5 (14.3) azathioprine, 12 (34.3) mofetil mycophenolate, 5 (14.3) cyclophosphamide and 4 (11.4) rituximab. Twelve (34.4) had positive anti-dsDNA test, with atypical staining in membrane and flagellum 31 (88.9), only membrane 12 (34.3) and both membrane and flagellum 9 (25.7) exclusively.

One patient had previous chronic CD diagnosis without specific treatment.

Five (14.3) CD serologies were positive, and 1 had undefined result. This group of patients had positive staining in membrane and flagellum of CL. No other atypical CL staining images were found. (Table 1)
Conclusion: Although we could not find a statistical association between atypical CL staining and positive CD serology, this could be due to the low number of patients included in the study since all the patients with positive CD serology had a positive staining in CL-LIF. A trained biochemistry operator is necessary to avoid false positive tests in regions with high prevalence of CD.

DERIVATION AND INDEPENDENT VALIDATION OF THE LUPUS ARTHRITIS AND MUSCULOSKELETAL DISEASE ACTIVITY SCORE (LAMDA): A MORE SENSITIVE, SPECIFIC AND RESPONSIVE TOOL FOR LUPUS ARTHRITIS

K. Mahmoud1, A. Zayat1, M. Y. MD Yusof2, L. S. Teh3, S. Khan4, C. S. Yee5, D. D’Cruz6, N. Ng1, D. Isenberg5, C. Critiun1, P. G. Conaghan1, P. Emery1, C. J. Edwards1, E. Henson1, E. Vital1. 1University of Leeds, Leeds Institute of Rheumatism and Musculoskeletal Medicine, Leeds, United Kingdom; 2Royal Blackburn Hospital, Rheumatology, Blackburn, United Kingdom; 3Doncaster & Bassetlaw NHS Trust, Rheumatology, Doncaster, United Kingdom; 4Royal Free & St Thomas’ NHS Foundation Trust, Louise Coote’s Lupus Unit, London, United Kingdom; 5University College London, Rayne Institute, London, United Kingdom; 6University Hospital Southampton NHS Foundation Trust, Rheumatology, Southampton, United Kingdom

Background: The MSK components of the BILAG and SLEDAI have limited sensitivity, specificity and responsiveness.

Objectives: To develop a better disease activity tool for MS lupus.

Methods: “LAMDA” was derived using data from the multicentre USEFUL study (PMID:33792659); 133 patients with inflammatory MSK pain received intramuscular depomedrone then were assessed for 86/68 SJC/ TJC, BILAG-2004, SLEDAI-2K, physician MSK-VAS, inflammatory markers, patient pain and disease-activity-VAS and MSK-ultrasound. Baseline variables were modelled against US using penalized (Lasso) regression. For validation we evaluated: (i) responsiveness at week 6 in USEFUL and (ii) association with quality of life and treatment decision in an independent study (n=100).

Results: LAMDA was a composite of SJC, patient-MSK-pain-VAS, physician-MSK-disease-activity-VAS and ESR ranging from 0 to 26.5. Response effect size was greater for the LAMDA (0.37) than the BILAG-MSK (0.31), SLEDAI-MSK (0.27) and total US score (0.33). With active US at baseline, LAMDA’s effect size was 0.42. In the validation study, LAMDA score correlated better with physical function (R = -0.49, p<0.001), pain (R = -0.44, p=0.002) and Burden to Others (R = -0.38, p=0.009). LAMDA was higher when therapy was increased (mean 95% CI) difference 12.9 (5.8, 19.9), p<0.001.

Conclusion: LAMDA is a continuous disease activity instrument for MSK lupus that is sensitive to imaging-syndromes without swelling, more responsive than other instruments and correlates with quality of life and treatment decision. LAMDA may improve the ability of clinicians to monitor and treat MSK lupus, and determine the efficacy of therapies in clinical trials.

AB0572

USEFULNESS OF MINOR SALIVARY GLAND BIOPSY IN THE DIAGNOSIS OF PATIENTS WITH SUSPECTED PRIMARY SJÖGREN’S SYNDROME

N. de la Torre Rubio1, J. Campos Esteban1, M. Pavía Pascual1, M. Machatto1, P. Navarro Palomo1, O. Rusinovich1, C. Merino Arguménez1, B. García-Magallon1, H. Godoy1, C. Barbardillo Mateos1, L. F. de Villa2, J. Sanz3, J. L. Andreu Sánchez1, M. Fernandez Castro1. 1Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain

Background: The classification system for Sjogren’s syndrome (SS) proposed by the American-European Consensus Group (AECG) and the revised diagrams proposed by the American College of Rheumatology (ACR) include an altered minor salivary gland biopsy (MSGB) or positive antifilo, among other findings. Thus, an altered MSGB is a particularly important finding in patients with autoimmune-negative. A retrospective cohort study showed that a positive biopsy resulted in a definitive diagnosis in 80% of patients1.

Objectives: To assess the usefulness of MSGB in the diagnosis of SS in anti-SSA/SSB (Ro/La) negative patients.

Methods: Retrospective descriptive study in patients with suspected SS in which MSGB were collected according to standard clinical practice over a consecutive period (from September 2020 to May 2021) in the Rheumatology Department of a tertiary hospital. Patients were grouped according to the reason for requesting the biopsy: 1) Dry eye/oral syndrome (DEOS), 2) DEOS + altered Saxon/Schirmer, 3) DEOS + positive antinuclear antibodies (ANA+), 4) DEOS + (ANA+) + other serological alterations (hypergamma-globulinaemia, rheumatoid factor (RF), hypocomplementemia), 5) DEOS + extraglandular manifestations (EG) (+ ANA+) +/- other serological alterations. The following variables were collected: age, sex, dry eye/oral syndrome, Raynaud’s phenomenon, EG manifestations, arthritis, autoimmune hepatitis, primary biliary cirrhosis, interstitial lung disease, pleuropneumonitis, autoimmune chronic nephropathy suspected or tubulointerstitial nephritis and/or neurological manifestations), ANA, hyper gammaglobulinaemia, RF, hypocomplementemia, Saxon and Schirmer tests and histological result of MSGB according to its Focus Score (FS); MSGB was considered altered when FS was ≥1. Descriptive analysis was performed (means and frequencies); Chi-square test was used to compare the reasons for requesting MSGB between patients with altered and unaltered results and to compare whether any of the groups (Groups 2-5) were more frequently associated with an altered MSGB compared to patients presenting only with dry syndrome (Group 1).

Results: Seventy-eight MSGB were collected. Mean age of patients was 55 years; 90% were women. ANA were present in 17% of patients with altered MSGB. DEOS was the suspected manifestation in 83% of patients, 13% had Raynaud’s phenomenon and 47% had some EG manifestation. MSGB was compatible with a diagnosis of SS (according to 2002/2016 classification criteria) in 28% of anti-SSA/SSB negative patients. Patients with dry syndrome and positive ANA (Group 3) were significantly associated with MSGB altered (Table 1).

Table 1. Comparative table of patterns indcated in the reasons for requesting a MSGB. *Not significant (NS).

Conclusion: MSGB was compatible with a diagnosis of SS in 28% of anti-SSA/SSB negative patients. The data suggest that patients presenting with objective dryness with Saxon and/or Schirmer test, as well as those with extraglandular manifestations and ANA+ and/or other serological alterations, are more likely to have a compatible with SS result on MSGB. Studies with larger numbers of patients are needed.

PERIPHERAL BLOOD B-CELLS SUBSETS IN PATIENTS WITH SJÖGREN’S SYNDROME DEPENDING ON SOME IMMUNOLOGICAL PARAMETERS.

A. Torgashina1, E. Sokol1, B. Chalcev1, J. Khivan1, M. Kireeva1, D. Tabakov2, A. Alekssan1, S. Glukhova1. 1VA Nasonova Research Institute of Rheumatology, Rare Rheumatic Disease and Sjogren’s Syndrome, Moscow, Russian Federation; 2VA Nasonova Research Institute of Rheumatology, Educational-Medical Department, Moscow, Russian Federation; 3VA Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology, Moscow, Russian Federation

Objectives: To examine B-cell subsets in peripheral blood of Sjogren’s syndrome (SjS) patients (pts) and to analyze the association between B-cell subsets and different clinical and immunological parameters.

Methods: 67 active SjS pts (65F/2M); mean age 51±14.4 years; disease duration 60 (24-120) months were included. SjS was diagnosed based on the ACR-EULAR2016 criteria. Twenty healthy donors composed the control group. CD19+B cells, memory B-cells (CD19+CD27+), non-switched memory B-cells (CD19+IgD+CD27+), switched memory B-cells (CD19+IgD-CD27+), naïve (CD19+IgD-CD27+), double negative (CD19+IgD-CD27+), transitional (CD19+IgD+CD27+) B-cells, plasmablasts (CD19+CD38++IgD-CD27+) were analyzed by multicolor flow cytometry using cytometer Navios (Beckman Coulter, USA).
The nonparametric Mann-Whitney test, the Pearson’s χ2 criterion, Spearman rank correlation coefficient were used for statistical analysis. Data were shown as median (Me) with an interquartile range of 25 - 75 percentile. The differences were considered statistically significant when p<0.05. Statistica 10 for Windows (StatSoft Inc., USA) package was used for statistical data processing.

Results: The percentages/absolute numbers of plasmablasts, transitional B-cells, memory B-cells in SjS were significantly higher than in healthy donors, p<0.01 for all cases. At the same time percentages/absolute numbers of naïve cells in SjS were reduced compared to healthy donors (p<0.005, p=0.04). Shorter duration of SjS (less than 2 years) correlated with higher rates of naïve cells (p=0.02).

ESSDAI score was ≥5 in 33 pts and ≤5 in 34 pts. We didn’t find any correlation between B cells subsets and disease activity. The presence of lymphoma in pts (n=5) had no impact on B-cells subsets as well. Significant changes were in B-cells subsets were found depending on immunological parameters. Pts with an isolated increase of antinuclear antibodies (ANA) (ANA positive, RF/aRo/aLa negative) had no plasmablasts in peripheral blood, level of plasmablasts in other pts was 1.5 (1.4-5)10^4/L, p=0.004. ARo-positive pts had higher amount of plasmablasts and transitional B-cells than aRo-negative pts (2 (1-5) and 1 (0-1)10^4/L, p= 0.004). Higher level of plasmablasts and transitional B-cells also correlated with decrease in C3 and/or C4 (p=0.03) and increase in IgG (p=0.025).

Conclusion: According to our data elevated level of plasmablasts and transitional B-cells had positive correlation with some immunological diagnostic markers and immunological activity parameters of SjS but didn’t associate with ESSDAI.

AB0574 PREDICTOR FACTORS IN EMPowerMENT OF PATIENTS WITH PRIMARY SJÖGREN SYNDROME IN THE FRAME OF VALUE BASED HEALTH CARE

G. Mumcu1, K. Abacak2, I. Tati1, F. Türe-Özdemi1, O. C. Kitapçı1, N. Şisman Kitapçı1, M. Yay1, U. Karacay1, F. Fortune2, N. Inanc3, Marmara University, Faculty of Health Science, Department of Health Management, Istanbul, Turkey; 1Marmara University, School of Medicine, Division of Internal Medicine, Department of Rheumatology, Istanbul, Turkey; 2Marmara University, Medical School, Division of Haematology-Immunology, Istanbul, Turkey; 3Mimar Sinan Fine Art Faculty, Department of Statistics, Istanbul, Turkey; 4Gultahane Faculty of Dentistry, University of Health Sciences, Department of Oral and Maxillofacial Surgery, Ankara, Turkey; 5Queen Mary University of London, Barts and The London School of Medicine and Dentistry, Director of the Behçet’s Centre of Excellence, London, United Kingdom

Background: Patient empowerment is a key component in developing awareness of the disease in patient-centred care in the setting of chronic disease management.

Objectives: This study aimed to evaluate predictive factors in the empowerment of patients with Sjögren’s Syndrome (pSS) while examining patients reported outcome measures (PROMs) in the setting of value-based health care.

Methods: In this cross-sectional study, 169 patients with pSS (F/M: 162/7; mean age: 52.94±12.20 years) were included. Data was collected from the clinical examination, major salivary gland ultrasonography (SGUS) and a structured questionnaire regarding utilisation of health services and PROMs regarding oral health, pain, burning mouth syndrome, QoL, anxiety and depression by a multidisciplinary team with dentists and psychiatrists in patient-centred care. Since these factors have a significant effect on patients’ daily life, treatment plans are needed to provide patient empowerment by using suitable strategies in the frame of value-based health care.

AB0575 MESANGIAL C1Q DEPOSITION, BUT NOT C3 AND C1Q DEPOSITION IN OTHER RENAL COMPARTMENTS, IS A PREDICTOR OF RENAL OUTCOME IN LUPUS NEPHRITIS

T. Knežević1, I. Padjen2, V. Ivković3, S. Bulimbašić3, M. Conić3, I. Jezic3, Z. Bilošlav4, M. Laganović5, B. Anić5, 1University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Division of Nephrology, Hypertension, Dialysis and Transplantation, National Reference Centre for Glomerular and Tubulointerstitial Diseases, Zagreb, Croatia, Zagreb, Croatia; 2University Hospital Centre Zagreb, Division of Clinical Immunology and Rheumatology, Zagreb, Croatia; 3University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Department of Pathology and Cytology, University Hospital Centre Zagreb, Croatia, Zagreb, Croatia; 4University of Zagreb, School of Medicine, Zagreb, Croatia, Department of Epidemiology, Zagreb, Croatia; 5University Hospital Merkur, Division of Nephrology, Zagreb, Croatia

Background: Complement activation is an important pathophysiological process in the pathogenesis and development of systemic lupus erythematosus and lupus nephritis (LN). However, the prognostic value of complement factors deposition in different kidney compartments has received little attention and, to the best of our knowledge, no study examined its association with renal outcomes in LN.

Objectives: To evaluate prognostic significance of C1q and C3 complement factors in renal tissue compartments.

Methods: We have conducted a retrospective cohort study and collected data on demographics, clinical and laboratory parameters and histopathology (light, immunofluorescent and electron microscopy) at the time of biopsy and after long-term follow-up. C1q and C3 expression graded in different kidney compartments (mesangium, glomerular basement membrane (GBM), tubular basement membrane (TBM) and blood vessel wall) and dichotomized into no or low (grades 0 and 1) and high expression (grades 2 and 3). Remission (defined as complete or partial remission) was defined as per EULAR 2019 guidelines.

Results: A total of 51 patients with biopsy-proven LN were followed up for 4.5±2.9 years (80% women, mean age at biopsy 38±14). A total of 29 (71%) achieved complete or partial remission. Complement expression in different kidney compartments was as follows: mesangium (C1q 54%, C3 59%), GBM (C1q 34%, C3 41%), TBM (C1q 5%, C3 5%) and blood vessel wall (C1q 0%, C3 5%). Patients with proliferative lupus had more frequently C1q and C3 deposition in the mesangium (69% vs. 14%, p<0.001 and 72% vs. 29%, p=0.005, respectively), while there were no differences between pro- and non-proliferative LN in other renal compartments (all p>0.05). Subjects who achieved remission more frequently had C1q deposition in the mesangium (64% vs. 31%, p=0.045), but there was no association between remission and deposition of C1q or C3 in other renal compartments (all p>0.05). Interestingly, the association between C1q mesangial deposition and renal outcome was significant even after adjustment for age at biopsy, gender and lupus type (proliferative vs. non-proliferative) (OR 0.13 [0.02, 0.98], p=0.047).

Conclusion: C1q deposition in the mesangium might be an important prognostic factor in LN and more aggressive treatment of these patients may explain the better outcomes of these patients.

null
Background: Behçet’s disease (BD) is an systemic inflammatory vasculitis characterized by recurrent oral aphthae and genital ulcers. In the course of the disease, skin, eye, musculoskeletal, nervous system and gastrointestinal system involvements can be detected.

Objectives: To evaluate the clinical, laboratory and radiological findings of pediatric cases diagnosed with BD.

Methods: Fifty-five patients (0-20 years old) who were followed up with the diagnosis of BD at the Pediatric Rheumatology outpatient clinic of Uludag University Faculty of Medicine between January 2011 and July 2021 were included in our study. The patients were diagnosed according to the diagnostic criteria of the International BD Study Group.

Results: Twenty-four (48%) of the patients were male and 26 (52%) were female. The mean age at the diagnosis of patients was 9 ±4.55 years (10.75±4.55 years in boys, 12.35±3.65 years in girls). Twenty patients (36.3%) had a family history of Behçet’s Disease. Oral aphthae were present in 86% (n=48) patients, while genital ulcers were in 32% (n=16) (Table 1). Of the nine patients with uveitis, 6 had panuveits, 2 had anterior uveitis and 1 had posterior uveitis. There was no difference in the distribution of symptoms according to the gender of the patients. HLA-B51 allele was found in 39 (78%) and ANA was positive in 14 patients (28%). Immunological tests showed that serum immunoglobulins were low in 11 (32.3%) of 34 patients. Low IgG levels were detected in 6 patients, low IgM levels were in 3, and low IgA levels were in 2. Thrombus was presented in three cases (thrombus in the right ventricle in one case, in the intracranial transverse sigmoid sinus and left jugular vein in two cases). The most commonly used drug for aphthae was colchicine (n=45, 82%). The use of biological agents according to patient manifestations is shown in Table 2. In the follow-up, clinical findings improved in 35 patients (70%). Complete improvement was detected only with biological agents in 8 patients with ulcers. One patient was operated due to the development of complicated cataracts secondary to uveitis. Three patients were diagnosed with Covid-19, one of them was followed without treatment, while two of them were treated with favipiravir at home. Three patients with Covid-19 infection were using only colchicine treatment.

AB0580 BEHÇET’S DISEASE IN OSLO NORWAY IN PERIOD 1999 – 2021
J. L. Lorentsen1, K. Lerang1, T. Garen1, O. Palm1. 1Rikshospitalet, Rheumatology, Oslo, Norway

Background: Behcet’s disease (BD) is a multisystemic, inflammatory disease, characterized by variety of clinical manifestations, including mucocutaneous, ocular, vascular, neurological (CNS) and gastrointestinal (GI) involvements. The disease can be seen at any age and occurs across gender, ethnic groups, and geographical areas. However, there are only a few studies from northern Europe.

Objectives: To study the demographics and clinical feature of patients with Behcet’s disease (BD) in Oslo Norway.

Methods: In this retrospective study we reviewed hospital records from Oslo University Hospital (OUS), a referral hospital for systemic inflammatory vasculitides in Norway. All patients living in Oslo with ICD-10 code M35.2 were identified, and their BD-related data recorded. Those fulfilling either the International Study Group criteria (ISG) or International Criteria for Behcet’s disease (ICBD) were included. Patients were defined as non-Norwegian when none of the parents was of Norwegian ancestry. The differences between groups were compared by Chi-square test using the Statistical Package for the Social Sciences (SPSS).

Results: We identified a total of 58 patients fulfilling the inclusion criteria (Table 1). Among them, 30 (52%) were females and 25 (43%) of Norwegian ancestry. Mean age at onset was 28 years, and at diagnosis 32 years.

The most prevalent clinical manifestations were oral ulcers (n=58, 100%), genital ulcers (n=49, 84%), and skin lesions (n=40, 69%). Ophthalmic complications (n=21, 36%), arthritis (n=20, 34%), vascular involvement (n=7, 12%), CNS (n=3, 5%) and gastrointestinal (GI) complications (n=4, 7%) were also present. There was no significant difference of clinical features between patients with Norwegian ancestry and those with non-Norwegian ancestry (data not shown).

Figure 1. Conclusion: BD was most prevalent among patients of non-Norwegian ancestry. We found a wide spectrum of clinical manifestations occurring during the disease course. Mucocutaneous lesions were most frequent, but potential serious manifestations were also present. These manifestations were similarly distributed between patients with Norwegian and non-Norwegian ancestry (Figure 1).

AB0581 TRACHEAL STENOSIS: AN IMPORTANT INVOLVEMENT IN GRANULOMATOSIS WITH POLYANGIITIS
O. Ozdemir Isik1, F. Tuncer1, O. Sadioglu Cagdas1, A. Yazici1, A. Cefle1. 1Kocaeli University, Faculty of Medicine, Rheumatology, Kocaeli, Turkey

Background: Granulomatosis with polyangiitis (GPA) is a granulomatous systemic vasculitis of unknown etiology that can affect many organs. Approximately 90% of patients with GPA have upper respiratory tract involvement, including the nasal cavity, sinuses, ear and trachea. Subglottic stenosis (SGS) may develop in some patients due to tracheal involvement.

Objectives: It is aimed to evaluate the general characteristics, treatments and disease prognosis of our GPA cases with tracheal stenosis as it is a significant cause of morbidity and mortality.
Methods: The data of 48 patients diagnosed with GPA between 2000-2021 were analyzed retrospectively and the data of 6 patients with tracheal stenosis (TS) were evaluated.

Results: TS was present in 13% of the patients. All patients with TS were female. The mean age of the patients with TS was 46.5±6.5 years, and the mean age of disease onset was 35.5±13.4 years, and the mean disease duration was 10.8±10.2 years. Constitutional symptoms were in 17% of patients, and 17% had manifestations of atherosclerosis, xanthomas, oedema, bloody nasal discharge and renal involvement. None of the patients had hearing loss, skin, eye and neurological involvement. 83% of patients had limited disease. While all patients had SGS, one patient also had glottic and bronchial stenosis. The most common symptoms in patients were hoarseness and shortness of breath. All patients received systemic treatment according to their organ involvement, local treatment (dilatation, steroid injection) was also applied to all patients. All patients had anti-neutrophil cytoplasmic antibody (ANCA) positivity. When patients with and without tracheal stenosis were compared, there was a difference in 5 terms of gender, lung and kidney involvement, presence of anemia, increased erythrocyte sedimentation rate, pANCA, cANCA and PR3-ANCA positivity, and myalgia. In addition, our patients with tracheal stenosis had a younger age of onset and a longer delay in diagnosis.

Conclusion: The incidence of SGS in large series has been reported as 8-23% of GPA patients. Although the number of cases in our study was small, this rate was 13%. Symptoms range from cough and shortness of breath to progressively life-threatening severe stridor. Early diagnosis and treatment are important. For this reason, TS is strongly emphasized.

Hospital of Bruneck, Department of Rheumatology, Bruneck, Italy; 23. Medical University Graz, Department of Rheumatology, Graz, Austria

Background: In most countries polymyalgia rheumatica (PMR) is diagnosed and managed by both general practitioners (GP) and rheumatologists. However, the referral pattern from GP’s to specialist around the world has not been described. The initial prednisolone dose recommended by EULAR-ACR is between 12.5 and 25 mg, but little is known about whether these guidelines are followed everywhere by GP’s in clinical practice.

Objectives: This study aims to describe the referral pattern and treatment strategy for PMR in general practice in several countries worldwide.

Methods: An English language questionnaire was drafted by a working group of rheumatologists and GPs from 6 different countries. The questionnaire contained questions on: 1. Respondent, 2. Referral pattern and 3. Prednisolone. Questionnaires were distributed to GPs via members of the International PMR/GCA study group. Answers were collected via an online survey tool (Redcap), from 3rd of November 2021 to 27th of January 2022. Countries with more than 15 GPs were included in the analysis.

Results: Data from 11 countries were analysed. Referral patterns differed widely among countries (Table 1). Almost all hospital initially seen by rheumatologists were referred to GPs for treatment. In all countries a proportion of the GP’s prescribed higher initial prednisolone doses than recommended, with a large variation between countries (Table 1).
Conclusion: Although many patients were referred to the hospital for initial PMR diagnosis or during the disease course, a large proportion of patients received treatment in general practice worldwide. GPs frequently use a higher starting dose of prednisolone and shorter treatment duration than recommended by EULAR/ACR.

AB0584 MANAGEMENT OF REFERRALS, TREATMENT STRATEGY, AND RESEARCH CHALLENGES IN POLYMALGIA RHEUMATICA AMONGST RHEUMATOLOGISTS WORLDWIDE: A QUESTIONNAIRE BASED STUDY

1: respondent, 2: referrals, 3: prednisolone, and 4: barriers to research. Questions concerned: patient journeys; the world manage the referral process of patients with PMR from GP's has not been described. EULAR/ACR guidelines recommend initial prednisolone doses between 12.5 and 25 mg, but it is unknown if guidelines are followed in daily clinical practice. Additional, the understanding of challenges for recruitment to clinical trials in PMR is currently limited.

Objectives: This study aims to describe the management of referrals, treatment strategy, and recruitment to clinical trials in PMR amongst rheumatologists worldwide.

Methods: An English language questionnaire was drafted by a working group of rheumatologists and GP’s from 6 different countries. Questions concerned: 1: respondent, 2: referrals, 3: prednisolone, and 4: barriers to research. Questions were distributed to rheumatologists via members of the International PMR/GCA study group. Answers were collected via an online survey tool (Redcap). 2nd of November 2021 to 27th of January 2022. Countries were grouped by income and geographical region based on the World bank classifications. Data were weight by number of inhabitants in a country, based on the United Nations age specific population count, divided by number of respondents in a country. Countries with more than 20 respondents were included.

**Data presented as weighted median (interquartile range) unless otherwise stated. GP: general practitioner.**

**Results:** Results from 27 countries were analysed including 1000 responders in total (Figure 1). There was large variation in time from referral to first assessment, initial dose of prednisolone was high, duration of treatment was relatively short, and a large proportion of patients with newly diagnosed PMR received prednisolone prior to rheumatological evaluation (Table 1). Concerning the 15% of respondents who performed research in PMR, 52% had participated in clinical trials and 56% of the responders experienced difficulties with recruitment.

**Conclusion:** This is the first description of current practice in managing referrals and treatment of PMR by rheumatologists worldwide. In general, median treatment duration was according to EULAR/ACR guidelines, but initial dose of prednisolone was often higher than recommended in many parts of the world. PMR patients were often seen more than two weeks after referral, and treatment had started prior to first rheumatological evaluation.

**AB0585**

**NEURO-BEHÇET’S DISEASE: A TUNISIAN EXPERIENCE**

A. Abya Chatti1, S. Skhiri1, A. Guiga1, W. Ben Yahia1, A. Attig1, N. Ghannouchi1, 1Hospital Farhat Hached, Internal Medicine, Sousse, Tunisia

**Background:** Behçet’s disease (BD) is a systemic inflammatory vasculitis with a wide range of manifestations including neurological involvement. Though neuro-Behçet’s disease (NBD) is relatively uncommon, it encompasses some of the most serious manifestations of BD. Its diagnosis can be challenging, as there is no specific diagnostic test.

**Objectives:** Our study aimed to describe epidemiological, clinical and paraclinical characteristics of BD, and compare them between patients with and without NBD.

**Methods:** We conducted a retrospective study, including all patients meeting the revised international study group criteria for BD, over an 18-year period. We divided patients into 2 groups, based on the presence or absence of neurological involvement, retained according to the international consensus recommendation criteria for NBD. Epidemiological, clinical and paraclinical features were then analysed and compared between the two groups.

**Results:** We obtained a cohort of 77 patients with a gender ratio (M/F) of 1.85 and a mean age at diagnosis of 34.4 years [20-60]. Mucocutaneous involvement inaugurated BD in 81.8% of cases, followed by joint involvement (19.5%), vascular involvement (17.9%), neurological involvement (10.7%) and ocular involvement (2.6%). Mucocutaneous involvement was dominated by oral aphthosis (100%) and genital aphthosis (79.2%) with a mean frequency of episodes per year of 8.3 ± 6.2 and 6.9 ± 5.1 respectively, followed by pseudo-folliculitis (66.2%), erythema nodosum (19.5%), and positive pathergic test (13%). Joint involvement (62.3%) was mainly peripheral (arthralgia in 98% and arthritis in 66.2%), axial involvement and sacroiliitis were observed in 14.6% and 10.4% of cases, respectively. Only one patient had a popliteal cyst. Vascular manifestations (36.4%) were venous thrombosis (92.9%), arterial thrombosis (12.9%) and arterial aneurysms (6.5%). Ocular manifestations (35%) were uveitis and vasculitis in 77.8% of patients respectively, with predominance of bilateral lesions (70.4%). Other manifestations were cardiac involvement (5.2%), intestinal involvement (3.4%) and fever (23.4%). One patient developed membranous glomerulonephritis without any other underlying aetiology. Biological inflammatory syndrome was found in 42.9% of patients. Twenty-eight patients developed NBD with 34 outbreaks during follow up. The mean delay from onset of BD was 6.3 years [0-26]. Parenchymal NBD was more frequent (73.5%), Non-parenchymal syndromes (38.2%) were acute meningeal (17%), cerebral venous thrombosis (11.8%), pseudotumour cerebri (5.9%) and isolated intracranial hypertension (2.9%). One patient developed peripheral neurological involvement. Headache
(59%) and motor deficits (32.4%) were the most common signs. Neurological examination most frequently revealed a pyramidal syndrome (32.3%). Severe forms (modified Rankin scale ≥2) dominated clinical presentations (64.7%). CSF study revealed abnormalities in 10 (35.7%) cases: Increased protein with pleocytosis in 6 cases with lymphocytic predominance (n=3), mixed formula (n=2) and PNN predominance (n=1), decreased glucose levels and increased pressure in 3 cases respectively, and one case of albuminocytological dissociation. The predilection sites of NBD lesions on MRI were brainstem and basai ganglia (35.5%, respectively), perriventricular white matter (28.5%), subcortical WM (23.5%), internal capsule (20.6%), centrum semiovale and cerebral cortex (11.8%, respectively) and cerebellum (3%). Comparison between the two groups revealed, in patients with NBD, an older mean age at diagnosis (37.7±11.97 vs 32.3 ±7.14, p=0.023) and a lower frequency of ocular involvement (21.4% in G1 vs 42.9% in G2, p=0.05). We found no statistically significant differences when comparing gender ratio and other clinical and biological features.

Conclusion: Ocular lesions were more frequent in patients without NBD. Large-scale studies are needed in order to determine markers associated to neurological involvement.

AB0586 OCULAR ISCHEMIC SYNDROME CAUSING ACUTE BINOCULAR VISION LOSS IN THREE PATIENTS WITH TAKAYASU ARTERITIS TYPE V: A THERAPEUTIC QUANDARY

A. Krishna1, U. Dhakad2, P. Dogga2, J. Dixit1, A. Pm1, King George’s Medical University, Clinical Immunology and Rheumatology, Lucknow, India; 2King George’s Medical University, Department of Clinical Immunology and Rheumatology, Lucknow, India

Background: Ocular Ischemic syndrome (OIS) is a rare manifestation in Takayasu Arteritis (TA) which can cause irreversible retinal ischemia and neovascular changes. Ocular ischemic syndrome denotes hypoperfusion of both anterior and posterior segments of eye and orbital structures as a result of common/arterial changes. Ocular Ischemic syndrome denotes hypoperfusion of both anterior and posterior segments of eye and orbital structures as a result of common/arterial changes. Ocular ischemic syndrome denotes hypoperfusion of both anterior and posterior segments of eye and orbital structures as a result of common/arterial changes. Ocular ischemic syndrome denotes hypoperfusion of both anterior and posterior segments of eye and orbital structures as a result of common/arterial changes. Ocular ischemic syndrome denotes hypoperfusion of both anterior and posterior segments of eye and orbital structures as a result of common/arterial changes. Ocular ischemic syndrome denotes hypoperfusion of both anterior and posterior segments of eye and orbital structures as a result of common/arterial changes.

Methods: Case series of three patients of TA satisfying 1990 ACR classification criteria.

Results: 18-year-old female presented with acute onset painless loss of vision in both eyes and severe vertigo. She appreciated hand motion on visual acuity testing. She was started on Methotrexate (MTX) and Prednisolone (PSL). In view of acute vertebrobasilar and carotid insufficiency, she underwent bilateral carotid and vertebral angioplasty. She tested 20/80 on visual acuity in both eyes and ambulated without support by two weeks after procedure. 15-year-old female presented with episodic vertigo, amaurosis fugax and claudication of both upper and lower limbs. She was kept on MTX and tapering doses of PSL and when dose of PSL reached less than 0.25mg/kg, she developed acute binocular vision loss with absent pupillary reflexes. Visual acuity testing revealed perception of hand motion in both eyes which improved to 20/40 within two weeks after increasing steroid dose to 0.5mg/kg and tocilizumab. 14-year-old female presented with acute binocular painless loss of vision with previous history of limb claudication. Examination revealed no light perception on visual acuity testing in both eyes with absent pupillary reflexes. She was started on tapering doses of PSL and MTX. Also, she underwent a bilateral carotid and vertebral artery angioplasty. By first week, she could identify hand motion in both eyes with absent pupillary reflexes. She was started on Methotrexate (MTX) and tapering doses of PSL and when dose of PSL reached less than 0.25mg/kg, she developed acute binocular vision loss with absent pupillary reflexes. Visual acuity testing revealed perception of hand motion in both eyes which improved to 20/40 within two weeks after increasing steroid dose to 0.5mg/kg and tocilizumab. 14-year-old female presented with acute binocular painless loss of vision with previous history of limb claudication. Examination revealed no light perception on visual acuity testing in both eyes with absent pupillary reflexes. She was started on tapering doses of PSL and MTX. Also, she underwent a bilateral carotid and vertebral artery angioplasty. By first week, she could identify hand motion in both eyes with absent pupillary reflexes. She was started on Methotrexate (MTX) and tapering doses of PSL and when dose of PSL reached less than 0.25mg/kg, she developed acute binocular vision loss with absent pupillary reflexes. Visual acuity testing revealed perception of hand motion in both eyes which improved to 20/40 within two weeks after increasing steroid dose to 0.5mg/kg and tocilizumab.

Conclusion: We suggest that combining vascular surgical and pharmaceutical intervention in acute vision loss in TA may restore vision, even in active disease. Prompt follow-up and wider sample size is needed to draw insights into ocular involvement in TA.

AB0587 THE RISK OF PATIENTS WITH POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS TO DEVELOP DIABETES AND OSTEOPOROSIS ON FOLLOW UP

M. Bahl1,2, M. Stöcker3, S. Tsiami1,2, X. Baraliakos1,2, J. Braun1,2, U. Kitz1,2, 1Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; 2Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany; 3Augusta-Kranken-Anstalt gGmbH, Pneumology, Bochum, Germany

Background: Patients with polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are commonly treated with glucocorticoids (GC) in different dosages. Therefore, the most common comorbidities that may develop are osteoporosis (OPO) and diabetes mellitus (DM).

Objectives: To study the development of these comorbidities in the management of PMR and GCA in a real-life setting.

Methods: In a retrospective study design, longitudinal data of patients with a clinical diagnosis of PMR and GCA treated in a tertiary center were studied. Patients and disease characteristics were documented according to clinical routine in patients in whom ≥2 documented visits ≥3 months apart had been documented.

Results: A total of 550 patients (382 PMR, 168 GCA) was analysed (Table 1). The time period of follow up (FU) ranged between 3 months and 13.6 years (mean 1.4 (0.3) years). The majority of patients received a diagnosis of PMR or GC.
GCA in our center while 29.5% of patients came for a second opinion. Their mean age was around 70 years, and most patients were female (Table 1). Eight GCA patients were already blind (4.6%) at first presentation, and 77 and 80 patients had a diagnosis of DM (15.5%) and OPO (16.0%), respectively, already at baseline. During FU 56 PMR (16.0%) and 7 GCA patients (4.2%) were diagnosed with another autoimmune disease, mainly with rheumatoid arthritis (n=50 (69.4%). The mean dose of GC differed substantially between groups (Table 1). On FU, 9 (2.4%) and 5 (3.0%) of PMR and GCA patients developed DM and 17 (4.5%) and 14 (6.4%) OPO, respectively. Thus, about 20% and 25% of patients with PMR or GCA finally had DM and OPO, respectively. Almost all patients received vitamin D and antiretroviral agents.

Values given as mean (SD)

**Conclusion:** In this large real-life cohort, patients with PMR and GCA aged around 70 years were seen by rheumatologists about 1-2 months after their first symptom but 8 GCA patients were already blind at first visit. DM and OPO were frequent comorbidities in both, PMR and GCA patients, already at baseline and during follow-up more patients developed these comorbidities despite prophylactic and therapeutic medication. OPO and DM should be a routine concern in the care of PMR and GCA patients - already when glucocorticoids are started.

Giant Cell Arteritis: Do Different Phenotypes of Presentation Mean Different Clinical Entities?

N. Italiano 1, F. Di Gianni 1, E. Elefanté 1, F. Ferro 1, P.A. Erba 2, R. Talanico 1, M. Mosca 1.
1University of Pisa, Rheumatology Unit, Pisa, Italy; 2University of Pisa, Department of Translational Research and New Technologies in Medicine and Surgery; Section of Nuclear Medicine, Pisa, Italy

**Background:** Giant cell arteritis (GCA) is a systemic vasculitis involving large and medium-sized blood vessels. Treatment is with high dose glucocorticoids. Steroid-sparing agents and Tocilizumab (TCZ) are used for refractory or relapsing disease. NHS England requires all GCA patients to be discussed in a regional multidisciplinary team meeting (MDT) prior to commencing TCZ. TCZ has only been permitted for a maximum of one year; this time limitation was extended during the Covid-19 pandemic (1). The monthly virtual Bristol and Bath regional MDT started in November 2018.

**Objectives:** We aimed to review: 1) Baseline data on all patients referred to the Bristol and Bath TCZ for GCA MDT, including demographics, clinical presentation and previous steroid-sparing agents used and 2) 12 month follow up data including number of completions, adverse effects, and flares on treatment.

**Methods:** The TCZ MDT referral form, adapted from the NHS England Blueteq approval form, was reviewed for all patients referred. 12 month follow up data was obtained from clinic letters.

**Results:** Baseline data

Thirty-eight cases were referred between November 2018 and September 2021. Of these, 31 were approved for TCZ usage; 100% fulfilled the criteria for either refractory (n=11) or relapsing (n=20) disease. Mean age was 74 years and 74.2% were female. Average disease duration was 161.5 days for the refractory and 827.3 days for the relapsing group. 77.4% had cranial GCA, 48.4% had large vessel involvement, 45.2% had visual symptoms and 25.8% had ischaemic visual loss. The positive investigations were PET-CT (48.4%), temporal artery ultrasound (41.9%) and temporal artery biopsy (32.3%).

64.5% had trialled a steroid-sparing agent at time of referral (61.3% methotrexate, 9.7% azathioprine, 6.5% leflunomide), 35.5% had received intravenous methylprednisolone. 58% were receiving greater than 40mg prednisolone at the time of referral. Glucocorticoid adverse effects of osteoporosis, weight gain, cataracts and hypertension were each seen in 19.4%; whilst diabetes, neuropsychiatric symptoms and sleep disturbance were each reported in 16.1%.

Those with ocular involvement tended to be referred earlier than those without (478.2 days vs 648.1 days), were referred on higher doses of glucocorticoids (71.4% vs 47.1% on ≥40mg) and had less steroid-sparing agents prior to referral.

**Follow up data**

In December 2021, a follow-up audit revealed 14/31 patients had completed at least 12 months of tocilizumab; 5 of these had had an extension under Covid-19 exceptional guidance (mean duration of 5.2 months). Of the remaining 17: 3 patients had stopped early (1 death, 1 moved away, 1 due to adverse effects of hypertension and gastro-intestinal side effects). 4 had not started tocilizumab and 10 had completed 12 months of treatment at that point.

Adverse events in the 14 patients at 12 months included: liver abnormalities (2/14; 14.3%), neutropenia (2/14; 14.3%), thrombocytopenia (1/14; 7.1%), soft tissue between onset and treatment of ≥ 3 months. Temporal artery biopsy was performed in 171 patients, resulting positive in 72%. Globally, about 38% of subjects (was characterized by a clinical profile compatible with extra-cranial GCA. In all cases, extra-cranial involvement was confirmed by (18F-fluorodeoxyglucose: FDG) positron emission tomography (PET). Moreover, patients who presented symptoms compatible with large-vessel involvement were characterized by a more relapsing course compared with patients with cranial involvement GCA profile (both in terms of dose of corticosteroids and use of steroid-sparing agents).

**Conclusion:** According to the literature data, different phenotypes of GCA exist and they may probably represent different clinical entities, also in terms of prognosis and therapeutic approach. This is particularly crucial in order to plan a tailored therapy and prevent disease damage in the short and long-term follow-up.

**Disclose of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.2797
infections (3/14; 21.4%), urinary tract infection (1/14; 7.1%) and lipid derangement (4/14; 28.6%). One case of GCA relapse occurred on TCZ (mild headache and raised inflammatory markers settled on small increase in prednisolone). After 12 months, mean prednisolone dose was 3mg (range 0-5mg).

**Conclusion:** All patients approved for Tocilizumab in the GCA MDT fulfilled NHS England criteria for either relapsing or refractory disease. The majority of cases had cranial disease, but almost half had either ocular or large vessel involvement, reflecting a severe spectrum of disease. Cases showed a high burden of glucocorticoid toxicity. Follow up data suggests that TCZ was effective in allowing glucocorticoid weaning and disease control, but with some adverse effects. Future work to follow up patients after stopping Tocilizumab would be informative, as the twelve month limitation on treatment is likely to be re-instated.

Table 1. Baseline characteristics of 39 newly diagnosed GCA patients.

**DISCUSSION:**

The follow-up time between groups was 20 (IQR 18.5-24.5) months vs 36 (IQR 24-60.5) months, respectively. At the last medical examination, all patients were in sustained remission, 6/11 (54.5%) and 17/28 (60.7%) had discontinued GCs. The prednisone equivalent dosage of 5mg/day was achieved at 5 (IQR 2.75-6.5) and 7 (IQR 5-10) months (p-value 0.078), respectively, while discontinuation of GCs was achieved at 7.5 (IQR 6.25-11.5) and 19 (IQR 14-24) months (p-value 0.015), respectively. No differences were observed as concerns GC-related adverse events at 1 year after the onset of GCA (1 event in 11 patients [9.1%] vs 3 events in 28 patients [10.7%]). In details, GC-related adverse events were development of diabetes (2/4), hypertension (1/4), or osteoporosis (1/4). Two patients in the first group (18.2%) and 9 in the second one (32.1%) experienced at least one relapse (median time to relapse was 6.5 [IQR 5.75-7.25] and 18 [IQR 12-24] months). Relapses required the association of MTX with TCZ (1/11 [9.1%]) or start of TCZ (1/11 [9.1%] in the former group, while they required an increase in steroid dosage (7/11 [63.6%]), switch from MTX to TCZ (1/11 [9.1%]), or reinstatement of MTX therapy after its discontinuation (1/11 [9.1%]) in the latter.

Overall, both drugs were well tolerated. 1/11 (9.1%) and 5/28 (17.9%) had discontinued TCZ and MTX, respectively, due to mild and reversible drug-related adverse events (4/6 general malaise or discomfort, 1/6 gastrointestinal symptoms, or 1/6 abnormal liver function tests). No serious infections were observed.

**Conclusion:** TCZ showed a faster steroid-sparing effect than MTX. Both immunosuppressants are safe, effective and allow the discontinuation of GCs.

**Figure 1.** Distribution of GCA subphenotypes

Of the 38 patients having TAB, 20(42.9%) were consisted with GCA. The main histopathological finding were inflammation rich in lymphohistiocytic cells in the temporal artery (44.7%) and fragmentation and loss of integrity of the internal elastic lamina (36.8%). All of the patients have been used corticosteroids with a median starting dose of 16 mg/day (8-64) had use pulse therapy. Any of conventional DMARDs (AZA, MTX, LEF, CYC) have been used in 60 of patients. In all cases, Tocilizumab was recommended after resistant/intolerant to conventional DMARDS (n=6). Follow-up data was based on 64 patients. During a median 5.8 (±4.0) years follow-up, 6 (9.3%) patients deceased. Thirteen (20.3%) had one or more relapses, 8 (61.5%) from isolated GCA group and 4 (30.7%) from Only LV GCA group.

**Conclusion:** GCA is less frequent than TAK in our centre. Female predominance and a seventh decade of disease onset was observed in our cohort. Heterogeneity of disease was observed in or cohort along with different frequent used diagnostic confirmatory modality among subphenotypes. Relapse rate was 20 percent during a 6-year follow-up with a 83% additional DMARD usage.

**DOl:** 10.1136/annrheumdis-2022-eular.3035

**Figure 1.** Distribution of GCA subphenotypes
Background: Temporal arteritis is the most common systemic vasculitis in patients aged >50 years, the most serious complications of which is visual loss. The arterial biopsy is the diagnostic gold standard; alongside the classic finding of transmural infiltrate and giant cells, other abnormalities have been described of which it is not yet known whether they identify specific clinical subsets. PET is not yet used for diagnosis, but it can be suggestive in patients with high clinical suspicion; it may be useful for assessing the extent of the disease in already diagnosed patients and for ruling out alternative diagnoses as infections and neoplasms. More recently, PET has been used to assess disease metabolic activity.

Objectives: The aim of our study is to evaluate, in patients with histologically confirmed temporal arteritis, correlations between pathological subsets, metabolic activity and different clinical behavior.

Methods: We have recovered the medical records of patients with the diagnosis of temporal arteritis made in our Rheumatology service from January 2007 until now. We selected those satisfying the ACR 1990 criteria and, finally, those with a positive biopsy. We analyzed age at onset of symptoms, diagnostic delay, presence of PMR, fever, constitutional symptoms, headache, temporal artery induration, visual loss; we analyzed CRP, ESR, plasmatic Hb, PLT count, hypocoagulability; it may be useful for assessing the extent of the disease in already diagnosed patients and for ruling out alternative diagnoses as infections and neoplasms.

Results: We analyzed 46 patients (F 32, M 14), average age at onset of symptoms of 75.5 yrs and average diagnostic delay of 3.2 months. Headache was reported by 37 patients, fever and asthenia by 26 and 24 respectively, jaw claudication and PMR by 18 and 7. 11 patients had visual loss while 4 and 2 respectively reported amaurosis and diplopia. Temporal artery induration was described in 24 patients. Tests of systemic inflammation were abnormal (mean CRP 6-21); 8/13 patients had not taken steroids prior to PET.

Conclusion: In our retrospective study we observed, in addition to transmural infiltrate and giant cells, the presence of lymphocytes, macrophages and small vessel vasculitis. No correlation was observed between clinical findings, biological and metabolic activity, apart from the increased presence of giant cells in PET positive patients. Visual loss is slightly more common in PET negative patients. This may be due to severity of the cases which needed early steroid treatment.

AB0594
ULTRASOUND INTIMA MEDIA THICKNESS CUT-OFF VALUES FOR CRANIAL AND EXTRACRANIAL ARTERIES IN PATIENTS WITH GIANT CELL ARTERITIS

K. Lópex Gloria1, P. Rodríguez-Merlos1, B. Serrano-Benavente1, J. C. Nieto Gonzalez1, C. Gonzalez1, I. Monteagudo Saez1, T. Gonzalez1, I. Castrejon1, J. M. Alvaro-Gracia1, J. Molina Collada1,1 Hospital Universitario Gregorio Marañón, Rheumatology, Madrid, Spain

Background: Ultrasound (US) is a valid imaging tool to detect signs of giant cell arteritis (GCA). Although the halo sign has always been considered the most useful finding for GCA diagnosis, modern high frequency transducers are able to precisely measure the intima-media thickness (IMT) of cranial and extracranial arteries. However, data on optimal cut-off values for IMT to differentiate patients and controls in clinical practice are limited.

Objectives: To determine the optimal cut-off value for IMT of cranial and extracranial arteries in patients with suspected GCA.

Methods: This is a retrospective observational study of patients referred to our US fast-track clinic with suspected GCA. All patients underwent bilateral US examination of the cranial and extracranial (carotid, subclavian and axillary) arteries within 24 hours per protocol. The exam was performed using an Esaote MyLab® with a 12-18 MHz frequency transducer for cranial arteries and an 8-14 MHz frequency transducer for extracranial arteries. The IMT was measured in gray scale mode and the presence of a non-compressible halo sign was checked in all arteries. The gold standard for GCA diagnosis was clinical confirmation by the referring rheumatologist after 6 months follow-up. Mean IMT values of each artery were compared between patients with and without GCA by independent samples T-Test. Receiver operating characteristics analysis was performed and the Youden index was used to determine the optimal cut-off value for IMT of each artery.

Results: Of the 157 patients with suspected GCA (67.5% female, mean age 73.7 years) referred to the fast-track clinic, 47 (29.9%) had GCA clinical confirmation after 6 months. 41 (87.2%) patients with GCA had positive US findings (61.7% had cranial involvement, 44.7% extracranial involvement and 19.1% a mixed pattern of cranial and extracranial arteries). The following IMT cut-off values showed the highest diagnostic accuracy: 0.44mm for the common superficial temporal artery; 0.34 mm for the frontal branch; 0.36 mm for the parietal branch; 1.1 mm for the carotid artery: 1 mm for the subclavian and axillary arteries. The area under the ROC curve of the IMT for a clinical diagnosis of GCA was 0.984 (95% CI 0.959 - 1) for common superficial temporal artery, 0.989 (95% CI 0.978 - 1) for frontal branch, 0.991 (95% CI 0.980 - 1) for parietal branch, 0.977 (95% CI 0.961 – 0.993) for carotid, 0.99 (95% CI 0.979 - 1) for subclavian and 0.996 (95% CI 0.991 - 1) for axillary arteries (Table 1).

BACKGROUND: Takayasu arteritis (TA) is a large vessel vasculitis rarely reported in children, and its incidence is extremely low in infants. Most articles on pediatric TA have not focused on infants. We present the largest case series of infantile TA aiming to characterize demographic and clinical data and compare it with existing data on older children.

OBJECTIVES: Characterize demographic and clinical data regarding TA and compare it with existing data on older children.

METHODS: We conducted an international multi-center retrospective cohort study. Epidemiological and clinical data were collected from patient charts by doctors from six centers.

RESULTS: Twelve patients (50% female) meeting the ACR criteria of TA were included. Median age of symptom onset was 11 months, with a diagnostic delay of 4 months and median time of follow-up of 7.5 years. The most common symptoms at presentation were hypertension (67%), BP difference between upper and lower limbs, and fever. The arteries most commonly involved at diagnosis were the ascending aorta, renal artery, and superior mesenteric artery. Different medications used included steroids, conventional and biological DMARDs, and immunosuppressive therapies. Half of the patients received biologic agents of which infliximab had the highest complete remission rate (40%). Other medications resulting in complete remission were cyclophosphamide (40%) and methotrexate (33%). None of the patients died.

CONCLUSION: This study presents the largest series of infantile TA. Compared to reported series on older children, infants with TA were more likely to receive biologic agents, develop complications and require invasive interventions.

INFANTILE TAKAYASU: CLINICAL FEATURES AND LONG TERM OUTCOME

A. Miller Barma1, F. Sztabnik2, S. Ōzen2, Z. Balik2, A. Borzutzky3,6, L. Fogel2, G. Goldberg2, Y. Butbul1,8,9, 1 Federal University of Rio de Janeiro, Rheumatology Unit, Rio de Janeiro, Brazil; 2 Rambam Medical Center, Pediatrics B, Haifa, Israel; 3 Federal University of Rio de Janeiro, Federal Rheumatology Unit, Rio de Janeiro, Brazil; 4 Hacettepe University, Pediatric Rheumatology, Ankara, Turkey; 5 Pontifical Catholic University of Chile, Department of Pediatric Infectious Diseases and Immunology, Santiago, Chile; 6 Washington University in St. Louis, Pediatrics, St. Louis, United States of America; 7 Kaplan Medical Center, Pediatric Rheumatology Unit, Rehovot, Israel; 8 Rambam Medical Center, Pediatric Rheumatology Unit, Haifa, Israel; 9 Technion - Israel Institute of Technology, The Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel

Disclosure of Interests: None.

OBJECTIVES:

1. To describe clinical features and long-term outcomes of Takayasu arteritis in children.
2. To determine how these features compare with the adult population.

BACKGROUND:

Takayasu arteritis (TA) is a chronic inflammatory vasculitis of unknown etiology that affects the aorta and its main branches. It is more common in East Asian populations and can affect both children and adults. The disease is characterized by progressive stenosis and occlusion of the affected arteries, leading to organ ischemia and potential organ damage. Early diagnosis and appropriate management are crucial to prevent complications and improve long-term outcomes.

METHODS:

A retrospective analysis of children diagnosed with TA in a tertiary pediatric rheumatology center in Israel was conducted. A total of 13 children were included in the study, with a median age at diagnosis of 9.2 years (range: 2-15 years). The clinical features and outcomes were compared with the adult population.

RESULTS:

The most common initial symptoms were fever, fatigue, and constitutional symptoms. Pain in the chest and limbs was also frequent. Five out of 11 children had hypertension as an initial symptom. On examination, the most common finding was auscultation of bruits over the affected vessels. Laboratory findings included anemia, leukocytosis, and elevated erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP). Arterial imaging using magnetic resonance angiography (MRA) was the most common imaging technique used to confirm the diagnosis and monitor disease activity.

Conclusion:

The clinical presentation and long-term outcomes of Takayasu arteritis in children are similar to those in adults. Early diagnosis and appropriate management are crucial to prevent complications and improve long-term outcomes.

AORTIC MANIFESTATIONS IN GIANT CELL ARTERITIS: SINGLE CENTRE 10-YEAR EXPERIENCE

F. Coath1, A. Sharma2, R. Enshad3, J. Mo3, J. Davies3, B. Dasqupta1. 1 Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom; 2 Southend University Hospital, Mid and South Essex NHS Foundation Trust, Radiology, Southend-on-Sea, United Kingdom; 3 Southend University Hospital, Mid and South Essex NHS Foundation Trust, Radiology, Southend-on-Sea, United Kingdom

Disclosure of Interests: None.

BACKGROUND:

Giant cell arteritis (GCA) is a non-infectious inflammatory condition affecting the aorta and its branches. It typically affects older patients, with a peak incidence in the seventh and eighth decades. The disease is characterized by the infiltration of granulomatous lesions, predominantly affecting the outer muscular layers of the affected arteries. GCA is often associated with polymyalgia rheumatica (PMR), and its diagnosis is typically based on typical clinical features, temporal artery biopsy, and laboratory findings. The aim of this study is to report the long-term outcomes of GCA patients managed in a single centre over a 10-year period.

METHODS:

A retrospective analysis of all patients with a diagnosis of GCA managed at the Southend University Hospital, UK, between 2011 and 2021 was performed. Data collected included demographics, clinical features, treatment, and outcomes. The primary outcome measures were freedom from recurrence and the need for steroid-sparing treatment. All patients were followed up at least annually, with a median follow-up of 5.2 years.

RESULTS:

A total of 126 patients were identified. The mean age at diagnosis was 72 years (range: 46-91 years), and 81 (64%) were women. PMR was present in 49 (39%) patients. The most common presenting symptoms were headache (59%), jaw claudication (31%), and visual disturbance (12%). Temporal artery biopsy was positive in 83 (66%) patients. Aortic involvement was present in 76 (61%) patients, with 24 (19%) having aortic root dilatation. The most common sites of aortic involvement were the arch (36%) and descending thoracic aorta (31%). At follow-up, 12 (9%) patients had recurrence, and 22 (18%) required steroid-sparing treatment. Freedom from recurrence at 5 years was 91% (95% CI: 86-95).

Conclusion:

This study highlights the importance of early and aggressive treatment in preventing recurrence and the need for steroid-sparing treatment in GCA. Further research is needed to identify predictors of recurrence and to optimize treatment strategies.

AB0597
FDG-PET/CT IN THE DIAGNOSIS AND FOLLOW UP OF TAKAYASU VASCULITIS

B. Gudbrandsson1, O. Palm2, O. Molberg3, H. Gilvedt4, M. Rehev5. 1 Östfold University Hospital, Rheumatology, Fredrikstad, Norway; 2 Rikshospitalet, Rheumatology, Oslo, Norway; 3 Oslo University Hospital, Division of Radiology and Nuclear Medicine, Oslo, Norway; 4 Rikshospitalet, Division of Radiology and Nuclear Medicine, Oslo, Norway

Disclosure of Interests: None declared

BACKGROUND:

Takayasu vasculitis (TAK) is a chronic disease, where clinic and serological markers as CRP/ESR may fail to predict development of new vascular lesions in the disease course (1). Similarly, 18-fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) studies show conflicting results on the association between vessel uptake of FDG and clinical and laboratory finding. A study on new FDG-PET activity scoring system, PETVAS was newly published but has not been validated in other cohorts (2). To date there are limited data on FDG-PET/CT finding at time of diagnoses before treatment induction and 18-FDG uptake and development of new stenosis during followup.

OBJECTIVES:

The goal of this study was to see 1) FDG-PET/CT uptake in newly diagnosed patients before any treatment start 2) FDG-PET/CT uptake and development of new vascular lesions during follow up magnetic resonance angiography (MRA) 3) assess PETVAS score before and after treatment induction.

METHODS:

All patients in a population-based TAK cohort with FDG-PET/CT at the time of diagnosis and after treatment induction were identified. Disease activity was assessed with the NIH activity score (1). Patients who had clinical, laboratory and MR-angiography prior to or right after FDG-PET/CT and a minimum of one follow up MRA. The clinical report from the FDG-PET/CT and MRA were reviewed and arteries/aorta regions of interest (sacrospinal arteries, aorta, iliac and femoral arteries) scored from 0-3, where 0 represent no uptake, 1 less then liver, 2 same as liver and 3 higher than liver and finally summarized these to PETVAS score.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular.3598
Results: Twenty-three patients fulfilled the study’s inclusion criteria. Twenty-one of the patients were females (91%) and twenty-two were European Caucasian. The mean age was 39.3 (SD 14) at the time of diagnosis (Table 1). Five patients were in clinical and laboratory remission at diagnosis (NIH=0). Correspondently, none of them had sign of active FDG vessel uptake at PET-CT. They had a median 7 in PETVAS (range 0-3.1). The remaining 17 patients had clinical active disease (NIH>1) at diagnoses. All 17 patients had uptake on PET/CT in at least one artery/aorta region. The mean PETVAS score at diagnosis was 21.5 (SD 8). At last imaging the patients had developed median 2 new lesions. All the arteries that developed new lesion had active uptake on the original PET/CT. Fourteen patients had FDG PET/CT after treatment start. The PETVAS score decreased from 22.4 (SD 8.7) to 10.7 (SD 6.8) after treatment start (p<0.001).

Conclusion: All patients with clinical active disease at diagnoses had pathological FDG uptake. Only arteries with increased FDG uptake in the vascula wall subsequently developed new lesion. The study also showed that the PETVAS score fell significantly after treatment induction.

AB0598 ASSOCIATION OF PROLONGED DISEASE DURATION AND TG/HDL-C RATIO IN ACCELERATING Atherosclerosis IN PATIENTS WITH TAKAYASU’S ARTERITIS
J. Du1, L. Pan2. 1Beijing An Zhen Hospital, Affiliated of Capital University of Medical Sciences, Rheumatology and Immunology, Beijing, China; 2Beijing An Zhen Hospital, Affiliated of Capital University of Medical Sciences, Rheumatology and Immunology, Beijing, China

Background: Takayasu’s arteritis (TA) is an autoimmune vasculitis that frequently occur in young women. Multiple previous studies have demonstrated that accelerated atherosclerotic changes were commonly found in TA patients1-4. More specifically, data indicated that as much as 27% of all TA patients developed carotid artery plaque, while which was only 2% in the age- and sex-matched healthy individuals[1]. In addition, up to 20% of TA patients developed stroke and/or transient ischemic attack(TIA), which had both been known to be associated with atherosclerotic lesions[5,6]. Inflammation of the vascular wall may promotes atherosclerosis (As) in TA,which accelerates the development of As.Higher triglyceride (TG)/HDL-C ratio was found to be associated with presence of endothelial dysfunction and As[7,8].

Objectives: This study aimed to identify the risk factors associated with the development of atherosclerosis in TA.

Methods: This retrospective study enrolled a total of 101 TA patients. All patients were divided into two groups according to the absence or presence of atherosclerosis[43 vs 58]. Baseline demographic features and clinical characteristics were compared between two groups. A logistic model was applied to determine the risk factors associated with the development of atherosclerosis.

Results: Our data suggested that the disease duration of patients in the atherosclerosis group was significantly longer than that of patients in the non-atherosclerosis group [96(18.00,180.00) vs 48.00(12.00,111.00) months] (p<0.015). In addition, the average age of patients with atherosclerosis was significantly older compared to patients without atherosclerosis [44.00 (38.00,48.00) vs 28.50 (24.00,37.00) years] (p<0.001). Logistic regression analysis showed that the risk of developing atherosclerosis increased by 9.2% per 1 year increase in the disease duration(p<0.005, OR 1.092,95%CI:1.027-1.162).Patients with TG/HDL-C ratio more than 0.8875 were associated with a 5.861 fold increase of risk developing atherosclerosis(p<0.001, 95%CI:2.299-14.939).

Conclusion: Our study indicated that prolonged disease duration and elevated TG/HDL-C ratio are associated with the development of atherosclerosis in TA patients.

AB0599 THE VALUE OF ULTRASOUND IN GCA FOLLOW-UP: RESULTS FROM A SCOTTISH SINGLE CENTRE.
A. Neville1, A. Ciechomska2. 1University of Glasgow, Institute of Infection, Immunity & Inflammation, Glasgow, United Kingdom; 2University Hospital Wishaw, Rheumatology Department, Wishaw, United Kingdom

Background: Ultrasound (US) is important diagnostically in GCA, but its value during follow-up is unclear1. In our centre, ad hoc follow-up US has been performed routinely.

Objectives: To describe how US appearances i) changed over time (at defined timepoints), ii) correlated with clinical relapse (at any time), iii) were affected by tocilizumab.

Methods: Patients diagnosed with GCA in NHS Lanarkshire, November 2018 - October 2021, were included. Treatment was in accordance with international guidelines2. Follow-up visit data included clinical status (remission, stable, relapse), treatment, and (when US performed) temporal artery (TA) and axillary artery (LV) intima media thickening (IMT) (TA~IMT>0.5MM; LV~IMT>1.0mm). Follow-up US were compared to baseline, pre-relapse or pre-tocilizumab.

Results: 55 patients were diagnosed with GCA; mean (SD) age 73.1 (8.0) years; 31 female (56.4%). Mean (SD) follow-up was 63.8 (40.6) weeks. All patients had baseline US (48 positive (TA+ or LV+)); 7 negative; 36 (65.5%) had ≥1 follow-up US. 7 patients had US at 6-12 weeks; all were clinically stable; all had positive baseline US; at 6-12 weeks, 3/7 remained TA+, 1/7 remained LV+ (TA-LV+). 25 patients had US at 16-36 weeks; 9/25 were in remission, 11/25 stable, 5/25 relapsing. Of remission patients, 7/9 had positive baseline US; at 16-36 weeks, 2/7 remained TA+. Of stable patients, all had positive baseline US; at 16-36 weeks, 4/11 remained TA+, 3/11 remained LV+. Of relapsing patients, 5/5 had positive baseline US; at 16-36 weeks, 2/5 remained TA+, 1/5 LV remained LV+.

a. Number of patients scanned.

15 patients had USS at 42-62 weeks; 8/15 were in remission, 3/15 stable, 4/15 relapsing. Of remission patients, 7/8 had positive baseline USS; at 42-62 weeks, 3/7 remained TA+. Of stable patients, 3/3 had positive baseline USS; at 42-62 weeks, 1/3 was TA-LV+, 1/3 remained TA-LV-. Of relapsing patients, 4/4 had positive baseline USS (3/4 TA+, 1/4 LV-); at 42-62 weeks, all were TA-LV+. The Table 1 below provides additional detail for each timepoint. 11 patients in total had clinical relapse (any time) and contemporaneous USS; mean (SD) time to relapse was 36.6 (18.3) weeks; median (IQR) prednisolone dose 7mg (4.9). At relapse, 2/11 were TA-LV+, 6/11 LV+, 3/11 TA-LV+. Comparing relapse USS to most recent USS pre-relapse, 4/11 were newly LV+, while other positive findings were seen previously. 11 patients treated with tocilizumab had ≥1 USS post-initiation of tocilizumab, which included at approx. 12 months follow-up. Ad hoc follow-up scans therefore appear unreliable in isolation, but the value of systematic longitudinal scanning warrants further study. Emergence of LV positivity was seen in several cases of relapse and may characterise an evolution in disease phenotype. Positive USS findings largely persisted at approx. 6 months despite disease control on tocilizumab.

Conclusion: While many patients had rapid normalisation of USS changes with treatment, others remained abnormal despite stable disease or remission, including at approx. 12 months follow-up. Ad hoc follow-up scans therefore appear unreliable in isolation, but the value of systematic longitudinal scanning warrants further study. Emergence of LV positivity was seen in several cases of relapse and may characterise an evolution in disease phenotype. Positive USS findings largely persisted at approx. 6 months despite disease control on tocilizumab.

ANALYSIS OF RISK FACTORS AND PROGNOSIS IN PATIENTS OF TAKAYASU’S ARTERITIS WITH CORONARY ARTERY LESIONS

J. Du1, L. Pan1, 1Beijing An Zhen Hospital, Affiliated of Capital University of Medical Sciences, Rheumatology and Immunology, Beijing, China

Background: Takayasu's arteritis (TA) can involve coronary artery lesions. The pathogenesis is complex and lacks the best treatment strategy. The coronary artery lesions were typical seen in the os/a of the left and right coronary arteries which were major risk factors for sudden death and ischaemia heart failure[1-2]. Coronary artery lesions is an important predictor of poor prognosis in TA patients.[3-4]. The prevalence of metabolic syndrome and its related characteristics (including dyslipidemia, diabetes and hyperinsulinemia) in TA patients are higher compared with healthy people.[5]. Thus, under the action of vascular inflammation and traditional risk factors, coronary artery stenosis or even occlusion occurs earlier, which can lead to MACE events.

Objectives: The aim of our study is to investigate the risk factors and prognosis of coronary artery lesions in TA patients.

Methods: This retrospective study enrolled a total of 120 TA patients. All patients were divided into two groups according to the absence or presence of coronary artery lesions in TA patients (61 vs 59). A logistic model was applied to determine the risk factors associated with the incidence of coronary artery lesions in TA patients. According to the before and after imaging comparison of TA with coronary artery lesions, the influencing factors of improving TA with coronary artery lesions were analyzed.

Results: The incidence of coronary artery lesions in TA patients increased by 1.618 times for each additional year (p=0.018, 95%CI: 1.199-2.132). The age and gender were more common in type IIb coronary artery lesions. The incidences of coronary artery lesions were more common in type IIb coronary artery lesions (21.70±1.71 years, p=0.001). TNF-α and interleukin-6 were significantly higher in the group with improved coronary imaging than in the group without improved coronary imaging (26.40(10.08 , 165.90) vs 21.70(pg/ dl,p=0.047;12.50(5.83 , 19.30) vs7.13(2.80 , 4.40)pg/dl,p<0.001).Numano type V (75.00% vs 27.27%, p=0.022) and vascular calcification (56.25% vs 9.09%, p=0.016) were significantly higher than those in the group without improved coronary imaging, while numano type lib in the group with improved coronary imaging was significantly higher than that in the group without improved coronary imaging(45.45% vs 6.25%, p<0.027).

Conclusion: Hyperlipidemia and age are the risk factors of coronary artery lesions in Takayasu arteritis.Numano type V and vascular calcification are not conducive to the improvement of TA with coronary artery lesions.All patients with TA of numano type lib should be screened for coronary artery. Early control of inflammation is more conducive to the improving imaging of arteritis coronary artery lesions.

BACKGROUND: Behçet syndrome (BS) is a unique vasculitis that can affect arteries and veins of all sizes. Thrombosis is an important component of vascular involvement in BS. Although several studies were conducted to highlight the mechanism of thromboinflammation in BS, it is still not fully understood.

OBJECTIVES: We performed a systematic review and meta-analysis of studies investigating thrombotic, fibrinolytic, and endothelial factors in BS.

METHODS: We searched PubMed and EMBASE with the keyword “Behçet” in title and/or abstract, from their inception up to April 2020. Titles and/or abstracts of all studies were screened independently by two reviewers (GGO and BY), and conflicts were solved by a third reviewer (GH). Studies comparing BS patients with and without thrombosis and studies comparing BS patients with thrombosis and patients with thrombosis due to other causes were analyzed separately. The pooled odds ratios (OR) with 95% confidence interval (CI) were calculated for binary outcomes and standardized mean difference (MD) for continuous outcomes using RevMan 5.3. We categorized the factors into 4 groups based on acting mechanism 1- those that decrease anticoagulant activity 2- those that increase procoagulant activity 3- those that decrease the activity of fibrinolytic system 4- pathogenic/endothelial factors.

RESULTS: Of 15848 articles, 15157 were excluded due to duplication and inappropriate study design after reviewing titles and abstracts. Full text review of the remaining 391 articles yielded 103 papers meeting our predetermined inclusion criteria. Factors significantly associated with BS thrombosis compared to BS without thrombosis were high frequency of factor V Leiden mutation (15 studies, OR 2.55, 95% CI 1.66-3.93), high homocysteine level (14 studies, MD: 4.27, 95% CI 2.31-6.22), high protein C level (5 studies, SMD: 0.80, 95% CI 0.15-1.45) and high alpha-antitrypsin level in Group 1; high factor level 8 (4 studies, MD: 17.17, 95% CI 7.79-6.55), high thrombin level (1 study, MD: 35.90, 95% CI 12.40-59.40), high neutrophil/lipophilicocyte ratio (2 studies, MD: 1.37, 95% CI 0.24-2.50) and high platelet/neutrophil complex level (1 study, MD: 10.50, 95% CI 0.76-20.24) in Group 2; high TAFI activity (1 study, MD: 28, 95% CI 4.12-51.88) in Group 3; high VEGF level (2 studies, SMD: 1.63, 95% CI 0.21-3.05), high CEC concentration (2 studies, SMD: 1.00, 95% CI 0.22-1.77), high MCP-1 level (1 study, MD: 74.16, 95% CI 61.29-87.03), high anti-C1q level (1 study, MD: 9.11, 95% CI 0.51-17.71), high platelet microaggregate formation (1 study, MD: 75.00, 95% CI 762-142.38), high frequency of P-selectin glycoprotein ligand 1 gen polymorphism (heterozygous (AB+AC+BC)) (1 study, MD: 1.88, 95% CI 1.07-3.31), high ADMA level (1 study, MD: 0.16, 95% CI 0.08-0.24), high PCAM-1 level (1 study, MD: 59.30, 95% CI 3.35-115.29) and low brachial artery flow-mediated (endothelium-dependant) dilatation (1 study, MD: -3.22, 95% CI -5.18-1.26) in Group 4.

Factors that were associated with BS thrombosis compared to thrombosis due to other causes including JAK-2 mutation, circulating endothelial cells, activated protein C resistance, tPA, and PAI were assessed in 1 study each. Age (y, median (IQR)) 74 (65, 81) 74 (65, 80) 74 (65, 81) (Figure 1). For these patients, hospital site showed a trend to be a significant factor (p = 0.08). Despite this, we observed that the number of patients with BS who had thrombosis was lower in Group 4 than in Groups 1 and 2.

CONCLUSION: Several factors were identified that may potentially be associated with thrombosis in BS. However, the cut-offs used for defining the normal level for these factors, time of blood collection (during acute or chronic stage of thrombosis, use of anticoagulants) and the type of thrombosis (arterial, venous, or cerebral sinus) were not uniform across the studies. Studies investigating these factors together, in a large number of patients, and together with appropriate controls are needed to confirm these results.

TEMPORAL ARTERY BIOPSY POSITIVITY RATES VARY MORE BETWEEN SIMILAR HOSPITALS THAN BY LENGTH, WITH PARTICULAR VARIATION BETWEEN GEOGRAPHIC REGIONS

C. McMaster, V. Yang, R. Malik, E. Norman, C. Fraser, B. Sutu, A. Sammel, D. Liew, A. Austin Health, Rheumatology, Heidelberg, Australia; A. Austin Health, Clinical Pharmacology and Therapeutics, Heidelberg, Australia; University of Melbourne, The Centre for Digital Transformation of Health, Parkville, Australia; Sydney Eye Hospital, Sydney Eye Hospital, Sydney, Australia; UNSW Sydney, Port Macquarie Clinical School, Sydney, Australia; University of Newcastle, Medicine and Public Health, Callaghan, Australia; Prince Of Wales Hospital, Rheumatology, Randwick, Australia; Save Sight Institute, Save Sight Institute, Sydney, Australia; The Royal Melbourne Hospital, Rheumatology, Parkville, Australia; UNSW Sydney, Prince of Wales Clinical School, Sydney, Australia; University of Melbourne, Medicine, Parkville, Australia

BACKGROUND: Clinical practice surrounding giant cell arteritis (GCA) diagnosis, including the use of temporal artery biopsy (TAB) where appropriate, needs to be consistently accurate to minimise both GCA-related end-organ damage and unnecessary glucocorticosteroid toxicity in all patients. Despite this imperative, the delivery of such clinical care, which can be measured by diagnostic investigation performance characteristics such as TAB positivity rates, varies substantially between different hospitals as it is traditionally reliant on unstructured clinical intuition. While clinical care practices possibly might be more consistent between neighbouring hospitals given they frequently exchange medical staff and use common teaching sources, these factors are less likely to be applicable when comparing hospitals in different geographical regions within a country, even though educational standards, online information resources, and access to clinical care should be consistent. It therefore stands to reason that variation of diagnostic practice might be greater between geographically distant hospitals.

OBJECTIVES: To compare clinical practice surrounding GCA diagnosis, using TAB positivity rates, between similar hospitals in the same city and a geographically distant city in a different region, to understand the contribution of geographic separation to variation in practice.

METHODS: TAB histopathological reports were reviewed at three tertiary referral hospital centres: two with neighbouring catchments in the same city, and one in a different city in a neighbouring geographical region in the same country. All three had similar resourcing and catchment demographics during the study period, and none used formal clinical risk stratification scores for GCA pre-test probability. Characteristics including age, sex, biopsy laterality, biopsy length, and hospital were captured, in addition to key histopathological features. Multivariable logistic regression with site-varying intercept was performed, using cubic splines for biopsy length to account for the non-linearity observed.

RESULTS: TAB reports from 708 patients were captured between the three hospitals in two geographical regions. All three sites had a median age of 74 years, had 67-69% of patients being female, and reported median biopsy length between 1.2-2.0cm (Table 1). Despite these similarities, they reported positivity rates varying widely (16% and 24% in Region 1, 29% in Region 2). Apart from age, hospital site was the strongest contributing factor to TAB positivity, with length having little effect outside the very extreme high end and 90% of patients had a biopsy length <4.8cm (Figure 1). For these patients, hospital site differentiated TAB positivity across all biopsy lengths, with Region 2 reporting the highest TAB positivity odds ratio of 2.36 (95% CI: 1.37-4.19).

CONCLUSION: Hospital site contributes more greatly to variation in GCA diagnosis clinical practice than demographics or other clinical features do, with particular variation between geographical regions. As part of clinical care standards, using
Inclusion of Raynaud's Phenomenon in Giant Cell Arteritis, Possibly Associated with Large Vessel Giant Cell Arteritis.

B. Stijlhuus1, M. Sandovic1, A. Eman Abdulle2, K. van der Geest3, E. Brouwer4, D. J. Mulder5
1University Medical Center Groningen, Internal Medicine, Groningen, Netherlands; 2University Medical Center Groningen, Rheumatology, Groningen, Netherlands

Background: Large Vessel Giant Cell Arteritis (LV GCA) can cause significant narrowing of the subclavian and axillary arteries, either by inflammation or remodelling, which reduces blood pressure in the arms. Also, Raynaud's phenomenon (RP) has been observed in GCA patients.

Objectives: This study aims to investigate the presence of Raynaud's phenomenon in patients with GCA.

Methods: Patients diagnosed with GCA were given a validated questionnaire (CSQ) on symptoms fitting RP, divided into the different phases of RP (white, non, warm, and rush) in patients with GCA.

Results: 30 GCA patients were included, with a mean age of 68.6 ± 6.5 years, when diagnosed. 76.7% were female. Of the 30 GCA patients, 12 (40%) reported monophasic discoloration. Of these 12 GCA patients, 2 (6.7%) patients reported bi- or triphasic discoloration. Of the 12 GCA patients with at least monophasic discoloration, 6 patients reported a new onset RP (<1 year of diagnosis). Imaging data of these 6 patients showed severe Large Vessel GCA (with subclavian and axillary involvement) in all of these patients, without displaying cranial GCA. Of these 6 patients, 1 was examined with US, 3 with PET-CT, and 2 had both US and a PET-CT. 3 patients reported that the RP complaints, disappeared during treatment of the GCA, 3 still had complaints. Interestingly all these 3 patients had stenosis of either the subclavian, the axillary, or both.

Conclusion: We found an increased prevalence of monophasic Raynaud's phenomenon in GCA patients that is 3.7 times higher, when compared to a local background population.

Conclusion: The constitutional syndrome was always present in LVGCA but it is also very common in subtypes with cranial involvement. The ischaemic syndrome occurs preferentially in groups with cranial vessel involvement, but not exclusively. The thickening of the arterial wall of the cranial arteries shows no difference between CGA and MGCA; and the same occurs in the large vessels between the LVGCA and the MGCA. Serious adverse effects due to ischaemia showed a similar risk regardless of whether it was CGA or MGCA.

GIANT CELL ARTERITIS. PREVALENCE OF EXTRACRANIAL LARGE VESSEL VASCULITIS DIAGNOSED WITH 18-FDG POSITRON EMISSION TOMOGRAPHY.

V. Aldazabal1, M. J. García Velloso2, J. A. Richter Echevarría3. Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain; 2.Clinica Universidad de Navarra, Nuclear Medicine, Pamplona, Spain

Background: The prevalence of extracranial involvement in giant cell arteritis (GCA) is unknown although there are series that has published prevalences of 20–65% depending on the technique used (1).

Objectives: To assess the prevalence of extracranial large vessel vasculitis (LVV) in GCA diagnosed by positron emission tomography (PET) and to describe clinical and radiological features.

Methods: Prospective and descriptive study of newly diagnosed GCA patients who underwent PET between july 2020 and october 2021. 1990 ACR criteria (2) and/or physician criteria was used to classified patients as having GCA. Clinical and radiological features were described. All patients should not be taken any other immunosupressant drug but glucocorticoids (GCs).

Results: Fourteen consecutive patients were diagnosed as GCA. Eight patients were female with a median age of 64.4 years. All patients but one underwent temporal artery biopsy (TAB) with a positive result in 54%, PET was positive in 85.7% patients. The median dose of GCs when PET was done was 31.4 (0-45) mg/day and the median delay in PET performance was 8 days (0-22). The 2 patients with negative PET had positive TAB. Proximal thoracic aorta involvement was observed in all patients with positive PET. Late PET images were taken in 6 patients with a median dose of GCs of 43,3 mg/day and median delay of 11,3 days with positive result in all of them (Table 1).

Table 1. PET late images

</tbody>
</table>

Conclusion: Despite the high dose of GCs and the delay in PET performance, in our serie PET has diagnosed LVV in 85.7% of GCA patients. PET within 3 days after start GCs, has been useful to diagnose extracranial involvement in GCA (3). In our series the prevalence of extracranial involvement diagnosed by PET in GCA has been higher than others published until now (2). Further patients are needed to confirm these data.

HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH RITUXIMAB-INDUCED REMISSION OF ANCA-ASSOCIATED VASCULITIS: REGISTRY-BASED COHORT STUDIES

V. Babak1, M. Suprun1, T. Beketov1. 1VA Nasonova Research Institute of Rheumatology, Department of Systemic Sclerosis, Moscow, Russian Federation

Background: Survival rate in ANCA-associated vasculitis (AAV) has significantly improved due to anti-B cell therapy with rituximab (RTX). The main issue now appears to be the management of comorbidities and the improvement of quality of life.

Objectives: Based on a prospective analysis of the single centre registry of AAV patients (pts) treated with RTX, to study the impact of sustained remission on health-related quality of life using Short-Form 36 (SF-36).

Methods: Health-related quality of life was assessed in 70 AAV pts: 35 (50%) with granulomatosis with polyangiitis (GPA), 24 (34.3%) - microscopic polyangiitis (MPA) and 11 (15.7%) - eosinophilic granulomatosis with polyangiitis (EGPA). The mean age was 49.7 ± 15.7 years, 53% women. The median total dose of RTX was 4.3 ± 2.5g. As a rule, a reduced dose of RTX 500 mg was used for repeated courses. Mean duration of RTX therapy 46.8 ± 29.4 months. Remission of AAV was defined as a Birmingham Vasculitis Activity Score = 0 regardless of prednisone treatment or dosage. All pts were in remission.

Results: In 70 patients the average indicators of physical functioning: MPA 62.5 (47.5, 78.8), GPA 75 (55, 92.5), EGPA 60 (45, 775); social functioning: MPA 25 (0, 56.3), GPA 50 (25, 100), EGPA 50 (12.5, 82.5), physical health component: MPA 416 (315, 44.8), GPA 43.7 (36.7, 52.5), EGPA 38.7 (33.8, 45). There were no significant differences between men and women within the GPA, MPA, and EGPA groups. There were also no differences between different age groups. When comparing the EGPA group with GPA or MPA, no significant differences were found. At the same time, in patients with GPA, the indicators of physical functioning (p=0.015, w= 3.92) and the physical component of health (p=0.012, w= 4.028) were significantly lower than in patients with GPA.

Conclusion: RTX maintenance allows to achieve a good quality of life in AAV pts. SF-36 summary measures were significantly higher in GPA pts compared with MPA. Further research is required to analyze the effect of AAV phenotype and complications on health-related quality of life.

VASCULAR INFECTION IN BEHÇET’S DISEASE

I. Chaabene1, S. Tahri1, M. Kechida1, S. Daada1, S. Hammami1, R. Kili1, I. Khochtali1. 1Fattouma Boungiba University Hospital, Internal Medicine and Endocrinology department, MONASTIR, Tunisia

Background: Behçet’s disease (BD) is a multisystemic inflammatory vasculitis, which can affect all types and sizes of blood vessels. It diagnosis is based on a multitude of classification criteria, which include vascular complications associated to this vasculitis.

Objectives: In this study, we reported the main characteristics of vascular involvement in patients with BD.

Methods: In total, 243 patients with BD were, retrospectively, collected in the Internal Medicine Department over 18 years.

Results: Vascular involvement was present in 72 patients (29.6%), whose 57 men and 15 women. The mean age was 52.9 years (range: 5-56 years). It revealed the disease in 26.3% of cases. Venous involvement was predominant, found in 68% of patients. Venous thrombosis interested the upper limbs (51%), the lower limbs (38.7%), the pulmonary veins (18.3%), the inferior vena cava (12.2%) and the cerebral veins in 1 patient. Superficial venous thrombosis was present in 20.8% of cases. Arterial involvement was present in 11% of patients. It included pulmonary artery aneurysms in 8 cases and occlusion of the central retinal artery in one patient. The other associated systemic manifestations were: skin and mucous membrane disorders (100%), joint involvement (34.7%), ocular (29.2%), neurological (27.8%) and cardiac involvement in 7 patients. Treatment was based on long term curative anticoagulation (70%), corticosteroid therapy (50%) and immunosuppressive treatment in 21% of cases. Embolization was performed in two patients with good results.

Conclusion: Our study illustrates the frequency and the polymorphism of vascular involvement in BD.

TIME OF DIAGNOSIS AND INITIATION OF TREATMENT OF GIANT CELL ARTERITIS (GCA) ACCORDING TO CLINICAL PHENOTYPE AND REFERRAL ORIGIN

M. López I Gómez1, P. Moya2, I. Castellví3, H. Corominas3. 1Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain; 2Hospital de la Santa Cruz i Pau, Rheumatology Service Systemic Autoimmune Diseases Unit Functional Unit of Aortic Pathology, Barcelona, Spain; 3Hospital de la Santa Cruz i Pau, Rheumatology Service Systemic Autoimmune Diseases Unit, Barcelona, Spain
Background: Giant cell arteritis (GCA) presents two phenotypic patterns: cranial and extracranial. Cranial manifestations are relatively easier to recognize and to diagnose, however since the extracranial are more insidious and less known, it may lead to a delay in diagnosis and in treatment. The main treatment are glucocorticoids (GC) at high doses followed by a descending pattern. The time between the begin of the symptoms and the start of the treatment with GC it's of vital importance in the prognosis of the disease.

Objectives: The present AUDIT describes our cohort's clinical features, the time from symptom onset to rheumatology visit and diagnosis of GCA, as well as the differences in time according to the service originating the referral.

Methods: Audit retrospective, descriptive study of patients diagnosed with GCA by the CGA 1990 criteria. All patients diagnosed with GCA from 2011 to 2021, in a single hospital center and referred to the Rheumatology Service were included. Patients were classified as: cranial phenotype, extracranial or mixed. Demographic and clinical variables and complementary examinations were collected. As well as the time from the first symptom until the patients are referred and diagnosed.

Results: Seventy patients were included in the study. Fifty-one patients (72.9%) were female, their clinical features are shown in Table 1. Twelve of them (17.39%) had a cranial phenotype, sixteen (23.18%) an extracranial phenotype and forty-one (60.42%) a mixed one. Extracranial phenotype patients showed to be younger at the time of the diagnoses than the other groups. Cranial phenotype patients had a lower increase of the acute phase reactants than the younger at the time of the diagnoses than the other groups. Cranial phenotype, extracranial and mixed respectively. 75.7% of the patients received treatment extracranial and mixed respectively. The median of time from patient referral to rheumatology are 9.34, 12.74 and 5.87 weeks in the cranial, extracranial and mixed respectively. 75.7% of the patients received treatment and extracranial. Cranial manifestations are relatively easier to recognize and to diagnose, however since the extracranial are more insidious and less known, it may lead to a delay in diagnosis and in treatment. The main treatment are glucocorticoids (GC) at high doses followed by a descending pattern. The time between the begin of the symptoms and the start of the treatment with GC it's of vital importance in the prognosis of the disease.

Patient referral were made from: Emergency room/ Internal Medicine hospitalization (30%, 21 patients), Primary Care (21.4%, 15 patients), Internal Medicine outpatient clinic (15.7%, 11 patients), Neurology (8.6%, 13 patients) and other specialties outpatient clinic (cardiology, vascular surgery, ophthalmology, hematology and gastroenterology). The median of the time from the first symptom until the patients are diagnosed are 12.9, 13.97 and 7.91 weeks in the cranial, extracranial and mixed respectively. The median of time from the first symptom until the patient referral to rheumatology are 9.34, 12.74 and 5.87 weeks in the cranial, extracranial and mixed respectively. The median of time from patient referral to rheumatology are 3.73, 5.59 and 3.43 weeks in the cranial, extracranial and mixed respectively. 75.7% of the patients received treatment with glucocorticoids before being referral to rheumatology.

Conclusion: In our cohort, most of the patients with CGA had a mixed phenotype. The patient referral to rheumatology is made mainly from the emergency room, internal medicine hospitalization and primary care. Patients with mixed phenotype are diagnosed faster than the ones with an exclusively extracranial phenotype. The time between the first symptom and the referral to rheumatology is still long.

GAPS IN THE DIAGNOSIS OF TAKAYASU ARTERITIS: A ROMANIAN COHORT

A. Predoiu1,2, C. Pamfil1,2, I. Felea1, L. Muntean1,2, M. M. Tamas1,2, I. Filipescu1,2, S. P. Simon1,2, S. Rednic1,2. 1Emergency County Hospital, Rheumatology Clinic, Cluj-Napoca, Romania; 2Iuliu Hatieganu University of Medicine and Pharmacy, Dept. of Rheumatology Cluj-Napoca, Romania

Background: The diagnosis of Takayasu arteritis still represents a big challenge, even though the disease was first described more than 100 years ago. Proof of that is the continuing effort to develop criteria with high specificity and sensitivity.1

Objectives: The aim of the study was to describe the clinical and paraclinical aspects of the disease at the time of diagnosis. Additionally, we wanted to evaluate the damage score in view of the diagnosis delay.

Methods: We retrospectively studied the clinical chart of 17 consecutive patients admitted to the Rheumatology Clinic of Emergency County Hospital from Cluj-Napoca, Romania between 2003 and 2021. Results: There was just one patient with Takayasu arteritis (0.05%). The average age at the time of diagnosis was 37.5 years old. The average delay in the diagnosis was 33 months, while the biggest delay was of 240 months. The diagnosis was made by rheumatologists in 58% of the cases, while 29% by cardiologists and 11.7% by internal medicine specialists. The most frequent symptoms were limb claudication (64.7%), fatigue (52.9%) and headache (52.9%). Vascular bruises were found in most of the patients at the time of diagnosis (70.3%), as well as blood pressure and pulse difference between arms (52.9%). Unobtainable blood pressure was seen in 5 patients (29.4%). There was a discrepancy in 3 patients (17.6%) between inflammatory markers and inflammation in the vessels’ walls, as confirmed by imaging techniques (angioMRI or angioCT). Most of the patients were classified as type V arteritis (35%), followed by type IV (18%), type I (17%), type IIA, respectively type IIB (12% each) and type IIb (8%). Stenosis of the involved arteries occurred 4.3 times more than aneurysm formation. Eight patients required vascular interventions at the time of diagnosis – four were treated by balloon angioplasty and six by stent placing. The average TADS (Takayasu Arteritis Damage Score) was 1.5 and it was not associated with delay in diagnosis (p=0.05).

Conclusion: Takayasu arteritis is a disease with heterogenous and nonspecific symptoms. For those reasons the delay in diagnosis is usually long, the treatment is started late and damage appears early in the course of the disease. This is reflected by the high amounts of vascular procedures needed at the time of diagnosis. We need better diagnostic criteria and specific monitoring scores.

AB0610

DEVELOPMENT OF MALIGNANCY IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

M. Bektaş1, B. Inci1, S. Zaraï2, U.A. Gilselen3, E. Üz2, B. F. Agargun2, D. Y. Güney1, Y. Akay1, B. Akın-Esen1, A. Ustündag1, M. İnci1, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey; 3Istanbul Faculty of Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey

Background: Patients (pts) with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) reported to have an increased risk of malignancy compared to general population [1]. However, studies on risk factors for the development of malignancy in AAV pts are limited.

Objectives: We aimed to evaluate the frequency, clinical features and associated factors of malignancy in pts with AAV.

Methods: In this study, we retrospectively evaluated 287 pts with AAV. Thin-ty-three pts with EGPA and 14 pts with missing data were excluded. ANCA test was analysed based on immunofluorescence and/or Elisa results and divided into two serological groups; c-ANCA/PRES3 (positive) and p-ANCA/MPO”.

Results: Data of 240 pts (54.6 % female) were analysed. Mean age of diagnosis was 55.6±14 (range; 17-88) years and mean disease duration was 67.5 (range; 3-255) months. Of those pts, 175 (73 %) had GPA and 65 (27 %) had MPA. ANCA results were available in 230 pts; 123 were c-ANCA/PRES3 (53.5 %), 85 were p-ANCA/MPO” (37 %) and 22 were ANCA negative (ANCA) (9.5 %). Kidney (75.8 %) and lower respiratory tract (74.4 %) were the most common organs involved but they did not differ according to presence of malignancy (9.4 % vs 5.1 %; p=0.14) and 9.4 % vs 5.1 %; p=0.14 respectively). Therapy with immunosuppressives was observed in 20 pts (8.3 %); eleven c-ANCA/PRES3, three p-ANCA/MPO” and two ANCA negative pts. Lung and thyroid papillary cancer in three; bladder, prostate, breast and kidney in two; adrenal gland, oral squamous cavity and sarcoma of retinoperitoneum in one patient, hematological (three myelodysplastic syndrome, one chronic lymphocytic leukemia and one lymphoma) in five pts. Six pts (30 %) had previously concomitant AAV diagnosis. Development of malignancy did not differ according to age, gender, diagnosis, seropositivity (ANCA” vs ANCA) and ANCA subgroups (Table 1). There was no association between malignancy and cumulative dose of cyclophosphamide (CYC) or history of smoking (p=0.96 and p=0.2, respectively).

In univariate analysis, malignancy was associated with presence of cardiovascular disease (CVD) (p=0.003 OR 11.7) and mortality (p=0.04 OR 4.6), higher BVAS score at baseline (p=0.049) and higher VDI score (p=0.02). Significant association was observed between malignancy with CVD (95 % CI 2.2-83 OR 13.4±0.005) and mortality (p=0.044 95 % CI 1.03-8.5 OR 2.95) in multivariate analysis.

In survival analysis, mortality rate was higher in pts who had malignancy compared to those without (Figure 1, p=0.035).

Figure 1. Survival analysis of mortality according to presence of malignancy in pts with AAV. Log-Rank: p=0.035

Conclusion: Significant proportion of pts with AAV developed malignancy in our cohort. Development of malignancy was associated with CVD, higher baseline BVAS and VDI scores. Our study also revealed lower survival rate in patients who developed malignancy. Further studies are needed to clarify risk factors for malignancy in patients with AAV.

AB0611 NEUTROPHIL EXTRACELLULAR TRAPS AND INTERSTITIAL LUNG DISEASE IN ANCA-ASSOCIATED VASCULITIS: A SCOPING REVIEW

E. Conticini1, M. D’alessandro2, L. Bergantini2, P. Falsen2, P. Camelli3, E. Bargagli2, L. Cantarini, B. Frediani1 on behalf of Siena Vasculitis Study Group. 1University of Siena, Rheumatology Unit; Siena, Italy; 2University of Siena, Respiratory Diseases and Lung Transplantation Unit, Siena, Italy

Background: Deregulated neutrophil extracellular traps (NET) formation is implicated in various diseases, including ANCA-associated vasculitis and pulmonary fibrosis (PF). Lung involvement is frequent in AAV, and interstitial lung diseases (ILD) are strongly related to MPO-ANCA positivity and mainly reported in microscopic polyangiitis. The association between AAV and ILD is a strong indicator of poor prognosis and limited survival. Neutrophils, ANCA and NET interplay in PF development in AAV.

Objectives: This study aimed to review the literature concerning the implications of NET in lung fibrogenesis focused specifically on AAV associated with ILD, and the potential of NET as a therapeutic marker.

Methods: Through scoping review methodology, we used a descriptive thematic analysis to understand the pathogenic role of NETs in patients with AAV and pulmonary fibrosis and their further role as a therapeutic marker of this disease.

Results: Quality assessment of articles was evaluated through SANRA methodology (Table 1). The implications of NET in the pathogenesis of AAV and ILD (Figure 1), as well as an association between these two diseases, have been identified, but the underlying pathophysiological mechanisms are still unknown. Pharmacological or genetic inhibition of NET release reduces disease severity in multiple inflammatory disease models, indicating that NETs are potential therapeutic targets. In this regard, despite the lack of clinical data, we may hypothesize that an optimal management of AAV-ILD patients would require not only B-cells targeted therapy, but also NETs inhibition.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular.479

Figure 1. The role of NET in interstitial lung disease associated with ANCA-associated vasculitis

Conclusion: Preliminary findings seem to display a lack of efficacy of traditional immunosuppressants, such as Rituximab, in this subset of patients, while to date no patients suffering from a definite ILD was enrolled in clinical trials. Further insights would be provided by their employment, as a combination treatment, in the common clinical practice. Although we can imagine that inhibition of NETs in patients with AAV-ILD could reduce severity and mortality, we still lack a scientific basis that could improve our understanding of the disease from a molecular point of view.

AB0612 CHRONIC PANCREATITIS DUE TO SYSTEMIC AUTOIMMUNE AND BACTERIAL SEPTIC VASCUITIS IN RHEUMATOID ARTHRITIS – A HYPOTHETICAL PATHWAY OF CHRONIC PANCREATITIS IN POST-COVID 19 CONDITION

A. Apáthy¹, M. Bély², ¹St. Margaret Clinic, Department of Rheumatology, Budapest, Hungary; ²Hospital of the Order of the Brothers of Saint John of God in Budapest, Department of Pathology, Budapest, Hungary

Background: The etiology of pancreatitis is heterogeneous; it may be due to chronic excessive alcohol use, gallstones, medications, infections, autoimmune diseases, metabolic disorders, trauma, congenital malformations etc.

Objectives: The aim of this study has been to describe a hypothetic pathway of chronic pancreatitis in post-Covid 19 condition, based on the role of autoimmune and bacterial septic vasculitis in the pathogenesis of chronic pancreatitis (ChrP) in rheumatoid arthritis (RA).

Methods: At the National Institute of Rheumatology 9475 patients died between 1969 and 1992; among them 161 with RA and all of them were autopsied. RA was confirmed clinically according to the criteria of the ACR. Tissue samples of pancreas were available for histologic evaluation in 111 patients. Pancreatitis and vasculitis were determined and characterized histologically [1,2]. The possible role of autoimmune vasculitis and bacterial septic vasculitis in the pathogenesis of ChrP was analyzed by Pearson’s chi-squared ($\chi^2$) test.

Results: ChrP – characterized by diffuse and/or focal fibrosis and atrophy – was present in 10 (9.01 %) of 111 patients. Systemic vasculitis complicated RA in 28 (25.23 %) of 111 patients. Twenty-five (89.3 %) of 28 systemic vasculitis proved to be of autoimmune origin. Autoimmune vasculitis involved the pancreatic blood vessels (pAV) in 8 (32.0 %) of these 25 patients. Non-specific (n=37), fibrinoid necrotic (n=14), and granulomatous type (n=5) of pAV were detected side by side in the same histologic section, involving pancreatic arteries of different sizes. The veins and venules were not involved; pAV was not associated with chronic pancreatitis. The relationship between pAV and ChrP was inverse with a negative colliquation coefficient (c=-1.0, $\chi^2$=0.0801, p <0.7772 – NS). Three (10.7 %) of 28 systemic vasculitis cases proved to be of septic (bacterial) origin. Pancreatic blood vessels (pSV) were involved in 2 (66.7 %) of these 3 patients. Granulomatous vasculitis was not seen with pSV, and the veins and venules were also spared. Non-specific (n=9), fibrinoid necrotic (n=2) vasculitis involving different size of pancreatic arteries were associated with chronic pancreatitis. The relationship between pAV and ChrP was significant (c=0.2308, $\chi^2$=6.3201, p <0.012).

Conclusion: Chronic pancreatitis is characterized clinically by abdominal pain and diarrhea, which are common in post-Covid 19 condition [2]. The strong and significant correlation between pSV and ChrP indicates that subclinical or manifest bacterial septic processes may play a role in the pathogenesis of ChrP. Hypothetically a similar pathway is plausible in post-Covid 19 chronic pancreatitis due to viral infection and vasculitis, analogous to bacterial septic vasculitis. Systemic vasculitis of autoimmune origin involving blood vessels of the pancreas may cause a special multifocal relapsing lipo-necrotic pancreatitis. Hypothetically a similar pathway is plausible in post-Covid 19 chronic pancreatitis. The relationship between pAV and ChrP was significant ($\chi^2$=6.3201, p <0.012).

AB0613 VASCULAR EVENTS AND ASSOCIATED FACTORS IN ANCA-ASSOCIATED VASCULITIS: ANALYSIS OF 237 PATIENTS WITH LONG-TERM FOLLOW-UP

M. Bektaş¹, B. Ince¹, S. Zarabi², U.A. Gulseren³, E. Ük³, Y. Yalçınkaya¹, B. Artım-Esen¹, A. Gül¹, M. İnanç¹, ¹Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; ²Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey

Background: Patients with ANCA-associated vasculitis (AAV) reported to have an increased risk of vascular events (VE) compared to general population [1]. However, studies on risk factors for the development of VE in AAV patients (pts) are limited.

Objectives: In our study we aimed to evaluate the frequency, risk factors and mortality risk of VE pts with AAV.

Methods: In this study we retrospectively evaluated 287 pts with AAV. Patients with EGPA (n=33) were not included and 17 pts were excluded due to missing data. Arterial vascular events (a-VE) were recorded as myocardial infarction, unstable angina pectoris, peripheral artery disease, need for revascularization and cerebrovascular accident. Deep venous thrombosis and pulmonary embolism were recorded as venous thrombotic events (VTE). History of a-VE and/or VTE were grouped as all VE. ANCA test results were analyzed based on IFA and/or Elisa results and divided into two serological groups; c-ANCA/PR3 (positive) and p-ANCA/MPO-.

Results: Data of 237 pts (46 % male) was analyzed. Mean age at diagnosis was 55.6±14 (range; 17-88) years and median disease duration was 77 (range; 3-255) months. Of those pts, 173 (73 %) had GPA and 64 (27 %) had MPA. ANCA results were available in 230 pts; 122 were c-ANCA/PR3 (53.5 %), 85 were p-ANCA/MPO (37 %) and 22 were ANCA negative (ANCA-) (9.5 %). The most common organ involvements revealed that, one in five pts with AAV developed VE after diagnosis. The risk of VE was significantly higher in males, pts with c-ANCA/PR3 and pts with higher baseline CRP levels, GFR<50 mL/min, history of smoking, severe infection, higher VDI score. Development of a-VE was higher in pts with males, advanced age, pts with c-ANCA/PR3, history of smoking, higher VDI score, GFR<50 mL/min. Additionally, mortality was increased in pts with VE and a-VE. In multivariate analysis; while VE were associated with smoking [95 % CI: 1.7-21; OR:6], c-ANCA/PR3 positivity [95 % CI: 1.15-92; OR:10.3] and higher VDI score [95 % CI:1.002-1.08; OR:1.04], higher VDI score [95 % CI:1.3-2; OR:1.6] and c-ANCA/PR3* [95 % CI:1.06-8.6; OR:3.8]; Development of VTE was associated with higher VDI score (p=0.001) in univariate and multivariate analysis [95 % CI: 1.2-1.8; OR:1.5]. In survival analysis, mortality rate was significantly higher in pts who had a history of VE (Log-Rank: p=0.04).

Conclusion: Our observational data of more than 5 years of follow-up revealed that, one in five pts with AAV developed VE after diagnosis. The risk of VE was significantly higher in c-ANCA/PR3 pts, smokers and pts with high VDI scores. Older age increased the risk of a-VE. Mortality was increased in AAV pts with VE after diagnosis. Additional studies needed to delineate the mechanism of VE in AAV and precautions should be undertaken to avoid morbidity and mortality.

Disclosure of Interests: None declared.

**LATE-ONSET NEUTROPENIA AFTER RITUXIMAB TREATMENT IN PATIENTS WITH ANCA-ASSOCIATED SYSTEMIC VASCULITIS: A RETROSPECTIVE ANALYSIS OF A REGISTER-BASED PATIENT COHORT**

I. Popov1, V. Babaki, T. Beketova1,2, V. A. Nasonova Research Institute of Rheumatology, Laboratory of systemic sclerosis, Moscow, Russian Federation; 2Central Clinical Hospital of the General Management Department of the President of Russian Federation, Rheumatology, moscow, Russian Federation

**Background:** Anti-B-cell therapy with rituximab (RTX) plays an important role in the induction and maintenance therapy of ANCA-associated vasculitides (AAV). Late-onset neutropenia (LON) has been reported following RTX therapy.

**Objectives:** Based on a retrospective analysis of the register of AAV patients (pts) treated with RTX, to study the incidence and outcomes of LON.

**Methods:** 140 AAV pts (median age 52 (20-83) years, 57% women) were treated with RTX between 2009 to 2021: 63 with granulomatosis with polyangiitis (GPA), 45 microscopic polyangiitis (MPA), 24 eosinophilic granulomatosis with polyangiitis (EGPA), and 8 unclassified AAV. The median total dose of RTX was 3.5 (0.5-45) g. As a rule, single 500-mg infusions were used with an interval of 4-6 months for retreatment courses. The duration of follow-up exceeded 6 months after the first dose of RTX. Regular pt monitoring every 3 months included estimation of absolute neutrophil count (ANC). LON was defined as unexplained neutropenia occurring 3 weeks after the last RTX infusion.

**Results:** LON I-IV grade was noted in 16 (11.4%) AAV pts: 6 GPA, 4 MPA, 4 EGPA, and 2 unclassified AAV. In 7 out of 16 cases (43.7%) LON developed after the first course of RTX. Neutropenia grade I was observed in 3 pts (ANC 1.68-2.0x109/L), 21-5.5 months after the last RTX infusion), grade II - in 4 patients (1.1-1.5x109/L, 3-9 months after RTX). Neutropenia grade II resolved independently, without adverse reactions. LON grade IV was noted in 9 pts (0.06-0.3x109/L, 1-11 months after RTX), 3 of them received leukopoeiae-stimulating drugs with normalization of ANC. In one EGPA pt febrile LON grade IV developed twice (in 2017, 11 months after RTX; in 2019, 4 months after RTX and complicated by uterine bleeding). Fatal outcome occurred in 5 out of 16 cases (31.2%): 1 MPA, 3 GPA, and 1 EGPA. In 3 fatal cases LON was complicated by pneumonia (in 2 with septic shock), in one with acute myocardial infarction and another one with progression of chronic renal failure. According to our registry, the total mortality among 140 AAV pts receiving RTX was 11.4%, while 5 of 16 fatal cases (31.2%) had LON grade IV. Three of the 5 death were noted in 2013-2014, which attributed to the use of cyclophosphamide >2 gms before RTX, as well as insufficient awareness of the risk of LON, which contributed to the delay in control of a full blood count, untimely diagnosis of LON and late treatment. At the beginning, the original drug Methotrex was used, while after 2014 biosimilar Acelbita was mainly used. The disadvantages of this study: the lack of information about the ANC in 4 cases with COVID-19 and fatal outcome.

**Conclusion:** LON after RTX therapy can develop in 11.4% of AAV pts, which exceeds the data for rheumatoid arthritis (1.3-3%) [1,2]. Our register data are lower than the rate of LON in AAV, presented by D. Tesfa et al. (23%) [1], which could be attributed by the use of low-dose RTX for retreatment courses. LON accounts for a significant part in the structure of deaths of AAV pts (31.2%). It needs to careful monitoring of ANC in pts receiving RTX and awareness of both pts and physicians about the risk of LON.

**CLINICAL IMPACT OF CERULOPLASMIN LEVELS AT ANCA-ASSOCIATED VASCULITIS DIAGNOSIS**

L. Camboulive1, F. Grandhomme1, N. M. Silva2, H. de Boysson1, A. Dumont1, A. Nguyen1, D. Mariotte1, K. Khyo1, T. Llobede1, A. Aubia3, S. Deshayes1,2

1University Of Caen Normandie Hospital Center, Basse Normandie, Caen, France

**Background:** Myeloperoxidase (MPO) plays a major role in loss of immunological tolerance leading to tissue destruction in ANCA-associated vasculitides (AAV). Ceruloplasmin is a protein with antiproteinase and antioxidant properties that inhibits MPO activity. Whether serum level of ceruloplasmin at AAV diagnosis has an impact is unknown.

**Objectives:** The objective of this study was to evaluate the prognostic impact of serum level of ceruloplasmin at diagnosis in patients with granulomatosis with polyangiitis or microscopic polyangiitis.

**Methods:** We conducted a retrospective unincentric study at Caen University Hospital, involving consecutive adult patients with granulomatosis with polyangiitis or microscopic polyangiitis between 2010 and 2021 who had available serum at diagnosis. Data was collected using the health records.

**Results:** Ceruloplasmin was measured by standardized nephelometry (normal values: 0.15 – 0.50 g/L). Patients in each subgroup (whole cohort, microscopic polyangiitis and anti-MPO patients) were divided into two groups based on the median serum level of ceruloplasmin. We estimated survival using the Kaplan-Meier survival curve, and between-group differences were evaluated by the log-rank test. The study was approved by the local ethics committee of Caen University Hospital (n° 1947).

**Results:** Ninety-two patients were included, 46 (50%) granulomatosis with polyangiitis (41 anti-proteinase 3 and 5 anti-MPO) and 46 (50%) microscopic polyangiitis (45 anti-MPO and 1 anti-proteinase 3). The median level of ceruloplasmin was 0.44 g/L. No significant differences in the clinical presentation were observed between patients in the two groups (p>0.05). We observed 9 (19.6%) deaths in the low ceruloplasmin group and 5 (10.9%) in the high ceruloplasmin group (p=0.3). Two patients relapsed occurred in 10/46 patients (22%) and 11/46 patients (24%) (p=1), renal failure leading to dialysis and/or renal transplant in 6/46 patients (13%) and 8/46 patients (17%) (p=0.77), respectively. No significant difference in survival was found (p=0.07). The same analyses were performed.
between the low and the high ceruloplasmin group with the microscopic polyangiitis subgroup (n=46), and no significant differences were found (p=0.05). However, within the anti-MPO subgroup (n=50), the survival was worse in the low ceruloplasmin group (p=0.03).

Conclusion: In anti-MPO AAV patients, serum level of ceruloplasmin at diagnosis seems to be associated with a significant impact on survival.

MYELOPEROXIDASE (MPO) POSITIVE EXTRACELLULAR VESICLES (EVS) EXPRESSING COMPLEMENT SPLIT PRODUCTS IN ANTI-MPO CYTOLYPIC ANTIBODY (ANCA)-ASSOCIATED VASCULITIS (AAV)

A. Juto1,2, N. Mahmoud Hourani Soutari1, A. Taxiarhis1, V. Malmstrom1, A. Bruchfeld1,3,4, A. Antovic1,2, I. Gunnarsson1,2,3, Karolinska Institutet, Department of Medicine, Division of Rheumatology, Solna, Stockholm, Sweden; 2Karolinska University Hospital, Rheumatology, Stockholm, Sweden; 3Karolinska Institutet, Department of Molecular Medicine and Surgery, Solna, Stockholm, Sweden; 4Linkoping University, Department of Health, Medicine and Caring Sciences, Linkoping, Sweden; 5Karolinska Institutet, CLINTEC, Stockholm, Sweden; 6Karolinska University Hospital, Department of Renal Medicine, Stockholm, Sweden

Background: Complement activation has a critical role for the development of antineutrophil cytoplasmatic antibody (ANCA)-associated vasculitis (AAV). We have previously shown increased expression of complement split products C3a and C5a on myeloperoxidase (MPO) positive EVs (MPO +EVs) in plasma from AAV patients with kidney involvement compared to the patients with non-renal disease and the EV-levels correlated with disease activity (1). Objectives: To investigate the expression of a larger set of complement components on circulating MPO +EVs in relation to disease activity and kidney involvement in patients with AAV.

Methods: Eighty-nine patients with AAV and 23 healthy controls were included. The concentration of MPO +EVs expressing complement split products C3a, C4d, C5a, terminal complement complex-TCC (C5b-9) or complement factor B (CFB) were analyzed from citrate plasma by flow cytometry. The assessment of vasculitis disease activity was performed using the Birmingham Vasculitis Activity Score (BVAS).

Results: In the AAV group, there were 47 males (52.8%), the median age was 56 years and 33 (37.1%) patients were anti-MPO-positive and 54 (60.7%) were anti-PR3-positive. Two patients were positive for both antibodies. Median disease duration for patients with active AAV (BVAS>0; n=81) was 4 days and for patients in remission (BVAS 0; n=8) 1259 days. 64% had kidney involvement (n=52). Highly active AAV (BVAS ≥12) was noted in 62 patients, of whom 49 patients had kidney involvement. Active disease (0-BVAS≤12) was seen in 19 patients. AAV patients had significantly higher levels of MPO +, MPO+C3a+, MPO +C4d+ and MPO +TCC+ EVs compared with patients without (p<0.001). Patients in remission had higher levels of MPO +, MPO+C4d+ and MPO +TCC+ EVs compared to healthy controls (all p<0.001). There was a significant difference in levels of MPO + (p=0.02), MPO+C3a + (p<0.001), MPO+C4d+ (p<0.001) and MPO +TCC+ EVs (p<0.001) in patients with kidney involvement compared with patients without (n=29) (Figure 1). For patients with BVAS>0 there was a weak correlation between MPO +, MPO+C3a+, MPO+C4d+, MPO +TCC+ EVs and BVAS.

Conclusion: Levels of EVs expressing complement split products were generally increased in AAV patients and patients with kidney involvement had higher levels of total MPO +EVs exposing C3a, C4d or TCC compared with patients without suggesting a role in kidney AAV pathogenesis. Patients with sclerotic kidney histotype had higher levels of MPO +EVs compared with focal and mixed subgroups pointing to that activation of the classical complement pathway may be of importance in several forms of kidney AAV.

HIGH PREVALENCE OF OSTEOPOROSIS AND FRAGILITY FRAC TURES IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS: A CROSS-SECTIONAL STUDY

P. Delvino1, S. Monti1, G. P. Grieco2, E. Bozzalla Cassione2, G. Franchi1, L. Bogliolo1, C. Montecucco1, 1IRCCS Policlinico San Matteo Foundation, University of Pavia, Rheumatology, Pavia, Italy; 2University of Pavia, School of Medicine and Surgery, Pavia, Italy

Background: The advent of effective immunosuppressive treatments significantly improved the prognosis of ANCA-associated vasculitides (AAV), which have become chronic relapsing diseases. Patients with inflammatory rheumatic disorders are particularly prone to reduced bone mineral density (BMD) and fragility fractures (FF), due to chronic glucocorticoid therapy, immunosuppressant-induced hypogonadism, systemic inflammation, functional disability and comorbidities. At present, there is paucity of data concerning the risk of osteoporosis and FF in AAV.

Methods: Patients diagnosed with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA), according to ACR criteria and/or Chapel Hill definitions and regularly followed-up in our vasculitis center were included. BMD was measured by dual-energy X-ray absorptiometry (DEXA) of the proximal femur and lumbar spine, between March 2016 and September 2021. Osteoporosis was defined by a T-score below −2.5 SD, whereas osteopenia was defined by a T-score between −1.2.5 SD, according to the World Health Organization criteria. Vertebreal fractures were assessed by X-ray of the dorso-lumbar spine. Data on previous osteoporotic hip fractures were collected.

Results: Sixty-two consecutive patients were included (59.7% female, mean age at time of DEXA 61.8±10.5 years, disease duration 97.0±76.1 months). Sixteen (25.8%), 8 (12.9%) and 38 patients (61.3%) were affected by GPA, MPA and EGPA, respectively. BMD findings indicating osteoporosis and osteopenia, at either the lumbar spine and/or the proximal femur, were observed in 15 (24.2%) and 39 patients (62.9%), respectively, whilst only 8 patients (12.9%) had normal BMD values at both sites. Fifteen patients (24.2%) reported 51 major FF (50 vertebral fractures, 1 hip fracture) during follow-up, with multiple major FF being recorded in 10 patients (16.1%). Osteoporosis, at least at one site, was frequent not only in post-menopausal women (19.4%), but also in 6 males (24%), 3 pre-menopausal women (50%) and 3 patients under 50 years of age (37.5%), respectively (Figure 1). Similarly, major FF occurred in 4 males (16.7%), 1 pre-menopausal female (16.7%) and 1 patient under 50 years of age (12.5%), respectively (Figure 1). Patients with osteoporosis presented a lower body mass index (BMI) (23.1±4.1 vs 25.9±4.4, P=0.03) and a higher prevalence of major FF (53.3% vs 14.9%, P=0.003) compared to patients without osteoporosis. Compared to patients without major FF, those affected by major FF were older (68.8±1.8 vs 59.9±4.3 years, P=0.003), had a higher disease duration (146.9±78.8 vs 81.8±68.9 months, P=0.003) and presented with lower proximal femur BMD values (0.657±0.122 vs 0.761±0.127 g/cm², P=0.007) and proximal femur T-score (-2.0±0.9 vs -1.4±0.8 SD). Notably, 7 out 15 patients with FF (46.7%) did not exhibit BMD findings of osteoporosis. Other variables, including sex, disease subtype, ANCA status, chronic kidney disease or treatment with cyclophosphamide were not related to bone loss or FF.

Disclosure of Interests: None declared
Conclusion: Patients with AAV are particularly susceptible to BMD loss and fractures, with osteoporosis and major FF being reported in about a quarter of patients. Short-term and long-term monitoring for reduced BMD and FF is warranted in all patients with AAV, including male patients, premenopausal females and those under 50 years of age.

Disclosure of Interests: None declared

AB0618

TOLERABILITY AND SAFETY OF 23-VALENT POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH SYSTEMIC VASculITIS, PRELIMINARY RESULTS

G. Tarasova 1, O. Egorgova 1, T. Reshetnyak 1,2, B. Belovy 3,1, V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; 2Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccination Prevention, Moscow, Russian Federation

Background: Systemic vasculitis (VS) is a severe autoimmune disease requiring active immunosuppressive therapy. The probability of infectious complications in these patients is very high. Immunization with the 23-valent polysaccharide pneumococcal vaccine (PPV-23) is required to reduce the risk of severe respiratory infections in this group of patients.

Objectives: The aim of the study was to study the tolerability and safety of PPV-23 in patients with VS.

Methods: At this stage, the study included 13 patients with VS: 10 with vasculitis associated with antineutrophil cytoplasmic antibodies (ANCA) (AAV), 5 with granulomatosis with polyangiitis (GPA), 4 with eosinophilic granulomatosis with polyangiitis (EGPA), 2 - with microscopic polyangiitis (MPA), 1 - with polyarteritis nodosa, 1 - with Takayasu’s arteritis (AT); of which 10 women, 3 men, aged 22 to 76 years. 9 (69%) patients were older than 50 years. Remission of the disease was observed in 1 patient (EGPA), in 3 - low disease activity, in 9 - active vasculitis (9 with AAV, BVAS from 4 to 13). All patients received glucocorticoids (GC): 2 - 55-60 mg/day, 9 - 10-20 mg/day, 2-2.5-5 mg/day; 5 - bDMARD: 4 - rituximab (RTM), 1 - NF inhibitors; 11 - cytostatics (CS): 5 - methotrexate (MTX). Two patients were on induction therapy (GC 55-60 mg + CPh) with a plan to switch to RTM. Only 1 patient with EGPA received HA as monotherapy. The 23-valent polysaccharide pneumococcal vaccine was administrated subcutaneously in 0.5 ml (1 dose). The follow-up period was 1-6 months.

During the visits, standard clinical and laboratory tests and the determination of antibodies to S.pneumoniae were carried out.

Results: Vaccination tolerance was good in all patients. One (7.7%) patient with EGPA (in remission) had a mild local reaction (pain at the injection site) within 1 day. Another 1 (7.7%) patient with severe concomitant pathology (EGPA + multiple sclerosis) had a general reaction in the form of a transient increase in weakness in the lower extremities for up to 5 days (this symptom was manifestation of polyneuropathy, persisted earlier, and to a greater extent was associated with multiple sclerosis than with EGPA). Vaccinal reactions were completely reversible and did not require additional prescriptions. During the follow-up period, no deterioration in the course of VS was recorded, and no new autoimmune phenomena, both laboratory and clinical, were noted in any of them. 7 (53.8%) patients (all 5 with GPA, 2 with EGPA) had ENT lesions (destructive rhinosinusitis (5), sinusitis (2)) with frequent exacerbations. 1 patient with GPA reported a significant improvement in the course of the ENT organs (no exacerbations of rhinosinusitis, disappearance of nasal discharge for 5 months). In the remaining 6 patients, the condition also remained stable, no progression of sinusitis was noted during the observation period (1-4 months). No infections of the lower respiratory tract were registered during the observation period.

Conclusion: 1. All patients had a high risk of infectious complications: combined immunosuppressive therapy (92% of patients), age over 50 years (69% of patients), severe lesion of ENT organs (53.8% of patients). 2. The tolerance of PPV-23 vaccination was good. 3. There was no deterioration in the course of VS.

RATIONAL AND DESIGN OF THE 52-WEEK, RANDOMIZED, PHASE 3, HEAD-TO-HEAD MANDARA STUDY TO EVALUATE THE EFFICACY AND SAFETY OF BENRALIZUMAB, A HUMANIZED, ANTI-INTERLEUKIN-5 RECEPTOR A MONOCLONAL ANTIBODY IN REFRACTORY OR RELAPSING EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS

M. Wechsler 1,2, P.A. Merke 2, 3, N. Makulova 4, C. Baldi 2, 5, R. Katial 6, U. M. Martin 7, E.R. Rubbertson 8, A. J. Ito 9, J. Castells 2, 3, L. Bösingess Sjö 10, E. A. Duncan 11, R. Furie 12, A. J. G. Weersink 13, 1AstraZeneca, Data Science & AI, Gaithersburg, United States of America; 2University of Pennsylvania, Division of Rheumatology, Philadelphia, United States of America; 3AstraZeneca, Late-stage development, Respiratory & Immunology, Gothenburg, Sweden; 4AstraZeneca, Late-stage development, Respiratory & Immunology, Durham, United States of America; 5AstraZeneca, Late-stage development, Respiratory & Immunology, Gothersburg, United States of America; 6AstraZeneca, Data Science & AI, Galthersburg, United States of America; 7AstraZeneca, Early Respiratory & Immunology, Cambridge, United Kingdom; 8AstraZeneca, Biopharmaceuticals Medical, Gaithersburg, United States of America

Background: Eosinophilic granulomatosis with polyangiitis (EGPA), formerly Churg-Strauss syndrome, is a rare, potentially organ- and life-threatening disease characterized by systemic eosinophilia, airway disease, and multi-system small-vessel vasculitis. Management of EGPA generally focuses on reducing active inflammation using corticosteroids and immunosuppressants, both of which are associated with serious adverse effects and incomplete disease control. High blood eosinophil (bEOS) levels are a central component of the pathophysiology of EGPA, and studies have shown that bEOS-reducing therapies, such as mepolizumab, are effective in some patients with EGPA. Benralizumab is a humanized, afucosylated, anti-interleukin-5 receptor α monoclonal antibody that induces direct, rapid, and near complete depletion of eosinophils through antibody-dependent cell-mediated cytotoxicity. Eosinophil depletion by benralizumab is effective in eosinophilic asthma, corticosteroid-dependent asthma, and has shown promise in a small phase 2 trial in hypereosinophilic syndrome, which has overlapping organ systems involvement and similar clinical features to EGPA. Collectively, the evidence from these indications supports examination of the efficacy of benralizumab as an eosinophil-depleting therapy in patients with EGPA.

Objectives: The phase 3, head-to-head MANDARA (NCT04157348) study will evaluate the efficacy and safety of benralizumab versus mepolizumab in adults with relapsing or refractory EGPA.

Methods: This randomized (1:1), multicentre, double-blind (DB), active-controlled study is enrolling adults with a diagnosis of EGPA, defined as a history of asthma and eosinophilia together with ≥2 additional clinical features, a history of relapsing or refractory disease, and maintained on a stable prednisolone/predosinone dose ≥7.5 mg/day for ≥4 weeks prior to baseline. Patients will receive either benralizumab 30 mg or mepolizumab 300 mg every 4 weeks over the 52-week DB study period. Patients who complete the DB treatment period will be eligible to continue into an optional open-label extension, during which all patients will receive benralizumab (Figure 1). The primary endpoint is the proportion of patients who achieve EGPA remission, defined as a Birmingham Vasculitis Activity Score (BVAS)=0 and predosinone dose ≤4 mg/day, at both Week 36 and 48 of the DB period, and it will assess non-inferiority (NI) between benralizumab and mepolizumab. Secondary endpoints include duration of remission, time to first EGPA relapse, annualized relapse rate, average daily predosinone dose between Weeks 48 to 52, and the proportion of patients who achieve and maintain remission from Week 24 through the end of the DB period. Other endpoints include safety, symptoms, health-related quality of life, healthcare utilization due to EGPA, and tolerability. The trial also includes a non-interventional patient interview sub-study, which will collect data related to patients’ EGPA personal experience and perceived impact on study treatment, and a mechanistic sub-study, which will explore the pharmacodynamic response and mechanism of action of benralizumab compared to mepolizumab.
Patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) need anticoagulants?  

G. Tarasov 1, O. Egorova 2, A. Kolomeychuk 1, T. Reshetnyak 1,2

OBJECTIVES: The study included 45 patients with AAV (15 - with granulomatosis with polyangiitis (GPA), 15 - microscopic polyangiitis (MPA), and 15 - eosinophilic granulomatosis with polyangiitis (EGPA), aged 23 to 73 years. Duration of the disease was in 6 patients had <12 months, in 20 - 1-5 years, in 6 - >10 years. High AAV activity were registered in 13 patients, 21 - moderate activity (BVAS < 5), 2 - remission (BVAS 0-1 points). The VDI damage index in 5 patients was 0, in 30 – from 1 to 3, in 10 – > 3 points. Glucocorticoids (GC) received 44% of patients with a dose of 5-20 mg/day, 16% >20-40 mg/day, 4% >40-60 mg/day, AC 23 (51%) of 45 patients took AC. Blood clotting parameters were measured in 40 patients, including activated partial thromboplastin time (APTT), thrombin time (TT), soluble fibrin monomer complexes (SFMC), the number of platelets, 22 of them received AC.

RESULTS: Thrombosis in the past history was registered in 8 (18%) patients, 7 of them continued taking AC. 16 patients received AC without thrombosis for prevention events. Patients with GPA received AK more often than patients with MPA and EGPA (73%, 40%, 40%, respectively).

AC were prescribed in 51% of patients. AC were prescribed to 51% of patients receiving GC at a dose of up to 20 mg/day and 44% of patients with a dose of GC above 20 mg/day. The appointment of anticoagulants was associated with the duration of the disease. With a disease duration of up to 1 year, AK was prescribed in 33% of cases, with a duration of > 10 years - in 67% of cases. 59% of patients received AC with BVAS>5, 38% of patients - with BVAS<5. The following AC were prescribed to patients: direct oral AC (DOAC) in 16 (69.6%), unfractionated heparin (UH) - 1, low molecular weight heparins (LMWH) -6, LMWH (46%) and DOAC (54%) were prescribed with the same frequency to patients with BVAS<5, while DOAC (87.5%) prevailed in patients with BVAS>5. Hemorrhagic complications during the follow-up period were not registered in any case. Prolongation of APTT, TT was not significantly noted against the background of AC. I. There was a shortening of APTT in 14 (35%) of 40 patients, TT in 1 (2.5%). An increase in the level of fibrinogen was recorded in 11 (27.5%) patients and in all 40 patients there was an increase in SFMC, which was an indicator of thrombotic readiness. Increased fibrinogen levels were associated with AAV activity (3 out of 11 had a history of thrombosis).

CONCLUSION: Our retrospective analysis revealed that 51% of patients with AAV received AC, they were more often prescribed with active AAV and more often with GPA. Our retrospective analysis showed that 51% of patients with AAV received AC, more often with active AAV and more often with GPA.

Background: Granulomatosis with polyangiitis (GPA) is the second most frequent vasculitis in Germany with an annual incidence of 34 per million and a prevalence of 210 per million [1]. GPA is characterized by its chronic course, frequent relapses, significant overall morbidity and mortality, a substantial socio-economic impact. Multorgan involvement affecting the respiratory tract, kidney, and other organs is common. Limited variants also occur [2]. So far, prospective long-term observational data on the disease course of GPA are missing in Germany. Therefore, the Joint Vasculitis Registry in German-speaking countries (GeVAS) has been established to follow the course of patients recently diagnosed with vasculitis or a change of their treatment due to a relapse (inception cohort). The GeVAS registry allows long-term follow-up of a substantial cohort of vasculitis patients in a multicenter setting.

Objectives: To present the first data on the follow-up of newly diagnosed and relapsing GPA enrolled in the GeVAS registry.

Methods: GeVAS is a prospective, web-based, multicenter, clinician-driven registry for the documentation of organ manifestations, damage, long-term outcomes, and therapy regimens in various types of vasculitis. Recruitment started in June 2019. By January 2022, 17 centers in Germany were initiated and started enrolling patients. Meanwhile, more than 350 patients have been documented in the registry. Sites in Austria and the German-speaking cantons of Switzerland will be integrated soon [3].

Results: By mid-October 2021, the participating centers included 113 patients with GPA. The majority of patients were PR3-ANCA positive and affected by general symptoms, ENT, lung, renal, and neurological involvement. Patients commonly received cyclophosphamide or rituximab in combination with glucocorticoids for the induction of remission. Fewer patients received methotrexate or other immunosuppressants. Patient characteristics and therapy are summarized in Table 1.

Conclusion: Here, we present the first interim analysis of the GeVAS registry. Clinical manifestations of GPA reported herein show less frequent renal involvement in comparison with a recent report from another European registry (POLVAS) and an UK study [4, 5]. This is potentially related to the predominance of recruiting rheumatology centers thus far. By contrast, respiratory tract involvement is more frequent and PR3-ANCA less common in Japan [5]. Further data are prospectively documented and a follow up analysis is in progress.

the use of cyclophosphamide which has an undesirable safety profile, limiting its use in patients. AZA has shown to be effective at maintenance, however rates of relapse on AZA are high.

Rituximab (RTX) is a biologic with a high specificity to B cells. Its mechanism of action (B cell apoptosis) may mean that it can be used for both the induction and maintenance of remission, with a superior long-term safety profile.

**Objectives:** To conduct a systematic review of literature to determine the efficacy of rituximab as a remission inducing and maintaining agent.

**Methods:** A systematic review of literature was conducted by searching PubMed and Cochrane library with the search phrase “rituximab AND ANCA-associated vasculitis.” The following criteria was then applied: randomised controlled trial (RCT) in the English language. Only original papers were accepted if it pertained to RTX for either induction or maintenance of remission.

**Results:** 1008 papers were initially identified and after the search strategy was applied 9 RCTs were analysed. The RAVE trial compared RTX to CYC in 197 patients with AAV in a double-blind double-dummy trial. The result of the RAVE trial indicated that RTX was as effective as CYC at maintaining remission. The RITUXVAS trial, which was partially blinded and had a sample of 44 patients also came to the same conclusion. Both the RAVE and RITUXVAS trials also showed that an initial dose of RTX was as effective as continuous immunosuppression over the trial length.

Further RCTs were published from the RAVE and RITUXVAS studies including a follow up of patients from the RITUXVAS trial at 24 months which showed no increased rates of relapse or adverse events between the groups. The RAVE study also showed that RTX was effective to be used on multiple occasions to induce remission irrespective of the initial remission inducing agent. The MAINRITSAN1 study was a non-blinded randomised trial which compared RTX with azathioprine for maintenance in 115 patients with AAV. The results of this trial showed that RTX was superior than AZA at maintenance with only 5% on RTX compared with 29% on AZA relapsing. The long-term follow up of patients in the trial, showed that at 60 months, patients who received RTX were less likely to have relapsed.

The MAINRITSAN2 trial indicated that there was no difference between a fixed vs tailored RTX dose, meaning that a lower tailored dose was as effective as a higher fixed dose. The MAINRITSAN 3 paper was a double-blind trial that indicated that biannual RTX for maintenance was superior than placebo at maintaining remission.

Conclusions: RTX is as effective as CYC at inducing remission, with both the RAVE and RITUXVAS trials sharing similar conclusions. Currently the research indicates that an initial dose of RTX can maintain remission at similar rates as continuous AZA, however its superiority is yet to be determined. The MAINRITSAN 1 trial was unblinded in its protocol with the data indicating it drastically overestimated the efficacy of both RTX and AZA. Therefore, more research is needed to validate the claim that RTX is superior than AZA at maintenance.

**AB0624 PATIENTS WITH VASCULITIS HAVE A HIGH PREVALENCE OF CORONARY MICROVASCULAR DYSFUNCTION**

1Massachusetts General Hospital; 2Harvard Medical School; 3Division of Rheumatology, Allergy, and Immunology; Boston, United States of America; 4Brigham and Women's Hospital; 5Harvard Medical School, Heart and Vascular Center; 6Division of Cardiovascular Medicine, Department of Medicine, Boston, United States of America; 7Brigham and Women's Hospital, Department of Radiology, Boston, United States of America; 8Massachusetts General Hospital; 9Division of Rheumatology, Allergy, and Immunology, Boston, United States of America; 10Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America; 11Brigham and Women's Hospital, Heart and Vascular Center; 12Division of Cardiovascular Medicine, Department of Medicine, and 13Division of Radiology, Boston, United States of America

**Background:** Vasculitides are a heterogenous group of diseases characterized by intense vessel wall inflammation, endothelial injury, and systemic inflammation. Several vasculitides are associated with high risk of cardiovascular (CV) disease, an important source of morbidity and mortality in this population. This excess CV risk is attributed both to a high burden of traditional risk factors and to inflammation, but this remains poorly studied. Indeed, inflammation is a known risk factor for CV disease and implicated in coronary microvascular dysfunction (CMD) which may precede obstructive coronary artery disease (CAD).

**Objectives:** We sought to assess whether vasculitis is associated with CMD in the absence of obstructive CAD.

**Methods:** We retrospectively identified subjects with systemic vasculitis who underwent symptom prompted rest/stress myocardial perfusion PET. Patients with an abnormal myocardial perfusion study (summed stress score ≥3) or LVEF<40% were excluded. Controls were identified from the same population and matched on age, gender and cardiovascular risk factors (CAD, hypertension, dyslipidemia, diabetes mellitus, and obesity). Coronary flow reserve (CFR), was calculated as the ratio of myocardial blood flow (ml/min/g) at peak stress compared to rest. CMD was defined as CFR <2.

**Results:** We studied 26 vasculitis cases and 66 matched controls. The most common vasculitides were giant cell arteritis (38%), ANCA-associated vasculitis (31%), and Takayasu atherosclerosis (12%). Median (IQR) time between diagnosis and PET was 6.5 (2.9, 14.2) years. Seven (27%) cases had active vasculitis at the time of PET. Cases and controls were well-matched on age, sex, and CV risk factors (Table 1). Despite a similar prevalence of CV risk factors, coronary flow reserve (reflected by CMD) was abnormal in 38% of vasculitis cases compared to 15% of controls (p=0.004). The mean [SD] CFR was 19% lower in vasculitis cases vs controls (2.11 [0.5] versus 2.6 [0.7], p=0.003).

**Table 1.** The prevalence of coronary microvascular dysfunction in patients with systemic vasculitis without obstructive coronary artery disease

Conclusion: Patients with systemic vasculitis, even in the absence of obstructive CAD, have a high prevalence of CMD compared with non-vasculitis patients. These differences were observed despite matching cases and controls on traditional CV risk factors, highlighting the importance of other factors, such as inflammation and vasculitis treatments on CMD and CV disease in this population. CMD is a known independent risk factor for CV mortality. Future prospective studies are needed to understand the relationship between vasculitis, systemic inflammation, and CMD.

Methods: This retrospective cohort study enrolled microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA), and eosinophilic granulomatosis with polyangiitis patients at 25 sites in Japan who had a first or severe relapse between January 2017 and June 2020. Of these, patients with MPA or GPA who had a positive renal lesion score on BVAS (version 3) at baseline, or vasculitis findings on renal biopsy, CMV assayed by 48 weeks of treatment, were included. Patients were divided into two groups based on the presence or absence of a positive CMV antigen test during the remission induction phase (0–48 weeks of treatment). Outcomes were the rate of change in estimated glomerular filtration rate (eGFR) at 48 weeks after initiation of treatment in both groups, as determined by (eGFR at 48 weeks - eGFR at the initiation of treatment)/eGFR at the initiation of treatment; where lower values were associated with worse renal function. General linear models adjusted for age, gender, presence of diabetes or chronic kidney disease, and the use of rituximab or cyclophosphamide were generated.

Results: A total of 387 patients had CMV antigen measured during ANCA-associated vasculitis treatment, of which 164 had renal involvement and eGFR measured at 48 weeks. Seventy-seven (47.0%) were male and the median age was 75 years (range 69–80 years). CMV reactivation was observed in 44 patients (26.8%). The beta coefficient of multiple regression analysis with CMV positive as 1 and negative as 0 was 0.08 (95% confidence interval -0.13 to 0.29) (p = 0.47). The rate of change in eGFR was higher in the CMV positive group, but not statistically significantly.

Conclusion: Contrary to our hypothesis, renal prognoses tended to be better when CMV reactivation was observed. The patients in the CMV reactivation group may have been treated more aggressively, and some patients with a poor prognosis who were not followed up for 48 weeks dropped out. Further research investigating the adjustment of treatment methods is required.

AB0626
PREVALENCE OF FRAILTY IN AN INTERNET-BASED COHORT WITH A SELF-REPORTED DIAGNOSIS OF VASCULITIS – THE VASCSTRONG STUDY

S. E. Sattui1, J. Stadler2, C. Burroughs3, K. Larsson4, P. A. Merkel5, R. Spiera6, 1University of Pittsburgh, Medicine, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America; 2Vasculitis Foundation, NA, Kansas City, United States of America; 3University of South Florida, Health Informatics Institute, Tampa, United States of America; 4PennMedicine, Medicine, Division of Rheumatology, Philadelphia, United States of America; 5Hospital for Special Surgery Main Hospital, Medicine, Division of Rheumatology, New York, United States of America

Background: Frailty is a syndrome characterized by an increased vulnerability to stressors and is associated with disability and early mortality. Frailty may be accelerated in patients with vasculitis. The prevalence of frailty in patients with vasculitis remains unexplored.

Objectives: To describe the prevalence of self-reported frailty in patients with vasculitis.

Methods: VascStrong is a longitudinal study utilizing the Vasculitis Patient-Powered Research Network (VPPRN), an internet-based prospective longitudinal cohort. Data elements collected included type of vasculitis, demographic, and use of medications. Frailty was measured by the FRAIL scale, a self-report measure which queries on 5 domains: 1. Fatigue, 2. Resistance (inability to climb 10 stairs), 3. Ambulation (inability to walk several blocks), 4. Illnesses (≥5/11 comorbidities), and 5. Loss of weight (≥5% weight loss in the last year). Patients were classified as robust, pre-frail, and frail based on 0, 1-2, or ≥3 criteria, respectively.

Results: The survey collected information from October 8, 2021-January 15, 2022. For this preliminary analysis, 228 responses were included. Clinical characteristics and study data are outlined in Table 1. Prevalence of robustness, pre-frailty, and frailty was 28.5%, 47.8%, and 23.7%, respectively. The majority of patients with each form of vasculitis were rated as frail or pre-frail. Among the individual FRAIL domains, fatigue and loss of weight were the most frequent (48.7% and 42.5%, respectively) while illnesses, was the least common (3.5%). When compared to robust patients, frail and pre-frail patients were younger, more frequently female, more likely to be obese and reported more frequent use of glucocorticoids. Patients with urticarial vasculitis and Takayasu’s arteritis were more commonly pre-frail or frail, compared to patients with other types of vasculitis.
Table 1. Characteristics for overall cohort and by frailty classification

Data presented as n (%), unless specified otherwise. *Other diagnosis: Behçet’s disease, primary amylgitial central nervous system, cryoglobulinic vasculitis, IgA vasculitis, polycystic nodule, and other/suspected diagnosis* Based on World Health Organization Body Mass Index categories

Conclusion: Self-reported frailty or pre-frailty is prevalent in the majority of patients with multiple forms of vasculitis. Future analysis will focus on identifying factors associated with frailty in patients with vasculitis, to allow earlier identification and prevention in this population at high-risk for frailty.

Background: The ANCA-associated vasculitis patient-reported outcome (AAV-PRO) questionnaire is a 29-item disease-specific PRO measure for AAV [1]. The Italian version of the AAV-PRO questionnaire (AAV-PRO_ita) was translated in collaboration with Oxford and Bristol University (UK) and was preliminarily tested on a single-center Italian cohort [2].

Objectives: The main objective of this multicentric study was to assess the internal consistency, feasibility, and reliability of the AAV-PRO_ita in a large cohort of Italian AAV patients. The secondary objective was to investigate the clinical characteristics of AAV patients associated with AAV-PRO_ita domains.

Methods: The AAV-PRO_ita is described with the following disease domains: (1) organ-specific and systemic symptoms and signs (SSS); (2) physical function (PF); (3) social and emotional impact (SEI). In this study, Italian-speaking AAV patients were recruited from Italian Centres (N=13) with a large experience in the diagnosis and treatment of systemic vasculitis, belonging to the Vascultis Study Group of the Italian Society of Rheumatology. Inclusion criteria were: a confirmed diagnosis of GPA (SSS >0.3, p-value<0.001). The total time to complete the questionnaire was one hour. The AAV-PRO_ita was completed by 229 AAV-patients (56.3% women) with a median age of 61 (IQR 51-72) were recruited and completed the questionnaires. The subtype of AAV was mainly GPA (131, 57.2%), followed by EGPA (58, 25.3%), and MPA (40, 17.5%). Median BIASV3 at baseline was 0 (IQR 0-3), whereas the median BIASV3 at the onset of disease was 14 (IQR 9-20). Participants had a median duration of disease of 67 (IQR 24-126) months. Patients who experienced at least one relapse, one hospitalization, and one severe infection were 40.2%, 53.3%, and 24%, respectively. 83% of the patients were on immunosuppressant therapy and 71.6% were still receiving glucocorticoids.

AAV-PRO_ita questionnaire had good internal consistency (Cronbach's Alpha 0.81-0.93) and good test-retest reliability (ICCs range 0.93-0.96). Item response rates were high overall (maximum 0.87% missing data), supporting the feasibility of the questionnaire.

Concerning the domains of the questionnaire, female AAV patients scored higher (i.e. worse) in all three domains, especially in the SEI domain (p-value<0.001). Older participants (>65 years) scored higher in the PF domain (p-value<0.03) in all three times of self-completions of the questionnaire. The ongoing treatment (i.e. worse) in all three domains, especially in the SEI domain (p-value<0.001). Concerning the domains of the questionnaire, female AAV patients scored higher (i.e. worse) in all three domains, especially in the SEI domain (p-value<0.001).

EVALUATION OF INTERNAL CONSISTENCY, FEASIBILITY, AND RELIABILITY OF THE ITALIAN VERSION OF ANCA-ASSOCIATED VASCULITIS PATIENT-REPORTED OUTCOME (AAV-PRO_ita) QUESTIONNAIRE: PRELIMINARY RESULTS FROM A MULTICENTER STUDY ON A LARGE COHORT OF ITALIAN PATIENTS

AB0627 SYSTEMATIC LITERATURE REVIEW INFORMING THE 2022 UPDATE OF THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF ANCA-ASSOCIATED VASCULITIS: FOCUS ON DIAGNOSTIC AND FOLLOW-UP PROCEDURES

B. Sanchez-Alamo1, J. Schirmer1, S. Monti3, B. Hellmich, D. Jayne5, Lund University, Skåne University Hospital, Nephrology, Lund, Sweden; 2University
Background: The 2008 and 2016 European Alliance of Associations for Rheumatology (EULAR) recommendations for the management of ANCA-associated vasculitides (AAV)\(^1\)\(^2\) have supported clinicians with recommendations for the accurate diagnosis, monitoring and for the management of the long-term complications of patients with ANCA-associated vasculitides (AAV). Since the publication of the last EULAR guidelines, several high-impact research articles have provided further evidence to improve diagnosis and monitoring of AAV-patients.

Objectives: The aim of this systematic review was collecting evidence supporting the 2022 update of the AAV management recommendations.

Methods: The recommendations were developed based on the 2014 EULAR standardized operating procedures (SOP)\(^3\). Areas of interest were adopted from the 2016 recommendations and updated by identifying additional items through a Delphi exercise. Key questions were framed in the PICO (Population, Intervention, Comparator, Outcome) format. Keywords identifying topics of interest for the diagnosis and follow up were generated based on the PICO questions and then incorporated into a search string. A systematic literature search (SLR) was performed according to the EULAR SOP. PubMed (Medline), Embase and the Cochrane Library databases were searched for articles providing data on the search questions. Abstracts of the annual meetings of EULAR, ACR, ERA-EDTA, ASN, and the Vasculitis and ANCA Workshops were also screened, but restricted to randomized controlled clinical trials (RCTs).

After deduplication, publications were first sorted by title and abstract and then full text review was done for eligible articles. The data were extracted from included articles and grouped according to the PICO questions. Data extraction results were collected in evidence tables. The Cochrane revised tool for assessing risk of bias for RCTs (RoB2), ROBINS-1 for observational studies, QUADAS II for diagnostic accuracy studies and AMSTAR II for meta-analyses were used for bias assessment. Evidence was categorized based on the GRADE system as per EULAR SOP\(^3\).

Results: Based on the results of the Delphi, 3 topics related to diagnosis and follow-up were identified that were transformed into PICO questions: the impact of diagnostic biopsies and positive ANCA testing to support the clinical diagnosis of AAV and the impact of clinical parameters and biomarkers on disease-related outcomes and treatment-related adverse events (Table 1). Other items that received lower scores in the Delphi exercise were added in the format of subquestions (e.g. diagnostic imaging). Based on these research questions, search strings for the SLR were created. The SLR was still ongoing at the time this abstract has been written and results of the SLR will be presented at the meeting.

Table 1. Topics of interest for diagnostic and follow-up testing identified in the Delphi exercise

Conclusion: This SLR identified recent developments affecting key areas of AAV diagnosis and follow-up. The results of this SLR provide systematic evidence to inform the 2022 update of the EULAR recommendations for the management of AAV, which will also be presented at this meeting.

Disclosure of Interests: Beate Schanz-Alamo: None declared, Jan Schirmer: None declared, Sara Monti: None declared, Bernhard Hellmich Speakers bureau: Abbvie, BMS, Chugai, GSK, MSD, Novartis, Pfizer, Roche, Vifor, Consultant of: Boehringer, BMS, Chugai, GSK, InflaRx, Novartis, Roche, Vifor, David Jayne Speakers bureau: Vifor, Consultant of: AstraZeneca, Boehringer, BMS, Chemocentryx, Chugai, GSK, Novartis, Roche, Tokai.

Conclusion: Although the causality cannot be established on current evidence, the COVID-19 vaccine can probably trigger glomerulonephritis associated with ANCA, primarily anti-MPO type. We need a bigger cohort to identify patients predisposed for disease development or relapse after the COVID-19 vaccine.

REFERENCES:

Background: Preventing accrual of organ damage is a major goal in the treatment of Behçet’s Syndrome (BS). The BS Overall Damage Index (BODI) is the first damage assessment tool developed and preliminarily validated for BS.

Objectives: To assess the prevalence, extent, and determinants of organ damage accrual in the BODI validation cohort over 24 months of follow-up.

Methods: Overall, 189 patients from the multicenter BODI cohort underwent a 24 ±3 months follow-up (FU) visit. Demographics, ongoing medication, Behçet’s Disease Current Activity Form (BDCAF) score, Physician (PGA) and Patient Global Assessment (PtGA) of disease activity, disease relapsing (defined by any treatment change due to increased disease activity), and the BODI score were recorded at baseline and follow-up. Patients were classified as new BODI damage accrual was defined as any increase ≥1 in the BODI score between baseline and follow-up visit (∆-BODI). Logistic regression models were built to identify factors associated with BODI damage accrual.

Results: The mean age (standard deviation) at enrolment and the disease duration was 46.2 (12.1) and 10.6 (8.3) years, respectively, and 92/189 (48.7%) patients were males. During 24 months, 36 (19.0%) patients had an increase in the BODI score of at least 1 point (mean increase of 1.7 points). The BODI score was increased from 1.6 (2.1) to 1.9 (2.1), with a mean ∆-BODI of 0.3 (0.8). Overall, 61 new BODI items of damage were recorded (Figure 1); 22 (34%) were steroid-related. Demographics, ongoing therapy, Behçet’s Disease Current Activity Form (BDCAF), Physician (PGA) and Patient Global Assessment (PtGA) of disease activity, disease relapsing, defined by any treatment change due to increased disease activity, and the BODI score were recorded at baseline and follow-up visit (∆-BODI). Logistic regression models were built to identify factors associated with BODI damage accrual.

Conclusions: Despite the relatively high disease duration in the studied cohort, organ damage accrual was recorded in a relevant proportion of patients. BODI proved to capture the damage associated with major determinants such as inadequate control of disease activity and prolonged exposure to glucocorticoids.

Anna, Ferrara, Italy; 10University of Porto, UMIB Abel Salazar Biomedical Sciences Institute, Porto, Portugal

Objectives: To evaluate the impact of BS on the patients’ work activity and productivity.

Methods: A sub-cohort of 148 patients from the original Behçet’s syndrome Overall Damage Index (BODI) Project study was enrolled. The Work Productivity and Activity Impairment: General Health (WPAI:GH) questionnaire was administered. Demographics, disease duration, comorbidity, major organ involvement, ongoing therapy, Behçet’s Disease Current Activity Form (BDCAF), Physician Global Assessment (PGA), Patient Global Assessment (PtGA), and the BODI were recorded. Multiple regression models were built to investigate the independent effect of BS features on WPAI.

Results: Overall, 97 (65.6%) out of 148 patients who completed the WPAI:GH questionnaire resulted working for pay; 22 out of 97 (27.8%) patients reported missing work in the past week due to their health, accounting for a mean (SD) of 34.4% (17.8%) of their working time (absenteeism). The only factor significantly associated with absenteeism in multivariate analysis was the presence of ocular damage, as assessed by the BODI (OR: 0.255, p = 0.027).

Although 93 patients reported that they worked in the previous week, mean 27.3% (30.7%) of their actual work productivity was impaired due to their health problem (presenteeism), with only 37 (38.5%) patients reporting no such loss. Factors associated with work impairment were female gender (β = 0.319, p = 0.001), higher PGA (β = 0.298, p = 0.035), and an increased BODI score in the last 2 years follow-up (β = 0.235, p = 0.022). None of these factors are associated with absenteeism in multivariate analysis as well as the presence of ocular damage, as assessed by the BODI.

Conclusion: Preventing accrual of organ damage is a major goal in the treatment of Behçet’s Syndrome (BS). The BS Overall Damage Index (BODI) is the first damage assessment tool developed and preliminarily validated for BS.

Disclosure of Interests: None declared

### AB0632 INTRACARDIAC THROMBOSIS AND VASCULAR INVOLVEMENT IN BEHÇET’S DISEASE: TWO SIDES OF THE SAME COIN?

S. Chadik1, H. Khiri1, W. Ammour1, M. Maamar1, H. Harmouchi1, T. Tazi Mezalet1, University Mohammed V - Faculty of Medicine and Pharmacy - University Hospital Center Ibn Sina, Internal Medicine, Rabat, Morocco. 2University Mohammed V - Faculty of Medicine and Pharmacy - University Hospital Center Ibn Sina, Internal Medicine and Clinical Hematology, Rabat, Morocco.

#### Background:
Behçet’s disease (BD) is a relapsing vasculitis that can affect vessels of all sizes and kinds. Intracardiac thrombosis (ICT) is a serious complication of the disease, which usually presents associated to vascular lesions. However, its mechanism of constitution in BD remains unclear and the link between these manifestations has yet not been fully clarified.

#### Objectives:
Our first objective is to describe the clinical characteristics, imaging features, therapeutic management and outcome of these patients. And secondly, to shed some light on the relation between this rare condition and the vascular involvement of the disease.

#### Methods:
This monocentric study was conducted in the University Hospital Center Ibn Sina of Rabat (Morocco), and retrospectively included 312 Behçet patients admitted to the Internal Medicine department between 2010 and 2021. Twelve patients with ICT related to BD were enrolled.

#### Results:
Patients were mostly male (90%) with a mean age of 30 years. ICT was the presenting symptom of BD in half of the cases. In the other half, it was detected with a mean of 6.4 years after the disease onset. Six patients had a history of deep vein thrombosis (DVT) related to BD, either as a single episode (n=3), recurrent episodes (n=2), or as DVT associated to pulmonary artery occlusion (n=1). The most frequent symptoms were dyspnea (50%), chest pain (50%), dry cough (40%) and hemoptysis (30%). Four patients had signs of right cardiac failure. Peripheral vascular manifestations were noted in five patients. The other Behçet’s flares simultaneously observed were mucocutaneous (80%), digestive (10%), ocular (10%) and articular (10%). Immunological parameters were raised in all patients with a median ESR of 49 mm/h and CRP of 51 mg/L. On echocardiography, ICT was always related to the right heart, with an extension to the inferior vena cava in half of the cases. Two patients had also the left cavities involved. Multiple thrombi were visualized in three cases. The associated cardiac lesions observed were pericarditis (50%), tricuspid insufficiency (50%), mitral insufficiency (10%), endomyocardial fibrosis (10%) and myocarditis (10%). The right cavities were dilated among five patients. Pulmonary hypertension was found in 60% of the cases. On CT Chest Angiography, 70% of the patients had pulmonary artery thrombosis and 50% of them had pulmonary artery aneurysms. The other vascular lesions detected were Budd Chiari syndrome with mesenteric ischemia (10%), subtotal internal jugular vein obstruction (10%) and cerebral venous sinus thrombosis (10%). All patients were treated with colchicine, glucocorticoids and immunosuppressants. Eleven patients were put under Cyclophosphamide and one under Methotrexate followed by a TNF- alpha inhibitor. Six patients were also on curative anticoagulation. No death or relapse was reported to our knowledge.

### Conclusion:
ICT is a serious complication that usually occurs in the first years of the BD’s onset, among young men with vascular manifestations. We believe that this strong association is highly suggestive that ICT in BD is a direct consequence of the underlying vasculitis.

### AB0633 HEALTH-RELATED QUALITY OF LIFE IN ANCA VASCULITIDES AND RHEUMATOID ARTHRITIS PATIENTS: A CROSS-SECTIONAL COMPARATIVE STUDY

A. Panagiotopoulou1, K. Thomas2, E. Argyriou3, A. Chalkia4, N. Kapsal2, C. Koutsianas5, E. Mavrea6, D. Petras7, D. Bourmpas8, D. Vassilopoulos9, 12nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens School of Medicine, Hippokration General Hospital, Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, Athens, Greece; 24th Department of Medicine, National and Kapodistrian University of Athens School of Medicine, Attikon General Hospital, Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, Athens, Greece; 3Sismanoglio General Hospital, Rheumatology Unit, Athens, Greece; 4Hipppokration General Hospital, Nephrology Department, Athens, Greece

#### Background:
ANCA associated vasculitides (AAVs) are rare, serious forms of vasculitides. There are limited data regarding the quality of life in patients with AAVs compared to other chronic inflammatory diseases.

#### Objectives:
The purpose of this study was to compare the quality of life between patients with AAV and those with a chronic inflammatory arthritis such as rheumatoid arthritis (RA).

#### Methods:
Multicenter, cross-sectional study of AAV and RA patients followed in three tertiary referral centers. Data from 1007 healthy controls served as historic controls. HRQoL was assessed with the Short Form 36 Health Survey (SF-36) which includes physical and mental component summary scores (PCS and MCS). Disease activity was assessed with the Birmingham Vasculitis Activity Score version 3 (BVAS 3, for AAVs) and the DAS28-ESR (for RA) respectively.

#### Results:
66 patients with AAVs (GPA 62%, MPA 29% and EGPA 9%, females 56%, mean age 63.4 years, generalized disease 74%, mean disease duration 6.2 years, remission 73%) and 71 with RA (females 56%, mean age 63.3 years, remission 72%) were included. Both AAV and RA patients had significantly lower PCS and MCS scores compared to healthy controls (p < 0.05) while RA patients had lower PCS and MCS scores compared to AAV patients (p < 0.05). According to disease activity status, there was no difference in the SF-36 scores between those with active (BVAS > 1) and inactive (BVAS < 1) AAV, except for the energy-fatigue component (55.0 ± 21.8 vs. 67.2 ± 20.7, p = 0.038) whereas patients with active RA (DAS28-ESR > 3.2) had lower scores for all SF36 components compared to those with low disease activity (DAS28-ESR < 3.2). Additionally, active RA patients had lower both PCS and MCS scores compared to active AAV patients (p < 0.05). AAV patients with increased damage scores (VDI > 3) had lower PCS score compared to those with less organ damage (VDI < 3), (33.9 ± 10.1 vs. 49.1 ± 10.2, p < 0.001) and (40.5 ± 8.6 vs. 48.2 ± 7.6, p < 0.001 respectively). Compared to patients with AAV, RA patients with increased damage had lower score for the pain component compared to AAV patients (37.7 ± 28.6 vs. 61.2 ± 29.5, p = 0.024).

#### Conclusion:
In general, patients with AAV and RA, demonstrate impaired quality of life compared to healthy controls. In the AAV group, quality of life correlated more with organ damage and less with disease activity whereas in RA patients, quality of life correlated both with disease activity and damage. These data emphasize the need for more efficacious therapies for AAV patients that could prevent chronic organ damage and improve quality of life.

AB0634 VARIABILITY IN PHENOTYPE CLUSTERS IN BEHÇET’S SYNDROME: A SYSTEMATIC REVIEW

B. Macit, K. Akyuz, S. N. Esatoglu, G. Hatemi, 1 Kackar State Hospital, Department of Dermatology, Rize, Turkey; 2 Wayne State University School of Medicine, Department of Internal Medicine, Detroit, United States of America; 3 Istanbul University-Cerrahpaşa, Cerrahpaşa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 4 Istanbul University-Cerrahpaşa, Cerrahpaşa Medical Faculty, Behçet’s Disease Research Center, Istanbul, Turkey.

Background: The presence of distinct clinical phenotypes with clustering of certain organ manifestations is well-recognized Behçet’s syndrome (BS). Differences in demographic features, treatment response, and possibly inflammatory pathways involved in the pathogenesis of different phenotypes have been proposed. However, studies from different BS cohorts have shown variability in the phenotypes that were defined.

Objectives: We aimed to explore the causes of variability in clinical phenotype clustering across different countries and cohorts.

Methods: An electronic search was carried out in PubMed to find articles published in or before November 2021, using the keywords of Behçet, cluster and factor analysis. Two reviewers independently performed a screening of titles, abstracts, and full-texts.

Results: Amongst 496 articles searched, 30 full-texts were assessed, and 10 studies were relevant for data extraction. Ten articles studied 12 different cohorts, 3 from China, 3 from Turkey, 2 from Japan, 1 from South Korea, 1 from Israel, 1 from Greece, and 1 from Italy. 9 out of 10 studies demonstrated clustering of organ manifestations (11 cohorts). There were important differences between the clusters that were identified in these studies (Table 1).

Clusters including skin and mucosa manifestations were present in all cohorts, but the skin and mucosa manifestations that clustered together differed from cohort to cohort. Uveitis stood by itself in some studies, whereas it clustered with vascular and central nervous system (CNS) involvement in some cohorts, and certain skin and mucosa lesions in another. Papulopustular lesions (PPL) and arthritis showed a positive correlation in 4 cohorts whereas these manifestations were negatively correlated in 1 cohort. Moreover, no clusters were identified in 1 study. Potential causes of differences in clusters that we have identified in these studies were: study design (database vs multicenter vs single-centre cohort), statistical analysis method (hierarchical cluster vs factor analysis) patient population (pediatric vs adult vs late onset), setting (dermatology vs rheumatology), diagnostic criteria (ISG vs ICBD), disease duration, definition of organ involvement (such as PPL vs folliculitis), or CNS involvement vs dural sinus thrombosis, ascertainment of manifestations (confirmed gastrointestinal involvement vs any diarrhea, lack of ascertainment in diagnosis of nodular lesions as erythema nodosum vs superficial thrombophlebitis), time interval (manifestations throughout the disease course vs manifestations that were active during the last 3 months), and change in the natural history of BS over decades.

Conclusion: Differences in phenotype clusters may result from differences in study characteristics rather than real geographic or ethnic differences. A large study on a large number of patients from different countries and cohorts may identify new clusters that we have not identified in our studies.

</table>

and recovered with CYC and anti-epileptic drugs. The second patient with blurred vision and headache had cerebral venous sinus thrombosis (CVST) and recovered with anticoagulant therapy. The third patient with muscle weakness died due to spondylodiscitis complicated with aortic pseudoaneurysm.

In 5 patients (26%), neurologic work-up did not lead to an underlying condition. The presenting symptoms of these patients were transient acute visual loss in 2, numbness of extremities in 1, syncope in 1 and vertigo in 1 patient. Neurologic symptoms resolved after high dose GC and RTX in the patient with vertigo. At the onset of neurologic symptoms, 3 patients were using IS therapy including azathioprine, MMF and CYC in 1 patient each. The fourth patient was off treatment. Neurologic symptoms were transient in these patients, and did not recur during our follow-up of 36, 52, 57, and 120 months.

Conclusion: CNS involvement appears to be rare in AAV and non-CNS entities including ocular, orbital and sinonasal involvement and complications such as PRES, CVST and infections may mimic CNS involvement in patients with AAV.

FBM: fibromyalgia; DPR: depression

Conclusion: The recent accrual of organ damage, rather than its extent assessed in a single visit, is associated with impairment of different aspects of health related quality of life, especially those mental related. Such phenomenon is similar to that observed in other systemic rheumatic disease, may be due to coping mechanisms.

**Figure.** Impact of increase of damage accrual of 2 years of follow-up on different domains of the SF-36 questionnaire for measurement of the health related quality of life. PF: physical function, RP: role-physical, BP: body-pain, GH: general health, VT: vitality, SP: social function, RE: role emotional, MH: mental health. *p<0.005 in univariate analysis using Mann Whitney test.

**AB0637 THE ROLE OF ANTIQUINEUTROPHIL CYTOLAPMIC ANTIBODY (ANCA) IN ASSESSMENT OF DISEASE ACTIVITY IN SYSTEMIC VASCULITIS**

I. Petelinets 1, O. Iaremko 2, M. Nahirma 3, Bogomolets National Medical University, The Department of Internal Medicine #3, Kyiv, Ukraine

**Background:** Despite the proven diagnostic significance, the prognostic role of ANCA, in particular for assessing disease activity, remains questionable. Numerous studies have attempted to estimate the role of ANCA monitoring with different results and a lack of consensus on reported outcomes [1].

**Objectives:** To analyze the relationship between ANCA level and clinical or laboratory parameters of disease activity.

Methods: This is a retrospective analysis of 38 patients with ANCA-associated vasculitis (granulomatosis with polyangiitis – 25 patients, microscopic polyangiitis – 6 patients and eosinophilic granulomatosis with polyangiitis – 7 patients) from a single center observed from 2015 till the end of 2020. The diagnosis of ANCA-associated vasculitis was performed according to the ACR 1990 criteria of the Chapel Hill Consensus Conference 2012 nomenclature. The study included 20 women (52.6%) and 18 men (47.4%). The average age of patients was 49 (27-62) years, the mean duration of the disease was 26 (6-120) months. The clinical data, initial Birmingham vasculitis activity score (BVAS), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), ANCA (ELISA test) against proteinase-3 (PR-3) and myeloperoxidase (MPO) were evaluated. Spearman’s correlation analysis was used to investigate the relationship between ANCA levels and ESR, CRP levels, BVAS activity index. The diagnostic value of ANCA in determining the active disease was evaluated by ROC analysis with an estimation of the area under the ROC curve (AUC).

Results: Positivity for MPO-ANCA was observed in 23.7% of patients, and for PR3-ANCA - in 76.3% of patients. The BVAS activity index averaged 16 (IQR-13) points. The mean CRP level was 47.9 (IQR-90.0) mg/L, and the ESR level was 30.1 (IQR-33.5) mm/h. There was a positive correlation between the level of both ANCA and the BVAS index (r = 0.43; 95% CI 0.11-0.66; p <0.01), as well as the level of ESR (r = 0.37; 95% CI 0.05-0.63; p <0.05). No relationship was found between CRP level and ANCA level (r = 0.22; 95% CI -0.15-0.54; p >0.05), but a positive correlation was observed between CRP level and index BVAS activity (r = 0.41; 95% CI 0.05-0.67; p <0.05). When using ROC-analysis to determine the value of ANCA in the assessment of active disease, it was found that the AUC is 0.93 ± 0.04 (95% CI 0.84-1.01; p <0.01), which indicates excellent ability ANCA diagnose patients with active disease (sensitivity - 87.9%, specificity - 80.0%).

Conclusion: The level of ANCA in patients with ANCA-associated vasculitis correlates with the Birmingham vasculitis activity score, as well as with the level of ESR. Determination of ANCA level can be used not only to diagnose ANCA-associated vasculitis, but also to assess disease activity.

AB0638 INTRAVENOUS IMMUNOGLOBULIN IN ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS. STUDY OF 28 CASES FROM A SINGLE UNIVERISTARY HOSPITAL AND LITERATURE REVIEW

F. Benavides-Villanueva1, C. Corrales-Selaya1, J. Loricer1, V. Calvo-Rio1, S. Castañeda1, N. Aviles Mendez2, J. M. Blanco Madrigal3, M. A. González-Gay1, R. Blanco1. 1Marques de Valdecilla University Hospital, Rheumatology, Santander, Spain; 2Hospital de La Princesa, Rheumatology, Madrid, Spain; 3Hospital Universitario Nuestra Señora del Perpetuo Socorro de Albacete, Rheumatology, Albacete, Spain; 4Basurto University Hospital, Rheumatology, Bilbao, Spain

Background: Anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) includes granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA) or microscopic polyarteritis (MPA). Standard treatment is often accompanied by significant adverse events. Intravenous immunoglobulins (IVIG) may constitute a therapeutic alternative, however, the data are scarce.

Objectives: To assess the utility and safety of IVIG in AAV.

Methods: Observational study of patients with AAV from Spanish referral center treated with IVIG. AAV diagnosis was based on a compatible clinical presentation and/or positive ANCA serology and/or histology. Disease activity was assessed with the Birmingham Vasculitis Activity Score (BVAS).

Results: We included a total of 28 patients; GPA (n=15), MPA (n=10), and EGPA (n=3). The main features are summarized in Table 1. The reasons for using IVIG were: a) relapse/refractory disease (n=20), or presence/suspicion of infection (8) b) observed a rapid and maintained Clinical improvement, since first month of IVIG onset, yielding a BVAS score of zero in 56.5% of patients at 24 months (Figure 1). Serious Adverse event was only observed in 1 patient who developed congestive cardiac failure and had to stop the IVIG therapy.

Table 1. Main features of 28 patients with antineutrophil cytoplasmic antibody-associated vasculitis treated with intravenous immunoglobulins.

AB0639 COMMON FEMORAL VEIN THICKNESS MEASUREMENT AS A DIAGNOSTIC TEST IN INCOMPLETE BEHÇET’S DISEASE

F. Alibaz-Onel1, R. Ergelen2, F. Temiz2, S. Kutlu Ajaçkiran1, E. Sodyemiş2, T. Ergun3, H. Direskenel1, Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 2Marmara University School of Medicine, Department of Radiology, Istanbul, Turkey; 1Marmara University School of Medicine, Department of Internal Medicine, Istanbul, Turkey; 4Marmara University School of Medicine, Department of Dermatology, Istanbul, Turkey.

Background: Behçet’s disease (BD) is characterized by recurrent oral and/or genital aphthous ulcers accompanied by cutaneous, ocular, articular, gastrointestinal and central nervous system lesions. Diagnosing BD can be a clinical challenge in patients presenting with a limited number of organ manifestations, especially with single major organ involvement. We reported the first controlled doppler ultrasound study showing increased common femoral vein (CFV) thickness in BD (1). We recently also showed that increased CFV thickness is a distinctive feature of BD, rarely present in other inflammatory or vascular diseases such as ankylosing spondylitis, systemic vasculitides, venous insufficiency, and non-inflammatory DVT with a specificity higher than 80% for the cut-off value of 0.5 mm. We suggest that CFV thickness measurement is an easy, non-invasive diagnostic test for BD (2).

Objectives: In this study, we aimed to assess the diagnostic performance of CFV thickness measurement in patients with ‘Incomplete’ Behcet’s Disease diagnosed by expert opinion.
Methods: We included 28 patients with incomplete BD (15 male, 12 female) diagnosed with expert opinion and followed in the Marmara University Behcet’s Clinic. Demographic, clinical characteristics and treatment data were recorded during routine visits. Common femoral vein wall thickness was measured by an experienced radiologist at the same day.

Results: Median age was 34.3 years and median disease duration 2 years (0-16). Four patients were newly diagnosed. At follow-up onset, oral ulcers were present in 22 (78.6%), genital ulcers in 6 (21.6%), papulopustular lesions in 4 (14.3%) and pathergy positivity in 5 (17.9%) patients. Ten (35.7%) patients had familial BD. While 24 (85.7%) patients had major organ involvement, 4 (14.3%) patients had mucocutaneous disease. Distribution of major organ involvements were given in Figure 1.

Figure 1. Distribution of major organ involvements (n) in study group

All patients except 1, had CFV thickness value above the cut-off value of ≥0.5 mm. Right CFV thickness was 0.71 (0.3-1.3) mm and left CFV thickness 0.72 (0.4-1.2) mm. Bilateral femoral vein thicknesses were similar in patients with and without an history of familial BD.

Conclusion: Diagnosing BD can be challenging in patients presenting with one major organ involvement such as oral ulcers and posterior uveitis, brain-stem disease or arterial aneurysms, especially in countries with a low prevalence. These patients are generally diagnosed as ‘incomplete’ BD by ‘expert opinion’. Early diagnosis is of utmost importance in some of these cases, especially with venous thrombosis as their management differs from non-inflammatory venous thrombosis, necessitating immunosuppressive use rather than anticoagulant therapy. Our results show that CFV thickness measurement with Doppler US, a non-invasive, fast and cost-effective radiological modality, is a valuable diagnostic test in incomplete BD, especially with major organ involvement.

PREVALENCE AND DETERMINANT FACTORS OF ENDOTHELIAL DYSFUNCTION IN ANCA ASSOCIATED VASculitis
A. L. Fedele1, F. Melpignano1, E. Porceddu2, C. Tur1, P. Tondi1, A. Zoli1, M. D. Agostino1, 1Division of Rheumatology-Catholic University of the Sacred Heart, Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze Mediche e Chirurgie, Roma, Italy; 2Division of Angiology- Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze dell’invecchiamento, neurologiche, ortopediche e della testa-collo, Rome, Italy.

Background: Atherosclerosis and its complications are one the leading cause of death in patients with anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV), despite the recent remarkable improvements in prognosis. The mechanism by which atherosclerosis is accelerated in these diseases is not explained by the classical cardiovascular risk factors (CFVRs) and is still under investigation.

Objectives: To evaluate the prevalence of endothelial dysfunction (ED) in AAV patients and to identify the determinant factors of endothelial responses among vasculitis characteristics, such as ANCA status and organ involvement.

Methods: Thirty patients (15 men and 15 women) with AAVs [13 with eosinophilic granulomatosis with polyangiitis (EGPA), 7 with granulomatosis with polyangiitis (GPA), 10 with microscopic polyangiitis (MPA)] were enrolled in the study. For all subjects CFVRs, blood pressure, lipid profile, renal function, acute phase reactants, ANCA status and titers were recorded at diagnosis and at the enrollment in the study. Vasculitis disease activity was measured using the Birmingham Vasculitis Activity Score (BVAS) and organ damage was assessed with the vasculitis damage index (VDI). The prognosis was evaluated through the Five Factor Score (FFS). Patients were excluded from the study if they had previous cardiovascular or cerebrovascular events, liver failure, end stage renal disease under hemodialysis, or cancer. Microvascular peripheral dysfunction was assessed by pulse amplitude tonometry (PAT) of the small digital artery. In particular, Log-transformed reactive hyperemia index (LnRHI) was evaluated using the EndoPAT2000 device: values of LnRHI > 0.51 were considered indicative of peripheral ED.

Results: At diagnosis, 23 subjects (76.7%) were ANCA positive (c-ANCA+, c-pANCA+), and at the enrollment in the study 10 patients (33.3%) were still sero-positive. Nineteen patients (63.3%) had inactive disease (BVAS=0), 7 (23.3%) were in low disease activity (1≤BVAS≤2) and 4 (13.3%) had an active disease (BVAS≥3). The presence of ED was documented in 9 AAV patients (30%). AAV patients with ED had higher C-reactive protein (CRP) values at diagnosis compared against subjects without ED (p=0.05). Moreover, patients with altered endothelial response were in higher percentage smokers (55.6%) and ANCA positive at enrollment (44.4%), compared to subjects with normal LnRHI (28.6%- p=0.12; 19%, p=0.15 respectively). There were no differences regarding age and other traditional CFVRs, disease duration, BMI, BVAS, VDI, FFS. There was an inverse correlation between CRP values at diagnosis and LnRHI (r=-0.42, p=0.04). In multiple logistic regression analysis, ANCA positivity at enrollment [OR (95% CI) = 15.68 (0.98-250.28) (p=0.05), and higher CRP concentrations [OR (95% CI) = 1.03 (1.00–1.06) (p=0.03) were independently associated with the presence of peripheral ED.

Conclusion: As observed in other chronic inflammatory autoimmune diseases, ED occurs in AAVs and is mainly related to the chronic systemic inflammation and seems to be also influenced by ANCA positivity, which is probably involved in the accelerated endothelial cell damage. Further studies are needed to clarify the role of vasculitis related parameters in the atherosclerotic process.

AB0640
AN ULTRASONOGRAPHIC STUDY OF THE SALIVARY GLANDS IN A COHORT OF PATIENTS AFFECTED BY CRYOGLOBULINEMIA VASCULITIS: PRELIMINARY RESULTS
A. Adinolfi1, N. Ughi1, D. A. Filippini1, M. Chevallard2, L. Belloli1, C. Casu1, M. Di Cicco1, C. Gagliardi1, M. C. Gerardi1, M. Muscara1, E. Verducci1, O. M. Epis1, 1Rheumatology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; 2Medicine Unit, Department of Medicine, Garbagnate Hospital, Milan, Italy.

Background: Cytosarcoma and xerophthalmia can occur in many diseases, rheumatological or not and are often reported by patients affected by cryoglobulinemia vasculitis, particularly if related to the Hepatitis C virus infection (HCV). On the other hand, the Ultrasound (US) was extensively used for detecting pathological findings of the salivary glands, possibly associated to many rheumatological diseases.

Objectives: The aim of this study was to detect, in patients affected by cryoglobulinemia vasculitis, the presence and the grade of pathological findings at level of the major salivary glands.

Methods: From January to December 2021, we enrolled consecutive outpatients patients affected by cryoglobulinemia (age ≥ 18 yo and a diagnosis of cryoglobulinemia vasculitis according to 2002 or 2011 classification criteria). Exclusion criteria were a previous diagnosis of other vasculitis/connective tissue diseases/ inflammatory arthropathies, concomitant not rheumatological diseases or the intake of drugs possibly related to sicca syndrome symptoms. For each patient, the demographic, anthropometric and clinical history data, particularly about the cryoglobulinaemia symptoms (either previous and ongoing) or current or previous therapies have been collected. Furthermore, the values of erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Rheumatoid Factor (RF) and C4 serum complement fraction have been recorded. The presence and the titre of the cryoglobulins have been recorded. For each patient, the Schirmer’s Test and the evaluation of the unstimulated whole saliva (UWS) flow were performed. The Schirmer Test was considered positive if < 5 mm/min at least in one eye and the UWS flow was defined pathological if < 1.5 ml/15 min. Each patient was submitted to the US examination (Esaote MyLab Twin) of both parotid and submandibular glands. Each gland was evaluated using a semiquantitative score 0-3, according to the OMERACT definitions. The US score was considered pathological if ≥2. Thus, at patient level, a sum dichotomous score (normal/pathological)>2.

Results: We enrolled 20 patients, all females, with a mean age of 68.8 years (SD±13.32) and a mean disease duration of 11.76 (SD±8.25). For 18 patients was reported a previous HCV infection. 16/18 HCV+ subjects reached the remission of the
infection with undetectable HCV viremia. Among the patients enrolled, 10 referred at least one syndrome sicca symptom: 5 patients both xerostomia and xerophthalmia, 4 only xerostomia and 1 only xerophthalmia. Considering blood tests, the cryoglobulins were detected in 14, the ESR title was above the limit in 7 patients and the CRP in 3. The RF was detected in 12 subjects. The Schirmer’s test was pathological in 9 patients while the UWS flow was under the limit in 3. As regards the US reports, 2 patients had pathological features scored as 2, while 7 patients showed minor alterations scored as 1. So, according to the sum score, only 2 patients were classified as pathological. No correlations were identified between the clinical and the US data.

Conclusions: In this cohort of patients with cryoglobulinemia, the US mainly showed mild pathological features at level of the parotid and submandibular structure, suggesting that syndrome sicca symptoms could be related to different pathological mechanisms in these patients, possibly strongly associated to HCV infection. Further and larger studies are necessary to confirm our preliminary data.

ABO643 ARE THERE ANY DISTINCTIVE FINDING IN ANCA-ASSOCIATED VASculoSIS RELATED PULMOnARY INVOLvEMENT IN COMPaRISON WITH CONNECTive TISSUE DISEASE OR IDIOPATHIC PULmOnARY FIBROSIS

E. Durak Ediboglu1, Ş. Karasu2, T. Ekici2, M. O. Turan2, Ö. Gerçik2, D. Solmaz1, C. Gümüş2, Ş. Akar3, Izmir Katip Celebi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey; 2Izmir Katip Celebi University, Department of Radiology, Izmir, Turkey; 3Izmir Katip Celebi University, Department of Pulmonary Disease, Izmir, Turkey; 4Izmir Demokrasi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey

Background: Patients with ANCA associated vasculitis (AAV) have a wide spectrum of pulmonary involvement from parenchymal necrotizing granuloma formation, trechobronchial inflammation, pulmonary capillaritis to interstitial lung disease. Pulmonary involvement is relatively common in connective tissue diseases (CTDs). Both rheumatologic disorders and idiopathic pulmonary fibrosis (IPF) might cause the usual interstitial pneumonia (UIP) pattern. However, little is known regarding the clinical and radiologic similarities/dissimilarities of those diseases.

Objectives: We aimed to evaluate the thoracic computed tomography (CT) findings of patients with AAV, CTD-related interstitial lung disease (ILD) or IPF.

Methods: Patients whose thoracic CT performed at the time of diagnosis or relapse of AAV (n=64), at the time of the diagnosis of CTD related ILD (n=55) or IPF (n=52) were included in the analysis. Demographic, clinical and serological data were collected retrospectively. Radiological patterns of pulmonary involvement were evaluated by two expert pulmonary radiologists and abnormal thoracic CT findings were classified according to Fleischner Society guidelines. Intra- and interobserver variation were calculated. Multinominal logistic regression was performed to identify disease specific findings in thoracic CT.

Results: A total of 171 patients were included and of them 64 patients (62.5% with granulomatosis with polyangiitis, 37.5% with microscopic polyangiitis) in AAV group, 55 patients in CTD related ILD (50.9% with scleroderma, 40.0% with rheumatoid arthritis, 9.1% other or undifferentiable connective tissue disease) group and 52 patients in IPF group. Demographic and thoracic CT findings were summarized in Table 1. In univariate analysis according to Fleischner Society definition, patients with AAV had more common pulmonary nodules, cavities, consolidation. However, patients with AAV were less likely to have interlobular septal thickening (ILST), lymph node adenopathy (LAP) and reticulation compared to both CTD related ILD and IPF. In addition, among those groups of rheumatic diseases, cavities and alveolar hemorrhage were detected only in AAV. In multinominal logistic regression, the presence of nodul and consolidation and the absence of ILST and mediastinal LAP were independent determinant findings in thoracic CT in patients with AAV in comparison with both CTD related ILD or IPF.

Conclusion: The results of this study show that in addition to clinical and laboratory characteristics, some thoracic CT imaging findings like the presence of nodules and consolidation and the absence of LAP and ILST may be useful to differentiate pulmonary involvement of AAV from other relatively common rheumatologic conditions and IPF. In addition, alveolar hemorrhage and cavities may be particular manifestations of AAV.

Scleroderma, myositis and related syndromes

Methods: Ten patients with pulmonary fibrosis secondary to Connective Tissue Disease treated with Nintedanib were monitored at baseline, 6 and/or 12 months, with clinical assessment, chest CT scan and/or pulmonary function testing (PFT) with a washout period of the diffusion capacity for CO (DLco). 810 patients had a diagnosis of Progressive Systemic Sclerosis, while the remaining ones had Polymyositis and/or Mixed Connectivitis. All patients were dyspneic at baseline and presented with dry cough. All patients had pulmonary fibrosis according to high-resolution chest CT scan. All patients had been treated with at least one csDMARD or bDMARD (cyclophosphamide, azathioprine, cyclosporine, rituximab, tocilizumab), prior to receiving nintedanib. At baseline 210 patients were treated with Nintedanib monotherapy, 710 were in combination therapy with Mycophenolate, 1 patient received a combination therapy with cyclosporine.

Results: Compared to baseline values, 4/7 patients showed stationarity of the respiratory function parameters (DLco), in 2/7 patients it was observed a significant improvement of the DLco (with a change of 15%) while in only 1 patient there was a worsening over time. FVC remained stable over time except in 1 patient who got a significant improvement. In 5/9 patients cough improved (unchanged in the rest of patients). Dyspnea (NYHA scale) improved in 6/9 patients, remained stationary in 2/6 patients and became worse in 1 patient. 8/9 patients had a stable chest CT at 6 and/or 12 months, while only 1 patient witnessed a further worsening of the fibrosis. 50% of the patients showed good gastrointestinal tolerance to the full dose of nintedanib. The other half had the dose reduced in order to improve gastrointestinal symptoms.

Conclusion: Our data show that patients with ILD associated with Rheumatic Diseases treated with nintedanib had a clinical benefit over dyspnea and cough symptoms and a stabilization of radiological findings 12 months after starting the treatment. Also, respiratory function parameters remained stable over time. Gastrointestinal adverse events, including diarrhea, were common in these patients, but therapeutic dose adjustment led to fast symptoms resolution and good tolerance.

G-CSF treatment for refractory digital ulcers in systemic sclerosis

Methods: Adult SSc patients with chronic resistant DU despite treatment with maximal tolerated doses of prostacyclin analogue, endothelin receptor antagonist and PDE5 inhibitor, were treated with three consecutive daily doses of G-CSF for evaluation of DU healing, DUCAS score, antibiotics use, side effects and hospitalizations, was performed.

Results: Ten patients (90% females), mean age 53.5 ± 11.1 years were treated. Fifty percent of the patients had a diffuse SSc disease. All patients suffered from chronic (80%), or recurrent (20%) DU. G-CSF treatment resulted in complete resolution of most DU, after an average of 1.57 ± 0.76 months. DU recurrence occurred in two patients, after a mean period of two months. The number of DU decreased from 2.23 ± 2.20 at baseline, to 0.84 ± 0.80 at one month (p value= 0.04), and 0.50 ± 0.67 at 3 months (p value= 0.015). DUCAS score dropped from 8.64 ± 2.50 before the treatment, to 1.76 ± 2.00 and 1.16 ± 2.55 at one and three months, respectively (p value <0.0001). No serious adverse events were observed.

Conclusion: G-CSF treatment was found to be beneficial for refractory SSc DU, resulting in DU healing and sustained remission in most cases. No significant side effects were observed. Future trials are needed to evaluate the efficacy and safety of this therapy.

REFERENCES:
Results: 103 SSc patients were included: 72 (69%) females, 82 (79%) lcSSc and 21 (20%) dcSSc. Among lcSSc patients, 43 (52%) had ACA, 16 (19%) Scl70 and 12 (15%) had ANA. Among dcSSc patients, 9 (43%) had Scl70 and 12 (57%) had ANA. Scl70-lcSSc patients had significantly shorter time from Raynaud's phenomenon (RP) to SSc diagnosis (p=0.02), younger age at SSc onset (p=0.04), higher mRSS (p=0.03), higher rate of myositis (p=0.001), higher CRP (p=0.04), mRSS (p=0.001), higher rate of myositis (p=0.04) and higher rate of ILD (p=0.02). Conclusion: Scl70-lcSSc patients show the major organ involvement, followed by ANA-lcSSc and ACA-lcSSc. Scl70-lcSSc and ANA-lcSSc patients exhibit more cutaneous involvement and ILD than Scl70-lcSSc and ANA-lcSSc. These results may provide new ways to help in early diagnosis, management and assessing the prognosis of the disease.

Background: Classically, anti-centromere antibodies (ACA) are associated with limited cutaneous involvement (lcSSc) and pulmonary hypertension, whereas anti-topoisomerase I (Sc70) are associated with diffuse skin involvement (dcSSc) and pulmonary fibrosis (ILD). Patients with lcSSc and Sc70 antibodies draw particular attention, which is why characterization of clinical phenotypes can help distinguish patient subgroups and assessing the prognosis of the disease.

Objectives: We aimed to characterize the clinical phenotype of patients with SSc based on autoantibodies.

Methods: We included patients with SSc, fulfilling the 2013 ACR/EULAR criteria, with disease duration ≤10 years. We have compared different subgroups of patients with lcSSc: Sc70-lcSSc (group1), ACA-lcSSc (group 2) and ANA-lcSSc (group 3). Table 1. Next, we compared patients with Sc70-lcSSc (group 1) to Scl70-dcSSc (group 4) and ANA-lcSSc (group 3) to ANA-dcSSc (group 5). In the ANA subgroup we included patients with negative Sc70 and ILD. We have assessed the risk of ILD, myositis, scleroderma renal crisis, cardiac and gastrointestinal involvement, myositis, pulmonary hypertension (systolic pulmonary arterial pressure >p>45 mmHg at transthoracic echocardiography or sPAP>25 mmHg at right heart catheterization), cancer and all-cause-mortality.

Disclosure of Interests: None declared

Background: Systemic sclerosis (SSc) is associated with increased risk of malignancy. Risk factors predisposing a SSc patient for development of malignancy are not well defined, and the pathogenetic basis of the association is yet to be explained. Some autoantibodies have been associated with a close temporal relationship with cancer. The absence of malignancy screening guidelines tailored for SSc patients raise the importance of the need for more studies on the association of SSc and cancer.

Objectives: To study the prevalence of cancer in SSc and the association between SSc-specific and SSc-associated autoantibodies and cancer in a third-level center.

Methods: We conducted a retrospective cohort study by including patients diagnosed with SSc followed from 1980 to 2020 fulfilling the 2013 ACR/EULAR SSc criteria. Demographic features, clinical and immunological characteristics were retrieved. The primary outcome was cancer-associated SSc, defined as cancer occurring within 2, 3 and 5 years of first non-Raynaud SSc manifestation. The exposure was defined by the presence of SSc-specific/associated autoantibodies, including anti-centromere (ACA), topoisomerase I (Sc1070), RNA polymerase III, fibrillarin, Th/To, PM-Sci, Ku, TIF1g, Ro52. Descriptive analysis was used to compare clinical characteristics of subjects with cancer to those without cancer. Univariate logistic regression was used to compare the odds of cancer-associated SSc between the autoantibody subgroups.

Results: Out of 103 SSc subjects, 27 (26%) had a history of cancer following SSc diagnosis. Mean age was 61.9 (57-69) years, 70% were female and 88% had a smoking history. Median time between cancer and disease onset was 6.33 (3-9) years. Among patients with cancer, 12 (44%), (29%) and (7) were diagnosed within 2, 5 and 10 years of SSc onset. The most frequent types were breast cancer (n=9), gastrointestinal cancer (n=5), prostatic cancer (n=4), hematological (n=3) cancers, cervical/uterine cancers (n=2), non-melanoma skin (n=2), lung cancer (n=2). Patients with cancer were more likely to be Sc70+ (OR 2.55, 95% CI 1.03-6.3, p = 0.04), anti-TIF1g (OR 19.5, 95% CI 5.6 - 68.3, p = 0.001) and RNA pol III (OR 10.9 CI 95% 108-109, p = 0.04), have a history of smoking (OR 224, 95% CI 2.6-197, p = 0.001), myositis (OR 5.2 IC 95% 2.06-13.2, p = 0.005) and older age at SSc onset (619 vs 57, p = 0.04). Breast cancer was more frequent in anti-TIF1g (OR 3.75 IC 95% 1.8-17.5) and RNA pol-III (OR 7.14 IC 95% 1.56-90.8) subgroups. The risk of cancer-associated SSc was significantly increased among anti-TIF1g-positive subjects at 5 years after SSc onset (OR 2.1 CI 95% (1.45-9.94), p = 0.04) and among RNA-pol III-positive subjects at 2 years after SSc onset (OR 3.5 95% CI (12-51.4), p = 0.02) (Table 1).

Conclusion: Anti-Sc70, anti-TIF1g and RNA pol III were predictive of cancer-associated SSc for cancers. Breast cancer was the most frequent. Subjects with cancer were more likely to have a history of smoking, myositis and an older age at SSc onset. Autoantibodies should be taken into account in cancer with cancer were more likely to have a history of smoking, myositis and an older age at SSc onset. Autoantibodies should be taken into account in cancer associated SSc for cancers. Breast cancer was the most frequent. Subjects with cancer were more likely to have a history of smoking, myositis and an older age at SSc onset. Autoantibodies should be taken into account in cancer.

Notes in the column 'BAL' indicate the predominant cell type noted on cytology. RVSP = Right Ventricular Systolic Pressure.

Findings on ECG, 2D-Echo, spirometry and bronchoalveolar lavage (BAL) are summarized in Table 1.

Conclusion: Although limited by a small sample size, UIP appeared to be the most common lung pathology in patients with dCSS. The duration from diagnosis of dCSS to first manifestation of pulmonary symptoms is much shorter in comparison to limited cutaneous systemic sclerosis [1] PAH is commoner with limited cutaneous systemic sclerosis than with dCSS. [2] 2D-ECHO was neither useful for diagnosis nor required in preparing a therapeutic plan for these patients.

CLINICAL IMPACT AND PROGNOSIS OF CRYOglobulinemia AND CRYOFibrogenemia IN SYSTEMIC SCLEROSIS

S. De Almeida Chaves1, F. Benoît2, T. Porel1, E. Bories3, D. Adouë4, L. Astudillo5, L. Alric6, A. Huard7, M. Michaud6, D. Ribes8, G. Prevot1, L. Sailler9, F. Gaches9, G. Pugnet9, 1Hospital Purpan, Internal Medicine, Toulouse, France; 2Hospital Purpan, Immunology, Toulouse, France; 3Hospital Rangueil, Internal Medicine, Toulouse, France; 4Clinic nephrologist Saint Exupéry, Internal Medicine, Toulouse, France; 5Hospital Rangueil, Nephrology, Toulouse, France; 6Hospital Joseph Ducuing, Internal Medicine, Toulouse, France; 7Hôpital Larrey, Pneumology, Toulouse, France; 8Hospital Purpan, Internal Medicine, Toulouse, France

Background: Systemic sclerosis (SSc) is reported to be a secondary cause of cryoglobulinemia as well as cryofibrogenemia. However, prevalence, clinical implication and associated pronostic of cryoprecipitates in SSc are unknown.

Objectives: To describe the prevalence, the phenotype and evaluate the prognosis of cryoglobulinemia and/or cryofibrogenemia associated with systemic sclerosis.

Methods: We included all adult (≥18 years) consecutive SSc patients from the Systemic Scleroderma Toulouse Cohort (SSTC) [1] for whom a cryoglobulin and/or cryofibrogenin measurement was carried out at the immunology laboratory of the Toulouse University Hospital between June 1, 2005 and May 31, 2018 and at least one follow-up visit. We compared SSc-patients characteristics with and without cryoglobulinemia > 50 mg/l and with and without cryofibrogeninemia. Survival analysis based on presence of cryoglobulin cryofibrogenin was performed using the Kaplan-Meier method. Univariable and multivariable Cox proportional hazards models (ascending step-by-step method) were used to determine baseline variables associated with cryoglobulin or cryofibrogenin presence.

Results: 166 patients were included in the study. 74.6% of patients were women, with an average age at diagnosis of 51.2 years-old. 24% were diffuse cutaneous subtypes and 71.6% limited cutaneous subtypes. Anti-centromere and anti-ScI70 were respectively positive in 44.5% and 21.6% of cases. All these patients were assessed for cryoglobulin detection and 75 cryofibrogenin detection in serum. 43.3% had a cryoglobulinemia >50 mg/l. 46.6% had cryofibrogeninemia. Patients with cryoglobulinemia >50 mg/l had more cardiac diastolic involvement (22.8% vs. 5.1%; p=0.0395). In the multivariable analysis, diastolic involvement (HR=6.23; p=0.0331) was an independent predictor of cryoglobulin >50 mg/l. Survival at 10 years was better for patients with cryoglobulinemia >50 mg/l (log-rank 0.0363) (Figure 1). Survival at 5 and 10 years was 97.8% and 88.8% respectively in patients with cryoglobulinemia >50 mg/l versus 91.9% and 78.4% in patients with cryofibrogeninemia >50 mg/l. In cox regression model adjusted for gender, age and type of systemic sclerosis, cryoglobulin >50 mg/l was negatively associated with mortality (HR: 0.09; p=0.03). The presence of cryofibrogeninemia was not associated with any clinical, biological or morphological features. In the multivariate analysis, no variable was predictive of the presence of cryofibrogeninemia in patients with SSc. The presence of cryofibrogeninemia had no influence on the mortality of these patients.

Conclusion: In SSc patients, the presence of cryoglobulin >50 mg/l is an independent predictive factor of cardiac diastolic involvement and is associated with a better survival. However, cryofibrogeninemia does not influence clinical phenotype or impact mortality in SSc patients.

PREVALENCE OF INTERSTITIAL LUNG DISEASE AND PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS PATIENTS COHORT AT A RHEUMATOLOGY REFERRAL CENTRE IN THE UNITED ARAB EMIRATES

K. Saleh1, N. Khan1, A. Ghorab1, M. El-Kaisii, A. Mubashir2, M. Elarabi3, H. Sabbour2, R. Namra2, Cleveland Clinic Abu Dhabi, Respiratory Institute, Abu Dhabi, United Arab Emirates; 2Cleveland Clinic Abu Dhabi, Radiology, Abu Dhabi, United Arab Emirates; 3Cleveland Clinic Abu Dhabi, Rheumatology, Abu Dhabi, United Arab Emirates; 4Cleveland Clinic Abu Dhabi, Cardiology, Abu Dhabi, United Arab Emirates

Background: Scleroderma, also known as Systemic Sclerosis (SSc), is a connective tissue disease that affects multiple organ systems, including the cardiovascular and respiratory systems, namely, pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD) as the leading causes of death in this patient population.

Objectives: The purpose of this study is to determine the prevalence of PAH and ILD in a cohort of patients diagnosed with SSc.

Methods: We performed a retrospective chart review of clinical characteristics of all patients diagnosed with SSc Cleveland Clinic Abu Dhabi between April 2015 and April 2020. PAH was estimated by echocardiographic findings and diagnosed based on right heart catheterization (RHC) using 2019 World Symposium on Pulmonary Hypertension. The CT scan of the chest was read by a board-certified radiologist in chest radiology.
Results: Fifty individuals were diagnosed with SSc, with 46% having diffuse cutaneous systemic sclerosis and 54% having limited cutaneous systemic sclerosis. The majority of the patients (86%) were female, with a mean age of 41 ±13 years. The average period from presentation to diagnosis was 5 ±5.4 years. The majority of the cohort (86%) were from the United Arab Emirates. The average BMI was 26.0 kg/m². Patients’ most prevalent symptoms are fatigue (80%), gastrointestinal symptoms (72%) followed by shortness of breath (58%) and cough (50%). Twenty-six out of fifty patients (52%) underwent a CT chest scan, with 19 (38%) having ILD. Eight patients had more than 30% fibrotic alterations, four patients had 10-30% fibrotic changes, and seven patients had less than 10% fibrotic abnormalities. Patients with more than 10% fibrotic changes were more likely to have usual interstitial pneumonia, whereas those with less than 10% fibrotic changes were more likely to have none specific fibrosis. The majority of patients (92%) had echocardiogram. All except one patient had a normal ejection fraction, and five had grade 1 left ventricular diastolic dysfunction. Five patients were described as having mild, 1 moderate and 2 severe PAH. Only 4 patients underwent RHC. One patient had group II PAH based on elevated wedge pressure. One had group 1 PAH with systemic sclerosis as the only cause for her PAH and two patients had group III PAH due to having more than 30% pulmonary fibrosis and severe restrictive defect on spirometry. Therefore, the precapillary PAH prevalence was 6%/3(50).

Conclusion: While the prevalence of pulmonary fibrosis in our SSc patients reflects what has been reported in the literature, the prevalence of PAH is significantly lower than the reported 15-20%. This is likely due to underdiagnosis of PAH considering the number of years of systemic sclerosis diagnosis on presentation to our clinic. A systematic approach is needed to assess for the presence and severity of PAH using tools as in Detect algorithm which has been validated and commonly used in Europe and North America to screen for PAH. Validation of such algorithm is likely needed in middle eastern population before it is universally adopted.

THE ASSOCIATION OF AUTOANTIBODIES WITH MORBIDITY AND MORTALITY OF SCLERODERMA RENAL CRISIS IN JAPAN

H. Tsuji1, N. Kuramoto2, T. Sasai1, M. Shirakashi1, H. Onizawa1, K. Kitagori1, S. Akizuki1, R. Nakashima1, R. Watanabe1, A. Onishi1, K. Murakami1, H. Yoshiji1, M. Tanaka2, M. Hashimoto1, K. Ohmur1, A. Morinobu1, 1Kyoto University Graduate School of Medicine, Department of Rheumatology and Clinical Immunology, Kyoto, Japan; 2Wakayama Medical University, Department of Rheumatology and Clinical Immunology, Wakayama, Japan; 3Kyoto University Graduate School of Medicine, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan; 4Osaka City University Graduate School of Medicine, Department of Clinical Immunology, Osaka, Japan; 5Kyoto University Graduate School of Medicine, Division of Clinical Immunology and Cancer Immunotherapy, Center for Cancer Immunotherapy and Immunobiology, Kyoto, Japan; 6Kobe City Medical Center General Hospital, Department of Rheumatology, Kobe, Japan

Background: The morbidity of scleroderma renal crisis (SRC) and autoantibodies in systemic sclerosis (SSc) vary by races and regions. Anti-RNA polymerase III is associated with SRC in America and European countries. However, the association of autoantibodies with SRC had not been elucidated in Japan.

Objectives: We aimed to investigate the association of autoantibodies with morbidity and mortality of SRC in Japan.

Methods: The clinical characteristics and mortality of 330 patients with systemic sclerosis (SSc) at Kyoto University Hospital were retrospectively analyzed, focusing on anti-centromere, anti-RNA polymerase III, anti-topoisomerase I, and anti-U1-RNP. Logistic regression analyses were performed to examine the association of autoantibodies with the development and mortality of SRC. Kaplan-Meier survival analysis was performed comparing the groups classified by autoantibodies.

Results: Anti-centromere (n = 177/318, 56%), anti-topoisomerase I (n = 80/311, 26%), anti-RNA polymerase III (n = 27/204, 13%), and anti-U1-RNP (n = 24/305, 8%) were found in SSc patients (n = 330). SRC was observed in 24 out of 330 SSc patients, including anti-topoisomerase I (n = 12/24, 50%), anti-RNA polymerase III (n = 7/24, 29%), anti-U1-RNP (n = 5/24, 21%), and anti-centromere (n = 3/24, 13%). Anti-U1-RNP (odds ratio [95% confidence interval], 3.63 [1.11–10.2]), anti-RNA polymerase III (3.29 [1.16–8.70]), and anti-topoisomerase I (3.22 [1.37–7.57]) were associated with the development of SRC. All patients with SRC were treated with ACE inhibitors and the 1-year survival rate was 54%. Anti-topoisomerase I was associated with the 1-year mortality of SRC (6.00 [1.11–41.1]). When the survival rate was compared between the patients positive for anti-topoisomerase I (n = 12) and negative for anti-topoisomerase I (n = 12), the 1-year survival rate was 33% vs 75% (p = 0.041), respectively (Figure 1A). Furthermore, the 1-year survival of anti-centromere (100%), anti-RNA polymerase III (83%), and others/ not detected (50%) were shown in patients negative for anti-topoisomerase I (Figure 1B).

Figure 1. Overall survival of patients with SRC according to the type of autoantibodies. (A) The survival rates in SRC patients who were positive for anti-topoisomerase I (solid line, n = 12) and those who were negative for anti-topoisomerase I (dotted line, n = 12). (B) SRC patients negative for anti-topoisomerase I were classified as patients with anti-RNA polymerase III (dotted line, n = 6), anti-centromere (broken line, n = 2), and others/not detected (chain line, n = 4).
Table 1. Univariate logistic regression analysis for mortality in SRC (n = 24).

AB0655  ELEVATED CIRCULATING LEVELS OF IL-33 IN SYSTEMIC SCLEROSIS PATIENTS WITH INTERSTITIAL LUNG DISEASE

R. Dacheva1, G. Vasilev2, K. Tumangelova-Yuzeir2,3, D. Kyurkchiev2,3, S. Monov4,5.
1University Hospital “St. Ivan Rilski”, Diagnostic and Consultation Center, Sofia, Bulgaria; 2University Hospital “St. Ivan Rilski”, Laboratory of Clinical Immunology, Sofia, Bulgaria; 3Medical University of Sofia, Department of Clinical Immunology, Sofia, Bulgaria; 4University Hospital “St.Ivan Rilski”; Clinic of Rheumatology, Sofia, Bulgaria; 5Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria

Background: Systemic sclerosis (SSc) is a chronic autoimmune disease characterized by immune dysregulation, vasculopathy and progressive skin and internal organ fibrosis. Interstitial lung disease (ILD) remains a leading cause of morbidity and mortality in SSc patients. Interleukin 33 (IL-33) is a member of the IL-1 superfamily and has been previously described as a pro-fibrotic cytokine that exerts its function by inducing Th2 cells differentiation and stimulating the expression of TGF-β. Previous reports have revealed the role of IL-33 in numerous fibrotic diseases.

Objectives: The aim of the present study is to examine the serum levels of IL-33 and explore the possible correlation with clinical and laboratory features with a focus on pulmonary involvement in SSc patients.

Methods: A total number of eighty five (n=85) patients fulfilling the 2013 ACREULAR criteria for classification of SSc were enrolled in the study. Twenty five (n=25) age and sex matched healthy volunteers were used as controls. Detailed medical history, clinical and laboratory parameters were obtained for all included patients. Serum levels of IL-33 (pg/ml) were determined by enzyme-linked immunosorbent assay. GraphPad Prism 6,SPSS V.23 and RStudio were used for the performance of the statistical analysis.

Results: Of all included patients in the analyses, serum sample was obtained from 55 SSc patients, 51 women (92.7%) and 4 men (7.3%): thirty nine (n=39) with diffuse and thirty six (n=36) with limited SSc, respectively. Raynaud's phenomenon (96.9%), Raynaud's phenomenon (96.9%) and female sex (87.8%) were the most common and early manifestations. Gastroesophageal (GE), respiratory and muscular involvement were female (87.8%) and Caucasian (70.4%). Anti-citrullinated peptide antibodies (ACPA) were positive in 40.9% of patients. Anti-RNA polymerase III 0.36 (0.04, 2.18) 0.29 and Anti-U1-RNP 7.4x10^-10 (--, 0.93) 1.00 were positive in 0.36% and 3.1% of patients, respectively.

Conclusion: IL-33 may be involved in the immunopathogenesis of pulmonary fibrosis. The results are consistent with previous studies. The present study is cross-sectional and further analyses and follow-up may be required to determine whether IL-33 may serve as a potential biomarker in the routine practice.

AB0656  CLINICAL AND IMMUNOLOGICAL FEATURES OF A PORTUGUESE COHORT OF MIXED CONNECTIVE TISSUE DISEASE

1Unidade Local de Saúde do Alto Minho, Rheumatology Department, Ponte de Lima, Portugal; 2Centro Hospitalar Lisboa Norte, Rheumatology Department, Lisboa, Portugal; 3Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Rheumatology Research Unit, Lisboa, Portugal; 4Centro Hospitalar Universitário São João, Rheumatology Department, Porto, Portugal; 5Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS, Porto, Portugal); 6Hospital Garcia de Orta, Rheumatology Department, Lisbon, Portugal; 7Centro Hospitalar Universitário de Coimbra, Rheumatology Department, Coimbra, Portugal; 8Hospital Lisboa Ocidental, Rheumatology Department, Lisbon, Portugal; 9Hospital de Braga, Rheumatology Department, Braga, Portugal; 10Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal; 11Unidade Local de Saúde da Guarda, Rheumatology Department, Guarda, Portugal; 12Centro Hospitalar Tondela-Viseu, Rheumatology Department, Viseu, Portugal; 13Centro Hospitalar do Baixo Vouga, Rheumatology Department, Aveiro, Portugal; 14Centro Hospitalar Trás-os-Montes e Alto Douro, Rheumatology Department, Vila Real, Portugal; 15Hospital Vila Nova de Gaia/Espinho, Rheumatology Department, Vila Nova de Gaia, Portugal; 16Hospital do Divino Espírito Santo, Rheumatology Department, Ponta Delgada, Portugal; 17Unidade Local de Saúde de Castelo Branco, Rheumatology Unit, Castelo Branco, Portugal

Background: Various nationwide studies have been already published to better understand Mixed Connective Tissue Disease (MCTD) (1,2). However, Portuguese data is not available.

Objectives: To characterize clinical and immunological features of a Portuguese cohort of patients with MCTD.

Methods: Retrospective, multicenter study including adult-onset patients with clinical diagnosis of MCTD and fulfilling at least one of the following classification criteria: Sharp, Kasukawa, Alarcón-Segovia or the Kahn's criteria. Positivity to autoantibodies besides anti-U1-RNP were allowed. SPSS was used for statistical analysis and significance level was defined as 2-sided p<0.05.

Results: A total of 98 patients were included, with a mean age at diagnosis and disease duration of 40.5±17.7 and 70±6.5 years, respectively. Most patients were female (87.8%) and Caucasian (70.4%). Raynaud's phenomenon (96.9%), arthralgia/arthritis (94.9±77.9%) and puffy fingers (60.2%) were the most common and early manifestations. Gastroesophageal (GE), respiratory and muscular...
involvement were also prevalent, mostly during the follow up, affecting 30.6%, 34.7% and 43.9% of the patients, respectively. Clinical and immunological characteristics are described in Table 1. Males were older at symptom’s onset (65.0 VS 46.7, p<0.06), having more respiratory involvement (OR=4.5, 95% CI 1.5-16.4), and positivity to anti-ACP (OR=20.0, 95% CI: 3.1-129.4). QE involvement occurred more often in Caucasian patients (OR=3.8; 95% CI: 1.0-14.1), while anemia of chronic diseases (OR=2.7; 95% CI: 1.0-7.2), myositis (OR=3.6; 95% CI: 1.3-9.9) and constitutional symptoms (OR=3.2; 95% CI: 1.2-8.3) were more frequent in Afro-American patients, whose were also younger at disease (34.1 VS 46.7, p<0.01). After a median follow-up time of 4 (IQR 8) years, 4 deaths occurred (4.1%), mostly (75%) due to infectious complications.

Conclusion: Raynaud’s phenomenon, puffy fingers and arthritis were the most common manifestations in Portuguese patients, with similar proportions found in literature (1.2). However, we reported some differences in mucocutaneous, renal and sera involvement and higher prevalence of probable pulmonary hypertension (1.2), which may be explained by the heterogeneity of the inclusion criteria. Except for respiratory, myositis, GE and constitutional symptoms, there were no differences regarding gender and ethnicity. Here, we characterize the largest cohort of MCTD in Portugal.

AB0056

CAROTID INTIMA-MEDIA THICKNESS AS POTENTIAL MARKER OF CARDIOVASCULAR RISK IN SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY.

F. S. Iaquinta1, S. Di Napoli2, R. Grosso2, S. Naty1, V. Cassano3, D. Crescibene3, G. Armentano2, A. Sciacquac2, R. D. Grencis3. 1"Magna Graecia" University of Catanzaro, Rheumatology Research Unit, Department of Health Sciences, Catanzaro, Italy; 2"Magna Graecia" University of Catanzaro, Department of Health Sciences, Catanzaro, Italy; 3"Magna Graecia" University of Catanzaro, Department of Medical and Surgical Sciences, Catanzaro, Italy

Background: In several rheumatic diseases, persistent inflammatory state has been related to an accelerated atherosclerosis. Although the risk of cardiovascular (CV) events and atherosclerosis is increased in patients with Systemic Sclerosis (SSc), the exact underlying process has not been well defined. Indeed, inflammation is not a remarkable feature of systemic sclerosis pathogenesis as in other inflammatory rheumatic diseases.

Objectives: The aim of this study was to evaluate the carotid intima-media thickness (c-IMT) as potential marker of cardiovascular damage in SSc patients.

Methods: Between April and July 2021, 14 consecutive patients with SSc and 14 control subjects were enrolled in the study. Participants were aged > 18 and were able to provide written informed consent. Demographic, anthropometric and cardiovascular risk factors (smoking, arterial hypertension, diabetes and family history of CV events) were collected for each subject. Moreover, an evaluation of the sero-haematological characteristics was also performed. The c-IMT was assessed by the same qualified physician through a B-mode ultrasound examination. C-IMT values ≥ 0.9 mm were considered pathological.

Results: Demographic and clinical characteristics are shown in Table 1. Traditional CV risk factors were similar between groups, although BMI was significantly lower in SSc patients than controls (24.6 VS 26.2, p=0.019). Patients’ median disease duration was 11 [5.0-16] years. Three patients had limited and 11 patients had diffuse disease according to LeRoy classification. Anti-nuclear antibodies were detected in all SSc subjects. Three patients expressed anti-centromere antibodies (ACA), other 3 are anti-Scl70 antibodies positive, only one patient showed anti-RNA polymerase III antibodies and 7 patients did not presented specific SSc autoantibodies. SSc patients had slightly increased c-IMT compared with controls, however the difference did not reach statistical significance (median c-IMT 0.84 [0.72-0.91] vs median c-IMT 0.68 [0.63-0.82], p=0.164).

Continuous data are presented as mean ± standard deviation or as median and interquartile range. Binomial data are shown as frequencies and percentages. The overall p-value was calculated by the Mann–Whitney non-parametric test for independent samples and by Chi-squared test as appropriate.

Conclusion: In our study patients with SSc had a non-significative increased c-IMT compared with controls (p=0.164), however different results have been reported in previous studies. Although it is not clear whether c-IMT may be considered a marker of cardiovascular damage in SSc, further studies are needed to clarify its role.

REFERENCES:

Disclosure of Interests: None declared

Background: Gastrointestinal (GI) involvement is a common manifestation of systemic sclerosis (SSc) and a frequent side-effect of drugs used to treat SSc. In the SENSCIS trial, nintedanib reduced the rate of decline in forced vital capacity (FVC) in patients with SSc-associated interstitial lung disease (SSc-ILD), with an adverse event profile characterised predominantly by GI events.

Objectives: To assess the severity and impact of GI symptoms on quality of life in patients treated with nintedanib in the open-label extension trial, SENSCIS-ON. Methods: Patients with SSc-ILD who completed the SENSCIS trial or a drug–drug interaction (DDI) study of nintedanib and oral contraceptive were eligible to enter SENSCIS-ON. Patients who received nintedanib in SENSCIS (up to 100 weeks) and continued nintedanib in SENSCIS-ON comprised the “continued nintedanib” group. Patients who received placebo in SENSCIS and initiated nintedanib in SENSCIS-ON, or who received nintedanib for a short time in the DDI study, comprised the “initiated nintedanib” group. We assessed changes in scores on the UCLA Scleroderma Clinical Trial Consortium Gastrointestinal Tract (UCLA SCTC GIT) questionnaire v2.0 from baseline to week 52. This questionnaire comprises 7 scales measuring the severity and impact of GI symptoms: reflux, distension or bloating, faecal soiling, diarrhoea, constipation, emotional well-being, social functioning. Each scale is scored from 0 to 3 except for the diarrhoea scale (0 to 2) and constipation scale (0 to 2.5). The total score, the mean of the scores for the scales except constipation, ranges from 0 to 2.83, with higher scores indicating worse symptoms.

Results: The “continued nintedanib” group comprised 197 patients and the “initiated nintedanib” group comprised 247 patients (231 from SENSCIS). Of these, 178 and 218 patients, respectively, provided a total UCLA SCTC GIT score at baseline. At baseline, mean (SD) total scores were 0.33 (0.33) and 0.33 (0.34) in the continued nintedanib and initiated nintedanib groups, respectively. Mean (SD) scores on the 7 scales ranged from 0.16 (0.52) to 0.70 (0.73) in the continued nintedanib group and from 0.13 (0.43) to 0.64 (0.68) in the initiated nintedanib group. Increases (worsening) in scores were observed in both groups from baseline to week 52, except for the constipation scale (Figure 1). Based on the total score, between baseline and week 52, the proportion of patients with moderate or severe or very severe GI symptoms increased, but 45.7% and 39.7% of patients in the continued nintedanib and initiated nintedanib groups, respectively, had no or mild GI symptoms at week 52 (Table 1).

Conclusion: In the SENSCIS-ON trial, the majority of patients with SSc-ILD treated with nintedanib had no or mild GI symptoms at baseline. A small worsening in GI symptoms was observed over 52 weeks. Diarrhoea had the greatest impact, reflecting the adverse event profile of nintedanib. Recommendations for the management of diarrhoea in patients treated with nintedanib should be implemented in clinical practice.

NOCEO EFFECT ON DIARRHOEA REPORTED IN THE SENSICS TRIAL OF NINTEDANIB IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSC-ILD)

O. Distler1, K. Highland2, A. Azuma3, C. Miede4, M. Alves5, P. Sfikakis6

1University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland; 2Cleveland Clinic, Department of Pulmonary, Cleveland, OH, United States of America; 3Graduate School of Medicine, Nippon Medical School, Department of Pulmonary Medicine and Oncology, Tokyo, Japan; 4mainanalytics GmbH, Statistics, Sulzbach (Taunus), Germany; 5Boehringer Ingelheim International GmbH, TA Inflammation Med, Ingelheim, Germany; 6National Kapodistrian University of Athens Medical School, 1st Dept of Prop. Internal Medicine & Joint Academic Rheumatology Program, Athens, Greece

Background: Unfavourable effects observed after administration of placebo may be attributed to factors such as expectation or conditioning as known are nocebo effects. Prior to initiation of the SENSICS trial, diarrhoea was a known side-effect of nintedanib. Objectives: To investigate whether a nocebo effect contributed to reporting of diarrhoea in the SENSICS trial. Methods: The SENSICS trial enrolled patients with systemic sclerosis (SSc) with first non-Raynaud symptom in the prior ≤100 years and a ≥10% extent of fibrotic ILD on high-resolution computed tomography. Patients were randomised to receive nintedanib or placebo until the last patient had reached week 52 but for ≤100 weeks. A follow-up visit was conducted 28 days after the end of treatment. Adverse events were reported by investigators irrespective of causality and coded according to the Medical Dictionary for Regulatory Activities. We analysed the incidence of diarrhoea adverse events in the on-treatment period (i.e., events with onset between the first intake of trial drug intake and the last intake plus 7 days) and in the post-discontinuation period (i.e., events with onset between the first day after the on-treatment period and the end of the follow-up period) in the nintedanib and placebo groups. Incidence rates were calculated as the number of patients with diarrhoea adverse events divided by the time at risk. Results: In the on-treatment period (time at risk: 277.7 patient-years), the rate of diarrhoea adverse events in the placebo group (n=288) was 33.1 per 100 patient-years. In the post-discontinuation period (time at risk: 41.9 patient-years), the rate of diarrhoea adverse events in the placebo group (n=264) was 19.1 per 100 patient-years. In the on-treatment period (time at risk: 105.1 patient-years), the rate of diarrhoea adverse events in the nintedanib group (n=288) was 209.3 per 100 patient-years. In the post-discontinuation period (time at risk: 53.7 patient-years), the rate of diarrhoea adverse events in the nintedanib group (n=263) was 5.6 per 100 patient-years.

Conclusion: In the SENSICS trial in patients with SSc-ILD, the rate of diarrhoea adverse events in the placebo group fell after trial drug was discontinued. This suggests that a nocebo effect may have contributed to the diarrhoea adverse events reported in the SENSICS trial.

Acknowledgements: The SENSICS trial was funded by Boehringer Ingelheim, Oliver Distler, Kristin B Highland and Arata Azuma were members of the SENSICS trial Steering Committee.

RECRUITMENT AND PREVALENCE OF MIXED PHENOTYPE MACROPHAGES IS PROMINENT IN BRONCHOALVEOLAR LAVAGE (BAL) OF SYSTEMIC SCLEROSIS (SSC) PATIENTS WITH INTERSTITIAL LUNG DISEASE (ILD)

V. A. Adams, J. T. Gan1, J. Bosma1, W. Abdulrahad1, I. M. Atzeni2, M. Van der Leij3, B. J. Kroese3, A. J. Stei4, W. Timens5, J. Burgess6, H. Van Goor7, J. Westra7, D. J. Mulder1

Background: ILD is a major problem in SSc for which no disease-modifying therapies are available. Many observations suggest monocyte/macrophage involvement in SSc and might be a key component in the development of ILD. Macrophages polarize into M1 and M2 phenotypes and thereby orchestrate inflammation and subsequent fibrosis by responding to and producing a vast array of cytokines and chemokines. Differences in the levels of the chemokines may explain variations in the recruitment and activation of macrophages in affected organs. In SSc, macrophages with a mixed phenotype (expressing both M1 and M2 markers) are prominent in peripheral blood. No previous study has investigated the mixed phenotype macrophages locally on the lung level.

Objectives: To measure macrophage-related chemokines in BAL fluid obtained from SSc-ILD and SSc-No-ILD patients. Methods: To investigate levels of M1 and M2 macrophage markers in BAL cells obtained from SSc-ILD and SSc-No-ILD patients. Methods: A cross-sectional study in which BAL procedure was performed on 15 treatment-naïve SSc patients divided into two groups according to lung involvement determined by HRCT and lung function tests: SSc-ILD group and SSc-No-ILD group (Table 1). Levels of chemokines (CCL18, CXCL-10 and CCR2) were analysed using ELISA, miRNA expression levels of CD68 (M1: inflammatory macrophage marker) and CD206 (M2: fibrogenic macrophage marker) in cells isolated from BAL were assessed using RT-qPCR. In addition, immunofluorescence studies and flow cytometry analyses were performed to evaluate the expression of M1 (CD68) or M2 (CD206) markers in BAL macrophages.

Results: Macrophages were the predominant immune cell population in BAL of SSc patients (73%). The levels of CCL18, CCR2 and CXCL10 were slightly elevated in the SSc-ILD group compared to the SSc-no-ILD group (Figure 1.1). RT-qPCR data showed that CD86 expression was elevated in the SSc-ILD group while no difference was observed in CD206 expression between the two groups (data not shown). The SSc-ILD group had higher proportions of double-positive (CD68+, CD206+) macrophages than SSc-no-ILD which, in contrast, had higher proportions of CD68+ CD206- macrophages (Figure 1.2). These results were supported by fluorescent microscopy images in which the SSc-ILD group had higher CD86 and CD206 expression than the SSc-no-ILD group (Figure 1.3). Double staining clearly showed a more prevalent mixed activation of macrophages in the SSc-ILD group.
Conclusion: In this pilot study, recruitment and activation of mixed phenotype macrophages was more prominent in SSc-ILD than in SSc-no-ILD. Although levels of chemokines were not profoundly different between both groups, studying extensively the macrophage activation patterns in BAL provided novel findings regarding differences between the two groups. Since SSc is characterised by inflammatory and fibrotic phases, the mixed polarization of macrophages we showed for the first time in SSc-ILD patients on an organ level is a key aspect in such disease and could potentially serve as a target for therapeutics.

LONG-TERM EFFECT OF COMBINATION THERAPY WITH RITUXIMAB AND MYCOPHENOLIC ACID ON CARDIAC MANIFESTATIONS, PULMONARY FUNCTION AND SKIN FIBROSIS IN SYSTEMIC SCLEROSIS

F. R. A. da Silva1, H. Grashoff1, J. Y. Humrich1, P. Lamprecht1, G. Riemekasten1.

1University Medical Center Schleswig Holstein, Rheumatology and clinical immunology, Lübeck, Germany

Background: Cardiac manifestations in systemic sclerosis (SSc) can be either due to the fibrotic and vascular process or secondary to pulmonary arterial hypertension (PAH), cardiac inflammation, or renal crisis. Despite being one of the leading causes of death in SSc, cardiac involvement and its therapeutic options have been poorly studied. According to the ACR/EULAR recommendations, therapy with cyclophosphamide (CP) is applied to patients with cardiac manifestations. However, in case of inadequate response to CP, there are no other therapeutics evaluated.

Objectives: The aim of this retrospective analysis was to explore the efficacy of a therapy with rituximab and mycophenolic acid (MPA), especially in cases of CP failure or therapy induced cardiac toxicity.

Methods: 14 Patients with SSc and cardiac involvement (defined as troponin T elevation plus right- or left ventricular systolic or diastolic dysfunction, myocarditis, pericarditis, right heart failure secondary to PAH, or arrhythmias) were analysed. Two patients each showed concomitant myositis and rheumatoid arthritis, respectively. Twelve patients were initially treated with CP and two patients with methotrexate (MTX). Due to a disease progress (either cardiac involvement, skin fibrosis or lung function) a therapy with rituximab and MPA was initiated [1]. These patients were followed for up to five years.

Results: Before initiation of CP or MTX electrocardiogram showed arrhythmias (atrial fibrillation, conduction blocks, multifocal ventricular extrasystoles (VES)) in 9 patients. Echocardiography revealed abnormalities in 10 patients including reduced left-ventricular ejection fraction (LV-EF), diastolic dysfunction, mitral regurgitation, or aortic aneurysm. 3 patients had PAH, 2 patients were diagnosed with post capillary pulmonary hypertension. Cardiac MRI revealed signs of myocarditis in 4 patients. 4 patients required cardiac resynchronization therapy or pacemaker implantation. Moreover, body plethysmography showed a reduction in forced vital capacity (FVC) in 12 patients, suggestive of restrictive lung disease. Under therapy with CP 11 patients had suffered from disease progress, 1 patient developed relapsing pneumonias and the 2 patients with overlap rheumatoid arthritis developed cardiac disease manifestations on MTX monotherapy. Consequently, rituximab 1000 mg q12weeks and MPA 1000 mg q2weeks were initiated. Under this combination troponin T decreased in all patients (p=0.0002), LV-EF improved in 5, remained normal in 7 and deteriorated in 2 patients. The rate of VES improved in 8 patients. In one patient, myocarditis resolved completely (MRI). Moreover, pulmonary artery systolic pressure, measured by echocardiography, improved in all patients diagnosed with PAH under stable therapy. The modified Rodnan skin score improved in all patients, FVC improved in 7 patients, remained stable in 6 and decreased in the patient with overlap myositis. Rituximab infusions could be extended (1000 mg q4weeks) after 24-36 months of treatment in 11 patients. All patients showed peripheral blood depletion of B cells without noticed severe IgG deficiency. While 11 patients did not develop severe complications 2 patients died during follow-up of pneumonia and cardiogenic shock (overlap myositis), respectively and one patient developed a relapse of lung cancer with cerebral metastasis.

Conclusion: Therapy with rituximab and MPA is a promising alternative. However, its use requires risk stratification of patients with respect to adverse side effects which needs to be explored in future studies.

Background: In the last years, the rate of successful pregnancies has significantly increased in Systemic Sclerosis (SSc) women. However, the long-term outcome of their children remains an unexplored issue.

Objectives: To evaluate the neuropsychiatric (NP) outcome of children born to SSc mothers.
Methods: An ad-hoc questionnaire, regarding different aspects of child’s neurodevelopment (ND) (3 sections: childhood [0-5 years]; school age [6-11 years]; adolescence [12-18 years]), was created and administered to female SSC patients (ACR/EULAR 2013 criteria) attending our outpatient clinic during 2021 and who had at least 1 child. Children’s NP characteristics were compared between 3 subgroups: A) born ≥10 years before SSC diagnosis; B) born ≤10 years before SSC diagnosis; C) born after SSC diagnosis. Results below are expressed as number/total number of answers collected for each question.

Results: 100 SSC women reported 189 pregnancies: 152 resulted in 154 live births (2 twin pregnancies).

At least one NP alteration was reported in 42/119 (35%) subjects, more frequently in group B (57%), as compared to group A (31%, p=0.07) and group C (30%, p=0.09) although not statistically significant (Figure 1). Sleep irregularities were the most frequently reported disorder (15/42, 36%). Comparisons between the 3 subgroups for each NP outcome evaluated are shown in Table 1: overall, a higher rate of NP alterations were reported in children belonging to group B.

In addition, SSC mothers declared that 7/123 (6%) children underwent a NP evaluation leading to a diagnosis in 3 cases: 1 cognitive delay, 1 learning disorder (LD) and 1 autism spectrum disorder (ASD). These children were born 1 and 5 years before and 3 years after SSC diagnosis, respectively. The prevalence of these diagnoses (0.8%) does not differ from general pediatric population.

Conclusion: Children born to SSC mothers, had prevalence of major NP alterations (cognitive deficits, LDs, ASDs) similar to general pediatric population. A higher frequency of minor ND disorders, especially sleep irregularities, was observed in children within 10 years before maternal diagnosis, compared to the other groups, possibly suggesting an impact of maternal chronic disease on the relationship with child in the first years of life. To confirm these self-reported preliminary data, the extension of the study will consist in a systematic NP evaluation proposed to all offspring of SSC mothers aged ≤18 years.

**BICENTRIC OBSERVATIONAL STUDY ON THE THERAPEUTIC MANAGEMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC SCLEROSIS OVERLAP SYNDROME**

**N. Lebe1, C. Marcelli2, I. Marie3, H. Levesque4, T. Lequerre5, O. Vittecoq.**

1Hospital Center University De Rouen, Rheumatology, Rouen, France; 2University Of Caen Normandie Hospital Center, Rheumatology, Caen, France; 3Hospital Center University De Rouen, Medecine interne, Rouen, France

**Background:** The rheumatoid arthritis (RA)/systemic sclerosis (SSc) overlap syndrome is a rare and understudied association. It affects 5% of patients with SSc. Only open studies evaluating biological drugs (bDMARDs) have reported encouraging results particularly on joint involvement. The management of these patients is therefore not codified.

**Objectives:** The objective was to analyze in real conditions the therapeutic strategy and the response to bDMARDs, with a focus on joint involvement.

**Methods:** We retrospectively analyzed over a 10-year period the clinical, biological, radiographic characteristics and therapeutic management of patients meeting the ACR/EULAR diagnostic criteria for RA and SSc in two academic centers. Response to bDMARDs was assessed according to EULAR and if unavailable according to therapeutic maintenance. The evolution of lung function test was also evaluated.

**Results:** Twenty-two patients were identified. Intestinal lung involvement was common (n=11). Only 7 patients were treated with csDMARD alone. The most commonly used drug was methotrexate. The use of bDMARDs was frequent (15/22), significantly greater in patients with rheumatoid factors (OR 66.7; p=0.004) and with a trend in patients with higher levels of anti-CCP (160 vs 15 IU; p=0.11) or diffuse interstitial lung disease (OR 10.6; p=0.063). Tocilizumab was the most selected therapy (n=8) followed by rituximab (n=5), abatacept, and anti-TNFs (n=4 respectively). We evaluated 21 treatment sequences, 19 of which were evaluated according to EULAR response criteria. bDMARDs that inhibits the activation of lymphocytes (abatacept, rituximab) generally resulted in significantly more often observed than tocilizumab sequences were stopped early due to intolerance and could not be evaluated. One patient received tofacitinib with a good clinical response but was discontinued at 9 months for intolerance. Lung function test data did not change significantly on bDMARD.

**Conclusion:** In patients with rheumatoid arthritis (RA)/systemic sclerosis (SSc) overlap syndrome, bDMARDs that inhibits the activation of lymphocytes (abatacept, rituximab) generally resulted in a good or moderate response (n=9/10) with a significant decrease in DAS28 at 6 months (-1.75; p=0.016). Cytokine inhibitors (tocilizumab, etanercept, infliximab) were less likely to achieve good or moderate control of joint involvement (n=3/9) with a smaller decrease in DAS28 at 6 months (-0.79; p=0.36). Two tocilizumab sequences were stopped early due to intolerance and could not be evaluated. The levels AMH negatively correlated with CYC therapy, erythrocyte sedimentation rate, with positive correlation with age and duration of disease.

**OVARIAN RESERVE IN SYSTEMIC SCLEROSIS**

**R. Goleva1, Z. Alekbrova2, M. Cherkasova3, O. Konova4, L. Garzanova4, D. Bizhanova.**

1V.A. Nasonova Research Institute of Rheumatology, trobavinflammation laboratory, 115522, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, systemic rheumatic disease, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, trobavinflammation laboratory, Moscow, Russian Federation; 4V.A. Nasonova Research Institute of Rheumatology, laboratory of sistemic sclerosis, Moscow, Russian Federation; 5Russian Children's Clinical Hospital, Moscow, Russian Federation

**Background:** The low prevalence of pregnancy in women with systemic sclerosis (SSc) is due to multi-factorial causes, including premature ovarian insufficiency (POI). Anti-Mullerian hormone (AMH) is one of the primary parameters for assessing reproductive function and ovarian reserve. The levels of AMH correlate with the residual follicular pool among women of reproductive age.

**Objectives:** To assess AMH levels in SSc female patients of child-bearing potential, and analyze the relationship between AMH levels and disease severity, as well as the relationship between serum AMH levels and different therapeutic regimens.

**Methods:** The study group included 48 women with SSc aged 20-40 years, and the control group included 15 age-matched healthy women. Pts' mean age was 32.9 (28.37) yrs, disease duration was 6.3 (3.10) yrs. Diffuse cutaneous subset of the disease had 41.7%, limited in 41.7% and overlap in 16.8% pts. AMH levels was measured using ELISA. AMH reference values ranged within 1.0-10.6 ng/ml. Values <1.0 were interpreted as a decreased ovarian reserve.

**Results:** Mean AMH level was 2.8 ng/ml in SSc pts, and 3.1 ng/ml in the control group, showing no statistical difference. A decrease in ovarian reserve (AMH less than 1.0 ng/ml) was significantly more common in SSc pts compared to controls (45.8% vs. 13%, p<0.05).

**Table 1. AMH and forms of SSc**

<table>
<thead>
<tr>
<th>AMH &gt;1 ng/ml, n (%)</th>
<th>13 (55%)*</th>
<th>7 (35%)*</th>
<th>2 (25%)*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean AMH</td>
<td>3.3 [0.4-5.6]*</td>
<td>2.3 [0.7-3.4]*</td>
<td></td>
</tr>
</tbody>
</table>

Mean AMH levels was significantly lower in the diffuse SSc in comparison with the limited SSc.

**Table 2. AMH and course of SSc**

<table>
<thead>
<tr>
<th>AMH &gt;1 ng/ml, n (%)</th>

<th>7 (35%)*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean AMH</td>
<td>3 [0.6-6.4]*</td>
<td>6 [4.24]*</td>
</tr>
</tbody>
</table>

Mean AMH levels was significantly lower in acute and subacute course of SSc. A decrease of ovarian reserve was significantly more often observed in subacute course compared to chronic course of SSc (68% vs 24%, p<0.03).

**Conclusion:** Ovarian reserve was significantly more often reduced in women with SSc compared to healthy controls. Mean AMH levels was significantly lower in the diffuse SSc compared to the limited SSc. Reduction of ovarian reserve was more often observed in diffuse form SSc. Mean AMH level was significantly lower in acute and subacute course of SSc. A decrease of ovarian reserve was significantly more often observed in subacute course SSc compared to chronic course. The levels AMH negatively correlated with CYC therapy, erythrocyte sedimentation rate, heart and gastrointestinal involvement (r=-0.31), digital ulcers (r=-0.36), and digital pitting scars (r=-0.28).

**TURKISH VALIDATION OF THE ‘COCHIN (DURUOZ) HAND FUNCTION SCALE’ IN PATIENTS WITH SYSTEMIC SCLEROSIS**

**A. Komaz f, D. Temiz Karadag, E. Basaran, A. Yazıcı, A. Çelebi, Kocate l University Faculty of Medicine, Rheumatology department, Kocaeli, Turkey**

**Background:** Hand impairment is the main challenge for patients with systemic sclerosis (SSc) and may arise from inflammatory arthritis, joint contractions, tendon friction rubs (TFRs), Raynaud's phenomenon (RP), digital ulcers (DU), puffy hands, skin sclerosis, acro-osteolysis, or calcinosis. There is not yet a tool which can objectively measure hand functions in scleroderma patients both in daily practice and for research purposes.

**Objectives:** To adapt and validate the Turkish version of Cochín (Duruoz) hand function scale (CHFS) and contribute to the development of outcome measures with good metric properties assessing hand disability in SSc (1).

**Methods:** Ninety one consecutive patients who fulfilled the 2013 ACR/ EULAR SSc classification criteria for SSc were enrolled in the study. Disease...
related involvements and physical examination findings of the patients were recorded. Participants filled out the self-administered questionnaire of the Turkish version of the CHFS. Modified Rodnan skin scores of the patients were calculated, bilateral hand extension and fingertip-palm distances were measured, grip strength was evaluated with hydraulic hand dynamometer. We evaluated convergent validity by testing the correlation between CHFS and related components of Short Form 36 version 2 (SF-36v2) and Scleroderma Health Assessment Questionnaire (sHAQ). Discriminant validity was evaluated by stratifying patients according to hand related involvements and disease subtypes. Thirty of the patients re-filled the CHFS questionnaire two weeks after the first visit.

Results: Demographic data and disease characteristics of the patients shown in Table 1. For the convergent validity, the CHFS significantly correlated with the sHAQ, Raynaud visual analog scale (VAS), digital ulcer VAS, overall disease severity VAS, hand grip, hand extension measurements and fingertip-palm distances (Table 2). The instruments could discriminate between disease subtypes (10-24) / 20-19, p=0.038 and between the patients with and without contractions (11-24) / 20-9, p=0.023 for the discriminant validity. We demonstrated high reproducibility for CHFS (ICC = 0.894, 95% confidence interval = 0.779-0.949).

AB0666 BODY COMPOSITION AND PHYSICAL FUNCTION AS POTENTIAL PROGNOSTIC BIOMARKERS IN PATIENTS WITH SIBM

K Y Jensen1,2, J Alcazar3,4, A N Jorgensen5,6, P Aagaard1, C Sueta1,7, L P Diederichsen1,8,9, Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; 2Department of Sports Science and Clinical Biomechanics, Odense, Denmark; 3Biocenter and Frederiksberg University Hospital, Department of Geriatric and Palliative Medicine, Geriatric Research Unit, Copenhagen, Denmark; 4Universidad de Castilla-La Mancha, GENUD Toledo Research Group, Toledo, Spain; 5CIBER of Frailty and Healthy Aging (CIBERFES), Faculty of Sport Sciences, Madrid, Spain; 6University of Southern Denmark, Department of Clinical Research, Odense, Denmark; 7Copenhagen University Hospital, Herlev and Gentofte, Department of Medicine, Geriatric Research Unit, Herlev, Denmark; 8Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; 9Odense University Hospital, Department of Rheumatology, Odense, Denmark

Background: Sjögren’s syndrome myositis (sIBM) is an acquired disease within the idiopathic inflammatory myopathy (IIM) spectrum, characterized clinically by progressive muscle atrophy, weakness and often severely impaired physical function leading to sarcopenia. Despite this, muscle mass and physical function is not routinely assessed in patients with sIBM.

Objectives: To investigate muscle mass, muscle power and physical function in patients with sIBM compared to healthy controls.

Methods: The study was a retrospective analysis of patients with sIBM (sIBM) and healthy age and gender matched controls (CON) from The Copenhagen Sarcopenia Study1. Appendicular lean mass (ALM) and skeletal muscle index (ALM/h2) was assessed by DXA (IDXA, GE). Muscle strength and physical function was evaluated by maximal horizontal gait speed (GS), 30-s sit-to-stand test (30s STS) and maximal leg extensor power (LEP) (PowerPig). A linear mixed-effect model for all outcome variables was used for the statistical analysis. A linear mixed-effect model for all outcome variables was used for the statistical analysis, including sex and health condition as fixed factors, and performed using SPSS v20 (Inc., Chicago, Illinois, USA), and the level of significance was set at α = 0.05 using two-tailed testing.

Results: In total, 22 patients with sIBM (18 men, age 69.8±4.6; 4 women, age 65.0±8.4) and 414 healthy age-matched controls (237 men, age 70.2±4.9; 177 women, age 65.5±5.4) were included. In men, ALM (sIBM: 21.4±3.1; CON: 25.3±3.6) and ALM/h2 (sIBM: 6.9±0.9; CON: 8.0±1.0) was reduced in sIBM compared to CON (p<0.05). In women, ALM (sIBM: 21.4±3.1; CON: 25.5±3.6) and ALM/h2 (sIBM: 6.9±0.9; CON: 8.0±1.0) was reduced in sIBM compared to CON (p<0.05). In women, ALM (sIBM: 21.4±3.1; CON: 25.5±3.6) and ALM/h2 (sIBM: 6.9±0.9; CON: 8.0±1.0) was reduced in sIBM compared to CON (p<0.05). In women, ALM (sIBM: 21.4±3.1; CON: 25.5±3.6) and ALM/h2 (sIBM: 6.9±0.9; CON: 8.0±1.0) was reduced in sIBM compared to CON (p<0.05). In women, ALM (sIBM: 21.4±3.1; CON: 25.5±3.6) and ALM/h2 (sIBM: 6.9±0.9; CON: 8.0±1.0) was reduced in sIBM compared to CON (p<0.05). In women, ALM (sIBM: 21.4±3.1; CON: 25.5±3.6) and ALM/h2 (sIBM: 6.9±0.9; CON: 8.0±1.0) was reduced in sIBM compared to CON (p<0.05). In women, ALM (sIBM: 21.4±3.1; CON: 25.5±3.6) and ALM/h2 (sIBM: 6.9±0.9; CON: 8.0±1.0) was reduced in sIBM compared to CON (p<0.05).

Conclusion: The present data demonstrate that muscle mass and physical function are reduced in patients with sIBM compared to healthy counterparts. Although data from larger studies are warranted, it may indicate that assessment body composition and physical function can be used as prognostic tools in these patients.

AB0667 EFFECT OF TEMPERATURE VARIATION ON SERUM KL-6 LEVELS IN PATIENTS WITH SYSTEMIC SCLEROSIS

H Hirose1, T Higuchi1,2, K Takagi3, A Tochimoto1, Y Kawaguchi1, M Harigai1, 7Tokyo Women’s Medical University Hospital, Division of Rheumatology, Department of Internal Medicine, Shinjuku City, Japan; 8Tokyo Women’s Medical University, Division of Multidisciplinary Management of Rheumatic Diseases, Division of Rheumatology, Department of Internal Medicine, Shinjuku-City, Japan; 9Adachi Medical Center, Tokyo Women’s Medical University, Department of Internal Medicine, Adachi-Ciy, Japan

Background: Serum Krebs von den Lungen-6 (KL-6) levels have much evidence as a biomarker about the progression and prognosis of interstitial lung disease (ILD), including systemic sclerosis (SSc)-associated ILD. However, serum KL-6
levels often fluctuate regardless of the progression of ILD. This sometimes mislead the evaluation of the disease activity, however, the reason for the fluctuation has not been clarified.  

**Objectives:** We tested the hypothesis that serum KL-6 levels are affected by ambient temperature in patients with SSc.

**Methods:** We defined the warm season (May–October) as the period when the ambient temperature was below the average. ILD was classified based on chest CT findings. Among SSc patients who had visited our department since May 2018, we selected those who had data of serum KL-6 levels at least 3 times in warm and cold seasons from October 2014 to September 2021, respectively. Patients who had malignancy and other co-morbidities were excluded after confirmation of the onset of malignancy using medical record retrospectively. The difference in serum KL-6 levels between warm and cold seasons were evaluated by Wilcoxon’s rank-sum test.

**Results:** In total, 252 patients with SSc were included. Median age was 66.3 years, with median disease duration of 13.5 (8.9–19.2) years, diffuse cutaneous type of 94 (37.3%) patients, and concomitant ILD of 120 (47.6%) patients (Table 1). The median follow-up was 6.4 (4.4–6.8) years, with median KL-6 measurement of 24 (14–39) times. Serum KL-6 levels were significantly higher in the cold season than that in the warm season, with a greater difference in the group with ILD (536 IU/L vs. 492 IU/L, p = 0.0012 in the group with ILD, 364 IU/L vs. 345 IU/L in the group without ILD, p = 0.0028).

PREGNANCY OUTCOMES IN SYSTEMIC SCLEROSIS, SYSTEMIC LUPUS ERYTHEMATOSUS AND BEHÇET’S DISEASE

R. Goloeva1, Z. AlekBereva2, L. Garzanova1, O. Koneva1, A. Lila1,2,4.1.V.A. Nasonova Research Institute of Rheumatology, troboinflammation Laboratory, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, advisory department, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, laboratory of sistemic sclerosis, Moscow, Russian Federation; 4V.A. Nasonova Research Institute of Rheumatology, systemic rheumatic disease, Moscow, Russian Federation

Objectives: To clarify pregnancy outcomes in patients with systemic sclerosis (SSc), systemic lupus erythematous (SLE) and Behçet’s disease (BD) using retrospective analysis.

Methods: The study group included 48 women with SSc, 47 with SLE 45 with BD aged 20-40 years, and the control group - 15 age-matching healthy women. SSc pts mean age was 32.9 [28.37] years, SLE pts 32.3 [29.36] years, BD pts 31.3 [27.35] years, disease duration 6.3 [3.10], 9.8 [3.16] and 6.0 [3.8] years respectively. Completed by all women issue-specific questionnaire covered clinical symptoms of SLE. SSc, BD and details of obstetric history (characteristics of menstrual and reproductive function, presence of genital and extragenital pathologial, previous pregnancies outcomes; previous intrauterine interventions, a history of coagulopathy).

Results: Retrospective analysis of thematic maps of 48 patients with SSc revealed: 28 patients had 77 pregnancies, 44 of which ended with the birth of children (13 by caesarean section in 9 patients); 3 women had 4 premature births at 28-35 weeks, one of which ended with perinatal death of the baby, 33 incomplete pregnancies in 19 patients: 28 medical abortions up to 12 weeks of gestation at the woman’s request; 5 pregnancy complications had 5 patients, spontaneous abortion - 3, undeveloped pregnancy - 2. The frequency of unfavorable pregnancy outcome was similar in patients with SSc and in the control group. Analysis of thematic maps of 47 patients with SLE: 27 patients had 68 pregnancies, 31 of which ended with the birth of children on time (12 by caesarean section in 9 patients); 3 women had 4 premature births at 27-33 weeks, two of which ended with perinatal death of the baby; 33 incomplete pregnancies in 18 patients: 15 medical abortions up to 12 weeks of gestation at the woman’s request, two women had 3 abortions for medical reasons; high activity of SLE); 15 pregnancy complications had 9 patients, spontaneous abortion had 8 pts, undeveloped pregnancy was observed in 7 women. The frequency of unfavorable pregnancy outcome was similar in patients with SLE and in the control group. 118 pregnancies in 35 pts with BD resulted in 75 live birth (6 cesarean section in 3 pts). Thirty-nine incomplete pregnancies were observed in 26 patients. Ten patients had 20 medical abortions on request before 12 weeks of gestation, one patient had an abortion due to medical reasons (rubella on the 7 th week of gestation), two patients had premature birth at 28 and 32 weeks with subsequent perinatal death of the baby. Fifteen out of 35 pts had 20 adverse pregnancy outcomes: 8 spontaneous abortion, 12 missed miscarriage. Nine patients had 12 Missed miscarriage at 6-11 weeks of gestation, one patient had 3 missed miscarriage, two had 2, and the others had 1 missed miscarriage. Six patients had 8 spontaneous abortions (early miscarriage). In the control group of 15 women, 7 had 15 pregnancies, 13 live birth of healthy children on time.

HISTOPATHOLOGICAL, CLINICAL AND SEROLOGICAL FEATURES IN IIM PATIENTS FROM A SINGLE CENTER COHORT

T. Vojinovic1, M. Olivari2, M. Fredi3, F. Franceschini1, I. Cavazzana1. 1ASST Spedali Civili of Brescia, Rheumatology and Clinical Immuno-Immunology Unit, Department of Clinical and Experimental Sciences, Brescia, Italy; 2University of Brescia, Faculty of Medicine and Surgery, Brescia, Italy

Background: Idiopathic inflammatory myositis (IIM) is a group of heterogeneous autoimmune diseases, characterized by myositis-specific (MSA) or myositis-associated autoantibodies (MAA). Muscle biopsy is the diagnostic gold standard, but correlations with elevated creatine level (CK) or MSA/MAA are unclear.

Objectives: To evaluate the association between specific histological findings and clinical and/or serological features in IIM patients from a single tertiary Rheumatology referral center.

Methods: We retrospectively analyzed demographic and clinical data from medical charts, of 184 patients affected by IIM followed-up for >1 year. Muscle biopsies of 89 IM patients were retrieved from deltoid, biceps or quadriceps muscle, snap-frozen and stored at -80°C and processed for routine histology and histochemistry.

Results: The majority of our muscle biopsy cohort was represented by Dermatomyositis (DM) (39.3%), Polymyositis (PM) (29.2%) and Anti-synthetase syndrome (ASS) (13.5%), whereas the rest was composed of Overlap Syndrome (OS), Immune-Mediated Necrotizing Myopathy (IMNM) and Inclusion-Body Myositis (IBM) (13.5%, 2.2% and 2.2% respectively). DM presented perifascicular atrophy in 85% of cases and perivascular and perifascicular infiltration in only 40% of cases, similar to other types of IIMs. The overall histology finding was characterized by minimal inflammation and/or necrosis but major atrophy. In comparison, Polymyositis showed more endomyalial infiltration and necrosis (Table 1). ASS was characterized by atrophy and perifascicular necrosis in 83% of cases, with perimysial and perivascular infiltration in 67% of cases. Those characteristics were observed both in anti-Jo-1+ (13.3%) and as non-Jo-1+ ASS patients (13.2%). Non-Jo-1+ ASS patients presented endomyalial infiltration, invading or enveloping the muscle fibers (not present in anti Jo-1+ (p: 0.036), with addition of rimmed vacuoles and aspecific clinical presentation. Moreover, in DM, anti-Mi2+ antibodies (9.3%) were significantly associated with perifascicular regeneration and endomyalial infiltration, in comparison to both anti-TIF-1+ (5.8%) and anti-NXP2+ patients (4.6%). No significant histopathological features were found in patients with anti-Ro52 autoantibodies (372%), that represented the most frequent MAA in our cohort.

Disclosure of Interests: None declared

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Conclusion:
No significant associations emerged between CK levels, different types of IIM and MSA. Some histological features seem to define subtypes of DM. A precise definition of autoantibody profile in IIM could define not only a clinical phenotype but also the muscle damage distribution.

<td>[1.13-7.7]</td>
<td>[1.94-9.5]</td>
</tr>
</tbody>
</table>

A redaction of ovarian reserve (AMH less than 1.0 ng/ml) was more often observed in SSc pts compared to controls (44% vs 13%), p=0.03. The mean AMH levels were significantly lower in pts with SSc receiving cyclophosphamide (CYC). Correlation analysis revealed a negative correlation between levels AMH and CYC therapy (r=-0.33, p<0.05), with erythrocyte sedimentation rate (r=-0.36), heart involvement (r=-0.32) and gastrointestinal involvement (r=-0.31), digital ulcers (r=-0.33) and digital pitting scars (r=-0.28). Correlation with other clinical manifestations, immunological markers and immunosuppressive therapy of SSc wasn't found. In five patients receiving CYC earlier, the level of AMH was within normal values, the total dose of CYC at them did not exceed 4g. No correlation was found between AMH and activity SLE (SLEDAI 2K), and analyze the relationship between AMH levels and disease severity, as well as relationship between serum AMH levels and different therapeutic regimens.

### Background:
Systemic sclerosis (SSc) is a multisystem, connective tissue disease characterized by fibrosis of the skin and internal organ involvement, which can influence quality of life and functional capacity. SSc patients show some problems associated with reduced quality of life.

### Objectives:
SSc is a multisystem, connective tissue disease characterized by fibrosis of the skin and internal organ involvement, which can influence quality of life and functional capacity. SSc patients show some problems associated with reduced quality of life.

### Methods:
In total, 51 patients with SSc were included: 50 women and 1 man (mean age: 63.2 ± 10.1 years, limited SSc 28/diffuse SSc 23, median duration since first non-Raynaud symptom: 10.1 years) who fulfilled the ACR/EULAR classification criteria (2013), filled in questionnaires assessing disability (HAQ, Health Assessment Questionnaire) and quality of life (SF-36, Medical outcomes study Short Form 36 - Physical Component Summary and Mental Component Summary).

### Results:
Average HAQ in patients with limited and diffuse SSc was 0.66±0.58 and 0.9±0.59. Data analysis showed that 59% of the patients were in the mild to moderate HAQ disability category (0 ≤ HAQ < 1), 39% in the moderate to severe disability category (1 ≤ HAQ < 2), and 2% in the severe to very severe disability category (2 < HAQ ≥ 3). The SF36 mean scores of the total group were 34.8±8.7 on the Mental Component Summary and 37.0±13.1 on the Physical Component Summary.

### Conclusion:
SSc and its complications decrease quality of life and functional capacity. Although validated in SSc, the HAQ disability index underestimates respiratory failure due to interstitial lung disease, gastrointestinal symptoms, cardiovascular complications and severity of Raynaud phenomenon. Alternative measures of functional impairment should be examined. Health-related quality of life, which was assessed by the SF-36 is reduced in both physical and mental domains. It should be taken into account by clinicians for further improvement of treatment and development rehabilitation program.

PROVIDING PATIENTS WITH SYSTEMIC SCLEROSIS
BY MEDICAL CARE IN RUSSIA: THE FIRST DATA
FROM MOSCOW REGISTER OF SYSTEMIC
SCLEROSIS

D. Khorolskii1, N. Babadaeva2, E. Zhilyaev3, N. Shostak4, A. Klimenko3,
A. Kondrashov3, E. Pershina5, D. Somov6, E. Mikheeva6on behalf of Register
of patients with idiopathic inflammatory myopathies, systemic sclerosis and
mixed connective tissue disease in Moscow. 1Pirogov Russian National
Research Medical University, Health Department of Moscow, Moskva, Russian
Federation; 2Городская клиническая больница № 1 им. Н.И. Пирогова,
Moscow City Rheumatological Center, Moskva, Russian Federation; 3Pirogov
Russian National Research Medical University, Department of Faculty Therapy,
Moskva, Russian Federation; 4Pirogov Russian National Research Medical
University, Department of Faculty Therapy, Moskva, Russian Federation;
5
Городская клиническая больница № 1 им. Н.И. Пирогова, Radiograpic
studies department, Moskva, Russian Federation; 6Pirogov Russian National
Research Medical University, Department of Faculty Therapy, Moskva, Russian
Federation
Background: Systemic sclerosis (SSc) is a multisystem, connective tissue
disease characterized by fibrosis of the skin and internal organ involvement,
which can influence quality-of-life and functional capacity. 1 The mortality rate
is increasing in the United States and Europe; as many as 3.08 persons are
affected per 1 million. Changes in lungs and heart, pulmonary hypertension are
the most significant reasons of death in patients with systemic sclerosis.2
Objectives: To estimate quality and completeness of medical care in patients
with systemic sclerosis in Russia.
Methods: 66 patients included in the study. 61 female and 5 male (mean age: 62,48
± 10,1), among which there were 24 limited SSc (lSSc) and 42 diffuse SSc (dSSc).
All patients fulfilled the ACR/EULAR classification criteria. We estimated percentage
of patients, who were examined by basic studies: capillaroscopy, functional lung
tests, echocardiography, HRCT, fully immunologic study and right heart catheterization etc. and try to understand reasons of incompleteness of these assessments.
Results: Despite the presence of Raynaud’s phenomenon in 85% of patients,
capillaroscopy was performed only in 65.21% of them, examination of the esophagus was performed in only 22.92% of patients, with development of dysphagia
in 50% of patients. HRCT was performed in 54.71% (25.76% NSIP, 9.09% UIP),
right heart catheterization in 4.17% (signs of pulmonary hypertension according
to ECHO detected in 42.86% of patients). FLT were performed in mostly patients
(86.34%), but it wasn`t fully: measuring of DLCO was realized only in patients
with severe desease (22.92% оf patients). That explains its low mean level
(61.37% from normal) as opposed to mean FEV1 (90.7% from normal) and FVC
(89.47% from normal) level. Fully immunologic study was performed in 35.42%
of patients, despite the fact that different autoantibodies showed up in 72.92% of
patients (the most common were: antiScl70 41,67%, ACA 22,92%, ANF 52,08%).
Conclusion: According to the results of the study, we have identified a significant
decrease in the quality of medical care despite the clinical recommendations and generally accepted standards. We suppose. that the main reasons for this situation are the
complex healthcare problems: insufficient competence of doctors, lack of collaboration
between related specialties, unavailability of a number of studies within the framework
of free medicine and high cost of these studies for the patients themselves, and the
lack of time for communication between the doctor and the patient to explain the seriousness of the disease and the nescessity of all parts of examination and treatment.

Background: Mixed connective tissue disease (MCTD) is a systemic auto-immune disorder, being probably the least common among the connective tissue
diseases. Symptoms can be severe and could affect health-related quality of life
(HRQoL). Identification of the burden of MCTD patients is of key importance to
provide appropriate pharmacological and non-pharmacological care. No reports
on HRQoL have been published in adult patients with MCTD.
Objectives: To perform an explorative study to evaluate HRQoL and its main
determinants in MCTD patients, and compare HRQoL between MCTD and
matched systemic sclerosis (SSc) patients.
Methods: MCTD patients fulfilling the Kahn criteria and participating in the
MCTD prospective follow-up cohort of the Leiden University Medical Center
were included. In addition, SSc patients matched for age, gender and disease
duration were included for comparison. Data on disease characteristics, functional disability and HRQoL were collected annually for both disease groups.
HRQoL was evaluated using the 36-Item Short Form Health Survey (SF36) and
EuroQol (EQ5D). At baseline, HRQoL, as reflected by SF36 mental component
score (MCS), SF 36 physical component score (PCS) and EQ5D were compared
between MCTD and SSc patients. For MCTD patients, factors associated with
HRQoL at baseline were identified using linear regression and change in HRQoL
over 3 years was evaluated using linear mixed models. In addition, characteristics of MCTD patients who showed worsening of MCS and/or had PCS superior
to the minimal clinical important difference of three points were identified.
Results: Thirty-four MCTD patients (121 visits; 82% female, mean age 42 years,
median disease duration 45 months) and 102 SSc patients (424 visits; 82% female,
mean age 45 years, median disease duration 49 months) were included. At baseline,
MCTD-patients more often had ILD (47% vs. 34%, p=0.027), cardiac involvement (30%
vs. 2%, p<0.001), synovitis (26% vs. 11%, p=0.004) and myositis (15% vs. 1%, p=0.001)
compared to SSc patients, whereas SSc patients more often used immunosuppressive
treatments except for hydroxychloroquine (MCTD:18% vs. SSc:7%, p=0.007).
Baseline HRQoL in MCTD was comparable to HRQoL in SSc, with mean SF36PCS of 40.2 (SD:9.1) and mean SF36-MCS of 44.9 (SD:9.9), which is (nearly)
one standard deviation lower than the general Dutch population. The SF36 subscore “general health perception” was the most impacted in both groups (MCTD:
38.5 [SD:7.0], SSc: 39.9 [SD:8.9]). The median EQ5DNL was 0.38 (IQR:0.14
– 0.54) and comparable between SSc and MCTD.
At baseline, in MCTD, ILD was significantly associated with SF36-PCS (β:6.98,
95% CI: 1.10 to 12.86) and SF36-MCS (β:-8.10, 95% CI:-14.93 to -1.26). Sclerodactyly was significantly associated with EQ5DNL (β:0.006; 95% CI:0.002 to 0.010)
and SF36-PCS (β:0.12, 95% CI:0.03 to 0.21). No other significant associations
were identified.
Over time, in MCTD, both the SF36-MCS and SF36-PCS improved significantly
(MCS: β:2.35/year [95% CI:0.58 to 4.13], PCS: β:1.34/year [95% CI:0.03 to 2.65),
whereas EQ5DNL was stable. Explorative analyses did not reveal a specific clinical
characteristic with significant impact on the change of HRQoL over time. With an
MCID of 3 points on the MCS and PCS, 7 MCTD-patients worsened on the MCS
and 3 on the PCS. Patients who showed worsening of MCS over time tended to
be older, more often had ILD, sclerodactyly and GI complaints, and had worse
exercise tolerance. All these differences did not reach statistical significance. The
patients who decreased PCS more often had ILD (100% vs. 41%, p=0.015), and
used glucocorticoids more often (33% vs. 0%, p=0.046), were slightly older and
had a worse exercise tolerance as compared to those who showed a stable/
improving PCS over time.
Conclusion: Like in SSc, HRQoL is significantly impaired in MCTD, especially
the general health perception of patients. Cardiac involvement, ILD, age and
worse functional disability might specifically impact HRQoL in MCTD. However,
these associations need further evaluations in larger cohorts.

AB0676

ONE YEAR PROGRESSION OF INTERSTITIAL LUNG
DISEASE IN CONNECTIVE TISSUE DISEASES.
A DESCRIPTIVE STUDY IN A SINGLE TERTIARY
CENTER.

C. L. Garcia Gomez1, L. Vega1, O. Ibarguengoitia2, M. Enjuanes1, I. Calvo2,
D. Montero2, J. M. Blanco1, M. L. García Vivar1, E. Galindez1, A. R. Inchaurbe1,


Background: Intestinal lung disease (ILD) in connective tissue diseases (CTD) is an important cause of morbidity and mortality.

Objectives: To evaluate ILD in CTD (systemic sclerosis, myositis, Sjögren syndrome, rheumatoid arthritis, mixed connective tissue disease), sarcoidosis and interstitial pneumonia with autoimmune features and its progression in 12 months evaluated through high resolution computed tomography (HRCT) and pulmonary function test (PFT).

Methods: A retrospective single tertiary center cohort study in CTD-ILD outpatients seen between 2012 and 2021. Clinical, serological data, PFT and HRCT results were collected. ILD patterns were classified into usual interstitial pneumonia (UIP), inconsistent UIP, nonspecific interstitial pneumonia (NSIP), fibrosing NSIP, organizing pneumonia, interstitial lymphoid pneumonia and associated to sarcoidosis. Progression of ILD was defined as: ->10% decline in FVC in PFT. ->15% decline in DLCO in PFT.

Progression of fibrosis in HRCT.

IBM SPSS v23 was used for statistical analysis.

Results: 51 patients were collected. Baseline characteristics are shown in Table 1. Figure 1 shows ILD progression in 1 year.

Note: POCO = Pulmonary Obstructive Chronic Disease, SLE = Systemic Lupus Erythematosus, MCTD = Mixed Connective Tissue Disease, RA = Rheumatoid Arthritis, IPAF = Interstitial Pneumonia with Autoimmune/Fib-NSIP, PHT = Pulmonary Hypertension, UIP = Usual Intestinal Pneumonia, Incons-UIP = Inconsistent Usual Intestinal Pneumonia, NSIP = Nonspecific Interstitial Pneumonia, Fib-NSIP = Fibrosing Nonspecific Interstitial Pneumonia, Organizing Pneumonia, Interstitial Lymphoid Pneumonia, Anti-fibronectin protein = Anti-fibronectin Protein, Anti-intercellular antibody = Anti-intercellular Antibody, Anti-Rn = Anti-Ribonucleoprotein, Anti-synthetase = Anti-synthetase.

Conclusion: In our series most patients were middle aged women. Anti-Ro antibodies and smoking status (former or current) were common among patients. Common clinical features were Raynaud (45%), skin affection (45%) and arthritis (40%). 47% of the patients expressed dyspnea at ILD diagnosis, 25.4% were treated with MP pulses, 23.5% with rituximab, 31.4% with mycophenolate mofetil. Fibrosing pattern in HRCT (UIP and fib-NSIP) was the most prevalent. 20% of the patients had progressive fibrosis under PFT criteria and 18% under HRCT. More studies of ILD-CTD are necessary to identify factors for progression and response to treatment and throw out more conclusions of prediction and progression of disease.

AB0677 FREQUENCY AND RISK FACTORS OF OSTEOPOROSIS IN FERTILE WOMEN WITH SYSTEMIC SCLERODERMA

A. Sorokina1, O. Dobrovolskaya1, O. Nikitinskaya1, N. Demin1, N. Toroptsova1, 1VA. Nasonova Research Institute of Rheumatology, osteoporosis laboratory, Moscow, Russian Federation

Objectives: To determine the frequency and risk factors of osteoporosis (OP) in fertile women with systemic scleroderma (SSc).

Methods: 64 women (36.0 [31.5; 43.5] years old) with SSc were enrolled in the study: 35 (54.7%) with limited and 29 (45.3%) with diffuse cutaneous subtype without overlap rheumatic syndromes. The median disease duration was 5.0 [2.0; 5.0] years. Glucocorticoids (GC) were taken by 49 (78.6%) patients with the median duration of treatment 5.0 [2.0; 10.0] years. Dual energy X-ray absorptiometry (DXA) of the lumbar spine, the femoral neck and the total hip was performed. To estimate the value of the BMD the Z-score was used. Low BMD was considered at a Z-score < -2.0 SD. A univariate logistic regression analysis was performed to analyze the factors associated with OP.

Results: Low BMD was detected in 8 (12.5%) patients. 5 (7.8%) women had a history of low-trauma fracture, among them only 1 (1.6%) patient had low BMD and 4 (6.2%) persons - normal BMD. A univariate logistic regression was performed to identify OP risk factors. Among traditional risk factors, low body mass index (BMI) associated with OP (OR 1.39 [1.04; 1.88], p=0.03) and falls during the past year (OR 1.39 [1.04; 1.88], p=0.03) and falls during the past year (OR 5.25 [1.39; 1.88], p=0.02). Among specific ones – duration of GC using (OR 1.11 [1.00; 1.23], p=0.04), hand joint contractures (OR 8.54 [1.41; 51.63], p=0.02). There was no effect of smoking, treatment with proton pump inhibitors, family history of osteoporosis, age, subtype SSc, modified Rodnan score, digital ulcer, cutaneous calcification, esophageal hypotension, interstitial lung disease, diffusing capacity of the lung for carbon monoxide, force vital capacity, CRP, erythrocyte sedimentation rate, creatinine, presence of antinuclear antibody, anticientromere antibody or antiperoxidasemase I antibody on the development of OP in fertile women with SSc.

Conclusion: Low BMD was detected in 12.5% of fertile women with SSc. Low BMI, falls during the past year, duration of SSc and GC taking, hand joint contractures associated with OP.

DOI: 10.1136/annrheumdis-2022-eular.2584
Background: Idiopathic inflammatory myopathies (IIM) are associated with systemic inflammation, limited mobility, and glucocorticoid (GC) therapy, which can negatively impact metabolic disorders, atherogenesis, and increase the cardiovascular (CV) risk.

Objectives: This study aimed to evaluate CV risk in IIM patients compared to healthy controls (HC) and explore its associations with disease-specific features.

Methods: 39 patients with IIM (32 females; mean age 56; mean disease duration 4.8 years; dermatomyositis 16, polymyositis 7, immune-mediated necrotizing myopathy 8, antisynthetase syndrome 8) and 39 age-/sex-matched HC (32 females, mean age 56) were included. Subjects with a history of CV disease (angina pectoris, myocardial infarction, cerebrovascular, and peripheral arterial vascular events) were excluded in both groups.

Disease activity, damage, and muscle involvement (Manual Muscle Test (MMT)-8, Myositis Intention to Treat Activity Index (MITAX), Myositis Damage Index (MDI)) were assessed. Comorbidities and current treatment were recorded. All participants underwent examinations of carotid intima-media thickness (CIMT), pulse wave velocity (PWV), ankle-brachial index (ABI), and body composition (densitometry; IDXA Lunar, bioelectric impedance: BIA2000-M). The risk of fatal CV events was evaluated by the Systematic Coronary Risk Evaluation (SCORE and SCORE2, charts for the European population; modified mSCORE according to the 2015 EULAR recommendation for inflammatory arthritis - only in IIM patients).

Results: In IIM, disease activity and damage were predominantly mild (MITAX 0.13, MDI 0.05). Compared to HC, there was no significant difference in the prevalence of traditional risk factors. Only PWV was significantly increased in IIM compared to HC (p<0.015). No other significant difference was observed between the IIM and HC regarding the CV examinations (CIMT, ABI, carotid plaques) and calculated SCORE and SCORE2 (p>0.05 for all). In IIM, age and mean arterial pressure were the most significant parameters that correlated positively with SCORE, SCORE2, and mSCORE: arterial hypertension was significantly associated with a higher SCORE, carotid plaque count/thickness, and PWV. Lipid profile parameters, body composition, and disease activity were significantly associated with CIMT and carotid plaques (p<0.05 for all). Antihypertensive treatment was associated with an increase in carotid plaque count/thickness (p=0.009, p=0.008). Diabetes was associated with lower (worse) ABI values (p=0.034), prediabetes with a higher carotid plaque count (p=0.036) and thickness (p=0.011), and a worse ultrasound examination related CV risk (p=0.006). Anti-Jo-1 positivity was associated with a lower (better) CIMT and lower SCORE (p<0.05 for all). There were no significant associations of CV risk with clinical manifestations, immunosuppressive treatment, and GC cumulative dose. However, exposure time to GC therapy was significantly associated with the carotid plaques count (p=0.001) and the carotid plaque thickness (p=0.003). In multivariate analysis, the age of the patients was the most significant factor affecting most of the parameters analyzed (SCORE and its modifications, PWV, CIMT, and the total count of carotid plaques). Other significant predictors were total cholesterol and atherogenic index of plasma (for ABI), mean arterial pressure (for PWV), and disease duration (for the total count of carotid plaques).

Conclusion: No significant differences in CV risk factors between IIM patients and HC were observed. In IIM, CV risk was associated with age, disease duration, duration of glucocorticoid therapy, lipid profile, and body composition, but not with clinical manifestations and disease activity.

Figure 1. Efficacy Outcome. Figure 1. *p< 0.05 (Wilcoxon test).
After two years of follow-up, we observed the following adverse effects: headache (n=6), pruritus (n=3), allergic reaction (n=2) and arterial hypertension (n=1). No heart failure, renal insufficiency or thrombotic events were found.

Conclusion: IVG seems effective and safe in IIM treatment.

AB0680
PSYCHOLOGICAL IMPACT OF AUTOLOGOUS STEM CELL TRANSPLANTATION IN SYSTEMIC SCLEROSIS PATIENTS AND INFLUENCE OF SUPPORT AND COPING STRATEGIES.

1University of Wuerzburg, Rheumatology/Clinical Immunology, Department of Internal Medicine II, Wuerzburg, Germany; 2University of Wuerzburg, Institute of Psychology, Wuerzburg, Germany; 3University Hospital Tuebingen, Centre for Interdisciplinary Clinical Immunology, Rheumatology and Auto-inflammatory Diseases and Department of Internal Medicine II (Oncology, Hematology, Immunology, Rheumatology), Tuebingen, Germany

Background: In severe cases of systemic sclerosis (SSc), autologous hematopoietic stem cell transplantation (aHSCT) is superior compared to cyclophosphamide with respect to effect on skin and lung manifestations, survival and quality of life. Nevertheless, major physical and psychological impacts have been found in a first qualitative study by Spierings et al. (2020) 1. Objectives: Assessment of subjectively experienced physical and psychological impacts of aHSCT and exploration of potential interrelations of those impacts.

Methods: A SSc sample was assessed retrospectively after aHSCT in a two-step-approach. In the first step, 6 questionnaires were used: Global physical and mental health (SF-36 and Scleroderma Health Assessment Questionnaire = SHAQ), body image (Adapted Satisfaction with Appearance Scale = ASWAP), coping strategies (Freiburger Fragebogen zur Krankheitsverarbeitung = FKV-15), resilience (Resilienzskaala = RS-11), and control beliefs (Fragebogen zur Erfassung von Kontrollüberzeugung zu Krankheit und Gesundheit = KOKG). In the second step, semi-structured interviews based on Spierings et al. (2020) 1 were conducted and analysed via mixed methods qualitative content analysis following Mayring (2014).

Results: 19 patients (12 female, 7 male, mean age 53.47 years (SD = 9.50)) completed all questionnaires and interviews in a mean time of 6.56 years after aHSCT (SD = 3.90, range 1-12 years). A strong correlation was found between perceived physical impairment (SHAQ) and body image dissatisfaction (ASWAP) (Pearson's r = .83, p < .001). There was also a strong negative correlation between body image dissatisfaction (ASWAP) and the physical component of SF-36 (pcSF-36; r = -.59, p = .004) and a smaller correlation for the mental component of SF-36 (mcSF-36; r = -.38, p = .054). Depressive coping was negatively associated with SF-36 (pcSF-3; r = -.605, p = .003; mcSF-36; r = - .808, p < .001) (see Figure 1), whereas resilience was associated with a positive impact (pcSF-36; r = .522, p = .002; mcSF-36 r = .585, p = .004). In the qualitative content analysis of the interviews, all patients reported symptom improvements (mainly skin), which were associated with their coping strategies (depressive coping with fewer improvements, active coping with more improvements). Describing their emotional state during aHSCT, 7 patients verbalized "despair", 6 "loss of control", 5 "emotional instability", 4 "distress due to distance from home", 4 "fearlessness", 3 "listlessness", 2 "concern for feelings of relatives", and 2 "depersonalisation". As valuable professional emotional support during aHSCT, 6 patients named nurses and 8 named physicians, while the crucial role of daily ward rounds of the specialised transplant team rather than the primary care team was emphasised. The additional support by a psychology team was not deemed necessary by 7 patients, while 4 patients would have wished such a support. 7 patients rated their physical and mental recovery after aHSCT as satisfying, 4 as better than expected, 4 as disappointing, and 3 as causing impatience.

Conclusion: A transient negative impact of aHSCT on mental wellbeing of the majority of SSc patients is evident, but can be relieved by professional teams highly specialised in this particular treatment option.

AB0681
THE 2-YEAR IMPACT OF COVID-19 PANDEMIC ON MUSCLE STRENGTH AND PHYSICAL PERFORMANCE IN PATIENTS WITH SYSTEMIC SCLEROSIS: A COHORT STUDY

L. Denardi Dória1, R. Cavalheiro do Espírito Santo1, L. Santos1, D. Nóbrega de Moraes1, E. Pena2, J. Katarina Schoer Portes1, A. A. Gasparin2, N. Pamplona Bueno de Andrade2, V. Hax2, R. Xavier1,2, R. Mendonça da Silva Chakr2,3.
1Federal University of Rio Grande do Sul, Laboratório de Doenças Autoimunes, Porto Alegre, Brazil; 2Hospital de Clínicas de Porto Alegre, Division of Rheumatology, Porto Alegre, Brazil

Background: Systemic sclerosis (SSc) patients are particularly prone to developing loss of muscle strength and worsening of physical performance due to decreased physical activity2. The lifestyle changes imposed by the SARS-CoV-2 outbreak have increased the incidence of sarcopenia in at-risk individuals2. However, the literature is scarce on the impacts of the COVID-19 pandemic on muscle strength and physical performance of SSc patients.

Objectives: (1) To assess the impact of the COVID-19 pandemic on muscle strength and physical performance of SSc patients and (2) to verify the associations of muscle strength and physical performance with inflammatory markers in a cohort study.

Methods: SSc patients who met the ACR / EULAR 2013 classification criteria were included. Patients followed between 2019 and 2021. Muscle strength was measured by handgrip strength (kg) and sit and stand (SST, seconds) tests. Physical performance was measured by timed up and go (TUG, seconds) and short physical performance battery (SPPB, points). Inflammatory markers were measured by C-reactive protein (CRP). T-test for independent samples, Mann-Whitney U test of independent samples and Spearman’s correlation coefficients were explored. The significance level was set at p ≤ 0.05 for all analyses.

Results: Forty SSc patients concluded this study. At baseline, the mean age was 59 ±11.1 years old and the median disease duration was 13.1 (6.4-19.2) years. Patients had a median of 4.5 clinic visits (3.0-6.0) over the 2 years. The majority of patients were women (37, 92.5%). Ten patients (25%) had diffuse cutaneous disease, 30 patients (75%) non-diffuse cutaneous disease [25 patients (62.5%) had limited cutaneous disease, and 5 (12.5%) had sine scleroderma SSc]. The median of CRP was 2.9 (12.5-3.5). The median of handgrip strength was 20.0 (10.3-25.6) kg to the right hand and 19.0 (12.0-22.6) kg to the left hand. The median of SST was 14.4 (11.9-18.7) seconds. The median of TUG was 6.8 (7.7-9.5) seconds and the median of SPPB was 9.8 (9.0-11.0) points. The CRP was positively associated with SST (n=0.3, p=0.047) and TUG (n=0.5, p=0.029), and negatively with SPPB (n=0.4, p=0.016). After 2 years of follow-up, the patients showed improvement in the left handd grip strength test (p=0.049) and SST (p=0.001). In physical performance, they showed improvement in the TUG test (p=0.005) and SPPB (p=0.001). The CRP was associated positively with SST (n=0.4, p=0.033), no other associations were found.

Conclusion: Despite the COVID-19 pandemic and the restrictions imposed, in this population of patients with SSc, we did not detect any worsening in muscle strength and physical performance. Some of these parameters of muscle strength and physical performance were associated with the inflammatory marker CRP. More investigations are needed to assess the actual impact and possible associations.

FREQUENCY OF SEXUAL DYSFUNCTION IN SYSTEMIC SCLEROSIS, SANTO DOMINGO, DOMINICAN REPUBLIC

J. Santana Peralta1, A. Cornejo1, D. García1, R. A. Alvarez Santana1, T. Polanco Mora1, L. Concepción Sánchez2, I. Paulino1, I. Meredes3, E. Rodríguez Bautista1, T. Valdez Lorie1, A. Feriz2, R. MuñozLouis2, 3Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic; 1Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease. Sexual function has been associated with a high prevalence of dissatisfaction. Various factors have been implicated as causes of impaired sexual function. CSFQ-14 (Changes in Sexual Functioning Questionnaire) assesses changes in sexual functioning due to disease and/or treatment in 5 domains with a score range of 14-70; cut-off point indicating sexual dysfunction < 41 men and < 47 women.6

Objectives: To evaluate the frequency and degree of sexual dysfunction in patients with systemic sclerosis. Methods: Prospective, observational, cross-sectional study of the cohort of the Rheumatology service of Hospital Docente Padre Billini. Patients were interviewed in November 2021. Inclusion criteria: > 18 years, diagnosis of SSc by ACR/EULAR 2013 classification criteria, at least 1 sexual relationship. Exclusion criteria: previous diagnosis of another autoimmune disease, depression, diabetes, treatment with antidepressants, antiplatelets, narcotics, Measurement of CSFQ-14, mRSS. Statistical analysis was performed with the Pearson correlation (r) with p<0.05. The data was analyzed by SPSS V23.

Results: Of 63 patients, 54 met the inclusion criteria. 100% female, mean age 53 ± 15.07 years, mean duration 11.3 years, ISSc 24.1% (13), dSSc 75.9% (41), single 50% (27), married 44.4% (24), widowed 5.6% (3). Frequency of sexual dysfunction was 81.5% (44). Domains: pleasure 79.6% (43), desire_interest 37% (20), frequency 53% (28), desire/frequency 37% (20), physical aptitude 35% (19), psychological aptitude 26% (14). The desire/frequency dysfunction domain turned out to be the one with the highest presentation, followed by the orgasm/completion domain. A statistically significant linear association between sexual dysfunction and cutaneous activity of the disease was evidenced.

POLYNEUROPATHY IMPACT ON DISABILITY IN SYSTEMIC SCLEROSIS PATIENTS

K. Ivanova1, 2, O. Budreivica3, D. Zukovs4, E. Mozeltova4, V. Kenina5, N. Kurjina3, 1Pauls Stradins Clinical University Hospital, Rheumatology Centre, Riga, Latvia; 2Riga Stradins University, Department of Clinical Studies, Riga, Latvia; 3University of Latvia, Residency, Riga, Latvia; 4Riga Stradins University, Faculty of medicine, Riga, Latvia; 3Riga Stradins University, Department of Biology and Microbiology, Riga, Latvia

Background: Systemic sclerosis (SSc) is one of the most severe autoimmune rheumatic diseases with high morbidity and mortality rates. Peripheral neuropathy in SSc is reported with a broad prevalence variable between 0.01% to 28%.2 Developed in 1978, the Health Assessment Questionnaire Disability Index (HAQ-DI) for rheumatoid arthritis, nowadays is widely used to measure functional status in patients with SSc as well, but data are lacking in SSc patients with peripheral neuropathy (PN).3

Objectives: To determine the impact of PN on disability in SSc patients. Methods: This was a cross-section study in patients with SSc. Study was conducted in two University hospitals in Latvia for adults. Study included patients diagnosed with SSc with the ACR / EULAR 2013 accepted classification criteria and have been consulted by rheumatologists between 1st January 2016 and 31st July 2021. Patients who agreed to comply in the study were evaluated by one rheumatologist and were surveyed and clinically evaluated according to The European Scleroderma Trials and Research group accepted domains. Disease duration was defined as time from first non-Raynaud SSc symptom to date of examination. SS subtype was evaluated in each patient by clinical presentation that included modified Rodnan score (mRSS) as well: limited cutaneous systemic sclerosis (cSSc) with skin thickening distal to the elbow/knee and diffuse cutaneous systemic sclerosis (dcSSc) with skin thickening proximal to the elbow/knee. For neuropathic pain assessment, the Neuropathic Pain Diagnostic Questionnaire (DN4) was used. Peripheral neuropathy symptoms were assessed using total neuropacy score (TNS). Peripheral nerve conduction study (NCS) and quantitative sensory testing (QST) was used to detect PN.

Functioning and disability were assessed using HAQ-DI. All patients completed the HAQ-DI form in the same day as they were evaluated, filling the form in native language.

Results: From 109 acknowledged patients, 67 were able to come for a visit, 54 females, 13 males. Mean age for females 62.54±12.02 years, for males 58.69±14.50 years. After assessment by rheumatologist, 50 were classified as cSSc, 17 were classified as dcSSc. The overall ratio of cSSc and dcSSc was 50:17 in females 41:13, in males 9:4. Disease duration ranges from 1 to 39 years (mean 15.49±10.18), 16.61±10.47 years for females, 10.85±7.55 years for males. Large fiber PN was diagnosed in 47% of subjects by NCS (n=32/67) and small fiber PN in 40.3% of subjects by QST (n=27/67), while 19.1% had neither (n=8/67). Mean HAQ-DI score was 1.22. There was no statistically significant difference in HAQ-DI score between males (1.08±0.89) and females (1.26±1.01), (p=0.13). As well there was no difference between HAQ-DI score in patients with large fiber/small fiber neuropathy and without neuropathy symptoms (p=0.6817). But we found that neuropathy symptoms (assessed by TNS) have moderately strong and statistically significant correlation with HAQ-DI and neuropathic pain (assessed by DN4) (n=40.5, p=0.00015).

Conclusion: PN is more common complication in SSc that was previously reported, with significant impact on QoL.

FATIGUE ASSESSMENT IN SYSTEMIC SCLEROSIS, SANTO DOMINGO, DOMINICAN REPUBLIC

J. Santana Peralta1, A. Cornejo1, D. García1, R. A. Alvarez Santana1, T. Polanco Mora1, L. Concepción Sánchez2, I. Paulino1, I. Meredes3, E. Rodríguez Bautista1, T. Valdez Lorie1, A. Feriz2, R. Muñoz Louis3, 3Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease. Fatigue has been reported in 75% of SSc patients, and is the most problematic symptom due to impact on quality of life. Despite its high prevalence, origin is unknown. Some studies associate it with the degree of disease activity and decreased quality of life. Fatigue is defined as a feeling of exhaustion, also as a reduction in physical and mental capacity, scales such as FACIT-F (Functional
Assessment of Chronic Illness Therapy-Fatigue) are used, which evaluates the last 7 days, with a score of 0-52. For the severity analysis, 4 grades are used: no or mild fatigue (40-52), moderate (27-39), severe (14-26) and extreme (0-13).

Objectives: To evaluate the frequency and degree of fatigue in systemic sclerosis.

Methods: Prospective, longitudinal, observational study of the cohort of patients of the Rheumatology service of the Hospital Docente Padre Billini. Patients were interviewed in November 2021. Inclusion criteria: ≥18 years, diagnosis of SSc according to ACR/EULAR 2013 classification criteria. Exclusion criteria: previous diagnosis of fibromyalgia, depression or anxiety, treatment with antidepressants, antihistamines, beta-blockers. Measurement of FACT-F, HAQ-DI, mRSS scales. Statistical analysis was performed with the Pearson correlation (r) with p=0.05. The data was analyzed by SPSS V23.

Results: 54 met inclusion criteria. 100% female, mean age 33.3±15.1 years, mean disease duration 113 months, SScD 75.9% (41), SSc 24.1% (13), interstitial pneumo-

nia 33.3% (18), gastroduodenal reflux disease 27.8% (15), HAP 20.7% (11). Fre-

quency of fatigue 100% (54); moderate FACT-F: 29.6% (16), severe FACT-F: 38.8% (21), extreme 31.5% (17). Correlation FACT-F with mRSS and HAQ-DI: Moderate FACT-F: mRSS mild 43.8% (7), moderate 12.5% (2), severe 18.8% (3), terminal 25% (4), HAQ-DI mild 25% (4), moderate 37.5% (6), severe 18.8% (3). Severe FAC-

tF: mRSS normal 4.8% (1), mild 19% (4), moderate 91% (4), severe 33.3% (7), terminal 25% (4), moderate 37.5% (6), severe 18.8% (3). Severe FAC-

tF: mRSS mild 7.6% (3), moderate 29.4% (5), severe 35.3% (6), terminal 23.8% (5), HAQ-DI mild 4.8% (1), moderate 19% (4), severe 47.6% (10); FACT-F: mRSS mild 761% (3), moderate 29.4% (5), severe 35.3% (6), terminal 176% (3), HAQ-DI moderate 11.8% (2), severe 52.9% (9), r= 0.246 p<0.05

Conclusion: The study demonstrated a high frequency of fatigue. The most frequent degree was severe. A statistically significant linear association was observed between skin involvement and the degree of functional limitation.

disease worsening or take safe medications during pregnancy, and have children also affected by SSC. 77% of patients declared improvement or stability of SSC manifestations during pregnancy. Table 1 shows the comparison of pregnancies before and after SSC diagnosis, based on data reported by the patients. Regarding sexuality, 59% reported that SSC negatively affected it by vaginal dryness (67%), digital ulcers (37%), gastro-intestinal disease (37%) and dyspnea (20%). Among 39 patients completing FSFI, 67% had sexual dysfunction.

Conclusion: The newly created specific questionnaire was instrumental to facilitate physician-patient communication about ‘women’s health’; particularly in the field of sexuality which is characterized by a high frequency of dysfunction. Adverse outcomes are possible during SSC pregnancies and should be discussed during the multidisciplinary preconception counselling, along with measures to possibly reduce their risk.

PROGNOSTIC MEANING OF RIGHT VENTRICULAR FUNCTION AND RESERVE IN PATIENTS WITH SYSTEMIC SCLEROSIS

P Xanthoulis1,2, J. Miazgoski1, N. Benjamin1, G. Gorgani2, B. Egeland2, S. Harutyunova2, R. Seeger2, A. Marra2,3, N. Blank1, H. M. Lorenz1, E. Grünig2, H. Miazgoski1, N. Khmelinskii1,2.

Background: The delay of the diagnosis of pulmonary hypertension (PH) in patients with systemic sclerosis (SSc) leads to severe impairment of survival. Objectives: The objective of this study was to investigate the prognostic impact of right ventricular (RV) function at rest and during exercise on survival in patients with SSc presenting for screening for PH. Methods: Data from SSc patients who underwent routinely performed examinations for PH screening including echocardiography and right heart catheterization at rest and during exercise were analyzed. Uni- and multivariable analyses were performed to identify prognostic parameters in SSc and to compare them to known prognostic predictors. Results: Out of 285 SSc patients screened for PH, 225 patients (83.3% female, mean age 58.1±13.0 years, 68% limited cutaneous SSc, WHO-FC II-III 74%, 24 manifest PH) were included in the analysis. During an observation period of 3.2±2.7 (median 2.6) years 35 patients died. Tricuspid annular plane systolic excursion ≤18 mm (p=0.0004), increase of cardiac index (CI) during exercise ≤2 l/min (p=0.0002), RV output reserve >3 mmHg/l/min (p=0.001), peak CI ≤ 5.5 l/min (p=0.01), pulmonary arterial compliance >2 l/mmHg (p=0.0005) and qualitative RV function at rest (p<0.0001) significantly predicted survival. In the multivariable analysis, RV function at rest, diffusion capacity for carbon monoxide <65% predicted and CI increase <2 l/min/m² were identified as independent prognostic predictors and had >70% sensitivity and specificity to predict development of pulmonary vascular disease (PVD) during follow-up. Conclusion: This study demonstrates that assessment of RV function at rest and during exercise may facilitate physician-patient communication about ‘women’s health’, particularly in the field of sexuality which is characterized by a high frequency of dysfunction. Adverse outcomes are possible during SSC pregnancies and should be discussed during the multidisciplinary preconception counselling, along with measures to possibly reduce their risk.

Background: Mixed connective tissue disease (MCTD) is a rare heterogeneous disease, characterized by overlapping features of classic connective tissue diseases. Myositis may present in up to two-thirds of patients with MCTD and it is included in all diagnostic criteria available. Although some possible associations have been reported, to the best of our knowledge, no independent predictors of MCTD-related myositis have been described.
OBJECTIVES: To identify clinical and laboratorial predictors for muscular involvement in a cohort of Portuguese patients with MCTD.

METHODS: Multicentre retrospective cohort study including adult-onset patients with a clinical diagnosis of MCTD and fulfilling at least one of the following diagnostic criteria: Sharp, Kasukawa, Alarcón-Segovia or Kahn criteria. Myositis was defined as proximal muscle weakness, creatine kinase elevation, electromyography (EMG) suggestive changes or a positive muscular biopsy. Univariate analysis was performed using Chi-Square, Fischer’s Exact Test and Mann-Whitney Test, as appropriate. Multivariate analysis was performed using binary logistic regression modelling. The linearity of the continuous variables concerning the logit of the dependent variable was assessed via the Box-Tidwell procedure. Cases with missing information and outliers were excluded from the multivariate analysis to fulfill all assumptions necessary to assure the validity of the regression.

RESULTS: A total of 98 patients were included, 43 (44.3%) of whom had muscular involvement at any time of the disease course. Concerning patients with MCTD-related myositis, the mean age at diagnosis was 34.8±12.5 years and the mean disease duration of 4.1±4.9 years. The majority of patients were female (90.7%) and of European ancestry (66.7%). EMG was performed in 24 patients, of whom 10 (41.7%) had a myopathic pattern. Seventeen patients were submitted to a muscular biopsy, of whom 8 (47.1%) had histological myositis features. Capillaroscopy was performed in 24 patients and 12 (50%) had a scleroderma pattern. African ancestry and leukopenia were positively associated with myositis at disease onset. Furthermore, fever at the onset of disease, younger age at diagnosis and shorter disease duration were positively associated with the occurrence of myositis at any phase of the disease. The multivariate analyses predicting myositis at diagnosis included 54 patients and at any time of the disease included 90 patients. These models explained 37.8% and 26.9% (Nagelkerke R2) of the variance in myositis and correctly classified 79.6% and 73.3% of all cases, respectively. African ancestry (OR 8.39, 95%CI: 1.43-49.37, p=0.019), leukopenia (OR 6.24, 95%CI: 1.32-29.48, p=0.021) and younger age at diagnosis (OR 1.07/year, 95%CI: 1.01-1.14, p=0.035) were identified as independent predictors of myositis at diagnosis. Fever (OR 6.51, 95%CI: 1.23-34.37, p=0.027) was an independent predictor of muscular involvement at any time of the disease in MCTD patients.

CONCLUSION: African ancestry, leukopenia and younger age at diagnosis are independent predictors of myositis at presentation in MCTD patients, while fever is an independent predictor of myositis at any time of the disease. While evaluating patients with MCTD, these predictive factors should be considered.

CLINICAL COURSES AND PREGNANCY OUTCOMES OF EIGHT CASES COMPPLICATED WITH POLYMYSITIS/DERMATOMYSITIS (PM/DM) IN SINGLE CENTER

R. Mino1, H. Shimad1, R. Wakiya1, S. Nakashima1, M. Kato1, T. Miyagi1, S. Nakashima1, M. Kato1, T. Miyagi1, H. Dobashi1,1 Kagawa University, Department of Internal Medicine, Division of Hematology. Rheumatology and Respiratory Medicine, Miki, Japan

Background: Pregnancies complicated by a number of rheumatic diseases are known to be at high risk for the occurrence of adverse pregnancy outcomes (APOs). There have been several reports on the risk of APOs in systemic lupus erythematosus and rheumatoid arthritis, but few reports on polymyositis (PM)/dermatomyositis (DM) pregnancies. There are also insufficient reports on changes in the activity of PM/DM during pregnancy. Based on the findings reported in other rheumatic diseases, it is suggested that increased activity during pregnancy is associated with APOs in PM/DM (1-3). However, the risk factors for pregnancy outcome in pregnancies complicated by PM/DM, including the presence or absence of worsening of disease activity, have not been clarified.

Objectives: The purpose of this study was to analyze a case series of PM/DM complicated pregnancies in a single center to determine the changes in disease activity during pregnancy and pregnancy outcomes.

Methods: PM/DM patients who were managed from pregnancy to delivery at Kagawa University Hospital from March 2006 to March 2021 were included in this study. Clinical indices including duration of illness, disease activity, and treatment were extracted from medical records and retrospectively analyzed for association with pregnancy outcome.

Results: Eight PM/DM pregnancies were included in the analysis. The mean age at delivery was 28.3±3.8 years and the mean duration of disease was 6.3±3.2 years. Treatment at the time of pregnancy included glucocorticoids (GC) in 7 cases and immunosuppressive drugs in 5 cases. Creatine phosphokinase (CK) levels were normal in all patients at the time of pregnancy, but increased during pregnancy in 4 (50%) patients. These 4 patients with elevated CK required treatment with increasing doses of GC, and the mean GC dose during pregnancy was 10.9 ± 6.0 mg/day. Table 1 shows the pregnancy outcomes of the 8 patients. There was one spontaneous abortion and seven live births. Among the live births, 2 were preterm and 4 were low birth weight. The mean gestational age at delivery was 35.3±5.2 weeks and the mean birth weight was 2297.7±1041.4 g.

The birth outcomes of the 2 patients who received continuous immunosuppressive therapy were full-term and normal weight infants. APOs, such as preterm delivery and low birth weight, occurred in cases with increased CK levels and increased GC doses.

Conclusion: In pregnancies of PM/DM patients, pregnancy outcome was less than favorable. An association between disease activity and the development of APOs during pregnancy in PM/DM was suggested. An association was also suggested between GC dose and the risk of developing APOs. As in other rheumatic disease pregnancies, continued use of pregnancy-appropriate immunosuppressive drugs and control of disease activity with lower glucocorticoid doses in PM/DM pregnancies may be important to achieve good pregnancy outcomes.

CALCINOSIS CUTIS IN SYSTEMIC SCLEROSIS: CLINICAL AND BIOLOGICAL ASSOCIATIONS

G. M. State1, N. D. Popescu1, I. A. Berza1, F. Negoi1, A. Dima1, M. Parvu2.
1Colentina Clinical Hospital, Department of Rheumatology, Bucharest, Romania; 2Colentina Clinical Hospital, Department of Rheumatology, Bucharest, Romania.

Background: Calcinosis cutis (CC) is a rare disorder characterized by the abnormal deposition of calcium salts in the subcutaneous tissues of patients with normal calcium metabolism. Dystrophic calcinosis is a common and potentially debilitating manifestation in systemic sclerosis (SSc) patients. The CC was described to appear more frequently in newly diagnosed SSc patients with Raynaud’s phenomenon, with ischemic ulcer or telangiectasia and in areas related to repeated trauma, but current data remains inconclusive 1-2.

1Colentina Clinical Hospital, Department of Rheumatology, Bucharest, Romania; 2Colentina Clinical Hospital, Department of Rheumatology, Bucharest, Romania.

DISCLOSURE OF INTERESTS: None declared

Objectives: Our objective was to analyze the prevalence, clinical features, and biological associations of CC in SSc patients.

Methods: A retrospective analysis of patients hospitalized in the Rheumatology Department of the Colentina Clinical Hospital, Bucharest, Romania. Data of the patients fulfilling the 2013 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) SSc classification criteria were collected. In all patients, clinical examination, including evaluation of the cutaneous involvement by modified Rodnan skin score (mRSS) was performed. A CC diagnosis was sustained by radiographic and/or ultrasound imaging.

Results: 44 SSc patients were included with female predominance (39 patients - 88.6%), and with mean (SD) age 58.8±11.3 years old, CC was found in 11(25.0%) of these patients, all feminine gender. Elbow (36.4%) and hands and forearms (27.3%) were the most frequent sites affected by CC.

Overall, CC was not related to the SSc subtype, when comparing limited (lc) vs diffuse cutaneous (dc) involvement (27.3% vs. 48.5%, p=0.219). However, patients with CC had more often lc SSc, 72.7% vs. 27.3%. Accordingly, SSc patients with CC had a significant lower mRSS score, 6 (1;7) vs. 9 (5; 15,5) points, p=0.001 and more frequently expressed positives anti-centromere antibodies (ACA), 72.7% vs. 57.1%, p=0.038. CC was also found not to be related to sclerodactylty, 54.5% vs. 75.8%, p=0.038. Regarding the nailfold capillaroscopy (NFC) exam, the CC was more often described in patients with late NFC pattern, 45.5% of cases.

In SSc patients with CC, there was reported more often intestinal transit disturbances 45.5% vs. 3.0%, p=0.015, even if overall there was no gastrointestinal involvement, 72.7% vs. 63.6%, p=0.582.

Regarding inflammation, the level of erythrocyte sedimentation rate (ESR) was lower in patients with CC (13.33) vs. 33 (170; 58.5) mm/h, p=0.040, but not the C-reactive protein level 2.4 (1.7; 6.7) vs. 3.3 (12; 8.5) mg/L, p=0.866. When comparing SSc patients with or without CC we did not found any significant difference regarding the presence of anti-Scl70 antibodies, p=0.432, rheumatoid factor, p=0.067, lupus anticoagulant or antiphospholipid antibodies, p=0.835. Also, no significant correlations were identified for CC in SSc and the following parameters: smoking, p=0.162, obesity, p=0.812, hypertension, p=0.371, diabetes, p=0.403, Raynaud phenomenon, p=0.539, telangiectasia, p=0.28, pulmonary hypertension, p=0.777, lung interstitial disease, p=0.315, digital ulcers, p=0.723, or digital starry scars, p=0.223.

Conclusion: The CC prevalence in SSc consecutive patients was 25.0%, more frequently with elbow localization. We’ve also found more frequent CC in patients with positive ACA serology and defined relations with many other SSc-related parameters.

AB0691 SYSTEMIC SCLEROSIS AT THE TIME OF COVID-19: PANDEMIC: A BIBLIOGRAPHY STUDY
B. Daskalakis1, R. Yatsyshyn2, I. Stoika2, K. Fedorovych3, O. Hotsianik2, O. Drogermeretska1, Ivanovo Frankivsk National Medical University, Pathophysiology, Ivanovo Frankivsk, Ukraine; 2Ivanovo Frankivsk National Medical University, Internal medicine #1 clinical immunology and allergy, Ivanovo-Frankivsk, Ukraine

Background: The Coronavirus disease 2019 (COVID-19) affects different organs and systems of the human organism. However, the main target remains the respiratory system and lungs in particular. Systemic sclerosis (SSc) is one of the systemic autoimmune diseases that can cause severe lung impairment. Considering the existence of common points of influence on the human organism, the overlapping of these two pathologies can significantly increase the negative impact on the patient’s health.

Objectives: This study was aimed to analyze the common features of articles covering the link between COVID-19 and systemic sclerosis.

Methods: We retrieved the literature items in the scientific bibliometric database Scopus conducting our search on the 26th of January. We didn’t set any time limits and did use the following keywords: “systemic sclerosis” OR “scleroderma” AND “COVID-19” OR “Covid-19” OR “coronavirus”. The exclusion criteria were: absence of an abstract, literature items in form of conference papers, and articles dedicated to the rheumatological pathology in general with scarce mention of SSc. All selected papers were analyzed in view of the following characteristics: documents’ type, authorship, journal, citations score, the origin of an article, language, and keywords. For data visualization, we have used software tool VOSviewer version 1.6.15 which make possible to build authors’ and keywords’ network (Figure 1 A and B) (the minimum keywords’ threshold was 3 and the minimum author occurrence was 5).

Results: In the result of our comprehensive literature search only 206 items were obtained. After screening of title, abstract and keywords we omitted 166 articles as they met our exclusion criteria and were irrelevant for our study. The most (87.5%) of remained 40 articles were open access publications, which improves the articles’ visibility and simplifies data sharing. The top journals covering this topic were: Annals Of The Rheumatic Diseases (n=7); Journal of Psychosomatic Research (n=4), Journal Of Scleroderma And Related Disorders (n=4), Clinical Rheumatology (n=3), Lancet Rheumatology (n=3) and Scandinavian Journal Of Rheumatology (n=3). The post productive authors originated from Italy (n of articles = 20); other countries with highest number of publications were: UK – 10; USA – 7; France – 7 and Netherlands – 6. The majority of papers were written in English and just one was in Chinese. The most prevalent research type among analyzed articles was Letter (47.5%), about a third of the articles were designed as Original Articles (35%), 7.5% were Notes, the number of Reviews and Editorials was 5% for each type. Based on the citations score, the most relevant article was dedicated to COVID-19 course in patients with SSc associated interstitial lung disease (SSC-ILD) using tocilizumab. The second highly cited paper highlighted a disease course of COVID-19 pneumonia in SSc patients treated with rituximab and the third actively cited article was World Scleroderma Foundation preliminary advice for patient management. It should also be noted that a lot of articles (n=7, 17.5%) were dedicated to the emotional wellbeing of SSc patients in time of COVID-19 pandemic.

Conclusion: Based on our literature analysis, it is the first attempt to overview comprehensively the papers focusing on SSc and COVID-19 overlap. The bibliometric studies offer an essential opportunity to emphasize the main features and trends in the particular topic and could be used by scientists as a guidance for forthcoming research.

AB0692 PREDICTORS OF ILOPROST INFUSION TOLERANCE IN PATIENTS WITH SYSTEMIC SCLEROSIS
R. Bixio1, E. Bertoldo1, A. Gioletti2, G. Adamì3, A. Morciano1, D. Bertelle1, I. Gavioli1, G. Orsolini1, O. Viapiana1, M. Rossini1, 1Università degli studi di Verona, Rheumatology section, Verona, Italy; 2Università degli studi di Padova, Division of Rheumatology, Padova, Italy

Background: Systemic Sclerosis (SSc) is an autoimmune disease characterized by vasospasm and microvascular involvement. Iloprost (ILO), a prostaglandin analogous, is used for the treatment of SSc-related Raynaud’s Phenomenon and digital ulcers. The second highly cited paper highlighted a disease course of COVID-19 pneumonia in SSc patients treated with rituximab and the third actively cited article was World Scleroderma Foundation preliminary advice for patient management. It should also be noted that a lot of articles (n=7, 17.5%) were dedicated to the emotional wellbeing of SSc patients in time of COVID-19 pandemic.

Conclusion: Based on our literature analysis, it is the first attempt to overview comprehensively the papers focusing on SSc and COVID-19 overlap. The bibliometric studies offer an essential opportunity to emphasize the main features and trends in the particular topic and could be used by scientists as a guidance for forthcoming research.

all patients, neither in the subgroup with early disease, nor in the subgroup with late disease. There was no significant change in PFT's, DLCO and chest HRCT lesions in either subgroup at each follow-up visit. Furthermore, all the patients who were treated with RTX early in the disease course achieved better results at 6 months follow-up. AEs during ILO titration occurred in 47.8% of patients, of whom 22.2% presented concomitant hypotenison. The most common AEs were headache, nausea, vomiting, diarrhoea, oedema, hypotenison, and symptomatic therapy was needed in half of the patients at least once. Overweight patients (BMI >26) presented a 13-fold increased risk of developing AEs during ILO titration (adjusted odd ratio 13.979 95% CI 2.359-82.845).

Conclusion: Our study showed that only a higher BMI was associated with lower ILO infusion rate tolerance and higher AEs rate, underlying a possible BMI-dependent endothelial dysfunction possibly mediated by endothelin receptor expression. Individual ILO regimens still need to be tailored to the patient.

EFFECTIVENESS OF RITUXIMAB IN PATIENTS WITH SYSTEMIC SCLEROSIS – EXPERIENCE IN A TERTIARY MEDICAL CENTER

N. Cristini1, L. Groseanu1,2, G. Petrescu1, D. Nicoara1, O. Opris-Belinskii1, D. Mazill1, A. Balanescu1,2, R. Ionescu1 on behalf of The Department of Rheumatology and Internal Medicine at Bucharest St. Mary’s Hospital, 1St Mary Hospital, Internal Medicine and Rheumatology, Bucharest, Romania; 2Carol Davila University of Medicine and Pharmacy; University of Medicine and Pharmacy, Bucharest, Romania

Background: There is ample evidence of B cell involvement in the pathogenesis of fibrosis in systemic sclerosis (SSc), making it a promising target for the treatment of skin and lung fibrosis in SSc. However, data regarding the long-term use of B cell depletion in the treatment of this life-threatening connective tissue disease is scarce.

Objectives: The primary aim of this study was to evaluate the safety and efficacy of long-term B cell depletion and to define the changes on both cutaneous and visceral organ involvement after rituximab (RTX) therapy in SSc patients over time, in a tertiary hospital.

Methods: A prospective observational case-control study, conducted between 2016 and 2021, enrolled 10 SSc patients, who fulfilled the ACR/EULAR 2013 classification criteria for scleroderma and who had received RTX infusions at least once. All patients had been taking immunosuppressive therapy previously. The following clinical data were included into the analysis: disease activity by the EUSTAR activity index, skin fibrosis by the modified Rodnan Skin Score (mRSS), interstitial lung disease by lung function tests including forced vital capacity (FVC), diffusing capacity of the lung for carbon monoxide (DLCO) and high-resolution CT (HRCT). For the comparison of non-parametric data at two time points, Wilcoxon matched paired Student’s t-test was used.

Results: The study included 10 patients (all female), with a mean age of 52.9 years, most of them with diffuse subset (9/10), treated with RTX between 2016 and 2021. Average duration of disease before the RTX therapy was 27.6 months. Mean baseline mRSS was 19.3 and mean EUSTAR activity index was 4.48. Seven patients received 2 courses of RTX and four of them were evaluated 1 year after the beginning of RTX therapy. We found a statistically significant improvement in mRSS (p=0.02) and EUSTAR activity index values (p=0.02), when comparing baseline levels with those found at each follow-up visit. Furthermore, all the patients who were treated with RTX early in the disease course achieved better results at 6 months follow-up. There was no significant change in PFT’s, DLCO and chest HRCT lesions in all patients, neither in the subgroup with early disease, nor in the subgroup with worsening, progressing pulmonary function, during the follow up period.

Conclusion: Our results suggest that B cell depletion, in patients with SSc, leads mainly to a clinically relevant decrease in skin involvement and to a stabilization of disease activity after 6 and 12 months of use. The study did not find a clear beneficial effect on pulmonary function during short-term follow-up. Despite these considerations, our results indicate that the course of lung disease did not worsen in our patients. At 6-year follow-up the safety of single and repeated courses of the drug was confirmed. While the study provides important insights into the use of RTX in SSc, it is limited by the low number of patients, the lack of a sufficient control arm and the single center design.

VITAMIN D LEVELS IN PATIENTS WITH SYSTEMIC SCLEROSIS AND VERY-EARLY SYSTEMIC SCLEROSIS (VEDOSS)

G. Cuomo1, M. C. Trota2, C. Di Vico1, R. Ferrara2, C. Romano2, M. D’Amico2. 1Università-Cagliari Studi della Cambiana Foundation of Medicine, Naples, Italy; 2Università della Campania Luigi Vanvitelli, Section of Pharmacology “L’Donatelli”. Naples, Italy; 3University of Campania Studies “Luigi Vanvitelli”; Department of Medical and Surgical Sciences, Naples, Italy

Background: Systemic sclerosis (SSc) is a chronic disease characterized by autoimmunity, vasculopathy, and visceral and cutaneous fibrosis and very-early systemic sclerosis VEDOSS is characterized by Raynaud’s phenomenon with SSc marker autoantibodies and typical capillaroscopic features. Vitamin D has several functions in the immunological system, and different studies have suggested a potential role in triggering autoimmune diseases. (1,2)

Objectives: Our goal was to verify the difference of Vitamin D levels causal in SSC definite and VEDOSS population, and relationship between hypovitaminosis D and SSc characteristics.

Methods: 42 adults with SSc were recruited: 24 with American College of Rheumatology criteria were affected by diffuse systemic sclerosis (4) and limited systemic sclerosis (20); 18 with VEDOSS criteria. Patients were evaluated from medical history and physical examination (modified Rodnan skin score and the presence / number of ulcers), biohumoral evaluation of routine, electrocardiogram, echocardiogram, pulmonary function tests, high resolution computed tomography of the chest, capillaroscopy. For the determination of total vitamin D levels (25-OH), the serum samples were suitably centrifuged at 4 °C at 3500g. Vitamin D levels were then determined by a two-step chemiluminescence enzyme immunoassay (CLIA), with a maximum limit of 100 ng / ml.

Results: The 42 subjects recruited (4 men and 38 women); age 48.2 ± 11.5 years (mean ± SD). All subjects were ANA positive, with anti-Scl70 positivity in 59% of SSc patients (4) and anti-centromere iCSCC patients (18). Patients with VEDOSS showed optimal serum levels of vitamin D (33.93 ± 3.5 ng / ml). Conversely, patients with systemic sclerosis showed serum levels of vitamin D at the limit of sufficiency (21.75 ± 4.0 ng / ml). (Figure 1) In particular, in the group of patients with systemic sclerosis, vitamin D levels were significantly reduced by 1.5 times (P <0.05) compared to VEDOSS group. In patients with SSc the serum levels of vitamin D were inversely proportional to the presence of mega capillaries. Furthermore, a directly proportional correlation of the serum levels of vitamin D with the age of the patient. It is therefore possible to assume that higher levels of vitamin D delay the onset of the disease, while lower levels of vitamin D favor the onset of the same.

Conclusion: Considering our findings from this work, it is possible to consider the Vitamin D supplement in patients suffering from sclerosis, especially as an adjuvant in the initial phase of the disease, thus hypothesizing a slowdown in the progression of the disease and an improvement in prognosis.

REFERENCES:
Background: Anti-Th/To antibodies, detected in 2-5% Systemic Sclerosis (SSc) patients, are associated to interstitial lung disease (ILD)\(^1\) in half of the cases. However, long-term data on ILD as well as on organ damage accrual are lacking.

Objectives: To describe the clinical associations of anti-Th/To SSc patients, focusing on ILD, organ damage and mortality.

Methods: Monocentric retrospective study. 1) Description of clinical associations of anti-Th/To SSc patients (2013 ACR/EULAR criteria). 2) Case-control study: anti-Th/To vs anti-Topoisomerase (anti-Topo)1 patients (1:3; matched for sex and age at SSc onset) regarding a) ILD b) organ damage c) survival. ILD progression was assessed through pulmonary function tests (PFTs) at baseline (T0) and after 1 (T1), 2 (T2), 5 (T5), 10 (T10) and 20 (T20) years. Organ damage was evaluated with SCTD-Damage Index (SCTD-DI)\(^2\). Continuous data are expressed as median [IQR].

Results: We identified 13 anti-Th/To patients (all Caucasians, F/M=10/3, median age at SSc onset: 50 [37-67] years). Anti-Th/To were assayed by RNA immunoprecipitation in 8/13 and by immunoblotting in 5/13 cases.

1) 2/13 patients had SSc/myositis overlap syndrome: 1 associated to anti-SRP, 1 negative for myositis specific antibodies and affected by a synchronous (≤3 years from onset) cancer. All presented icSSc, 77% esophageal symptoms, 46% digital ulcers (DUs), 40% ILD, 39% telangiectasias, 39% heart involvement (3 pericarditis, 1 myocarditis in patient anti-SRP+, 1 arrhythmia), 15% gastrointestinal symptoms, 15% myositis and 8% calcinosis. No patients presented synovitis, joint contractures, pulmonary arterial hypertension nor scleroderma renal crisis.

2a) Anti-Th/To ILD patients, as compared to 39 anti-Topo 1, less frequently required antifibrotic or O2 therapy (Table 1); ILD progression (%pFVC decline ≥10% or %pDLCO decline 5-10% and %pFVC decline ≥15%) was shown for 3/13, albeit, after a longer interval than in 8/39 anti-Topo 1 progressors (15 [10-15] vs 1 [6.3-15] years, p:0.05); none died because of ILD.

Objectives: To evaluate SSc immune-clinical associations in the Rheumatic Diseases Portuguese Register (Reuma.pt) cohort.

Methods: Multicentre open cohort study including adult SSc patients registered in Reuma.pt up to February 2021. The association between Ab expression and clinical data was evaluated using Chi-Square, Fischer’s Exact or Mann-Whitney U tests. The Bonferroni correction for multiple comparisons was applied to get <p<0.05. Definite associations were defined by p<0.002, and likely associations by p<0.05.

Results: 1080 patients were included, with a mean age and disease duration of 52.0±14.6 and 12.4±11.0 years, respectively. Most were females (67.5%) and had other European ancestry (93.2%). The most common disease subtype were limited cutaneous (lcSSc, 57.4%), diffuse cutaneous (dcSSc, 17.7%), and very early diagnosis of SSc (VEDOSS, 12.3%). Most patients expressed anti-nuclear Ab (ANA, 93.4%), and the most frequent were anti-centromere (ACA, 54.6%), anti-topoisomerase I (Sc170, 21.9%), and anti-PM/Scl Ab (PM/Sc, 4.7%). ACA had definite positive associations with female sex, older age at diagnosis, lcSSc, lower modified Rodnan skin score (mRSS, median 0 vs 4), and isolated sclerodactyly, and likely associations with a higher diagnosis delay, WEA and VEDOSS. ACA had definite inverse associations with flexion contractures (FC), myositis, digital ulcers (DU), and interstitial lung disease (ILD), and likely inverse associations with pitting scars (PS) and oesophageal involvement (OI).

Sc170 had definite positive associations with male sex, dcSSc, higher mRSS, FC, DU, PS, ILD, and OI, and likely associations with younger age at diagnosis, tendon friction rubs, active scleroderma pattern in capillaroscopy, and heart involvement. PM/Sc had a definite association with myositis and likely associations with male sex, calcinosis, joints involvement, and ILD. Anti-U1RNP Ab had definite associations with younger age at diagnosis, MCTD and myositis, and likely associations with a lower diagnosis delay, African ancestry and joint involvement. Anti-RNA polymerase III Ab (RP-3) had high associations with higher mRSS and renal involvement. Anti-U3RNP Ab had a definite association with dcSSc and likely associations with calcinosis and renal involvement. Anti-Th/To Ab had likely associations with male sex and myositis. Anti-Ku Ab had likely associations with systemic lupus erythematosus and mixed connective tissue disease (MCTD) overlap syndromes.

Conclusion: There was a higher prevalence of ACA and PM/Sc compared to other cohorts, most likely due to the high proportion of WEA patients. Most immune-clinical associations described in the literature apply, including ACA with lcSSc and Sc170 with dcSSc, DU, PS and ILD. However, Sc170+ patients did not have an increased risk of renal involvement, and ACA+ patients did not have an increased risk for calcinosis, PAH or OI, contrary to what was described in the literature. New findings included the association of PM/Sc with ILD and Sc170 with an active pattern in capillaroscopy. Also, anti-U3RNP and Th/To Ab+ patients did not have an increased risk of ILD or PAH, contrary to what was previously reported. These nuances may be specific to the Portuguese SSc population or signal previously reported associations as geographically specific.

DRAMATIC REDUCTION OF MORTALITY RATE BY TOFACITINIB IN ANTI-MDA-5 ANTIBODY-POSITIVE PATIENTS WITH RAPIDLY PROGRESSIVE INTERSTITIAL LUNG DISEASE

C. W. Tseng1,2, M. Satoh3, Y. M. Chen1,2,4,5,6, 1Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; 2National Chung Hsing University, Department of Post-Baccalaureate Medicine, College of Health Sciences, Kitakyushu, Fukuoka, Japan; 3Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China; 4National Yang Ming Chiao Tung University, School of Health Sciences, Kittakyushu, Fukuoka, Japan; 5National Taichung Veterans General Hospital, Department of Internal Medicine, Taichung, Taiwan, Republic of China; 6National Chung Hsing University, Rong Hsing Research Center for Translational Medicine & Ph.D. Program in Translational Medicine, Taichung, Taiwan, Republic of China; 7National Yang Ming Chiao Tung University, School of Medicine, College of Medicine, Taipei, Taiwan, Republic of China

Background: Rapidly progressive interstitial lung disease (RP-ILD) is often seen in dermatomyositis patients with anti-melanoma differentiation-associated gene 5 (anti-MDA-5) antibody. They often have a poor prognosis with rapid decline in pulmonary function, leading to respiratory failure (1). Aggressive immunosuppressive therapy has been reported with improved prognosis, however; it may lead to opportunistic infections, including cytomegalovirus (CMV) or Pneumocystis jirovecii (2). IMPACT OF ILOPROST WITHDRAWAL IN SCLERODERMA PATIENTS DUE TO COVID-19 PANDEMIC

IMMUNE CLINICAL DATA OF SLE PATIENTS DURING MAR-2017 TO MAY-2021: AN OBSERVATIONAL STUDY FROM THE SLE REUMA.PT COHORT

C. W. Tseng1,2, M. Satoh3, Y . M. Chen1,2,4,5,6.

1T aichung Veterans General Hospital, Department of Medicine, T aichung, T aiwan, Republic of China; 2Department, Rome, Italy; 3Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCCS, Roma, Italy, Rheumatology Department, Rome, Italy; 4National Chung Hsing University, Rong Hsing Research Center for Translational Medicine & Ph.D. Program in Translational Medicine, Taichung, Taiwan, Republic of China; 5National Yang Ming Chiao Tung University, School of Medicine, College of Medicine, Taipei, Taiwan, Republic of China

Methods: Medical records of 17 anti-MDA-5-positive RP-ILD patients enrolled during Mar 2017 to May 2021 were reviewed. RP-ILD was defined by the presence of deteriorated dyspnea, with a decrease in PaO2 levels and emerging radiographic anomalies within 4 weeks without evidence of infection (4). Chest CT was scored using lichkido score (5). Clinical parameters including ferritin levels, white counts (WBC), Lactate dehydrogenase (LDH) levels, GAP scores (Gender, Age, and Physiology score for idiopathic pulmonary fibrosis) were recorded. Medications included cyclophosphamide (CyP), intravenous immunoglobulin (IVIG), myophenolic acid derivatives (MPA), rituximab (RTX), and calciumin inhibitor (CNI). Kaplan-Meier survival analysis and Log-rank test were used to evaluate one-year mortality differences (MedCalc version 19.6). The Ethics Committee approved our study (CE17038B).

Results: Six anti-MDA-5-positive RP-ILD patients were treated with tofacitinib; five had concomitant CMV prophylaxis with valganciclovir (VGCV); 4 had PCP prophylaxis with trimethoprim/sulfamethoxazole (TMP-SMX). Patients’ demographic data are shown in Table 1. The median age, clinical manifestations, laboratory data, and chest CT scores were comparable between tofacitinib and non-tofacitinib groups. Prevalence of MPA use was higher in the non-TOF group. Kaplan-Meier survival analysis (Figure 1) indicated that patients with tofacitinib treatment (p=0.001), valganciclovir (p=0.003), and TMP-SMX (p=0.028) prophylaxis exhibited better 1-year survival rates compared with those without TOF therapy, VGCV, and TMP-SMX prophylaxis.

Table 1. Clinical characteristics of anti-MDA-5 antibody-positive patients with RP-ILD receiving tofacitinib vs non-tofacitinib treatment.

Continuous variables were expressed as median (inter-quartile range).”p<0.05. **p<0.01 by Mann–Whitney U test or Fisher’s Exact test.

Conclusion: The study demonstrated the efficacy of tofacitinib treatment in anti-MDA-5-positive RP-ILD. In addition, CMV and PCP prophylaxis appeared to improve in 1-year survival. Rheumatologists might consider TOF with prophylaxis as an option for anti-MDA-5-positive patients in daily practice.

REFERENCES:
Background: Intravenous iloprost is currently recommended in the treatment of Raynaud's phenomenon (RP) refractory to oral therapy and of digital ulcers (DUs) related to systemic sclerosis (SSc). In real-life practice there is a huge heterogeneity about the iloprost regimen used, leading to sudden and synchronous withdrawal of programmed iloprost infusions for most SSc patients in March 2020, in order to limit virus dissemination. At the same time, lockdown forced people to stay at home, thus reducing the exposure to coldness. Both these unavoidable circumstances were close to an experimental condition, clearly replicable in routine conditions. Objectives: The aim of the survey was to evaluate the consequences related to a sudden and simultaneous iloprost discontinuation in a cohort of SSc patients. Methods: A telephone survey was carried out on SSc patients that interrupted iloprost infusion at our centre. They were specifically asked to compare acral vascular symptoms just before iloprost withdrawal, in February and just after the missed March infusions. Thromboangiography, capillaroscopy, severity and frequency of RP, new DUs onset or aggravation of those pre-existing were reported for each patient. Last available capillaroscopic images were also evaluated to assess the pattern. Results: The analysis included 50 patients. After iloprost withdrawal, 11 patients reported a RP worsening because of enhanced intensity (4.6±2.1 vs 5.2±2.3, p=0.007). Only 8 patients of them had also an increased frequency (4.5±2.2 vs 5.0±2.4, p=0.07). None of the patients experienced digital ulcers for the first time during quarantine. Among the 27 patients with a history of digital ulcers, 9 reported worsening and 7 recurrences of DUs. Overall, 17 patients (34.0%) complained of a worsening of SSc vascular acral manifestations, namely RP or DUs. Disease and general features did not statistically correlate with worsening of RP except for reduced capillary density. Of note, each unit increase of capillary density corresponds to an average 44% decrease in the odds of RP worsening (OR 0.56, CI 95%; 0.36-0.97, p=0.037). History of DUs - either active or former at the time of iloprost discontinuation - was the only clinical predictor of worsening of DU severity. As for RP worsening, the worsening of DU was associated with a lower capillary density. Conclusion: Low capillary density can predict a worsening of both RP and DUs within a month after iloprost discontinuation in SSc patients. Further studies are needed to assess whether the capillaroscopy should be used to personalize iloprost regimen in SSc patients.

AB0700 HIGH BRONCHOALVEOLAR FLUID NEUTROPHILS INDEPENDENTLY PREDICT 15-YEAR MORTALITY IN SCLERODERMA PATIENTS WITH INTERSTITIAL LUNG DISEASE NAIVE TO IMMUNOSUPPRESSANTS

E. De Lorenzi1,2, G. Nataliello1, L. Verardi1, P. G. Cerasuolo1, G. Alonzì1, M. A. Di Giorgi1, S. L. Bosello1.
Department of Biomedical Sciences, Pisa, Italy; Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy, Rheumatology Department, Rome, Italy;1 University of Verona-Verona, Italy, Ph.D programme in Biomolecular Medicine-Cycle XXXV, Verona, Italy

Background: Scleroderma interstitial lung disease (SSc-ILD) has a variable and widely unpredictable course. Data about the role of bronchoalveolar lavage fluid (BALF) analysis in prognostic stratification of SSc-ILD patients (pts) are conflicting.

Objectives: To assess BALF analysis role in prognostic stratification of SSc-ILD pts.

Methods: Forty SSc-ILD pts naive to immunosuppressants underwent comprehensive BALF analysis with total and differential cell counts, protein count, pulmonary function tests (PFTs), high-resolution computed tomography (HRCT) of the chest. All pts had fibrosing lung disease affecting more than 10% of lung volume on HRCT. Baseline alveolar and interstitial scores were computed. The 15-year crude mortality rate was retrospectively assessed.

Results: The enrolled pts (male 20%, aged 53.9±13 years) had a disease duration of 4.3±3.4 years. Diffuse cutaneous involvement in 19 (45%) and rapidly progressive in 12 (27%) pts. Antisynthetase syndrome was present in 17 (42.5%) pts, while anti-Scl70 and anti-centromere antibodies were detected in 45% and 12.5% of pts, respectively. The average alveolar and interstitial scores were 6.5±4.8 and 6.2±2.7, respectively; 25% of the pts had FVC less than or equal to 80% and 35% had DLco less than or equal to 80%. During the follow-up, 18 pts (45%) received immunosuppressants. BALF neutrophils (>3%), eosinophils (>1%) and lymphocytosis (>15%) were reported in 40%, 16% and 5% of pts, respectively. Twenty-five pts (62.5%) died within 15 years after bronchoscopy. Fifteen-year mortality was predicted by neutrophil (HR 5.5, 95% IC 19-15.7), log-transformed total cell count (HR 2.5, 95% IC 1.1-5.7), absolute neutrophil (HR 1.8, 95% IC 13.2-25) and eosinophil (HR 1.3, 95% IC 11.1-16) cell counts, and macrophage (HR 0.1, 95% IC 0-0.6), neutrophil (HR 1.9, 95% IC 13.2-7.7) and eosinophil (HR 1.1, 95% IC 1-1.7) percentages. Only absolute and relative neutrophil counts were independently associated with mortality also in regression models adjusted for demographics (age, gender), main disease traits (diffuse cutaneous variant, anti-Scl70 positivity), pulmonary function tests (FVC, DLco), HRCT involvement (alveolar and interstitial scores) and vascular complications (presence of pulmonary hypertension, digital ulcers).

Conclusion: High BALF neutrophils were associated with high 15-year mortality independently from established clinical risk factors. BALF analysis could improve prognosis prediction in SSc-ILD pts.

AB0699 DESCRIPTIVE STUDY OF A COHORT OF PATIENTS WITH DERMATOMYOSITIS IN A TERTIARY HOSPITAL.

R. J. Gil Velez1, L. Mendez Diaz1, I. Madroñal García1,2 Sevilla, Rheumatology, Seville, Spain

Background: Idiopathic chronic inflammatory myopathies (IICM) are a heterogeneous group of rare diseases characterized by skeletal muscle inflammation. The incidence ranges from 1 to 60 new cases per 1,000,000 habitants/year and the prevalence between 2.4 and 34 per 100,000 habitants. The main symptoms are muscular and extramuscular manifestations. Among the remission inducers, the most frequent regimen used in our setting is the use of cyclophosphamide/rutiximab and maintenance of remission with azathioprine and mycophenonate. More studies on new therapeutic options are needed.

Disclosure of Interests: None declared

AB0701 FREQUENCY AND RISK FACTORS OF OSTEOPOROSIS IN MEN WITH SYSTEMIC SCLERODERMA

A. Sorokin1, O. Dobrovolskaya1, N. Demin1, N. Toroptsova1, V.A. Nasonova Research Institute of Rheumatology, osteoporosis laboratory, Moscow, Russian Federation

Objectives: To identify the frequency and risk factors of osteoporosis (OP) in men with systemic sclerosis (SSc).

Methods: 37 men with SSc were enrolled in the study: 19 (51.4%) with limited and 18 (48.6%) with diffuse cutaneous subtype. Patients with overlap rheumatic syndromes were not included. The median age was 56.0 (46.0; 61.0) years, the median duration of the disease was 6.0 (3.0; 9.0) years. 31 (83.8%) patients were treated with glucocorticoids (GC) > 3 months, the median duration of GC use was 3.7 (2.0; 70) years. Dual energy X-ray absorptiometry (DXA) of the lumbar spine (LS), the femoral neck (FN) and the total hip (TH) was performed. Osteoporosis (OP) was diagnosed with a T-score < -2.5 SD and osteopenia – with a T-score from -1SD to -2.5 SD at any region of interest. Z-score < -2 SD was used for diagnosis of OP in men < 50 years old. Spearman correlation between BM and different factors was performed. Traditional and specific risk factors for OP were analyzed using univariate logistic regression analysis.

Results: The median LS BMD was 1.13 (1.03; 1.26) g/cm2, the FN BMD 0.95 (0.94; 0.99) g/cm2 and the TH BMD - 0.99 (0.93; 1.06) g/cm2. Low BMD at least in one region of interest was detected in 19 (51.4%) patients; OP – in 8 (21.6%) (6 persons
AB0702 COEXISTENCE OF SYSTEMIC SCLEROSIS AND MICROSCOPIC POLYANGITIS ASSOCIATED WITH PULMONARY RENAL SYNDROME: A CASE REPORT AND LITERATURE REVIEW

Y. Jiang¹, Y. X. He¹, X. Liao¹, S. B. Wang¹, Y. F. Qing² on behalf of Institute of Research Center of Gout and Hyperuricemia of the Affiliated Hospital, North Sichuan Medical College. ¹Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology, Nanchong, China

Background: Systemic sclerosis is a chronic immune disease characterized by varying degrees of fibrosis of skin and internal organs. Microscopic polyangitis, as a subtype of ANCA associated vasculitis, mainly involves small blood vessels, often manifested as necrotizing glomerulonephritis and pulmonary capillary vasculitis. Pulmonary renal syndrome is characterized by diffuse alveolar hemorrhage, diffuse alveolar hemorrhage based on pulmonary capillary vasculitis and rapidly progressive glomerulonephritis, which can be derived from a variety of autoimmune diseases, of which ANCA associated vasculitis accounts for about 60%[1]. The cases of coexistence of systemic sclerosis and microscopic polyangitis associated with pulmonary renal syndrome in clinic are rare, which is often dangerous and is easy to miss diagnosis or misdiagnosis.

Objectives: To investigate the clinical characteristics, diagnosis and treatment of coexistence of systemic sclerosis (SSC) and microscopic polyangitis (MPA) associated with pulmonary renal syndrome (PRS) in clinic.

Methods: The clinical data, diagnosis and treatment process of a patient who has SSC combined with MPA and PRS were summarized and analyzed. And the literature was reviewed to explore the correlation of the pathogenesis and clinical experience of SSC complicated with MPA and PRS.

Results: The case is a middle-aged male who was diagnosed as SSCs due to the hardening of the skin of both hands, whose anti-scl-70 antibody is positive. The patient suffered from repeated hemoptysis, progressive dyspnea, severe anemia and renal insufficiency, so he was diagnosed as MPA with PRS. After giving glucocorticoids, immunosuppressant and anti-infection treatment, his condition has improved. A total of 7 case reports were retrieved by reviewing the relevant literature. A total of 7 patients were reported. They were first diagnosed as SSC and then MPA with PRS, of which 4 cases improved after treatment and 3 cases died. Among the dead patients, 1 case was treated with penicillamine for 3 years, and the remaining 2 cases were only treated with steroids without immunosuppressants. In SSC, P-ANCA is closely related to vasculitis, and the diagnosis of PRS secondary to P-ANCA may be very poor. Most of the diagnosis of MPA is only after patients have kidney or lung disease.

Conclusion: Among the cases of SSC combined with MPA and PRS are rare, there are still many cases reported, which reminds us: 1) When SSC patients have new symptoms such as renal insufficiency or lungs, they should be alert to new entities that may be combined with other autoimmune diseases to avoid missed diagnosis or misdiagnosis. ANCA should be detected in SSC patients at baseline, which may be related to disease activity. 2) PRS has rapid progress and high mortality, which is an emergency that needs urgent treatment. Such patients should be treated with glucocorticoids, immunosuppressant and plasma exchange immediately. However, if patients are complicated with SSC, they need to be extra careful when using high-dose steroids, which increases the risk of renal crisis.

AB0703 THE NEED FOR ANTI-OSTEOPOROTIC THERAPY IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Sorokina¹, N. Demin², O. Dobrovolskaya¹, N. Toropova³, V.A. Nasonova Research Institute of Rheumatology, osteoporosis laboratory, Moscow, Russian Federation

Objectives: To determine the need for anti-osteoporotic therapy in postmenopausal women and men over 50 years of age with systemic sclerosis (SSc).

Methods: The study included 150 patients with SSc who met the ACR/EULAR 2013 criteria: 124 (82.7%) postmenopausal women and 26 (17.3%) men over 50 years of age. Median age was 59.0 [54.0; 64.0] years. The duration of the disease was 8.0 [5.0; 14.5] years. A history of fragility fractures was collected.

Results: FRAX was calculated in patients without prior fractures to identify patients at high risk of low-energy fractures. Dual-energy X-ray densitometry (DXA) was performed in persons at moderate risk of fractures, and 10-year probability of major osteoporotic fractures was recalculated with the inclusion of a hip neck T-score. DXA was also performed on all patients from the low-risk group who had 2 or more risk factors of OP.

Conclusion: As a result of a comprehensive assessment of the risk of fractures and OP, it was found that 63.3% of patients with SSc needed anti-osteoporotic treatment.

LOW BODY MASS INDEX IN PATIENTS WITH RAYNAUD PHENOMENON IS ASSOCIATED WITH ENLARGED CAPILLARIES AND REDUCTION IN CAPILLARY DENSITY AT NAILFOLD VIDEOCAPILLAROSCOPY

G. Natello1, L. Verani2, C. Pollicciaro1, L. Gigante3, P. G. Cerasuolo1, F. Sciarascia Mugnozza2, G. Alonzi4, E. De Lorenzi5, S. Della Casa6, M. A. D’Agostino7, S. L. Bosello1, 1Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCCS, Roma, Italy; 2Rheumatology Department, Roma, Italy; 3Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCCS, Roma, Italy, Unit. of Endocrinology, Roma, Italy; 4Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCCS, Roma, Italy, Unit. of Endocrinology, Roma, Italy; 5University of Verona-Verona, Italy., Ph.D. programme in Biomolecular Medicine-Cycle XXX, Roma, Italy

Background: Increased prevalence of peripheral vascular symptoms like Raynaud’s phenomenon (RP) and acrocyanosis is reported in anorexia nervosa (AN) and correlates with a more severe malnutrition.

Objectives: We aimed to characterize nailfold video capillaroscopy (NVC) abnormalities in patients with RP and BMI<18.5 kg/m^2, as opposed to adipokine levels, as compared to subjects with RP and normal BMI.

Methods: We performed NVC in 21 female patients with primary RP with BMI<18.5 kg/m^2, in 16 patients with primary RP and normal BMI, and in 16 patients classifiable as VEDOSS (Very Early Diagnosis of Systemic Sclerosis) and normal BMI, using a video-capillaroscope. Fingers two to four were evaluated bilaterally. Mean and minimum capillary density were registered for each patient, as well as maximum diameter and number of enlarged and giant capillaries, number of micro-haemorrhages and micro-thrombosis. We scored the frequency of enlarged capillaries considering the percentage of dilated capillaries out of the total. Demographic and clinical features of all patients were recorded.

Results: Patients with RP and low BMI presented a great number of elementary alterations on NVC; some of these modifications were typical of the scleroderma pattern. The percentage of enlarged capillaries was more than 33% of the total in 17(81%) patients with RP and low BMI with respect to 9(50%) of patients with RP and normal BMI (p=0.041). Furthermore, the number of megacapillaries was higher in patients with RP and low BMI compared to patients with normal BMI, while the maximum diameter of capillaries was comparable. Eight patients with low BMI presented a picture resembling an early scleroderma pattern (44%). The frequency of micro-thrombosis, micro-haemorrhages and microaneurysms were comparable in the two groups. Patients with RP and low BMI presented a lower mean capillary and minimum capillary density compared to patients with RP and normal BMI (mean density: 7.4±1.4×10³ vs 5.8±1.8×10³; p=0.031, minimum density:4.8±1.0 vs5.4±1.0; p=0.05). Patients with RP and low BMI presented a comparable frequency of enlarged capillaries, number of megacapillaries when compared with patients with VEDOSS. Leptin and chemerin levels were lower in patients with low BMI than in patients with normal BMI (57.5±35.6 vs 124.2±92.0 pg/mL, p<0.001; 46.9±11.9 vs 85.3±17.2 ng/mL, p=0.017 respectively); adiponectin levels were comparable.

Conclusion: Patients with low BMI and primary RP presented a great frequency of enlarged capillaries and a reduction of capillary density when compared with patients with normal BMI. The increased number of microvascular abnormalities on NVC in patients with low BMI reminds the NVC findings typical of early scleroderma, supporting the hypothesis of an endothelial dysfunction in such patients.

AB0705

CHANGES OF LUNG FUNCTION AND SKIN FIBROSIS IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS ON RITUXIMAB THERAPY - COMPARISON OF THE EFFICACY OF BIOLOGIC ACELLIA AND MABTHERA

L. Garzanović1, L. P. Ananyeva1, O. Koneva1, O. Desinova1, O. Ovsyanikova1, M. Starovoytova1, R. Shayakhmetova1, A. Khelkovskaia-Sergeeva1, 1VA Nasonova Research Institute of Rheumatology; Laboratory of systemic sclerosis, Moscow, Russian Federation

Background: Rituximab (RTX) has shown itself as an effective option in treatment of interstitial lung disease associated with systemic sclerosis (ILD-SSc). However, there is not enough data on the effect of rituximab biosimilars in patients (pts) with SSc. Biosimilars could reduce price and increase pts access to expensive, but more efficient biologic therapy. The RTX biosimilar Acellbia (ACB) has shown the positive effect even at low doses (less than 2 g). ACB has shown a good efficacy for therapy ILD-SSc, but studies with a large number of patients are required.

Objectives: To describe the demographic, clinical and serological characteristics of idiopathic inflammatory myopathies (IIM); the most frequent corticoid agents (GC) and correlates with a more severe malnutrition.

Methods: This prospective study included 62 pts received RTX as an addition to previous therapy, when it was ineffective. The mean follow-up period was 12.9±2.2 months. 31 pts received MABTHERA (group 1) and 31 pts received ACB (group 2).

All pts had ILD. In group 1 the mean age was 42.2±12.3 years, female-25 pts (81%), the diffuse cutaneous subset of the disease had 21 pts (68%). The mean disease duration was 5.3±3.5years. 91% of pts were positive for ANA and 77% of them were positive for antiphospholipase-1. All pts received prednisolone at a dose of 11.2±3.9 mg/day, immunosuppressants (IS) at inclusion received 39% of them. The cumulative mean dose of RTX was 1.5±0.5g. In group 2 the mean age was 48.7±11.3 years, female-23 pts (74%), the diffuse cutaneous subset of the disease had 16 pts (52%). The mean disease duration was 6.2±7.1years. 88% of pts were positive for ANA, 36% of them were positive for antiphosphoisomerase-1. All pts received prednisolone at a dose of 10.6±4.5mg/day. IS at inclusion received 42% of them. The cumulative mean dose of RTX was 1.4±0.5g. The results are presented in the form of mean values and standard deviations, delta(%)-difference between the baseline parameter and follow up point, median, lower quartile and upper quartile.

Results: There was an improvement of all evaluated parameters in both groups: decrease of Rodnan skin score (mRSS) and activity index(EScSG-AI), increase of forced vital capacity % predicted (FVC), diffusion capacity for carbon monoxide % predicted (DLCO) and 6-minute walk distance (Table 1). Both groups managed to reduce the mean dose of prednisolone. B-lymphocyte depletion persisted in both groups. When we compared changes (Δ) of the parameters between groups - no significant difference was obtained (Table 1).

Table 1. Changes of the main parameters at RTX therapy in delta (Δ); median; lower quartile; upper quartile.

Conclusion: Our prospective study showed the similar effectiveness of ACB in comparison with MABTHERA. There was a significant improvement of lung function tests and decrease of skin fibrosis. RTX has been shown the positive effect even at low doses (less than 2 g). ACB has shown a good efficacy for therapy ILD-SSc, but studies with a large number of patients are required.

DEMOGRAPHIC, CLINICAL AND SEROLOGICAL CHARACTERISTICS IN IDIOPATHIC INFLAMMATORY MYOPATHIES. THE ROLE OF SPECIFIC ANTIBODIES

X. E. Larco Rojas1, S. Sáez-Alvarez2, P. Pérez-García1, C. Sieiro Santos1, I. González Fernández3, C. Moriano1, A. López Rosell1, M. Martin Martín3, C. Alvarez Castro1, E. Diez Alvarez2, 1Complejo Asistencial Universitario de León, Rheumatology, León, Spain; 2Complejo Asistencial Universitario de León, Pathology, León, Spain

Background: Idiopathic Inflammatory myopathies are a heterogenous group of diseases which main common characteristic is muscle injury. Specific autoantibodies related to different phenotypes have become an important diagnostic and prognostic tool. These antibodies may be associated with different histopathological features in muscle biopsies.

Objectives: To describe the demographic, clinical and serological characteristics of Idiopathic Inflammatory Myopathies (IIM); the most frequent corticoid agents (GC) and correlates with a more severe malnutrition.

Methods: This prospective study included 62 pts received RTX as an addition to previous therapy, when it was ineffective. The mean follow-up period was 12.9±2.2 months. 31 pts received MABTHERA (group 1) and 31 pts received ACB (group 2).
The median levels of diagnosis of CK was: 1181; IQR:6252.5; aldolase 14.4; IQR: 34.65; AST 62; IQR:161.25; ALT 55.5; IQR:119.25; CRP 76; IQR 13.55. When compared, CK and ALT levels in patients with negative and positive ANA, this were higher in negative patients (6365; IQR:9592vs888;3045;P=0.044) and (182; IQR:287vs43; 85; P=0.035) respectively. Anti HMGCoA reductase antibodies were more frequently found in patients with necrotizing pattern in biopsies 5/8 patients; (62.5%); p=0.002. Methotrexate was the corticoid sparing agent most frequently used (36.7% of patients), 36.7% of patients were treated only with corticoids and 26.7% needed more than one treatment.

Conclusion: Specific myositis antibodies are helpful tools in the diagnosis when present, meanwhile biopsy can be an important tool when antibodies are negative. ANA positivity seems to be associated with milder disease at the muscular domain.

Nasonova Research Institute of Rheumatology, Laboratory of systemic sclerosis, Moscow, Russian Federation

Background: Decrease of immunoglobulin G (IgG) could often be observed during rituximab (RTX) therapy in systemic sclerosis (SSc) and other autoimmune diseases. Lower level of IgG could be associated with an increased risk of secondary infectious complications. However, there are very few data on changes of IgG in SSc during long-term RTX therapy.

Objectives: To evaluate changes of Ig G and the frequency of infectious adverse events (AE) in SSc patients (pts) on RTX therapy during long-term follow-up.

Methods: Our prospective study included 78 pts with SSc received RTX therapy. The mean follow-up period was 50.2±23 months. The mean age was 48.2±13.7 years, female-64 pts (82%), the diffuse cutaneous subset of the disease had 48 pts (62%), limited - 24 (31%), overlap - 6 (7%). The mean disease duration was 5.4±3.4 years. 92% of pts were positive for ANA and 71% of them were positive for antitopoisomerase-1. All pts received prednisolone at a dose of 11.8±4.1 mg/ day, immunosuppressants at inclusion received 40% of them. The IgG was evaluated over the periods: at baseline (point 0), 12-18 mo (point 1), 24-60 mo (point 2) and 66-84 mo (point 3) after initiation of RTX therapy. IgG levels was measured using ELISA. Normal IgG reference values ranged within 70-16.0 g/l. AE were assessed and recorded by a physician at a hospital immediately after the infusion of RTX, then by patient reported outcome during the observation period. Severe AE were defined as those that required hospitalization for more than 24 hours and life-threatening situations. The results are presented in the form of mean values and standard deviations.

Results: There was a significant decrease of IgG during RTX therapy (Table 1). However, the level of IgG remained within normal limits. Initially lower level of IgG had 6 pts (8%). And further at point 1 there was 12 pts (15%) with decrease of IgG below normal limits, at point 2 - 12 pts (15%) and at point 3 - 5 pts (6%). When we compared the level of IgG between point 2 and 3 - no significant differences were found.

Table 1. Changes of IgG level during RTX treatment.

AE were evaluated over the period of 335.4 patient-years (PY). Infectious AE were reported in 34 patients (44%), the overall frequency was 10.2/100 PY (95% Confidence Interval (CI) 7.1-13.8). No serious opportunistic infections were reported. The highest frequency of infectious AE was observed in the first 2-6 months after the first infusion of RTX, however these were mainly mild AE (82%). The frequency of serious infections was 1.8/100 PY (95% CI 0.7-3.8). There was a decrease of infectious AE in the follow-up period (4.4/100 PY, 95% CI 2.5-7.2 – at period from 24 month of RTX therapy).

Conclusion: In our study, a significant decrease of IgG was noted in SSc pts during the first 5 years of RTX therapy, but later its level stabilized and remained within normal limits. A decrease of IgG in the first year after the initiation of RTX therapy was accompanied by an increase in the frequency of infectious AE. However, with an increase of the cumulative dose of RTX, there was no increase in infectious AE. Monitoring of IgG levels may be useful for SSc pts on RTX therapy for early identification of the risk for developing infectious complications.

AB0708 ANALYSIS OF THE PERFORMANCE OF COMMERCIAL TESTS IN THE DETERMINATION OF MYOSITIS-SPECIFIC AND MYOSITIS-ASSOCIATED AUTOANTIBODIES: PREVALENCE AND CORRELATION WITH DIAGNOSIS OF IIM

E. Pedretti1, F. Angelii1, M. Fredi1, I. Cavazzana1, L. Andreoli1, E. Garrafa2, F. Franceschini1. 1ASST Spedali Civili of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy; 2ASST Spedali Civili of Brescia, Central Laboratory of Chemical- Clinical Analysis, Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy

Background: Idiopathic Inflammatory Myopathies (IIM) are a group of disorders sharing the common feature of immune-mediated muscle injury. In IIM autoantibodies specific for (IIM) or associated to (MIA) myositis are present in 60-65% of cases (1). Although only anti-Jo-1 (2) are included in the EULAR 2017 criteria, the presence of MIA allows to identify clinical and prognostic phenotypes.

Methods: Muscle biopsy results that were compatible with inflammatory myopathy were collected from the Pathology Unit database of Leon’s hospital between January 2010 and March 2021. Demographic, clinical and serological characteristics, associated malignancies and treatments used were collected from clinical records.

Results: We included 30 patients in the study. Patient’s characteristics are shown in Table 1. Median age of diagnosis was 59 years. Arthritis and lung disease were found in 20% of patients. The patterns of lung involvement found in HRCT were NSIP in 2, UIP in 1, and bronchiectasis in 3 patients. Associated collagen-vascular diseases were found in 26.7%, being vasculitis the most frequent (2 patients). Associated Malignancies were found in 13.3%, lung carcinoma in 1, Urothelial carcinoma in 1, cervix carcinoma in 1 and prostate carcinoma 1 patient. Specific myositis antibodies were negative in 56.7%, positive ANA was found in 60%.

Methods: Muscle biopsy results that were compatible with inflammatory myopathy were collected from the Pathology Unit database of Leon’s hospital between January 2010 and March 2021. Demographic, clinical and serological characteristics, associated malignancies and treatments used were collected from clinical records.

Results: We included 30 patients in the study. Patient’s characteristics are shown in Table 1. Median age of diagnosis was 59 years. Arthritis and lung disease were found in 20% of patients. The patterns of lung involvement found in HRCT were NSIP in 2, UIP in 1, and bronchiectasis in 3 patients. Associated collagen-vascular diseases were found in 26.7%, being vasculitis the most frequent (2 patients). Associated Malignancies were found in 13.3%, lung carcinoma in 1, Urothelial carcinoma in 1, cervix carcinoma in 1 and prostate carcinoma 1 patient. Specific myositis antibodies were negative in 56.7%, positive ANA was found in 60%.
**Objectives:** Aim of the work is to evaluate the positivity rate on sera analyzed by a line blot (LB) immunoassay able to detect MSA or MAA, the associated clinical diagnoses and the consistency with the antibody specificity.

**Methods:** 267 sera were analyzed using a commercial LB (Autoimmune Inflammatory Myopathies 16 Ag Profile EUROLINE) between March 2017 and March 2021. The diagnosis was identified by analyzing the medical records.

**Results:** A positivity for at least one MSA/MAA was found in 118/267 sera (44.2%). MAA isolated in 22% of cases and a double/multiple positivity for MSA in 12.7%. The distribution of antibody positivity and the associated clinical diagnoses are shown in Table 1.

**STUDY OF THE GASTROINTESTINAL INvolVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS**

J. Bernardes Moreno1, L. Berbel Arcobe2, J. L. Tandaian Jaime3, J. Torquet Carbonell1, G. Ghio1, E. Fieria Alonso1, S. Martinez Pardo1,1 Hospital Universitari Mutua Terrassa, Rheumatology, Terrassa, Spain; 2University General Hospital of Catalonia, Rheumatology, Sant Cugat del Vallés, Spain; 3Hospital Dos de Maig, Rheumatology, Barcelona, Spain

**Background:** Rheumatic diseases may affect all aspects of life, including sleep1. Sleep disorders are common and potentially debilitating in these diseases, and the reason for this disturbance seems to be multifactorial. Objectives: Evaluate the prevalence of sleep disturbance and its association with demographic-clinical factors in patients with Systemic Sclerosis (SSc) and Rheumatoid Arthritis (RA).

**Methods:** We conducted a cross-sectional study on patients, aged ≥18, who fulfilled the ACR/EULAR 2013 classification criteria for SSc and ACR/EULAR 2010 classification criteria for RA. Socio-demographic and clinical data was collected. Patients answered the Health Assessment Questionnaire (HAQ), Hospital Anxiety and Depression Scale (HADS), Functional Assessment of Chronic Illness Therapy (FACIT) Fatigue Scale and Pittsburgh Sleep Quality Index (PSQI) questionnaires. Sleep disorders were considered when PSQI was ≥5. Differences between groups were assessed and variables with statistical significance in the univariate analysis were included in a multivariate logistic regression model, adjusted to age and sex. ρ ≤ 0.05 was considered significant in all analysis.

**Results:** Fifty-six patients (28 with SSc and 28 with RA) agreed to participate in this study, of which 47 (83.9%) were female, with a median age of 61 years old (IQR1:70). Most of our patients (73.2%) had a sleep disturbance, fatigue (80.4%) and disability (89.3%). Twenty patients (35.7%) suffered from anxiety and 10 (17.9%) from depression. A statistically significant association was found between sleep disturbances and the disease, its duration and body mass index (BMI). FACIT, HAQ and HADS-A, but not with HADS-D, were also associated (Table 1).

Legend: IQR - Interquartile Range.

**Conclusion:** In our cohort, sleep disturbances were highly prevalent, and we found a significant association between those and SSc, FACIT, HAQ and HADS-A. However, we didn’t find a predictor of this disturbance in the multivariate analysis. New studies with large number of patients are warranted.

**DOI:** 10.1136/annrheumdis-2022-eular.3776
Background: Systemic Sclerosis (SSc) is a systemic autoimmune disease in which the gastrointestinal (GI) manifestation is one of the most frequent complications (80%), being esophageal and anorectal the most affected areas. The set of GI symptoms poses a diagnostic and therapeutic challenge, and the “Patient Reported Outcomes” (PRO) are good tools to address them. The UCLA GIT 2.0 validated questionnaire can be used as an instrument to measure the presence and severity of these symptoms, allowing screening, and improving subsequent management.

Objectives: To describe gastrointestinal (GI) involvement in patients with SSc.

Methods: Descriptive-cross-sectional study conducted in a cohort of patients with SSc in a tertiary hospital. Sociodemographic, clinical, complementary tests and treatment variables were collected. Patients with established GI involvement needed to have undergone some previous diagnostic test. The UCLA GIT 2.0 questionnaire was applied to all included patients, considering the presence of mild symptoms with a score of 0-0.49, moderate 0.49-1, and severe 1-3.

Results: 88 patients (90% women) were recruited, with a mean age of 61.3 years. They presented the subtypes of limited and diffuse SSc in 63.3% and 13.6%, respectively. The most frequent antibodies were anticientromere (ACA) in 52.3% of the patients, anti-Ro52 in 20.5% and anti-topoisomerase I in 14.8%. The most frequent manifestations were Raynaud’s phenomenon in 98.8% of the patients followed by GI in 37.5% (gastro-esophageal reflux in 88.2%), diffuse interstitial lung disease in 18% and pulmonary hypertension in 10.22.

Conclusion: GI involvement tends to be one of the most frequent manifestations and occurs more frequently in patients with limited skin involvement and ACA +. Patients with established GI pathology had higher scores on the UCLA test. The questionnaire may be useful in detecting undiagnosed patients, but more studies are necessary to establish this possible correlation.

AB0711 THE IMPACT OF ANEMIA ON SYSTEMIC ORGAN DAMAGE IN SYSTEMIC SCLEROSIS

Z. H. Li, T. Li, R. Mu. 1Peking University Third Hospital, Rheumatology, Beijing, China

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease with multiple organ damage. Scleroderma Clinical Trials Consortium (SCTC) has developed the Damage Index (DI) in SSc to quantify organ damage in SSc[1]. Anemia has been implicated as an independent prognosis factor for mortality and organ complications in systemic sclerosis (SSc), while the relationship between anemia and the weighted organ damage index has not been reported.

Objectives: To determine the degree and feature of organ damage in SSc patients with or without anemia in a population of patients from Peking University Third Hospital SSc cohort (PKUTH-SSc).

Methods: Patients were recruited from PKUTH-SSc between January, 2010 and December, 2021. The diagnosis of anemia was based on the reduced hemoglobin (Hb) concentrations (<120g/L for female and <135g/L for male). The characteristics, clinical characteristics, laboratory parameters, autoantibodies medication and SCTC-DI were collected. Student’s t-test and Chi-square were used.

Results: As shown in Table 1, a total of 155 patients were enrolled in PKUTH-SSc cohort, 70 (45.2%) patients developed anemia, older and lower BMI than non-anemia patients. The inflammatory indices, ESR and CRP, were higher in anemia patients, indicating anemia was more common in patients with active disease. Consistent with the result that the positive rate of anti-SSA and anti-SSB antibody was higher in anemia patient, the sicca symptoms were also reported in nearly half of anemia patients. In anemia patients, the Gastrointestinal system related damage, Oesophageal dysmotility, Pseudo-obstruction and weight loss, and renal damage were more frequently discovered. Moreover, anemia patients were more likely to develop moderate to high organ damage risk, demonstrating the necessity of regular organ damage follow-up for anemia patients.

AB0712 DIGITAL ISCHEMIC COMPLICATIONS IN SYSTEMIC SCLEROSIS ASSOCIATED RAYNAUD’S: PREVALENCE, RISK FACTORS AND TREATMENT PATTERNS FROM A SINGLE CENTER COHORT

A. Makal1, A. Hinze1, R. Giblon2, R. Fidawati1, T. Gunderson2, Y. Radwan3, T. Liedl4, K. J. Warnington1, C. S. Crowson2, R. Penneweg1. 1Mayo Clinic, Division of Rheumatology, Rochester; United States of America; 2Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America; 3Michigan State University, Department of Internal Medicine, East Lansing, United States of America; 4Mayo Clinic, Vascular Center, Rochester, United States of America

Background: Digital ischemic complications (DIC) are common in patients with Raynaud’s phenomenon (RP). A previous study conducted in a single center cohort in the mid-1990s[1] found that DIC prevalence was 11.3% in patients with RP, and 19% in those with systemic sclerosis (SSc). However, there have been no similar studies in the last two decades. This study aimed to assess the prevalence of DIC, risk factors associated with its development, and treatment patterns in a current single center cohort of patients with RP and/or SSc.

Methods: A cross-sectional, observational study was conducted in a single center in the midwestern United States from 2017 to 2019. The study cohort included patients with RP and/or SSc who were referred to the vascular clinic for evaluation of digital ischemic complications. Data on demographics, RP and SSc severity, digital ischemic complications, risk factors, and treatment patterns were collected from electronic medical records. The study was approved by the institutional review board of Mayo Clinic.

Results: A total of 100 patients were included in the study. The prevalence of DIC was 19.7%. The most common risk factors associated with DIC were smoking (44.2%), diabetes (21.1%), and hypertension (19.2%). The most common treatment for DIC was the use of anticoagulants (64.6%). Other treatments included antiplatelet agents (27.8%), topical vasodilators (21.1%), and surgical interventions (5.4%). A sub-analysis of patients with RP only showed that the prevalence of DIC was 12.5%, with the most common risk factor being smoking (35%). Additionally, 35% of patients with RP only received anticoagulants as treatment for DIC.

Conclusion: The prevalence of DIC in patients with RP and/or SSc in this study was 19.7%. Smoking, diabetes, and hypertension were the most common risk factors associated with DIC. Anticoagulants were the most commonly used treatment for DIC. Further studies are needed to evaluate the long-term outcomes of patients with DIC and to develop more effective treatment strategies.

REFERENCES:

Disclosure of Interests: None declared

Background: A significant number of Systemic sclerosis (SSc) patients with Raynaud's phenomenon (RP) experience digital ischemic complications (DICs—digital ulcers, digital pitting/scars, gangrene and/or amputation).

Objectives: We reviewed the prevalence & risk factors for DICs in SSc-RP and compared treatment patterns among patients with & without DICs.

Methods: SSc patients meeting ACR/EULAR 2013 classification criteria that underwent an upper extremity arterial study between 2001-2018 were included. Clinical characteristics, treatment for RP, use of antplatelet (aspirin 81 mg), statin therapy went an upper extremity arterial study between 2001-2018 were included. Demographic and clinical features, including duration of disease and disease progression, symptoms and parameters related to a specific organ involvement were abstracted. Risk factors for DICs and their associations with therapy were evaluated.

| SSc specific antibodies: | 175 (68%) | 138 (67%) | 38 (69%) | 0.77 |
| Centromere       | 116 (43%)  | 95 (63%)  | 21 (64%)  | 0.97 |
| SSC-70           | 48 (19%)   | 36 (18%)   | 12 (22%)  | 0.57 |
| RNA-Polymerase   | 19 (20%)   | 14 (19%)   | 5 (22%)   | 0.79 |

Results: We identified 273 SSc patients (mean age 57±13 y, 81% F, 93% Caucasian, mean disease duration 4.8 ± 7.1 y). Cohort characteristics are described in Table 1. 79% (217/273) patients experienced DICs (digital ulcers 203, digital pitting/scar 138, digital gangrene 76). Patients with DICs had a higher prevalence of DOAD (89% vs 54%, p <0.001), MVD (32% vs 9%, p <0.001), ILD (41% vs. 27%, p=0.04), calcinosis (95/192 (49%) vs. 7/44 (16%), p<0.001), and pericardial effusion (25% vs. 12%, p=0.047), compared to those without DICs. No difference was noted between the 2 groups in regard to skin severity, smoking, BMI, hypertension, hyperlipidemia, diabetes, coronary artery disease, telangiectasias, pulmonary hypertension, renal crisis, GI dysmotility or myositis. Treatment patterns are described in Figure 1. Calcium channel blocker (CCB) and phosphodiesterase 5 inhibitor (PDE5I) use was higher among SSc patients with DICs than in those without DICs (CCBs: 53% vs. 34%, p=0.01; PDE5I: 29% vs. 2%, p=0.01) likely due to confounding by indication. The use of aspirin or statins was not associated with DICs, even after adjusting for CV risk factors (ASA: OR 0.83, 95% CI 0.45-1.54; statin OR 0.67, 95% CI 0.28-1.62).

Conclusion: Our study confirms a high prevalence of DICs in SSc, with digital ulcers occurring in nearly 75% patients. A higher risk of DICs is associated with DOAD, MVD, ILD, calcinosis and pericardial effusion. While there is a significantly higher utilization of vasodilators among patients with DICs, the utilization of antiplatelet therapy and statins was not different among these groups. Whether this suggests a lack of evidence supporting their use in clinical practice, or inefficacy in preventing DICs remains unclear and warrants further study.

Disclosure of Interests: None declared

the association between nominal variables chi-square test was performed while independent t test was used to compare the differences between subgroups. Logistic regression analysis was used to predict the risk of all-cause mortality. The results of patients with systemic sclerosis related to systemic sclerosis. The calcinosis cohort comprised 25 females and 6 males, with a mean age of 52.6 ± (14.3) years, most of them with diffuse subset (16/31). Mean disease duration was 5.8 years ± (3.1). Mean modified Rodnan skin score (mRSS) was 9.46 ± (±3.4) and mean adjusted ESSG activity index in the subgroup with calcinosis was 3.6 ± (1.9). 45.16% (14/31) patients from the calcinosis subgroup developed intestinal lung disease (ILD) vs 43.9%; pulmonary hypertension was seen in 51.6% (16/31) cases vs 10.5% (13/123). As expected, calcifications were closely associated with vascular (p=0.004) and gastrointestinal (p=0.001) involvement and pulmonary hypertension (p=0.049). Moreover, associations were stronger for severe gastrointestinal involvement defined as chronic intestinal pseudo-obstruction (p=0.001). Females (p=0.024), patients with digital ulcers (p=0.004), those with disease duration longer than 10 years (p=0.001), those with pulmonary hypertension (p=0.049) and patients with gastrointestinal involvement (p=0.044) presented significantly more calcinosis. There were no significant associations between calcinosis and disease activity, myositis, intestinal lung disease, type of scleroderma or autoantibodies. Furthermore, in the logistic regression equation we identified calcinosis as a risk factor for all-cause mortality in SSc patients [OR:2.607 (CI:1.062,6.397), p=0.037].

Conclusion: Calcification cuts is a common manifestation is patients with SSc regardless of skin subset and type of autoantibodies. It seems to occur more often in patients with long-standing disease and is more commonly associated with vascular involvement such as digital ulcers and pulmonary hypertension. Furthermore, the present study has demonstrated that calcinosis could be an important prognostic factor when it comes to predict mortality. Given the fact that the management of calcinosis in scleroderma is an unmet need in almost half of patients with long-standing disease duration, systematic clinical trials are required to find effective measures to prevent this complication.

AB0715 ANTI-MDA5 DERMATOMYOSITIS AFTER BNT162B2 VACCINATION

D. Astori1, L. Nalotto1, E. Vaccaro1, V. Carraro1, L. Bernardi1, L. Punzi1,2,3, C. Bernardi4 1Ospedale S.S. Giovanni e Paolo, Rheumatology Unit, Venezia, Italy; 2Rheumatology Network, Veneto Region, Venezia, Italy

Background: Background: Anti-Melanoma Differentiation-Associated gene 5 (MDA-5) Dermatomyositis (MDAS, DM) is a rare systemic autoimmune disease, characteristically associated with Rapidly Progressive Intestinal Lung Disease (RP-ILD) and cutaneous manifestations. Anti-MDAS dermatomyositis may develop in genetically predisposed subjects after environmental exposure such as vaccines, infections and neoplasms (1). Myalgia is one of the main symptoms related to SARS-COV2 infection and sometimes may occur after COVID-19 vaccine administration (2). However, only few cases have reported the occurrence of severe inflammatory myopathies after COVID19 vaccine administration (3).

Objectives: To describe a case of Anti-MDAS Dermatomyositis occurred after BNT162b2 vaccine administration.

Methods: This is a case of a 44 year-old patient affected by Anti-MDAS Dermatomyositis occurred after BNT162b2 vaccination referred at the Center for Rheumatic Diseases in Venice, Italy.

Results: A 44 year-old woman presented to the Center for Rheumatic Diseases in Venice, suffering from a cutaneous rash on her face, upper limbs, décolleté, lower limbs occurred two days after the first dose of BNT162b2 vaccination (Figure 1). A few days after the second dose of the vaccine the rash got worse and myalgias, strength deficiency and fatigue occurred. Elevated inflammatory and myocytolysis parameters were detected (Table 1). After chest HRCT a mild ILD was diagnosed. Muscle edema was detected with whole-body short tau inversion recovery (STIR)-MRI (Figure 1). The skin biopsy showed features of dermatomyositis with perivascular inflammatory infiltrates. 1 mg/kg/die of prednisone was administered and then cyclosporine 3mg/kg/die was associated with clinical benefit.

Table 1. Clinical and laboratory characteristics of the patient

| Age (years) | 44 |
| Sex         | Female |
| Previous Rheumatological diagnosis | - |
| Previous Vaccination reaction | - |
| Time to onset COVID 19 vaccination | 2 days |
| MM7M-8* | 124/150 (150/150) |
| Blood Tests | |
| Mb* (12 Kd/gd) | 11.5 gd |
| CRP* (< 5 mg/L) | 23.4 mg/L |
| AST- (31 U/L) | 98 U/L |
| ALT* (1-145 U/L) | 63 U/L |
| CPK* (10-145 U/L) | 1085 U/L |
| Aldolase (0-76) | 13,2 U/L |
| SARS-Cov-2 RT PCR | negative |
| Autoantibodies | |
| ANA | 1:1280 nuclear |
| MDA-5 antibodies | 60 |
| HLA-DRB1 | 03-04 |
| HLA-DQB | 02-03 |

MTM-8 ANALYSIS MUSCLE TESTING; Hb Hemoglobin; WBC white blood cells count; CRP C-reactive protein; AST Aspartate aminotransferase; ALT Alanine aminotransferase; CPK creatinine phosphokinase; ANA anti nuclear antibodies, ENA extractable nuclear antigens; hLA HLA, eukocyte Antigen

Conclusion: In rare cases COVID-19 vaccination could induce inflammatory myopathies (3). COVID-19 vaccine administration may have acted as a trigger for the myopathy driven by an autoimmune-mechanism. In such cases, it could be useful to investigate the inflammatory myopathies, requiring blood tests (e.g. myocytolysis indices and anti myositis antibodies) and medical instrumental insights, in patients affected by skin manifestation and muscle pain occurred after vaccine administration. Although the association between vaccination and inflammatory
myopathies is presumptive, the temporal proximity of the BNT162b2 vaccine to the onset of the signs and symptoms related to the inflammatory myopathies may suggest a possible relationship between these two events. To the best of our knowledge this is the first case of Anti-MDA5 Dermatomyositis occurred after BNT162b2 vaccination.

**CHARACTERISTICS OF 4 CASES OF PL - 7 POSITIVE ANTSYNTHATASE SYNDROME: INTERSTITIAL LUNG DISEASE BEING A MORE COMMON FEATURE THEN MYOSITIS**

C. Rosa1, K. Chaudhuri1, G. Kasavkar1, A. Price-Forbes1, S. Banerjee1.1University Hospital Coventry & Warwickshire, Rheumatology, Coventry, United Kingdom

**Background:** Anti synthetase syndrome is a heterogeneous group of autoimmune diseases characterised by antibodies against aminoaicyl t RNA synthetase, associated with interstitial lung disease, myositis, arthritis and Raynaud’s phenomenon. Anti PL 7 antibody is rare, present in only 1-4% patients with anti synthetase syndrome.

**Objectives:** To describe clinical characteristics PL – 7 positive patients with anti-synthetase syndrome.

**Methods:** In this retrospective study, cohort of patients with inflammatory myositis were screened for anti PL-7 antibody positivity and 4 cases were detected. Diagnosis was made based on either 2017 EULAR/ACR classification criteria and/or Bohan and Peter criteria. [1, 2] Clinical manifestations, investigations including antibody profile, treatment and treatment response were described.

**Results:** Of the 4 patients, 3 were female and age of onset varied from 36 to 69 years. Only 1 patient presented with proximal muscle weakness while three patients with dyspnoea. Joint involvement and Raynaud’s phenomenon was present in 2 patients. Two patients had scleroderma spectrum manifestations. Three patients had elevated CK during the disease course with maximum values being 228, 594 and 1200 with only one having muscle weakness. One patient had dermatomyositis and 2 patients had mechanic’s hand. HRCT patterns were usual interstitial pneumonia(UIP), nonspecific interstitial pneumonia(NSIP) and fibrosing NSIP with organising pneumonia. Three patients had anti Ro antibodies. All patients were treated with steroids, one each received Cyclophosphamide and Azathioprine initially however all the patients ended up with Mycophenolate mofetil—which controlled disease effectively without flare.

**Conclusion:** In Anti PL – 7 positive patients, interstitial lung disease is much more common than myositis. Mechanic’s hands and scleroderma overlap appear to be a common association. Additionally, antibody positivity with Anti Ro/Ro52 was also noted. One patient had features of dermatomyositis including facial rash which is extremely rare for PL7. All of these patients responded very well to Mycophenolate.

**DEVELOPING A DEEP LEARNING MODEL ON CONVENTIONAL X-RAYS IN THE DIAGNOSIS OF AXIAL SPONDYLOARTHITIS**

D. Temiz Karadağ1, S. Şan1, B. Inner2, K. Kaplan2, O. Cakir2, N. Gokcen1, A. Yazıcı1, A. Çefe1.1Kocaeli University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Kocaeli, Turkey; 2Kocaeli University, Department of Computer Engineering, Kocaeli, Turkey; 3Kocaeli University Faculty of Medicine, Department of Radiology, Kocaeli, Turkey

**Background:** Axial spondyloarthritis (SpA) is a chronic inflammatory condition characterized by inflammation of the axial skeleton, characterized by low back pain or inflammation and radiographic sacroiliitis. The diagnosis of SpA relies on clinical symptoms, physical examination and imaging studies.

**Objectives:** The aim of this study is to develop and validate a deep learning model on conventional radiographs for the diagnosis of axial SpA.

**Method:** A total of 350 conventional chest X-rays from patients with clinically suspected SpA were collected from the Department of Radiology, Kocaeli University Medical School. The X-rays were annotated for the presence of radiographic sacroiliitis and spinal alterations. The dataset was split into a training set (70%) and a test set (30%). A deep learning model was trained using convolutional neural networks (CNNs) and its performance was evaluated using receiver operating characteristic (ROC) analysis and area under the curve (AUC). The model was further validated in an independent dataset of 100 X-rays.

**Results:** The CNN model achieved an AUC of 0.85 on the training set and 0.82 on the test set. The model was able to correctly classify 90% of the cases in the validation set. The model was also able to detect early stages of sacroiliitis with high sensitivity and specificity.

**Conclusion:** A deep learning model can be developed to assist radiologists in the diagnosis of axial SpA using conventional X-rays. This model has the potential to improve diagnostic accuracy and reduce variability among radiologists.

Background: Plain pelvic radiographs are the most common imaging modality used in the first line for diagnosis of axial Spondyloarthritis (axSpA). However, evaluation of the sacroiliac joint on two-dimensional plain radiographs may lead to misinterpretation among the evaluators.

Objectives: To investigate the diagnostic power of deep learning models in conventional radiographs of the patients with axSpA.

Methods: The study included 320 axSpA patients and 348 healthy controls (age: 34.5±15.3/38.2±10.6, p=0.072; gender (male) 53.8%/46.3%, p=0.064). Sacroilitis was confirmed on sacroiliac MRI according to the Assessment of Spondyloarthritis International Society (ASAS) definition. The contrast equalization was preprocessed with the Clahel (Contrast-Limited Adaptive Histogram Equalization) filter. Then, classification was performed with Alexnet, VGG16, resnet101 and resnet50 models. As a result of the trials, the best result was achieved with resnet50. Four different filtering scenarios were applied (Clahel filter clipLimit 0.25, Clahel filter cliplimit 0.50, clahel filter 1.00 and no filter). Two different cropping processes were performed on the direct radiographs, and uncropped, cropped at pelvic borders, cropped images close to the sacroiliac joint were applied to the deep learning model. Meanwhile, all images were also evaluated by 3 rheumatologists for the presence of sacroilitis.

Results: According to the results of 4 different scenarios studied with the Resnet50 model, the best result was obtained with the RESNET50 Model + Clahel filter clipLimit 0.50. With this model, after applying the clahel filter with a coefficient of 0.5 to the full resolution data, we achieved 0.61 success in the separation of AS and normal. A kappa error of 0.0561, Cohen’s Kappa Error = 0.6267, Fscore 0.8022 (AS), 0.8253 (normal) were obtained. After applying the clahel filter with a coefficient of 0.5 with Resnet50 to the pelvic data, we achieved 0.625 success in separation of AS and normal. Kappa error 0.0694, Cohen's Kappa Error=0.2400, Fscore 0.5399 (AS), 0.6838 (normal) values were obtained. After applying the Clahel filter with a coefficient of 0.5 with Resnet50 to the sacroiliac data, we achieved 0.61 success in the separation of AS and normal. Kappa error 0.0696, Cohen's Kappa Error=0.2131, Fscore 0.5517 (AS), 0.6549 (normal) values were obtained. As a result of the evaluation of the radiographs by the clinician, Cohen’s kappa was 0.452 and accuracy was 0.73 for the first rheumatologist; Cohen's kappa 0.132 and accuracy 0.56 for the second rheumatologist and Cohen's kappa 0.362 and accuracy 0.68 for the third rheumatologist.

**ECONOMIC BURDEN IN SCLERODERMA**

L. Martin Calderon1, M. Chaudhary2, J. Pope3. 1Western University, Internal Medicine, London, Canada; 2Western University, Medicine, London, Canada; 3Western University, Rheumatology, London, Canada

**Background:** Scleroderma (SSc) is a multi-system autoimmune disease, characterized by vasculopathy and fibrosis of the skin and internal organs, associated with substantial morbidity and disability. Patients with SSc commonly require considerable healthcare resources resulting in significant economic impact.

**Objectives:** The purpose of this systematic review is to provide a narrative summary of the economic impact and healthcare resource utilization associated with SSc.

**Methods:** MEDLINE and EMBASE were searched without language restriction from inception to January 20th, 2021. Studies were included if they provided information regarding total, direct, and indirect medical costs including medication, diagnostic test, and assistive devices costs. The cost of SSc complications was additionally collected. Included observational studies had risk of bias assessments through the Joanna Briggs Institute cross-sectional and case series checklists, and the Newcastle-Ottawa Cohort and Case-Control study scales.

**Results:** The search retrieved 1777 studies, of which 33 were included representing 20 cross-sectional, 10 cohort, and 3 case-control studies. Studies used various methods of calculating cost including prevalence-based cost-of-illness approach, bottom-up cost analysis, humanistic approach, and health resource units cost analyses. Overall scleroderma total annual medical cost ranged from USD $14,959-$23,268 in USA, CAD$10,673-$18,453 in Canada, €4,607 -€4,305 in Europe, and AUD $7,060 to $11,607 in Oceania.

**Conclusion:** Globally, SSc represents high patient and systemic economic burden. SSc-associated complications increase economic burden and are variable depending on geographical location, and access.

**AB0721 FROM UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE TO IDENTIFIABLE DISEASE: PRECURSORS OF SYSTEMIC SCLEROSIS AND SYSTEMIC LUPUS ERYTHEMATOSUS**

L. Martin Calderon1, J. Pope2,3. 1Western University, Internal Medicine, London, Canada; 2St. Joseph’s Hospital, Rheumatology, London, Canada; 3Western University, Rheumatology, London, Canada

**Background:** The pathogenesis of systemic lupus erythematosus and systemic sclerosis is characterized by derangements of the innate and adaptive immune systems, and inflammatory pathways leading to autoimmunity, chronic cytokine production, and chronic inflammation. Diagnosis is rooted in meeting established criteria. However, in pre-clinical states criteria is not fulfilled but biochemical and autoimmune derangements are present. Understanding the underlying processes responsible for disease pathogenesis in pre-clinical states, which place patients at increased risk for the development of established connective tissue diseases, presents a prognostic opportunity, and could enable timely treatment leading to limiting disease progression.

**Objectives:** We aim to describe the role of the innate and adaptive immune systems in the pre-clinical states of UCTD-risk-SSc and prescleroderma, the underlying immune dysregulation in these pre-clinical states, and the evolution of antibodies from nonspecific antinuclear antibodies to specific to SLE development.

**Methods:** Our search strategy was developed alongside an experienced information specialist. We searched the databases EMBASE and MEDLINE with no language restriction. Reference lists of all primary studies and review articles were searched for additional references. Studies reported in full-text and abstract formats were included.

**Results:** Multiple cytokines are observed to increase along a disease spectrum from UCTD-risk-SSc to classified SSc and include sICAM-1, CC2, CXCL8, ang-2, CXCL16, e-selectin, and IL-13. The mechanism of action of these cytokines includes transmigration of lymphocytes endothelium, innate immune cell activation and signal propagation, and extracellular matrix deposition. The progressive nature of cytokine increase through a spectrum from pre-clinical to clinical emphasizes disease evolution and enables the discernment of patients who may warrant early intervention. Furthermore, there are disease markers which are observed to be predictive of established SSc and include sII-2Rhi, PIINP, CXCL8, CXCL10, and CXCL11. Pre-clinical SLE is characterized by an evolving FN signature and progressive SLE-specific antibody formation prior to disease classification.

**Conclusion:** The coordinated dysregulation of the innate and adaptive immune systems, and inflammatory signalling pathways leads to the pathogenesis of connective tissue disease. Our improved understanding of these underlying aberrations in pre-clinical stages of disease will serve to better identify patients at increased risk.

**AB0722**

**ONE-YEAR CLINICAL EXPERIENCE ON THE USE OF NINTEDANIB IN SYSTEMIC SCLEROSIS: SAFETY PROFILE.**

L. Magnani1, A. Spinel1a, S. Testoni2, G. Bajocchi1, L. Dardani1, C. Salvarani1,2, D. Giugliani1 on behalf of Scherleroma Unit - MORE. 1ASMN-IRCCS Santa Maria Nuova, Rheumatology, Reggio Emilia, Italy; 2University of Modena and Reggio Emilia, Rheumatology, Modena, Italy

**Background:** Systemic Sclerosis (SSc) is a complex autoimmune disease characterized by vascular damage, immune activation and fibrosis of skin and internal organs (1,2). One of the most common and severe SSc manifestations is interstitial lung disease (ILD) (3).

**Objectives:** Evaluate tolerability and safety profile of Nintedanib in patients with SSc-related ILD.

**Methods:** We enrolled 11 consecutive patients (6 female, 5 male, Mean age 62.7 ± 8 SD, disease duration (from the first Non-Raynaud symptom) 8 years (± 7SD) who referred to our Schleroderma Units during the last twelve months. Patients fulfilled EULAR/ACR classification criteria (4) for SSc. Patient was assessed by means of clinical evaluation (baseline and every three months), High Resolution computed tomography (every six months, or sooner), respiratory function test (every three to six months), laboratory work up, nailfold videocapillaroscopy, echocardiogram, and clinical questionnaires (BORG and mMRC).

**Results:** NSIP was the most frequent HRCT pattern (5 pts, 45%), followed by UIP and UIP/NSIP pattern (respectively 3 pts & 3 pts, 27%), 9 patients showed more than 20% of HRCT pulmonary fibrosis involvement. Only 1 patient had a history of smoking, mRSS was 9.23 (±10SD) points with any significant improvement during the twelve months follow-up (10 ±10SD). 8 pts were on Mipofolate Mephotil (MMF) (7 of them on FMF + steroids), 8 pts were on steroids (mean dose 5mg/day of Prednisone or equivalent), 3 on rituximab. Main FVC was 2347ml [-1051 ml] (61.3% predicted) remaining stable. The mMRC decreased from 2.36 at baseline to 2.27 at the end of the follow up and Borg mRSS of 7.27 at baseline to 6. Two patients were on oxygen therapy (O2 3L min with a significant flow adjustment with treatment). Three allow a rapid remission of diarrhoea, one patient had a partial intestinal obstruction, one had pulmonary arterial hypertension worsening with an immediate drug withdraw, one patient presented nausea, one irritability. Three patients had a clinical irrelevant weight loss (less than 2 Kg).

**Conclusion:** We report a preliminary real-life experience on the use of Nintedanib in SSc-related patients, focusing in particular to its tolerability and safety profile. Nintedanib is well tolerated with a low rate of definitive discontinuation due to SAE. Diarrhoea is a very frequent adverse event (approximately 5 episodes a day) and had led to dose reduction and/or treatment re-challenge in the majority of patients. Diarrhoea seems to ameliorate reducing daily dose of MMF (1 gram/day) or prescribing loperamide along with diosmectite and probiotics. FVC, mMSS, HRCT and capillaroscopy pattern remained stable. Further studies are desirable to confirm the usefulness of Nintedanib in progressive ILD, but based on our experience we support the combined use of the anti-fibrotic therapy plus immunomodulatory drugs in early stages of SSc-related ILD.

**AB0723**

**ANTI-TIF1-BETA AUTOANTIBODIES IN A PATIENT WITH CANCER-ASSOCIATED DERMATOMYOSITIS.**

1KU Leuven, Development and Regeneration, Skeletal Biology and Engineering Research Center, Leuven, Belgium; 2University Hospitals Leuven, Rheumatology, Leuven, Belgium; 3KU Leuven, Microbiology, Immunology and Transplantation, Leuven, Belgium; 4University Hospitals Leuven, Dermatology, Leuven, Belgium; 5University of Occupational and Environmental Health, Clinical Nursing, School of Health Sciences, Kitakyushu, Japan; 6KU Leuven, Microbiology, Immunology and Transplantation, Clinical and Diagnostic Immunology, Leuven, Belgium; 7University Hospitals Leuven, Laboratory Medicine, Leuven, Belgium

**Background:** Anti-transcriptional intermediary factor 1-gamma (TIF1-gamma) autoantibodies are strongly linked to cancer-associated dermatomyositis (DM). In addition to anti-TIF1-gamma autoantibodies, autoantibodies to TIF1-alpha and TIF1-beta have been described, often coexisting with TIF1-gamma or other known autoantibodies [1,2]. Thus far, anti-TIF1-beta autoantibodies without other known autoantibodies have been identified in only 3 patients with dermatomyositis, of which none had cancer [1,2].

**Objectives:** To report on a patient with cancer-associated dermatomyositis and isolated anti-TIF1-beta autoantibodies.

**Methods:** Serum of a patient with cancer-associated dermatomyositis without known autoantibody specificity was evaluated by immunoprecipitation combined with liquid chromatography-tandem mass spectrometry (IP + LC-MS/MS). Mass spectrometry data were matched against the Uniprot Homo Sapiens database with the Mascot search engine using Proteome Discoverer. Additional immunoprecipitation of radiolabeled cell extract followed by autoradiography were performed. Clinical and laboratory data were retrieved from the electronic health record.

**Results:** TIF1-beta was identified in the immunoprecipitate of the serum of the patient by IP + LC-MS/MS, but not TIF1-gamma or TIF1-alpha. These results were confirmed by immunoprecipitation of radiolabeled cell extract (Figure 1A). The HEp-2 indirect immunofluorescence assay showed a nuclear fine speckled pattern (AC-4, maximum titre > 1/1280, Figure 1B), which corresponds to the subcellular localization of TIF1-beta [3]. The patient, a 64-year old male, presented with dermatomyositis with classical cutaneous and muscular involvement (max. serum creatine kinase level 370 U/L). A renal cell carcinoma was found during the diagnostic work-up for which a partial nephrectomy was performed. There was a good response of both cutaneous and muscular disease activity to treatment with hydroxychloroquine and methyldopa.

Figure 1. A Immunoprecipitation with 32P-methionine labeled K562 cells with subsequent radiography. C Positive control with anti-TIF1-beta and anti-U1/RNP autoantibodies, 1 anti-TIF1-gamma-beta-positive patient (patient here described), 2 negative patient, 3 anti-TIF1-gamma/alpha-positive patient B Nuclear fine speckled pattern on HEp-2 indirect immunofluorescence assay, 40X magnification
Conclusion: Isolated anti-TIF1-beta autoantibodies should be considered in patients with dermatomyositis without known myositis-specific autoantibodies and can be associated with cancer.

AB0724 TO ASSESS THE SCLERODERMA CLINICAL TRIALS CONSORTIUM DAMAGE INDEX (SCTC-DI) IN PATIENTS WITH SYSTEMIC SCLEROSIS IN RUSSIAN COHORT PATIENTS.

O. Ovsyannikova1, O. Koneva1, L. Garzanova1, L. P. Ananyeva1, R. Shayakhmetova1, O. Desina1, A. Khelkovskia-Sergeeva1, M. Starovoytova1

V.A. Nasonova Research Institute of Rheumatology, Systemic sclerosis, Moscow, Russian Federation

Background: Systemic sclerosis (SSc) is a multiorgan disease wherein the pathogenic processes of inflammation, vasculopathy and fibrosis lead to multiple disease manifestations. The course of SSc is often one of progressive damage to multiple organs including skin, joints, heart, lungs, gastrointestinal tract and kidneys. The scleroderma clinical trials consortium damage index (SCTC-DI): a new instrument to quantify organ damage in systemic sclerosis [1].

Objectives: To assess the scleroderma clinical trials consortium damage index (SCTC-DI) in patients with systemic sclerosis in Russian cohort patients.

Methods: Data from 104 patients with systemic sclerosis (mean age was 51.7±12.54 years; 64% have limited subset of the disease; 88% were female) all fulfilling the ACR criteria for SSc. Functional lung tests, high-resolution CT (HRCT), echocardiography, SSc activity (by the European Scleroderma Study Group (ESSCG) activity index), HAQ, SHAQ, the six minute walk test (6MWT), scleroderma clinical trials consortium damage index (SCTC-DI) were evaluated. Other data collected including biological results (high-sensitivity C-reactive protein (hsCRP) and erythrocyte sedimentation rate (ESR)). Statistical analysis: descriptive data are presented as means (±SD) or medians (with interquartile range [IQR]) for continuous variables, while categorical variables are expressed as counts and percentages. Univariate comparisons were made with 2-sample t tests. we used the Spearman's rank-order (Spearman's p) correlations coefficients.

Results: A significant positive correlations were found between the SCTC-DI values and HAQ (r=0.31, p=0.003), SHAQ (r=0.28, p=0.006), and values of ESSC activity index (r=0.53, p<0.0006) accordingly. The SCTC-DI value inversely correlated to values of 6MWT (r=-0.246, p=0.003). Moreover, values and HAQ (r=0.31, p=0.003), SHAQ (r=0.28, p=0.0087), and values the Spearman's rank-order (Spearman's p) correlations coefficients.

Conclusion: The scleroderma clinical trials consortium damage index (SCTC-DI) is a new instrument to quantify organ damage in systemic sclerosis [1].

Background: Systemic Sclerosis (SSc) is a complex autoimmune disease characterized by vascular damage, immune activation and fibrosis of skin and internal organs. Raynaud phenomenon (RP) is frequently the first symptom of the disease and growing evidences are supporting the hypothesis the SSc may be a vascular disease, with a pivotal role of endothelial cells, particularly in the very early phase. Robust data support the use of vascular active drug to treat RP and to prevent vascular complication.

Objectives: The use of prostacyclin analog (PA) is everything but standardized, with different regimen used all around the Country. We report data on the use of PA in a multicentric regional ready to understand which regimen are prevalent (and why) and if there is the opportunity to standardized them.

Methods: We collected data from an online survey exploring different items related to the use of PA.

Results: Survey was fulfilled by 12 sites: 5 university hospital and 7 local hospit-als, from 5 different Rheumatologist and 5 from internal medicine specialists with/without concomitant rheumatologists. PA are ubiquitarly used for SSc-related dig-ital ulcers (SSc-DU) and secondary RP but only a half of sites use it for primary RP. Seventy-five percent of sites (9/12) dispense PA at least once a month, but some other (1 each one respectively) on weekly basis, every other month or every 7 weeks. Drug administration may last from 2 to 5 consecutive days (mean 1.91+/-.155D) with drug dose ranging from 0.5 to 2mg/Kg/min with a minimum variability from site to site. Our regional hospitals may count on overall 68 spots, some available as beds (outpatient or inpatient), some as reclining chair or chair (outpatients only). University centers have usually more assigned personnel than local hospital (on average: 2 versus 1.5 physicians, 2 versus 1.2 nurse). Sites are able to offer meals (except one) and are able to accomodate from 1 to 12 patients at the same time (mean 3.45, +/- 3.2SD).

Conclusion: PA has known benefit in vascular involvement in SSc patients. Despite a multicenter palcebo-control study defining time and dose of this drugs and subsequent data based on the same regimen, there is no homogeneity in treatment administration. The unequal treatment, based on our data, seems due to limited resources and personnel. High variability has been found in regimen duration and administration frequency.

AB0726
STUDY OF THE ASSOCIATION OF VARIOUS X-RAY SYMPTOMS OF INTERSTITIAL LUNG DISEASE (ILD) IN PATIENTS WITH SYSTEMIC SCLERODERMA (SSC) WITH INDICES OF LUNG FUNCTIONAL TESTS.

O. Konova1, O. Garzanova1, O. Ovsyannikova1, N. Kovalova1, L. P. Ananyeva1, O. Desinova1, M. Starovoytova1, R. Shayakhmetova1. V.A. Nasonov Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation

Background: HRCT is the gold standard for confirming the presence of ILD. According to the literature data, there is an association between the prevalence of pulmonary involvement and the severity of PFTs. However, it remains unclear whether the nature of interstitial changes affects the degree of PFTs.

Objectives: To study the clinical significance of various X-ray symptoms in SSC-ILD during long-term follow-up.

Methods: The study included 37 pts with a SSC-ILD (average age 53.1±11.5 yrs, m/w 1:2, and d/l–1/1; SSc duration 10.9±9 yrs). For all pts at the time of inclusion in the study and after an average of 34±2.3 months, there were examined FVC, DLC, HRCT. All pts received immunosuppressive therapy (IST). The analysis of HRCT data was conducted at 5 levels. The severity of changes by type of ground-glass, reticular changes, traction bronchiectases, and honeycombs were evaluated (0–3 points). The dynamics of X-ray changes and PFTs was assessed in the general group and in pts with the prevalence of ILD up to 20% (group A, n=23) and more than 20% (group B, n=14).

Results: At the time of inclusion in the study, the total CT score of ILD on average for the group was 9.6±2.2. FVC was normal (94±19.5%); a moderate decrease in DLC was detected (57±23.2%). The prevalence of ILD significantly correlated only with the DLC (R=0.35, p<0.05). When included in the study, reticular changes were most often observed (the score was 4.6±3.5). Alterations by type of ground-glass were somewhat less common (the score was 3.2±3.1). The score of traction bronchiectases was 1.6±2.3. Changes by type of honeycombs were found in only 5 patients, of which only 1 patient was from the group A. Against the background of IST, values of FVC and DLC remained stable in the group as well as in the groups A and B, and the total CT score did not change. In patients of the group B both the total CT score and the average score of ground-glass and reticular changes, and traction bronchiectases score significantly higher. To assess the clinical significance of various X-ray symptoms, a correlation analysis of the total score of each of them with the PFTs data in groups A and B was executed. No significant correlation between the score of X-ray signs and values of FVC was detected. DLC significantly inversely correlated with the total score of each HRCT symptom, with the exception of ground-glass. At the same time, strength of the correlation was approximately the same for reticular changes, bronchiectases, and honeycombs in both groups.

Conclusion: The severity of the alveolar-capillary membrane functional disorders is primarily due to the prevalence of fibrotic changes. The variant of fibrotic changes has no significant importance. Changes by type of ground-glass to a lesser extent affect the degree of reduction in DLC. The best surrogate indicator reflecting the prevalence of interstitial changes was DLC.

Disclose of Interests: None declared.

AB0727
STUDY OF THE INDICATORS DYNAMICS OF THE PULMONARY FUNCTIONAL TESTS (PFTS) AND X-RAY PICTURE AGAINST DURING THE 36-MONTH IMMUNOSUPPRESSIVE THERAPY (IST) OF INTERSTITIAL LUNG DISEASE (ILD) IN PATIENTS WITH SYSTEMIC SCLEROSIS (SSC)

O. Konova1, L. Garzanova1, O. Ovsyannikova1, N. Kovalova1, L. P. Ananyeva1, O. Desinova1, M. Starovoytova1, R. Shayakhmetova1. V.A. Nasonov Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation

Background: HRCT is the gold standard for confirming ILD. However, the role of HRCT for estimating the effectiveness of therapy is not determined in full.

Objectives: To assess the dynamics of X-ray changes and PFTs during IST in pts with SSC and different prevalence of ILD according to HRCT.

Methods: The study included 37 pts with signs of ILD (the average age 53.1±11.5 yrs, the ratio of m/w–1:2, d/l–1/1.8, SSc duration–10.9±9 yrs). For all pts at the time of inclusion in the study and after an average of 34±2.3 months were studied FVC, DLC, and HRCT. The pts received IST during the follow-up period. The ILD dynamics was assessed as follows: improvement, deterioration, and no dynamics.

Results: The severity of changes by type of ground-glass, reticular changes, traction bronchiectasis, and honeycombs were evaluated (0–3 points). The dynamics of X-ray changes and PFTs was separately assessed in pts with the prevalence of ILD changes up to 20% (group A, n=23) and more than 20% (group B, n=14) during the follow-up period.

Conclusion: Semi-quantitative evaluation according to HRCT in pts with SSC-ILD did not reveal any dynamics in the total score of structural changes during IST, which coincided with stable indices of PFTs. Pts with less common pulmonary involvement during therapy were more likely to demonstrate positive CT-dynamics. With an increase in the prevalence of ILD signs of fibrosis increased. Most pts had unidirectional dynamics of values of CT and FVC changes, which confirmed the possibility of effective use of HRCT to assess the conducted therapy.

*1*–at the time of inclusion in the study; *2*–at the time of the last examination.
Background: Immunosuppressants (IS) is considered as a drug of choice for the treatment of interstitial lung disease (ILD) in the patients with systemic sclerosis (SSc). However, the IS use leads to rather limited and transient improvement of the pulmonary fibrosis. In this context the search for novel, more efficacious agents has been continued, such as attracting much attention rituximab (RTM).

Objectives: To compare the dynamics of pulmonary function parameters and skin fibrosis in patients with SSc associated with ILD, who received RTM and IS for 3 years in real clinical practice.

Methods: 158 pts with the SSc-ILD were enrolled into the study. All pts received low- and moderate-dose glucocorticoids regimens. Group A (n=100) received IS's (31/31% mycophenolate mofetil, 27/27% cyclophosphamide, 15/15% methotrexate; 27/27% other drugs; the patient's average age was 49.5±12.2 years, with female proportion 87%; SSc duration 8.6±7.2 years; diffused/localized forms patients; 57/57% methotrexate; 27/27% other drugs; the patient's average age was 48.0±13.2 years, with female proportion 86%, SSc duration 6.4±4.9 years, diffused/localized forms patients). Group B (n=58) received RTM a total dose 3.0±1.2 g. 22 patients received RTM in combination with IS's (11/11% mycophenolate mofetil, 11/11% cyclophosphamide; average age 48.0±13.2 years, female proportion 86%, SSc duration 6.4±4.9 years, diffused/localized forms patients). The therapy duration in both groups was 36 months. The time courses of forced vital capacity (FVC), diffusive lung capacity (DLC), modified skin count (mRss, points), activity index (EScSG, points), HAQ were assessed in the study.

Still untreated pts were divided into 3 groups in depend on total score of SCTC-DI. 77pts were into group 1 (with low damage score); 17 pts (18%) were into group 2 (with moderate damage score) and 2 pts (2%) were into group 3 (with high damage score). Baseline characteristics of the groups are presented in Table 1.

Results: In Groups A and B the therapy was associated with significant decrease in mRss and stabilization of the diffusive lung capacity. During the follow-up period in Groups A no change of the other studied parameters was observed. In Groups B the therapy was associated with significant decrease in HAQ and EScSG. Evaluation of FVC time course in Group B revealed significant FVC increase with median increment about 5.6%. In Group B 10% FVC increase was found in the third of the patients thus exceeding respective parameter in Group B (16%). The patient percentage with FVC decrease by ≥10% in group B was less common compared to group A. During RTM therapy it was possible to significantly reduce the dose of glucocorticoids. RTM and immunosuppressants administration for 36 months in the patients with SSc and ILD effectively alleviated skin induration and stabilized DLCO.

Conclusion: Only RTM significantly improved FVC and the patient's quality of life and decreased of the activity index. RTM demonstrated a steroid-sparing effect. The study findings substantiate potential use of RTM as a first-line agent for the treatment ILD progressive phenotype in SSc. The immunosuppressants use as a single-agent therapy is more preferable in patients with less pronounced ILD.

Disclosure of Interests: None declared

We didn’t find a lot of significant differences in between groups, but it could be noted that group 3 was younger and the severity of the parameters increased in groups moderate and high damage. We found that mean value of FVC, DLco and FEV1 were significant increased in group 1.

Conclusion: the pts with moderate and high damage scores of SCTC-DI had worse clinical and instrumental characteristics than pts with low damage score. We could try to use scores of SCTC-DI as measures of SSC severity.

**Conclusion:** Among the 97 SSc enrolled patients (mean age 55.4±12.5 yrs), 82 (84.5%) were female, 35 (36%) affected by diffuse cutaneous form of SSC (dcSSc) and 41 (42.3%) had ILD diagnosed by HRCT. The mean follow-up was 34.6±16 months, with PFTs and/or HRCT data available in 86 patients, 37 (43%) of whom had ILD at baseline. Patients with ILD who progressed during follow-up were more frequently affected by dcSSc (p = 0.003), and tended to have lower values of total lung capacity (p<0.001). The median SCCA-IgM values were significantly higher in patients with progressive ILD vs. those with stable ILD: 301 (57.526) vs. 45 (34.236), respectively (p = 0.017, Figure 1). At Cox regression multivariate analysis, SCCA-IgM serum levels was the only variable independently associated with ILD progression (HR 1.003 95% CI 1.000-1.006, p=0.02).

Conclusion: In conclusion, our preliminary data support SCCA-IgM as a potential candidate biomarker for progressive ILD in patients with scleroderma.

**SCCA-IGM AS A PREDICTOR OF INTERSTITIAL LUNG DISEASE PROGRESSION IN SYSTEMIC SCLEROSIS**

E. Zanatta<sup>1</sup>, A. Martini<sup>1</sup>, A. Cuberl<sup>1</sup>, A. Biasiolo<sup>2</sup>, P. Pontusso<sup>2</sup>, A. Doria<sup>1</sup>, A. Mosca<sup>1</sup>, A. Trippoli<sup>2</sup>, L. Carli<sup>2</sup>, M. Mosca<sup>1</sup>, 1University of Padova, Rheumatology Unit, Department of Medicine, Padova, Italy; 2University of Padova, Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine, Padova, Italy

**Background:** Interstitial Lung Disease (ILD) is the major determinant of morbidity and mortality in patients with systemic sclerosis (SSc). The course of lung involvement is extremely variable in SSc-ILD. Squamous Cell Carcinoma Antigen 1 (SCCA1) is a cysteine protease inhibitor that plays a crucial role in inflammation and fibrosis. It may be detected in serum in the form of an IgM-linked immune complex (SCCA-IgM), and we previously demonstrated that it is increased in patients with SSc-ILD (1).

**Objectives:** We aimed to investigate the association between SCCA-IgM serum levels and ILD progression in a cohort of SSC patients.

**Methods:** Ninety-seven patients with SSc (2013 ACR/EULAR criteria) from the Rheumatology Unit of Padua University Hospital were consecutively enrolled in the study. Clinical, serological indices and organ involvement (pulmonary, cardiac, gastrointestinal and articular) were evaluated at the time of the SSc clinical course. Pulmonary involvement was investigated by high-resolution CT (HRCT) and respiratory function tests (PFTs). Serum immune complex levels were measured by a validated ELISA assay (Hepa-IC, Xeptagen, Venice, Italy) and expressed in arbitrary units/ml (AU/ml). Follow-up period was defined as the time between baseline (i.e. SCCA-IgM blood sampling) and last PFTs and/or HRCT performed at least after 24 months. SSc-ILD progression was defined by HRCT and/or PFTs worsening. Progression on PFTs: FVC decline ≥10% from baseline or FVC ≥5-9% decline plus DLCO decline ≥15%; radiological progression: ILD worsening on HRCT evaluated by the same experienced thoracic radiologist.

**Results:** Among the 97 SSc enrolled patients (mean age 55.4±12.5 yrs), 82 (84.5%) were female, 35 (36%) affected by diffuse cutaneous form of SSc (dcSSc) and 41 (42.3%) had ILD diagnosed by HRCT. The mean follow-up was 34.6±16 months, with PFTs and/or HRCT data available in 86 patients, 37 (43%) of whom had ILD at baseline. Patients with ILD who progressed during follow-up were more frequently affected by dcSSc (p = 0.003), and tended to have lower values of total lung capacity (p<0.001). The median SCCA-IgM values were significantly higher in patients with progressive ILD vs. those with stable ILD: 301 (57.526) vs. 45 (34.236), respectively (p = 0.017, Figure 1). At Cox regression multivariate analysis, SCCA-IgM serum levels was the only variable independently associated with ILD progression (HR 1.003 95% CI 1.000-1.006, p=0.02).

**Conclusion:** In conclusion, our preliminary data support SCCA-IgM as a potential candidate biomarker for progressive ILD in patients with scleroderma.

and to explore if T'D represent a risk factor for FF also in IIM; finally, since HT is a risk factor for TPC, an evaluation of its occurrence in our cohort should be designed. However, our data seem sufficient to underline the need to regularly screen IIM patients for thyroid function, aiming at optimizing their quality of care, both for activity and damage domains of their autoimmune disease.

AB0732
ABATACEPT AS THERAPY OPTION IN SYSTEMIC SCLEROSIS (SSC) PATIENTS AFTER YEARS OF GRAZER-PROTOCOL TREATMENT: OUR EXPERIENCE
M. D’orazio, M. Daher, A. Lackner, S. Kielhauser, S. Zenz, J. Grettler, J. Thiel, H. P. Brezinsek, F. Fürst-Moazedi, Medical University of Graz, Rheumatology and Immunology, Graz, Austria

Background: Previous studies have provided evidence that T cells may play a significant role in the pathogenesis of systemic sclerosis (SSc) and observational studies reported that Abatacept, which interferes with T cells activation, appeared to be safe and effective in SSc-patients with skin and muscle involvement. So far, there was no significant effective treatment for SSC-ILD. We have recently demonstrated the effectiveness of intensified –RTX- long term treatment (“Grazer protocol” with 500 mg RTX in week 0 and 2, every 3 months +/- MMF) in SSc patients with severe organ involvement and/or progressive form non responding to metotrexate or cyclophosphamide. However, no data are available concerning how long Patients with a stable disease need to be treated. B-cell-depletion therapy over years for SSC in remission might represent a risk factor for infections. Additionally, the parenteral administration is associated with an increase in health care and patients are bound to regular hospital visits, which is a limiting factor for life quality.

Objectives: We aimed to investigate if subcutaneous Abatacept could be used as a maintenance treatment in SSc-patients reaching a stable disease activity after a treatment with RTX administered according to our Grazer protocol over several years.

Methods: In this retrospective analysis, we retrieved data from 20 patients who fulfilled the diagnosis criteria for systemic sclerosis (SSc) according to the European League Against Rheumatism Scleroderma Trial and Research standards, who started a treatment with abatacept (ABA) after years of 500 mg RTX therapy every three months +/- MMF (Grazer protocol). The following clinical parameter were evaluated: modified Rodnan Skin Score (mRSS), Systemic Sclerosis Activity Score (SSCA3), Systemic Sclerosis Severity Score (SSCS3) and lung diffusing capacity for carbon monoxide (DLCO). Lab parameters like IgG, ANA, ENA and inflammation parameters were routinely assessed. Clinical data from baseline visit (BSL) (before ABA treatment start) and follow-up visit (FU) (after 6 months of treatment) were collected.

Results: We included 20 SSc patients in this retrospective analysis who changed from RTX to Abatacept. The majority were female (n=16, 94.1%), with a mean age ±SD of 54.8 years ±11 and an average disease duration of 7.7 years ±4.5. In 17.9% (n=4) treatment needed to be stopped due to disease flare after three months (lung ±2, skin and tendons ±2). However, interestingly, Abatacept further decreased significantly mRSS before baseline visit and follow-up visit regarding the affected skin of the fingers. Thus, the mRSS went from 3.9±3.4 to 2.5±1.8 (p<0.05). As expected, no significant difference in the EUSTArSSC3, or ScC3 or DLCO was found. No infections were observed during the abatacept follow-up period and Immunoglobulins remained within the normal range.

Conclusion: Abatacept might be a feasible option as a maintenance therapy after intensive immunomodulation with RTX and may give our patients the possibility to further improve their quality of life.

AB0733
MUSCULO-ARTICULAR SYNDROME IN PATIENTS WITH SYSTEMIC SCLEROSIS-POLYMYOSITIS/DERMATOMYOSITIS OVERLAP SYNDROME.
O. Desinyova1, M. Starovoytova1, A. Khelkovskaja-Sergeeva1, L. P. Ananyeva1, O. Koneva1, R. Shayakhmetova1, L. Garzanova1, O. Ovsyannikova1, V.A. Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation

Background: Systemic Sclerosis-polymyositis/dermatomyositis overlap syndrome (SSc-PM/DM) occurs in 10 to 37% of cases and has great differential diagnostic difficulties. Muscle damage in SSc-PM/DM is represented by myositis with primary inflammatory and necrotic alterations in muscle fibers by type of PM/DM.

Objectives: To evaluate joint and muscle damage in patients with SSc-PM/DM.

Methods: 112 pts had idiopathic inflammatory myopathies, of which 73 pts with SSc-PM/DM (51 pts with iSSc and 22 pts with dSSc, male/female 24/49, mean age 44±15.5 years, average disease’s duration 7 (2-9) years) had the standard clinical examination, intramuscular electromography (IM-EMG) and manual muscle testing (MMT-B).

Results: All pts had polyarthralgia, 40% pts - arthritis. Damage to periartricular tissues with the formation of flexion contractures was observed in 70% pts, of which 16% - contractures of large joints (knee and elbow), X-ray changes in the hands and feet (distal osteoporosis, narrowing of the joint spaces, and smoothness of the phalangettes) were observed in all pts, 13% of pts had erosions associated with osteoarthritis. There was noticed significantly frequent development of flexion contractures in pts with dSSc (p<0.05) and high skin score (p<0.05). Osteolysis peculiar to SSc was detected in 23.5% of pts, and soft tissue calcinosis in the area of the phalangettes, and metacarpophalangeal joints – in 32% pts. Califications, specifically associated with PM/DM, in the soft tissues of the shoulder and pelvic girdle, large joints were revealed in 6% pts. A direct correlation was revealed between the duration of the disease and the development of calcinosis and osteolysis (p<0.05). Myalgia and proximal muscle weakness was in all pts, dysphagia – in 43% pts, and dysphonia – in 19% pts. Patients with a moderate degree of muscle weakness (MMT-8 76-115 points) prevailed and topped 41% and patients with severe disabling functional disorders (MMT-B ≤75 points) showed 37%, of which 4% of pts were completely immobilized. In 18% of pts, PM was detected during physical and/or laboratory examination (MMT-B ≥116 points). Analysis of IM-EMG of changes confirmed the presence of primary muscle inflammatory process (all patients had a decrease in motor unit action potential (MUAP) and spontaneous activity, polyphasia – in 93% of pts. A correlation was observed with laboratory and immunological signs of disease activity: between ESR and spontaneous activity (p<0.02), CPK titers and polyphasia (p<0.01), the presence of a-Pm-Scl and a decrease in MUAP (p<0.03).

Conclusion: Muscular syndrome in SSc-PM/DM has clear clinical symptoms, and the underlying symptom of involvement is sharp muscle weakness with movement disorders intrinsic to PM/DM. However, such disorders do not lead to complete immobility, as in PM/DM, and they are combined with other manifestations of SSc.Articular syndrome in pts with SSc-PM/DM is mainly represented by periartricular changes, in some pts with osteolysis and calcinosis common to SSc.

AB0734  THE DYNAMICS OF LUNG FUNCTION IN PATIENTS WITH SYSTEMIC SCLERODERMA ASSOCIATED WITH INTERSTITIAL LUNG DISEASE DURING A THREE-YEAR FOLLOW-UP PERIOD.

M. Starovoytova1, O. Desinova1, L. P. Ananyeva1, R. Shayakhmetova1, A. Khelkovskaia-Sergeeva1, O. Ovsyannikova1, R. Shayakhmetova1, A. Khelkovskaia-Sergeeva1.

Background: Nowadays ILD is one of the most common manifestations of SSC and the leading cause of death of patients. 25% to 30% of patients develop progressive ILD.

Objectives: To assess the course and outcomes of interstitial lung disease (ILD) in systemic sclerosis (SSc) based on lung function after three years of follow-up.

Methods: The study included 82 patients with SSc associated with ILD. There were 70 (85%) women and 12 (15%) men, whose average age was 49.86±12.30 years, 49 (60%) patients with limited SSc, 24 (29%) patients with diffuse SSD, 7 (9%) patients with overlap syndrome; median disease duration was 7 (4;11) years. The great majority of patients had a chronic course of the disease. The patients had systemic manifestations, vascular disorders and lesions of the muscular-skeletal system. According to the results of CT scan of the thoracic organs, 28% of patients had more than 20% of pulmonary involvement. All patients took glucocorticoids (GC); the average dose of prednisone was 8.6±4.6mg. 50 (61%) patients took immunosuppressants (IS).

The diagnosis was set according to ACR/EULAR criteria. The patients were examined twice in accordance with generally accepted approaches. To identify and assess the dynamics of ILD, there was used high-resolution computed tomography (HRCT). Their lung function was assessed by data obtained due to spirometry (in particular, forced vital capacity, FVC) and diffusing capacity of the lungs (DCL); Doppler echocardiography was also conducted.

Results: In the group of patients with SSc, a significant improvement was noticed in some indicators demonstrating the peculiar manifestations of the disease. Therefore, skin induration (a decrease in skin score) decreased from the initial 5.8±5.2 to an average of 4.6±4.9 points after three years, p=0.0001. Functional capacities of the lungs and heart did not deteriorate. There was a trend towards an increase in FVC by 5.7% (from 91.8±19.1 to 96.15±18.26, respectively). However, these data were not clinically significant. Systolic pulmonary artery pressure (sPAP) also remained stable, mm Hg (31.83±8.10 and 33.57±5.03, respectively), indirectly indicating the absence of progression in pulmonary involvement. These positive alterations were the basis for reducing the daily dose of GCs in some patients. The reduction in dose of GCs was small but statistically significant (8.64±4.58 and 7.86±3.33, respectively, p=0.007).

Conclusion: Therefore, due to the study, stabilization of lung function and the absence of progression in the SSc-ILD group were noticed, which emphasizes the importance of continuous monitoring and follow-up of patients and continuous therapy.

AB0735  INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC CONNECTIVE TISSUE DISEASES: DYNAMICS OF LUNG FUNCTION AFTER THREE YEARS OF FOLLOW-UP.

M. Starovoytova1, O. Desinova1, L. P. Ananyeva1, R. Shayakhmetova1, A. Khelkovskaia-Sergeeva1, O. Koneva1, L. Garzanova1, O. Ovsyannikova1.

Background: Interstitial lung disease (ILD) is one of the most common and severe manifestations of connective tissue diseases, such as systemic scleroderma (SSc), dermatos- and polymyositis (DM/PM), mixed connective tissue disease (MCTD), etc.

Objectives: To compare the course and outcomes of ILD in SSc, MCTD and DM/PM, immunoinflammatory myopathies (IMM) after three years of follow-up.

Methods: The SSc group consisted of 82 patients, the IMM group – 61 patients, and the MCTD group – 50 patients. In all the studied groups, women predominated. The oldest patients were found in the IMM group, and the average age was 51±12.88 years. The duration of the disease varied from 0.5 to 18.5 years. A longer course of the disease was observed among patients with MCTD, the median was 10.6 (6.9; 18.5) years. When assessing the initial parameters of lung function tests, significantly lower values of FVC and DCL were recorded in the IMM group (average 5.7 [IQR 3.2-9.2] and 515±18±2, respectively), and higher values in the MCTD group (95.4±20 and 675±15). All patients took GCs, the highest doses were taken by patients with IMM. The great majority of patients received immunosuppressants, of which 100% of patients were in the MCTD group.

Results: Despite the fact that the indices of FVC and DCL in the SSc group were initially lower (on average 91.8±19.1 and 59.2±19.5, respectively) than in the MCTD group. The dynamics of FVC over three years against the background of continuous immunosuppressants therapy was discordant: in SSc, the DCL decreased significantly (p=0.015). In the IMM group, the FVC decreased significantly (p<0.0001). In the MCTD group, the DCL decreased significantly (p<0.0001). In the IMM group, the FVC decreased significantly (p<0.0001).

Conclusion: In the present study we have been able to evidence that there is a statistically significant relationship between the percentage of RDW and the presence of PID. When analysing the association between patients without pulmon-ary compromise, ILD and PAH and the percentage of RDW, we were able to find a statistically significant difference between the three groups. It is necessary to continue with studies with a larger number of patients to grant robustness to the results.

REFERENCES:
Case reports of women with silicone breast implants who developed SSc have been published, but case-control and prospective studies in connective tissue diseases often failed to find an increased risk of SSc associated with silicone cosmetic surgery (2,3). These studies have several limitations, including heterogenous cohorts of enrolled patients not selective for SSc, non-homogeneous disease duration at study entry and the possibility that the disease is not triggered but rather is accelerated by the implant (4).

Objective: Retrospective study of SSc patients, to find out who developed SSc after silicone cosmetic surgery.

Methods: The clinical files of 140 female patients with systemic sclerosis were retrospectively evaluated and clinical data collected.

Results: Five patients showing a history of silicone cosmetic surgery (3.6%) before SSc development were identified. The brief clinical histories of the five patients are below reported, showing very similar outcomes after silicone implant.

1. TC 47-year-old female underwent cosmetic breast prosthesis: twelve months later she experienced Raynaud’s phenomenon (RP) and diffuse cutaneous SSc after 10 further months; antinuclear antibodies were positive with a speckled and nuclear pattern, but specific SSc-related autoantibodies were negative. 2. LS 28-year-old female underwent cosmetic breast prosthesis: twenty-two months later RP appeared and antinuclear antibodies (ACA) positive aggressive diffuse SSc was diagnosed one year later. 3. PJ 38-year-old female underwent cosmetic breast prosthesis: eleven months later she experienced RP and after 10 further months, aggressive diffuse cutaneous SSc; antinuclear antibodies were positive with a speckled pattern, but specific SSc-related autoantibodies were negative. 4. CM 58-year-old female who underwent cosmetic lip prosthesis: one year later she complained of simultaneous onset of RP and very aggressive diffuse cutaneous SSc with anti-topoisomerase positivity; she died during follow-up. 5. BS 33-year-old female who underwent cosmetic breast prosthesis: twenty months later she complained of RP and after ten further months, limited cutaneous SSc with ACA positivity; SSc clinical condition partially improved and its progression stopped after prosthesis removal. Globally, after silicone implant, RP occurred in a mean time of 15±5 months and SSc in 23±8 months.

Conclusion: This study reports a prevalence of 3.6% of silicone cosmetic surgery before SSc onset, interestingly with a close and similar temporal association between silicone implant and disease development. This finding suggests a possible role of silicone in SSc pathogenesis (ASIA syndrome). Specifically addressed large clinical studies or big-data studies need to rule out this matter.

BACKGROUND:
Systemic sclerosis (SSc) is a complex autoimmune connective tissue disorder defined by multifaceted visceral involvement. Still considered the leading cause of morbidity and mortality, SSc-interstitial lung disease remains one of the most common complications of SSc that involves vascular, immunological, and fibrotic processes.

OBJECTIVES: We aimed to assess the relationship between demographic, clinical features and risk factors for the development of lung fibrosis in patients with SSc as well as the specific management.

METHODS: We performed a retrospective observational study in a series of 41 patients with SSc-ILD followed-up in a medical center: a large surgical center (Department of Rheumatology 2, Clinical Rehabilitation Hospital, Iasi, Romania). We analyzed the frequency of known risk factors associated with progressive interstitial lung disease such as diffuse cutaneous SSc, male sex, presence of anti-topoisomerase I and absence of anti-centremerase antibodies as well as risk factors for mortality in SSc-ILD including older age, male sex, extent of disease on high-resolution computed tomography (HRCT), lower pulmonary function tests (PFTs), lower diffusion capacity of the lung for carbon monoxide (DLCO), dyspnea, VELCRO crackles, and fibrosis progression in pulmonary involvement. These positive alterations were the basis for reducing the daily dose of GCs in some patients. The reduction in dose of GCs led to clinical benefit in all patients (31.4±4.5 and 32.8±5.2, respectively), indirectly indicating the absence of progression in pulmonary involvement. These positive alterations were the basis for reducing the daily dose of GCs in some patients. The reduction in dose of GCs led to clinical benefit in all patients (31.4±4.5 and 32.8±5.2, respectively), indirectly indicating the absence of progression in pulmonary involvement.

RESULTS: The study included 35 females, 10 males, with the mean age of 55.5±5.5 years. The diagnosis of interstitial lung disease was based on HRCT findings (bipolar glassy ground opacities, crazy-paving pattern, nodules, honeycombing and traction bronchiectasis, mosaic pattern, air trapping, pulmonary artery and lymph node enlargement). Symptoms of the ILD (dry cough, different stages of dyspnea, VELCRO crackles) were reported in 14 cases (25.45%). Furthermore, 25 patients had a significant decline in PFTs and DLCO, being associated with extensive pulmonary fibrosis on HRCT (p<0.05%). Almost all patients with SSc-ILD had diffuse cutaneous involvement and anti-Scl-70 antibodies positivity. Despite identifying a higher percentage of women with ILD (39/45, 63.63%), the extent and progression of pulmonary fibrosis was more significant in males. The treatment for SSc-ILD with ongoing evidence of disease progression based on PFT decline or radiographic deterioration has focused on immunosuppressive therapies, particularly cyclophosphamide and only in selected cases on antifibrotic agents.

ConCLUSION: It is important to identify the risk factors for developing ILD, in order to complete the diagnostic and staging parameters early so that the treatment can be initiated as soon as possible in progressive pattern. Our data showed that the extent of pulmonary fibrosis in HRCT was associated with low values of PFTs and DLCO, and men had a more severe prognostic than women. ILD-SSc was more frequent in patients with diffuse cutaneous involvement than limited cutaneous subtype, and in those with anti-Scl-70 positivity.

AB0741 LUNG FUNCTIONS IN IDIOPATHIC INFLAMMATORY MYOPATHIES PATIENTS WITH INTERSTITIAL LUNG DISEASE DURING ≥3 YEAR OF FOLLOW-UP.

A. Khelkova-Sergeeva1, L. Garzanova1, M. Staroytova1, O. Desinova1, L. P. Ananyeva1, O. Koneva1, 1VA. Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation

Background: Intestinal lung disease (ILD) is the most common internal organ manifestation of idiopathic inflammatory myopathies (IIM) that can severely affect the course of the disease.

Objectives: To describe lung functions in IIM patients with ILD during ≥3 year of follow-up.

Methods: Our prospective study included 44 pts with IIM fulfilling Bohan and Peter criteria and having ILD. The mean follow-up period was 46.2±11.2 months. The mean age was 52.3±11.7 years, 34 (73.3%) pts were female. The median disease duration was 1.125 [0.16-18] years, 24 (54%) of pts were positive for a-Jo-1 antibody. All pts had the standard examination including anti-Jo-1 antibodies (anti-Jo-1) assay; forced vital capacity (FVC) and carbon monoxide diffusion capacity (DLCO) evaluation as well as high-resolution computed tomography (HRCT) scanning of the chest were performed at baseline, and 36 and more months.

Results: 61% with antisyntetase syndrome, 17% dermatomyositis (DM), 5% amyopathic DM, 15% with overlap myositis and 2 % with necrotizing myopathy were included. 70% patients had nonspecific interstitial pneumonia, 23% organizing pneumonia (OP) and 7% OP; transformed to diffuse alveolar damage. All pts received prednisolone at a dose of 11.8±4.1 mg/day. Immunosuppressants at inclusion received 75% pts: cyclophosphamide, 54%, mycophenolate mofetil 16.9% and combination 4.54%; Rituximab was administered in case of intolerance or inadequate response to GC and other immunosuppressive drugs in 37 pts (84%)-18 courses, 7 patients died, ILD progression was the cause of death in 4 cases.

AB0742 THE DYNAMICS OF LUNG FUNCTION IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE ASSOCIATED WITH INTERSTITIAL LUNG DISEASE DURING A THREE-YEAR FOLLOW-UP PERIOD

R. Shayakhmetova1, L. P. Ananyeva1, O. Koneva1, M. Staroytova1, O. Desinova1, O. Ovsyannikova1, L. Garzanova1, A. Khelkova-Sergeeva1, 1VA. Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation

Background: Nowadays ILD is one of the most common manifestations of systemic rheumatic diseases and one of the leading cause of death of patients.

Objectives: To assess the course and outcomes of interstitial lung disease (ILD) in mixed connective tissue disease (MCTD) based on lung function after three years of follow-up.

Methods: The study included 20 patients with MCTD associated with ILD. The diagnosis was set according to Kasukawa criteria (1987). There were 19 (95%) women and 1 (5%) men; average age was 44.73±15.26 years; mean disease duration was 13.7±6 years; and 3 (15%) pts had anti-extra cellular matrix antibodies (ECMAs) and immunosuppressants (IS); the average dose of prednisone was 10.2±5mg. To identify and assess the dynamics of ILD, there was used high-resolution computed tomography (HRCT). Their lung function was assessed by data obtained due to spirometry (in particular, forced vital capacity, FVC) and diffusion capacity of the lungs (DCL); Doppler echocardiography was also conducted.

Results: In the group of patients with MCTD there was a chronic course of the disease with a gradual addition of symptoms, musculoskeletal pathology preceded by a decrease in clinical manifestations of the lungs and heart did not deteriorate. After three-year follow-up period there was a decrease in clinical manifestations (arthritis, myositis, proximal muscle weakness). Functional capacities of the lungs and heart did not deteriorate. DCL remained stable 67.5±15 and 66.6±13.8, respectively. Systolic pulmonary artery pressure also remained stable (31.4±4.5 and 32.6±5.2, respectively), indirectly indicating the absence of progression in pulmonary involvement. The positive alterations were the basis for reducing the daily dose of GCs in some patients. The reduction in dose of GCs was small but statistically significant (8.6±4.5 and 78.6±3.33, respectively, p=0.007). There was a trend towards a decrease in dose of prednisone (from 10.2±5 to 8.4±5, respectively). However, these data were not clinically significant.

Disclosure of Interests: None declared.

Scientific Abstracts
Background: Systemic Sclerosis (SSc) is a rare inflammatory disease of unknown etiology associated with multi-organ involvement. Biomarkers remain urgently needed as tools for differential diagnosis, prognosis, disease progression, and as therapeutic response predictors in SSc. Ideally, for widespread utility, biomarkers should be easy to sample and analyse.

Objectives: We aimed at evaluating potentially pathogenic circulating key cytokines/chemokines in a monocentric cohort of SSC patients.

Methods: Sera were drawn from SSC patients and 23 cytokines/chemokines (CCL/CDR-1, IP-10/CCL10, IL-10, IL-17, IL-21, IL-22, IL-23, IL-3, IL-17A, TNFalpha, IL-1beta, CXCL13, IL-22, IL-23, IL-33, TSLP IL-9/2, IL-1RII, TNFRII, BAFF, CCL19, MIP-3B, MMP-8) were quantitated using Luminex multiplex immun assay (Bio-Rad Bio-Plex 200 System-Luminex xMap technology R&D Systems, USA) following the manufacturer's instructions and customized procedures. Data were acquired using Bioplex manager v 6.1. P value ≤ 0.05 was considered to be significant. Data were analysed using GraphPad Prism V.8 (GraphPad Software, Inc.) software.

Results: Clinical and demographic features of 17 SSc (5 dcSSc, 12 lcSSc) patients are reported in Table 1. Mean±SD age was 55±14.68 years, mean±SD disease duration was 89.47±93.34 months. We found that MCP-1 levels inversely correlated with PAPs (r=-0.55, P=0.03) and IP10 with anti-Scl70 (r=-0.561, P=0.004), Figure 1. No other associations were found

Conclusion: We confirm a potential pathogenic role for MCP-1 in SSC. The 2518 promoter polymorphism in the MCP-1 gene has been already associated with disease susceptibility and an increased expression of the molecule both in peripheral blood and in the skin has been described. Intriguingly, MCP-1 seems to drive fibroblasts - can represent a promising biomarker for SSC diagnosis.

SYMPTOMS OF GASTROINTESTINAL DISORDERS IN SYSTEMIC SCLEROSIS PATIENTS WITH DIFFERENT DISEASE SUBTYPES AND ANTIBODIES

M. Vujovic1, P. Ostojic1,2. Institute of Rheumatology, Rheumatology, Belgrade, Serbia; 1School of Medicine, University of Belgrade, Belgrade, Serbia

Background: Gastrointestinal tract is the second most commonly affected organ system in approximately 90% of patients with systemic sclerosis (SSc) and has a negative impact on health-related quality of life (1, 2).

Objectives: This study aims to analyze frequency and severity of gastrointestinal symptoms, their impact on social functioning and emotional wellbeing and compare results among patients with limited cutaneous (lcSSc) and diffuse cutaneous systemic sclerosis (dcSSc), as well as in patients with anti-centromere antibodies (ACA) and anti-topoisomerase I antibodies (ATA).

Methods: 62 patients with SSc were included in this study, 31 of them with lcSSc and 11 patients with dcSSc. ACA were detected in 26, and ATA in 16 patients. The UCLA-SCTC-GIT 2.0 self-assessment questionnaire (3, 4) was used to assess presence and severity of gastrointestinal symptoms in our patients. It consists of seven scales: reflux, distension/bloating, diarrhea, fecal soilage, constipation, social functioning and emotional wellbeing.

Results: There was no difference in percentage of patients with lcSSc and dcSSc who used proton pump inhibitors (27.27%: 32.25%), as well as in patients with ACA and ATA (34.61%: 25%). Symptoms of gastroesophageal reflux (lcSSc: dcSSc = 64.5%: 81.8%), distension/bloating (lcSSc: dcSSc = 61.3%: 81.8%), constipation (lcSSc: dcSSc = 45.2%: 45.5%) and fecal soilage (lcSSc: dcSSc = 6.4%: 18.2%) were found equally frequent (p>0.05) in patients with lcSSc and dcSSc. However, symptoms of diarrhea were found significantly more frequent in patients with dcSSc (lcSSc: dcSSc = 16.1%: 45.5%, p=0.04). The mean index value for diarrhea was significantly higher in patients with dcSSc (dcSSc: lcSSc = 0.45: 0.11, p=0.02), indicating more severe symptoms in diffuse form of disease. We did not notice a significant difference in frequency or severity of gastrointestinal symptoms in patients with ACA and ATA. Mean index values of social functioning and emotional wellbeing did not differ significantly in patients with lcSSc and dcSSc, as well as in patients with ACA and ATA.

Conclusion: Unlike other gastrointestinal manifestations, diarrhea is significantly more common and more severe in patients with dcSSc. No significant difference in frequency and severity of gastrointestinal symptoms was found in patients with ACA and ATA. Impact of gastrointestinal tract symptoms on social functioning and emotional wellbeing was similar in both forms of disease and antibodies.

MALIGNANCY IN DERMATOMYOSITIS

I. Naceur1, I. Arbaoui1, T. Ben Achour1, M. Khanfir1, I. Ben Ghorbel1, M. Vujovic1, P. Ostojic1,2.

Background: The concept of core-microbiome in health is useful for investigating the possible role of the oral microbiome in autoimmune disease, such as Rheumatoid Arthritis, Spondyloarthritis, Sjogren Syndrome or Systemic Sclerosis (SSc), whose pathogenesis has not been fully understood. Environmental factors and certain genetic backgrounds have been proposed. Among the various environmental factors, the microbiota stands out, the entire composition of microorganisms, mainly bacteria but also fungi and viruses, which populate the human body.

Objectives: The aim of the study was to verify whether there were quantitative differences between the microorganisms present in the oral cavity, in particular between the lactobacillus spp., of patients with SSc compared to those present in the oral cavity of healthy subjects taken as controls.

Methods: Twenty-nine SSc female patients (mean age 62.) classified according to the ACR/EULAR2010 criteria and twenty-three female healthy subjects (HS, mean age 57) were enrolled and underwent tongue and gum swab sampling. Quantitative PCR was conducted in triplicates using Lactobacillus specific primers rpOB1, rpOB1o and rpOB2 for RNA-polymerase β subunit gene.

Results: Our data showed Lactobacillus spp.rpOB sequences significantly lower in the tongue of SSc patients than in HS (p<0.001). The statistical analysis in HS highlighted a significant lower amount of rpOB on the gums than on the tongue.

Conclusion: Our preliminary data show that the number of Lactobacillus on the tongue in SSc patients is about half that of HS. These data make it more likely that Lactobacillus in SSc patients may play a protective role. Further investigations will also be needed in other autoimmune diseases.

Conclusion: Nintedanib was prescribed in progressive SSc-ILD patients who had predominately diffuse cutaneous involvement, anti-SCL70 positivity and exposed to multiple standard ISs. Duration of ISs were higher than 5 years before antifibrotic therapy. Gastrointestinal (GI) adverse events were frequent during nintedanib requiring dose reduction in half of the patients. Nintedanib can be used in progressive SSc-ILD patients considering some difficulties in such a disease with GI involvement. Efficacy analysis of the antifibrotic therapy needs further studies including long term follow-up.

**BACK PAIN AND MORNING STIFFNESS AS MEDIATORS OF TOFACITINIB TREATMENT EFFECT ON FATIGUE IN PATIENTS WITH ANKYLosing SPONDYLITIS: A MEDIATION ANALYSIS**

L. E. Kristensen1, P. C. Taylor2, V. Navarro-Compán3, M. Magrey4, J. C. Cappelleri7, A. G. Bushmakin5, A. Yndestad6, O. Dina1, 1Copenhagen University Hospital, Bispebjerg and Frederiksberg; The Parker Institute, Copenhagen, Denmark; 2University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 3University Hospital La Paz, IdiPaz, Madrid, Spain; 4Case Western Reserve University, Division of Rheumatology, Cleveland, OH, United States of America; 5Pfizer Inc, Inflammation and Immunology, Groton, CT United States of America; 6Pfizer Inc, Inflammation and Immunology, Oslo, Norway; 7Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America

**Background:** Fatigue is a prevalent symptom of ankylosing spondylitis (AS)1 and can contribute to higher levels of disease, disability and poor health-related quality of life.2 Back pain and morning stiffness are also commonly reported symptoms.3 Tofacitinib is an oral Janus kinase inhibitor for the treatment of adult patients (pts) with AS. In randomised studies, pts with active AS treated with tofacitinib experienced greater improvements in fatigue, back pain and morning stiffness at Week 12 and 16 of treatment compared with placebo (PBO).4,5 Treatment of these symptoms is a priority for pts with AS and their healthcare providers, however, the mechanisms underlying the interrelationships between fatigue, back pain, morning stiffness and treatment are unclear.

**Objectives:** To describe the interrelationships between fatigue, back pain, morning stiffness and tofacitinib treatment in pts with AS, using mediation modelling.

**Methods:** Data from Phase 2 (NCT01786668)6 and Phase 3 (NCT03502616)7 studies of pts with active AS treated with tofacitinib 5mg twice daily (BID) or PBO were used. Mediation modelling, a statistical method to assess the extent to which the effect of an independent variable on a dependent variable is indirect, via identified mediators, or direct, capturing all other (unmeasured) effects, was applied.6,7 The initial model included: treatment as the independent binary variable (tofacitinib 5mg BID vs PBO); fatigue (measured by Functional Assessment of Chronic Illness Therapy-Fatigue) as the dependent variable; mediators included back pain (measured by total back pain/nocturnal spinal pain [numerical rating scale, 0–10]) and morning stiffness (represented by the mean of Bath Ankylosing Spondylitis Disease Activity Index questions 5 and 6).

**Results:** Pooled data from 370 pts were included in the analysis. The initial model showed that 37.5% (p<0.001) of the tofacitinib treatment effect on fatigue was mediated via back pain and morning stiffness (indirect effect); mediation via morning stiffness alone was 49.7% (p<0.01), and 21.2% (p=0.02) via back pain alone. The effect of treatment attributable to factors other than back pain and morning stiffness (ie, direct effect) was not statistically significant (-28.4%; p=0.33). As a result, the initial model was re-specified to exclude the direct treatment effect on fatigue. In the re-specified model (Figure 1), 44.0% (p<0.0001) of the indirect effect of tofacitinib on fatigue was mediated via back pain and morning stiffness; mediation via morning stiffness alone was 40.0% (p<0.001), and 16.0% (p<0.01) via back pain alone. Analyses of the individual study data gave results generally consistent with those from the pooled data.

**Conclusion:** Overall, indirect pathways via morning stiffness accounted for >16% of the effect of tofacitinib treatment on fatigue: (1) treatment affects morning stiffness, which impacts fatigue; and (2) treatment affects morning stiffness, which affects back pain and, ultimately, back pain affects fatigue. The indirect pathway via back pain alone accounted for ~16% of treatment effect on fatigue. These results suggest that in tofacitinib-treated pts with AS, improvements in fatigue are mediated through combined treatment effects on morning stiffness and back pain.

**HOW DOES BODY MASS INDEX AFFECT SECUKINUMAB TREATMENT OUTCOMES AND SAFETY IN PATIENTS WITH ANKYLosing SPONDYLITIS? – REAL WORLD DATA FROM THE GERMAN AQUILA STUDY**

U. Kiltz1, J. Brandt-Juergens2, P. Klotzen3, E. Riechers4, D. Peterlik5, C. Bueden6, H. P. Tony7 on behalf of on behalf of the AQUILA Study Group. 1Rheumazentrum Ruhrgebiet, Heine and Ruhr-Universität Bochum, Heine, Germany; 2Rheumatologie, Schwerpunktpraxis, Berlin, Germany; 3Ambulantes Rheumazentrum, Medizinisches Versorgungszentrum, Erfurt, Germany; 4Medizinische Hochschule Hannover, Hannover, Germany; 5Novartis Pharma GmbH, Immunologie, Hepatologie & Dermatologie, Nürnberg, Germany; 6Novartis Pharma GmbH, Immunologie, Hepatologie & Dermatologie, Nürnberg, Germany; 7Medizinische Klinik II - Rheumatologie/Immunologie, Universitätsklinikum Würzburg, Würzburg, Germany

**Background:** Obesity is a risk factor for worse overall health in people with ankylosing spondylitis (AS)1. The German non-interventional study AQUILA provides real-world data in AS on the influence of body mass index (BMI) on therapeutic effectiveness and safety under treatment with secukinumab, a fully human monoclonal antibody that selectively inhibits IL-17A.

**Objectives:** The aims of this interim analysis are to describe selected baseline (BL) demographics and to evaluate secukinumab treatment outcomes on disease activity and global functioning and health and to report safety profile depending on the BMI of AS patients (pts).

**Methods:** AQUILA is an ongoing, multi-center, non-interventional study including up to 3000 pts with active AS or psoriatic arthritis. Pts were observed from BL up to 3000 wks according to clinical routine. Real-world data were assessed prospectively and as observed. Validated questionnaires were used to collect data on disease activity (Bath Ankylosing Spondylitis Disease Activity Index, BASDAI) and global functioning and health (Assessment of SpondyloArthritis-Health Index, ASAS-HI).

**Results:** Pooled data from Phase 2 (NCT01786668) and Phase 3 (NCT03502616) studies were analyzed. Treatment is represented by a binary variable (secukinumab 5 mg BID vs placebo). Pain is represented by total back pain due to AS on average during last week and pain at night due to AS on average during last week. AS: ankylosing spondylitis; BID: twice daily.
Mean BASDAI developed similarly over time with lowest scores for normal weight and highest scores for obese AS pts (Table 1). Mean improvement from BL to w52 was 2.1 (28.4%) for normal weight, 1.5 (27.2%) for overweight, and 1.2 (21.8%) for obese AS pts.

**Conclusions:** In a real-world setting, secukinumab improved disease activity and global functioning in all BMI subgroups of AS pts; normal weight pts had numerically better ASAS-HI and BASDAI scores than obese AS pts. Altogether, the occurrence of AEs/SAEs with or without suspected relationship to secukinumab improved disease activity and global functioning in all BMI subgroups of AS pts; normal weight pts had numerically better ASAS-HI and BASDAI scores than obese AS pts. There were no events with fatal outcome or unexpected safety signals in either subgroup.

of TNFi therapy may be possible in a real-world setting and if REDOSER tool (3) is an appropriateness criteria for reducing the dose of BT.

**Objectives:** Describe the percentage of patients with inflammatory rheumatic diseases (IRD) who continue with dose reduction of biological therapy (BT). Evaluate relapse in clinical practice after 2 years of follow-up. Identify factors associated with relapse.

**Methods:** Retrospective observational study. Patients with axial spondyloarthritis (axial SpA), psoriatic arthritis (PSA) and rheumatoid arthritis (RA) in BT dose reduction. Inclusion criteria: Axial SpA according to ASAS criteria, PSA according to CASPAR criteria and RA according to ACR2010 criteria, who have started reducing the dose of BT treatment between 2009-2019 at the Hospital Regional Universitario de Málaga, Spain. Protocol: patients with TB are followed prospectively in a monographic consultation with a pre-established protocol. The day of dose reduction = baseline visit (v0). **Variables:** Maintained dose reduction: % of patients who maintained dose reduction from the start of optimization to the index date (data collection). Relapse at 12 and 24 months: % of patients who, after starting dose reduction, returned to the previous or usual dose. Other variables: Demographic, time to diagnosis and evolution of the disease, clinical-analytical: disease activity (DAS28, DAPSA and BASDAI) and physical function (HAQ, BASFI). Previous treatments. Appropriateness criteria for reducing the dose of BT according to REDOSER tool (1): inappropriate, 2. uncertain. Statistical analysis: Descriptive, bivariate, multivariate logistic regression (VD: relapse).

**Results:** One hundred twenty-nine patients with axial SpA, PSA and RA in BT dose reduction were included. The mean time from the start of BT to dose reduction was 38.1 months (16.6-73.1). The mean time in dose optimization was 19.5±15.7 months. At the end of follow-up, 70.2% of the patients (87/pts) achieved a sustained dose reduction. At 12 months and 24 months, 12.4% and 11.6% of patients relapsed, respectively. At the end of follow-up, there were no differences between baseline inflammatory activity and after 24 months in dose reduction measured by the different indexes: DAS28 (1.9±0.7 vs 2.1±1.7, *p*=0.323; DAPSA (5.4±4.9 vs 4.8±4.7, *p*=0.718) and BASDAI (1.5±1.1 vs 1.4±1.3, *p*=0.887). Retrospectively, we evaluated the appropriateness of optimization according to the REDOSER tool (1) at the end of follow-up and it was observed that 85% of patients who maintained the dose reduction had an appropriate REDOSER and 14.5% uncertain and none inappropriate *p*<0.001.

**Conclusion:** Dose reduction of BT in IRD is possible in most patients, maintaining low disease activity or remission at 24 months, compared to baseline. Relapse was associated with a longer evolution time of the IRD, a longer diagnostic delay, a higher inflammatory activity measured by the respective indexes and a uncertain or inappropriate result of the REDOSER tool. This tool can be very useful used prior to the assessment of TB dose reduction

**REAL LIFE DOSE REDUCTION OF BIOLOGICAL THERAPY IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES. UTILITY OF THE REDOSER TOOL**

**S. Manrique Arija**1, A. M. Cabezas-Lucena1, F. Godoy-Navarrete2, M. Morales-Agüila1, R. Redondo1, N. María-Vázquez1. 1UCG of Rheumatology at the Hospital Regional Universitario de Málaga (HRUM), Institute for Biomedical Research in Malaga (IBIMA), Malaga University, 2UCG of Rheumatology Hospital Universitario de Jaén, UCG of Rheumatology, Jaen, Spain

**Background:** The long-term use of standard dosing of TNFi therapy is costly and not without side effects, including infections, tuberculosis and potential malignancies (1,2). Hence, we undertook this study to determine whether dose reduction

**Conclusion:** In a real-world setting, secukinumab improved disease activity and global functioning in both AS and PsA pts. Both, male and female AS pts had a higher treatment response when diagnosed early. Interestingly, delay in diagnosis appeared to be BMI-dependent in female AS pts and PsA pts of both genders. However, in contrast to AS, treatment response of early- and late-diagnosed PsA pts did not differ in the further course.

DOI: 10.1136/annrheumdis-2022-eular.41
treatments for AS patients (5, 6). Data on disease activity and disease control in AS patients treated in real life settings are limited. **Objectives:** To evaluate the average disease activity status in the study population and assess the percentage of AS patients with a suboptimal treatment response following at least 12 weeks of treatment with TNFi and/or NSAIDs.

**Methods:** INVISIBLE was a real-world evidence study in Germany, Austria and Belgium. Adult patients with confirmed diagnosis of AS for at least 6 months and ongoing treatment with TNFi and/or NSAIDs for at least 12 weeks prior to enrolment were included. Primary data were collected at a single visit and medical history data from available patient files.

**Results:** 474 adult AS patients were included. 67% of patients were male, mean symptom duration 18.2 years. 77% of 696 patients were HLA-B27 positive. Appr. 23% of patients received NSAIDs, 42% received TNFi, 30% received both NSAIDs and TNFi, 5% received other treatment for at least 12 weeks prior to enrolment. Mean Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS) scores were 3.4 and 2.2, respectively. Appr. 40% of patients achieved a BASDAI score ≥4 and appr. 50% an ASDAS ≥2.1. Patients with a BASDAI score ≥4 achieved higher scores in most physician and patient reported outcomes. Overall appr. 35% of patients were not satisfied with their current symptom state according to Patient Acceptable Symptom State (PASS). Of patients with a BASDAI score ≥4 appr. 61% were not satisfied according to PASS.

**Conclusion:** Results from the non-interventional study INVISIBLE showed that a high proportion of AS patients receiving NSAIDs and/or TNFi have high disease activity according to BASDAI and ASDAS in real life settings. These results suggest that in some patients, disease control and treatment response are suboptimal under current treatment strategy.

FIRST SPANISH STUDY ON THE EFFECTIVENESS OF ULTRASOUND-GUIDED INJECTION OF CORTICOSTEROIDS INTO THE SACROILIAC JOINT OF PATIENTS WITH Spondyloarthritis.

M. A. Ramirez Huargana1, D. Castro-Corredor2, A. E. Plasencia Ezaíne3, M. Paulino Huertas2, R. Arenal Lopez1, J. Anino-Fernández2, C. C. Ramos Rodríguez2 on behalf of REUDOL.

**Background:** Sacroilitis may be the main manifestation or a complication of any of the variants of spondyloarthritis. The few studies performed in patients with spondyloarthritis mainly evaluate the improvement in pain using a visual analog scale (VAS) and are limited by the need for an operating room and guidance based on fluoroscopy, tomography, or magnetic resonance. The advent of new ultrasound devices has meant that during the last decade, alternative approaches have been proposed for ultrasound-guided injection of the sacroiliac joint.

**Objectives:** To determine clinical improvement (Bath Ankylosing Spondylitis Activity Index [BASDAI], Ankylosing Spondylitis Disease Activity Score [ASDAS], acute-phase reactants, and the VAS score) after ultrasound-guided injection of corticosteroids into the sacroiliac joint of patients with spondyloarthritis.

**Methods:** We performed an observational, descriptive, and retrospective study at Ciudad Real General University Hospital (HGUCR), Ciudad Real, Spain. We reviewed the register of procedures carried out between June 1, 2020 and May 31,
2021 and included all patients with spondyloarthritis and inflammatory low back pain despite treatment with nonsteroidal anti-inflammatory drugs, biologics, or both. All patients underwent ultrasound-guided injection of the sacroiliac joint with corticosteroids (betamethasone chondrose 6 mg in each joint). We excluded patients whose clinical history did not contain the study variables and in whom modifications to pharmacologic treatment could have reduced the effectiveness of the injection. The outcome measures were presence of adverse effects/complications, reduction in the VAS score for inflammatory pain (>0=3 points), reduction of ≥1.1 points in the ASDAS score, reduction of ≥2 points in the BASDAI score, and reduction in the VAS score for inflammatory pain (>0=3 points). These data were analyzed by comparing means (t test) for the variables VAS, BASDAI, ASDAS, CRP, and ESR.

**Conclusion:** Ultrasound-guided injection of corticosteroids into the sacroiliac joint of patients with spondyloarthritis and active sacroiliitis leads to an improvement in pain despite treatment with nonsteroidal anti-inflammatory drugs, biologics, or both. All patients underwent ultrasound-guided injection of the sacroiliac joint with corticosteroids (betamethasone chondrose 6 mg in each joint). We excluded patients whose clinical history did not contain the study variables and in whom modifications to pharmacologic treatment could have reduced the effectiveness of the injection. The outcome measures were presence of adverse effects/complications, reduction in the VAS score for inflammatory pain (>0=3 points), reduction of ≥1.1 points in the ASDAS score, reduction of ≥2 points in the BASDAI score, and reduction in the VAS score for inflammatory pain (>0=3 points). These data were analyzed by comparing means (t test) for the variables VAS, BASDAI, ASDAS, CRP, and ESR. The potential association between the variables and a favorable clinical response was evaluated by calculating the odds ratio. The protocol was approved by the Research and Ethics Committee of Integrated Care Management, Ciudad Real, Spain.

**Results:** We analyzed 32 patients with spondyloarthritis (age 42.69±8.19 years, females 56%, 25/36) with a VAS score of 78±80.79, BASDAI of 5.43±1.48, and ASDAS of 3.27±0.86 before the procedure. At 2-3 months, 75% of patients had improved: VAS 3.81±2.33 (–4.07, p<0.001) and BASDAI 3.24 ± 1.6 (–2.19, p<0.001). At 5-6 months, 59.37% had improved: VAS 4.63±2.31 (–3.25, p<0.0001), BASDAI 3.57±1.67 (–1.86, p<0.0001), and ASDAS 2.27±3.71 (–1.0, p<0.0001). Bone marrow edema resolved in 87.5% of cases compared with the previous magnetic resonance scan. Analysis of factors potentially associated with improved clinical response as measured using the VAS, BASDAI, and ASDAS did not reveal a significant association with the variables analyzed (age, time since diagnosis, grade of sacroiliitis by radiography, presence of HLA B27 (+), and peripheral and extra-articular manifestations, type of treatment). However, all the patients whose symptoms improved (EVA, BASDAI, and ASDAS) had had bone marrow edema on their magnetic resonance scan <1 year before the treatment. Only 5 patients experienced injection site pain, which lasted 1-2 days. No other adverse effects were reported.

**Conclusion:** Ultrasound-guided injection of corticosteroids into the sacroiliac joint of patients with spondyloarthritis and active sacroiliitis leads to an improvement in symptoms that is maintained at 5-6 months. The procedure is effective, safe, inexpensive, and easy to apply.

**Conclusion:** X-ray progression of coxitis in axSpA practically does not depend on the activity of the disease, nor on local signs of inflammation in the HJ, detected by ultrasound and MRI. X-ray progression of HJ lesions is less common in patients receiving bDMARDs therapy.

**Table AB0758 GOLIMUMAB AFTER DISCONTINUATION OF NON-TNF INHIBITORS IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES: FOUR-YEAR RETENTION RATE IN THE SPANISH BIOBADASER REGISTRY**

**Objective:** To assess the probability of retention (persistence or drug survival) of golimumab in patients with rheumatic diseases when used after discontinuation of non-TNF biologics and targeted synthetic disease-modifying antirheumatic drugs (tsDMARDs) have been studied as first-line therapy or after TNFi discontinuation, data on the use of TNFis after discontinuation of these drugs is scarce.

**Background:** Treatment options for rheumatic diseases have evolved to include mechanisms of action beyond tumor necrosis factor inhibitors (TNFi). While non-TNF biologics and targeted synthetic disease-modifying antirheumatic drugs (tsDMARDs) have been studied as first-line therapy or after TNFi discontinuation, data on the use of TNFis after discontinuation of these drugs is scarce.

**Objectives:** We assessed the probability of retention (persistence or drug survival) of golimumab in patients with rheumatic diseases when used after discontinuation of non-TNF biologics or tsDMARDs in the BIOBADASER database. We also compared the probability of retention of patients who initiated golimumab after discontinuation of non-TNF biologics or tsDMARDs with that of patients who initiated it after discontinuation of TNFis.

**Methods:** Characteristics of all adults with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (SpA) who had initiated golimumab after discontinuation of non-TNF biologics or tsDMARDs in the BIOBADASER database were analyzed. The probability of golimumab retention was assessed with the Kaplan-Meier method, and differences between groups with the log-rank test. Patients were censored if they were withdrawn from the study after 3 years of follow-up. The time of observation was defined as the interval between the last TNFi or tsDMARD dose and the first dosing of golimumab, with the patients divided into two groups (∆BASFI hip >0 and ∆BASFI hip = 0).

**Results:** A total of 125 patients (85 [68%] women) with RA (n=72), axSpA (n=23), or PsA (n=30) had initiated golimumab after discontinuation of non-TNF biologics or tsDMARDs and were right-censored if they were still treated with golimumab at the last observation point. We also compared the probability of retention of patients who initiated golimumab after discontinuation of non-TNF biologics or tsDMARDs with that of patients who initiated it after discontinuation of TNFis.

**Results:** A total of 125 patients (85 [68%] women) with RA (n=72), axSpA (n=23), or PsA (n=30) had initiated golimumab after discontinuation of non-TNF biologics or tsDMARDs and were right-censored if they were still treated with golimumab at the last observation point. We also compared the probability of retention of patients who initiated golimumab after discontinuation of non-TNF biologics or tsDMARDs with that of patients who initiated it after discontinuation of TNFis.

**Results:** A total of 125 patients (85 [68%] women) with RA (n=72), axSpA (n=23), or PsA (n=30) had initiated golimumab after discontinuation of non-TNF biologics or tsDMARDs and were right-censored if they were still treated with golimumab at the last observation point. We also compared the probability of retention of patients who initiated golimumab after discontinuation of non-TNF biologics or tsDMARDs with that of patients who initiated it after discontinuation of TNFis.
RA patients (28% at year 3) than in axial SpA (68%) or PsA (49%) (p = 0.002) (Figure 1). As second line therapy, the 3-year retention rate of golimumab was slightly lower when it was initiated after non-TNFi biologicals/tsDMARD than when the previously discontinued therapy was a TNFi (32% vs 55%, p = 0.119), but the figures were similar when it was initiated as third (52% after non-TNFi biologicals/tsDMARD vs 50% after TNFi, p = 0.838) or as fourth/subsequent line of therapy (37% vs 44% respectively, p = 0.554).

Conclusion: We present, for the first time, 4-year retention rates for golimumab in patients who discontinued non-TNFi biologicals or tsDMARDs, most of them in third and fourth/subsequent line of therapy. In this difficult-to-treat rheumatic population, overall golimumab retention rates were favorable through 4 years of treatment, with higher rates in SpA and PsA compared to RA patients.

STUDY ARTHRITIS (PSA) IN REAL WORLD PRACTICE: SECUKINUMAB (SEC) IN PATIENTS WITH PSORIATIC ARTHRITIS (PSA) IN REAL WORLD PRACTICE: FACTORS ASSOCIATED WITH THE RETENTION OF SECUKINUMAB (SEC) IN PATIENTS WITH PSORIATIC ARTHRITIS (PSA) IN REAL WORLD PRACTICE: RESULTS FROM THE RETROSPECTIVE FORSYA STUDY

1University Hospital of Toulouse, Department of Rheumatology, Toulouse, France; 2RCTs Clinical Research Organisation, Biostatistics, Lyon, France; 3Novartis Pharma SA, Medical affairs, Rueil Malmaison, France; 4Hôpital Henri Mondor, Assistance Publique - Hôpitaux de Paris, Department of Rheumatology, Créteil, France; 5Hôpital Cochin, Assistance Publique - Hôpitaux de Paris, Department of Rheumatology, Paris, France; 6University Hospital of Tours, Department of Rheumatology, Tours, France; 7University Hospital Montpellier, Department of Rheumatology, Montpellier, France; 8CHU Brest Department of Rheumatology, Brest, France; 9CHU Clermont Ferrand, Department of Rheumatology, Clermont Ferrand, France; 10CHU de Besançon, Department of Rheumatology, Besançon, France

Background: While data on real-life retention of SEC in patients (pts) with PSA is accumulating, there are no data on predictive factors for this retention.

Objectives: The primary objective of FORSYA study was to assess whether objective signs of inflammation (OSI) were predictive of SEC retention at 1 year.

Methods: French retrospective study collecting between October 2019 and September 2020 data from axSpA pts a) having initiated and received at least one dose of SEC between August 11th 2016 and August 31st 2016, b) with at least a one year follow-up period. Retention of SEC at 1 year was estimated by the Kaplan Meier (KM) method. OSI were defined by at least one of the following within the 3 months before initiation of SEC: CRP > N, confirmed clinical dactylitis, confirmed clinical synovitis or ultrasonography power-Doppler positive synovitis except on MTP of first toe. Preselected factors at initiation of SEC retention at 1 year (≥ 1 OSI, age, sex, BMI, smoking status, axial feature, past or present psoriasis / uveitis / Inflammatory Bowel Disease (IBD) / active arthritis or synovitis, diagnostic delay, disease duration, SEC line of biologic therapy, SEC maintenance dose, concomitant csDMARD, concomitant oral corticosteroids, ≥ 1 comorbidty) were analyzed by multivariate cox model regression. Only variables with < 20% missing data were included in the model after imputation and stepwise selection (significance level for entering variables = 20%, for removing variables = 10%). OSI was forced into the model whatever its significance level or rate of missing data.

Results: In total, 475 pts (male: 40.2%, mean age: 51.9 ± 12.2 years, mean disease duration: 9.3 ± 6.8 years) from 48 centers were included in the analysis. At initiation of SEC, 62.2% of pts had ≥ 1 OSI and respectively 11.0%, 19.5% and 68.9% were in 1st, 2nd and ≥ 3rd line (L) of biologic/targeted synthetic DMARD. The overall 1 year KM survival rate for SEC was 63% [95%CI: 59%–66%] and was numerically greater in 1st L vs 2nd and ≥ 3rd L (82% [72%–93%], 62% [52%–72%], 61% [56%–66%] respectively). The overall survival rates for PSA pts with or without OSI were 62% [56%–68%] and 71% [62%–80%]. In multivariate analysis, absence of OSI, longer disease duration and lack of prior exposure to anti-TNF inhibitors were associated with a better SEC retention at 1 year (Table 1).

Interpretation for predictor: HR> 1: the hazard of discontinuation at 1 year is X times higher in category vs reference.

Conclusion: The overall retention of SEC at 1 year in daily practice at the time of its launch in France was 63% for PSA patients and OSI, disease duration and prior exposure to TNF inhibitors were identified as predictive factors of SEC retention.

Background: Data on the extent of treat-to-target (T2T) recommendations application in SpA patients across Asia Pacific region is lacking. APLAR SpA Registry aimed to assess the utility of T2T on long term clinical outcomes, and to improve disease management and inform health care policy.

Objectives: To provide a snapshot of the registry including demographics, disease activity and medication use.

Table 1. Predictive factors of SEC 1 year retention of SEC identified by multivariate cox regression analysis (multiple imputation + Stepwise selection)
Methods: Patients fulfill the CASPAR 2006 for psoriatic arthritis (PsA) and 2009 ASAS criteria for axial spondylitis (AxSpA) were recruited. This cross-sectional analysis included the first 188 patients recruited across 7 Asia Pacific regions (Hong Kong, Singapore, Korea, Thailand, India, Qatar & Pakistan).

Results: 83 patients PsA and 115 AxSpA patients were included. They had moderate inflammation (DAPSA: 19.61±14.29, ASDAS: 2.32±1.07). Majority of PsA patients received conventional synthetic disease-modifying drug (csDMARDs, 81%) with relatively low prevalence of biologic DMARDs (bDMARDs) (24%). Most AxSpA patients used NSAIDs (79%) while nearly half of them received bDMARDs (49%). Other details listed in Table 1. Prevalence of bDMARDs use in our registry was lower than that from the USA (Corrona PsA Registry, 59%), Turkey & Canada (PsA-tID, 40%) and the Netherlands AxSpA registry (56%) (1-3).

Regarding T2T, 28% and 44% of PsA patient achieved minimal disease activity (MDA) and Disease Activity in Psoriatic Arthritis low disease activity (DAPSA LDA) respectively. The proportion of patients achieving target in other cohorts were 46% for MDA (PsAr-ID) and 46% for DAPSA LDA (Corona) (1, 2), 37% and 47% of AxSpA patient achieved Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)<4 and Ankylosing Spondylitis Disease Activity Score (ASDAS) LDA. Proportion of patients achieving ASDAS LDA were similar to the Netherlands registry for patients with ASDAS LDA or BASDAI<4 (Figure 1A)(3). Patient on bDMARD were more likely to achieve treatment target (Figure 1B). There were no significant difference between socio-economic status and disease features between bDMARD user and non-user.

INCIDENCE OF ANTERIOR UVEITIS IN AXIAL SPONDYLOARTHRITIS DURING SECUKINUMAB TREATMENT: TWO YEARS REAL LIFE EXPERIENCE FROM TURKIBIO REGISTRY

Background: Secukinumab (SEC), a human anti-IL-17A monoclonal antibody, has similar treatment response rates to tumor necrosis factor (TNF) inhibitors in patients with axial spondyloarthritis (SpA). However, the efficacy of SEC on anterior uveitis (AU) is unclear.

Objectives: This study aimed to evaluate the risk of new-onset or relapsing AU in axial SpA patients treated with SEC.

Methods: In this prospective cohort study, 130 axial SpA patients receiving SEC at the TURKIBIO registry between 2019 and 2021 were evaluated. Demographic and clinical characteristics and data about the presence of AU pre or post-treatment were collected. The univariate and multivariate logistic regression analyses were performed to evaluate the predictors of AU development.

Results: The mean age of the patients (F/M: 59/71) was 47.4±10.9 years. The median follow-up time was 540 days (IQR: 330-630), SEC was the first biological agent in 50 (38.4%) patients and 35 (26.9%) patients were using at least one concomitant conventional synthetic DMARD (Table 1). While continued SEC therapy was in 93 (71.5%) patients, treatment withdrawal was in 37 cases (in 26 due to ineffectiveness, two adverse events and nine other reasons). Overall, 15 (11.5%) patients had a history of AU before the SEC. During follow-up, AU attacks were seen in the 6 cases (4 were new-onset and 2 were flare) and 5 of these patients had a history of inadequate response to TNF inhibitors. The frequency of AU was

AB0762
calculated as 3.42 per 100 patient-years during SEC treatment. The only significant predictor of AU development was the baseline high C-reactive protein (CRP) level on multivariate analysis (p = 0.003, OR: 1.063 [95% CI 1.021-1.107]).

Conclusion: In this real-life data from the TURKBio registry, the incidence of AU in axial SpA patients treated with SEC was calculated as 3.42 per 100 patient-years. A high baseline CRP level was an independent factor for developing AU.

AB0763 PERSONAL APPROACH IN AXIAL SPONDYLOARTHROPATHY MANAGEMENT

B. Bugaj1, J. Wielinska2, J. Swierkot1, K. Bogunia-Kubik2. 1Polish Academy of Sciences, Laboratory of Clinical Immunogenetics and Poland; 2University, Department of Rheumatology and Internal Medicine, Wroclaw, Poland

Background: Spondyloarthopathies (SpAs) are a group of diseases characterized by arthritis in the spine (axialSpA - axSpA) and peripheral joints, and extra-articular symptoms like uveitis, psoriasis or inflammatory bowel diseases. The onset of the disease is difficult to observe. Due to the lack of a pathognomonic test, diagnosis is based on a combination of physical examination, laboratory test and imaging results. The pathogenesis of SpAS is not fully understood, and genetic, environmental and immunological factors are assumed to play a pivotal role.

Objectives: The study aimed to evaluate selected polymorphisms (ERAP1 rs2287987, ERAP2 rs2549782, TNF rs1800629, TNFRSF1B rs1061622, FCGR2A rs1801274) as prognostic factors of clinical presentations, and response predictors of anti-TNF treatment in axSpA patients.

Methods: The study enrolled 216 Caucasians: 106 axSpA patients and 110 healthy controls. AS patients were diagnosed according to modified New York criteria, while n-axSpA patients were diagnosed according to ASAS criteria. Genotyping was performed using LightSNip assays on the Real-Time PCR Instrument. Clinical data were assessed at baseline, as well as after three and six months of anti-TNF treatment. In addition, information about extra-articular symptoms was collected.

Results: The statistical analysis revealed that TNFRSF1B rs1061622-GG was significantly associated with a higher VAS score at baseline (TT + G vs GG, p = 0.001), and a higher BASDAI score corrected for the first therapy cycle (X1C BASDAI: TT + TG vs GG, p = 0.005). Moreover, homozygotes were more frequently observed with a lack of BASDAI improvement after six months (X1C BASDAI: TT+GG vs TG, p = 0.045, OR = 2.46, 95%CI 1.00-6.12). ERAP1 rs2287987- GG was more frequently observed with uveitis (AA vs GG, p = 0.049, OR = 4.636, 95%CI 1.101-21.24). The GG genotype of TNFRSF1B rs1061622 was more common in patients with uveitis than TT variant (GG vs TT, p = 0.042, OR = 5, 95% CI 1.08-20). Associations between genetic variants and clinical outcomes were evaluated using laboratory parameters. A lack of the ESR improvement after six months of treatment was more frequently detected between ERA patients observed by EULAR2022 and 18% (AG vs AA + GG, p = 0.027, OR = 2.72, 95% CI 1.115-6.137) and TNFRSF1B rs1061622-GG (TT vs G+, p = 0.020, OR = 3, 95% CI 1.27-6.9) compared to other genotypes. After three months of therapy, the GG variant of ERAP2 rs2549782 polymorphism was more common among individuals with the lack of ESR improvement than T allele carriers (GG vs T+, p = 0.037, OR = 2.76, 95% CI 1.13-6.72). Differences were also detected between the FCGR2A rs1801274 polymorphism, and X1C BASDAI score after six months. The low disease activity (BASDAI < 3) and BASDAI improvement was more frequently observed in patients carrying the A allele than the GG genotype (AA+AG vs GG, p = 0.028, OR = 4.545, 95% CI 1.337-16 and p = 0.012, OR = 6.212, 95% CI 1.683-20.47, respectively). The AG genotype was more common among patients with remission (BASDAI < 2) compared to homozygotes (AG vs AA+GG, p = 0.046, OR = 2.36, 95% CI 1.05-5.13).

Conclusion: Genetic profiling of patients will help to identify those at risk of high initial disease activity or the presence of extra-articular symptoms. Identifying patients less responsive to treatment may allow selecting a drug with an appropriate efficacy profile.

AB0764 FACTORS ASSOCIATED WITH REMISSION AFTER GRADUAL DECLINE OF TNFI IN SPONDYLOARTHRITIS

S. Abdelmalek1, L. Lefkri1, Issad Hassani Beni messous hospital, Rheumatology, Algiers, Algeria

Background: The natural history of axial spondyloarthritides (axSpA) includes periods of remission interspersed with flares. It is recommended to target remission during the disease management, the 2 most used definitions are ASAS partial remission and inactive disease (ASAS <1.3 and/or BASDAI score <3.6). The factors associated with the gradual decline of biologics after achieving remission have been little explored.

Objectives: The objective of this work was to assess the proportion of patients with axSpA treated with TNFi in whom remission was maintained concomitantly with tapering at 3 years of follow-up and to identify the factors associated with this remission.

Methods: Single-center prospective descriptive study. A total of 44 patients included who attempted to space TNFi injections (etanercept, infliximab, adalimumab) among the 192 patients treated with bDMARDs, all of the patients fulfilled the ASAS criteria for SpA. Data collected: socio-demographic, clinical-biological and imaging data up to 3 years of follow-up.

Results: At the 3-year visit, a biologic decrease was achieved in 22.9% (86.4% maintenance of remission and 9.1% with relapse). That is a total of 19.8% (38/192) of patients (mean age 34.2 ± 8.1 years; 71% of men with HLAB27 positive 63.2% with low BMI in 68.4%) maintained clinical remission with TNFi tapering at the 3-year visit. There was a significant association between ASAS (p <0.001), BASDAI (p <0.001) and CRP (p = 0.004) per visit and maintenance of remission. Likewise, patients in remission more often presented strictly axial damage without enthesitic or peripheral damage and minimal structural on conventional radiography (p = 0.03). They reported low smoking and stopping use of NSAIDs. Factors associated with successful 3-year TNFi spacing were a shorter delay between diagnosis and initiation of the biologic (0.9 [0.64-1.3]) and initial presentation of acute illness according to patient examination (2.37 [1.06-5.26]), lower initial BASDAI and BASFI (respectively 1.3 [0.84-1.8] and 0 [0.74-1.4]) and a lower NSAID score (0.715 [0.43-0.9]).

Conclusion: AxSpA patients in remission as defined by ASAS had significantly lower objective signs of inflammation concomitantly but also over time. It is possible to maintain this remission after gradual decline in the biologies at 3 years in axSpA. Low activity and functional scores, as well as low consumption of NSAIDs are predictive of the success of tapering. Discontinuation treatment is not recommended due to the high risk of relapse.

ANALYSIS OF THERAPY IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHROPATHY WHO ACHIEVED THE ASAS PARTIAL REMISSION AND THE CLINICAL-LABORATORY REMISSION AT THE 3RD YEAR OF FOLLOW-UP

D. Timokhina1, T. Dubinina1, A. Demina1, O. Kirchevskaya1, S. Erdes1

1. V.A. Nasonova Research Institute of Rheumatology, Laboratory of axial spondyloarthritis, Moscow, Russian Federation

Background: The main goal of “T2T” strategy for spondyloarthritis (SpA) is to achieve clinical remission or inactive disease. In 2001, the ASAS formulated criteria for partial remission [1], and the Russian Expert Group for Study of SpA (ExSpA) revealed that patients more often achieved remission when taking NSAIDs, a quarter of patients who achieved the clinical-laboratory and the ASAS partial remission, it was included 66 patients followed for at least 3 years, of which 37 (56%) were men. The average age of patients was 31.5 (5.7) years, the average duration of the disease was 22.1 (17.0) months, 63 (95.4%) patients were HLA B27 positive. The criteria for clinical-laboratory remission include the following indicators (at least during 6 months): ASDAS≤1,3, BASDAI ≤1,0, morning stiffness<30 min., absence of swollen joints, absence of enthesitis, nocturnal pain ≤1,0 (NRS), spinal pain≤1,0 (NRS), active extra-articular manifestations, normal levels of CRP and ESR [2]. The criteria for ASAS partial remission include a value not above 2 units in each of the 4 domains: patient global, pain, function, inflammation [1].

Results: Initially, no patients met the ASAS partial remission and the clinical-laboratory remission criteria. By the 3rd year of follow-up, the clinical-laboratory remission was achieved by 21 (31.8%) patients; the ASAS partial remission - 29 (44.0%) patients. When analyzing therapy at the 3rd year of follow-up of patients with early axSpA who achieved the clinical-laboratory and the ASAS partial remission, it was revealed that patients more often achieved remission when taking NSAIDs, a quarter of patients achieved remission on combined therapy with biologics and NSAIDs (Table 1). It is noting that a quarter of patients canceled therapy on their own.

<table>

AB0767 COMPARISON OF THE CLINICAL-LABORATORY REMISSION AND THE ASAS PARTIAL REMISSION IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS

D. Timokhina1, T. Dubinina1, A. Demina1, O. Krichevskaya1, S. Erdes2.
1VA. Nasonov Research Institute of Rheumatology; Laboratory of axial spondyloarthritis, Moscow, Russian Federation
2VA. Nasonov Research Institute of Rheumatology; Laboratory of axial spondyloarthritis, Moscow, Russian Federation

Background: The main goal of "T2T" strategy for spondyloarthritis (SpA) is to achieve clinical remission or inactive disease. In 2014, the ASAS formulated criteria for partial remission [1], and the Russian Expert Group for Study of SpA achieved clinical remission or inactive disease. In 2001, the ASAS formulated criteria for clinical-laboratory remission in patients with early axial SpA (axSpA) at 3rd year of follow-up.

Objectives: to compare the ASAS criteria for partial remission and the clinical-laboratory criteria in patients with early axial SpA (axSpA) at 3rd year of follow-up.

Methods: The study included patients with early axSpA (ASAS criteria 2009 with inflammation back pain duration less than 5 years) from the CORSAR cohort (Early SpondyloArthritis Cohort), formed at the V.A. Nasonov Research Institute of Rheumatology. The cohort includes 175 patients with axSpA. The analysis included 66 patients followed for at least 3 years, of which 37 (56%) were men and 29 (44%) women. The average age of patients was 31.5 (5.7) years, the average duration of the disease was 22.1 (17.0) months, 63 (95.4%) patients were on LBA B27 positive. The criteria for clinical-laboratory remission include the following indicators (at least during 6 months): ASDAS≤1.3, BASDAI ≤1.0, morning stiffness≤30 min., absence of swollen joints, absence of enthesitis, nocturnal pain ≤1.0 (NRS), spinal pain≤1.0 (NRS), no active extra-articular manifestations, normal levels of CRP and ESR [2]. The criteria for ASAS partial remission include a value not above 2 units in each of the 4 domains: patient global, pain, function, inflammation [1].

Results: Initially, no patients met the ASAS partial remission clinical-laboratory criteria. At 3 year of follow-up, the clinical-laboratory remission was achieved by 21 (31.8%) patients; the ASAS partial remission - 29 (44.0%) patients. We matched patients who achieved the ASAS partial remission (n=29) to criteria for clinical-laboratory remission and, conversely, patients who achieved the clinical-laboratory remission (n=21) to criteria for ASAS partial remission. When comparing the criteria for clinical-laboratory remission to the group of patients who achieved the ASAS partial remission, it turned out that the criteria were achieveable (more than 93%), the fewest patients with ASAS partial remission achieved the criteria for clinical-laboratory remission met the ASAS criteria for partial remission (graph 1).

Conclusion: The criteria for clinical-laboratory remission are comparable to the ASAS criteria for partial remission in patients with early axSpA and can be used in a practice of rheumatologists. Further research is needed to analyze the various remission criteria for axSpA and their applicability in a practice.

AB0768 INFLUENCE OF CONTINUOUS NON-STEROIDAL ANTI-INFLAMMATORY DRUGS INTAKE ON BONE MARROW EDEMA IN NON-RADIOGRAPHIC SPONDYLOARTHRITIS

D. Ben Nessib1, M. Yasmine1, H. Ferjani1, W. Triki1, K. Maatallah1, D. Kaffel1, W. Hamdi1, Kassab Institute of orthopedics, Rheumatology, Tunisia, Tunisia

Background: The concept of non-radiographic axial spondyloarthritis (nr-axSpA) has revolutionized the classical understanding of axSpA. Indeed, it facilitated the classification of patients with axSpA who did not present substantial structural damage as it was only detectable on magnetic resonance imaging of the sacroiliac joints (MRI-SIJ) [1]. Continuous non-steroidal anti-inflammatory (NSAIDs) intake has been reported as a potential factor reducing the sensitivity of MRI-SIJ to detect bone marrow edema (BME).

Objectives: The aim of the study was to investigate the effect of continuous NSAIDs intake on BME in nr-axSpA.

Methods: We undertook a cross-sectional study including nr-axSpA according to the ASAS criteria and treated with NSAIDs at baseline. Socio demographic data as well disease characteristics were recorded. Disease activity parameters were also collected including the duration of morning stiffness, night awakenings, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), MRI-SIJ was performed for all the patients. All the images were screened for bone marrow edema with the corresponding sequence (short tau inversion). Patients were grouped according to NSAIDs intake: G1: continuous versus G2 occasional. The level of significance was fixed for p<0.05.

Results: The study included 43 nr-axSpA patients. There was a female predominance with a sex ratio of 0.43. The mean age of the patients was 42±12 years [20-71] and the mean disease duration was 17±9.7 years [4-38]. The mean morning stiffness duration was 47±34.56 ±15-240] minutes. The mean spinal VAS was 5.9±2.6 [0-10]. Nearly 41% of the patients had an active disease with a mean BASDAI of 4.7±2.1 [0-8.6]. The prescribed NSAIDs were as follows: Diclofenac (44 %), Indomethacin (8%), Ketoprofen (18%), Meloxicam (3%), Celecoxib (3%), Piroxicam (3%) and Naproxen (21%). Nearly half of the patients were continuously taking NSAIDs (52.6%) versus occasional intake (47.4%). Four patients failed two NSAIDs and were treated with a third one. Both groups were comparable for age (p=0.193), sex (p=0.386), and disease duration (p=0.4). Similarly, there were no statistically significant differences regarding disease activity parameters between both groups: numerical rating scale of pain (p=0.713), ESR (p=0.314), CRP (p=0.644), morning stiffness (p=0.428), night awakening (p=1), as well as BASDAI (p=0.514). Regarding MRI-SIJ findings, hyper signal in STIR sequence was comparable between both groups (G1: 35% vs G2:33%, p=0.914). Moreover, the increased signal with Gadolinium injection on T1-weighted images was similar between both groups (p=0.113).

Conclusion: Our study showed that continuous NSAIDs intake was not associated with significant changes in MRI-SIJ features. This study suggests that a NSAID-free period is not necessary before assessing bone marrow edema on MRI-SIJ.

TREATMENT OUTCOMES OF PATIENTS WITH BIOLOGICAL THERAPY DURING PREGNANCY AND EFFECT OF PREGNANCY PLANNING ON TREATMENT PREFERENCE OF RHEUMATOLOGISTS

V. Erez1, S. B. Kocaer1, G. Can1, M. Biriinkel1, F. Onen1, I. Sarı1. 1Dokuz Eylül University School of Medicine, Division of Rheumatology, Izmir, Turkey

Background: Rheumatic diseases occur mostly in adults at reproductive age. In addition to the impact of disease course on fetal and maternal health, safety concerns regarding the effects of biological drugs on the course of pregnancy have come to the fore with the introduction and widespread use of them. Unlike other biological treatments, all tumor necrosis factor (TNF) antagonists can be used during pregnancy.

Objectives: To investigate clinical features, treatment characteristics and pregnancy outcomes of patients with biological treatment and evaluate impact of planning pregnancy on treatment preference.

Methods: The study was planned between January 2015 and December 2021. Patients who received biological treatment at conception were determined retrospectively. Demographical data, clinical features, treatment characteristics and pregnancy outcomes were recorded.

Results: 15 patients (mean age 37±2.4) were included. Mean age at diagnosis was 25.6±5.4 and age at gestation was 33±3.9. Mean follow-up duration was 96±55 months. Median period of biological therapy was found 37 (1-156) months. Six (40%) patients were diagnosed with Axial Spondyloarthritis, 6 (40%) Psoriatic Arthritis, 1 (6.6%) Rheumatoid arthritis. While 12 (80%) patients had planned (wanted) pregnancies, 10 (66%) patients were evaluated as eligible for pregnancy in terms of rheumatological disease by rheumatologists. 13 (86.6%) patients were in remission/partial remission before pregnancy, 5 (33.3%) patients were using steroid and disease modifying anti-rheumatic drugs (DMARDs) were stopped before conception. 10 (66.6%) patients were receiving certolizumab, 4 (26.7%) patients were receiving adalimumab. It was found that the treatment of the patient who received rituximab was interrupted due to the pregnancy planning. While certolizumab treatment continued in 6 (60%) patients during pregnancy, the treatment of patients receiving adalimumab was discontinued within 6 months after birth. Activation of disease was occurred in 2 patients whose therapy was interrupted. Biological treatment was restarted during pregnancy in 3 of 9 patients whose biological treatment was discontinued. No perinatal complication was developed except premature rupture of membranes in one patient. It was observed that all infants were healthy at birth, but baby of the mother who received certolizumab was diagnosed mental retardation in early childhood.

Conclusion: In this study, it was established that the majority of patients using TNF antagonist during pregnancy,

1-Having wanted/planned pregnancy,

2-Being in remission or low disease activity before pregnancy,

3-Not experiencing disease activation during pregnancy.

In this study, it was concluded that having a pregnancy plan may be an important factor for rheumatologists to decide type of TNF antagonist, and physicians tend to prefer certolizumab in patients with pregnancy plan.

Table 1. Baseline clinical and treatment characteristics

| Age, years | 37±2.4 |
| Age, at diagnosis | 25.6±5.4 |
| Age, at gestation | 33±3.9 |

TREATMENT OF ANKYLOSING SPONDYLITIS (AS) WITHIN 1 YEAR AFTER DELIVERY

O. Krichnevskaya1, E. Elyin2, T. Dubinina1, S. Glukhova1, A. Demina1, I. Andrianova1. 1VA Nasonova Research Institute of Rheumatology, Laboratory of axial spondyloarthritis, Moscow, Russian Federation

Background: Prescribing therapy to women after childbirth is still a difficult task in Russia due to the well-established ideas among patients and pediatricians of the incompatibility of lactation and treatment. Monitoring AS activity in patients without lactation is also important: maintaining physical and mental health are necessary for full-fledged care of the newborn and the joy of motherhood.

Objectives: To describe the frequency of drug use in women with AS within 1 year after childbirth, to determine the relationship with AS activity, to compare the incidence of diseases in children under one year whose mothers received and did not receive AS therapy during breastfeeding.

Methods: 44 pts with confirmed AS (modified New York criteria, 1984) were followed within 1 year after childbirth. The average age of the pts was 32.5±5.8 years. BASDAI at 1, 6 and 12 months after delivery was: 2.4 [1,4;4,2]; 2.6 [1,4; 4,4]; 2.7 [1,5; 4,1], respectively. ASDAS-CPR was: 2.0 [1,2; 2,7]; 1.9 [1,4; 2,5]; 1,7[1,3; 2,3], respectively. AS activity in pts with and without lactation did not differ. 41 pts (93.2%) had been continuing lactation during 1 month after delivery, 27 (61.4%) pts – during 1 month after delivery, 17 (38.6%) pts – during 1 month after delivery. Adherence to nonsteroidal anti-inflammatory drugs (NSAIDs) therapy was defined as the ratio of the actual dose taken to the prescribed dose. The total dose of NSAIDs was determined by the NSAID intake index (M. Dougados, 2001).

Results: NSAIDs. Ibuprofen was the drug of choice in pts with lactation, 74,1% and 88,2% of pts received it at 1, 6 and 12 months after delivery. Women without lactation received various NSAIDs in 100% of cases. The index of NSAID intake in pts with lactation increased during the first six months after delivery and after 1, 6 and 12 months after delivery and it was: 0 [0; 25]; 33,3 [12; 42,1] and 33,3 [17; 50], respectively (p < 0,05 compared to 1 month after delivery). The index of NSAID intake at 1 and 12 months after delivery in pts without lactation was higher than in pts with lactation (p < 0,05). Adherence to NSAID therapy in pts with lactation was increased during follow-up period after 1, 6 and 12 months after delivery. The index of NSAID intake was: 10 [0; 100]; 71 [30; 100] and 100 [50; 100], respectively (p < 0.05 compared to 1 month after delivery). There was no effect of NSAIDs intake on the AS activity.

Sulfasalazine (SSZ) because of arthritis in the 3rd trimester of pregnancy was received by 5 pts (11,4%); 2 of them independently canceled SSZ after childbirth due to fear of its negative effect on the baby during breastfeeding, both had recurrent arthritis within a year after childbirth. Against the background of lactation, only 1 woman received SSZ at a dose of 1.5 g per day.

DMARD. During the year after childbirth, 17 (38,6%) pts had a need for bDMARD, however, for insufficient availability only 11 pts (25%) received bDMARD: 1 (certolizumab pegol, CZP) within 1 month after childbirth, 8 (CZP – 4, ADA – 4) within 2–6 months, 11 (CZP – 4, adalimumab – 4, infliximab – 1, golimumab – 1, etanercept – 1) within 7 – 12 months of delivery. Of these, 4 pts (all of them intake CZP) received TNF inhibitors during lactation, AS activity in pts with lactation increased during the first six months after delivery and after 1, 6 and 12 months after delivery was: 2.7 ± 0.6 and 2.4 ± 0.5, respectively. In pts with lactation, the same trend was noted: ASDACRP was 2.8 ± 0.5 and 2.1 ± 0.3, respectively.

There were no differences in the frequency of acute respiratory viral infections, atopic dermatitis, the need for antibiotics, and the frequency of hospitalizations in breastfed children whose mothers received and did not receive AS therapy during lactation.

Conclusion: NSAIDs in low doses do not affect AS activity. According to our data performed on a small group of patients with AS, the effectiveness of TNF-alpha therapy does not differ against the background of lactation and without it. It is necessary to increase the knowledge of patients and pediatricians about therapeutic possibilities during lactation to avoid unjustified drug cancellation.

Disclosure of Interests: None declared

EVALUATION OF THE EFFICACY OF INHIBITORS OF TUMOR NECROSIS FACTOR ALPHA FOR PATIENTS WITH ANKYLOSING SPONDYLITIS IN REAL CLINICAL PRACTICE.

E. Rozochkina1, E. Koltssova1, D. Murtazalieva1, E. Zhilayeva2, E. Koshkarova3, G. Lukina4,5. 1.A.S. Loginov Moscow Clinical Scientific Center; Rheumatology, Moscow, Russian Federation; 2European Medical Center; Rheumatology; Moscow, Russian Federation; 3UCB – Aston Consulting-, Rheumatology, Moscow, Russian Federation; 4VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 5VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: The question of the comparative efficacy of tumor necrosis factor-alpha (TNF-α) inhibitors is topical today, because the research data that were distributed in random sequence mainly reflect the efficacy of the only specific drug, and the available data obtained in the ankylosing spondylitis (AS) treatment use of a network meta-analysis are limited.

Objectives: To make a comparative evaluation of the efficacy of various TNF-α inhibitors for patients with AS in real clinical practice.

Methods: The study involved patients with a reliable diagnosis of AS (according to the 1984 New York criteria) who received TNF-α inhibitor during the 12-month
course of therapy, from 2018 to 2022. The efficacy of the drugs was evaluated by the ASDAS (CRP) (Ankylosing Spondylitis Disease Activity Score) and BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) – disease activity indices obtained 6 and 12 months after the start of therapy. Comparison of indicators between drugs was carried out using a non-parametric Kruskal-Wallis test, designed to test the equality of the medians of several samples.

Results: The study involved 257 patients with AS who were treated with various TNF-α inhibitors, among which Adalimumab was taken by 77 patients (29.96%), Golimumab - 20 (7.78%), Infliximab - 15 (5.84%), Certolizumab pegol - 27 (10.51%) and Etanercept - 118 (45.91%). The mean age of the involved patients was 46.1 ± 11.4 years old, the mean age at the onset of the disease was 28.7 ± 11.7 years old. The majority of patients were males - 167 (64.98%), 143 (55.64%) had Higher education, 163 (63.42%) were married, 103 (40.08%) had been working and - 150 patients (58.37%) had never smoked before the study. Mean ASAS (CRP) and BASDAI, disease activity indices, values for each drug before therapy, 6 and 12 months after the start of therapy are presented in Table 1. «Head-to-head» comparison of medical preparations revealed no significant differences between TNF-α inhibitors in terms of the studied parameters (p > 0.05).

Table 1. Basal features

</tr>
<tr>
<td>Non-radiographic axial spondyloarthritis (SpA), clinical manifestations (axial, peripheral affectation and both)</td>
<td>6 (9.8%)</td>
</tr>
</tbody>
</table>

There was no association between the different diagnoses and drug suspension, both variables were independent (p=0.702) with a 5% significance level. There was also no evidence of a significant relationship between the type of involvement (axial/peripheral/both), and the suspension of treatment (p=0.743).

Conclusion: The suspension of the drug due to AEs was small in our sample (8.2%) and the AEs detected were mild (including a mucocutaneous candidiasis). No serious AEs were observed. We found an overall drug survival of 70% in our study. These data are consistent with those published in the different clinical trials of the drug (FUTURE I, II and V, MEASURE I, II and III, PREVENT...). Therefore, we can conclude that Secukinumab constitutes a drug with a good security profile.

Vasculitis: 1. **Adalimumab: 43 (30.9%), Eternecer: 28 (20.1%), Infliximab: 26 (18.7%).

Corticosteroids: 20 (14.4%), Golimumab: 10 (7.2%).** Corticosteroids: 9 (6.6%), Tocilizumab: 9 (6.6%).

Infliximab: 7 (5.1%), Tocilizumab: 5 (3.7%), Golimumab: 4 (2.9%), Ustekinumab: 4 (2.9%).

Rituximab: 2 (2.9%), Abatacept: 1 (0.7%), Anakinra: 1 (0.7%).

1. mean ± standard deviation.

Conclusion: Clinicians should be aware that PRs may develop with biological agents other than TNF-α inhibitors. Additionally, it is important to keep in mind that the development time of PRs could be variable. The mechanism(s) behind PRs remain unknown, and there is no currently available diagnostic or therapeutic protocol (2). The decision whether to continue or discontinue biological agents should be individualized. We found that the majority of patients can be managed without discontinuing biological agents. Finally, we believe that the experience of our large cohort can help physicians in clinical practice where sufficient protocol is lacking.
AB0775 EFFICACY, SAFETY AND SURVIVAL OF SECUKINUMAB IN SPONDYLOARTHRITIS.

M. López I Gómez1, N. Del Val del Amo1, L. Ibarrola1, U. Astigarraga Urkia1, J. Mendizabal1, G. Sada1, S. Garcia Perez1, I. Paniagua Zudaire1, L. Garrido Courel1, L. Horcada1, R. Gutierrez1, C. Fito-Manteca1. Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain

Background: Secukinumab (SCK) is a fully human monoclonal antibody that selectively inhibits IL-17A indicated for both axial and peripheral spondyloarthritis (SpA) and psoriatic arthritis (PsA). In this paper we present our experience with SCK since its approval, in a tertiary hospital.

Objectives: To describe the efficacy, survival and safety of SCK treatment in real clinical practice in patients with SpA and PsA.

Methods: We performed a descriptive, retrospective analysis of patients diagnosed with SpA according to ASAS criteria and PsA according to CASPAR criteria. For this purpose, data were collected from the medical records of 75 patients treated with SCK in the rheumatology service.

To evaluate efficacy in the Spa group, analytical variables (C-reactive protein (CRP)), the Ankylosing Spondylitis Disease Activity Score (ASDAS) scale and the EULAR Spondyloarthritis Disease Activity Index (SAA) were assessed at baseline and at 12 months. Survival was evaluated with respect to the causes of drug discontinuation and its association with individual baseline characteristics, such as metabolic syndrome. Safety was evaluated by analyzing intercurrent infections or neoplasms requiring discontinuation.

Results: Seventy-five patients with spondyloarthritis included in treatment with SCK were analyzed, 40 had SpA and 34 had PsA. The mean age at diagnosis was 45.1 years (SD 11.3) and the median time from diagnosis to onset of SCK was 4.5 years (IQR 1-10) (Table 1).

</table>

Statistically significant improvement was observed in both pathologies in VAS (-2.1 SD 3.1) (p 0.003). Despite the improvement in CRP, in both groups of -3.7 mg/L (SD 15) was not statistically significant. Regarding ASDAS, in the Spa group, 2 patients (5.3%) showed great improvement (>3.1), 9 patients (23.7%) clinical improvement (>1.1), 17 patients (42.5%) improvement (<1.1), 6 patients (15%) showed no improvement and 4 patients (10.5%) worsening.

The overall drug survival to date is 19.41 months (SD 13.6), 18(4.8) in the Spa group and 18 (SD 12.6) in the AP group (Figure 1).

Conclusions: In our cohort, SCK showed a statistically significant improvement in the VAS scale in both groups. A 23.7% of patients with SpA showed clinical improvement according to ASDAS values, 5.3% showed great improvement and 42.5% showed mild improvement. The overall drug survival to date is 19.41 months (SD 13.76) slightly longer in the SpA group than in APs. SCK seems to be a safe drug as none of our patients presented infections during its use.

AB0776 CLINICAL AND LABORATORY PECULIARITIES OF TREATMENT-REFRACTORY ANKYLOSING SPONDYLITIS.

K. Sakhareva1, S. Erdes1, M. Cherkasova1, V.A. Nasonova Research Institute of Rheumatology, Axial spondyloarthritis, Moscow, Russian Federation

Background: Despite the availability of newest guidelines for the treatment of ankylosing spondylitis and various groups of genetically engineered biological drugs, there are still patients with refractory, i.e., resistant to therapy (with two or more genetically engineered drugs), AS, maintaining high clinical and laboratory activity.

Objectives: To analyze the clinical peculiarities of patients with refractory AS and to identify markers for early detection of such cases.

Methods: Patients who received 2 or more GEBDs and demonstrated a primary or secondary failure were considered cases of refractory ankylosing spondylitis. Twenty-four (16%) patients with refractory AS (mNYC 1984) were enrolled, including 14 males, 10 females. This group was selected from 150 successive AS patients admitted to the clinic of the Scientific Research Institute of Rheumatology in 2020–2021. Ninety-three per cent of patients had HLA B 27, the mean age was 39 [31.5; 49] years, the age of onset of the disease was 21.7 [15.5; 29] years, the duration of the disease was 173 [11; 24]. They were treated with drugs of various groups (i-TNF-α, IL-17, and Janus kinase inhibitors). The refractory AS patients were compared to a control group with the corresponding gender, age of onset and duration of the disease admitted successively to the Institute during the same period. The examination followed the ASAS recommendations. All patients had additional nephelometric assay of SAA level using commercial reagent kits, reference value < 5 mg/L.

Figure 1. Secukinumab survival in both groups

17 patients (23%) discontinued treatment, with a median duration of 12 months (SD 4.68), 12 (70.6%) due to ineffectiveness, 1 (5.9%) by their own decision, 3 (17.6%) due to persistent mechanical pain and 1 (5.9%) due to neoplasia (gastric adenocarcinoma). The clinical variables of metabolic syndrome were evaluated (Table 1) none of these characteristics had a statistically significant association as a cause of drug discontinuation. No patient presented infections that required discontinuation of the drug. No association was detected between drug discontinuation or the development of metabolic syndrome.

Disclosure of Interests: None declared

*The total number was not matched because the data of some patients could not be accessed.*
Spondyloarthritis is a chronic inflammatory disease associated with increased cardiovascular morbidity and mortality due to accelerated atherosclerosis. Recent studies have reported the benefit of TNF inhibitors in reducing cardiovascular morbidity and mortality due to accelerated atherosclerosis. Recent studies have reported the benefit of TNF inhibitors in reducing atherosclerosis assessed with carotid intima-media thickness (CIMT) and flow-mediated dilatation (FMD) in patients with spondyloarthritis (SpA).

Methods: We performed a cross sectional study including 47 patients meeting ASAS 2009 criteria for SpA. Patients with traditional cardiovascular risk factors were excluded. We collected clinical data, therapeutic modalities and biological tests including total cholesterol, HDL, LDL and triglyceride after 12 hours of fasting. FMD and mean CIMT (mean value of right and left carotid artery) were measured with a Mindray Resona 7 ZST+ ultrasound machine by an experienced radiologist.

Results: Among the 47 subjects, 18 patients (38%) were receiving TNF inhibitors for a median duration of 36 months (IQR 25-75%; 24-72) (9 were on Etanercept, 7 were on Adalimumab, one patient was on Infliximab and one was on Golimumab). The group treated with TNF inhibitors had a median age of 43 years (IQR 25-75%; 36-46.5) and a median duration of the disease of 12 years (IQR 25-75%; 9.5-22). Median ASOS and BASDAI scores were 2.60 (IQR 25-75%; 1.48-3.1) and 2.60 (IQR 25-75%; 1.55-3.75) respectively. On the other hand, patients naïve to TNF inhibitors had a median age of 32 years (IQR 25-75%; 55-42), median disease duration of 7 years (IQR 25-75%; 3-12.5), median ASOS of 2.13 (IQR 25-75%; 1.61-2.91), and median BASDAI of 2.40 (IQR 25-75%; 1.55-3.75). When comparing the two groups, there was no significant difference regarding disease activity scores ASOS (p=0.431) and BAS-DAI (p=0.793) as well as biochemical variables; total cholesterol (p=0.483), HDL (p=0.395), LDL (p=0.263) and triglyceride (0.092). In contrast, patients on TNF inhibitors were significantly more aged (p=0.009) and had a significantly higher duration of the disease (p=0.004). Doppler ultrasound examination showed a median CIMT of 0.56 mm (0.48-0.64) in patients treated with TNF inhibitors versus 0.55 mm (0.48-0.60) in patients naïve to TNF inhibitors with no significant difference (p=0.238). Patients on TNF inhibitors had lower values of FMD (with a median of 12.5 (6.7-16) versus 15.5 (10-24.5)). However this difference was not significant (p=0.182).

Conclusion: In our study, biological treatment with TNF inhibitors did not affect endothelial function and subclinical atherosclerosis in patients with spondyloarthritis. Given the small size of our study population and its heterogeneity in terms of age and duration of the disease, no conclusions can be drawn. Further longitudinal studies that involve larger samples are necessary.

COMPARISON OF TNF-α INHIBITORS EFFICACY BETWEEN RHEUMATIC DISEASES AND INFLAMMATORY BOWEL DISEASES

T. Nuriakhmetova, D. Abdulganieva, A. Odincova, E. Sukhorukova, J. Shevnina, Kazan State Medical University, Hospital therapy, Kazan, Russian Federation; Kazan State Medical University, Hospital therapy, Kazan, Russian Federation; Kazan State Medical University, Central Scientific Research Laboratory, Kazan, Russian Federation; Republican clinical hospital n.a. N.A. Semashko, Outpatient clinic, Simferopol, Russian Federation

Background: The immunogenicity of TNF-α inhibitors (TNFi) is known to affect the efficacy of these biologic drugs. No previous studies compared this effect head-to-head between different groups of immune-mediated diseases.

Objectives: To compare the effect of immunogenicity of TNFi and their trough level on their efficacy in rheumatic diseases (RD) (ankylosing spondylitis (AS) and rheumatoid arthritis (RA)) and inflammatory bowel diseases (IBD) (Crohn’s disease (CD) and ulcerative colitis (UC)).

Methods: 123 patients receiving infliximab (INX) (n=36, 29.3%), adalimumab (ADM) (n=49, 39.8%) and certolizumab pegol (CZP) (n=38, 30.9%) were included into the study. 70 (56.9%) of them had RD (50 (40.7%) with AS and 20 (16.3%) with RA) and 53 (43.1%) of them had IBD (38 (30.9%) with CD and 15 (12.2%) with UC). The specific criteria were used to assess the response to the treatment (ASAS20 for AS, EULAR for RA, CDAI for CD and Mayo Score for UC).

Measurement of trough level of TNFi and the level of anti-drug antibodies (ADAb) was performed with the use of commercially available ELISA kits. The threshold of low trough level depended on the diseases based on the guidelines: 1 μg/mL for INX in RD group and 5 μg/mL for INX in IBD group, 5 μg/ml for ADM, and 20 μg/l for CZP.

Results: Efficacy of TNFi was 1.3 times more prevalent among patients with RD than among IBD patients (n=60, 85.7% vs n=35, 66%, OR 1.3, 95%CI 1.0 to 1.6, p=0.01). Rate of response to INX and ADM was comparable between the diseases while CZP was more efficient in RD (4.8% vs 35.3%, OR 1.3, 95%CI 1.0 to 2.0, p=0.031). Median trough levels of TNFi did not differ between the groups (p>0.05). Low level was determined in 26 (40.6%) patients with RD and 27 (45.8%) patients with IBD. Low level of TNFi most often was found in patients with UC (n=12, 80%, OR 5.6, 95%CI 1.49 to 20.99, p=0.006). Only INX low level was more prevalent in IBD patients than in RD (87% vs 46.2%, OR 5.7, 95%CI 1.1 to 29.2, p=0.046).

The rate of low level of other TNFi was comparable between the groups (p>0.05). In RD group low level was associated with loss of response (80%, OR 6.0, 95%CI 1.2 to 30.7, p=0.036) while in IBD group no relation was found (51.4% vs 50%, p>0.05). Positive ADAb were determined in 22 (17.9%) patients: 14 (20%) in RD group and 8 (15.1%) in IBD group. TNFi did not differ significantly by the rate of ADAb-positivity (p>0.05). Association of loss of response with ADAb was observed in 4 (40%) patients with RD and 2 (11.1%) patients with IBD. Inefficacy of TNFi due to immunogenicity was 6 times more frequent in RA than in IBD (p=0.05). ADAb to INX (a chimeric antibody) were found only in patients with inefficacy (n=2, 66.7%, p=0.067). After exclusion of patients receiving ADM (a humanized antibody) 3 (75%) non-responders to INX or CZP with RD had positive ADAb while significantly less non-responders among IBD patients were ADAb-positive (n=2, 14.3%; OR 0.06, 95%CI 0.004 to 0.84, p=0.044).

Conclusion: Most of non-responders with RD had either low trough level of TNFi or ADM, while in IBD group only half of cases of non-response could be attributed to the effect of ADAb or low trough level of TNFi.

Spondyloarthritis - clinical aspects (other than treatment)

AB0781 MALAYSIA SPONDYLOARTHRITIS ACCELERATED MANAGEMENT (SAM) MODEL: EXPEDITING AXSpA PATIENT JOURNEY FROM EARLY REFERRAL, DIAGNOSIS AND ACCESS TO OPTIMAL CARE

F. Yahya1, H. Mohd Yusof2, A. Mohd3, S. Ch'ng Suyin4, S. C. Gun1, M. Mohd Zain1, S. Sockalingam1, S. L. Lau1, C. Bao Jing4, J. Tiong1, I. S. Lau4, R. Sengupta5, 1University of Malaya, Rheumatology, Kaula Lumpur, Malaysia; 2Medical University, Rheumatology, Selangor, Malaysia; 3Hospital Ta'fah, Rheumatology, Seremban, Malaysia; 4Novartis, Rheumatology, Petaling Jaya, Malaysia; 5Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom

Background: Axial spondyloarthritis (axSpA) is an important cause of inflammatory back pain (IBP). It is under-recognized, leading to significant delays in diagnosis. Early recognition and diagnosis are crucial to achieve the best outcomes for patients and in Malaysia, significant gaps in the clinical management of axSpA remain. Therefore, we sought to implement a strategy to improve the time to diagnosis and management of axSpA in Malaysia by collaborating and adopting guidance from an international axSpA expert.

Objectives: The objectives were to improve disease recognition among healthcare practitioners (HCPs), reducing time to specialist referral and diagnosis whilst improving disease management by developing and implementing a new patient care model called the Spondyloarthritis Accelerated Management (SAM) and measure its effectiveness in 3 Rheumatology centers in Malaysia.

Methods: The SAM initiative was developed by the Malaysian SpA Consortium Working Group involving 8 Malaysian rheumatologists from 3 local centers and 1 international axSpA expert from the UK as part of the steering committee. Selections were based on clinical expertise. The first local alignment meeting on model structure was held in July 2020 with subsequent meetings held to address key barriers to early axSpA diagnosis and timely access to quality care. A care model with feasible key performance indicators (KPIs) was established, adapted and tracked monthly in the 3 rheumatology centers (Figure 1). Referential tools were developed to facilitate early referrals to rheumatologists. These included a QR-coded ‘3-F’ referral guide and a patient self-screening tool with a patient self-referral letter all hosted on the Malaysian Society of Rheumatology (MSR) website, educational talks to HCPs and public awareness forums on IBP and axSpA. Data were collected on referral source, duration of referrals, knowledge on IBP and axSpA diagnosis and timely access to quality care. A care model with feasible key performance indicators (KPIs) was established, adapted and tracked monthly in the 3 rheumatology centers (Figure 1).

Results: At 1 year after the initiative was launched. Baseline data collected were from August to October 2020 and 1 year data were from November 2020 to November 2021.

Conclusion: The SAM initiative has shown promising initial results in improving referrals of patients with IBP, promoting earlier diagnosis and establishing the importance of having timely access to optimal care. A nationwide implementation is being planned to improve the recognition of the axSpA in Malaysia.

AB0782 SERUM PENTRAXIN 3 AS A BIOMARKER IN PATIENTS WITH SPONDYLARTHRITIS.

Z. Tanosoka-Stenista1, A. Drelich-Zbroja2, K. Grzeczkow2, 1Medical University of Lublin, Department of Rheumatology and Connective Tissue Diseases, Lublin, Poland; 2Medical University of Lublin, Department of Interventional Radiology and Neuroradiology, Lublin, Poland; 3Independent Public Teaching Hospital No 4, Department of Rheumatology and Connective Tissue Diseases, Lublin, Poland

Background: A proper evaluation and management of patients with spondyloarthritis (SpA) requires the use of biomarkers, facilitating early diagnosis, reflecting disease activity and clinical response to therapies. The chronic, systemic inflammatory process is responsible for increased CV risk in SpA patients. Pentraxin 3 (PTX3) is an inflammatory marker, a member of long pentraxin superfamily, argued to be involved in pathogenesis of both inflammation and atherosclerosis. PTX3 is produced locally in the inflamed tissue, by different cell types including macrophages, endothelial cells, synoviocytes, but not hepatocytes. PTX3 is produced in walls of blood vessels, in atherosclerotic plaques, as a response to pro-inflammatory cytokines.

Objectives: The aim of the study was to assess the role of PTX3 as a biomarker in patients with SpA and to evaluate the relationship between PTX3 and CV risk markers (carotid intima-media thickness (cIMT), lipid profile).

Methods: The study group consisted of 40 consecutive patients with SpA: 29 patients with psoriatic arthritis (PsA) and 11 patients with ankylosing spondylitis (AS). The group consisted of 16 (40%) women and 24 (60%) men, with the mean (SD) age 43.9 (12.0) (range 25–68) and disease duration 7.8 (7.8) years (range 1–30). An assessment of the disease activity included laboratory inflammatory parameters (erythrocyte sedimentation rate (ESR), C-reactive protein, CRP) and clinical assessment (in patients with peripheral SpA (pSpA) joints counts and disease activity score in 28 joints (DAS28); in patients with axial SpA (axSpA) Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and pain of the spine according to the patient in visual analogue scale (VAS). A measurement of carotid intima-media thickness (cIMT) was performed using high-resolution B-mode ultrasonography to estimate features of atherosclerosis (cIMT> 0.9 mm and/or presence of atherosclerotic plaques).

Results: The median (IQR) PTX3 concentration in SpA patients was 3.39 (2.22–3.88) ng/ml. The mean (SD) value of ESR was 27.7 (28.3) mm/h and CRP concentration 13.6 (19.9) mg/l. The mean values of clinical indices were as follows: DAS28 3.8 (1.1), BASDAI 4.02 (2.1), BASFI 4.22 (2.2), VAS spine pain 41.4 (24.0). The mean (SD) cIMT value was 0.77 (0.23) mm (range 0.48–1.33). The features of atherosclerosis were detected in 7 (17%) patients. No significant correlations were found between PTX3 and other inflammatory markers (ESR, CRP). There were no correlations between PTX3 concentration and the clinical indices of the disease activity (DAS28, BASDAI, BASFI, VAS spine pain). No differences of PTX3 concentrations were detected between pSpA and axSpA patients. The PTX3 concentrations were significantly higher in patients with definite atherosclerosis (cIMT> 0.9 mm) than in patients with subclinical or no atherosclerosis (cIMT< 0.9) (5.79 (3.84-8.59) vs 3.06 (2.0-3.52) ng/ml, p=0.01), as well as in patients with atherosclerotic plaques in comparison with no plaques (6.79 (4.96-8.59) vs 3.26 (2.0-3.71) ng/ml, p=0.02) (Figure 1).
Background: The diagnostic delay in patients with axial spondyloarthritis (axSpA) is one of the most important barriers for an early diagnosis of these patients. The diagnostic delay is defined as the time from the onset of symptoms until the diagnosis is confirmed. The diagnostic delay in patients with axSpA has been reported to be a significant contributor to the diagnostic delay. The diagnostic delay in patients with axSpA is known to be a significant factor in the delay of referral to rheumatologists, the delay in the performance of imaging tests, and the delay in the diagnosis of patients with axSpA.

Methods: In this cross-sectional study, we consecutively enrolled 153 patients with axSpA and 153 age- and sex-matched controls who were not diagnosed with axSpA. Patients were assessed in the rheumatology clinic of the Hospital Universitario de Bellvitge in Barcelona, Spain, and the rheumatology clinic of the Hospital Universitario de la Princesa in Madrid, Spain.

Results: The mean age of patients with axSpA was 38.2 years (range, 18-80 years), and 59% were women. The mean duration of symptoms before referral to the rheumatologist was 2.8 years (range, 0.1-10 years). The mean duration of symptoms before the diagnosis of axSpA was 3.2 years (range, 0.1-10 years). The mean duration of symptoms before the performance of imaging tests was 2.5 years (range, 0.1-10 years). The mean duration of symptoms before the diagnosis of axSpA was 3.2 years (range, 0.1-10 years).

Conclusion: The diagnostic delay in patients with axSpA is a significant barrier to the early diagnosis of these patients. The diagnostic delay in patients with axSpA is due to the delay in referral to the rheumatologist, the delay in the performance of imaging tests, and the delay in the diagnosis of patients with axSpA.

<sup>a</sup>Work-related reasons of WPAI-score have been calculated for pts in employment (N=340);<sup>b</sup>regular physical training in the context of axSpA;<sup>c</sup>rehabilitation sport and/or functional training;<sup>d</sup>ASAS-HI, Assessment of SpondyloArthritis International Society-Health Index; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BMI, Body Mass Index; n, number of pts; patients; SD, Standard Deviation; WPAI, Work Productivity and Activity Impairment; yrs, years.

Conclusion: Pt advocacy group membership was associated with increased prescribed NPTM in axSpA. Pt organizations may support the implementation of guidelines and improvement of self-management strategies in pts with axSpA, which may influence work participation.

Disclosure of Interests: Dirk Meyer-Olson Speakers bureau: AbbVie, Biocad, Chugai, Eli Lilly, Grünenthal, Janssen, MSD, Novartis, Pfizer, Roche and UCB, Consultant of: AbbVie, Amgen, Biocad, Chugai, Eli Lilly, Grünenthal, Janssen, MSD, Novartis, Pfizer, Roche and UCB, Grant/research support from: AbbVie, Amgen, Biocad, Fresenius, GSK, Novartis and Pfizer.

Background: Patients generally have higher scores than males on most items on self-report questionnaires, including MDHAQ/RAPID3 (multi-dimensional health assessment questionnaire/routine assessment of patient index data). MDHAQ/RAPID3 was validated in patients with rheumatoid arthritis (RA), but is informative in all diseases studied, including spondyloarthritis (SpA). More SpA patients are men than RA patients, suggesting lower scores, but MDHAQ scores are higher in SpA than RA.

Objectives: We compared self-reported MDHAQ/RAPID3 scores in RA vs SpA patients according to gender.

Methods: Patients who met classification criteria for RA or SpA (axial SpA and psoriatic arthritis) completed MDHAQ at a routine rheumatology visit. The MDHAQ includes 10 activities for physical function (FN) (8 identical to HQ), scored 0-3, total 0-30, divided by 3 for 0-10 score, 3-10 visual numeric scales (VNS) for pain (PN), patient global assessment (PATGL), and fatigue (FT), a 60-symptom checklist (ROS60) and a RADA1 self-report of painful joints (0-48). RAPID3 is a 0-30 index of FN + PN + PATGL. Means and standard deviations (SDs) of age, education, and 7 MDHAQ scores were computed in patients with RA versus SpA, and in subsets of female versus male patients with either RA or SpA. Unadjusted differences were evaluated using Student’s t and chi-square tests; mean differences were adjusted for age, gender and education using analysis of covariance.

Results: 170 patients were studied, 102 with RA and 68 with SpA. 82% of patients with RA and 47% of patients with SpA were female (<p=0.001); age and education did not differ between the 2 groups (ANOVA). All 7 MDHAQ scores analyzed were higher in patients with SpA than in those with RA, although only differences for FN were statistically significant (ANOVA). Within both the RA and SpA groups, however, all 7 scores were higher in women than in men, statistically significant for FN, PATGL, RAPID3 and fatigue in RA, and only for fatigue in SpA. In analyses adjusted for gender, FN, PATGL, FT, and RAPID3 were statistically significantly higher in SpA than in RA (Table 1).

Conclusion: The self-reported disease burden measured by MDHAQ / RAPID3 was higher in patients with SpA than in those with RA, despite having a lower proportion of women, who generally have higher scores on all patient self-report questionnaires, including MDHAQ/RAPID3, within both the RA and SpA groups.

Gender differences may lead to underestimation of the greater disease burden in SpA compared to RA.

Table 1. Mean differences in the MDHAQ scores between RA and SpA patients.

* p<0.05.

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease encompassing radiographic (traditionally known as ankylosing spondylitis) and non-radiographic forms that lead to chronic pain, structural damage, and disability.1 The International Map of Axial Spondyloarthritis (IMAS) survey is an initiative developed to generate insights into the real-life experiences of people living with axSpA to ultimately improve quality of life.2

Objectives: To assess the burden and daily experience of patients with axSpA in the United States.

Methods: The IMAS survey generates a report on patient-reported aspects of disease burden and experience with axSpA using adaptations of the original Atlas of axSpA questionnaire developed in collaboration with patients, the Axial Spondyloarthritis International Federation, and clinical academic experts. In this US adaptation of the IMAS survey, a 30-minute online survey was administered to US patients aged ≥18 years who completed screening questions, self-reported having been diagnosed with axSpA by a healthcare provider, and were under the care of a healthcare provider between July 22, 2021, and November 10, 2021. Survey questions were tailored to reflect differences in the US healthcare systems and the availability of treatments. This analysis presents a portion of the US data describing patient demographics, clinical characteristics, journey to axSpA diagnosis, and the emotional impact and overall burden of disease on quality of life using the General Health Questionnaire 12 (GHQ-12), the Assessment of SpondyloArthritis international Society – Health Index (ASAS-HI), and a global limitation index of 18 activities of daily living. All results were reported descriptively using summary statistics.

Results: Survey data from 228 US patients with axSpA were collected in this analysis. The mean age was 45 years, 60% of patients were female, and the mean BMI was 27.7 kg/m² (Table 1). Participating patients had an average of 5.6 comorbidities, with anxiety (43%), depression (41%), and hypertension (32%) as the most commonly reported comorbidities. Among all patients, the mean age at onset of first symptoms was 26 years and the mean age at diagnosis was 35 years; overall, mean diagnostic delay was greater in female than in male patients (11.2 vs 5.2 years; Figure 1A). According to the validated GHQ-12, over half of the patients (57%) were at risk for psychological distress (GHQ-12 score ≥3; Figure 1B). Patients who were older (>40 years old), physically inactive, or who had active disease (BASDAI ≥4) were at risk for psychological distress. Most patients (82%) reported descriptively using summary statistics.

Background: The patient reported Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) includes the six components fatigue, neck, back or hip pain, pain or swelling in other joints, tenderness, morning stiffness severity and duration on a 0-10 scale.

Objectives: To explore the driving factors for the BASDAI in pregnant patients with axial spondyloarthritis (axSpA).

Methods: Anonymized pooled data of the European Network of Pregnancy Registries in Rheumatology (EuNeP) were used. The four participating registries are located in France, Germany, Norway and Switzerland, and collect data of women with child wish, during and after pregnancy prospectively and nationwide on regular time points. For the analysis, women who fulfilled ASAS classification criteria for axSpA and for whom a pregnancy outcome was reported until 12/2019 or 07/2020, depending on the registry, were selected. Mean BASDAI and its components were analysed descriptively.

Results: A total of 332 pregnancies from 304 women with axSpA were eligible. The Norwegian registry contributed half of the pregnancies (50.3%), followed by Germany (26.2%), France (15.4%) and Switzerland (8.1%). Mean maternal age was 31 years, the average disease duration 5 years. Mean BASDAI was 3.0 before conception, 3.4, 3.4 and 3.5 in the 1st, 2nd and 3rd trimester, and 3.4 within 6 months postpartum. The figure shows mean values of the BASDAI and its individual components in the different time periods. Fatigue was higher than the mean score during all phases, and especially elevated in the 1st and 3rd trimester. Furthermore, values for neck, back or hip pain were higher than the mean score, especially from 2nd trimester on. All other components were lower than the mean score. Therefore, the results should be confirmed by other studies.

No correlation was found between the weekly number of hours of PA and the evaluated scores. No significative difference was found between the two groups regarding CRP (16.11 mg/L vs 39.67 mg/L, p=0.107). However, no significative difference was found in clinical enthesitis scores were significantly lower in physically active patients (MASES 1.79 vs 4.22, p=0.007, LEI 1.51 vs 1.72 and SPARCC of 2.97 vs 4.32. Patients who performed regular PA had significantly lower disease activity evaluated with BASDAI (3.53 vs 5.45, p=0.007), ASDAS-CRP (2.64 vs 3.44, p=0.045) and ASDAS-ESR (2.84 vs 3.7, p=0.44). Clinical enthesis scores were also significantly lower in physically active patients (MASES: 1.74 vs 4.22, p=0.007, LEI: 0.95 vs 2.11, p=0.038, SPARCC: 1.79 vs 4.22, p=0.029). However, no significative difference was found between the two groups regarding CRP (16.11 mg/L vs 39.67 mg/L, p=0.107). No correlation was found between the weekly number of hours of PA and the evaluated scores.

Discussion: Physical activity was associated with lower disease activity scores and lower clinical enthesis score. This highlights the importance of physical activity as a non-pharmacologic treatment in SA for the management of disease activity and entheseal involvement.

ABO791 MADRID SONOGRAPHIC ENTHESIS INDEX: USEFUL OUTCOME IN THE DIAGNOSIS OF AXIAL Spondyloarthritides

C. S. Bellagha1, M. Slouma1, S. Ben Dha1, J. C. Bellagha1, L. Metouli1, R. Dhahri1, I. Gharsallah1, B. Louzir1,2. 1The Military Hospital of Tunis, Department of Rheumatology, Tunis, Tunisia; 2The Military Hospital of Tunis, Department of Internal Medicine, Tunis, Tunisia

Background: Madrid Sonographic Enthesis Index (MASEI) is an ultrasound (US) score for the evaluation of enthesis including inflammatory abnormalities and chronic damage in spondyloarthritides (SpA) [1]. This score includes bilaterally: planter aponeurosis, Achilles tendon, distal and proximal patellar ligament, distal quadriceps, and brachial triceps tendons.

Objectives: We aimed to study the diagnosis value of MASEI score in axial spondyloarthritis.

Figure 1. Means of BASDAI components before, during and after pregnancy (the table presents means ± standard deviation).

DOI: 10.1136/annrheumdis-2022-eular.1284
Methods: We conducted a case-control study including 74 subjects divided into 2 groups: G1 - 37 patients fulfilling the Assessment of SpondyloArthritis international Society (ASAS) criteria for axial SA; G0 - 37 healthy controls matched for age and sex. Eight hundred eighty-eight entheseus were assessed by a musculoskeletal experienced sonographer who was blinded to the clinical data concerning patients and controls. The MASEI was calculated for the 2 groups. For G1, we collected the following parameters: disease activity using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS-ESR). Statistical analysis was performed using IBM SPSS Statistics software version 21. A Receiver Operator Curve (ROC) analysis was performed to determine the cut-off of MASEI able to discriminate G0 from G1.

Results: The study included 29 men (78%) and 8 women (22%) in each group. The mean age was 44.51 ± 12.08 years. The mean age of onset was 38.06 ± 11.36 years. The mean disease evolution of 9.02 ± 7.83 years. The mean BASDAI and ASDAS-ESR were 4.47 ± 2.21 and 3.26 ± 1.31. MASEI score was significantly higher in patients compared to healthy controls (25.76 ± 9.8 versus 8.32 ± 6.65, p <0.0001). A cutoff of 18 of the MASEI was able to distinguish G1 from G0 with a sensitivity of 81.1% and specificity of 91.9%. The area under curve (AUC) ± 6.65, p <0.0001). A cutoff of 18 of the MASEI was able to distinguish G1 from G0.

Conclusion: Our study showed that MASEI score is significantly higher in SpA patients and seems to have a diagnostic accuracy. Besides, MASEI was able to distinguish between SpA patients and healthy controls with a cut-off of 18. Those results agree with the findings of other researchers in the field [2].

AB0792 HIP INVOlVEMENT IN SPOndyloarthRITIS: ANALySIS OF ASSOCIATEd FACTORS

H. Tinbi1, M. Slouna1, S. Rahmouni1, A. Abdennadher1, K. Amri2, S. Crotoiu3, I. Elashed2, S. Slouma1, S. Rahmouni1, A. Abdennadher2, K. Amri2, Y. Mallat2, H. Tbini1, M. Slouma1, S. Rahmouni1, A. Abdennadher2, K. Amri2, Y. Mallat2

Background: Hip involvement occurs in about one-third of patients with spondyloarthropathy (SA) [1]. It can be responsible for significant disability and functional impairment.

Objectives: This study aimed to assess the associated factors with hip involvement in SA.

Methods: We conducted a cross-sectional study, including 165 patients with SA diagnosed according to Assessment of SpondyloArthritis international Society (ASAS) criteria over a period from 2017 to 2021. Demographic, clinical, biological and radiographic data were collected. We compared following parameters at the time of diagnosis of coxitis: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS-ESR), modified Stoke Ankylosing Spondylitis Spine Score (mSASSS), Bath Ankylosing Spondylitis Radiology Index (BASRI), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). We used logistic regression analysis to identify factors associated with hip involvement in SA.

Results: A total of 165 Patients were enrolled (121 men and 44 women), the mean age was 46.13 ± 13.07 years. The mean disease of disease onset was 35.01 ± 12.55 years. The average diagnostic delay was 37.54 ± 50.51 months. The average disease duration was 10.91 ± 9.64 years. Eighty seven percent of patients had axial spondyloarthropathy, 72% had extra-articular manifestations. Mean ESR and CRP values were 3749 ± 28.1 mm and 30.14 ± 43.55 mg/L, respectively. Mean BASDAI and ASDAS-ESR values were 4.18 ± 3.09 ± 1.13, respectively. Hip involvement was noted in 60 patients (36.4%). It was bilateral in 75% of cases (n=45). A total number of affected hips was 105. Following parameters were significantly higher in patients with hip involvement: age over 40 years old (73.3 vs 56.3%, p=0.030), symptoms duration over 10 years (60% vs 40.2%, p=0.015), elevated CRP (87.9% vs 73.7%, p=0.036), radiographic sacroiliitis (95% vs 82.7%, p=0.023), frequency of pulmonary involvement (25.0% vs 11.4%, p=0.023), frequency of osteoporosis (20.0% vs 8.6%, p=0.034), BASMI (3.71 vs 1.65, p<0.001), BASRI spine (5.97 vs 2.91, p<0.001), and mSASSS (16.24 vs 8.50, p<0.001). However, no association was found between HLA-B27 and hip involvement (50% vs 28.6%, p=0.099). A multivariable logistic regression model showed that age over 40 years (OR=2.568 [1.020 - 7.083], p=0.045), radiographic sacroiliitis (OR=5.656 [1.007 - 31.769], p=0.049), and very high disease activity (ASDAS-CRP≥3.5) (OR=5.328 [1.774 - 16.002], p=0.003) were independently associated with hip involvement in SA.

Conclusion: Our study showed that age, symptoms duration, radiographic sacroiliitis, extra-articular manifestations, axial structural damage, elevated CRP, and very high disease activity were associated with hip involvement. These findings suggest that the control of disease activity and inflammation may prevent the onset of hip involvement. There are controversial findings regarding the association between HLA B27 gene and hip involvement [2].

AB0793 FACET JOINT DISEASE IN PATIENTS WITH AXIAL SPOndYLOArTHRITIS: A RETROSPECTIVE CONVENTIONAL COMPUTED TOMOGRAPHY STUDY

G. Slobodin1, M. Sagiv1, T. Kriehs2, A. Shouval1, S. Crotoiu3, I. Elashed2, Bnai Zion Medical Center, Rheumatology, Haifa, Israel; 2Bnai Zion Medical Center, Internal Medicine, Ramat Gan, Israel; 3Bnai Zion Medical Center, Internal Medicine, Haifa, Israel; 4Bnai Zion Medical Center, Radiology, Haifa, Israel; 5Sheba Medical Center, Radiology, Ramat Gan, Israel

Background: Facet joints’ (FJ) ankylosis was reported to occur frequently in patients with ankylosing spondylitis (AS). However, a detailed FJ evaluation was not reported in patients over the spectrum of axial spondyloarthropathies (AxSpA).

Objectives: To analyze structural lesions in the FJ of patients with different forms of AxSpA, using computed tomography (CT).

Methods: All available conventional CT studies of the cervical, thoracic, lumbar spine, or studies of the chest or abdomen of patients with AS or non-radiographic AxSpA (nrAxSpA) from a single medical center cohort were analyzed for the presence of erosions, ankylosis, joint-space narrowing, osteoarthropathy, subchondral sclerosis, subchondral cysts and vacuum phenomenon by 2 experienced readers. All patients, as well as age and gender matched control group, who performed conventional CT of the spine for any cause, but did not have a known rheumatic disease, had to be at the age of 50 years or less at the time of the study. The findings were binarically scored as present/absent. Several types of changes could be noted in the same FJ. All FJ findings were compared between groups of AxSpA patients and controls, separately for the cervical, thoracic and lumbar spine. Further, AxSpA patients were subdivided into three groups of which FJ findings were compared: AS patients with (AS+) or without (AS-) syndesmophytes on the cervical or lumbar radiographs, and patients with nrAxSpA as per pelvic radiograph. Fisher’s exact test or Chi-Square test at < http://vassarstats.net >, were used to compare between groups.

Results: 95/666 FJs (49/44 patients) were assessed in the AxSpA/control group patients, respectively. The study group consisted of 16 AS+ patients, 22 AS- patients, and 11 nrAxSpA patients. FJ ankylosis was significantly more prevalent in all spinal segments of the AS+ group compared to the two other groups. Erosions were seen almost exclusively in patients with AS. Joint-space narrowing and osteoarthropathy were noted in all segments and all subgroups of AxSpA patients, including those with nrAxSpA.

Conclusion: FJ involvement is prevalent in all forms of AxSpA, including its non-radiographic form. Facet joints of all spinal segments are involved in AxSpA patients.

AB0794 HOPELESSNESS IN PATIENTS WITH ANKYLOSING SPONDYLITIS
A. Komac1, N. Gokcen1, A. Yazici1, A. Cetin1, Kocaeli University Faculty of Medicine, Rheumatology department, Kocaeli, Turkey

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease leading to loss of function that is strongly related to impaired psychological status. Therefore, depression and anxiety are frequently investigated in these patients (1). However, hopelessness, regarded as a valuable psychological factor characterized by negative expectations and negative emotional states, was not well studied in AS patients (2).

Objectives: The aim of the study is to investigate the frequency of hopelessness in patients with AS and its relationship with clinical parameters and disease activity indices.

Methods: The study was designed as a prospective cross-sectional study. 113 AS patients were included in the study. Demographic data, clinical variables, laboratory results were recorded. Disease activity (ASDAS-CRP and ASDAS-ESR), patients’ functionality (BASFI, BASMI), enthesitis (Leeds enthesitis index) and quality of life (SF-36) were assessed. Hopelessness was evaluated by Beck hopelessness scale (BHS). The relation of BHS scores with the clinical variables was assessed. The strength of the correlations were regarded as very strong (0.8-1). Multiple linear regression analysis was performed to find the association between BHS scores and other clinical variables.

Results: Minimal, mild, moderate, and severe hopelessness were observed in 46 (40.7%), 36 (31.9%), 22 (19.5%), and 9 (8.0%) patients, respectively. Disease duration (p=0.025), ASDAS-CRP (p=0.033), ASDAS-ESR (p=0.015), visual analogue scale (p=0.030), all SF-36 subscales (all p<0.025), BASFI (p=0.024), and BASMI (p=0.009) were statistically different among the groups. BHS scores were higher in patients with high and very high disease activity (p=0.027) (Figure 1). BHS scores showed weak correlation with ASDAS-CRP, ASDAS-ESR, visual analogue scale, BASMI, Leeds enthesitis index, and BASFI. Moreover, negative moderate correlations were detected between BHS scores and SF-36 subscales except social functioning and body pain, which were found weak correlation. In multiple linear regression analysis, BASMI-maximal intermalleolar distance, SF-36 energy, SF-36 mental health, and SF-36 general health were found associated with BHS scores (Table 1).

Conclusion: Higher level of hopelessness is strongly related to higher disease activity in AS patients. Furthermore, higher BHS scores are negatively correlated with SF-36 subscales. Especially, lower energy and impaired mental health are associated with higher level of hopelessness.

AB0795 ARE PATIENTS WITH ANKYLOSING SPONDYLITIS AFRAID OF FALLING COMPARED TO HEALTHY CONTROLS?: THE ROLE OF BALANCE AND POSTURE
H. Bulbul1, Y. Ulus2, A. Bilgec3, 1Termes, Physical Medicine and Rehabilitation, Termes, Turkey; 2Onoduk Mayas University - Faculty of Medicine, Physical Medicine and Rehabilitation, Samsun, Turkey

Background: Fear of falling is a low perception of self-efficacy in avoiding falling during basic, non-hazardous activities of daily life, and concern about falling. It is a risk factor for falls and individuals without a history of falls may have fear of falling. Although it has been shown that the risk of falls is increased in patients with ankylosing spondylitis (AS), there is a lack of sufficient data on the fear of falling in AS patients and the relation of falls with spinal mobility and balance in these patients is controversial.

Objectives: The aims of this study were to compare the fear of falling and balance parameters of AS patients with healthy controls and to evaluate the relation of fear of falling with spinal mobility, balance parameters, pain, disease activity, and functional capacity in patients with AS.

Methods: Forty patients diagnosed with AS and 50 gender-age matched healthy controls were included. Demographic data and the number of falls within the last one year were questioned for all participants. Fear of falling by Falls Efficacy...
Conclusion: T1-Mapping allows for accurately characterizing lesions at the sacroiliac joint in patients with suspected axial spondyloarthritis and, thus, may combine information from two conventional sequences and CT into one in the future while providing superior capacity for quantification. However, in our study mixed lesions and inhomogeneous bone marrow remained problematic. Thus, further sequence development is needed before its implementation in clinical routine.

28.6% of patients had a family history of SpA. 14.3% had ≥1 uveitis outbreaks, 47.8% had ≥3 uveitis outbreaks and 38.1% had 6-11 uveitis outbreaks. 102 (53.7%) uveitis outbreaks fulfilled 1 criterion, 38 (20%) uveitis outbreaks fulfilled 2 criteria, 19 (10%) uveitis outbreaks fulfilled 3 criteria and 5 (2.6%) uveitis outbreaks fulfilled 4 or more. The results of the linear regression model revealed that the uveitis was more severe in patients with smoking history (β=0.34), axial and peripheral involvement (β=0.43), a BASDI (Bath Ankylosing Spondylitis Disease Activity Index)-4 (β=0.32), positive HLA-B27 (β=0.29), female sex (β=0.19), patients with CRP (C-reactive protein) elevation (β=0.002) and a history of bilateral ocular involvement (β=0.32) while shorter disease evolution (β=0.02) and normal vitamin D levels (β=−0.03) were associated with a better outcome.

Conclusion: We identified factors associated with adverse outcomes in SpA by developing a prognostic outcome score that integrates ocular inflammatory activity, ocular complications and refractoriness to treatment.

AB0798
THE PRESENCE OF HEEL ENTHESIS DURING PHYSICAL EXPLORATION IN PATIENTS WITH RADIOGRAPHIC AXIAL SpondyloarthritIS IS ASSOCIATED WITH POORER OUTCOMES AFTER 2 YEARS OF FOLLOW-UP. DATA FROM REGISPONSER-AS
C. López-Medina1, M. A. Puche Larribua1, M. L. Ladehesa Pineda1, R. E. M. Granados1, F. U. Pillar1, E. Collantes Estevez1. 1Reina Sofia University Hospital, Rheumatology, Cordoba, Spain

Background: Enthesitis represents one of the most important peripheral musculoskeletal manifestations in patients with axial Spondyloarthritis (axSpA). The prevalence and the burden of the disease associated with this symptom have been widely studied in axSpA and Psoriatic Arthritis (PsA). However, studies evaluating specifically the heel enthesis and its impact over time are scarce.

Objectives: A) to evaluate the prevalence of patients with heel enthesis during physical examination in patients with radiographic axSpA (r-axSpA); b) to evaluate the association of heel enthesis with higher Patient Reported Outcomes (PROs); c) to assess the impact of the heel enthesis on the outcome measures after two years of follow-up in these patients.

Methods: Observational and prospective study during 2 years of follow-up that included patients with r-axSpA from the REGISPONSER-AS study (Spanish Rheumatology Spondyloarthritis Registry). The patients were divided into two groups according to the presence on heel enthesis on physical exploration during the study visit. The PROs evaluated were the Global VAS, BASDAI, ASDAS, BASMI and the mental and physical components from the SF12 questionnaire. Linear regression models were performed using the PROs as the dependent variable and the presence of heel enthesis as the explanatory variable, adjusting for bDMARDs intake and age. The impact of the heel enthesis on PROs over two years of follow-up was evaluated using mixed models for repeated measures adjusting for confounders. Finally, the achievement of ASDAS Low Disease Activity (ASDAS-LDA) and ASDAS Inactive Disease (ASDAS-ID) after 2 years of follow-up between the two groups were evaluated.

Results: 749 patients were included (mean age 48.4 years; 75.3% men). 46 (6.1%) patients suffered from heel enthesis on the study visit. Patients with heel enthesis showed an increase (β coefficient, 95%/CI) in Global VAS (1.32, 0.52-2.12), BASDAI (1.49, 0.81-2.18), ASDAS (0.45, 0.12-0.77) and BASFI (0.54, 1.78-17.30) compared with patients without heel enthesis after adjusting for confounders. The impact of the presence of enthesis on the PROs after two years of follow-up is shown in Table 1. Patients with heel enthesis showed higher scores during the two years of follow-up in Global VAS, BASDAI, ASDAS and BASFI. In addition, the percentage of patients who achieved ASDAS-ID after 2 years of follow-up was lower in patients with heel enthesis (15.9% vs. 31.5%, p<0.030) in comparison with patients without enthesis. No differences were found regarding ASDAS-ID.

Conclusion: In patients with r-axSpA, the presence of heel enthesis on physical exploration was associated with poorer scores on the outcome measures after two years of follow-up, in comparison with patients without heel enthesis. The achievement of a low disease activity is less likely in patients with this manifestation.

Disclosure of Interests: None declared.

AB0799
ANATOMICAL ABNORMALITIES OF THE LOWER LUMBAR SPINE DO NOT CHANGE THE COURSE OF NON-RADIOLOGICAL AXIAL SPONDYLOARTHRITIS
D. Becker-Capeller1, S. Kapslimalakou2. 1Rheumatologic Practice, Clinic Dr. Hancken, Stade, Germany; 2Klinik Dr. Hancken GmbH / MVZ Radiologie und Nuklearmedizin, Radiology Department MRI Spine Center, Stade, Germany

Background: Diagnosing early spondyloarthritis (SpA) is crucial for effective therapeutic intervention. Magnetic resonance imaging (MRI) helps us to diagnose non-radiographic SpA (n-raxSpA) in an early stage according to the criteria of the imaging arm of the Assessment of Spondyloarthritis International Society (ASAS) classification. Diagnosis of sacroiliitis using MRI has limitations because of the lack of specificity and sensitivity. Several differential diagnoses are well known and should be considered.

Objectives: To investigate the presence of anatomical anomalies of the lower lumbar spine in our cohort of early diagnosed n-raxSpA patients fulfilling the criteria of axSpA and show if they cause a difference in the outcome.

Methods: Patients (n = 56, age < 45 years, symptom duration 3–24 months) recently diagnosed with sacroiliitis using MRI and meeting the ASAS criteria for axial SpA were followed-up for 2 years. We retrospectively analyzed the anatomical anomalies of the lower lumbar spine on MRI and, if available, on radiographic images.

Results: MRI on t0 revealed that 15 (26.7%, 1 female and 14 males) of 56 patients had anatomical anomalies of the lower lumbar spine, indicating bone marrow edema with clinical axSpA according to the ASAS classification criteria. Spondylosis, assimilation joints, and dysraphia were found in 4 (7.1%), 7 (12.5%), and 7 (12.5%) patients, respectively. The presence of HLA-B27 and assessment results (CRP-ASDAS and BASDAI, BASMI) were similar to patients without the mentioned anatomical anomalies. Patients with spondylosis and dysraphia of the lower spine and those without anomalies displayed similar progression of MRI findings between t0 and t2.

Conclusion: In addition to the well-known inflammatory causes of sacroiliitis, such as pregnancies or intensive sporting activity, anatomical peculiarities could not be considered non-inflammatory reasons. Contrary to the latest literature, they are not responsible for non-specific sacroiliitis. No difference in the development of axial SpA was observed when patients with and without anatomical changes were compared.

ULTRASONOGRAPHY OF SUPRASPINATUS ENTHESES IN AXIAL SPONDYLOARTHRITIS
C. S. Bellagha1, M. Slouma1, S. Ben Dhia1, J. Ben Katibi1, L. Metoui1, R. Dhiarn2, I. Gharsallah1, B. Louzig3. 1The Military Hospital of Tunis, Department of Rheumatology, Tunis, Tunisia; 2The Military Hospital of Tunis, Department of Internal Medicine, Tunis, Tunisia

Background: Several scoring systems have been developed to quantify ultrasound (US) abnormalities of the entheses in patients with spondyloarthritis (SpA). These scores included entheses of the lower limb, triceps tendon, and lateral epicondylar tendon [1][2]. Studies regarding the involvement of supraspinatus enthesis in patients with SpA are scarce.

Objectives: This study aimed to assess the supraspinatus enthesis in patients with axial SpA using ultrasonography.

Disclosure of Interests: None declared.
Objectives: To examine the construct validity and responsiveness of ASAS HI in relation to TNFi treatment.

Methods: In this investigator-initiated 52-week prospective observational study (MANGO study; NCT02011386)(3), axSpA patients initiated sc. Golimumab 50 mg every month. Key inclusion criteria were BASDAI ≥4.0 and saccroilitis on radiography and/or MRI.

Results: 45 of 53 TNFi naïve patients completed ASAS HI at weeks 0, 4, 16 and 52. 55.6% were male, 75.6% HLA-B27 positive, median age 34.6 yrs (IQR 28.3-46.1) and symptom duration 5.1 yrs. (2;13)(Table 1A). ASAS HI decreased from week 0 to weeks 4, 16 and 52, from median 10.0 (IQR 8.11) to 7.0 (23.10), 5.5 (13.8) and 4.0 (1.75);(Wilcoxon-Pratt; all p<0.001). Patients with low ASAS HI (score 0-5, good health state(4)) at week 16 and 52 had significantly lower ASDAS, BASDAI, BASFI, pain, pt. global and CRP than patients with moderate to high ASAS HI (6-17) (Table 1B). Patients with a decrease of >3 clinically meaningful change(3)) or >30% (S) in ASAS HI from week 0-16 had significantly larger reductions in ASDAS, BASDAI, BASFI, pain, pt. global and SPARCC MRI spine inflammation score (Table 1C). At baseline, ASAS HI correlated with BASFI and SPARCC SIJ inflammation score (rho: 0.37-0.38, p<0.05), and changes in ASAS HI from week 0-16 correlated with changes in ASDAS, BASDAI, BASFI, pain, pt. global (0.51-0.67, p<0.001) and change in MRI SIJ inflammation score (0.30, p<0.05). ASAS HI had high responsiveness (Table 1D).

Conclusion: ASAS HI showed good construct validity and responsiveness.

Median (IQR), Mann-Whitney test. p<0.05, **p<0.01, ***p<0.001. Standardized response mean (SRM) and effect size (ES) ≥0.50 to ≤0.80 and ≥0.80 represents moderate and high responsiveness.
It increases mortality and comorbidity in patients with immune-mediated inflammatory diseases.

**Objectives:** The main objective is to estimate the prevalence of NAFLD in three of the most common rheumatologic pathologies: rheumatoid arthritis (RA), axial spondyloarthritis (SpA-ax) and psoriatic arthritis (PsA). As a secondary objective, the possibility of finding associated risk factors in this group of subjects that may imply a higher risk of developing NAFLD is proposed.

**Methods:** We conducted a prospective single center observational study which included patients diagnosed with RA, SpA-ax, and PsA attended in the Rheumatology department of a tertiary hospital from January to April 2021. Anthropometric parameters, history related to cardiovascular risk factors and disease activity at the time of the visit were collected. Additionally, blood tests and transitional elastography were performed in all patients and the presence of NAFLD was assessed by the fatty liver index (FLI) scale. Different variables were considered to study their association with NAFLD.

**Results:** 90 patients were included: 28 diagnosed with RA, 36 with SpA-ax and 26 with PsA. 41.1% were male (age range: 27-79 years). Patients with previous liver disease were excluded from the study. 22 (27.2%) patients had NAFLD measured by FLI ≥ 60. No significant differences in prevalence of hepatic steatosis were found between the 3 groups, although values were higher in patients with PsA. The variables that were significantly associated with the development of NAFLD in our cohort were: body mass index (BMI), abdominal perimeter, blood glucose level, HOMA-IR (Homeostatic Model Assessment for Insulin Resistance), HDL, TG, GGT, ferritin and uric acid levels. The rest of the variables studied did not show statistically significant differences (Table 1).

**Conclusion:** Hepatic steatosis was present in 27.2% of patients vs 25% estimated prevalence in the general population. Identification of risk factors involved would allow better control of the comorbidities associated with NAFLD.

The fact that the prevalence found in our sample population is so close to that of the general population, may be related to a good inflammatory control of the underlying disease. Further prospective studies with larger sample sizes are needed to find additional predictive factors for the development of NAFLD in this group of diseases.

**AB0804** ASSOCIATIONS BETWEEN ULTRASOUND CHRONIC LESIONS IN PERIPHERAL ENTHESES AND RADIOGRAPHIC STRUCTURAL SPINAL CHANGES IN MEN AND WOMEN WITH ANKYLOSING SPONDYLITIS

A. Deminger1,2, A. Geijer3-4, N. Nilsson3, M. Hedberg5, L. T. H. Jacobsson1, H. Forsblad-D’elia1,2,1 Institute of Medicine, Department of Rheumatology and Inflammation Research, Göteborg, Sweden; 2Region Västra Götaland, Sahlgrenska University Hospital, Department of Rheumatology, Göteborg, Sweden; 3Institute of Clinical Sciences, Department of Radiology, Göteborg, Sweden; 4Region Västra Götaland, Alingsås Hospital, Section of Internal Medicine, Alingsås, Sweden; 5Region Västra Götaland, Södertälje Södertörn Hospital, Section of Rheumatology, Borås, Sweden

**Background:** Ankylosing spondylitis (AS) is characterised by spinal bone formation and enthesitis. Whether patients with spinal bone formation have a...
generalised bone formation phenotype also involving the peripheral entheses is not fully known.

**Objectives:** To assess in cross-sectional analyses the association between chronic ultrasound (US) lesions in peripheral entheses with spinal bone formation and factors associated with spinal bone formation, overall and by sex.

**Methods:** The entheses at 14 sites at the extremities were examined in 173 patients (54 % men, mean age (SD) 55 (13) years and symptom duration 29 (13) years) with AS (modified NY criteria) using US. Entheses were assessed for structural components (enthesophytes, calcifications and erosions) according to the OMERACT definition [1]. Each lesion was evaluated 0 or 1 and summarised to a damage score (0–42). Spinal radiographs from the same time point were graded according to the modified Stoeke Ankylosing Spondylitis Spine Score (mSASSS) and presence of syndesmophytes were determined. The associations between US damage score and mSASSS and factors associated with spinal bone formation were analysed with Spearman’s correlation analysis overall and by sex. Also, Mann Whitney’s test and multivariable logistic regression analysis with presence of ≥ 1 syndesmophyte as dependent variable and age, sex, BMI, smoking status, CRP, and US damage score as independent variables were used.

**Results:** Presence of any US structural component was found in 158 (91 %) of the patients with no significant difference between men and women (95 % vs 87 % respectively, p = 0.15). The US damage score was median (IQR) 4 (2 to 6) in the total group with a higher score in men compared to women, 4.5 (2 to 7) vs 3 (2 to 5), p = 0.002. In analogy, more men had presence of syndesmophytes in the spine compared to women, 63 % vs 35 %, p < 0.001 and men had higher mSASSS compared to women; median (IQR) mSASSS in men 14 (3 to 43) compared to 2 (0 to 11.5), p < 0.001. Men had higher body mass index (BMI), but there were no sex differences for age, symptom duration, CRP, and smoking status. The results from correlation analyses for US damage score and mSASSS, age, symptom duration, CRP, smoking status, and BMI are presented in the Table 1. Spinal bone formation (mSASSS) was positively correlated with the US damage score in the total group and in men. In both men and women, higher age was associated with higher US damage score. A comparison between patients with and without syndesmophytes showed that patients with syndesmophytes had higher US damage score than patients without syndesmophytes, median (IQR) is 3 (3 to 7) and 3 (1 to 5) respectively, p < 0.001. In the multivariable logistic regression analyses the US damage score was not independently associated with presence of syndesmophytes in the total group or in men. If age was excluded from the analyses though, the US damage score was significantly associated with presence of syndesmophyte, odds ratio (95 % CI) for total group 1.20 (1.05 to 1.37) and for men 1.26 (1.05 to 1.51).

**Conclusion:** Structural lesions were common in the entheses in patients with long-standing AS. Men had more severe bone formation in the spine and the peripheral entheses compared to women. Chronic lesions at the entheses accumulate with increasing age and US damage score could not independently identify patients with syndesmophytes in this cohort with long-standing AS. However, if age was not considered, there was an association between bone formation in the peripheral entheses and the spine in men with AS.

**DISCLOSURE OF INTERESTS:** Anna Deminger: None declared, Mats Geijer: Speakers bureau: UCB Pharma, Novartis, Abbvie, Nicklas Nilsson: None declared, Martin Hedberg: None declared, Lennart T.H. Jacobsson: None declared, Helena Forsblad-d’Elia: None declared, C. Wang: 1 Shaoxing Medical University, Key laboratory of Cellular Physiology

**Background:** Ankylosing Spondylitis (AS) is a complex chronic inflammatory autoimmune disease that mainly affects the spine. Natural Killer (NK) cells are classified among the recently discovered innate lymphoid cell subsets and have capacity to influence both innate and adaptive immune responses. However, the status of NK cells remains debated in AS.

**Objectives:** This study aims to clarify the level of peripheral NK cells in AS patient.

**Methods:** We used CNKI, CBM, Wanfang data and Chinese science, scientific and technological journal data, PubMed, Embase, Web of science, Cochrane library and Medline to collect relevant literature data, and sorted out the proportion of NK cells in AS patients. Random effects were selected to assess pooled data, inconsistency was assessed using I-squared index (I²), and Egger’s test was used to assess potential publication bias (STATA v.12.0).

**Results:** A total of 11 case-control studies involving 561 AS patients and 592 healthy controls (HC) were included in this study; AS patients had a significantly lower proportion of CD16+CD19+ NK cells compared with HCs ( SMD=-0.41, 95%CI (-0.71,-0.11), P<0.05, ) (Fig 1), with no publication bias according to Egger’s test(b=0.50, P=0.63).

**Conclusion:** The proportion of CD16+CD19+ NK cells in AS patients was significantly reduced, suggesting disturbance of NK closely involved in the pathogenesis of AS.

**GENDER AND IMAGING PROGRESSION IN EARLY AXIAL SPONDYLOARTHRITIS: RESULTS FROM A 48-MONTH FOLLOW-UP (ITALIAN ARM OF SPACE STUDY),**

M. Lorenzin1, A. Ortolan2, S. Vio3, G. Cozzi3, V. Scapini4, G. De Conti4, A. Doria4, R. Ramonda1,1 University of Padova, Department of Medicine DIMED, Rheumatology Unit, Padova, Italy; 2University of Padova, Department of Medicine DIMED, Rheumatology Unit, Padova, Italy; 3University of Padova, Radiology Unit, Padova, Italy

**Background:** Gender differences in disease presentation and imaging features of early axial-spondyloarthritis (axSpA) have not been thoroughly investigated.

**Objectives:** To assess the influence of gender on spinal/pelvic radiographic progression and magnetic-resonance-imaging (MRI) features in early-stage axSpA.

**Methods:** Baseline data from the Italian arm of the SPondyloArthritis-Caught-Early-cohort, including patients with chronic-back-pain (CBP; duration>3 months and <2 years; onset=45 years) were analyzed. Patients underwent a diagnostic work-up, including MRI and X-rays of the sacroiliac joints (SIJ) to establish a diagnosis of axSpA (according ASAS criteria). Clinical features, disease-activity and functional indices, imaging were collected at baseline (T0) and yearly during 48-months. Spinal and SIJ X-rays and MRIs were performed every 2-years and scored independently by 2 readers following Stoke Ankylosing Spondylitis Spinal Score System modified by Cremer (mSASSS) (score 0-72) modified New York criteria grading system (mNY criteria) (score 0-4 per each joint) and Spondyloarthritis Research Consortium of Canada (SPARCC) (score of 0-40 for SIJ and 0-92 for the spine).

**Results:** Out of 98 CBP patients, 91 had axSpA (83.5% non-radiographic; 16.5% radiographic). 47% were male. At T0 males were younger with less axial symptoms duration (p=0.04); had more frequently human-leukocyte-antigen (HLA)-B27 (p=0.02); radiographic sacroiliitis with bilateral/symmetric pattern (p<0.02) and more signs of spondylitis (p=0.03). Females presented more frequently an associated peripheral/entheseal involvement (p=0.04) and a non-radiographic form (p=0.03). Functional and disease-activity indices decreased with slightly higher Maastricht Ankylosing Spondylitis Enthesitis Score (MAS-ES), Visual Analogue Scale of pain (VAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional index (BASI) values in females (p<0.04). Males showed a slight increase for both pelvic and spinal radiographic progression than females (Figure 1 A-E). At T0, 62 (68.1%) axSpA patients presented inflammatory lesions on MRI-SIJ, with more signs of active sacroiliitis in males (83.7% vs. 54.2%; p=0.03). Fifty-seven (62.6%) patients showed inflammatory-corner-lesions on MRI-spine: the frequency of inflammatory-corner-lesions on MRI-spine was higher in females, instead these lesions no differed between males and females, while the localization varied: prevalently cervical/thoracic lesions were observed in females, instead lumbar lesions in males (p<0.05). We also found a higher prevalence of signs of active anterior spondylitis without active sacroiliitis on MRI in females (29.2% vs. 14.0%; p=0.03). Signs of enthesitis were found in 68.1% patients, with slightly higher compared over-time with descriptive-statistics; multi-variate-logic-regression model was constructed to assess predictors of spinal and SIJ radiographic progression at 48-months.

**Conclusion:** AxSpA is a group of inflammatory diseases with multiple clinical manifestations (axial, peripheral, skin, eye, and intestine) including ankylosing spondylitis (AS), reactive arthritis, psoriatic arthritis (PsA), arthritis associated with inflammatory bowel disease, and non-radiographic axial spondyloarthritis. AS is genetically related to HLA-B*27 [10]. The etiology and pathogenesis of this disease are unknown. Notwithstanding, the misleading hypothesis suggests that it may be triggered by the formation of HLA-B*27 homodimers. The risk of developing SpA is 5-7% in positive HLA-B*27 individuals [1,2].

**RELAPSE INCIDENCE ACCORDING TO HLA-B*27 IN PATIENTS WITH SPONDYLOARTHRITIS IN A SPECIALIZED CENTER IN COLOMBIA**

O. J. Felipe Díaz1, W. G. Rojas Zuleta1, C. Orozco-González2, A. E. Pantoja Marquez2, C. Corón1, C. L. Giraldo Herrera3, M. M. Rabiosa-Fernández4, D. Becerra-Arias3, J. H. Donado Gómez5, N. Duque Zapata5, 1Medicarte, Rheumatologist, Medellín, Colombia; 2Medicarte, Epidemiologist, Medicarte Research Group (GIM), Medellín, Colombia; 3Medicarte, Rheumatologist, Cali, Colombia; 4Medicarte, Epidemiologist, Medicarte Research Group (GIM), Cali, Colombia; 5Medicarte, Epidemiologist, Medicarte Research Group (GIM), Bucaramanga, Colombia

**Background:** Spondyloarthritis (SpA) is a group of inflammatory diseases with multiple clinical manifestations (axial, peripheral, skin, eye, and intestine) including ankylosing spondylitis (AS), reactive arthritis, psoriatic arthritis (PsA), arthritis associated with inflammatory bowel disease, and non-radiographic axial spondyloarthritis. AS is genetically related to HLA-B*27 [10]. The etiology and pathogenesis of this disease are unknown. Notwithstanding, the misleading hypothesis suggests that it may be triggered by the formation of HLA-B*27 homodimers. The risk of developing SpA is 5-7% in positive HLA-B*27 individuals [1,2].

**Objectives:** Explore the relapse incidence and its associations with HLA-B*27 in SpA patients.

**Methods:** SpA patient cohort in a specialized multicentric health institution in Colombia (November 2011 to June 2021). Relapse was defined as the BASDAI increment ≥1 + 2≤ final BASDAI ≤4. A stratified analysis was performed for HLA-B*27 between diagnosis, current medication, and relapse. For group comparisons χ2 and Wilcoxon tests were used, according to variable distribution. Logistic regression model was run in order to explain relapse incidence.

**Results:** 515 patients were included, among whom 60.9% were HLA-B*27 positive. 870% had an AS diagnosis (53.3% of men), 11.4% (64.4% of women) non-radiographic axial spondyloarthritis and 1.55% PsA (62.5% of women). Table 1 shows demographic and clinical characteristics. The relapse incidence was associated with positive HLA (Odds Ratio-OR:2.14 Chi2=0.986-4.674, p=0.055) and with time of disease evolution (OR 1,05 IC95% 1.02-1.091, p=0.001) adjusting for sex.

* p value for the difference between HLA-B*27 positive and negative groups. IQR: interquartile range

**Conclusion:** In SpA patients, HLA-B*27 frequency is higher in AS patients compared to other SpA forms. Furthermore, this is associated with a higher relapse risk and longer time of disease evolution.

**References:**

Background: Costovertebral (CV), costotransverse (CTr), sternoclavicular (SC) and manubriosternal (MS) joint involvements may be in spondyloarthritis (SpA). However, the radiological and clinical characteristics of these involvements need further assessment.

Objectives: In this study, we aimed to determine the characteristics of CV, CTr, SC, and MS joint involvements in SpA patients. Methods: SpA patients (searched from the hospital data-processing system according to ICD-10 system to determine the patients having M07 (enteropathic arthropathies), M45 (ankylosing spondylitis (AS)), M46 (other inflammatory spondyloarthropathies) and M48 (other spondyloarthropathy) codes) who have been requested a chest computed tomography (CT) for any reason between January 2010 and December 2020 included in this retrospective cross-sectional analysis. Chest CT reports were reviewed, and any CV, CTr, SC or MS joint involvement attributed to SpA accepted as positive CT for SpA involvement. Demographic/clinic data including smoking status, disease characteristics (duration, drug history, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Mobility Index (BASMI) and other related parameters) at the time of CT scan were collected and analyzed.

Results: After the confirmation of the diagnoses among 1700 patients, total of 339 SpA patients were included in the study. 244 were diagnosed with ankylosing spondylitis (AS), 66 with psoriatic arthritis (PsA), 14 with enthesopathic arthropathy, 13 with peripheral SpA, and 2 with non-radiographic axial SpA. According to CT reports, the number of patients with inflammatory changes in any of the CV, CTr, SC or MS joints on thoracic CT were 44. Of these patients, 42 were diagnosed with AS (95.5%), 1 with PsA (2.3%), and 1 (2.3%) with peripheral SpA. 39 CV, 9 SC, 5 MS joints, and 3 CTr joints were affected. Joint involvements (17%) were higher in patients with AS than in other patient groups (p<0.001). In the chest CT positive group, Schober’s test, and chest expansion were significantly lower than chest CT negative group. Smoking history, C-reactive protein (CRP) value at diagnosis and at CT evaluation, and disease duration were associated with joint involvement. Demographic and clinical characteristics of patients with and without chest CT involvement were shown in Table 1.

Data are presented as median (25-75 percentile) or number (%) CT; computerized tomography, BMI; body mass index, ESR; erythrocyte sedimentation rate, CRP; C-reactive protein, BASDAI; Bath Ankylosing Spondylitis. Disease Activity Index, BASMI; Bath Ankylosing Spondylitis Mobility Index, BASFI; Bath Ankylosing Spondylitis Functional Index

Conclusion: In this study, we have found that CV, CTr, SC, and MS joint involvement on thorax CT were more common in men and smokers and were associated with disease duration and appears to affect chest expansion and Schober’s tests. In previous studies, CV and CTr joint involvement in AS patients with chest pain have been 12% and 8%, respectively [1,2]. Our study showed that 17% of AS patients had involvement regardless of pain symptoms. As this is the preliminary data and the CTs will be re-evaluated by our radiologist, we will be capable to report more unbiased results.

†Female vs. male; ‡Divorced/separated vs. single/married/widow; ‡Sick leave/unemployed vs. other employment status.

Conclusion: Almost half of the axSpA patients reported to have negatively impacted their social life. Being female, divorced/separated, on sick leave/unemployed, with higher disease activity, poor mental health, and anxiety increase the likelihood of worsening social life. As relationships with others and engagement in social or community activities influence quality of life, greater attention to enabling individuals to participate socially through controlling disease activity and addressing mental health comorbidity in the management of axSpA.

†Female vs. male; ‡Divorced/separated vs. single/married/widow; ‡Sick leave/unemployed vs. other employment status.

Conclusion: Higher healthcare utilization was associated with higher disease activity, greater functional limitation, and longer diagnostic delay, in younger and females axSpA patients. Optimal monitoring of axSpA patients may help to minimise healthcare utilisation in patients with axSpA.

AB0811 RESPIRATORY TRACT INFECTIONS AND RISK FACTORS FOR INFECTION IN A SPONDYLOARTHRITIS CLINIC IN TASHKENT: IS THERE A DIFFERENCE BETWEEN PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS?

N. Frede1, E. Rieger1, R. Lorenzent1, A. Venhoff1, A. M. Kanne1, M. Von Deimling1, N. Bartholomä1, J. Thiel1, R. Vol1, N. Venhoff1. 1 Medical Center - University of Freiburg, Faculty of Medicine, University of Freiburg, Department of Rheumatology, Freiburg, Germany

Background: Respiratory tract infections (RTIs) are the most common infections in patients with rheumatic diseases under immunosuppressive treatment. RTIs may cause significant morbidity with reduced quality of life (QOL), increased healthcare costs and may lead to interruption of DMARD therapy. However, to date only limited data on infection risk in spondyloarthritids (SpA) patients are available.

Objectives: To assess the occurrence of respiratory tract infections in a real-world SpA cohort and determine associated factors.

Methods: Questionnaire-based screening and retrospective medical chart analysis of a monocentric cohort of 314 SpA patients comprising 168 psoriatic arthropitits (PsA) and 146 axial spondyloarthritids (axSpA) patients.

Results: Out of 314 SpA patients, 89% had a history of upper respiratory tract infections (URTIs) and 31.1% of lower respiratory tract infections (LRTIs) within the last two years (Table 1). In a linear regression model LRTIs were associated with glucocorticoid (GC) therapy (p=0.015), CRP level (p=0.018), previous history of severe respiratory infections (p=0.007) as well as absence of HLA B27 (p=0.024). In general, patients with LRTIs were significantly older (p=0.007), had increased functional impairment (p<0.001), a reduced health-related QOL (p<0.001), poorer sleep quality (p=0.001) and more depression (p=0.001). 46% of patients had required antibiotics for RTIs within the last two years. Antibiotic therapy was associated with smoking (p=0.006), biologic therapy (p=0.005) and poor sleep quality (p=0.005). Smoking was associated with LRTI (p=0.009), but not URTI. Female patients reported a significantly higher frequency of LRTI (p=0.003), sinusitis (p=0.001), pharyngitis/laryngitis (p=0.009) and had more received courses of antibiotics than male patients (p=0.032).

There were no significant differences between PsA and axSpA regarding frequency of URTI or LRTI, though axSpA patients had tendentially more overall RTIs. Biological therapy did not lead to a significantly increased occurrence of infections, but was associated with increased antibiotic therapy (p=0.039). Patients with a history of pneumonia had received anti-IL17 therapy more frequently (p=0.002), while there was no significant association with anti-TNF therapy (p=0.156). Patients on GC had a relative risk for LRTIs of 10.1136 / annrheumdis-2022-eular.2966

AB0812 EFFECT OF PRO-INFLAMMATORY CYTOKINE-INTERLEUKIN 6 ON THE COURSE OF ANKYLosing Spondylitis in Patients after COVID-19

N. Abdurakhmanova1, K. Akhmedov2, 1Tashkent Medical Academy, Department of internal diseases #3, Tashkent, Uzbekistan; 2Tashkent Medical Academy, Department of internal diseases #3, Tashkent, Uzbekistan

Background: Everyone knows that COVID-19 not only has a severe effect on the pulmonary system, but also triggers a whole cascade of autoimmune reactions. The study of the effect of the pro-inflammatory cytokine - interleukin 6 (IL-6) on the clinical course of patients with ankylosing spondylitis (AS) undergoing COVID-19 is an important problem in rheumatology.

Objectives: To study the significance of the pro-inflammatory cytokine-IL-6 on the clinical features of the course of AS in patients who have undergone COVID-19.

Methods: In the period from 2020-2021, 44 patients with a diagnosis (AS) were hospitalized in the City Clinical Hospital # 3 of Tashkent city. The patients were divided into two groups: Group I - 20 patients with AS who underwent COVID-19 and Group II of 24 patients with no history of AS who had COVID-19 infection. The average age of patients in group I was 32 ± 4.1 years and in group II - 36.5 ± 5.2 years. All patients underwent clinical and laboratory studies, including studies of serum IL-6 levels. Disease activity was assessed using the BASDAI and ASDAS scales, pain was assessed using a numerical rating scale (NRS), and peripheral joint damage was assessed by the presence of pain and swelling in 44 joints. All patients underwent PCR, as well as ELISA-IHLA tests for the presence of antibodies to COVID-19.

Results: Clinical examination of the patients revealed the presence of pain in the spine, which was assessed using the numerical rating scale – (NRS) in group I it was 8.5 ± 1.2 points and 5.9 ± 2.3 points in patients of group II. Examination of peripheral joints showed an average number of painful joints (PJ) of 16.9 ± 3.2 in group I and 8.6 ± 2.7 in group II, the number of swollen joints (NSJ) 8.8 ± 2.1 in group I and 4.2 ± 1.7 in group II. The study of AS activity using the BASDAI scale showed an average level of 5.1 ± 1.7 points in group I and 4.4 ± 2.1 points in group II. And the study of activity on the ASDAS scale showed an average level of 4.0 ± 1.7 points in group I and 2.5 ± 0.8 points in group II, which indicates a high activity of the pathological process in group I and medium-high activity in group II. The IL-6 level in group I was 10.2 ± 2.1 / mg / ml and 4.2 ± 2.1 / mg in group II and 1.39 µg / ml in the control group.

Conclusion: 1. The clinical course of AS in patients who have undergone COVID-19 is characterized by a more pronounced disease activity according to the BASDAI and ASDAS scales, a high intensity of pain syndrome according to a NRS, as well as a high level of IL-6.

2. A high level of IL-6 in group I indicates the impact of COVID-19 on the course, activity and severity of the autoimmune process in patients with AS, which is many times higher than in patients of group II, which allows us to consider it as a biomarker of damage to the articular and connective tissue in this infection.

Background: There is currently no consensual definition of flare in axial spondyloarthritis (axSpA).

Objectives: The aims of this study were to determine thresholds of variations of BASDAI associated with patient-reported flare and to test performance of ASAS preliminary definitions of flare.

Methods: This prospective study was proposed to all patients registered on the Spondy+ platform, a secure e-health platform for SpA patients. Every week during one year, patients were invited to connect to the platform to fill a BASDAI questionnaire, a 0–10 pain visual analogic scale and to answer to the following question: “has your disease flared up since last week?” Variations of BASDAI and pain between connections were assessed and associated to the change of perception of a flare. ROC curves were built to assess performances of BASDAI and VAS to identify patient-reported occurrence and resolution of flare. Performance of ASAS preliminary definitions of flare was also assessed.

Results: 99 patients participated to this study for an average duration of 309 ± 148 days. 92% of them reported at least one episode of flare over follow-up. Area under the ROC curve (AUC) was significantly higher for ΔBASDAI than for Δpain, to predict outbreak of flare (0.81 vs 0.77, p<0.02). In contrast, ΔBASDAI and Δpain were comparably accurate to predict flare resolution with no significant difference of AUC (0.78 vs 0.80, p=0.4). Best performance was obtained for an increase of 0.2 points of BASDAI (sensitivity=70%; specificity=79%) and 0.5 of pain VAS to predict outbreak of a flare and a decrease of 0.4 points of BASDAI and 0.5 of pain VAS to predict flare resolution (Figure 1). None of the ASAS definitions yielded sensitivity values higher than 37% whereas specificity was higher than 95% for all of them.

Conclusion: ΔBASDAI appeared as a suitable variable to monitor both occurrence and resolution of SpA flare, as reported by patient.

Disclosure of Interests: None declared

Figure 1. Sensitivity (red dots) and specificity (blue dots) according to ΔBASDAI (panels A,C) and Δpain (panels B,D) threshold as predictors of outbreak (panels A,B) or resolution (panels C,D) of flare.
HLA-B27 (p=0.034), functional impairment (p=0.001) and depression (p<0.001). Patients reporting restless sleep had significantly more depressive symptoms (p<0.001) and highly reduced physical and mental HRQoL (p<0.001). Satisfaction with health was rated significantly lower (p<0.001). Patients with axial involvement (axSpA/axPsA) reported worse sleep quality (p=0.002) and waking too early (p=0.038) despite 73.7% receiving biologics. Sleep quality and early awakening correlated with BASDAI (p<0.001). Smokers had a reduced HRQoL (p=0.018) despite younger age (p=0.008). Female patients had worse sleep quality (p<0.001), needing more time to fall asleep (p=0.022), not being able to sleep through the night (p=0.026) and feeling unrestful in the morning (p<0.001). They had a reduced physical (p=0.019) and mental HRQoL (p=0.003), more depressive symptoms (p=0.040) and lower functional capacity (p=0.002). Functional capacity was associated with younger age (p<0.001), sex (p=0.042), smoking (p=0.008), sleep quality (p<0.001) and depression (p<0.001). 66.2% of patients have been assessed longitudinally, before and 3y later during COVID19 pandemic. Physical and mental HRQoLs were stable over time. Functional capacity had decreased slightly. Subjective QoL during the COVID19 pandemic was not reduced compared to before. Regarding depressive symptoms, there was a mild but significant improvement over time (p=0.019). Furthermore, we observed an improvement of environmental QoL (p=0.034) during COVID pandemic. Overall subjective QoL as well as satisfaction with health did not change significantly. Patients who had changed therapy (37% of the cohort) still had a reduced physical HRQoL (p=0.022) as well as significantly more depressive symptoms (p=0.010) and perceived their overall QoL as being worse (p=0.016).

**Conclusion:** Despite treatment many SpA patients have a reduced HRQoL and impaired sleep quality with significant differences between male and female patients. Impact of COVID19 pandemic was low.

**DOIs:**

DMARD-use (p=0.046) and less use NSAID (89.5 % vs 96.6 %; p=0.02). There were no statistically significant differences in prevalence of comorbidities between AS and nr-axSpA groups except hypertension which was higher in nr-axSpA patients (24.6 % vs 14.4 %; p=0.016) and digestive disorders which was most frequently detected in patients with AS (12.5 % vs 5.9 %; p=0.05). The prevalence of cardiac disorders (p = 0.068) and diabetes (p = 0.09) was nearly statistically significant. The multivariate analysis showed that hypertension is associated to AS form (OR: 1.976; IC [1.088-3.589]).

**Conclusion:** Comorbidities were common in both axSpA populations with small differences between AS and nr-axSpA. These results highlight the importance of identifying and managing comorbidities.

**PREDICTORS OF REMISSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW**

A. S. Pinto1, B. Farisogullari2, P. Machado3. 1Unidade Local de Saúde da Guarda, Rheumatology, Guarda, Portugal; 2Faculty of Medicine, Hacettepe University, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey; 3University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom

**Background:** Achievement of remission is a desirable outcome in axSpA, and the identification of remission predictors may further aid in the clinical and personalisation of management of the disease.

**Objectives:** To systematically review and summarize the predictors of remission in patients with axSpA.

**Methods:** A comprehensive search was performed in MEDLINE, EMBASE, Cochrane CENTRAL, and 2020-2021 abstracts of ACR and the EULAR annual meetings. To identify the relevant studies, medical subject headings and keywords related to “axial spondyloarthritis,” “remission,” and “prognostic study” were used. Studies were included if: patients were diagnosed with axSpA by a physician; age ≥18 years; the study assessed the potential predictive or prognostic factors related to remission, according to any definition; and the statistical analysis included multivariable analysis. The methodological quality of the included studies was assessed using the Quality of Prognosis Studies in Systematic Reviews tool.

**Results:** The systematic literature review (SLR) comprised 22 articles from 4245 citations identified in our search (Figure 1). Two studies investigated “sustained remission” (at least in 3 consecutive follow-up visits), while the others assessed “point remission” (at single points in time). The most commonly used remission criteria were: Bath Ankylosing Spondylitis Disease Activity Score (BASDAI), inactive disease (14 studies) and Assessment of SpondyloArthritis international Society partial remission (ASAS-PR; 11 studies) criteria. However, other non-validated definitions, most of them including Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) cut-offs, were also used. In 19 studies, subjects were treated with biological disease-modifying antirheumatic drugs (bDMARDs) with or without concomitant conventional synthetic antirheumatic drugs (cDMARDs) or non-steroidal anti-inflammatory drugs (NSAIDs), while in one study patients were treated with a Janus kinase inhibitor, upadacitinib. Study duration ranged from 12 weeks to 8 years. Younger age, HLA-B27 positivity, male gender, lower baseline BASDAI, lower baseline Bath Ankylosing Spondylitis Functional Index (BASFI) and treatment with tumour necrosis factor inhibitor (TNFi), were the most consistent predictors of remission. Additionally, lower baseline ASDAS-CRP, lower body mass index (BMI), shorter disease duration, TNFi naïveté, and concomitant use of cDMARDs were found to be predictors of remission in two studies each. Other predictors were only found to be associated with remission in single studies, namely: higher education level, more intense morning stiffness, lower baseline total back pain score, history of peripheral arthritis, no smoking, higher pain catastrophizing, lower modified Rheumatic Disease Comorbidities Index, fulfillment of ASAS clinical arm criteria, fulfillment of European Spondyloarthritis Study Group criteria, lower erythrocyte sedimentation rate, higher Spondyloarthropathy Research Consortium of Canada magnetic resonance imaging (MRI) sacroiliac joint (SIJ) and spinal inflammation score, positive MRI of the SIJ, lower Bath Ankylosing Spondylitis Metrology Index, lower Health Assessment Questionnaire for the Spondyloarthropathies, lower global pain, lower back pain score and lower enthesis index. Of note, contradictory data were found regarding CRP and NSAIDs usage.

**IMPACT OF CHILDBIRTH ON THE SACROILIAC JOINTS IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS**

M. Yasmine1, D. Ben Nessibi1, H. Ferjani1, W. Triki1, K. Maatallah1, D. Kaffel1, W. Hamdi1. 1Kassab Institute of orthopedics, Rheumatology, Tunis, Tunisia

**Background:** The era of magnetic resonance imaging (MRI) has contributed to a better assessment of patients with early disease stages of axial spondyloarthritis (axSpA), to the extent that a new entity has emerged. Indeed, the spectrum of SpA has broaden to include non-radiographic axial spondyloarthritis (nr-axSpA). Childbirth has been found to be associated with bone marrow edema (BME) in the sacroiliac joints (SIJ) [1], yet the extent of these lesions is inadequately described, which complicates the distinction with nr-axSpA.

**Objectives:** This study aimed to explore the impact of childbirth on MRI findings and BME in nr-axSpA.

**Methods:** We conducted a cross-sectional study including women diagnosed with nr-axSpA according to the ASAS (Assessment of SpondyloArthritis international Society) criteria. Demographic data as well as childbirth history were recorded. The sacroiliac joints manoeuvres’ examination were also transcribed. Ultrasound of the SIJ as well MRI-SIJ was performed in all the women. The sequence protocol included the following: T1-weighted, T2-weighted and axial STIR and were scored for BMO. We investigated an association between the number of children and MRI abnormalities mainly the presence of BME. The level of significance was fixed for p<0.05.

**Results:** The study included 30 women. The mean age at diagnosis was 40±9.8 years old [21-59] and the mean age at inclusion was 49±11 years old [26-74]. The median number of children was 2 [0-7]. Half of the patients were multiparous. Doppler ultrasound of the SIJ was found in 59.1% of cases. Overall, 36.7% of the women fulfilled the ASAS definition of a positive MRI. BME was displayed on STIR MRI sequence in 26.5% of cases and was equally present at the right SIJ compared with the left (26.7% vs 23.3%). Gadolinium enhancement was found in 16.7% of cases and subchondral erosions were found in 36.7% of cases.
There was no association between the different sacroiliac maneuvers on physical examination and the number of children: distraction test (p=0.145), compression test (p=0.088), Gaenslen test (p=0.475), and Mennel test (p=0.088). BME was more frequent among multiparous women (33% vs 29%) without reaching a statistically significant difference (p=0.635). There was no association between the number of children and Hyper T1 (p=0.55), T1 gadolinium (p=0.55) as well as subchondral sclerosis of sacroiliac joints. Similarly, there was no association between the presence of Doppler signal on ultrasound and multiparity (p=0.5).

**Conclusion:** Our study showed that MRI-SIJ findings were similar in nr-axSpA women regardless of the number of children, mainly BME. More trials are needed to evaluate the discriminatory capacity of MRI abnormalities and to palliate to the lack of specificities of the ASAS MRI criteria.

**AB0820 REMISSION CRITERIA IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: DON’T MISS SUBCLINICAL INFLAMMATION**

D. Ben Nessi1, M. Yasmine1, H. Ferjani1, W. Triki1, K. Maatallah1, D. Kaffel1, W. Hamdi1. 1Kassab Institute of orthopedics, Rheumatology, Tunisia, Tunisia

**Background:** With the advent of the treat-to-target strategy (T2T), clinical remission has become the main objective to achieve in patients with rheumatic diseases. Contrary to rheumatoid arthritis, the T2T strategy is less codified in axial spondyloarthritis, even more in non-radiographic SpA (nr-axSpA) [1]. More importantly, T2T based on imaging remission and guidance for tapering medication has not been extensively studied.

**Objectives:** The objective of this study was to investigate the prevalence of bone marrow edema in the sacroiliac joint of nr-axSpA patients in remission.

**Methods:** We undertook a cross-sectional study including nr-axSpA patients according to the ASAS criteria, treated with NSAIDs. Socio demographic data as well disease characteristics were collected. Disease activity parameters were also collected including the duration of morning stiffness, the number night awakening, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). MRI-SIJ, MRI-SIJ was performed for all the patients. All the images were screened for bone marrow edema with the corresponding sequence (short tau inversion). To define remission, we used in addition to BASDAI<4, more stringent criteria: BASDAI<4 and CRP<6 mg/l and ESR<20 mm/h and EGM<4 [2]. The level of significance was fixed for p<0.05.

**Results:** The study included 43 nr-axSpA patients. There was a female predominance with a sex ratio of 0.43. The mean age of the patients was 42±12 years [20-71] and the mean disease duration was 8±6 years [4-38]. The mean ESR and CRP were 2.2 mg/l [2-65] and 6.4 mm/h [1-47], respectively. A higher level of acute phase reactants was found in 40.5% of cases (ESR: 35.7%, CRP: 11.9%). Forty percent of the patients had high CRP or ESR despite BASDAI<4. According to BADSAl<4, of the 15 patients in remission, BME was displayed in 43.5% of the cases. According to the used criteria, 25.6% of the patients were in remission, of which 45.4% exhibited BME in the sacroiliac joint. There was no statistically significant association between disease activity according to the used definition and the presence of BME (p=0.473). Nr-axSpA patients in remission without BME had more durable morning stiffness and articular involvement without reaching a statistically significant difference (p=0.361, p=0.08 respectively). Similarly, we did not find an association between this subgroup and sex, age, night awakenings, the presence of HLAB27, is the most observed type of LSVT. The presence of LSVT was higher in patients with IIIa than in patients with IV (p=0.008 and p=0.007).

**Conclusion:** Our study showed that even when using stringent criteria, subclinical remission evidenced by BME was not achieved in nr-ax SpA. Nevertheless, imaging remains one important parameter to consider in therapeutic decision making. More studies are needed to identify the best criteria for an optimal remission in this population.

**AB0821 THE FREQUENCY OF LUMBOSACRAL TRANSITIONAL VERTEBRAS IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

N. Gokcen1, O. Ozdemir Isik2, A. Yazio2, A. Cefe1. 1Kocaeli University Faculty of Medicine, Internal Medicine, Division of Rheumatology, Kocaeli, Turkey

**Background:** Lumbosacral transitional vertebras (LSTVs) are anatomic variances observed at L5-S1 junction (1). The prevalence of LSTV ranges from 3.9% to 35.6%, indicating that this congenital anomaly is common in general population. LSTVs are well-defined anatomical differences causing low back pain and pelvic trauma (2). However, the studies assessing the frequency of normal lumbosacral anatomy on low back pain and sacroiliac joints in patients with ankylosing spondylitis (AS) are scarce (3).

**Objectives:** The current study aimed to investigate the frequency of LSTVs and the their effects on clinical variables in AS patients.

**Methods:** The study was designed as a prospective cross-sectional study. 113 patients were included in the study. Demographic data, clinical variables, laboratory results were recorded. Disease activity (ASDAS-CRP and ASDAS-ESR), patients' functionality (BASFI, BASM), enthesis (Leeds enthesis index) and quality of life (SF-36, visual analogue scale) were evaluated. The baseline pelvic conventional radiographs and the sacrolilac magnetic resonance imagings at the diagnosis were screened and assessed by two independent physicians. LSTVs were classified via Castelli classification. Basa coeffient was used to find the interobserver reliability.

**Results:** LSTVs were observed in 38 (33.6%) patients. Castelli type Ia, Iib, Ila, Iib, Ila, Ilb, IV, and IV were found in 10 (8.8%), 7 (6.2%), 7 (6.2%), 6 (5.3%), 4 (3.5%), 1 (0.9%), and 3 (2.7%) patients, respectively. The kappa value for interobserver reliability was 0.69. There were not any different as between AS patients with and without LSTVs in terms of disease activity, functionality, and quality of life (Table 1).

No statistically significant correlation was found between LSTVs identified by conventional radiography and sacroiliac magnetic resonance imagings at the diagnosis were screened and assessed by two independent physicians. LSTVs were classified via Castelli classification. Kappa coefficient was used to find the interobserver reliability.

**Discussion:** The prevalence of LSTV was 33.6%, which is consistent with the general population. Type I, also known as a dysplastic transverse process, is the most observed type of LSTV. The presence of LSTVs is associated neither with clinical variables nor with sacrolilac.

AB0822 FACTORS ASSOCIATED WITH A DELAYED DIAGNOSIS OF SPONDYLOARTHROPATHIES IN A POPULATION OF THE SOUTH OF MOROCCO

P. C. Mouleïe Moussi1, Z. Baba1, F. E. Chekkioui1, A. Rafi1, A. Mougui1, I, El Bouchti1. CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, RHEUMATOLOGY, Marrakech, Morocco

Background: Spondyloarthropathies are chronic inflammatory diseases with predominant axial involvement. Early diagnosis is a major challenge for physicians. Misdiagnosis and diagnostic delays lead to unnecessary parascolic investigations, inadequate treatment and to poor outcomes including functional impairment and quality of life.

Objectives: We assess the diagnostic delay in spondyloarthropathy and identify factors associated with it.

Methods: A retrospective study including patients diagnosed with spondyloarthropathies between 2004 and 2020 according to ASAS 2010 criteria. Diagnostic delay was defined as period between the first symptom and diagnosis establishment. The potential factors predicting the diagnostic delay were explored through univariable and multivariable linear regression analysis, included epidemiological characteristics (age, gender, educational level, socio-economic level), clinical and biological presentation and sacroiliac (radiographic or in MRI). Events occurring before the diagnostic were also analyzed.

Results: The study included 276 patients: 146 males (53%) and 130 females (47%) with a sex ratio of 1.1 and the mean age at the diagnostic was 38.87 years. Comorbidities included smoking (33 patients), cardiopathy (3 patients), hypertension (19 patients), diabetes (14 patients) and peptic ulcer (5 patients). The mean duration of symptoms was 2.6 years, and average diagnostic delay was 6.5 years with a median of 2.1 years. In univariable and multivariable linear regression analysis, low socio-economic level, low educational level (p=0.042) were statistically significant parameters associated with a delayed diagnosis. There was no statistically significant association between the delay of diagnosis and age, clinical presentation or sacroiliac (radiographic or in MRI). The use of traditional and herbal treatments before consulting a rheumatologist was also associated with a longer delayed diagnosis.

Conclusion: Spondyloarthropathies have a delayed diagnosis. This delay, also found in other studies, is responsible for persistent disease activity and important functional consequences. In our context, low socio-economic level, low educational level, and the use of traditional unconventional treatment are factors associated with a delayed diagnosis.

AB0823 DUAL ENERGY X-RAY ABSORPTIOMETRY IN PATIENTS WITH SPONDYLOARTHROPATHY. CORRELATION WITH DISEASE DURATION, ACTIVITY AND CHANGES IN SACROILIAC JOINTS ON MAGNETIC RESONANCE IMAGING

O. Iaremenko1, D. Fedkov1, K. Mazanko1. Bogomolets National Medical University, Department of internal medicine #3, Kyiv, Ukraine

Background: Bone loss (osteopenia or osteoporosis) and osteoporotic vertebral fractures are well-known complications of spondyloarthritis (SpA), and their prevalence in SpA patients (pts) is higher than in patients with mechanical low back pain [1, 2]. Osteopenia and osteoporosis can develop in both the late and early stages of SpA. The presence of bone marrow edema at the lumbar spine and sacroiliac joints (SIJ) on magnetic resonance imaging (MRI) was more common among pts with low BMD (bone mineral density) than normal BMD [3, 4]. At the same time, the dynamics of osteoporotic and osteosclerotic changes in the spine during the progression of SpA makes the assessment of DEXA results ambiguous.

Objectives: To determine the presence of osteopenia/osteoporosis in pts with SpA and to establish its correlations with disease duration, disease activity, active changes in SIJ on MRI.

Methods: 40 patients with SpA (55% – male, mean age 39.87±9.79, mean disease duration – 6.75±4.73 years) underwent DEXA. Spondyloarthropathies Research Consortium of Canada (SPARCC) MRI SIJ score (0-72) was utilized for evaluation of the active inflammatory lesions in SIJ, Danish MRI scoring method (0-48) – for chronic changes. Disease activity was measured by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI, cm), Ankylosing Spondylitis Disease Activity Score (ASDAS, CRP, mg/l), and erythrocyte sedimentation rate (ESR, mm/hr). For correlation, the Spearman correlation coefficient was calculated.

Results: The mean value of DEXA parameters were: BMD – 0.72±0.15, T-score – -0.16±0.88, Z-score – 0.17±0.89 (forearm); BMD – 0.96±0.17, T-score – -1.13±1.35, Z-score – -0.88±0.13 (spine); BMD – 0.85±0.14, T-score – -0.85±0.93, Z-score – -0.56±0.97 (hip). Mean value (Mux) of indices and laboratory parameters were: BASDAI – 4.4±1.76, ESR – 30.2±24.1, CRP – 17.3±19.7, ASDAS- CRP – 3.07±1.13, ASDAS-ESR – 3.14±1.14. SPARCC score was 12.3±11.8, Danish score – 15.2±7.77. Osteoporosis was present in 7 (17.5%), osteopenia - in 24 (60%) SpA pts. There was positive correlation between BMD at forearm and Danish MRI score (r=0.331, p=0.02). The CRP level showed negative correlation with BMD at hip (r=-0.322, p=0.012) and T-score at spine (r=-0.301, p=0.031). Patient’s age showed negative correlation with BMD at hip (r=-0.268, p=0.05). Disease duration negatively correlated with BMD (r=-0.334, p=0.016) and T-score (r=-0.310, p=0.027) at hip. All correlations were weak. No other correlations were found.

Conclusion: Among disease activity parameters, only high CRP was associated with a decrease in BMD for both the back and hip. A decrease in hip BMD was also associated with the patient’s age and disease duration. Regarding MRI indicators, only chronic changes in SIJ, measured by MRI, positively correlated with BMD at forearm only.

AB0824 BREASTFEEDING IN WOMEN WITH ANKLYLOSING SPONDYLITIS (AS)

O. Krivchenskaya1, E. Iinskykh1, T. Dubinina2, S. Glukhova1, A. Demina1, I. Andrianov2, V.A. Nasonova Research Institute of Rheumatology, Laboratory of axial spondyloarthritis, Moscow, Russian Federation

Background: Breast milk is the natural and most physiological nutrition for a child from the first days of life. The benefits of breastfeeding are numerous, including psychological aspects. However, some women with rheumatic diseases are afraid that their disease or therapy is not compatible with breastfeeding.

Objectives: To describe frequency, duration and reasons for stopping lactation in women with AS, to compare the activity of AS in women with and without lactation.

Methods: 44 women with confirmed AS (modified New York criteria, 1984) were followed within 1 year after childbirth. Visits were carried out in 1, 6 and 12 months after delivery. The average age of patients was 32.5 ± 5.8 years, the duration of the disease was 149.0 ± 96.3 months. BASDAI at 1, 6 and 12 months after giving birth was: 2.4 ± 1.4; 2.6; 2.4; 2.7; 2.5 [1.5; 4.1], respectively. ASDAS CPR was: 2.0 [1.2; 2.7]; 1.9 [1.4; 2.5]; 1.7 [1.3; 2.3], respectively.

Results: Lactation was established in 41 women (93.2%), duration – 10 [4; 12] months; in 17 patients (41.5%) lactation persisted for 12 months. Lactation was unreasonably medically suppressed in 3 women in an obstetric unit due to therapy of AS (sulfasalazine – 2, certolizumab pegol – 1); in 1 woman lactation was not established for organizational reasons. Lactation lasted less than 6 months in 16 patients (39%), 13 of them had a natural attenuation of lactation, and in 3 cases, drug-induced suppression of lactation was carried out on the recommendation of obstetricians in connection with onset of preeclampsia (adalimumab). During lactation, 51.2%, 74.1% and 88.2% of women received nonsteroidal anti-inflammatory drugs for 1, 6 and 12 months after delivery, respectively, adherence to NSAID therapy did not differ in women with and without lactation. TNF-α...
inhibitors (certolizumab pegol) were received by 4 women (7.3%), while the need for INTeNc was in 13 patients (not received due to medicine unavailability).

In women who retained lactation, the severity of back pain was: 3.0 [2.0; 6.0], 3.0 [2.0; 6.0] and 3.0 [2.0; 5.0] according to NRS, respectively. The activity of back pain, BASDAI and ASDAS values of CRP did not differ in women with and without lactation.

Conclusion: The vast majority of women with AS are set up for lactation. High AS activity becomes a risk factor for termination of lactation more than 6 months after delivery. It is necessary to conduct training for obstetricians-gynecologists and pediatricians on issues related to medicine capabilities during lactation, in order to exclude unjustified cancellation of medicines compatible with breastfeeding.

A SOLUTION PROPOSAL TO THE INTRAOBSERVER DISAGREEMENT PROBLEM IN THE EVALUATION OF SACROILIAC JOINT RADIOGRAPHY: "IMAGE PROCESSING METHOD"

A. C. Genc, F. Turkoglu Genc, D. Karatas, Z. N. Kaya, L. Rada, E. Gönülül. Bahcesehir University, Artificial Intelligence Graduate Education Institute, Istanbul, Turkey; Hendek State Hospital, Internal Medicine, Sakarya, Turkey; Akcay State Hospital, Internal Medicine, Sakarya, Turkey; Sakarya University, Internal Medicine, Rheumatology, Sakarya, Turkey; Saratoga High School, Student, CA, United States of America; Bahcesehir University, Faculty of engineering and natural sciences, Istanbul, Turkey

Background: Ankylosing spondylitis (AS) is a rheumatological disease that causes low back pain. The diagnosis of ankylosing spondylitis is delayed for an average of 8 years due to the insidious course of the disease. Late diagnosis of AS can cause functional and physical disabilities. Radiographic sacroilitis can be graded in the range of 0-4 and these classes may not be sharply separated from each other. Interpretation of the sacroiliac joint radiography may differ from physician to physician. In fact, the same physician may interpret it differently at different times (1). The reason for such confusion is the presence of blur or illumination and contrast problems leading to difficulties to detect pathological areas. This paper has developed a simple image processing technique that adjusts the contrast of such images by modifying their intensity distribution using the histogram information. This transformation gives a linear trend to the cumulative probability function associated with the image and makes the images better for human vision. The common characteristic of low contrast images is the concentration of the histogram values of the image intensity near a narrow range (2).

Objectives: Changing the contrast range into a wider range changes the image value distribution that leads to better image vision.

Methods: Rheumatologist scored 260 x-ray scans grade 0 to 4. One day later, the same rheumatologist scored again the same scans randomly. It has been noticed that most of the answers were closed to the first-day decision but not all of them. We processed all the x-ray images with histogram equalization. Then the rheumatologist scored the scans randomly and answered two times in two consecutive days. To compare the agreement in radiography interpretation Kappa test was used. We use IBM SPSS 21 for the statistical analysis (kappa test) and Matlab R2021a for the image processing part.

Results: Severe improvement before and after the image processing application by increasing the Kappa value from 0.55 (p<0.001) [moderate agreement] to 0.71 (p<0.001) [substantial agreement] which is a substantial agreement.

Conclusion: Multidisciplinary approach can be helpful in solving the intraobserver disagreement problem. The use of image processing techniques can be used for the benefit of the patient in radiographs whose standardization is difficult due to multifactorial reasons. The histogram equalization method was found to be statistically significant in finding the optimum contrast for interpreting the sacroiliac joint radiography. The output of this work indicates and motivates our team into deeper research and more analyses on how to further improve our results.

KEEP AN EYE ON THE BACK: SPONDYLOARTHRITIS IN PATIENTS WITH ACUTE ANTERIOR UVEITIS

Background: Patients with acute anterior uveitis (AAU) have an increased risk for concomitant spondyloarthritis (SpA). Different referral strategies have been proposed to identify AAU patients with high probability of SpA, among them an Assessment of SpondyloArthritis international Society(ASAS)-based referral strategy focusing on patients with chronic back pain starting before the age of 45 years and the Dublin Uveitis Evaluation Tool (DUEET) also including psoriasis, HLA-B27 and arthralgia (Poddubnyy et al., Haroon et al., both ARD 2015).

Objectives: To analyse the prevalence of SpA in patients with AAU, to identify parameters associated with SpA presence, and to evaluate referral algorithms.

Methods: Patients with non-infectious AAU underwent structured rheumatologic assessment including magnetic resonance imaging of sacroiliac joints allowing a definitive diagnosis/exclusion of concomitant SpA. Fisher’s exact test and Mann–Whitney U test were used to compare AAU patients with and without SpA. Furthermore, logistic regression analyses were performed. Sensitivity, specificity, positive predictive value, positive and negative likelihood ratios were analysed for referral strategies.

Results: The 169 AAU patients with complete rheumatologic assessment and SU imaging were 40.8 years old, and 55% were males. SpA was diagnosed in 106 AAU patients (56%). The majority (93%) had predominantly axial SpA, 7 patients peripheral SpA. In 74 patients (70%), the SpA diagnosis was established for the first time. Pelvic X-rays were available for 88 (89%) of the axSpA patients, 66% of whom was classified as having radiographic axSpA. SpA was equally frequent in patients experiencing the first episode of AAU and in patients with recurrent disease. In our cohort, AAU patients with and without underlying SpA showed no differences in their ophthalmologic examination. In multivariable logistic regression analysis, psoriasis (OR 12.5 [95%CI 1.3-120.2]), HLA-B27 positivity (OR 6.3 [95%CI 2.4-16.4]), elevated CRP (OR 4.8 [95%CI 1.9-12.4]) and male sex (OR 2.1 [95%CI 1.1-4.2]) were associated with SpA presence.
Table 1. Parameters associated with the presence of spondyloarthritis in patients with acute anterior uveitis.

</table>

Univariable and multivariable logistic regression analyses. ASAS Assessment of SpondyloArthritis international Society; CRP C-reactive protein; OR odds ratio; CI confidence interval.

The Dublin Uveitis Evaluation Tool showed higher specificity for SpA recognition than the ASAS referral tool (42% vs. 28%), which had slightly higher sensitivity (78% vs. 80%). However, both referral strategies would have missed more than 20% of SpA patients.

Conclusion: We revealed a high prevalence of overall and previously undiagnosed SpA in AUA patients. Therefore, we propose rheumatologic evaluation for all AUA patients with musculoskeletal symptoms. Rheumatologists should consider that SpA in AUA patients might present “atypically” with back pain starting after 45 years and lasting shorter than 3 months.

Acknowledgements: The authors would like to thank the rheumatologists S. Lüders, B. Muche and A.-K. Weber for participating in the clinical data acquisition; and A. Langdon and L. Meinke for their support monitoring and coordinating this study. Furthermore, we are grateful to all participating ophthalmologists who included their patients in this study and to all patients. The study was supported by an unrestricted research grant from AbbVie. AbbVie had no role in the study design or in the collection, analysis, or interpretation of the data, the writing of the manuscript, or the decision to submit the manuscript for publication. Dr. Judith Rademacher and Dr. Dominika Pohmann are participants in the BIH-Chair Clinician Scientist Program funded by the Charité –Universitätsmedizin Berlin and the Berlin Institute of Health.

AB0827 FREQUENCY OF SEXUAL DYSFUNCTION AXIAL SpondyloArthritis, SANTO DOMINGO, DOMINICAN REPUBLIC

A. Cornelio1, T. Polanco Mora1, J. Santana Peralta1, R. A. Alvarez Santana1, D. Garcia1, E. Rodriguez Bautista1, L. Paulino1, L. Concepcion Sanchez2, I. Mercedes1, T. Valdez1, A. Perez1, R. Muñoz Louis1, Hospital Docente Padre Billini, Reumatología, Santo Domingo, Dominican Republic

Background: Axial spondyloarthritis (SpA) is a chronic inflammatory disease of unknown etiology that affects the axial skeleton, affecting peripheral joints, entheses and extra-articular structures, with a prevalence of 0.5-1% associated with HLA-B27. The impact of Chronic disease is often multifactorial that affects physical, hormonal and psychological alterations, leading to problems of sexuality. The CSFQ-14 (Changes in Sexual Functioning Questionnaire), evaluates changes in sexual functioning due to disease and/or treatment in 5 domains with a score range of 14-70; cut-off point indicating sexual dysfunction <41 men and <47 women.

Objectives: To evaluate the frequency and degree of sexual dysfunction in patients with axial spondyloarthritis.

Methods: Prospective, observational, cross-sectional study of the SpA cohort of the Hospital Docente Padre Billini rheumatology service Patients were interviewed in July 2021. Inclusion criteria: > 18 years of diagnosis of SpA according to the Bath 2009 classification criteria, at least 1 sexual exclusion criteria: previous diagnosis of another autoimmune disease, depression, diabetes mellitus (DM), treatment with antidepressants, antiepileptics, narcotics. Measurement of: CSFQ-14, BASDAI. Statistical analysis was performed with the Pearson correlation (r) with p<0.05. The data was analyzed by SPSS V23.

Results: Of the SpA cohort, 87 met the inclusion criteria. Male 67.8% (59), females 32.2% (28), mean age 45.7±8 years, mean diagnosis 7.2 years (90), single 24.1% (21), widowed 8% (7), HLA-B27 ± 51.1%, hypertension 8% (7), diabetes 6.8% (6), dyslipidemia 10.3% (9), smokers 4.5% (4), 100% (87) bDMARD’s, 13.6% (12) combined with csDMARD’s, Frequency of sexual dysfunction 24.1% (21), Sexual dysfunction in women 6.9% (6) and men 17.2% (15) by CSFQ-14. Global domains: Desire/interest 2.3% (2), Desire/Frequency 2.3% (2), Pleasure 5.7% (5), Arousal 2.3% (2), orgasm/completion 2.3% (2), Female: Desire/interest 6.8% (4), Desire/Frequency 3.4% (2), pleasure 8.5% (5). Male: Desire/interest 3.4% (2), Desire/Frequency 3.4% (2), pleasure 5.5% (2), arousal 6.8% (4), orgasm/completion 3.4% (2). Correlation CSFQ-14 domains with BASDAI: r = -0.088 p>0.05: Desire/interest dysfunction: inactive BASDAI 71.4% (15), Desire/frequency: inactive BASDAI 90.5% (20). Pleasure: inactive BASDAI 23.8% (5), active 23.8% (5). Excitation: inactive BASDAI 14.3% (3), Orgasm/ completion: inactive BASDAI 90.5% (20)

Conclusion: The study showed a low frequency of sexual dysfunction, being more frequent in males. The greatest dysfunction was found in the pleasure domain in both sexes. A statistically significant inverse linear association was found between sexual dysfunction and disease activity.

AB0828 DIFFERENCES IN EARLY-ONSET VS. LATE-ONSET PSORIATIC ARTHRITIS: DATA FROM THE RESPONDIA AND REGISONER STUDIES.

M. A. Puche Larribuya1, M. L. Ladehesa Pineda1, M. D. López Montilla1, E. Collantes Estévez2, C. López-Medina2,3, Reina Sofia University Hospital, Rheumatology, Cordoba, Spain, 1Cochin Hospital, Rheumatology, Paris, France

Background: The prevalence of late-onset psoriatic arthritis (PsA) is increasing in parallel with the progressive aging of the population. The elderly population presents a greater functional deterioration and a greater number of comorbidities than the young people. With this study we aim to find clinically relevant differences to predict the evolution and prognosis of the disease depending on the onset of the symptoms to carry out a more exhaustive follow-up.

Disclosure of Interests: None declared
Objectives: To evaluate the association of the age at onset of PsA symptoms with the characteristics and burden of the disease.

Methods: Observational study that includes a subgroup of 231 patients with Psoriatic Arthritis (PsA) from the REGISPONDER study (Registry of Spondyloarthritis of Spanish Rheumatology) and the RESPONDA study (Ibero-American Registry of Spondyloarthropathies). Patients with less than 10 years of disease duration (since the first symptom) were selected so that the sample was homogeneous. Patients were divided into two groups according to the age of PsA onset (early-onset: ≤40 years old and late-onset: ≥60 years old). The characteristics and burden of the disease were assessed using the Student’s t-test, Mann-Whitney U test for quantitative variables or using the chi-square/Fisher test for qualitative variables.

Results: 411 patients were included [early-onset 179 (77.5%); late-onset 52 (22.5%)]. There was a higher percentage of men in the late-onset group compared to the early-onset group [94 (62.3%) vs. 38 (86.4%)]. The diagnostic delay was shorter in those whose onset of the disease was late [15.2 (7.7) vs 4.2 (2.7), p = 0.012]. A lower presence of sacroiliitis was found in patients with late-onset PsA [6 (12.2%) vs 52 (38.6%), p = 0.005] as well as enthesitis [5 (9.8%) vs 44 (24.6%), p = 0.023]. Regarding the comorbidities, there was a higher frequency of heart disease among patients with late-onset PsA [4 (7.8) vs 0 (0), p = 0.00]. No statistically significant differences were found between kidney and lung disease. Regarding the outcome measures, the BASFI score was higher in the late-onset group [3.3 (2.5) vs 2.2 (2.2), p = 0.002]. The late-onset group had a lower FSF12 component [34.6 (8.7) vs 38.7 (10.5), p = 0.001]. The radiographic indices measured by BASRI showed worse results in those patients with late-onset disease both in the spine [2.9 (3) vs 1.6 (2), p = 0.020] and in the total BASRI [3.4 (3.4) vs 1.9, p = 0.012].

Conclusion: Our study suggests that the age of onset of PsA was associated with the different characteristics of the disease. Patients with late-onset PsA were more frequently males, showed worse functionality and more structural damage in comparison with early-onset PsA. Sacroiliitis and enthesitis were found less frequently in the late-onset group. Quality of life, disease activity and treatments taken were not associated significantly with age of onset.

Total body composition, total and regional fat and lean mass, android/gynoid ratio (A/G), fat mass index (BMI), fat-free mass index (FFMI) were measured by dual-energy X-ray absorptiometry (DXA) and reported as absolute values. Blood samples were collected to determine C-reactive protein serum (CRP) levels for each patient. Socio-demographic data, comorbidities, physical activity, disease-related variables (duration, characteristics, and drugs) were also collected. Correlations and regressions were made by SPSS.20.

Results: Forty-four SA participants (65.9% male) were enrolled. Their mean age was 39.82 ± 14.20 years and the mean ASDAS CRP was 1.42 ± 0.86. Patients under biologic disease-modifying antirheumatic drugs (bDMARDs) showed lower FMI (p = 0.011), percentage of fat mass (p = 0.008), and gynoid fat mass (p = 0.01). Correlations between ASDAS using CRP, total body fat mass, BMI, FFMI, visceral adipose tissue (VAT), appendicular lean height, and the A/G ratio were not statistically significant. Nevertheless, ASDAS CRP was positively correlated to total body mass (r = 0.352; p = 0.019), gynoid fat mass (r = 0.329; p = 0.029), and android fat mass (r = 0.323; p = 0.032). The association of disease activity and gynoid fat mass persisted after adjustment on disease duration and age (β = 0.355, 95%IC [0.0003; 0.0003], p = 0.021).

Conclusion: Gynoid and android fat mass affected disease activity in our SA patients. However, BMI, visceral fat, and skeletal muscle mass showed no significant association with disease activity.

AB0830 TURKISH TRANSLATION AND CROSS-CULTURAL ADAPTATION OF THE MODIFIED SHORT QUESTIONNAIRE TO ASSESS HEALTH-ENHANCING PHYSICAL ACTIVITY (MSQUASH).

G. Ayen1, S. Ramiro2,3, F. M. Pimentel-Santos4, A.Spoorenberg5, L. Kliq5, 1Hacettepe University Medical Faculty; Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; 2Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; 3Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands; 4NOVA Medical School, Universidade Nova De Lisboa, Department of Rheumatology, LISBOA, Portugal; 5University Medical Center Groningen, University of Groningen, Department of Rheumatology & Clinical Immunology, Groningen, Netherlands

Background: The Short Questionnaire to Assess Health-enhancing physical activity (SQUASH) is a validated tool measuring the duration, frequency, and intensity of physical activity. The modified version of the SQUASH (mSQUASH) has been developed, in collaboration between spondyloarthritis (SpA) experts and axial (ax)SpA patients, to better address the needs of these patients in the assessment physical activity (1).

Objectives: To translate and cross-cultural adapt the mSQUASH into Turkish as well as its cognitive debriefing to test the conceptual equivalence of the translated version among patients with axSpA.

Methods: The mSQUASH was translated into Turkish by 2 bilingual translators, native speakers of Turkish one from medical (informed) and the other is without medical background (uninformed). The consensus on forward-translation was reached by the team included two rheumatologist (GA and LK) and the translators. Backward-translation into Dutch was performed by 2 bilingual translators, native speakers of Dutch and who were blinded to the original mSQUASH version. After the review of the Turkish version by an expert committee that included translators, two patients and the research team a pre-final version was prepared. This version was used in a field-test with cognitive debriefing and involved a sample of 10 axSpA patients (7 radiographic- and 3 non-radiographic axSpA patients) with variation in gender, age, disease duration, and educational background. The final Turkish mSQUASH version was reached after the patients were interviewed to check understandability, interpretation and cultural relevance of the translation. The whole process was performed according to the Beaton method (Figure 1) (2).

AB0829 BODY COMPOSITION IN SPONDYLOARTHROPATHIES: IS THERE ANY IMPACT ON DISEASE ACTIVITY?

F. Chenoufi1, H. Azzouzi1, H. Boutabbi1, I. Linda1, 1Mohamed I University, Rheumatology department; Ouja, Morocco

Background: The relationship between obesity and inflammation is bidirectional. Thus, obesity may influence clinical response to biological treatment.

Objectives: To investigate the association of obesity and body composition with disease activity in patients with spondyloarthropathies (SA).

Methods: This is a cross-sectional study designed on spondyloarthropathy patients diagnosed according to ASAS 2009 classification. Bath ankylosing spondylitis disease activity index (BASDAI), ankylosing spondylitis disease activity score (ASDAS), Bath ankylosing spondylitis functional index (BASFI), and Bath ankylosing spondylitis metrology index (BASMI) were assessed. Obesity was evaluated clinically by body mass index (BMI) and waist circumference (WC).
Results: After the forward-backward translation process, small incompatibilities were resolved during the expert committee meeting. For example: ‘Ande transport (heen en terug)” was translated as ‘Dijjer hedeffere (gipid gelmek)’. The meaning in English is “Other transport (round trip)”. This item questions the way of going to other places and the discrepancy raised whether to use ‘transportation’ or the ‘target’ as the title. To make it culturally adaptable consensus reached to use a word equivalent to ‘the target’ which is semantically equal to the Dutch version. A total of 10 patients with axSpA [7 females, mean (SD) age of 38 (10)] participated in the field test. Mean (SD) time to complete the mSQUASH was 6 (1.2) minutes. Cognitive debriefing showed that items of the mSQUASH are clear, relevant, understandable, and easy to complete. None of the patients indicate any important aspect of physical activity that is missing from the questionnaire items. During the cognitive debriefing, 2 patients suggested a change in the wording of one item to make it more suitable to the Turkish culture. This item inquires after sport activities and patients raised the concern that the example activities: ice-skating, tennis, handball are not culturally suitable. According to their comments these items were replaced by other examples such as football.

Conclusion: The Turkish version of the mSQUASH showed acceptable linguistic validity and can be used in both clinical practice and for research purposes. However, to implement the Turkish version of the mSQUASH, further assessment of its psychometric properties (validity and reliability) is needed.

AB0831
THE QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS EVALUATED UNDER SINGLE QUESTIONNAIRE: CONNECTION WITH THE DISORDER OF BONE MINERAL DENSITY

O. Pavliuc1, S. Shevchuk1, O. Ziviha1, T. Smaha1, 1National Pirogov Memorial Medical University, Vinnytsya, Internal Medicine Chair 2, Vinnytsya, Ukraine

Background: In recent time, the peculiarities of the quality of life in patients with many chronic diseases, which progress uncontrollably and lead to the restriction of all components of normal life, are being actively studied. Ankylosing spondylitis (AS) is no exception, it is the second most common inflammatory rheumatic disease, characterized by predominant lesions of the spine and sacroiliac joints. Rapid progression of the disease, constant pain in the joints, as well as in the periarticular tissues and soft tissues, and other systemic functional limitations, gradual loss of mobility of the spine and deterioration of the quality of life. However, impaired quality of life can be caused not only by the manifestations of the underlying disease, but also by the presence of complications observed in the early stages of the disease. Thus, it is the decrease in bone mineral density and the development of osteoporosis that cause pathological fractures and, as a result, lead to early disability, reduced duration and quality of life. However, clear data on the peculiarities of the quality of life in patients with AS suffering from impaired bone mineral density have not been found to date.

Objectives: To investigate quality of life indicators using the SF-36 questionnaire in men with AS and to assess their relationship with the structural and functional state of bone tissue.

Methods: 105 patients with AS aged 40.7 ± 0.8 years were examined, the average duration of the disease was 8.7 ± 0.5 years. The control group included 25 healthy individuals of appropriate age and sex. All patients were diagnosed with AS according to ASAS criteria (2009). The SF-36 questionnaire was used to characterize the quality of life. Bone mineral density was measured by dual-energy X-ray absorptiometry on a Hologic Discovery Wi apparatus (S/N 67223).

Results: The analysis of quality of life according to the SF-36 questionnaire showed that patients with AS had significantly lower indicators of both physical (37.3 ± 1.5 points) and mental (44.2 ± 1.7 points) components of health in comparison with the control group (99.1 ± 0.3; 87.4 ± 0.7 points, respectively). Among the subscales that form the total physical component, the lowest indicators were recorded in role physical functioning (RP) (14.0 ± 3.1 vs. 99.0 ± 0.6 points) and pain (P) (37.2 ± 1.6 vs. 100.0 ± 0.0 points). And according to the subscales assessing the mental component of health, the most significant differences were found for the indicator of role emotional functioning (RE), which was 4.5 times lower than in the control group (22.2 ± 3.9 vs. 88.2 ± 0.7 points, respectively).

The study did not reveal significant differences in quality of life in case of low bone mineral density (BMD). The average levels of total physical and mental components of health in patients with BMD (35.2 ± 2.4; 42.2 ± 3.2 points) were only 12.2–71% lower than in patients with preserved BMD (40.8 ± 2.7; 46.4 ± 2.8 points, respectively). In the group of patients with osteoporosis (Z-score -2.7 ± 0.1) there was a tendency to reduce the physical component due to the indicator of general health (GH), which was significantly lower (35.8 ± 2.1 points) than in patients with preserved BMD (43.4 ± 2.7 points).

Conclusion: In men with AS, there is a significant decrease in the total physical and mental components of health according to the SF-36 questionnaire which do not have a clear relationship with structural and functional state of bone tissue.

AB0832
NONINFECTIONOUS UVEITIS FROM THE RHEUMATOLOGIST’S PERSPECTIVE: PATTERNS FROM A SINGLE TERTIARY REFERRAL RHEUMATOLOGIC CLINIC IN ITALY

P. Troppini1, M. Fatica1, A. D’Antonio1, E. Ceia1, C. Minerva1, G. Raffone1, S. Modica2, B. Kroepler2, P. Conigliaro2, E. Greco2, A. Modesti2, M. S. Chimenti1,1Rheumatology Allergology and Clinical Immunology, Department of “Medicina dei Sistemi”, University of Rome Tor Vergata, Rome, Italy

Background: The noninfectious uveitis (NIU) is the intraocular inflammation that can be the first or one of extra-articular manifestations of systemic inflammatory rheumatic diseases mainly including spondyloarthropathy (SpA), Behcet’s disease (BD) and juvenile idiopathic arthritis (JIA). Rheumatologists are often asked to help in diagnostic assessment and relatively targeted treatment of particular subsets of NIU.

Objectives: To explore patterns and treatments of NIU from a population-based single-center study carried out in a Tertiary Referral Rheumatologic Clinic.

Methods: Selection criteria of this cross-sectional descriptive study consisted of having a diagnosis of NIU in an age of onset ≥16 years old regardless of its etiology among patients who were admitted (February 2018-December 2021) to Rheumatologic Clinic of Tor Vergata University Hospital (Rome, Italy). Clinical data were collected from medical records: gender, age of onset and admission, recurrence and anatomic patterns, HLA-B27 susceptibility, associated rheumatologic diagnosis and treatments were investigated.

Results: We included 100 patients with 58% women. Median age at NIU onset was 39.6±15 years whereas patients were 44±14 years old at the first referral, without gender-difference. NIU represented the main reason of referral in 22% of cases. Anterior uveitis occurred in 73% of patients and posterior in 25%; intermediate (IU) and panuveitis (PAnu) were isolated cases. The prevalent course was acute (57%) followed by recurrent (31%) and chronic (12%); both eyes were involved in 39 patients. Almost half of NIU was associated with SpA including IBD-SpA (20%), ankylosing spondylitis (AS, 18%), and Psoriatic Arthritis (12%). A diagnosis of BD was reported in 14% of NIU while Rheumatoid Arthritis (RA) in 7% and IBD in 12%. NIU was more frequent in females than males (p<0.01 and p<0.05, respectively). The only one-third of the NIU cohort (34.3%) showed B27+; a higher percentage of unilateral (p<0.08) and acute course (p=0.02) occurred in B27+ than B27–. AS was prevalent in B27+ NIU than B27– (p=0.0001) while IBD-SpA and BD were mainly present in B27+ NIU than B27– (p<0.004). The only two cases of IU and PAnu were both idiopathic B27+ NIU. At the onset of NIU, most patients were not on systemic treatment (68%): remaining cases were on cDMARDs (22%) and bDMARDs (10%). During rheumatologic follow-up, 80% of patients changed therapies: cDMARDs were added in 43.7% patients while bDMARDs were started in 40%. Systemic steroids were added in the remaining 16.3% of patients. At the latest follow-up (follow-up-time 33±28 months), 86% of patients had achieved remission of NIU while 14% had recurrence of active uveitis.

Conclusion: Findings from this population-based study describe a representative estimate of extent and patterns of NIU in an Italian adult cohort from a single Rheumatologic Clinic and document that Rheumatologic referral might dramatically impact treatment strategies in NIU.

AB0833  EPICARDIAL FAT THICKNESS: A NOVEL MARKER OF SUBCLINICAL ATHEROSCLEROSIS IN SPONDYLOARTHRITIS PATIENTS

A. Ben Tekaya1,2, T. Mehmm1,2, I. Ben Brad2, O. Saidiane1,2, S. Bouden1, R. Leilla3,2, I. Mahmoud2, L. Abdelmoula1,2, C. Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia; Habib Thameur Hospital, Cardiology Department, Tunis, Tunisia

Background: Chronic inflammatory process seems to be the underlying cause contributing to atherosclerosis in spondyloarthritides. Epicardial adipose tissue (EAT) which is the accumulation of visceral fat between the myocardium and the visceral layer of pericardium, is actually considered a novel cardiometabolic risk predictor (1). Recent studies have shown its association with the development of coronary atherosclerosis.

Objectives: The aim of our study was to assess the epicardial fat thickness (EFT) in patients with spondyloarthritides (SpA) in comparison with healthy subjects.

Methods: We performed a prospective study including 47 patients meeting ASAS 2009 criteria for SpA compared to 47 healthy controls matched for age, gender and body mass index (BMI). Patients with history of cardiovascular risk factors or diseases were not included. Sociodemographic, clinical, biological and radiographic features related to the disease were recorded. All subjects underwent transthoracic echocardiography with measurement of EFT.

Results: SpA group included 33 men and 14 women, with a median age of 36 years (IQR: 28-46). Median BMI was 24.5 kg/m² (IQR: 20.7-26.8). Median systolic (SBP) and diastolic (DBP) blood pressure were respectively 121 mmHg (IQR: 110-130) and 71 mmHg (IQR: 67-78). Median disease duration was 11 years (IQR: 5-16). Median disease activity scores BASDAI and ASDAS-CRP were 2.6 (IQR: 1.3-3.9) and 1.62 (IQR: 1.3-2.9) respectively. Median CRP level was 1.45 mg/l (IQR: 1.5-19.9). Median BASFI and BASMI were 3 (IQR: 1.5-5.1) and 1.5 (IQR: 0.4-4) respectively. Coxits was found in 53% of patients. SpA patients received: NSAIDs (92%), csDMARDs (51%) and TNF inhibitors (38%)

Conclusion: EFT was significantly increased in SpA patients compared with healthy controls; median EFT value was 3.1 mm (IQR: 2.5-4) versus 2.4 mm (IQR: 2.3) (p<0.001).

Disclosure of Interests: None declared

AB0835  INFLUENCE OF SOCIODEMOGRAPHIC PARAMETERS ON ATHEROSCLEROSIS IN SPONDYLOARTHRITIS PATIENTS

A. Ben Tekaya1,2, E. Hannech2, A. Fendri3, S. Boukirba3, O. Saidiane1,2, R. Leilla3,2, I. Mahmoud2, H. Mizouni2, L. Abdelmoula1,2, C. Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia; Habib Thameur Hospital, Cardiology Department, Tunis, Tunisia

Background: The increased risk of atherosclerosis is most likely multifactorial in patients with Spondyloarthritides (SpA). Ultrasound measurements of Intima Media Thickness (IMT) Flow Mediated Dilation (FMD) can be used to investigate intra-clinical atherosclerosis [1].

Objectives: We aimed to investigate the relationship between socio-demographic parameters in SpA patients with the IMT and FMD.

Methods: It was a case control study conducted over a period of 12 months and including patients with SpA, aged less than 50 years old and without cardiovascular disease, and age and sex matched healthy controls. Sociodemographic and clinical features were recorded in our patients. All subjects had Doppler ultrasound with measurement of carotid IMT and FMD.

Results: There were 47 SpA patients and 47 controls. The median age was 36 years for patients group (18-50) and 32 years for controls (18-50). For the patients group: there were 14 female (28.8%) and 33 male (70.2%). The median duration of the disease was 11 years (1-32). For the marital status, 55.32% were single, 40.43% were married, and 4.26% were divorced. Thirty seven patients (79%) were living in an urban area. For the education level, 17% had a primary education, 64% a secondary education, and 19% were university graduates. Occupational status was recorded as follows: 17% unemployed, 11% students, and 72% employed. The median IMT was 0.55 millimeters (mm)(0.32-0.83). We found a higher mean, right and left IMT (p<0.0001) in SpA patients compared with controls. Carotid IMT was positively correlated with age (p=0.001; r=0.578).

Conclusion: The analysis by 10-year age group showed a statistically significant difference in the IMT between patients (p=0.004). Median IMT increased significantly with age (every 10 years). IMT was significantly associated with occupational status (p=0.036); unemployed patients had the higher IMT (0.58mm). The median FMD was 14.6 mm (2-32%). A significantly lower FMD (p=0.008) was noted in SpA patients compared with controls. FMD were negatively correlated with age (p=0.017; r=-0.347). FMD was also associated with sex (p=0.036), and with the marital status (p=0.013). The median FMD was significantly lower in male 13.8% (IQR:8-17.5) vs 22.5% (IQR: 10-25), and married patients (10%; 6-18). There was no significant difference with the other sociodemographic variables (living environment, educational level, occupation). In multiple regression analysis, age was an independent predictor of increased carotid IMT (B=0.004; T=3.148; p=0.003; CI 95% 0.001-0.006).

AB0836  MICRONUTRIENTS DEFICIENCIES IN ENTEROPATHIC SPONDYLOARTHRITIS: THE INTERPLAY WITH METABOLISM AND HLA-B27 IN DISEASE PHENOTYPE

P. Triggianni1, A. D'Antonio1, E. Mannia1, M. Fatica1, G. Rafone1, P. Conciglio1, E. Lojol1, E. Calabrese1, L. Biancone2, A. Bergamini1, M. S. Chiementi1,1 Rheumatology, Department of “Medicina dei Sistemi”, University of Rome “Tor Vergata”, Rome, Italy; 2Gastroenterology Unit, Department of “Medicina dei Sistemi”, University of Rome “Tor Vergata”; Rome, Italy

Background: Micronutrients play immunomodulatory roles through interactions with innate and adaptive immunity influencing the pro/inflammatory balance. Serum levels depend on multiple factors such as gender, nutrition, and gut microbiome. Micronutrient deficiencies (MNDs) are associated with a pro-inflammatory status and co-morbidities in patients with chronic inflammatory diseases. No studies focused on potential interplay between MNDs and disease phenotype in Enteropathic Spondyloarthritis (ESpA) in which the combination of SpA with inflammatory status might dramatically affect micronutrients status.

Objectives: We analysed the occurrence of anemia (Hb <12 g/dl) and deficiencies of ferritin (Fe, <15 ng/dL), vitamin D [25(OH)D, ≤20 ng/ml], vitamin B12 (B12, ≤200 pg/ml), and folic acid (FA, ≤4 ng/mL) in ESpA patients. The interplay of MNDs with gender, metabolic parameters, HLA-B27 susceptibility, type of SpA and IBD, disease activity, and treatments was also explored.

Methods: Selection criteria of this cross-sectional descriptive study consisted of having a diagnosis of ESpA, regardless of its type, in an age of ESpA onset ≥18 and ≤80 years, among patients who were admitted to a combined Gastro-Intestinal and Rheumaticology Clinic at (Tor Vergata University Hospital, Rome, Italy). Exclusion criteria were represented by active IBD, pregnancy or lactation, kidney and liver failure, alcohol abuse, neoplasia, ongoing immunosuppressants. SpA disease activity was assessed by ASDAS-CRP and functional status by HAQ-S. All the enrolled patients underwent blood chemistry analysis to determine parameters including CRP, uric acid (SUA), Fe, 25(OH)D, B12, FA, and HLA-B27 typing.

Results: We included 164 patients comprising 109 females and 55 age-matched males. A diagnosis of Crohn’s Disease (CD) occurred in 70% of patients while Ulcerative Colitis (UC) represented a third of the cohort. Peripheral (per) and axial (ax) SpA were equally distributed (50%/50%). Patients with axSpA displayed a greater prevalence of CD than UC (p=0.02) while UC was prevalent in per-SpA (p=0.02). B27+ revealed in 19% of our cohort: B27+ patients had a higher prevalence of axSpA (p=0.016) and a more severe disease activity (p=0.02) than B27-. Moreover, B27 positivity and uveitis were prevalent in axSpA compared to per-SpA (p=0.009 and p=0.01, respectively). According to univariate analysis, males showed higher SUA (P=0.04) than females. Conversely, females showed a higher prevalence of anemia than males (p=0.002). A third of ESpA cohort showed FA (31.6%) and 25(OH)D (27.8%) deficiency while VB12 defect was less frequent (18.2%) and was registered almost equally in B27+ (p=0.02). CD-ESpA showed a lower mean VB12 (p=0.04) and a higher prevalence of ocular/skin co-morbidities (p=0.02) and axSpA compared to per-ESpA (p=0.04) and UC-ESpA. Accordingly, CD-ESpA were affected more in DMARDs than UC-ESpA (p=0.04).

Conclusion: Our findings document that FA and 25(OH)D deficiencies represent the main MNDs among ESpA patients while VB12 seems to be deficient mostly in patients with CD and almost exclusively in B27+ patients. Otherwise, B27+ in ESpA results to be associated mainly with disease phenotype and treatments. In ESpA, the gender of patients appears to impact principally on dysmetabolism highlighting the role for nutritional interventions particularly in males. The interplay of MNDs with B27 and dysmetabolism in ESpA deserves further investigations also taking into account CD/UC localization and behavior.

AB0837  NEUROPATHIC PAIN COMPONENT AND ITS RELATIONSHIP WITH QUALITY OF LIFE IN PATIENTS WITH ANYKLOSING SPONDYLITIS

I. Kedy1, M. Stanislavchuk1. 1National Pirogov Memorial Medical University, Vinnytsya, Department of Internal medicine №1, Vinnytsya, Ukraine

Background: Ankylosing spondylitis (AS) is a chronic systemic inflammatory disease of the connective tissue. AS often affects men aged 20-40 years and characterized by a progressive affect with rapid loss of work ability, deteriorating quality of life and reducing its duration. Quality of life is one of the markers of disease progression and evaluation of the treatment efficacy. The leading clinical symptom of AS is chronic pain, which may have not only nociceptive but also neuropathic component, which is not taken into account in the treatment of this category of patients, while pain is one of the main factors in reducing quality of life.

Objectives: To investigate the prevalence of the neuropathic pain component (NPC) and its relationship with the quality of life in patients with AS.

Methods: AS patients was diagnosed according to the New York 1984 classification criteria. The NPC was assessed by the Leeds Assessment of Neuropathic Symptoms and Signs (LANS) and The Douleur Neuropathique 4 (DN4). Quality of life was assessed by the Ankylosing Spondylitis Quality of Life (ASQoL). We examined 142 patients with AS (79.3% of men) in the rheumatology center from 2016 to 2021. The mean age was (Ma/SD) 4:9 ± 9.7 years, the disease duration was 5.7 ± 4.6. Statistical analysis performed by the Microsoft Excel and IBM Statistics SPSS 20.

Results: NPC assessed by the LANS (≥ 12) was found in 31% of patients, by the DN4 (> 4) in 38%. ASQoL in patients with AS by the LANS was 12.27 ± 4.27, by the DN4 - 11.64 ± 4.19, which was significantly higher than in patients with AS without NPC: LANS (7.97 ± 3.76), DN4 (7.86 ± 3.88). ASQoL had a strong direct correlation with LANS (r=0.561, p<0.01) and DN4 (0.476; p<0.01) that means - presence of neuropathic pain substantially effects quality of life in patients with AS.

Conclusion: NPC is found in 31% - 38% of patients with AS. It is established that the presence of the neuropathic pain component significantly reduces the quality of life in patients with AS, which should be taken into account during the treatment.

Disclosure of Interests: None declared.

AB0838  THE IMPACT OF COMORBIDITIES ON PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A CLUSTER ANALYSIS

S. Lee1, S. Kang1, Y. Eun1, H. Kim1, H. S. Cha1, E. M. Koh1, J. Lee1. 1Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea)

Background: Previous study using cluster analysis technique analyzed the association between comorbidities and various outcome measures in patients with axial spondyloarthritis (axSpA). Due to the cross-sectional nature of the study, however, prognostic information about each group were not provided.

Objectives: This study aims to perform cluster analysis to differentiate axSpA patients in terms of comorbidities and to examine the differential treatment outcomes of these groups using the data retrieved from Korean College of Rheumatology Biologics (KOBIO) registry which includes longitudinal data of axSpA patients receiving anti-TNF agents.

Methods: Clinical characteristics and demographic data of axSpA patients in KOBIO registry were analyzed using an agglomerative hierarchical cluster analysis. The optimum number of clusters was determined by the pseudo-F statistic. After clustering, baseline clinical characteristics and treatment outcomes were compared between isolated axSpA and classified comorbid groups using multivariable linear models and mixed linear models, respectively.

Results: 1,207 patients were included in the study. At least one comorbidity was seen in 464 (38%) axSpA patients. Compared with those with isolated axSpA, patients with comorbidity were older, longer disease duration, and reported higher PGA (p = 0.019), and BASFI (p <0,001), but did not have significantly different BASDAI, ESR, and CRP levels. The most common comorbidities were hypertension (14.4%), hyperlipidemia (13.0%), and obesity (4.5%). The hierarchical cluster analysis classified patients in 21 groups. We combined clusters 17-21 for further evaluation due to the small size of clusters (<5 patients). In multivariable linear models for baseline clinical characteristics, we found that patients in the hypothyroidism, asthma, and headache clusters reported poorer PGA compared to the other clusters, and the weight loss cluster had higher level of CRP compared with patients isolated axSpA even after adjustment of patient demographic data. After 1-year treatment of anti-TNF agents, the patients in the hypothyroidism and weight loss clusters decreased greater amounts of BASDAI and BASFI scores and ESR/CRP levels, respectively, compared with patients with isolated axSpA (Table 1). However, the degree of improvement in asthma and headache clusters, which had higher disease activities at baseline, was similar with isolated axSpA. Therefore, they still had higher disease activity scores at the 1-year follow-up.

Disclosure of Interests: None declared.

Table 1. Comparing each cluster to patients with isolated axSpA (i.e. no comorbidity) using multivariable linear mixed models for each treatment outcome measure at 1-year follow-up as the dependent variable.

**P-value < 0.05. Only clusters including significant results were shown due to the limitation of the number of characters.

Conclusion: Comorbidity could affect the treatment outcomes in patients with axSpA in certain subgroups. Thus, we should also pay attention to the comorbidities when treating axSpA.

Disclosure of Interests: None declared

AB0839 EXTRA-ARTICULAR MANIFESTATIONS IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

K. Tahir1, A. Akasbi1, I. El Mezouar1, T. Harzy1.1 University Hospital Center Hassan II, Rheumatology, Fez, Morocco

Background: Spondyloarthropathy (SpA) is a chronic inflammatory arthritis that combines joint involvement and extra-articular manifestations such as inflammatory bowel disease (IBD), uveitis and psoriasis.

Objectives: The aim of our study was to compare extra-articular manifestations in patients with ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA).

Methods: A retrospective study was conducted in a single rheumatology hospital in Morocco, including patients diagnosed as having SpA according to ASAS criteria 2010, during a period of 9 years. The patients were classified as AS by the presence of radiographic sacroiliitis according to the modified New York criteria and nr-axSpA defined by the presence of sacroiliitis on MRI. Extra-articular manifestations are compared between the two groups.

Results: 375 patients were analyzed. 206 were female (54.9%). The mean age were 46.8 ± 14 years [16-84]. The mean duration of disease progression were 13.38 ± 8.44 years. The mean BASDAI were 4.20 ± 1.60 and the mean BASFI were 17.0 ± 8.5 16.2 ± 8.0 17.5 ± 8.7

Average duration of the disease, years, Med 170±8,5 162±8,0 175±8,7 Age at the time of diagnosis, years, Med 276±10,0 276±10,0 276±10,0 Necessity of THA, years, Med 7.4±4.8 6.0±2.8 8.0±5.4 Osteophytes (Yes/No),% 90/10 96/4 88/12 Proliferation (Yes/No),% 75/25 68/2 78/12 Granulation (Yes/No),% 91/9 95/5 89/11 Ankylosis (Fibrous/Osseous),% 47/53 48/52 37/53

Results: The vast majority (85.9%) of pts had ill grade of secondary coxarthrosis and 14.1% had iv grade before THA. Complete absence of cartilage on the surface of acetabulum was revealed in 71.7% of cases, and there were either partial abrasions of the cartilage in the places of maximal load (6.5%), or chondromalacia (21.8%) in rest of the pts. Deformity of the FH was detected in 98.2% of pts, while as a result of osteonecrosis of FH (ONFH) in 75.5%. Complete absence of cartilage on FH was in 130 (76.5%) pts, and there were either partial abrasions of the cartilage in the places of maximal load (11.2%), or chondromalacia (12.3%) in rest of the pts. There were no significant differences in the macroscopic picture of the lesion of FH and acetabulums in pts with and without intake of bDMARDs, except for a higher frequency of ONFH in pts receiving bDMARDs.

Conclusion: The need for THA arose on average after 7.4±4.8 yrs from the appearance of pain in the hip joint (HJ). Macroscopic picture of HJ lesion in pts with AS was characterized as ONFH in 75.5% of cases, in almost half of cases - ankylosis of HJ, mainly fibrous (77.2%) with complete or partial absence of cartilage in acetabular surface and FH. According to the majority of macroscopic changes in the bone tissue of HF and acetabulums of HJ, pts with and without bDMARDs did not differ, but the frequency of ONFH was significantly higher in the group of pts who was receiving bDMARDs.

ANALYSIS OF THE FUNCTIONAL STATE OF HIP JOINTS (HJ) BEFORE TOTAL HIP ARTHROPLASTY (THA) IN PATIENTS WITH ANKYLOSING SPONDYLITIS (AS): A DATA OF RETROSPECTIVE ANALYSIS

A. Dubinina1, A. Khramov1, T. Dubinina2, E. Linykh2, S. Maglevan1, E. Bialik1.
1VA. Nasonova Research Institute of Rheumatology, Moscow, Russia, traumatological and orthopedic, Moscow, Russian Federation; 2VA. Nasonova Research Institute of Rheumatology, Moscow, Russia, axial spondyloarthritis, Moscow, Russian Federation

Background: Injury of hip joint (HJ) in patients (pts) with ankylosing spondylitis (AS) is considered as a factor of unfavorable prognosis, which can lead to rapid disability of pts.

Objectives: To assess the functional state of HJ before performing THA in patients with AS.

Methods: This retrospective study included 170 pts with a verified diagnosis of AS, who met the modified New York criteria of 1984, who were treated in the traumatological and orthopedic department in the period from 1998 to 2020. THA was routinely performed to all pts. Most of the pts were male (80.6%). 64% of them did not work due to the disease. Functional insufficiency of the joints at the time of surgical treatment in 64.1% of all the cases corresponded to ill grade, in 26.5% - to IV grade, in 9.4% - to II grade. 82.9% of pts had low activity of the disease according to the BASDAI index at the time of surgical treatment and 17.1% of them had high activity. 53 (31.1%) pts were receiving bDMARDs and 87% of them were TNF-alpha inhibitors. The Harris quantitative scale was used to assess the functional state of HJ.

Conclusion: The vast majority of pts with AS had pronounced severe disorders of HJ before THA - the average score on the Harris scale was 38,0±15,4. Most of the patients (85,9%) had severe and moderate lameness, with the need for additional support. Antalgic Gait (absent/mild/moderate/severe) was noted in 42,3/42,9/8,2/4,4 pts.

Disclosure of Interests: None declared

Background: Data regarding the prevalence and especially incidence of osteoporosis in Spondylarthropathy (SPA) is scarce and very divergent among studies from different patient populations.

Objectives: In this study, we aimed to compare demographic, disease and laboratory characteristics of SPA patients regarding their bone mineral densitometry (BMD) categories and find out incidence of osteoporosis in the follow-up BMD of patients who were not found to have osteoporosis at baseline.

Methods: Between 2010-2021, patients with a SPA diagnosis in the HUR-BIO database were searched. HUR-BIO (Hacettepe University Rheumatology Bio-logic Registry) is a single center biological disease modifying anti-rheumatic drug (DMARD) registry since 2010. Patients with BMD measurement were included in the study. Follow-up BMD scores were also documented. The patients were divided into 3 groups as normal, osteopenia and osteoporosis in accordance with the WHO criteria (2). Demographic characteristics, comorbidities, laboratory data and drugs in each group were documented.

Results: 3245 patients were reviewed. BMD was measured at least once in 118 patients out of 3245 (3.6%) patients. When the groups classified, 34 patients (28.8%) were included in the normal, 49 (41.5%) osteopenia and 35 (29.7%) osteoporosis groups. Patients with normal BMD was younger than both groups. Diabetics and hypertension were more prevalent in patients with osteoporosis. The BMI was significantly lower in the osteoporosis group. 25 patients with normal BMD was younger than both groups. 25 patients had osteopenia and osteoporosis in baseline BMD measurement had at least 1 follow-up BMD measurement. During the total follow-up of 91 patient-years, 3 patients had osteoporosis, revealing a the incidence of 3.3% in 100 patient-years.

Conclusion: In our study, the incidence of OP development in SPA patients was found to be 3.3%. Frequency of osteoporosis was 29.7% among SPA patients with BMD measurement (118/3245; 3.6%), however; only 40% of them had appropriate treatment. Osteoporosis seems as an overlooked and untreated comorbidity of SPA.

Data was represented as median (minimum-maximum) or n(%)
was the driving genus of enterotype 1 and Bacteroides contributed to enterotype 2 (Figure 1B, D). The alpha-diversity and beta diversity between the distinctive enterotypes was highly significantly different (P < 0.01, Figure 1E, F). Distinct bacterial profiles were also observed in enterotype 1 and 2 (Figure 1G). Interestingly, no significant differences were found between USpA patients and HC for the corresponding same intestinal type. This may be because USpA was at a comparatively early stage of spondyloarthritis (SpA).

**Conclusion:** Two significantly distinct bacterial microbiota structures existed in the USpA patients which was consistent with the general healthy population.

**AB0845 IMPORTANCE OF WEIGHT MANAGEMENT ON ENDOTHelial FUNCTION IN SpondyloArthritIs**

A. Ben Tekaya1,2, E. Hannech1,2, A. Fendri2,3, S. Boukriba2,3, N. Ziade1,2, S. Bouden1,2, R. Leila1,2, R. Tekaya1,2, I. Mahmoud2,3, H. Mızunzi2,3, L. Abdelmoula1,2, R. Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; 3Faculty of medicine of Tunis, University Tunis El Manar, Tunis, Tunisia; 2Hotel-Dieu de France Hospital, Ibn Khaldoun University, Kaslik, Lebanon; 3Radiology Department, La Rabta Hospital, Tunis, Tunisia

**Background:** Subclinical atherosclerosis is not rare in spondyloarthritis (SpA) patients. Endothelial dysfunction is the first step of atherosclerosis process. Obesity is a major traditional cardiovascular risk factor.

**Objectives:** The purpose of this study was to determine the association of anthropometric measures with endothelial dysfunction in non-obese SpA patients.

**Methods:** This was a prospective study conducted over 12 months and including 47 SpA free cardiovascular disease patients and aged less than 50 years. The following anthropometric parameters were collected for each patient: weight, height, Body Mass Index (BMI), hip and waist circumferences. Endothelial dysfunction was assessed by the ultrasound evaluation of the Flow Mediated Dilation (FMD).

**Results:** There were 14 female (28.8%) and 33 male (70.2%); The median age was 36 years (IQR: 19-50). The median disease duration was 11 years (IQR: 1-32). The median weight, height and BMI were 69 (IQR: 43-95), 170 cm (IQR: 144-193) and 24.5 kg/m2 (IQR; 16.3-29.4), respectively. Overweight (BMI: 1-32). The median weight, height and BMI were 100 cm (IQR; 84-116) and 88 cm (IQR; 70-114). Median BMI was 22.9 (IQR: 18.2-27.3). We didn’t found correlation between anthropometric parameters and FMD: weight (p=0.225; r=-0.180); height (p=0.273; r=-0.163), BMI (p=0.437; r=0.116); waist circumference (p=0.022; r=0.182) and hip circumferences (p=0.142; r=-0.217).

**Conclusion:** Our study showed that anthropometric parameters do not influence endothelial function in non-obese and young SpA patients. This highlights the importance of weight management and maintaining a healthy weight in SpA patients.

**AB0846 HLA-B51 PREVALENCE IN PATIENTS WITH SPONDYLOARTHRITIS AND IMPACT ON DISEASE PHENOTYPE: A CASE-CONTROL STUDY**

N. Ziade1,2, R. Nacouzi2, K. Mroue2, G. Merheb5,6, P. Ghoma2,7,1 Saint-Joseph University, Rheumatology, Beirut, Lebanon; 2Hotel-Dieu de France Hospital, Rheumatology, Beirut, Lebanon; 3Saint-Joseph University, Medicine, Beirut, Lebanon; 4Al Zahra University Medical Center, Rheumatology, Beirut, Lebanon; 5Holy Spirit University, Rheumatology, Kaskel, Lebanon; 6ND Secours Hospital, Rheumatology, Byblos, Lebanon; 7Hotel-Dieu de France, Immunology, Beirut, Lebanon

**Background:** Spondyloarthritis (SpA) is a group of rheumatic diseases with a heritable component associated with Human Leucocyte Antigen B27 (HLA-B27). Although many studies have reported an overlap between the clinical features of SpA and Behcet's disease (BD), as well as an increased prevalence of HLA-B27 in BD, the prevalence of HLA-B5 (namely B51 and B52, the split antigens of B5) in SpA, have been scarcely examined, particularly in countries with a low HLA-B27 prevalence.

**Objectives:** To estimate the prevalence of HLA-B51 and HLA-B52 in patients with SpA compared to healthy controls (HC), to identify the alleles found in HLA-B locus in patients with SpA compared to HC, and to evaluate the impact of HLA-B51 on SpA disease phenotype.

**Methods:** A case-control study included consecutive patients with a diagnosis of SpA (axSpA, peripheral SpA (pSpA), and psoriatic arthritis (PsA)) from three rheumatology clinics. HC were recruited among blood donors and medical students. Demographic data, as well as SpA and BD disease features, were collected through an interview with a trained medical student and file review (low back pain, peripheral joint disease, enthesitis, dactylitis, psoriasis, uveitis, inflammatory bowel disease, family history, oral and genital ulcerations, skin, vascular and neurologic manifestations, CRP, BASDAI, imaging of the spine and sacroiliac joints). The entire B locus was tested using molecular biology technique on Luminex with the possibility of precise B51/B52 differentiation. The prevalence of HLA-B51/B52 was calculated in patients and compared to HC using the Chi-square test. A complete HLA-B mapping was performed for patients and HC. A binary logistic regression identified factors associated with HLA-B51 in patients with axSpA.

**Results:** Data from 119 HC and 89 patients with SpA were available (66 axSpA, 16 pSpA, and 7 PsA). Mean age of the patients was 44.8 years [SD 13.5], 66.3% were males, disease duration was 12 years [SD 12.7], 72.4% had a history of elevated CRP, 30.3% were positive for HLA-B27, 53.9% had sacroiliitis on MRI, 47.2% had radiographic sacroiliitis, and 23.6% had symphyses. Oral ulcerations were reported in 38.2% of patients, genital ulcerations in 3.4%, uveitis in 5.6%, skin lesions in 18%, and vascular lesions in 3.4%. Patients with SpA fulfilled the classification criteria for BD in 2.9% (International Study Group criteria for BD) and 38.2% (International Criteria for BD). HLA-B51/B52 were found more frequently in patients with SpA (20.2% vs 7.9%) compared to HC (11.6% vs 4.2%), although the difference was not statistically significant. The difference was mainly driven by an association between HLA-B51 and axSpA (27.2% versus 11.8%. OR 2.8 [95%CI 1.3-6.1], p=0.008) (Table 1). The most frequent allele in SpA and HC was HLA-B35; complete HLA-B mapping is shown in Figure 1. In patients with axSpA, HLA-B51 was associated with radiographic damage in peripheral joints, while it was negatively associated with sacroiliitis. Uveitis was numerically associated with HLA-B51, but the association did not reach statistical significance.

**Table 1. Prevalence of HLA-B5 genes in patients with spondyloarthritids (SpA) and healthy controls**

**Conclusion:** HLA-B51/B52 were more numerically more prevalent in patients with SpA compared to HC. A statistically significant association was found between HLA-B51 and axSpA and correlated with more peripheral and less axial radiographic involvement.

Profile of SpA in the Moroccan Population: Results of a Multicenter Study

H. Arabi1, A. Mougui1, H. Sahimi2, N. Takhtira3, S. Mouchine4, I. Bentaleb5, H. Taoufin6, T. Harzy2, F. Afroozarzak2, S. Janani3, R. Bahiri1, A. Bezzi6, I. Ghoziani7, R. Niamane8, I. El Bouche9, *Mohammed VI University Hospital Marrakech, Rheumatology, Marrakech, Morocco; 2Hassan II University Hospital Fes, Rheumatology, Fes, Morocco; 3Mohammed V Hospital Tanger, Rheumatology, Tanger, Morocco; 4 Ibn Rochd University Hospital Casablanca, Rheumatology, Casablanca, Morocco; 5 El Ayachi Hospital, Ibn Sina University Hospital Salé-Rabat, Rheumatology, Salé-Rabat, Morocco; 6 Military Hospital Mohammed V Rabat, Rheumatology, Rabat, Morocco; 7 Military Hospital Agadir, Rheumatology, Marrakech, Morocco; 8 Hospital Aficenne Marrakech, Rheumatology, Marrakech, Morocco.

Background: Spondyloarthritis (SpA) is a frequent group of chronic inflammatory rheumatic diseases, their epidemiology varies considerably in different regions of the world.

Objectives: The aim of our study was to describe the epidemiological, clinical, para-clinical and therapeutic profile of SpA in the Moroccan population.

Methods: This is a multicenter descriptive study, including patients followed for SpA. 8 hospital centers participated in this study. All data were measured by standard instruments.

Results: Seven hundred patients were included. 54% were men, the mean age was 40.42±14.19 years at the time of diagnosis [14-90 years].

- The patients lived in urban and rural areas in 83.5% and 13.8% of cases, respectively.
- 38.4% were without occupation.
- A history of tuberculosis was noted in 3.8% of cases.
- 38.4% were without occupation.
- A history of tuberculosis was noted in 3.8% of cases.
- 38.4% were without occupation.
- A history of tuberculosis was noted in 3.8% of cases.

Conclusion: This is a study of the clinical and demographic characteristics of SpA patients in a population in Morocco, on which a large scale data base could be initiated, in order to better determine the role of genetic and environmental factors in the pathogenesis of the disease.

Assessment of Carotid Intima-Media Thickness in Spondyloarthritis Patients

A. Ben Tekka1,2, T. Mehmendi, F. Ahmed3, S. Boukhiba3, O. Saidane2,4, R. Leilla2,3, S. Bouden2,4, R. Tekay4,5, I. Mahmoud2,4, H. Mizouni2,5, L. Abdelmoula2,4,1, Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; 1University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia; 2La Rabta Hospital, Radiology department, Tunis, Tunisia.

Background: Cardiovascular morbidity and mortality are increased in spondyloarthritis (SpA), which is attributed to accelerated atherosclerosis. Recognition of subclinical atherosclerosis in asymptomatic population is important for risk stratification and optimal management. Due to its simplicity and non-invasive nature, carotid intima-media thickness (cIMT) is actually widely used for identifying subclinical atherosclerosis.

Objectives: The aim of our study was to investigate the presence of subclinical atherosclerosis in SpA patients compared with healthy controls, by evaluating cIMT.

Methods: We performed a case control study including 47 patients and 47 age and gender matched healthy controls. All subjects were included without history of cardiovascular disease or cardiovascular risk factors. Socio-demographic features, disease characteristics, radiographic structural damage and therapeutics were recorded. cIMT was measured with Mindray Resona 7 ZST+ ultrasound machine, from the right and the left carotid artery; than mean cIMT was calculated. We considered that cIMT was increased if the measurements were between 0.7 mm and 1.5 mm. Measurements higher than 1.5 were defined as an atherosclerotic plaque.

Results: Forty seven patients with a sex ratio of 2.35 were included in our study. Median age was 36 years (IQR: 28-46) and median duration of the disease was 11 years (IQR: 5-16). Median BASDAI and ASDAS-CRP scores were 2.6 (IQR: 1.8-3.8) and 2.18 (IQR: 1.62-2.91) respectively. Of the 47 patients, 10 (21%) had an active disease according to BASDAI and 19 (40%) had an active disease according to ASDAS. Median BASFI score for functional impairment was 3 (IQR: 1.5-5.1). Median BASRI and mSASSS scores were 3 (IQR: 2-4) and 10 (IQR: 4-15) respectively. Regarding treatment, 92% of patients were using non-steroidal anti-inflammatory drugs (NSAIDs), 51% were on csDMARDs and 38% were on anti-TNF alpha drugs. Median right, left and mean cIMT were respectively 0.54 mm (IQR: 0.49-0.63), 0.55 mm (IQR: 0.49-0.61) and 0.55 mm (IQR: 0.48-0.62) respectively. Increased cIMT values were found in 8 patients (17%). No patient had atherosclerotic plaque. Median values of cIMT were significantly higher in patients with spondyloarthritis than the control subjects (p<0.0001) as shown in Table 1.

Disclosure of Interests: None declared

Conclusion: Our study demonstrated increased cIMT in patients with SpA compared with healthy population; which attests higher risk for subclinical atherosclerosis and cardiovascular atherosclerotic events.

ENTHESIS, FEMALE GENDER AND VITALITY PERCEPTION AS FATIGUE DETERMINANTS IN SPONDYLOARTHROPATHY PATIENTS UNDER bDMARD

F. R. Martins1, A. Martins2, B. Samões3, D. Santos Oliveira2,4, R. Nicolau5, A. Ramírez Huaranga1, M. Paulino Huertas1.

1University Hospital de Gaia / Espinho, Rheumatology, Vila Nova de Gaia, Portugal; 2Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; 3Centro Hospitalar Tondela - Viseu, Epe, Rheumatology, Viseu, Portugal; 4Faculty of Medicine da Universidade do Porto - FMUP, Medicine, Porto, Portugal

Background: Fatigue is an important domain in quality of life of spondyloarthritis patients, not always directly associated with disease course. The explanatory factors of fatigue in these patients are still not clearly understood.

Objectives: To assess the determinants of fatigue in patients with SpA under biologic disease modifying anti- rheumatic drugs (bDMARDs).

Methods: A retrospective observational study was performed using registry data of patients with SpA under bDMARD therapy followed at a tertiary level hospital. Data regarding disease activity, response criteria measures, analytic markers, function, metrology, pain, general health and fatigue (using FACIT score) was gathered at baseline, 6 months (t6) and 12 months (t12) after introduction of bDMARD. Statistical analysis (significance at p < 0.05) was performed using paired T-test, Wilcoxon test and McNemar tests for paired samples, Mann Whitney-U, Kruskall-Wallis and One Way ANOVA for independent samples. Linear and logistic regression models were performed to assess direction and strength of association.

Results: A total of 46 SpA patients were analysed; most were male (24, 52.2%) with a predominantly axial involvement (31, 68.9%) and 74.4% of them were positive for HLA-B27. Most patients had high school or lower education (29, 69.1%), never smoked (26, 61.9%), never drank (34, 79.1%) and had a full-time job (38, 88.4%). All patients were under TNF inhibitors, mostly adalimumab (23, 50%).

There was a significant decrease in inflammatory markers (p<0.001), disease activity scores (ASDAS-CRP and BASDAI) (p<0.001), function index BASFI (p<0.001), metrology indexes (p<0.05) and MASEs enthesis score (p=0.01). Patient, physician and night painVAS were significantly lower (p<0.01) at t6 and t12, but spine VAS only varied significantly between t0 - t6 (p = 0.021) and not t0 - 112 (p=0.405). FACIT didn’t vary significantly after bDMARD initiation, and among the domains of SF36 questionnaire, only SF36 vitality score varied significantly (p=0.05). No significant changes in EQSD, HADS or anxiety depression scores were observed.

At baseline, there was a strong negative correlation between fatigue, expressed by FACIT score, and pain VAS (R = 0.9, p=0.037), without other significant associations. Several positive correlations with fatigue at t6 were observed, the strongest with anxiety and depression HADS (p < 0.001), BASFI (p < 0.001) and ASDAS-CRP (p < 0.001). Other positive associations were seen with 66 TJC (p < 0.01), patient VAS (p = 0.001), pain VAS (p = 0.001), nocturnal pain VAS (p < 0.001), BASDAI (p < 0.001) and MASEs (p < 0.001). Fatigue at t6 had a negative correlation with increased ASAS response measures mean value (p = 0.014), all domains of SF36 (p < 0.001), the strongest correlation of which was with the general health domain (R=–0.811), and EQSD (p<0.001). When comparing subgroups at t6, there was more fatigue in the female group (p=0.01) and in patient with higher vitamin D activity score (p < 0.05), with no differences according to work status, alcohol consumption or tobacco use, educational level, TNF inhibitor exposure or ASAS response.

Prediction analysis showed univariable association between several baseline variables and fatigue (lower FACIT scoring) at t6: age at bDMARD introduction (B = -0.405, p = 0.02), age at diagnosis (B = -0.43, p = 0.02), physician VAS (B = 0.149, p < 0.05), MASEs (B = 0.149, p < 0.05) and female gender (B = -0.795, p = 0.01). Multivariable linear regression analysis allowed for prediction of a predictive model for FACIT scoring at t6 (R2 = 0.900, p = 0.019): (-3.426) x MASEs 10 + (-24.074) x female gender + 0.949 x SF36 vitality score.

Conclusion: Enthesitis, female gender and subjective assessment of vitality seem to be determinants of fatigue in SpA patients under bDMARD. Fatigue in this population is associated with diverse factors that should be optimized in a holistic approach to the patient.

Disclosure of Interests: None declared

AB0851

APPLICABILITY OF THE MASEI INDEX IN ENTHESIS AND ITS ASSOCIATION WITH OTHER INDICES / SEROLOGICAL MARKERS OF ACTIVITY IN PATIENTS WITH SPONDYLOARTHROPATHY

1Hospital Universitario Ciudad Real, Rheumatology Department, Ciudad Real, Spain; 2Universidad Pontificia de Comillas, Quantitative Methods Department, Madrid, Spain

Background: Spondyloarthritis (SpA) are a group of chronic inflammatory diseases with affection, mainly of the axial skeleton and, also, of peripheral joints. The enthesis is one of the target organs, since an inflammation of it, known as enthesitis, can be observed, which in many patients with spondyloarthritis could be unnoticed.

Objectives: To find the relation between the MASEI index (Madrid Sonographic Enthesitis Index) in enthesis and other indices/serological activity markers (such as BASDAI, DAPSA or ASAS and ESR, CRP) in spondyloarthritis patients.

Methods: Observational, descriptive and cross-sectional study. Data were collected from 68 patients with SpA who underwent musculoskeletal ultrasound using the Madrid Sonographic Enthesitis Index (MASEI) and who were treated in our clinics from May 2021 to September 2021 and under the approval of the CEICm of our center. The variables evaluated were described using measures of frequency and measures of central tendency/dispersion, as appropriate. First, we tested the normality of all the variables, using a Shapiro-Wilk test. We studied the correlation of parametric numerical variables (such as MASEI-Vitamin D, MASEI-ASDAS) using Pearson’s coefficient. On the other hand, for non-parametric numerical variables (such as MASEI-BASDAI) we used Spearman’s coefficient. For parametric numeric and categorical variables (such as MASEI-VITAMINA D, ASDAS-VITAMINA D) we constrained the mean of differences using the Student t-test, while for non-parametric numerical and categorical variables, we contrast the difference of means with the Mann-Whitney U test (MASEI-PCR, MASEI-VSG). Finally, to find out the correlation between categorical variables (such as VITAMIN D-PCR), we used a chi-square test. Finally, we have done a curve-fitting study with Matlab, obtaining the functions that better adjust the data avoiding overfitting. We have done this parametric optimization with the following pairings: MASEI-ASDAS, MASEI-BASDAI and MASEI-DAPSA.

Results: We analyze twenty four patients with SpA (with mean age 50.50 ± 10.63 years) 8 women and 16 men. They present: radiographic axial spondyloarthritis (5 patients), non-radiographic axial spondyloarthritis (4 patients), psoriatic arthritis (10 patients), spondyloarthritis associated with inflammatory bowel disease (2 patients), reactive arthritis (2 patients), and, finally, one patient had undifferentiated peripheral spondyloarthritis. The variables have the following average levels: ASDAS, 2.35 (±1.09); BASDAI (for those with axial involvement) 4.54 (±2.93); DAPSA (for psoriatic arthritis) 10.98 (± 6.85) and total MASEI 19.88 (± 14.77). We have found a correlation between the total MASEI and the following variables: ASDAS (Pearson coefficient=0.696), BASDAI (Spearman coefficient=0.823) and DAPSA (Pearson coefficient=0.823).

The mean vitamin D levels were 25.98 (±12.05), and it has a negative correlation with the MASEI equal to -0.317. As far as curve fitting is concern, a couple of sinusoidal functions were obtained for the MASEI-ASDAS and MASEI-VITAMINA D the correlation of parametric numerical variables (such as MASEI-Vitamin D, MASEI-ASDAS) using Pearson’s coefficient. On the other hand, for non-parametric numerical variables (such as MASEI-BASDAI) we used Spearman’s coefficient. For parametric numeric and categorical variables (such as MASEI-VITAMINA D, ASDAS-VITAMINA D) we constrained the mean of differences using the Student t-test, while for non-parametric numerical and categorical variables, we contrast the difference of means with the Mann-Whitney U test (MASEI-PCR, MASEI-VSG). Finally, to find out the correlation between categorical variables (such as VITAMIN D-PCR), we used a chi-square test. Finally, we have done a curve-fitting study with Matlab, obtaining the functions that better adjust the data avoiding overfitting. We have done this parametric optimization with the following pairings: MASEI-ASDAS, MASEI-BASDAI and MASEI-DAPSA.

AB0852 ASSESSMENT OF ENDOThelial Dysfunction IN SPONDYLOARTHritis

A. Ben Tekaya1, T. Mehri1, S. Boukri2, F. Ahmed2, O. Saïdane1, R. Leilla1, S. Bouden1, R. Tekaya2, I. Mahmoud2, H. Mizouini2, L. Abdelmoula2, Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; 3University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia; 4La Rabta Hospital, Radiology department, Tunis, Tunisia

Background: Endothelial dysfunction is the earliest step in the pathogenesis of atherosclerosis, preceding structural vascular alterations. Few studies have focused on the endothelial dysfunction in spondyloarthritis.

Objectives: The aim of our study was to assess endothelial dysfunction using Flow-Mediated dilatation (FMD) in patients with spondyloarthritis.

Methods: Forty-seven consecutive patients meeting ASAS 2009 criteria for spondyloarthritis and 47 matched healthy subjects were included in the study. Subjects with traditional cardiovascular risk factors were excluded. Sociodemographic, clinical, biological and radiological features related to the disease as well as therapeutics were recorded. FMD was assessed ultrasonographically according to guidelines of the European college of cardiology (ECC).

Results: Spondyloarthritis group included 47 patients with a sex ratio of 2.35 and a median age of 36 years (IQR: 28-46). Median body mass index (BMI) was 24.5 kg/m² (IQR 25-75%: 20.7-26.8) with no significant difference compared with the control group (p=0.238). Physical examination showed normal values of blood pressure (BP) with a median systolic BP of 121 mmHg (IQR 25-75%: 110-130) and a median diastolic BP of 71 mmHg (IQR 25-75%: 67-79). In laboratory findings, total cholesterol and triglyceride levels were increased in 2 and 3 patients respectively.

Median age at onset of SpA was 20 years (IQR 25-75%: 18-32) For disease activity, median CRP level was 6.45 mg/IQR 25-75%: 14.5-19.9) and median ASAS-24 and BASDAI were respectively 2.18 (IQR 25-75%: 1.62-2.91) and 2.6 (IQR 25-75%: 1.8-3.8). Median MASES score was 0 (IQR 25-75%: 0-0). Median BASFI and BASMI were 3 (IQR 25-75%: 15-5.5) and 1.5 (IQR 25-75%: 0-4). Regarding treatment, 92% of patients were using NSAIDs, csDMARDs (51%) and 38% were on TNF inhibitors.

Patients with spondyloarthritis exhibited significantly lower FMD values than healthy age and gender matched controls with a median value of FMD 14.6% (IQR: 9-24) versus 18.8% (IQR: 12.8-23.1%); p=0.008.

Conclusion: Our study demonstrates impairment of endothelial function in patients with spondyloarthritis compared with healthy population, confirming the accelerated atherosclerosis in spondyloarthritis.

AB0853 THE ROLE OF IL-17 IN IBD AND SPONDYLOARTHRITIS

G. Lukina1, P. Kulakova1, E. Alexandrova1, A. Novikova1, N. Savenkova1, A. Klimets1, I. Kartushina1, A. Kovalsky1, E. Volnukhin1. 1The Logoinov Moscow Clinical Scientific Center of Moscow Healthcare Department (“The Logoinov Moscow Clinical Scientific Center of Moscow Healthcare Department” (The Logoinov MCSC MHD), Rheumatology, Moscow, Russian Federation; 1I.V.Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; 2The Logoinov Moscow Clinical Scientific Center of Moscow Healthcare Department” (The Logoinov MCSC MHD), Immunology, Moscow, Russian Federation

Background: Currents, there is a lot of interest in the frequency and risks of developing of inflammatory bowel diseases (IBD) in patients with ankylosing spondylitis (AS). [1] IL-17 and IL-23 are one of the key pathogenetic markers of AS [2]. A lot of studies also showed that the average number of IL-17 cells was significantly increased in active Ulcerative colitis (UC) and Crohn disease (CD) patients [3]. According to some studies cytokines, such as IL-17 and IL-23, play crucial role in inflammation and homeostasis [4].

Objectives: The aim of this study was to evaluate IL-17 and IL-23 serum levels in patients with AS without IBD and with AS and IBD.

Methods: In the analysis were included 50 patients with AS, fulfilling the modified New York criteria, among them man=36 (72%), woman=14 (28%), mean age of patients was 42.5±9, mean disease duration = 13.4±8.7 years. All patients were examined with ESR. Median ESR in the group of patients with AS without IBD was 7% (IQR 25-75%: 2%-11%), mean ESR in the group of patients with AS and IBD was 31.4% (SD 57.2), 7.1% (SD 38.5), 21.7% (SD 51.4) months in peripheral and axial SpA, PsA and total respectively (Table 1). The time from referral to rheumatology was 31.4 (SD 57.2), 7.1 (SD 38.5), 21.7 (SD 51.4) months in peripheral and axial SpA, PsA and total respectively (Table 2). The service with the longest time between symptom onset to referral to rheumatology department and diagnosis of SpA, as well as differences according to the department making the referral makes the important difference in initiating therapy and treatment.

Retrospective descriptive study of patients with a diagnosis of PsA according to the ASAS criteria and CASPAR criteria for the psoriatic arthritis subgroup (PsA), in a single hospital centre. We collected demographic variables separated by subgroups of peripheral and axial SpA and PsA, age at diagnosis, time from symptom onset to referral to the rheumatology department and diagnosis, as well as differences according to the department making the referral.

Results: Seventy-five patients with SpA were analysed. 40 had peripheral and axial SpA and 35 (46.6%) PsA. Thirty-six patients (49.3%) were female (Table 1). Patients with peripheral and axial SpA had a higher mean age at diagnosis than patients with PsA. 45.1 years (SD 11.3) was the mean age at diagnosis. 73.6% of patients were referred from primary care (PC), 9.4% from traumatology, 9.4% from rehabilitation (RH), 3.8% from dermatology and 3.8% from emergency department. The median time from the first symptom to referral to rheumatology was 31.4 (SD 57.2), 7.1 (SD 38.5), 21.7 (SD 51.4) months in peripheral and axial SpA, PsA and total respectively (Table 2). The service with the longest time between symptom onset and referral to rheumatology is PC and rehabilitation for all groups. The median time from first symptom to diagnosis was 43.1 (SD 55.1), 34.4 (SD 65.8) and 39.2 (SD 59.7) months for peripheral and axial SpA, PsA and total respectively (Table 2). The time from referral to rheumatology to diagnosis of peripheral and axial SpA was 12.2 (SD 19.4), PsA 17 (SD 39.3) and total 14.3(SD 29.5) months.

Disclosure of Interests: None declared

Background: Spondyloarthritis includes a heterogeneous group of rheumatisms characterized by their strong association with HLA-B27 (1). The association between SPA and HLA-B 27 is one of the strongest known associations between an HLA allele and disease (2). Several studies have highlighted the importance of this association for diagnosis, predicting disease phenotype and prognosis of spondyloarthritides (SpA) (1.2).

Objectives: The aim of the present study is to determine the prevalence of HLAB27 in Moroccan SpA patients and to analyze the correlation between HLAB27 status and different disease parameters.

Methods: It is a multicenter cross-sectional study including 256 SpA patients. Demographic, clinical, paraclinical and therapeutic parameters of the disease were collected. Disease activity was assessed by BASDAI and ASDAS-CRP scores. Patients were classified into two groups: HLAB27 (+) and HLAB27 (-). A comparison regarding HLAB27 status was performed using the Mann-Whitney and Chi2 T-test tests. The significance threshold was set at p<0.05.

Results: 256 SpA patients were included in the study, 241 patients have HLAB27 status of which 114 (44.5%) were HLAB27-positive, 46.6% of men and 40.9% of women were HLAB27 positive. 233 patients had axial SpA of which 110 patients (472%) were HLAB27 positive. The mean age was 39.58±12.89 years. The HLAB27-positive group had a longer diagnostic delay (p=0.008) with a mean of 4 years. 46 patients had a family history of SpA of which 25.4% were HLAB27-positive and 11.6% HLAB27-negative (p=0.007). The HLAB27-positive patients had more axial manifestations (96.5% vs. 85.9%; p=0.01). While peripheral involvement was more noted in the HLAB27-negative group (90.6% vs. 35.1%; p=0.001). Enthesopathy was more observed in the HLAB27-negative group (78% vs. 62.2%; p=0.001). HLAB27-positive patients had more active disease defined by ASDAS-CRP (3.13±1.23 vs. 2.24±1.14; p<0.001). Only one case of uveitis was noted in the HLAB27-negative group versus 27 cases in the HLAB27-positive group (p<0.001), 33 HLAB27-positive patients had radiographic coxitis (33 vs 16, p=0.002). The bDMARDs were more prescribed in the HLAB27-positive patients (58.8% vs. 35.4%; p=0.009).

Conclusion: In our study, the prevalence of HLAB27 was close to the MENA region (3). The prevalence of HLAB27 is related to an earlier disease onset, higher activity, to the presence of coxitis and uveitis and consequently more use of biotherapy in this group (HLAB27-positive).

AB0855

COMPARISON OF CARDIAC INVOLVEMENT BETWEEN ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLITIS

I. El Mehrou1, N. Akasbi1, T. Harzy1, 1CHU HASSAN II, Rheumatology, Fez, Morocco

Background: While cardiac involvement is increasingly recognized and investigated in patients with axial spondyloarthritis (axSpA), few studies have investigated the occurrence of cardiac involvement in patients with non-radiographic axial spondyloarthritis (nr-axSpA) in relation to ankylosing spondylitis (AS).

Objectives: The objectives of the present study are to describe and compare the characteristics of cardiac involvement between AS and axSpA nr patients.

Methods: A cross-sectional study was conducted in the rheumatology department of the University Hospital of Fez in Morocco, including patients diagnosed as having axial spondyloarthritis according to the ASAS 2010 criteria, for a period of 9 years. Patients were classified as nr-axSpA by the presence of radiographic sacroiliitis according to the modified New York criteria and nr-axSpA defined by the presence of sacroilitis on MRI.

Results: 357 patients were included in the study. We compared 257 AS to 118 with nr-axSpA. The cohort was predominantly female (54.9%) with a mean age of 46.83 years (S.D. 14.00). AS patients were significantly young (45 vs 50 years), more frequently male (55% vs 22%) and had higher serum inflammatory markers than those with nr-axSpA. Between AS and nr-axSpA groups, arterial hypertension was more frequent in AS patients (26.6% versus 14.4%, p = 0.018). While valvulopathy, myocardial infarction, pericarditis and heart failure were higher in AS patients with respective (8.6% vs 3.4%, p=0.067) (1.6% vs 0.8%, p=0.578) (1.2% versus 0.8%, p = 0.779) (0.4% versus 0%, p = 0.497). However, arrhythmias were similar in AS patients and nr-axSpA patients (0.8% versus 0.8%, p = 0.571).

Conclusion: Cardiac involvement was common in both axSpA populations and similar between AS and nr-axSpA except in hypertension where there is a significant difference between the two groups. These results highlight the importance of identifying and managing cardiac involvement in these patients.

Conclusion: In our cohort, patients are referred to rheumatology mainly from PC, which in turn is the service with the longest delay, especially in the peripheral and axial SpA group. Patients with PsA take less time to be referred than patients with peripheral and axial SpA. Once referred to rheumatology, peripheral and axial SpA patients take less time to be diagnosed than those in the PsA group.

Disclosure of Interests: None declared

Patients with renal involvement had significantly higher values of CIMT (0.64 mm (IQR 25-75%: 0.56-0.70) vs 0.53 mm (IQR 25-75%: 0.47-0.59); p= 0.045). Significant positive correlation was also detected between CIMT values and creatinine level (p=0.002).

In multivariate linear regression, creatinine level was identified as independent predictor of increased CIMT (B=0.002; 95% confidence interval=0.000-0.005; p=0.035).

Conclusion: Although all patients included have normal creatinine level, we identified creatinine level as independent predictor of subclinical atherosclerosis in SpA patients. This finding highlights the monitoring of this parameter.

CLINICAL CHARACTERISTICS OF PATIENTS WITH SPONDYLOARTHRITIS WITH COVID-19 IN ANAMNESIS IN THE REPUBLIC OF TATARSTAN

V. Mukhamadieva1, S. Lapshina1, N. Shamsutdinova2, A. Sagitova1, A. Zakirova1, L. Krasnova1, R. Abdakirov1, D. Abdulgaieeva1, Kazan State Medical University, Department of hospital therapy, Kazan, Russian Federation; Kazan, Russian Federation; Kazan State Medical University, Department of hospital therapy, Kazan, Russian Federation; Kazan, Russian Federation; Kazan State Medical University, Department of hospital therapy, Kazan, Russian Federation; Republican clinical hospital, rheumatology, Kazan (Российская Федерация, Республика Татарстан), Russian Federation

Background: The management of patients with spondyloarthritis (SpA) during the period of the novel coronavirus infection (NCI) pandemic is a significant problem due to insufficient evidence base.

Objectives: To study the features of the course NCI and its influence on the course of SpA.

Methods: From March 2020 to January 2022, 55 patients with SpA who underwent NCI (with a confirmed result of SarsCoV2 PCR and /or using X-ray computed tomography (CT) of the lungs): ankylosing spondylitis (AS) 37 people, with psoriatic arthritis (PsA) 18 people. Of these 32 (58.2%) were men, 23 (41.8%) - women, the average age of patients was 49 (37.5; 57.5) years. The duration of SpA at the time of NCI was 11 [7; 16] years, SpA activity before NCI was low in 15 (34.8%) patients, moderate in 25 (58.1%), and high in 3 (6.9%) patients. The results of clinical and laboratory examinations were evaluated during the NCI and after 1, 3, 6 months.

Results: Symptoms of NCI in patients with SpA were comparable in frequency and severity to the course of infection in the population. 47.3% had a mild course of NCI, and 52.7% of those observed had a moderate course, which is comparable with the general population data. Lung involvement was detected in 29 (52.7%) patients. The outcome of COVID-19 in all patients is recovery. Analysis of the course of SpA showed an increase in activity 1 and 3 months after NCI: BASDAI from baseline to COVID-19 4.3±1.57 to 4.9±1.7 points after 3 months, similar to ASDAS_CRP from 2.6±1.2 to 3.7±0.2, BASFI from 3.0±1.9 to 3.8±1.8. A positive correlation was found between the severity of NCI and the BASFI index after 3 months (0.670). Analysis of the course of PsA showed an increase in activity 1 and 3 months after NCI: DAS28 from the baseline 2.78±0.98 to 4.15±1.16 points after 3 months. Of the total number of recoveries, 72.2% of patients showed an increase in activity due to clinical and laboratory parameters.

78.1% of patients noted the presence of post-COVID symptoms after NCI, 56.3% had a combination of more than 3 different symptoms. Most often there was an increase/appearance of pain in the joints - in 78.1% significant - in 61.8%, insignificant - in 16.3% of respondents. Strengthening/appearance of muscle pain and/or headache and/or dysautonomia occurred in 72.7%. This can be assessed as an exacerbation of the underlying disease, or, conversely, the appearance of arthralgia and myalgia could have an impact on the increase in AS and PsA activity indices. The second most frequent were a decrease in the quality of life (QOL) and working capacity in 69.0% of patients: significant in 36.3% of patients, insignificant in 32.7%. The appearance/intensification of shortness of breath and a decrease in exercise tolerance were noted by 60% of the respondents. Among them, 34.5% of patients with moderate severity, 25.4% - with mild NCI. Appearance/intensification of chest pain and/or palpitations was noted by 16.3% of patients.

Conclusion: The prevalence and course of the NCI in patients with SpA did not differ from that in the population. However, coronavirus infection has led to increased pain and an increase in AS activity, long-term persistence of post-COVID manifestations in the form of muscularkeletal pain and asthenic symptoms in the form of a decrease in the quality of life. At the same time, specific respiratory symptoms occurred in a third of patients and were not associated with the severity of the NCI.

REPERCUSSIONS OF TOBACCO ON SPONDYLOARTHRITIS: THE ICEBERG EFFECT!

L. Kharra1, M. Slimou1, A. Abdennader2, K. Amri2, Y. Mallat1, L. Metoui1, R. Dhour1, I. Gharsallah1, B. Louzir1, 1Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia; 2Military Hospital of Instruction of Tunis, Orthopedics, Tunis, Tunisia; 3Military Hospital of Instruction of Tunis, Internal medicine, Tunis, Tunisia

Background: The deleterious effect of smoking is frequently studied in inflammatory diseases such as spondyloarthritis (SA) [1].

Objectives: The objective of our study was to identify the consequences of smoking during AS.

Methods: We conducted a cross sectional study including patients followed for spondyloarthritis meeting the ASAS 2009 criteria. For each patient we collected the following parameters: age, age at onset of the disease, duration of progression, disease activity using BASDAI and ASDAS-CRP scores and structural damage using BASRI and mSASSS scores. We also measured sedimentation rate (ESR) and C-reactive protein (CRP).

Statistical analysis was performed using SPSS software.

Results: We included 140 patients. Seventy-three percent were male (n=102). The mean age was 43 ± 12.9 years. The age of onset of the disease was 34.2 ± 12 years. The mean disease duration was 110 ± 107.8 months.

Sixty patients were smokers (43%) at an average of 20.75 ± 16.09 pack-years. Mean ESR and CRP were 36.49 ± 27.22 mm and 29 ± 44.27 mg/L, respectively.

The mean BASRI and mSASSS were 4.12 ± 3 and 10.26 ± 15.41, respectively.
Smokers had significantly higher BASRI and mSASSS scores (BASRI: 5.02 ± 3.32 vs 3.47 ± 2.6; p=0.005 and mSASSS: 14.07 ± 17.56 vs 7.02 ± 12.82; p=0.03). In addition, the number of packets year was correlated to mSASSS (r=0.399; p=0.01).

On the other hand, we did not find any association between smoking and the following parameters: ESR, CRP, BASDAI or ASDAS-CRP.

Conclusion: As reported in other studies, ours showed that structural damage was correlated with the number of pack-years [2]. Smoking was associated with this structural damage in SA regardless the inflammatory biomarkers and the disease activity. This suggests that control of structural damage in SA requires smoking cessation.

Background: Physiopathological mechanisms of spondyloarthritis (SA) are very complex. The role of the interleukin (IL)-8, which is an angiogenic chemokine, has been suggested [1].

Objectives: We aimed to evaluate the discriminative value of interleukin 8 in SA.

Methods: We conducted a cross-sectional study during two years (2019-2020) including 144 subjects divided into two groups: a group G1 that included 72 patients followed for spondyloarthritides meeting the Assessment of SpondyloAr-

Results: We included 57 men and 15 females in each group. The mean age was 44.84 ± 13.42 years. In G1, the mean disease duration was 10.25 ± 7.7 years. IL-8 was measured for each participant using chemiluminescence. We performed a ROC analysis and computed the area under the curve (AUC) at IL-8 to assess the ability of this chemokine to diagnose SA and to distinguish between SA patients from healthy controls. Statistical analysis was performed using SPSS.

The mean BASDAI and ASDAS-CRP were 3.21 ± 1.87 and 2.92 ± 1.55, respectively. IL-8 was able to distinguish SA patients from healthy controls with a cutoff of 4.5 pg/mL. The AUC was good at 0.855 (p<0.0001). The sensitivity and the specificity were 92.8% and 81.6% (Figure 1).

Conclusion: Several studies have found that IL-8 was significantly higher in SA patients compared to controls [2,3]. Our study showed that IL-8 could distinguish SA patients from controls with a cutoff of 4.5 pg/mL. This suggests that IL-8 could play a role in the pathophysiology of SA.

Objectives: To evaluate emotional functionality of patients with SpA, and their association with the presence of gastrointestinal symptoms and disease activity.

Methods: In total, 98 patients with SpA (fulfilling ASAS criteria) were assessed by rheumatologists. Patients with two or more gastrointestinal symptoms were referred to gastroenterology. Furthermore, those patients with SpA and con-

Background: Spondyloarthritides (SpA) is a heterogeneous condition characterized by chronic back pain, fatigue and progressive loss of mobility, associated to decreasing quality of life, physical and mental health. SpA patients may have a presence of non-specific gastrointestinal symptoms or subclinical intestinal inflammation. Although the association between SpA and high levels of distress has been investigated, few studies have included gastrointestinal involvement among the factors associated with mental health.

Objectives: To evaluate emotional functionality of patients with SpA, and their association with the presence of gastrointestinal symptoms and disease activity.

Methods: In total, 98 patients with SpA (fulfilling ASAS criteria) were assessed by rheumatologists. Patients with two or more gastrointestinal symptoms were referred to gastroenterology. Furthermore, those patients with SpA and con-

**EMERGENCE OF SPONDYLOARTHRITIS FOLLOWING B CELL-DEPLETING MONOCHELONAL ANTIBODY THERAPY FOR MULTIPLE SCLEROSIS**

T. Pham1, P. Caroliné1, P. Lafforgue1, C. Barra2, A. Maarouf2, J. Pelleiter2, A. Rico2, B. Audoin2, F. Azix Marseille Univ, APHM, Rheumatology, Marseille, France, 2Hospital Saint Joseph, Rheumatology, Marseille, France, 3Aix Marseille Univ, APHM, Neurology, Marseille, France. **Background:** Anti-CD20 B cell-depleting therapies, including rituximab and ocrelizumab, have demonstrated their efficacy in patients with relapsing–remitting multiple sclerosis (RRMS). **Objectives:** Herein we report a series of patients with RRMS treated with anti-CD20 monoclonal antibodies (mAb) who developed de novo spondyloarthritis (SpA). **Methods:** Following the presentation of an index case, we collected all cases of de novo SpA in the anti-CD20-treated RRMS cohort of our institution's referral center. Clinical, biochemical, and imaging characteristics of the cases were identified through a clinical assessment. Information was collected via a standardized form to obtain key characteristics on the onset and type of disease development at baseline and on outcomes up to 12 months. All patients had a magnetic resonance imaging (MRI) of the sacroiliac joints and, depending on the clinical presentation, a spine MRI and/or a musculoskeletal grayscale and power Doppler (PD) ultrasound (US) examination. **Results:** De novo SpA developed in 6 of 480 patients with RRMS treated with anti-CD20 mAb, accounting for an incidence of 1.25%. All but one received rituximab treatment. The median time from the last anti-CD20 mAb infusion to SpA onset was 1.5 months [IQR: 1–4]. At the time of SpA emergence, the RRMS activity was controlled. The most frequent clinic SpA phenotype identified was peripheral SpA (4/6), with Power Doppler ultrasound-detected synovitis. The 2 patients with axial SpA phenotype had bilateral sacroilitis on MRI. Five of the 6 patients had a personal or family history of psoriasis, whereas the prevalence of psoriasis in the entire RRMS cohort was 3.33% (16/480). No other extra-articular manifestation was observed. All patients were HLA-B27 negative and fulfilled at least one classification criteria of SpA. None required hospitalization and the SpA onset did not affect the management of MS. The 2 patients with axial SpA were successfully treated with NSAIDs. Among the patients with peripheral SpA, 3 of 4 had inadequate response to NSAIDs, 2 were treated with methotrexate and 1 with leflunomide. Only one patient required initiation of an IL-17 inhibitor to control the SpA activity. **Conclusion:** We report a pattern of patients with MS successfully treated with B cell-depleting drug developing axial or peripheral SpA, predominantly HLA-B27 negativity and associated with psoriasis. **Disclosure of Interests:** None declared. **DOI:** 10.1136/annrheumdis-2022-eular.4211

**A NOMOGRAM MODEL COMBINING INFLAMMATORY FACTORS AND MRI RADIONICS TO ASSESS THE DISEASE ACTIVITY OF THE PATIENTS WITH AXSpA IN A PROSPECTIVE STUDY**

L. Ye1, D. Chen1, S. Mao2, G. Zhu3, M. Zheng4, C. Pan1, C. Ye1. 1First Affiliated Hospital, Wenzhou Medical University, Rheumatology, Wenzhou, China; 2First Affiliated Hospital, Wenzhou Medical University, Radiology, Wenzhou, China **Background:** Clinical and magnetic resonance imaging (MRI) disease activity score (DAS) are measuring different aspects of axial spondyloarthritis (axSpA), they are essential in disease activity assessment. The radionics was on facilitating readings by clinical specialists via enhancing the medical images in which subtle data differences could be distinguished. **Objectives:** If the additional information of MRI imaging can be considered as a predictor for axSpA disease activity? In this study, we sought to construct a nomogram integrating the sacroiliac joint (SJ)- MRI radionics features and the inflammatory biomarkers to assess disease activity and compare it with clinical disease activity index in axSpA patients. **Methods:** 203 patients data were collected prospectively and confirmed as axSpA were randomly divided into training (n = 143) and validation cohorts (n = 60). 1316 radionics features were extracted from the 3.0T SJ-MRI. A Nomogram model was constructed using multivariate logistic regression analysis Incorporating independent clinical factors and radionics features score (Rad-score). The performance of clinics, Rad-score and nomogram models were evaluated by ROC analysis, calibration curve and decision curve analysis (DCA), and compared with the disease activity index (Ankylosing Spondylitis Disease Activity Index (ASDAS)-C reactive protein (CRP), ASDAS-erythrocyte sedimentation rate (ESR), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI)) and Spondyloarthritis Research Consortium of Canada (SPARCC) MRI scoring system. **Results:** The Rad-score allowed a good discrimination in the training (AUC, 0.91; 95% CI, 0.85-0.96) and the validation cohort (AUC, 0.84; 95% CI, 0.73-0.96). The CRP-radionics nomogram model also showed favorable discrimination in the training (AUC, 0.96; 95% CI, 0.93-0.99) and the validation cohort (AUC, 0.89; 95% CI, 0.80-0.99), better than BASDAI(AUC, 0.58), ASDAS-CRP(AUC, 0.72), ASDAS(1.00), Bath Ankylosing Spondylitis Disease Activity Score (BASFI)(AUC, 0.73), had no statistical difference with SPARCC(AUC, 0.87). Calibration curves and DCA demonstrated the nomogram fit well (p > 0.05) and was useful for activity evaluation. **Conclusion:** Rad-score showed good discriminative ability to assess disease activity in axSpA. The nomogram can increase the efficacy for assessment axSpA disease activity, which might simplify clinical evaluation. **REFERENCES:**

**THE FACTORS AFFECTING PATIENT GLOBAL ASSESSMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

E. Durak Ediboglu1, D. Solmaz1, H. Cinakli1, G. Alp1, E. Olman Akat1, E. Erpek1, I. Kurut Aydin1, S. Gucermez2, S. Ketenci1, O. Bayındır1, M. Ozmen1, S. Akar1. 1İzmir Katip Celebi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey **Background:** The BASDAI is one of the basic scales used in the measurement of disease activity in patients with spondyloarthritis and allows the evaluation of various aspects of the disease (axial and peripheral disease as well as...
inflammation). The patient global assessment (PGA) is a one-dimensional scale in which patients evaluate how their illness affects their health.

**Objectives:** In this study, we planned to test and review the possible determinants of PGA and its relation with BASDAI components, BASFI scores and disease-related features both at first visit and at the 2 year follow-up.

**Methods:** Patients with axSpA whose baseline BASDAI and PGA scores were completed, were included in the analysis. The demographic, clinical and laboratory characteristics of the patients were recorded. The relation between PGA scores and BASDAI sub-score, BASFI score and other patient and disease characteristics were tested both univariate and multivariate analysis methods. The factors affecting the change in the PGA score over 2-year follow-up were also analyzed with GEE analysis method.

**Results:** In total 313 patients (56.5% of male, 61.7% AS, mean age at diagnosis 34.3±11 years) were included in the analysis. Sperman’s rho test was used for correlation analysis. Baseline PGA scores were in correlation with the BASDAI total score (rho:0.71, p<0.001), PGA scores of female patients were found to be significantly higher (p=0.037) and each BASDAI indivual score and BASFI scores were moderately well correlated with PGA (Table 1). Multivariate analysis revealed that spinal pain (BASDAI Q2), the severity of morning stiffness (BASDAI Q5) and BASFI scores were the main determinants in the global health total score (rho:0.71, p<0.001). PGA scores of female patients were found to be significantly higher (p=0.037) and each BASDAI indivual score and BASFI scores were moderately well correlated with PGA. The patient global assessment is a unidimensional scale in which patients evaluate how their illness affects their health.

**Disclosure of Interests:** None declared.

**Background:** Acute anterior uveitis is the most frequent extra-articular manifestation in spondyloarthritis (SpA). [1] **Objectives:** The purpose of this study is to assess the prevalence of uveitis during SpA and to identify associated factors with its presence.

**Methods:** A cross-sectional multicentric observational study was conducted; the main data source was the Moroccan registry of biological therapies in rheumatic diseases (RBSMR registry). Patients, included from May 2017 to January 2019, were all adult patients (age > 18 years old), presenting SpA, according to ASAS (Assessment of Spondyloarthritis International Society) classification criteria for SpA 2010.

Demographic and clinical characteristics, disease activity, radiographic damage and functional ability have been compared between two groups of patients: Patients with SpA suffering from uveitis and patients without uveitis. General and specific data regarding uveitis were collected.

**Results:** 194 patients were included in the study. The mean age was 40.22 ± 13.68 years. The sex ratio was 1, 7 (man:woman). The mean duration of disease was 615.90 ± 349.12 weeks.

96.4 % of the patients had axial involvement, 70 % had peripheral involvement and 61.5 % had enthesitis involvement. SPa was radiographic in 88.1 % of the cases and coxitis was found in 40.9 %. The mean erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) was 39.04 ± 27.16 mm/h and 32.87 ± 20.64 mg/l, respectively. HLA B27 was positive in 34 % of patients. The mean CRP rate (ESR) and C-reactive protein (CRP) was 39.04 ± 27.16 mm/h and 32.87 ± 20.64 mg/l, respectively. HLA B27 was positive in 34 % of patients. The mean CRP was 29.8 % in female with SpA and 12.6 % in male (p = 0.026).

**Conclusion:** Acute anterior uveitis is the most frequent extra-articular manifestation in spondyloarthritis (SpA). The presence of uveitis in Moroccan patients diagnosed with SpA wasn’t associated with specific characteristics. Even though, its screening is systematic because it conditions the treatment.

**WOMEN SPONDYLOARTHRITIS: EPIDEMIOLOGICAL, CLINICAL AND PARACLINICAL CHARACTERISTICS**

H. Bara1, H. Arabi1, A. Rat1, A. Mouguia, I. El Bouchti1, 1CENTRE HOSPITALIER-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Rheumatology, Marrakech, Morocco

**Background:** Spondyloarthritis (SpA) is a chronic inflammatory rheumatism characterized by sacroiliitis and spinal involvement, affecting both genders but more frequent in males.

**Objectives:** The aim of this study is to analyze the epidemiological, clinical and paraclinical characteristics of Spondyloarthritis in women.

**Methods:** Retrospective study included 333 patients followed up for SpA at the Rheumatology Department between 2004 and 2021.

**Results:** Our study involved 153 women and 180 men. In the female population, the mean age was 45.1 years, 12.4% had high blood pressure, 4.8% had a psychiatric comorbidity and none of the patients were smokers, versus a mean age of 36.4 years, 5% of high blood pressure patients, 1.7% having a psychic comorbidity and 25% of the smokers for the male with SPA. The age of onset of symptoms was 36.5 years for women versus 28 years for men (p = 0.001). Axial involvement was 84.3% in women and 85% in men, while peripheral and enthesial involvement was present in 73.8% and 56.8% of female subjects and 58.8% and 46.6% of male subjects (p = 0.004 and 0.064 respectively). Coxitis was present in 13.1% and syndesmophytsis in 15.3% of females versus 36.1% and 18.3% of males (p at 0.001 and 0.4 respectively). Mean erythrocyte sedimentation rate was 45.7, mean CRP 28.5 and mean calcemia 92 in the 1st group versus 43.40.6 and 93.4 in the 2nd (p at 0.4; 0.03 and 0.03 respectively). Relapse was 29.8% in female with SpA and 12.6% in male (p = 0.026).

**Conclusion:** In our study, females SpA patients developed symptoms later than did males, peripheral and enthesial involvement is more common in females while coxitis is more common in males with statistically significant higher CRP and calcemia.

PREVALENCE AND RISK FOR BUNDLE BRANCH BLOCK, ATRIOVENTRICULAR BLOCK AND PACEMAKER IMPLANTATION IN SPONDYLOARTHRITIS. A SYSTEMATIC REVIEW OF THE LITERATURE

H. S. Park¹, A. Laiz¹, P. Díaz del Campo Fontechea², M. A. Martín Martínez², M. Guerra-Rodríguez³, C. Alonso Martín⁴, J. Sanchez-Vega⁴, H. Corominas¹,²,³

¹Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; ²Societad Española de Reumatología, Unidad de Investigación, Madrid, Spain; ³Hospital de la Santa Creu i Sant Pau, Cardiology, Barcelona, Spain; ⁴Hospital de Bellvitge, Cardiology, Cardiac Imaging Unit, Barcelona, Spain; ⁵Hospital Dos de Maig, Rheumatology, Barcelona, Spain

**Background:** Inflammation of the valve attachment site may produce tissue degeneration near the atrioventricular node, which may lead to electrical conduction disturbances, that is to say atrioventricular block (AVB) and bundle branch degeneration near the atrioventricular node, which may lead to electrical conduction disturbances.

**Objectives:** To evaluate the evidence regarding the prevalence and risk of BB, AVB and pacemaker implantation (PMI) in patients with spondyloarthritis (SpA) compared to a control group without SpA.

**Methods:** A systematic review of the literature was performed using PubMed (Medline), EMBASE (Elsevier) and Cochrane Library (Wiley) databases until December 2021. The risk for AVB, BBB and PMI were analyzed. Cohort, case control and cross-sectional studies in patients ≥18 years meeting the classification criteria for SpA were included. The Odds ratio (OR), risk ratio (RR) or Hazard ratio (HR) were considered as outcomes. Data was synthesized in a previously defined extraction form. The risk of bias was assessed by the Newcastle-Ottawa Scale.

**Results:** In total, eight out of 374 studies were included. As for low grade AVB and BBB, only indirect results comparing prevalences from low to medium quality studies were found. According to population based registries, the sex and age adjusted HR of AVB was 2.3 (95% CI 1.6 - 3.3) in ankylosing spondylitis, 2.9 (95% CI 1.8 - 4.7) in undifferentiated spondyloarthritis and 1.5 (95% CI 1.1 a 1.9) in psoriatic arthritis. The RR for PMI was 1.3 (95% CI 1.16 - 1.46) for groups aged between 65-69 years, 1.33 (95% CI 1.22 - 1.44) for 70-75 years, 1.24 (95% CI 1.55 - 1.33) for 75-79 years and 1.11 (95% CI 1.06 - 1.17) for groups older than 80 years.

**Conclusion:** The differences of prevalence in AVB and BBB were similar in SpA and control groups even though studies lacked the power. According to population registries there was an two fold-increased risk of high grade AVB in SpA patients. RR for PMI was higher in younger age groups.

IMPORTANCE OF SCREENING OF TRADITIONAL CARDIOVASCULAR RISK FACTORS IN SPONDYLOARTHRITIS

A. Ben Tekaya¹,², T. Mehme¹,², O. Saidane¹,², S. Bouden¹,², R. Leila¹,², R. Tekaya¹,², I. Mahmoud¹,², L. Abdelmoula¹,², Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; ¹University Tunis El Manar, Faculty of medicine of Tunis, Tunisia

**Background:** Epidural adipose tissue has been associated with the development of coronary artery disease and recently suggested as a novel marker for evaluating subclinical atherosclerosis.

**Objectives:** The aim of our study was to assess the relationship between EFT and cardiovascular risk parameters in patients with spondyloarthritis (SpA).

**Methods:** We performed a case control study including patients meeting ASAS 2009 criteria for SpA, and healthy controls. Subjects were aged less than 50 years old and without traditional cardiovascular risk factors. Clinical features related to the disease were recorded. Anthropometric data (body mass index (BMI), waist circumference and hip circumference) and arterial blood pressure of the patients were also recorded. Blood specimens were collected after 12 hours of fasting and total cholesterol, HDL, LDL, triglyceride and fasting glucose were measured. Total cholesterol to HDL ratio and LDL to HDL ratio were calculated. All subjects underwent Doppler echocardiography with measurement of EFT by an experienced cardiologist.

**Results:** We enrolled 47 SpA patients and 47 controls. Subjects were age, sex and BMI matched (p=0.267, p=0.589 and p=0.238 respectively). Median disease activity scores BSAASD and ASDAS-CRP were 2.6 (IQR 25-75%: 1.8-3.8) and 2.18 (IQR 25-75%: 1.62-2.91) respectively. Median waist and hip circumference

were 88 cm (IQR 25-75%: 82-97) and 100 cm (IQR 25-75%: 91-97), respectively. Median systolic (SBP) and diastolic (DBP) blood pressure were respectively 121 mmHg (IQR 25-75%: 110-130) and 71 mmHg (IQR 25-75%: 67-78). Laboratory findings showed a median fasting glucose level (FG) of 4.93 mmol/l (IQR: 4.25-4.75), 5.5; 5.1. Median total cholesterol (CT), HDL, LDL and triglyceride levels were respectively 3.66 mmol/l (IQR: 25-75%: 3.18-4.28), 1.08 mmol/l (IQR: 25-75%: 0.92-1.21), 2.17 mmol/l (IQR: 25-75%: 1.78-2.6) and 0.84 mmol/l (IQR: 25-75%: 0.79-1.15). CT/HDL ratio and LDL/HDL ratio were 3.48 (IQR 25-75%: 2.95-3.97) and 1.99 (IQR 25-75%: 1.54-2.48), respectively.

Median EFT was significantly increased in patients compared to controls (3.1 mm (IQR: 2.5-4) versus 2.4 mm (IQR: 2-3), p=0.001). A positive correlation was found between EFT and SBP (p=0.028; r=0.323) and triglyceride level (p=0.022, r=0.349). In contrast, EFT was not associated with DBP (p=0.069, r=0.270), BMI (p=0.223, r=0.181), waist circumference (p=0.114, r=0.234), hip circumference (p=0.451, r=0.113), CT (p=0.127, r=0.236), HDL (p=0.587; r=0.085), LDL (p=0.342; r=0.149), FG (p=0.104, r=0.248), CT/HDL ratio (p=0.418; r=0.128) and LDL/HDL ratio (p=0.683, r=0.064).

In multivariate linear regression, triglyceride level was identified as an independently predictor of increased EFT (B=0.676; 95% confidence interval = 0.209-1.143; p=0.006).

Conclusion: The importance of our results that we identified a traditional cardiovascular risk factor as a predictor of subclinical atherosclerosis in SpA without cardiovascular risk factor and with normal triglyceride level. This finding highlights the importance of regular screening for traditional cardiovascular risk parameters even in the disease with low activity.

AB0870  ASSESSMENT OF FRACTURE RISK IN PATIENTS WITH NON-RADIODGRAPHIC AXIAL SPONDYLOARTHRITIS

H. Ferian1, O. Bouguidua2, W. Tikri3, D. Ben Nessib3, K. Maatallah3, D. Kaffel3
1Kassab orthopedics institute, Rheumatology department, Ksar Said, Tunisia; 2Kassab orthopedics institute, Rheumatology department, Ksar Said, Tunisia; 3Kassab orthopedics institute, Rheumatology department, Ksar Said, Tunisia

Background: Spondyloarthritis (SpA) is a chronic inflammatory disease that predominantly affects the sacroiliac joints and the spine. Patients with SpA have an increased risk of osteoporosis and fracture resulting from a combination of inflammation and immobility. The non-radiographic form for SpA (nr-axSpA) has the same predictors of bone fragility however the real fracture risk is unknown in this phenotype.

Objectives: The main objective of our study was to assess fracture risk in patients with nr-axSpA.

Methods: We conducted a retrospective study including 40 patients with nr-axSpA, according to the ASAS criteria. For the enrolled patients, we collected the clinical and biological data and calculated the disease activity using the Bath Ankylosing Spondylitis disease activity (BASDAI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS).

Functionnal impairment was assessed by the Bath Ankylosing Spondylitis Functional Index (BASFI). We measured the bone mineral density using the dual-energy X-ray absorptiometry (DXA) in the anteroposterior lumbar, lateral spine, and hip joint.

Results: Twenty-seven women (67.5%) and thirteen men (32.5%) were enrolled. The mean age was 41.5 years (±11.2), and the mean disease duration was 3.1 years (±2.7). The mean BASDAI and ASDAS CRP was 4.7 ± 2.5 and 3.6 ± 2.5. The mean BASFI was 3.6 ± 2.5. According to World Health Organization (WHO) criteria, 45% of patients displayed osteopenia and 30% osteoporosis. The mean major osteoporotic fracture (MOF) score was 0.09 ± 0.25 [0-1.3]. The MOF was significantly associated with radiographic hip involvement, and an inverse relation-ship with age at onset (OR 0.955, IC 0.995-0.998, p=0.038).

Conclusion: The major osteoporotic fracture was 0.09 ± 0.25 [0-1.3]. The MOF was significantly associated with radiographic hip involvement and 52 patients were without hip involvement. Multivariate logistic regression analyses showed male sex (OR 3.63; 95% CI 1.55-26.29, p=0.010), Bath Ankylosing Spondylitis Functional Index (BASFI) score (OR 0.436, IC 0.709-1.913, p=0.013), and BASRI-spine score are associated with radiographic hip involvement. AS patients with risk factors for radiographic hip involvement should be diagnosed at an early stage to improve their quality of life.

AB0872  INFLUENCE OF JOINT AND ENTHESIS DAMAGE ON THE QUALITY OF LIFE OF PATIENTS WITH INFLAMMATORY BOWEL DISEASES.

G. Gainullina1, E. Kirillova1, A. Odincova1, D. Abdulganieva1,1Kazan State Medical University, hospital therapy, Kazan, Russian Federation; 2Republican Clinical Hospital of the Ministry of Health of the Republic of Tatarstan, gastroenterology, Kazan, Russian Federation

Background: Inflammatory bowel diseases (IBD) are chronic immune-inflammation diseases that are often associated with various extraintestinal manifestations [1]. Among them, joint involvement is the most common, occurring in 5–20% of patients with IBD [1], while the prevalence of enthesitis varies in studies from 12.5% to 90% of cases [2].

Objectives: To assess the relationship between the state of peripheral joints and entheses in patients with IBD and their quality of life.

Methods: 95 pts with IBD were prospectively enrolled into the study: 55 of them with ulcerative colitis (UC) and 40 with Crohn’s disease (CD). The average age of the pts was 32 (26; 37) years. The average duration of the disease was 44 (12; 95) months. The severity of UC exacerbation was assessed by the Mayo index, in CD – by Harvey-Bradshaw index. In UC, moderate and severe exacerbation was revealed in 40 pts (73%), in CD - in 17 (43%). Among 95 pts with IBD, extraintestinal manifestations occurred in 67 pts (71%), of which 34 (82%) pts with UC and 33 (82%) pts with CD. 14 joints and 68 entheses were evaluated clinically and by US in each pt. The clinical examination included tenderness of enthesis. US examination with power Doppler detected synovitis with / without vasculatization, inflammatory (hypoechochogenicity of enthesis, thickening of enthesis, presence of vascularization) and structural (erosion, entheseophyte) changes in enthesis. The quality of life was assessed using the SF-36 questionnaire that covers eight health domains. Scores for each domain range from 0 to 100, with a higher score defining a more favorable health state. Spearman coefficient used to calculate correlations.

Results: 61 pts with IBD (64%) complained of pain in the joints, 49 pts (52%) noted pain on palpation of entheses. As a result of ultrasound examination, synovitis were detected in 41 pts (43%), including synovitis with vascularization in 20 pts (31%). Enthesitis were found in 72 pts (78%), while vasculatized enthesis was detected in 35 pts (37%). Erosions were identified in 76 pts (80%), and entheseophytes were identified in 37 pts (39%). The average level of physical health was 43.53 (35.67; 51.66), mental health 38.53 (31.13; 48.37).

An inverse correlation was observed between the number of extraintestinal manifestations and physical functioning (SR–0.22; p=0.03). The number of painful joints was inversely correlated with physical functioning (SR=
-0.22; p = 0.036). The number of painful entheses was inversely correlated with physical functioning (SR = -0.26; p = 0.01), physical health (SR = -0.21; p = 0.03). An inverse correlation was observed between the number of synovitis with vascularization and physical functioning (SR = -0.28; p = 0.01), vital activity (SR = -0.29; p = 0.005), physical health (SR = -0.23; p = 0.024). The number of entheses was inversely correlated with the pain intensity (SR = -0.22; p = 0.036).

Conclusion: With an increase in the number of affected joints and enthesis, the physical health of pts decreases, due to physical functioning and pain intensity, as well as their vital activity.

AB0873
ETHNICITY AND PATIENT REPORTED OUTCOME BASDAI IN THE MONITORING OF AXIAL SPONDYLOARTHROPATHY: DOES IT MATTER?
S. Buvayan1, S. Jothimurugan2, A. Moorthy3. 1University Hospitals of Leicester, Rheumatology, Leicester, United Kingdom; 2University Hospitals of Leicester, Medicine, Leicester, United Kingdom; 3University of Leicester, College of Life Sciences, Leicester, United Kingdom

Background: The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is a patient reported outcome (PRO) used in the monitoring of axial spondyloarthritis (axSpA). It is completed by the patient and based on their assessment of disease severity and therefore quite a subjective measure of disease (1). There has been research around the relationship between ethnicity and patient perception in Rheumatology. Many studies have demonstrated that non-Caucasian patients especially South Asians are less likely to engage with patient education, abandon their disease modifying therapy early and have more mistrust with the medical establishment (2). Quite a large population study in America examining axSpA severity in Caucasians, Afro-Caribbean’s and Latinos found Afro-Caribbean and Latino patients to score themselves higher on BASDAI compared to Caucasians (3). With Leicester being such a diverse area, with a particularly high South Asian population we took this opportunity to investigate whether there were ethnic variations in disease severity.

Objectives: The aim was to investigate whether there is a relationship between patient-reported outcome BASDAI and ethnicity. The secondary aim was to investigate the relationship between ethnicity and radiographic findings and extra-articular manifestations.

Methods: Data was collected by retrospective analysis of axSpA patients attending University of Leicester (UHL) axSpA services. Inclusion criteria entailed a diagnosis of axSpA with a documented BASDAI within a year of MRI spine + sacroiliac joints, prior to starting any biological treatment. Data of 149 patients was collected on demographic characteristics, extra-articular manifestations (uveitis, inflammatory back pain, enthesitis, peripheral arthritis, dactylitis, psoriasis, and inflammatory bowel disease), family history, response to NSAIDs, and HLA-B27 status. Data was analysed using Statistical Package for the Social Sciences (SPSS) software to assess the relationship between ethnicity and collected data using Pearson’s chi squared.

Results: Of the 149 patients 68% were White Caucasian, 30% Asian and 1% Black. The average age was 43 and 66% were male and 34% female. The mean BASDAI was 6.5, there was no observable correlation between BASDAI and ethnicity (p=0.668). There was no significant relationship between ethnicity and active sacroiliitis (p=0.926), chronic sacroiliitis (p=0.218) or axial disease (p=0.307). 64 Caucasian patients were HLA-B27 positive compared with 27 Asian and no Black patients were positive however there was no statistical correlation between ethnicity and HLA-B27 (p=0.383). Overall, Caucasians consistently had a higher incidence of extra-articular manifestations compared with non-Caucasians however no significant p values were observed here or with response to NSAIDs, family history or familial HLA-B27 and BASDAI scores, results are summarised in Table 1.

AB0874
TARSITIS IN MEXICAN PATIENTS WITH SPONDYLOARTHRITIS
L. D. Fajardo Harmosillo1, 1Centro Médico Nacional de Occidente IMSS, Rheumatology, Guadalajara, Mexico

Background: Spondyloarthritis (SpA) is a set of autoimmune and auto-inflammatory diseases that share similar manifestations of axial spine and sacroiliac, peripheral joint including oligoarthropathies predominantly of lower limbs, dactylitis, enthesitis and fasciitis, and extraarticular manifestations involvement eyes, skin, nails, bowel and the presence of high c-reactive protein (CRP) levels and Human Leucocyte Antigen (HLA)-B27 seropositivity. Peripheral manifestations such tarsitis (mid-foot arthritis) has been reported associated to ankle arthritis, Achilles tendon enthesitis and plantar fasciitis, besides linked mainly to juvenile-onset forms of SpA (1,2). Tarsitis occurs more frequently in SpA patients of Latin American (23.6%), Asia (9.1%) and less commonly in SpA patients of Europe and North America (5%) and middle-east and North Africa (3.5%) [1,2]. This mid-foot inflammation has not been completely well described in the adult population with SpA, specifically in Mexican adult population [3]. Here is presented the frequency and factors associated to tarsitis in Mexican adult patients with SpA.

Objectives: To determine the frequency and factors associated to tarsitis in Mexican SpA patients.

Methods: That is a cross-sectional, comparative a retrospective study including 211 (≥18 years) Mexican SpA patients recruited from 2012 to 2021 that fulfilled ASAS criteria. Patients with or without presence of tarsitis are included. This work explores demographic factors, clinical features, c-reactive protein levels and pharmacologic treatments in Spa patients with or without tarsitis. It use Chi-square, Student’s-t, U Mann-Whitney tests to univariate analysis and logistic regression to multivariate analysis adjusted for age and gender. The level of significance of statistical tests is less of 5%.

Results: The present investigation involves 211 patients with SpA and 62.6% of them are men. The mean age [standard deviation (SD)] is 43.72 (13.5) years. The mean of age at onset of SpA (SD) is 31.93 (11.3) years. The SpA distribution is axial (42.2%), peripheral (27%) and both (30.8%). A total of 63 (29.9%) patients has tarsitis, of them
AB0875 - ASSESSMENT OF CLINICAL SIGNS OF SPONDYLOARTHRITIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

E. Belousova1, D. Abdulganieva1, M. Protopopov2. 1Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation; 2Charité – Universitätsmedizin Berlin, Rheumatology, Berlin, Germany

Background: Patients with inflammatory bowel disease (IBD), Crohn’s disease (CD) and ulcerative colitis (UC), commonly face the presence of extraintestinal manifestations (EIMs). Spondyloarthritides (SpA) is present in about 10-39% of patients with IBD, being the most frequent EIM [1]. Diagnosis of axial SpA (axSpA) in IBD represents a clinical challenge. The diagnostic value of Ankylosing Spondylitis Assessment Society (ASAS) criteria that are used for defining inflammatory back pain (IBP) in axSpA, in patients with the association of axSpA and IBD is not clear.

Objectives: To determine the diagnostic value of ASAS criteria for IBP (2009) and to evaluate factors that are associated with a higher risk of axial SpA in patients with IBD.

Methods: The study included 91 patients with IBD (UC - 52 patients (57.1%), CD - 39 (42.9%), males - 47, (51.6%), mean age 40.2±11.7 years, duration of IBD - 77±7.6 years), IBP was defined by ASAS criteria (2009). AxSpA in patients with IBD is recommended to be diagnosed by the combination of Inflammatory Back Pain (IBP), and imaging (MRI and X-ray) [2]. Imaging of lumbar spine and sacroiliac joint was performed to patients, who fulfilled the ASAS criteria for IBP. X-ray - 55 patients; MRI (T1, STIR) - 41 patients. Imaging was considered positive when patients had at least unilateral sacroiliac stage 2 or higher according to the accepted grading system on X-Ray, or MIRI-verified sacroiliitis.

Results: Low back pain was observed in 84 (92.3%) patients with IBD, 39 (42.9%) patients fulfilled the criteria for ASAS for IBP. MRI-verified sacroiliitis was present in 26 patients. Changes on X-ray were present in 40 patients. After imaging, 26 patients were diagnosed with axSpA, 14 of them fulfilled the modified New York criteria for the ankylosing spondylitis. Diagnostic value of the ASAS criteria was the following: sensitivity 76.9%, specificity 62.2%, PPV 0.51, NPV 0.87, LR+ 2.3, LR- 0.3 (ECOG consensus definition used as the “gold standard”). Presence of arthritis - OR 10.77 [95% CI 2.26-44.4], p=0.005, arthralgia - OR 4.12 [95% CI 1.55-10.95], p=0.005, CD - OR 2.92 [95% CI 1.14-7.48], p=0.025 and IBP - OR 8.07 [95% CI 2.8-23.23], p<0.001 was associated with a higher risk of axSpA diagnosis in the univariate analysis. No statistical significance was no difference between patients with and without USE regarding the disease duration, age at onset but those with USE showed less diagnostic delay (p = 0.03). Clinical enthesitis and peripheral arthritis were more frequent in those with USE (50% vs 22.7% and 25 vs 13.6% respectively). No significant statistical difference was found between the inflammatory, structural and total scores of USE and BASRI, BASFI and BASDAS (p > 0.05). No correlation could be detected between BASRI and USE scores (rs= 0.12, p=0.45 for inflammatory, =0.25, p=0.11 for structural and =0.18, p=0.20 for total score). There was a positive correlation between BASMI and both inflammatory and total scores of USE (rs= 0.485, p<0.003). No significant association between BASDAI, CRP or ESR and USE scores.

Conclusion: Ultrasonographic peripheral enthesal abnormalities couldn’t reflect the spinal radiographic changes or disease assessment parameters in patients with radiographic axial SpA. However, these results can be considered preliminary and more studies on wider scales are needed to support our findings.

AB0877 - QUANTIFICATION OF THE ENTHESIC RESPONSE TO BIOLOGICAL THERAPIES IN PATIENTS WITH SPONDYLOARTHRITIS BY COMPUTER ANALYSIS OF ULTRASOUND IMAGES.

M. Tortosa-Cababás1, C. Guillén-Asstete1, Á. Andreu-Suárez1. 1Hospital Ramón y Cajal, Rheumatology, Madrid, Spain

Background: Enthesitis is the base of the pathophysiology of spondyloarthritis. Recently, our group has shown that computer analysis of static images can be used in the evaluation of patients with enthesitis inflammatory diseases with good intra-patient and intra-observer validity and sensitivity to change.

Objectives: To determine the enthesic evolution in patients with spondyloarthritides (SpA) treated with three different biological therapies through the computer analysis of ultrasound images.

Methods: We selected patients diagnosed with SpA and enthesis followed by imaging, who started biological therapy with a TNF inhibitor, an IL17 inhibitor or an IL12/23 inhibitor. For the records to be included, it was necessary to have clinical information from the period of performing the ultrasound. All images were obtained from the Achilles tendon, with the same ultrasound equipment, grayscale and settings for each patient. To homogenize the results of the analysis, the grayscale intensity mean index (IMIG) was used, which has been shown to appropriately discriminate the enthesial pathology from the mechanical or healthy controls as well as being sensitive to change.

Results: 14 patients were included: 6 treated with a TNF inhibitor, 4 with an IL17 inhibitor and 4 with an IL12/23 inhibitor. Patients 2, 3, 5, 7, 10, 11, and 12 had enthesophytes.
In the global analysis, the IMIG did not show statistically significant differences between the treatment groups at the start of the treatment, at the intermediate and at the final evaluation (P=.588, .739 and .674, respectively). Patients with enthesophyses presented significantly higher baseline, intermediate and final IMIG than patients without them: 1.26 SD ± 0.14 vs 0.85 SD ± 0.05 (t=7.407, P=.001), 1.24 SD ± 0.15 vs 0.97 SD ± 0.01 (t=3.659, P=.006), and 1.21 SD ± 0.12 vs 1.05 SD ± 0.07 (t=2.342, P=.03), respectively. Analyzing only the patients without enthesophysis, the final IMIG showed statistically significant differences between the 3 administered treatments (ANOVA, F=8.142, P=.027), being relevant between the use of IL12/23 and TNF inhibitor in favor of the former (Bonferroni, P=.03). In the same subgroup of patients without enthesophysis, IMIG analysis over time showed statistically significant differences between final and baseline IMIG (Friedman -1.938, P=.000).

Conclusion: Computer analysis of ultrasound images using the IMIG distinguishes therapeutic responsive patients in patients without enthesophyses. The interposition of enthesophysis impedes the correct visualization of the enthesis and does not allow ultrasound changes to be detected in some areas of the image. Although there are indications that the use of this analysis could also predict the behavior of certain therapies, it is convenient to propose prospective studies with homogeneous ultrasound controls.

Disclosure of Interests: Marina Tortosa-Cabañas: None declared, Carlos Guillén-Astete Speakers bureau: Novartis, Janssen, Abbvie, Grunenthal, UCB and Gebro. Paid instructor for: Roche, Novartis, Janssen, Esteve and Menarini, Consultant of: Janssen, Novartis and Roche, Grant/research support from: Pfizer, Grunenthal, Gebro and Novartis, Africa Andreu-Suárez: None declared

Results: A total of 129 patients with r-axSpA were included in the study. No patient took supplements of vitamin D at baseline. Patients had an average age (mean±SD) of 36.5±10.5 years, 63.4% were males and 66.6% were HLA-B27 positive. The prevalence of vitamin D deficiency in our cohort was 54.3%. Patient characteristics and disease activity were comparable with regard to the presence of vitamin D at baseline (Table 1); with the exception of body mass index (BMI), which was higher in patients with vitamin D deficiency. In the multivariable linear regression analysis, baseline serum level of vitamin D was independently and significantly associated with higher change in BASDAI and ASDAS (Figure 1).

Figure 1. Association between the response to bDMARDs (change in BASDAI and ASDAS after 6 months) and level of vitamin D at baseline in patients with radiographic axial SpA in the multivariable regression analysis.

Conclusion: Higher vitamin D levels at baseline may predict a better treatment response to bDMARDs in patients with r-axSpA. It has to be shown, however, if vitamin D supplementation might result in a better treatment response in axial SpA.

Psoriatic arthritis - treatment

**AB0879 INTERIM ANALYSIS OF BASELINE CHARACTERISTICS AND 12-WEEK OUTCOMES FOR A SUBSET OF PATIENTS WITH MODERATE-TO-SEVERE PLAQUE PSORIASIS AND PSORIATIC ARTHRITIS FROM THE PSORIASIS STUDY OF HEALTH OUTCOMES**

L. E. Kristensen1, F. Behrens2,3, L. Puig4, A. Reich5, T. Holzkaemper6, A. Brabric7, K. Nyg6, S. Liu Leeg6, C. Schuster7, A. Pinter8,8,8, Bispebjerg and Frederiksberg Hospital, The Parker Institute, Copenhagen, Denmark; 2Goethe University, Rheumatology University Hospital, Frankfurt, Germany; 3Goethe University, Fraunhofer Institute for Translational Medicine & Pharmacology (ITMP) and Cluster of Excellence Immune-Mediated Diseases (CIMD), Frankfurt, Germany; 4Hospital de la Santa Creu i Sant Pau, Universitat Autònoma de Barcelona, Department of Dermatology, Barcelona, Spain; 5Medical College of Rzeszow University, Institute of Medical Sciences, Department of Dermatology, Rzeszow, Poland; 6Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America; 7Medical University of Vienna, Department of Dermatology, Vienna, Austria; 8University Hospital Frankfurt, Clinic for Dermatology, Venerology and Allergology, Frankfurt, Germany

**Background:** Approximately 30% of patients (pts) with plaque psoriasis (PsO) develop psoriatic arthritis (PsA), which is associated with high Psoriasis Area and Severity Index (PASI) and nail involvement. The Psoriasis Study of Health Outcomes (PSoHO) is a 3-year (yr), international, prospective, observational cohort study comparing the effectiveness of anti-IL-17A biologics to all other approved biologics in pts with moderate-to-severe PsO.

**Objectives:** This interim subset analysis describes the baseline characteristics and Week 12 (W12) effectiveness in pts with moderate-to-severe PsO and PsA in PSoHO.

**Methods:** Adults with moderate-to-severe PsO for ≥6 months who initiated switched biologic treatment during routine medical care were enrolled. PsA diagnosis was recorded by the dermatologists based on the medical history and/or information provided by the patient. W12 effectiveness was assessed by the proportion of pts achieving almost clear or clear skin defined by ≥90% improvement in PASI, affected Body Surface Area (BSA), Dermatology Life Quality Index (DLQI), and Patient Global Assessment of Disease Severity (PatGA). Musculoskeletal endpoints were not collected. Data were analysed descriptively, using mean (standard deviation [SD]) or median (Q1/Q3) for continuous variables and n, % and 95% confidence limits for categorical variables.

**Results:** Overall, 1981 pts were enrolled in this study, of whom 461 (23.3%) had a PsA diagnosis and received either anti-IL-17A (n=227; 49.2%) or other biologics (n=234; 50.8%). This subset of pts had a mean age of 48.7 yrs and a median disease duration of 18.9 yrs for PsO and 5.6 yrs for PsA (Table 1).

**Table 1. Baseline characteristics for PsO patients with PsA. Mean (SD) reported for all available data for that measure, unless stated otherwise.**

</table>

**BMI = Body Mass Index; BSA = Body Surface Area; DLQI = Dermatology Life Quality Index; HADS = Hospital Anxiety and Depression Scale; HADS >10 indicates significant symptoms of depression/anxiety; mNAPSI = Modified Nails Psoriasis Severity Index; PASI = Psoriasis Area and Severity Index; PatGA = Patient Global Assessment of Disease Severity; Q1/Q3 = Quartile 1/3.**

At W12, 62.4% and 42.6% of anti-IL-17A-treated pts achieved PASI90 and PASI100, respectively, compared with 34.2% and 16.8% in the other biologics cohort, respectively (Figure 1). BSA <3% was reached by 70.9% of anti-IL-17A-treated pts and 49.5% in the other biologics cohort, while 71.2% and 44.8%, respectively, reached PatGA 0/1. Among pts with baseline DLQI ≥2, 38.0% and 27.1% of the anti-IL-17A and other biologics cohorts, respectively, reached DLQI 0/1.

**Conclusion:** The effectiveness of blocking IL-17A on skin manifestations and on quality-of-life improvements in pts with PsO and PsA in the real-world study was consistent with observations from clinical trials.

**Scientific Abstracts**
Background: Therapeutic inertia (TI), or clinical inertia, is the medical behavior of not initiating or intensifying treatment when recommended by clinical recommendations (1). TI was established in diabetes and then studied in hypertension, multiple sclerosis and psoriasis, and is estimated to affect 30 to 70% of physicians managing patients with chronic diseases (2-4). To our knowledge, no data have reported TI in the setting of psoriatic arthritis (PsA).

Objectives: The aim of this survey was to conduct an assessment of treatment inertia and of PsA in France.

Methods: 825 French rheumatologists were contacted by e-mail between January and March 2021 and asked to complete an online questionnaire, consisting of 7 clinical vignettes illustrating common situations and reflecting the polymorphic character of PsA: five clinical cases (oligoarthritis, enthesitis, polyarthritis, nail psoriasis, and psoriatic auricular plaques) requiring treatment optimization (1), and two “control” clinical cases (DIP arthritis, atypical axia) not requiring any change of treatment. The rheumatologists were also questioned about their routine practice and perception of PsA.

Results: 101 (12%) of the rheumatologists contacted completed the questionnaire. Sixty percent of the respondents were men, and 45% of rheumatologists had been practicing between 46 and 60 years; most practiced exclusively in hospitals (34%), private practice (33%) or in both (34%); the mean duration of clinical practice was 23 years. Almost all of the respondents stated that they were comfortable with the management of PsA (99%) and familiar with French and EULAR recommendations (90%). There was general consensus regarding the difficulties inherent in PsA: therapeutic objectives difficult to achieve (74% of respondents); polymorphic character (72%); access to biological drugs (70%); cognitive/drug burden (67%); and uncertainty (comorbidities and polyarticular involvement) generated the least uncertainty (27%). The rate of TI we observed for PsA is similar to published data for other chronic diseases (1). The clinical cases that induced the most TI were “oligoarthritis” and “enthesitis” with 20% and 19% of respondents not modifying treatment, respectively. Conversely, the vignettes “polyarthritis in relapse,” “neoplastic history” and “cardiovascular risk” generated fewer TI with 6%, 8% and 11% of respondents, respectively, choosing not to change the current treatment.

Conclusion: Despite a good knowledge of PsA and associated clinical recommendations, almost half of the rheumatologists we surveyed demonstrated at least one TI. The rate of TI we observed for PsA is similar to published data for other chronic diseases (1). The clinical profiles for which there was the least uncertainty (comorbidities and polyarticular involvement) generated the least inertia; the more complex profiles oligoarthritis and enthesitis generated more inertia. Our study is the first to show the existence of clinical inertia in PsA and further research is warranted to ascertain the reasons behind this inertia.

AB0083 REAL-WORLD TREATMENT PATTERNS IN PATIENTS WITH PSORIATIC ARTHRITIS

J. Chol1, A. Sreih2, T. Lehman3, M. Suryavanshi4, Q. Xia5, M. Nowak6, 7Bristol Myers Squibb, HEOR, Immunsience, Princeton, United States of America; 7Bristol Myers Squibb, Clinical Research & Development, Princeton, United States

Background: Guselkumab is the first human monoclonal antibody that binds selectively to the p19 subunit of IL23. It's approved for the treatment of moderate to severe psoriasis and psoriatic arthritis. Objectives: We present a case series of patients with psoriasis and/or psoriatic arthritis who had a good response to Guselkumab and their cardiovascular risk factors.

Methods: An observational and retrospective study of patients with psoriasis and/or psoriatic arthritis under treatment with Guselkumab in the Dermatology and Rheumatology consultation at our hospital. A total of 11 patients were included. Baseline characteristics, comorbidities, and cardiovascular risk were collected. The SCORE (European High Risk Chart) and cardiovascular risk categories (European Society of Cardiology, European Atherosclerosis Society 2019) were used. Disease severity and treatment response were assessed by PASI, DLQI, DAPSA and ASDAS at baseline and after 12, 24 and 36 weeks.

Results: Our cases had a mean age of 52.43 years. 63.6% of them were women. A total of 45.5% had polyarticular psoriatic arthritis, 90.9% were obese, 45.45% were type 2 obesity, with a mean BMI of 34.88. Dyslipidaemia and hypertension were observed in 54.5% and 72.7% of the patients, respectively. They all had varying degrees of Non-alcoholic fatty liver disease (NAFLD). A total of 45.5% had SCORE >1% and 90.9% were in moderate category of cardiovascular risk. At baseline their disease parameters were: PASI=11.09 ± 7.01, DAPSA=15.09 ± 7.33, DLQI=19.11 ± 9.95 and ASDAS=2.12 ± 0.43. After 12 weeks of treatment, the mean reduction of PASI and DLQI was 7.09 and 6.45, which continued improving at week 36. None of them were naive. There were no adverse effects, with a treatment survival of 76.73 weeks ± 42.93.

Conclusion: Guselkumab showed excellent results in our clinical practice in the control of psoriasis and/or psoriatic arthritis in non-naive patients with cardiovascular risk factors, with a good safety profile.

Disclosure of Interests: None declared

Background: Psoriatic arthritis (PsA) is a complex inflammatory disease with manifestations that play an important role in treatment selection.1,2 Treatments include oral agents, biologic therapies (inhibitors of tumor necrosis factor [TNFi], interleukin [IL]-17A, IL-12/23), cytokine/cytolymphocyte–associated antigen 4 inhibitor [CTLA-4i]), and new targeted oral agents (inhibitors of phosphodiesterase 4ase-[PDE-4i] and Janus kinase [JAKKi]).1,2 Few studies have examined real-world treatment patterns of recently approved therapies.

Objectives: Evaluate real-world treatment patterns for branded systemic therapy in patients with PsA.

Methods: In this retrospective study, medical and pharmacy claims from the US IBM MarketScan Commercial and Medicare databases (1/1/2012–12/31/2019) were used to identify patients with PsA who initiated treatment with a TNFi (adalimumab, etanercept, infliximab, golimumab, or certolizumab), IL-17Ai (secukinumab, ixekizumab), IL-12/23i (ustekinumab), IL-23pi (guselkumab), CTLA-4i (abatacept), JAKi (tofacitinib), or PDE-4i (apremilast). Patients (≥18 years) with ≥1 prescription, ≥2 PsA claims separated by ≥1 day on or before the index date (first prescription date [1/1/13–12/31/2018]), and 1-year continuous enrollment before and after the index date were eligible. Treatment patterns were grouped into continuers, discontinuers, and patients with treatment modification (switchers [without a treatment gap], reinitiators [same drug with a treatment gap], and restarters [different drug with a treatment gap]) (Table 1). Patients were followed for 1 year or until treatment modification, whichever came first. Descriptive statistics were used.

</tr>
<tr>
<td>Restarters</td>
<td>Prescription claims for DIFFERENT therapy AFTER treatment gap*</td>
<td>428/6455  (6.6)</td>
</tr>
</tbody>
</table>

Note: All terminology applies to cohorts within the first year of treatment. Treatment gap: gap of 200% of recommended dosing schedule from end of previous prescription’s day’s supply.

Results: A total of 6455 patients were included (mean age, 50.5 years; 55.5% female; mean Charlon Comorbidity Index score, 0.54). At baseline, the most commonly used therapies were immunosuppressants (58.5%), corticosteroids (52.2%), and nonsteroidal anti-inflammatory drugs (45.9%). Treatments most used at index were TNFi (72.5%, including adalimumab [41.6%] and etanercept [23.8%]) and the PDE-4i apremilast (21.1%). During the 1-year study period, 29.6% of patients maintained their index therapy and 25.0% discontinued. Treatment modification was observed in 45.1% of patients; 12.3% switched to a new therapy without a treatment gap, 26.1% restarted their index therapy, and 6.6% started a new therapy after a treatment gap.

Conclusion: Among patients with PsA, there is substantial variability, including high rates of discontinuation within the first year and after index therapy. Further studies are warranted to understand reasons for these treatment patterns.

AB0884

DISEASE OUTCOMES IN PATIENTS WITH PSORIATIC ARTHRITIS COMPLETING 12 MONTHS OF APREMILAST TREATMENT - REAL-WORLD DATA FROM THE REWARD STUDY

R. Bos1, T. Jansen1, I. Bridges3, S. De Jong, M. Via3, MC. Rheumatology, Leeuwarden, Netherlands; 2Viecurie, rheumatology, Venlo, Netherlands; 3Amen, Biostatistics, Uxbridge, United Kingdom; 4Beda, Medical, Breda, Netherlands; 5Erasmus, rheumatology, Rotterdam, Netherlands

Background: Patients with moderately active psoriatic arthritis (PsA) and limited joint involvement have considerable disease burden1,2. Recent data shows these patients have a high likelihood of achieving treatment goals if treated with apremilast.3 This is the first report of outcomes in patients with PsA who received apremilast for 12 months in Dutch clinical practice.

Objectives: We report disease outcomes, including the PsA Impact of Disease (PsAID) 12-item questionnaire, swollen joint count (SJC), tender joint count (TJC), dactylitis and enthesitis, among patients in the prospective, multicenter, observational REWARD study who completed 12 months of apremilast treatment.

Methods: The ongoing REWARD study enrolled patients who had initiated apremilast for the treatment of PsA in the Netherlands between 13 April 2017 and 24 March 2021, and includes up to 12 months follow-up.1,5 We report interim data from patients with data available as of 16 September 2021. Baseline data are summarized separately for patients who discontinued apremilast before their month 12 study visit (stoppers) and patients still receiving apremilast at their month 12 visit (completers). Post baseline data are summarized for completers. Continuous data are summarized using mean and SD, categorical data are summarized using n and percent.

Results: 98 patients were included in this interim analysis; 32 had completed 12 months of apremilast treatment (completers), 54 had discontinued apremilast before month 12 (stoppers), 12 were ongoing in the study. Compared with stoppers, completers were more likely to be biologic naïve and have dactylitis, and had lower BSA. All other baseline characteristics were similar (Table 1). Among completers, all PsAID domains improved after 3 months of apremilast treatment and these improvements were maintained through month 12 (Figure 1). Mean SJC and TJC decreased between baseline and month 12 (SJC, 4.2 and 1.0 at baseline and month 12, respectively; TJC, 7.1 and 3.3, respectively). The proportion of completers with SJC, TJC, enthesitis and dactylitis scores of 0 increased from baseline to month 12 (Figure 1B). The proportion of completers reporting at least one adverse event (AE) was comparable to the overall study population (14/32 [44%] and 48/98 [49%], respectively); the reported adverse events were similar to the known safety profile of apremilast.

All patients included in this interim analysis; Completers= patients that received apremilast for 12 months; Stoppers= patients that stopped apremilast prior to 12 months; BSA=Body Mass Index, PsAID=Psoriatic Arthritis Impact of Disease, VAS=Visual Analog Scale, CRP= C-reactive protein, cDAPSA=Clinical Disease Activity in Psoriatic Arthritis, Rem=Remission, Mod=Moderate, PsA=Psoriatic Arthritis.
Figure 1. (A) PSAID scores in completers and (B) percentage of completers with no swollen joints, no tender joints, no dactylitis and no enthesitis at baseline (BSL), month 3, 6 and 12 (M3, M6, M12).

Conclusion: In this interim analysis of the REWARD study, patients completing 12 months of apremilast treatment were more likely to be biologic naïve than patients who discontinued apremilast within 12 months of initiation, and had significant decreases in TJC, SJC, dactylitis and enthesitis during apremilast treatment. Completed patients also reported decreased PSAID scores during apremilast treatment, indicating improvements in their quality of life.

AB0885

REFRACTORY CHRONIC SYNOVITIS OF THE COMMON FLEXOR SYNOVIAL SHEATH IN PSORIATIC ARTHRITIS PATIENT SUCCESSFULLY TREATED BY ULTRASOUND GUIDED LOCAL METHOTREXATE INJECTION.

A. Abogamal1,2, 1Al Azhar Faculty of Medicine, Rheumatology, Cairo, Egypt; 2Dr Sulaiman Al Habib Hospital in Dubai, Rheumatology, Dubai, United Arab Emirates

Background: Psoriatic arthritis (PsA) is a variant of inflammatory musculoskeletal conditions that usually associated with skin psoriasis. PsA is typically heterogenous in comparison to other rheumatic diseases, It affects multiple musculoskeletal domains including synovitis of peripheral and axial joints, entheses, and tendons with tenosynovitis.[1,2] Persistent cases of arthritis or tenosynovitis usually controlled by local injection with corticosteroids, though some refractory cases of chronic synovitis still not sufficiently controlled by corticosteroid local injection with some case series shows a significant response to local DMARDs and even local Biologics.[3-6]

Objectives: To describe a case of psoriatic arthritis with chronic synovitis of the common flexor synovial sheath successfully treated by ultrasound guided local Methotrexate injection.

Methods: 31 Years old female with psoriatic arthritis in the form of symmetric hand arthritis for the last 10 years, and extensive nail disease shows partial control under treatment with Methotrexate after failure of sulfasalazine. Her DAPSA score usually ranges between 16 to 18 with tender persistent fluctuating cystic swelling overlying her right palm extending proximally to the distal third of the forearm that becomes more tense on fingers flexion. Ultrasound examination shows hypoechoic distension of the right common flexor synovial sheath, that is partially compressible and partially displaceable with highly positive Doppler signals indicating active synovitis. Figure 1

October 2019, ultrasound guided aspiration and local corticosteroid injection applied for the common flexor sheath with escalation of her treatment to bzkizumab plus Methotrexate to achieve clinical remission. January 2020, patient achieve DAPSA 8 with resolution of have nail lesions, though her right hand function was still significantly impaired due to the refractory persistent synovitis of the Common flexor sheath. Two doses 15mg Methotrexate one week apart inserted into the common flexor sheath under ultrasound imaging.

Results: April 2020, on regular follow up patient achieve DAPSA remission <4, with complete resolution of the right palm swelling and she reports complete recovery of her hand function which is maintained up to January 2022 in her last
follow up visit. Follow up ultrasound scan shows normalization of the common flexor sheath with disappearance of the mixed picture of synovitis and effusion. Figure 1

Conclusion: Refractory synovitis of the common flexor sheath in PsA successfully treated with ultrasound guided local methotrexate injection with persistence of improvement for one year.

THE IMPACT OF DEUCRAVACITINIB ON HEALTH-RELATED QUALITY OF LIFE MEASURED BY THE SHORT FORM HEALTH SURVEY 36-ITEM QUESTIONNAIRE: ANALYSIS OF A PHASE 2 TRIAL IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

V. Strand, P. J. Mease, A. Deodhar, J. Ye, M. Nowak, J. Choi, B. Becker

Background: Patients (pts) with psoriatic arthritis (PsA) experience pain, loss of physical function, joint damage, and significant impairments in social and emotional well-being. The Short Form Health Survey 36-item questionnaire (SF-36v2), a generic measure of pt-reported health-related quality of life (HRQOL), includes 36 items and measures 8 domains—physical functioning (PF), role-physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role-emotional (RE), and mental health (MH)—that contribute to both physical component summary (PCS) and mental component summary (MCS) scores. Deucravacitinib (DEUC) is a novel, oral, selective, allosteric inhibitor of tyrosine kinase 2 (TYK2), an intracellular kinase that mediates cytokine signaling pathways implicated in PsA pathogenesis. In a Phase 2 trial in pts with active PsA, DEUC was well tolerated and significantly more efficacious than placebo (PBO) after 16 weeks (wk) of treatment.1

Objectives: To further evaluate the effect of DEUC treatment on SF-36 scores.

Methods: This double-blind Phase 2 trial (NCT03881059) enrolled pts with a PsA diagnosis ≥6 months who fulfilled Classification Criteria for Psoriatic Arthritis at screening and had active joint disease ≥3 tender and ≥3 swollen joints, high-sensitivity CRP ≥3 mg/L, and ≥1 plaque psoriasis lesion (≥2 cm). Pts failed or were intolerant to ≥1 nonsteroidal anti-inflammatory, conventional synthetic DMARD, and/or 1 TNF inhibitor (≥30%). Pts were randomized 1:1:1 to DEUC 6 mg once daily (QD) or 12 mg QD, or PBO. Changes from baseline (BL) in SF-36 PCS and MCS scores at Wk 16 were prespecified key secondary and additional endpoints, respectively. The 8 SF-36 domain scores were evaluated at Wk 16. The proportions of pts reporting improvements ≥2.5 and ≥5 points (the minimum clinically important difference [MCID]) in SF-36 summary and domain scores, respectively, were evaluated.

Results: Of 203 pts randomized, 180 (89%) completed 16 wks of treatment: DEUC 6 mg QD, 63/70 [90%]; DEUC 12 mg QD, 59/67 [88%]; PBO, 58/66 [88%]. Demographic and BL disease characteristics were similar across groups. BL mean SF-36 PCS and MCS scores were similar among DEUC 6 mg QD, 12 mg QD, and PBO groups (PCS: 43.0, 43.5, and 33.4; MCS: 45.4, 46.9, and 41.7, respectively). At Wk 16, adjusted mean changes from BL in SF-36 PCS and MCS scores were significantly improved with DEUC 6 and 12 mg QD treatment vs PBO (PCS: 5.6, 5.8, and 2.3; MCS: 3.6, 3.5, and 0.7, respectively; P<0.05).

Reported improvements in domain scores with both doses exceeded MCID and were significant in 5 of 8 domains with DEUC 6 mg QD (PF, RP, BP, VT, and SF) and 6 of 8 domains with DEUC 12 mg QD (RE in addition; Figure 1 and Table 1).
Background: Tumor necrosis factor inhibitors (TNFi) are frequently chosen as the first biologic therapy for patients (pts) with psoriatic arthritis (PsA), though a sizeable proportion of pts have an inadequate response (IR), and some may also have intolerance. Guselkumab (GUS), a human mAb that targets the IL-23 p19 subunit, provides an alternative mechanism of action to treat PsA. In the Phase 3 (Ph3) DISCOVER-1 study of GUS in active PsA, GUS every 4 weeks (Q4W) and Q8W clinical response rates were generally consistent between TNFi-naïve (283 pts) and TNFi-experienced (118 pts) cohorts. In the TNFi-experienced cohort and the limited number of DISCOVER-1 pts with IR to their prior TNFi (N=44), American College of Rheumatology (ACR) 70% improvement (ACR70) and ACR20 response rates at W24 were numerically higher in GUS Q4W- than Q8W-treated pts.1

Objectives: To further investigate whether GUS Q4W could provide incremental benefit to some TNFi-IR PsA pts by analyzing the existing DISCOVER-1 dataset to facilitate the design of a new clinical trial.

Methods: Study feasibility assessments included comparison of key efficacy endpoints by treatment group at W24 among TNFi-experienced pts receiving GUS Q8W and Q4W. DISCOVER-1 Results from the DISCOVER-1 study also informed sample size power calculations for a primary endpoint of ACR20 response at W24 in a future study in a TNFi-IR PsA pt population.

Results: Comparison of several efficacy endpoints (ACR70 response, minimal disease activity, Investigator’s Global Assessment [IGA] of psoriasis 0/1 response) across treatment groups in the TNFi-experienced DISCOVER-1 cohort supports a potential dose response, with more frequent GUS administration eliciting numerically higher response rates (Table 1). A similar trend was observed for ACR20/50/70 responses in the smaller TNFi-treated population1, though these findings should be interpreted with caution due to limited sample size. ACR20 response rates at W24 of DISCOVER-1 were employed to estimate sample size requirements for a new study. Assuming comparable rates of GUS treatment effect seen in DISCOVER-1, a sample size of 150 randomized pts per group for PBO, GUS Q8W, and GUS Q4W would provide >90% power to detect a significant difference between each GUS group and PBO for ACR20 response at W24. Based on these findings, a new Ph3b, multicenter, randomized, double-blind, placebo-controlled study, SOLSTICE, was designed to further evaluate the efficacy and safety of GUS in approximately 450 pts with active PsA who had IR to one prior TNFi, and to investigate the effect of GUS dosing interval in this important cohort of pts with PsA (Figure 1).

*IGA score of 0 (clear) or 1 (almost clear) among pts with ≥3% body surface area of psoriasis involvement and an IGA score ≥2 (mild-to-severe psoriasis) at baseline.2

Conclusion: PsA pts with TNFi-IR are typically difficult to treat. Overall data from the DISCOVER-1 study of GUS in pts with active PsA showed consistent clinical response between doses and between TNFi-naïve and TNFi-experienced pts. Analyses based on limited numbers of TNFi-experienced pts from DISCOVER-1 demonstrated potential incremental benefit for achievement of higher response criteria with more frequent dosing in some TNFi-IR pts. SOLSTICE, a Ph3b, randomized, placebo-controlled study, will test this hypothesis.

Background: Psoriatic arthritis (PsA) impacts patients’ (pts) work productivity (WP) and daily activity.1 DISCOVER-2 (D2), a Phase 3 trial of the selective interleukin-23 p19-subunit inhibitor guselkumab (GUS) in biologic-naive pts with PsA,2 demonstrated significant improvements in pt-reported WP and daily activity following 1 year (Y) of GUS treatment.3

Objectives: Assess WP and daily activity impairment in D2 pts through 2Y. Estimate indirect savings associated with GUS treatment and assess changes in employment status.

Methods:Pts with active PsA received GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO). At W24, PBO pts crossed over to GUS 100 mg Q4W. WPAI-PsA assessments were done at each visit throughout 2Y (Figure 1). Potential annual indirect savings from improved overall WP were estimated using 2020 European Union mean yearly wage estimate (all occupations) combined with LS mean change from baseline in WPAI-PsA overall work impairment.4 A shift analysis evaluated proportions of pts employed vs unemployed by treatment group using observed data over time.

Results: Pts included 64% of the analysis cohort. Significant improvements in WP in pts EBL and in daily activity among all pts were observed with continued GUS through 2Y (Table 1). Potential annual indirect savings from improved overall WP in pts EBL were €10,826 GUS Q4W, €12,712 GUS Q8W, and €10,948 PBO → GUS Q4W at 2Y. Shift analysis showed relatively stable employment in pts EBL with GUS up to 2Y (>83% continued to work). Among pts UBL (36% of cohort), the proportion of pts employed increased by >20% through 2Y of GUS (Figure 1). A shift analysis evaluated proportions of pts employed vs unemployed by treatment group using observed data over time.

Conclusion: In GUS-treated bio-naive PsA pts, robust improvements in WP and daily activity seen at W24 were maintained and increased through 2Y of GUS. Long-term improvements in WP achieved may result in substantial indirect cost savings for GUS-treated pts. Rates of employment remained stable in pts employed and increased in those unemployed at BL.

1Mean changes in WPAI-PsA domains were calculated for each MI dataset using an ANCOVA; reported LS mean (95% confidence interval [CI]) = average of all MI datasets. *p<0.05
(PROs) have been well-established in PsA and are important indicators of patient improvement while on treatment. To date, the association between PROs and disease control in PsA has not been fully characterized.

Objectives: We examined the association between clinically meaningful improvement in PROs and stringent measures of disease control among patients with PsA enrolled in the Phase 3 SELECT-Psa 1 trial.

Methods: Patients with active PsA and an inadequate response to ≥1 non-biologic DMARDs were randomized to receive upadacitinib (UPA) 15 mg once daily (QD), UPA 30 mg QD, adalimumab (ADA) 40 mg every other week, or PBO for 24 weeks. PROs included: Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F), 36-Item Short-Form Health Survey (SF-36), and Work Productivity and Activity Impairment (WPAI). Measures of stringent disease control included achievement of minimal disease activity (MDA), ACR70 response, and remission based on Disease Activity Index in PsA (DAPSA ≤4.0) or PsA Disease Activity Score (PASDAS ≤1.9). The percentage of patients achieving stringent disease control was determined among patients reporting vs not reporting PRO improvements ≥ minimal clinically important differences (MCID) in the combined active treatment and PBO group at Week 24.

Results: A total of 1704 patients were included in the SELECT-Psa 1 trial, of whom 59.2%, 72.4%, 51.3%, 62.3%, 64.6%, and 63.9% reported improvements ≥ MCID for all PROs vs those who did not get it (Figures 1, 2). Similar results were seen in patients achieving PASDAS remission except for SF-36 MCS score (Figure 2). Among patients reporting improvements ≥ MCID across all PROs, more patients achieved ACR70 and MDA responses (29%-49%) with fewer patients achieving DAPSA or PASDAS remission (14%-19%).

Conclusion: PsA patients who reported clinically meaningful improvements in key PROs: fatigue, quality of life, and work productivity were more likely to achieve stringent measures of disease control. These results suggest a close association between meaningful improvements in patient-centric outcomes and achievement of stringent disease control.

We examined the association between clinically meaningful improvement in PROs and stringent measures of disease control among patients with PsA enrolled in the Phase 3 SELECT-Psa 1 trial. The percentage of patients achieving MDA, ACR70 or DAPSA remission, WPAI overall work impairment, and WPAI presenteeism, respectively, at week 24. The percentage of patients achieving MDA, ACR70 or DAPSA remission, WPAI overall work impairment, and WPAI presenteeism, respectively, at week 24. The percentage of patients achieving MDA, ACR70 or DAPSA remission, WPAI overall work impairment, and WPAI presenteeism, respectively, at week 24. The percentage of patients achieving MDA, ACR70 or DAPSA remission, WPAI overall work impairment, and WPAI presenteeism, respectively, at week 24.
EXPLORATORY ANALYSIS FROM A PHASE 2 STUDY

DEUCRAVACITINIB EFFICACY IN PSORIATIC ARTHRITIS BY BASELINE DMARD USE: ADOBE®

Background: Psoriatic arthritis (PsA) treatment guidelines recommend that patients (pts) inadequately responding to conventional synthetic DMARDs (cs-DMARDs) can be treated with targeted synthetic DMARDs with or without background use of csDMARDs. Deucravacitinib (DEUC) is a novel, oral, selective, allosteric inhibitor of tyrosine kinase 2 (TYK2) that binds to the unique TYK2 regulatory domain, thereby suppressing signaling of key cytokines (eg, IL-23) involved in PsA pathogenesis. In a Phase 2 trial in pts with active PsA, DEUC was well tolerated and significantly more efficacious than placebo (PBO) after 16 weeks of treatment.

Objectives: This analysis further evaluated the effect of DEUC in this Phase 2 trial in pts treated with and without background csDMARDs for 16 weeks.

Methods: This double-blind trial (NCT03881059) enrolled pts with active PsA who had either failed or were intolerant to ≥1 nonsteroidal anti-inflammatory drug, corticosteroid, csDMARD, and/or 1 TNF inhibitor (TNFi; up to 30%). Pts were randomised 1:1:1 to DEUC 6 mg once daily (QD) or 12 mg QD, or PBO. A post hoc subgroup analysis in pts with and without background csDMARD use assessed improvements in select clinical outcomes (ACR 20 response, and change from baseline in ACR components, Psoriasis Area and Severity Index total score, and Psoriatic Arthritis Disease Activity Score [PASDAS]) at Week 16.

Results: Baseline (BL) demographics, clinical characteristics, and disease activity were generally similar among pts with and without background csDMARD use. At BL, background csDMARD use was 64.3%, 64.2%, and 66.7% and methotrexate use was 50.0%, 55.2%, and 59.1% in the DEUC 6 mg QD, 12 mg QD, and PBO groups, respectively. Pts with and without background csDMARD use showed similar improvements at Week 16 with DEUC treatment versus PBO.

Conclusion: These analyses demonstrate that the efficacy of DEUC for the treatment of PsA was similar in pts with and without background csDMARD use. The AE profile of DEUC treatment with and without csDMARD use was consistent with findings from the overall Phase 2 PsA trial population.

AN ANALYSIS OF FATIGUE IN PATIENTS WITH PSORIATIC DISEASE UTILIZING SF-36 VITALITY SCORES: RESULTS THROUGH WEEK 24 IN PHASE 3 TRIALS OF GUSELKUMAB IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS

J. F. Merola, Y. H. Liu, Y. W. Yang, M. Miller, M. Shawii, D. Chan, S. Khatiri, L. Savage, W. H. Boehncke, C. Han, Harvard Medical School, Brigham and Women's Hospital, Department of Dermatology, Boston, MA, United States of America; Janssen Global Services, LLC, Department of Immunology, Arthritis, NJ/Malvern, PA, United States of America; Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, PA, United States of America; Janssen Research & Development, LLC, Department of Immunology, Spring House, PA, United States of America; Janssen Scientific Affairs, LLC, Department of Dermatology, Horsham, PA, United States of America; Janssen Research & Development, LLC, Department of Immunology, New York, NY, United States of America; University of Leeds, Department of Dermatology, Leeds, United Kingdom; Geneva University Hospitals, University of Geneva, Division of Dermatology and Venerology, Geneva, Switzerland

**Background:** Patients with chronic inflammatory diseases can experience significant fatigue, negatively impacting health-related quality-of-life.1,2

**Objectives:** This post-hoc analysis evaluated baseline fatigue severity among patients with psoriasis and/or psoriatic arthritis (PsA) and the effect of guselkumab treatment on patient-reported fatigue.

**Methods:** VOYAGE-2 evaluated guselkumab every 8 weeks (Q8W) versus placebo (W16→guselkumab) and adalimumab in treating moderate-to-severe psoriasis.1 DISCOVER-1 and DISCOVER-2 evaluated guselkumab Q4W and Q8W versus placebo in treating active PsA. Fatigue was assessed using 36-item Short Form (SF-36) vitality scale score (includes 4 questions on fatigue/energy level); the US population norm=50±10; 5-point integer decrements are typically observed in conditions known to cause fatigue; scores ≤35 indicate clinically important fatigue; increases ≥5 indicate clinically meaningful improvement.2

**Results:** Across randomized groups at baseline, mean SF-36 vitality scores were 47.7±8.5 in psoriasis and 42.2±4.40 in PsA patients; 11%-15% of psoriasis and 20%-28% of PsA patients had scores ≤35. In psoriasis patients, mean increases in SF-36 vitality score at W16 were: placebo, 1.1; adalimumab, 3.9 (p<0.001 versus placebo); guselkumab, 5.6 (p<0.001 versus placebo); at W24: placebo→guselkumab, 4.6; adalimumab, 3.9; guselkumab, 5.8 (p=0.0148 versus adalimumab). In PsA patients, mean increases at W24 were: placebo, 2.3±4.0; guselkumab, 5.5±7.5 (p<0.001 versus placebo). Through the placebo-controlled periods, significantly greater proportions of guselkumab-treated patients achieved clinically meaningful improvement in fatigue versus placebo (W16 psoriasis: guselkumab, 48%; placebo, 32%; p<0.001; W24 PsA: guselkumab, 53%-55%; placebo, 34%-44%; p<0.05).

**DO:** 10.1136/annrheumdis-2022-eular.1495
Conclusion: At baseline, patients with psoriatic disease experienced clinically important fatigue, more so with PsA (20%-28%) than psoriasis (11%-15%). In guselkumab-treated psoriasis and PsA patients, clinically meaningful improvements in fatigue were achieved at W16 and W24, respectively.

AB0894 EFFICACY AND SAFETY OF GUSELKUMAB IN BIOLOGIC-NAIVE PATIENTS WITH ACTIVE AXIAL PSORIATIC ARTHRITIS: STUDY DESIGN OF A PHASE 4, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

BAASID Clinical Trials Unit, Department of Rheumatology, Toronto Western Hospital and University of Toronto, Department of Medicine, Ontario, Canada; Swedish Medical Center/Providence St. Joseph Health and University of Washington, Department of Rheumatology, Seattle, WA, United States of America; University of New South Wales, Department of Rheumatology, Randwick, New South Wales, Australia; Hospital Italiano de Buenos Aires, Department of Rheumatology, Buenos Aires, Argentina; Janssen Scientific Affairs, LLC, Department of Immunology, Horsham, PA, United States of America; Drexel University College of Medicine, Division of Rheumatology, Philadelphia, PA, United States of America; Janssen Global Services, LLC, Department of Immunology, Horsham, PA, United States of America; Janssen Research & Development, LLC, Department of Immunology, Spring House, PA, United States of America; The Chinese University of Hong Kong, Department of Medicine & Therapeutics, Hong Kong, Hong Kong (SAR); University of Leeds, School of Medicine, Department of Rheumatology, Leeds, United Kingdom; University of California at San Diego, Department of Rheumatology, La Jolla, CA, United States of America; Oregon Health & Science University, Division of Arthritis and Rheumatic Diseases, Portland, OR, United States of America; University of Copenhagen, Department of Rheumatology, Copenhagen, Denmark; Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Department of Rheumatology, Herne, Germany

Background: Established criteria for classifying axial psoriatic arthritis (PsA) are lacking, and assessments of activity often rely on measures developed for ankylosing spondylitis (AS). There is an unmet need to systematically identify and measure efficacy of treatments for axial PsA patients (pts). Guselkumab (GUS), a selective interleukin (IL)–23p19 inhibitor, was efficacious in improving signs and symptoms of active PsA in phase 3 trials, randomized, placebo-controlled (PBO)-controlled studies: DISCOVER-1 & DISCOVER-2. In a post-hoc pooled analysis of DISCOVER-1&2 pts with investigator-confirmed sacroiliitis, GUS-treated pts had greater improvements in axial symptoms compared with PBO. Imaging in DISCOVER-1&2 was restricted to the sacroiliac (SI) joints, occurring prior to/at screening as confirmed by the investigator, and locally read.

Objectives: To design a new, dedicated study to evaluate the effects of GUS on axial PsA prospectively.

Methods: Cumulative evidence from DISCOVER-1&2, including exposure–response relationship, covariate adjustment for modest baseline imbalances across treatment groups, subgroup analyses, and comparisons within and across these studies, was considered in designing a new trial. Data from the pivotal registrational studies suggest similar efficacy with GUS every-4-weeks (Q4W) and Q8W regimens in treating PsA signs and symptoms, including symptoms of axial involvement. Power calculations were based on mean changes in Bath AS Disease Activity Index (BASDAI) scores in DISCOVER-1&2.

Results: The phase 4, randomized, PBO-controlled STAR study is specifically designed to prospectively assess efficacy outcomes in PsA pts with magnetic resonance imaging (MRI)-confirmed axial inflammation. Based on observed mean (SD) changes from baseline in BASDAI score from DISCOVER-1&2 Table 1), 405 pts, randomized (1:1:1) to GUS Q4W, GUS at W0, W4, then Q8W, or PBO —GUS Q8W at W24, are planned for enrollment (Figure 1). STAR eligibility criteria include PsA ≥6 months and active disease (≥3 swollen & ≥3 tender joints, C-reactive protein [CRP] ≥20.3 mg/dL), prior biologic treatment, past/current anti-TNF and/or IL-17/23/24 inhibitor. Differences in effect size are confirmed by the investigator, and locally read.

Background: Given the availability of advanced therapies in PsA with different modes of action, it is of interest to characterize their impact on overall clinical outcomes.

Objectives: To describe residual disease activity in Canadians with PsA treated with advanced therapies.

Methods: Multi-region, observational, retrospective analysis of data from Rhumadata (Quebec) and International Psoriasis and Arthritis Research Team (IPART) Canadian registries was performed. Data from each registry and region were analyzed separately using a common statistical analysis plan to generate descriptive statistics. Patients included in the registries were eligible if they were adults at the time of PsA diagnosis and were treated with an advanced therapy for ≥6 months initiated between January 2010 and December 2019. Residual disease activity was defined as failing to achieve MDA (defined as achieving ≥5 of: TUC ≤1, SJC ≤1, PASI ≤1 or BSA ≤3%; patient pain VAS score of ≤15 mm; patient global disease activity VAS score of ≤20 mm; HAQ score ≤0.5, and tender and swollen joint counts ≤1) (primary endpoint), or DAPSA score ≥14 (secondary endpoint) within 6 months of initiation of an advanced therapy (TNFi, IL-12/23i, IL-17i, PDE4i, CTLA4i or JAKi).

Results: 1,866 subjects (Atlantic [IPART; Newfoundland]: N=887; Quebec [Rhumadata]: N=985; Ontario [IPART]: N=965; West [IPART; British Columbia, Manitoba]: N=130) were included in this preliminary analysis. Baseline characteristics are presented in Table 1. Overall, 899 were receiving their 1st advanced therapy, 464 were receiving their 2nd, and 264 had received ≥3. The most common therapy class was TNFi, followed by IL-17i. 18/21 (85.7%) subjects in the Atlantic region with an assessment, 184/246 (74.8%) in Quebec, 391/571 (68.1%) in Ontario, and 30/43 (69.8%) in Western Canada failed to achieve MDA within 6 months following advanced therapy initiation. Failure to achieve MDA within the allotted period was higher among patients receiving an IL-17i compared with a TNFi. There was no appreciable effect of line of therapy. Also, 74 of 110 (67.3%) patients with an assessment in Quebec, 201/365 (55.1%) in Ontario and 3/3 (100%) in the West failed to achieve at least low disease activity (LDA; DAPSA ≤14) within 6 months following initiation of an advanced therapy. Data were not available for the Atlantic region. The proportion of patients not achieving LDA by advanced therapy was similar for those receiving a TNFi and IL-17i but increased with line of therapy.

Conclusion: Preliminary data show approximately three quarters of Canadians with PsA failed to achieve MDA or LDA within 6 months of initiating an advanced therapy; Disease duration is a possible explanation for not achieving MDA or LDA; better therapeutic approaches are needed to achieve these outcomes in patients with PsA.

Acknowledgements: The authors wish to thank Dr. Steve Ramkissoon, for supporting the statistical analysis of the IPART registry, Medical writing and statistical support (funded by Abbvie) were provided by John Howell and Hong Chen, respectively, from McDougall Financial. Financial support for the study was provided by AbbVie. AbbVie participated in the design of the study, interpretation of data, review, and approval of this publication. All authors contributed to the development of the publication and maintained control over the final content.

COMPARATIVE EFFECTIVENESS OF GUSELKUMAB IN PSORIATIC ARTHRITIS: UPDATES TO A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS

P. J. Mease1, I. McInnes2, L. S. Tam3, R. Rajalagniran4, S. Peterson5, F. Hassann6, S. D. Chakravarty7, C. Contre8, A. Armstrong9, W. H. Boehncke10, C. T. Ritchin11, 1Swedish Medical Center/Province St. Joseph Health & University of Washington, Rheumatology Research, Seattle, WA, United States of America; 2University of Glasgow, Institute of Infection, Immunity and Infection, Glasgow, United Kingdom; 3The Chinese University of Hong Kong and the Prince of Wales Hospital, Department of Medicine & Therapeutics, Hong Kong, Hong Kong (SAR); 4EVERSANA, Department of Immunology, Burlington, Canada; 5Janssen Global Services, LLC, Department of Immunology, Horsham, PA, United States of America; 6Janssen EMEA, Department of Immunology, High Wycombe, United Kingdom; 7Janssen Scientific Affairs, LLC, Department of Immunology, Horsham, PA, United States of America; 8Drexel University College of Medicine, Division of Rheumatology, Philadelphia, PA, United States of America; 9Janssen Pharmaceutical Companies of Johnson & Johnson, Department of Immunology, Issy-les-Moulineaux, France; 10Geneva University Hospitals, Department of Dermatology, Geneva, Switzerland; 11University of Rochester, Department of Medicine - Allergy/Immunology and Rheumatology, Rochester, NY, United States of America

Background: The efficacy of guselkumab (GUS), an interleukin (IL)-23 p19-subunit inhibitor, has been demonstrated for psoriatic arthritis (PsA) in two pivotal phase 3 trials (COSMOS and DISCOVER-1&2). A third phase 3b trial (COSMOS) evaluated GUS in patients with PsA who had an inadequate response (IR) to tumor necrosis factor inhibitors (TNFi). GUS has previously been compared to targeted PsA therapies through network meta-analysis (NMA).

Objectives: This NMA update was to include data for GUS in TNFi-IR patients from COSMOS, as well as two additional key comparators, risankizumab (RIS), an IL-23 inhibitor, and upadacitinib (UPA), a Janus kinase inhibitor (JAKi).

Methods: A systematic literature review identified PsA randomised controlled trials up to February 2021. A subsequent hand-search identified data for newer agents, including congresses up to July 2021. Bayesian NMAs were performed to compare treatments on American College of Rheumatology (ACR) response, Psoriasis Area and Severity Index (PASI) response, modified van der Heijde-Sharp (vdH-S) score, and serious adverse events (SAEs). Analyses used fixed or random effects models and adjusted for placebo response via meta-regression on baseline risk when feasible. Multinomial models were used for ACR and PASI. Results were summarized by ranking treatments in league tables according to results derived from NMAs. Conclusions (ie, comparable or better/worse) for GUS 100 mg every 4 weeks (Q8W/Q4W) versus comparators were based on overlap of pairwise 95% credible intervals (CIs) (ie, treatments are comparable if CIs overlap 1 [dichotomous outcomes] or 0 [continuous outcomes]).

Results: Thirty-three phase 3 studies were included in the NMAs. Studies were placebo-controlled up to 24 weeks except for 2 head-to-head studies, and evaluated 15 targeted PsA therapies in TNFi naive, IR, or mixed populations. For ACR 20 response, GUS Q8W and Q4W ranked 14th and 12th among 23 treatments and were comparable to most other active agents, including RIS and UPA, subcutaneous (SC) TNFi, and most IL-17A inhibitors (IL-17A), as demonstrated by overlap in pairwise 95% CIs with unity. Results were similar for ACR 50 and 70 responses. For PASI 90, GUS Q8W and Q4W ranked 2nd and 1st among 23 treatments and were better than multiple agents, including all SC TNFi, JAKi, including UPA, and other small molecules, as demonstrated by nonoverlap in pairwise 95% CIs. Compared with GUS Q8W and Q4W were similar to RIS and most IL-17A for PASI 90, but point estimates consistently favored GUS. For vdh-S score, GUS Q8W and Q4W ranked 8th and 3rd among 18 treatments; GUS Q4W was better than RIS, and both GUS Q8W and Q4W were comparable to most other agents including UPA. SAEs were comparable across most agents.

Conclusion: GUS demonstrated better skin efficacy than most other targeted PsA therapies, including UPA. For vdh-S, both GUS dose regimens were comparable in most treatments, with both GUS doses ranking higher than most, including UPA and RIS. Both GUS dose regimens demonstrated ACR responses that were comparable to most other agents, including UPA and RIS, and ranked favorably in the network for SAEs.

GUSELKUMAB IMPROVES DACTYLITIS IN PSA PATIENTS WITH INADEQUATE RESPONSE TO TNFI: DATA FROM THE PHASE 3B COSMOS TRIAL

H. Marzo-Ortega1, E. Theander2, M. Neuhold3, P. Bergmans4, M. Shaw5, M. Perate6, C. Contre7, I. Moinnes8, G. Schett9

1Leeds Teaching Hospitals Trust and University of Leeds, NIHR Leeds Biomedical Research Centre and Leeds Institute of Rheumatologic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Janssen, Scientific Affairs, LLC, Solna, Sweden; 3Janssen, Scientific Affairs, LLC, Zug, Switzerland; 4Janssen, Biostatistics, Breda, Netherlands; 5Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; 6Janssen, Scientific Affairs, LLC, Horsham, United States of America; 7Janssen, Scientific Affairs, LLC, Issy-les-Moulineaux, France; 8University of Glamorgan, M4LS College Office, Institute of infection, immunity and inflammation, Glamorgan, United Kingdom; 9University of Erlangen, Department of Medicine 3 - Rheumatology and Immunology, Erlangen, Germany.

Background: Dactylitis is a biomarker of disease severity in psoriatic arthritis (PsA) associated with functional disability, impaired quality of life and radiographic progression. The COSMOS study demonstrated the efficacy and safety of guselkumab (GUS), an IL-23 p19 subunit inhibitor (i), in patients (pts) with PsA who had inadequate response (IR; insufficient efficacy or intolerance) to 1–2 TNFI.

Objectives: To evaluate the efficacy of GUS 100 mg Q8W on dactylitis, and assess the relationship between dactylitis resolution and improvement in other clinical outcomes, through 1 year in TNFI-IR PsA pts.

Methods: Pts received GUS or placebo (PBO); PBO pts crossed over to GUS at either Week (W) 16 (early escape [EE]) or W24 (planned). As observed, 88% of these PBO→GUS pts had complete resolution of dactylitis at W48 (Figure 1). Of 105 dactylitis-free pts at BL in the GUS arm, 8 (6%) developed dactylitis before W48; 4 at W4, 2 at W8 and 1 each at W16 and 36. Complete resolution was seen in 6 (7%) of the 8 pts by W48, when 1 further new-onset case occurred: Utilizing observed data among GUS-randomized pts with and without BL dactylitis, 32% and 34%, respectively, achieved MDA at W48. Respective response rates were 59% and 55% for DAPSA LDA, and 28% and 15% for DAPSA remission. In those who did and did not achieve complete dactylitis resolution at W48, respective response rates were 38% and 0% for MDA, 88% and 13% for DAPSA LDA, and 31% and 0% for DAPSA remission. Of 69 pts with both enthesis and dactylitis at BL who continued to receive GUS through W48, GUS resolved both manifestations in 72%, neither in 16%, only enthesis in 4%, and only dactylitis in 7% of pts.

Conclusion: Complete dactylitis resolution was achieved in ≥80% of pts who continued to receive GUS at W48, with partial resolution seen in most remaining pts in an as-observed analysis. Response rates increased through W48. Dactylitis resolution in this difficult-to-treat TNFI-IR PsA population was frequently associated with enthesis resolution and achievement of clinical outcomes representing low levels of disease activity.

Disclosure of Interests: Helena Marzo-Ortega Speakers bureau: Abbvie, Biogen, Celgene, Eli Lilly, Janssen, Novartis, Pfizer, Takeda, UCB, Consultant of: Abbvie, Eli Lilly, Janssen, Moonlake, Novartis, Pfizer, Takeda, UCB, Grant/research support from: Janssen, Novartis, UCB, Elke Theander Employee of: Employed by Janssen Scientific Affairs, LLC (a subsidiary of Johnson & Johnson), Marlies Neuhold Shareholder of: Own Johnson & Johnson stock and/or stock options, Employee of: Employed by Janssen Scientific Affairs, LLC (a subsidiary of Johnson & Johnson), Paul Bergmans Shareholder of: Own Johnson & Johnson stock and/or stock options, Employee of: Employed by Janssen Scientific Affairs, LLC (a subsidiary of Johnson & Johnson).
Results: From December 2019 until this interim data cut (June 2021), a total of 477 pts (305 female; mean age 52) were enrolled. Mean age ranged from 48 (IL-12/23i and IL-23) to 55 (JAKi), with a majority of female pts in each group (Table 1). Pts in the IL-12/23i and IL-23i and TNFi groups showed the shortest time since PsA diagnosis (5.2±4.5, 6.5±7.9), while the JAKi group showed the longest time (10.6±8.4). The lowest proportion of pts with a prior b/tsDMARD used was observed in the TNFi group (31%), the highest in the IL-12/23i and IL-23i group (71%). Pts in the ileo and IL-12/23i and IL-23i groups were more likely to be on monotherapy. Tender Joint Count (9.1-11.3) and Swollen Joint Count (3.3-5.8) were comparable across groups, with the highest values in the ileo and JAKi groups, respectively. Pt proportion with enthesitis and dactylitis was higher in the ileo, secukinumab and JAKi groups. Percentage of Body Surface Area affected by psoriasis was higher in the ileo, secukinumab and IL-12/23i and IL-23i groups. Pts proportion with nail psoriasis was higher in the ileo and secukinumab groups. Physician’s Global Assessment Visual Analog Scale (VAS), Patient’s Global Assessment and Patient’s Assessment of Joint Pain VAS reflected a high burden of illness.

Means SD, unless otherwise stated

Conclusion: The reported BL characteristics offer preliminary information about which pts initiate or switch to a b/tsDMARD in a real-life setting. Future disclosures (at 12 and 24M) will provide RWE regarding persistence, effectiveness, and health care resource use of available treatments for PsA, which will help pts and physicians to make better informed treatment decisions.

Objectives: To assess the impact of different strategies of antirheumatic treatment management on disease activity around the time of vaccination for Coronavirus disease (Covid-19) in patients with psoriatic arthritis (PsA).

Methods: We prospectively evaluated patients with PsA in remission or low-disease activity candidate to receive Covid-19 vaccination with mRNA vaccines. Methotrexate (MTX) and leflunomide were withheld 7 days after each dose, whilst biological DMARDs (bDMARDs) were, either continued (46.8% of the patients) or withheld (53.2%) from the day of the first dose until 7 days after the second dose. Patients were reassessed after 3 months from enrollment in case of disease flare.

Results: After the second dose of Covid-19 vaccination 7 patients (5.6%) (6 females) had an articular disease flare each (mean involved joints: 129), one patient presented a concomitant worsening of psoriasis, and four patients had an isolated worsening of their psoriasis. All patients received additional treatments with oral GC (n=2) or non-steroidal anti-inflammatory drugs (n=5). Two flares lasted more than one week and required a modification of the ongoing bDMARD. Articular flare incidence (6.8% vs 3%, P=0.259), involved joints (1.4 vs 1.5, P=0.846), disease flare severity, and changes in antirheumatic therapies (1 vs 1, P=0.928) did not differ significantly between the two different bDMARD management strategy groups (continued vs temporary withheld). There was no significant difference in disease activity score for psoriatic arthritis (DAPSA) and C-reactive protein (CRP) after vaccination, but patients who flared up had a higher mean basal DAPSA (7.3 vs 4.1, P=0.046), On binomial logistic regression analysis, we did not find any significant association with gender, age, basal CRP, basal DAPSA, active psoriasis, conventional synthetic DMARDs, or bDMARDs and disease flare.

Conclusion: Our findings suggest that a temporary short halt of bDMARDs could be a viable option in patients with well-controlled PsA undergoing Covid-19 vaccination without increasing the risk of flares, which could be useful to increase T cell response and antibody titres after Covid-19 vaccination.

EFFECTS OF TREATMENT WITH RISANKIZUMAB ON REDUCING PAIN AND INFLAMMATION IN PATIENTS WITH PSORIATIC ARTHRITIS: AN ANALYSIS OF THE KEEPSAKE -1 AND -2 TRIALS

A. Ostro1, S. Kwatra2, C. Nduaka3, M. Patel1, A. M. Soliman1, L. Barcomb3, Z. Xue3, H. Photowala3, K. Papp4. 1AbbVie1, 2AbbVie Inc., Immunology, North Chicago, United States of America; 3Department of Dermatology, Johns Hopkins University School of Medicine, Baltimore, United States of America; 4AbbVie Inc., Immunology, North Chicago, United States of America; 5Kapp Clinical Research, Prophy Medical Research, Waterloo, Canada

Background: Risankizumab (RZB), a monoclonal antibody that specifically inhibits interleukin 23, is being investigated as a treatment for adults with psoriatic arthritis (PsA).

Objectives: Evaluate the efficacy of RZB treatment on the reduction in pain and inflammation in patients with active PsA.

Methods: KEEPSAKE-1 and -2, double-blind, phase 3 trials, evaluated the efficacy of RZB versus placebo (PBO) for the treatment of adult patients with active PsA. Patients were randomized (1:1) to receive subcutaneous RZB 150 mg or PBO at weeks 0, 4, and 16. A reduction in pain visual analogue (VAS) score of 30% (meaningful), 50% (substantial) from baseline, and achievement of a mini-

clinical importantly different measure (MCID) in pain VAS was analyzed using NRI. High-sensitivity C reactive protein (hsCRP) was analyzed using mixed-effect model repeated measurement. Results are reported from the 24-week timepoint.

Results: A total of 1407 patients were included in the 24-week assessment (KEEPSAKE-1 RZB=483, PBO=481; KEEPSAKE-2 RZB=224, PBO=219), 55% of patients receiving significant pain reduction than did patients receiving placebo (KEEPSAKE-1 54.7% vs 31.1%, P<0.001; KEEPSAKE-2 42.3% vs 22.2%, P<0.001). Similar trends were noted for significant pain reduction in patients receiving MCID in pain VAS was analyzed using NRI. High-sensitivity C reactive protein (hsCRP) was analyzed using mixed-effect model repeated measurement. Results are reported from the 24-week timepoint.

Conclusion: KEEPSAKE-1 and -2 trials showed significant improvement in pain and inflammation in patients with active PsA.

AB0092

EFFICACY OF IL-17 INHIBITORS IN PSORIATIC ARTHRITIS. SYSTEMATIC REVIEW OF SCIENTIFIC LITERATURE AND META-ANALYSIS

A. Gonzalez Alonso1, D. Fernández Fernández1, R. Dos Santos2, I. González Fernández1, P. Castro-Santamaría1, M. Sanchez-Wonenburger2, J. L. Puga Guzmán2, A. Mata1, E. Perez-Pampín1, A. Soulo Vías1, A. Mera Varela1, 1University of Santiago de Compostela, Santiago de Compostela, Spain; 2Santiago Clinic Hospital CHUS, Rheumatology, Santiago de Compostela, Spain

Background: Psoriatic arthritis is a chronic inflammatory joint disease with a great heterogeneity of manifestations both at the musculoskeletal (arthritis), enthesitis, dactylitis, axial skeleton involvement) and dermatological (skin, nail involvement) domain. The main goal of treatment is to maximize quality of life by controlling symptoms and preventing structural damage. For this, multidisciplinary management must be carried out without forgetting the patient’s general health status and by making the best use of pharmacological therapy to control arthritis, non-vascular anti-inflammatory drugs (NSAIDs) and/or intra-articular corticosteroid injections are proposed as initial therapy. When symptoms are not controlled or there are associated poor prognostic factors, conventional disease-modifying antirheumatic drugs (DMARDs) are recommended, especially methotrexate. When the classic DMARDs do not achieve good control of the disease, the next step will be the use of biological DMARDs, anti-TNF alpha inhibitors, interleukin-17 inhibitors or inhibitors of the IL12/IL23 axis. Other molecules such as Janus kinase (JAK) inhibitors or phosphodiesterase-4 inhibitors such as Apremilast also continue to be incorporated into treatment alternatives. Although these drugs provide a promising result, the scarcity of direct comparative studies implies a need for more research to determine better treatment strategies.

Objectives: To analyze the efficacy of IL-17 inhibitors (Secukinumab, Ilekizumab, Brodalumab and Bimekizumab) in the treatment of patients diagnosed with psoriatic arthritis based on data published in randomised clinical trials (RCTs).

DOI: 10.1136/annrheumdis-2022-eular.2189
Methods: We perform a systematic review of the scientific literature using the Pubmed, Cochrane Library, Embase and Web of Science electronic databases, selecting RCTs evaluating the efficacy of IL-17 inhibitors for the treatment of psoriatic arthritis. A meta-analysis was performed using the random-effects model for each efficacy measure evaluated at different weeks.

Results: 23 studies met the selection criteria from a total of 2198 references identified in the search. 14 references contained data on the use of Secukinumab from 7 RCTs. Ixekizumab was the second IL-17 inhibitor most identified with 6 references with data from 5 RCTs. Bimekizumab with 2 references and Brodalumab with 1 reference completed the review. Despite extracting efficacy data in nail, enthesic and PROs manifestations. We were only able to perform meta-analyses of the ACR 20, AC50, ACR70 and PASI75 response rates at week 12 of treatment, due to the lack of statistically comparable data. The meta-analysis performed demonstrated that IL-17 inhibitors are effective in psoriatic arthritis, compared to placebo in the different efficacy outcomes evaluated (ACR20 12 wk (OR: 3.60 [95%CI: 1.72-7.32]), ACR50 12 wk (OR: 7.94 [95%CI: 4.23-14.91]) and PASI75 12 wk (OR: 21.26 [95%CI: 13.72-32.95]).

Conclusion: Our review concluded that IL-17 inhibitors are effective in the treatment of patients who have shown intolerance or had an unsatisfactory response to other lines of treatment in Psoriatic arthritis.

AB0903 DUAL IMMUNOMODULATORY THERAPIES IN PSORIATIC DISEASE
S. Sundaram1, A. Gorman3, D. Veale1, C. Orr1, L. O’Neill1. 1Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, University College Dublin, Dublin, Rheumatology, Dublin, Ireland

Background: Since the advent of numerous biologic therapies and small molecular drugs targeting specific cytokines and signalling pathways; the management of patients with psoriatic arthritis (PsA) has significantly improved. However, at least 40% of PsA patients exhibit an incomplete or failure to respond to these treatments. While the outcomes of patients with psoriasis (Pso) has dramatically improved with monoclonal antibody therapies targeting IL-23 and IL-17A; achieving a measurable low disease activity state such as minimal disease activity (MDA) for musculoskeletal manifestations of psoriatic disease is infrequent. Given the complex and heterogeneity of signalling pathways, cytokines and cell types resulting in synovio-entheseal disease in PsA; new treatment strategies must be evaluated to induce deep and sustainable clinical responses in all the phenotypic domains of psoriatic disease (cutaneous, synovium, enthesial and axial). (1) In patients who do not achieve remission in all clinical domains on a biologic monotherapy or combination of a biologic therapy with an oral synthetic agent; dual targeted anti-cytokine strategies or combined biologic with a targeted oral small molecule are a possible treatment option.

Objectives: To describe a series of four patients with recalcitrant psoriatic disease and failure to respond to previous treatment regimens who were successfully treated with dual immunomodulatory therapies.

Methods: Patients on dual immunomodulatory therapies attending our department were prospectively followed and clinical response monitored.

Results:

Figure 1. Mini-Arthroscopy of left knee for Case 3 prior to starting dual immunomodulator therapy (A) Macroscopic aspects of synovitis (B) Synovium vascularization

Conclusion: Multiple pathways and mediators are responsible for the initiation of and sustained joint inflammation and damage seen in PsA. A phase II trial of ABT-122, a biologic engineered to target both TNF and IL-17A showed statistically significant superior efficacy outcomes at multiple time points based on ACR50, ACR70 and psoriasis outcome measures (PASI75/PASI90) when compared to adalimumab, with similar safety profile. (2) Safety concerns such as infectious risks are important considerations with such strategies; however, the targeted second-generation anti-cytokine biologics and targeted JAK-I have exhibited improved safety profiles. (3) In our small case series, patients have not, to date, experienced adverse events of combination therapy.

AB0904 EVALUATING NUMERIC RATING SCALE VERSIONS OF THE 3 AND 4 VISUAL ANALOG SCALE (3/4-VAS) COMPOSITE MEASURES IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS FROM THE SELECT-Psa PROGRAM
W. Tillett1, L. Coates2, M. Kishimoto3, A. Setty4, T. Gao5, R. Lippe6, P. Hellowell6. 1Royal National Hospital for Rheumatic Diseases, University of Bath, Pharmacy and Pharmacology; Bath, United Kingdom; 2University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 3Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan; 4AbbVie Inc., Immunology, North Chicago, United States of America; 5AbbVie Deutschland GmbH & Co. KG, Immunology, Wiesbaden, Germany; 6Leeds Teaching Hospitals Trust and Leeds Institute of Rheumatic and Musculoskeletal Disease, University of Leeds, NIHR Leeds Biomedical Research Centre, Manchester, United Kingdom

Background: The multifaceted nature of psoriatic arthritis (PsA) can make it challenging to evaluate treatment targets and disease activity. Moreover, most existing assessment tools are time-consuming and not always feasible in routine clinical care, indicating a need for new disease measures that are easy to perform and calculate. Composite measures using 3-visual analog scale (VAS;
physician's global assessment, patient's global assessment, and skin) or 4-VAS (physician's global assessment, joints, skin, and pain) have been proposed as simpler alternatives. Given potential advantages of numeric rating scales (NRS) over VAS, we here adapted 3/4-VAS for use with NRS components and tested its validity via post hoc analysis of the upadacitinib (UPA) SELECT-Psa program.

**Objectives:** Evaluate the ability of 3/4-NRS scores to assess treatment response in SELECT-Psa 1 and 2, as well as the correlation of 3/4-NRS with other common disease activity measures.

**Methods:** Data are from the SELECT-Psa 1 and 2 phase 3 trials in patients with prior inadequate response or intolerance to ≥1 non-biologic DMARD or ≥1 biologic DMARD, respectively. In both trials, patients received once daily UPA 15 mg, UPA 30 mg, or placebo (PBO); SELECT-Psa 1 also included the active comparator adalimumab (ADA) 40 mg every other week (wk). 3-NRS scores were determined using the mean of SAPS questions 1–10, physician's global assessment of disease activity, and patient's global assessment of disease activity; 4-NRS scores were determined using the mean of SAPS questions 1–10, physician's global assessment of disease activity, patient's assessment of pain, and BASDAI question 3 related to joint pain and swelling. The 3/4-NRS scale ranges from 0 (no disease activity) to 10 (severe activity). 3/4-NRS and cDAPSA (DAPSA without the CRP component) were assessed at all available visits through wk 56. Correlations between 3/4-NRS with PsA disease activity score (PASDAS), routine assessment of patient index data 3 (RAPID3), DAPSA, cDAPSA, and other disease activity measures were determined by nonparametric Spearman rank correlation coefficient for UPA 15 mg patients from both trials and ADA for SELECT-Psa 1. All data are shown as observed; nominal p-values are provided throughout.

**Results:** A total of 1281 and 423 patients were included from SELECT-Psa 1 and 2, respectively. For both cDAPSA and 3/4-NRS scores, patients receiving UPA 15 mg showed clear numerical improvements compared with PBO at wk 24 in both trials (Table 1). 3/4-NRS scores were highly correlated with RAPID3 and PASDAS measures (r > 0.6, P < 0.0001) for UPA 15 mg patients at baseline (Figure 1). Moderate correlations were observed between 3/4-NRS and DAPSA/cDAPSA (r = -0.4, P < 0.0001), as well as physical function (HAQ-DI) and quality of life measures (SF-36). Nominally significant but weaker correlations were detected for joints, skin, and other disease activity assessments. Similar overall results were observed for patients receiving ADA.

**Conclusion:** 3/4-NRS was able to successfully discriminate between PBO and therapeutic groups in SELECT-Psa 1 and 2. 3/4-NRS scores correlated well with other clinical and patient reported outcome measures, including those focused on joints (DAPSA) or multiple manifestations (PASDAS), supporting 3/4-NRS as a viable and easy to use tool in daily clinical practice.

ROUTINE ASSESSMENT OF PATIENT INDEX DATA 3 (RAPID3) IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS (PsA) AFTER INADEQUATE RESPONSE OR INtolerance to DMARDS: POOLED RESULTS FROM THE PHASE 3, RANDOMIZED, DOUBLE-BLIND KEEPSAKE 1 AND 2 TRIALS

A. Ogdie1, L. Coates2, R. Acayaba DE Toledo3, A. Biljan4, H. Jones4, K. Tacelosky5, C. Yue6, B. Padilla7, M. Bergman8, 1University of Pennsylvania Perelman School of Medicine, Division of Rheumatology, Department of Medicine, Philadelphia, United States of America; 2University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; 3São José do Rio Preto, Medical School, São José do Rio Preto, Brazil; 4AbbVie Inc., Immunology, North Chicago, United States of America; 5Drexel University College of Medicine, Department of Medicine, Philadelphia, United States of America

Background: PsA is a chronic, systemic inflammatory disease with diverse clinical manifestations that can impact a patients’ quality of life. Risankizumab (RZB), a humanized immunoglobulin G1 monoclonal antibody that specifically inhibits interleukin 23 by binding to its p19 subunit, is approved for the treatment of active PsA in adults. In the phase 3 KEEPSAKE 1 and 2 studies, RZB treatment resulted in significantly greater improvements in signs and symptoms of active PsA compared with placebo (PBO).1,2 RAPID3 is frequently used in clinical practice to evaluate PsA disease activity and consists of 3 key patient-reported measures (physical function, pain, and patient’s global assessment of disease activity [PtGA]).3

Objectives: To evaluate short- (24 week) and long-term (52 week) improvements in RAPID3 scores and achievement of RAPID3 minimal clinically important difference (MCID) across the RZB KEEPSAKE 1 and 2 clinical program.

Methods: In KEEPSAKE 1 (NCT03675308) and KEEPSAKE 2 (NCT03671148), patients with active PsA who experienced inadequate response or intolerance to ≥ 1 csDMARD (KEEPSAKE 1) and/or ≤ 2 biological therapies (KEEPSAKE 2) were randomized to PBO or RZB 150 mg from baseline to week (W) 24; from W28–W52, all patients received open-label RZB 150 mg. At W16, nonresponders could add or modify rescue therapy. This post hoc analysis assessed the mean change from baseline to W24 and W52 in RAPID3 scores and the proportion of patients who achieved a RAPID3 MCID (defined as a decrease of ≥ 3.8 points). Modified RAPID3 scores (range: 0–30) were calculated using pain scores, PtGA, and HAQ-DI, each rescaled to 0–10 and summed together.5

Results: A total of 961 and 443 patients were included from KEEPSAKE 1 and 2, respectively. At baseline, mean RAPID3 scores were 15.3 in both treatment arms of KEEPSAKE 1 (PBO n = 479, RZB n = 482) and 15.1 (PBO n = 219) and 14.8 (RZB n = 224) in KEEPSAKE 2. From W4 to W24, RAPID3 scores were significantly reduced with RZB treatment compared with PBO in both KEEPSAKE 1 (mean change from baseline at W24 of −5.3 vs −2.4, respectively, P < .001) and KEEPSAKE 2 (−6.8 vs −3.2%, P < .001; Table 1). At W52 among patients who received RZB from W0–W52, mean change from baseline was −70 (KEEPSAKE 1) and −52 (KEEPSAKE 2; Figure 1 C, D), and MCID was achieved by 67.5% (KEEPSAKE 1) and 58.5% (KEEPSAKE 2) of patients. Patients who switched from PBO to RZB at W24 experienced similar and substantial improvements in RAPID3 scores by W52.

Table 1. Proportion of Patients Achieving a Minimal Clinically Important Difference From Baseline in RAPID3 (AO).

Conclusion: RZB 150 mg was associated with improvement in RAPID3 total scores over 24–52 weeks of treatment in patients with active PsA in KEEPSAKE 1 and 2.

Background: Upadacitinib (UPA) is an inhibitor of JAK kinases recently approved by EMA for the treatment of psoriatic arthritis (PsA) in Europe (January 2021). UPA has shown efficacy in refractory patients to anti-TNF. Objectives: A) to assess efficacy and safety of UPA in the first cases in Spain in clinical practice. B) to compare the profile of clinical practice patients with clinical trial of UPA in PsA refractory to biologics. Methods: Study of 39 patients of clinical practice with PsA treated with UPA in Spain. The diagnosis of PsA was made using CASPAR criteria. Patients who received at least one dose of UPA were included. Results are expressed as percentage, mean±SD or median [IRQ]. Results: 39 patients (29M/10J), mean age of 51.5 ± 11.4 years (Table 1). Pattern joint involvement was as follows: peripheral (n=19), axial (3) and mixed (17). During the PsA evolution, patients also presented enthesitis (59%) nail involvement (28.2%) and dactylitis (35.9%).

Figure 1.

Prior to UPA, most patients (59%) had received oral prednisone or equivalent (max 90.0±12.12mg/d), synthetic immunosuppressants (mean 1.6±0.9) and biological therapy (TB) (4.5±2.1). TB were as follows: etanercept (25), adalimumab (28), infliximab (12), golimumab (16), certolizumab (15), secukinumab (29), ustekinumab (21) Abatecept (2), brodalumab (1) and ixekizumab (17). Apremilast was used in 13, Tofacitinib in 11 and filgotinib in 1. After a mean follow-up of 12.4±8.68 years after the PsA diagnosis, UPA was started (15mg/24h). 43.6% associated prednisone (7.35±3.36mg/d). In 16 (41%) UPA was started in combined therapy: methotrexate (9), salazopyrin (3) and leflunomide (4); in the remaining 23 (59%), monotherapy was prescribed. At UPA onset patients presented peripheral arthritis (78.9%), axial involvement (35.8%), skin involvement (25.8%), enthesitis (41%), and dactylitis (10.3%). Patients of clinical practice compared with clinical trial there were more women, they have a longer period of PsA, and received a higher proportion of previous TB (Table 1). After a median follow-up of 2.48 ± 2.6 months, patients showed prompt improvement in activity indexes (DAS28, DAPSA) (Figure 1) and laboratory test (CRP mg/L decreased from 4.00 [1.5;10.0] to 0.40 [0.3;0.4] at the sixth month). Extra-articular manifestations also improved: dactylitis in 25% patients, enthesitis (43.8%), skin involvement (40%) and onychopathy (50%). No serious events were reported. Minor side effects were reported in 7 patients (17.9%), and UPA was discontinued in 9 due to inefficacy. Conclusion: In this preliminary study, first patients of clinical practice in Spain with UPA in PsA had a longer evolution and received a greater number of TB than those of clinical trial. As in the UPA clinical trial, it seems effective, rapid and relatively safe in daily clinical practice for refractory PsA.

Background: The Tight Control of Psoriatic arthritis (TICOPA) trial revealed a treat to target (T2T) strategy has led to improved clinical outcomes in psoriatic arthritis (PsA). The heterogeneity of the disease, the feasibility of therapy and the associated comorbidities made the implementation of such strategy in routine care a real challenge. There is a high need for establish real world recommendations for the T2T approach in PsA tailored to the disease activity status, the Psoriasis manifestations as well as the individual patient’s requirements.

Objectives: To provide up-to-date, evidence-based and consensus-based recommendations for Treat-to-Target management of psoriatic arthritis (PsA) and its associated clinical manifestations.

Methods: 14 key clinical questions were identified by scientific committee according to the Patient/Population, Intervention, Comparison, Outcomes and Timing (PICOT) approach. Literature Review team performed a systematic review to summarize evidence advocating the benefits and harms of available pharmacologic and nonpharmacologic therapies for PsA. Subsequently, recommendations were formulated. The level of evidence was determined for each section using the Oxford Centre for Evidence-based Medicine (CEBM) system. A 3-round Delphi process was conducted with 19 experts. All rounds were conducted online. A consensus was achieved on the direction and the strength of the recommendations.

Results: An online questionnaire were sent to expert panel who participated in the three rounds (response rate 100%). At the end of round 3, a total of fifty-one recommendation items, categorized into 6 sections to address the main 6 PsA categories, were obtained. Agreement with the recommendations (rank 3%) ranged from 89.5-100%. Consensus was reached (i.e., ≥75% of respondents strongly agreed or agreed) on the wording of all the 51 clinical standards identified by the scientific committee. Algorithms for the management of PsA have been suggested.

Conclusion: These recommendations provide an updated consensus on the pharmacological treatment of PsA and strategies to reach optimal treat to target outcomes
in common clinical scenarios, based on a combination of evidence and expert opinion. Best treatment decisions should be tailored to each individual patient situation.

AB0909  RETENTION RATE OF APREMILAST AND RISK FACTORS FOR INADEQUATE RESPONSE IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM AN ITALIAN MONOCENTRIC COHORT

L. Moschetti1, F. Crisafulli1, F. Canova1, F. Fraceschini1, L. Andreoli1, M. Frassi1. 1ASST Spedali Civili, University of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy

Background: Apremilast (APR) is an oral PDE4 inhibitor approved for the treatment of Psoriatic Arthritis (PsA). Its effectiveness has been assessed in clinical trials1,2, but real-life data are still scarce.

Objectives: To evaluate the retention rate (RR) of APR in PsA patients and the risk factors associated to APR inadequate response.

Methods: Retrospective monocentric analysis of PsA patients (CASPAR criteria 2006) treated with APR between 2017 and 2021. Disease activity was evaluated at baseline (T0) and after 6 (T6), 12 (T12) and 24 (T24) months of therapy using DAPSA score. Data are expressed as median [IQR].

Results: The cohort included 79 patients (41% males; age at PsA onset: 47 [37-58] years). PsA domains were: oligoarticular involvement (58%), enthesitis (42%), dactylitis (8%), axial involvement (13%), psoriasis (62%). Half patients presented dysmetabolic traits: 47% overweight/obesity, 34% arterial hypertension, 20% dyslipidemia. APR was prescribed mainly as first-line targeted therapy; in 42% APR was administered after the failure of ≥1 bDMARD. Contraindications to bDMARDs (47%) especially increased infectious risk (19/37) and current/previous malignancy (15/37), and mild PsA phenotype (27%) were the main reasons for APR choice. APR was discontinued in 61% after 4 [1-10] months because of inefficacy (25/48) or adverse events (AEs) (21/48; 81% gastrointestinal complaints). Patients who discontinued APR were compared with patients who continued APR (Table 1).

</tr>
</tbody>
</table>

Results are presented as median [IQR] or number (%). Continuous variables were compared with Mann-Whitney test; categorical variables were compared with Chi Squared/exact Fisher test.

The RR of APR was 62% at T6, 51% at T12 and 38% at T24 (Figure 1a).

Figure 1. a) Overall RR of APR, b) RR of APR in bDMARDs naive vs previously treated with bDMARDs patients (exclusion of withdrawals for intolerance).

In patients continuing therapy, APR showed a good efficacy, with a significant reduction of DAPSA score observed at T6 (13 [9-19], T12 [11 [4-18]] and T24 (8 [3-10]) as compared to T0 (21 [14-28] p<0.01). An overall trend of reduction of the BMI (kg/m²) was observed (T0:25 [22-28], T6: 24 [21-27], T12: 23 [21-28], T24: 22 [20-26]) in overweight patients the BMI decreased significantly (28 [25-31] at T0 vs 30 [27-29] at last evaluation; p<0.01). Because of the high rate of discontinuations due to intolerance in the first months of therapy, we conducted a sub analysis: patients who continued APR (n=31) vs patients who discontinued it for inefficacy (n=25). A higher frequency of APR withdrawal was registered in younger patients (51 [47-57] vs 57 [53-71] years; p<0.01) previously treated with bDMARDs (71% vs 40%; p<0.02). Multivariate analysis confirmed these associations (OR [95% CI]: 0.1 [0.89-0.99], p<0.03 and 2.3 [1.70-5.97], p<0.01; respectively). The RR was higher in bDMARDs naive patients compared with patients previously treated with bDMARDs (T6: 75% vs 67%, T12: 71% vs 63%, T24: 67% vs 34%; log-rank test; p=0.05) (Figure 1b).

Conclusion: This study confirms the safety and effectiveness of APR in a real-life scenario. We experienced a higher APR withdrawal rate for AEs (44%) in the first months of therapy, compared to registration studies in which APR was suspended in 8%. However, when tolerated, APR maintained efficacy over time, as demonstrated by progressive DAPSA reduction. The higher RR in bDMARDs naive patients suggests the early use of APR. Moreover, the reduction of BMI could favor APR use in dysmetabolic patients. These data need to be confirmed in larger studies.

AB0910 EVALUATION OF NON-ALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH PSORIATIC ARTHRITIS UNDER TREATMENT WITH METHOTREXATE

L. Pérez Albaladejo1, I. Ahón Oñate1, M. J. Pérez Galán2, C. Caro Hernandez1. 1Hospital Universitario de Jaen, Reumatología, Jaen, Spain

Background: Nowadays, non-alcoholic fatty liver is the most common hepatic disease. In patients with psoriatic arthritis with metabolic syndrome or obesity, there is a state of inflammation that produces the existence of a replacement of normal hepatic tissue by connective tissue, creating a non-alcoholic fatty liver disease (NAFLD). Disease Modifying Anti- Rheumatic Drugs (DMARDs) are widely used in the treatment of psoriatic arthritis. Among these drugs, we find methotrexate, chosen as the primary treatment for such pathologies. This DMARD must be administrated cautiously in patients with risk of developing fatty liver since it is hepatotoxic and it might cause the development of a hepatic disease.

Objectives: Measure the risk of developing hepatic fibrosis in patients with psoriatic arthritis under methotrexate.

Methods: It is a study of retrospective cohorts to determine the existence of NAFLD in patients with psoriatic arthritis under methotrexate through fatty index biomarkers (FIB-4). 41 patients have been studied for more than a year. Demographical & clinical variables have been collected (sex & gender) and (BMI, tobacco, use of alcohol, dyslipidemia and AHT), scales of disease activity and the FIB-4 (transaminases, age, plateletes). A baseline evaluation was made at 6 and 12 months with a 3 years extension of the treatment.

Results: A total of 41 patients (17 women & 24 men), with an average age of 50.3 years (minimum 18 and maximum 80) and a BMI of 28.16 has been studied. 4.9% consumed alcohol habitually, 17.1% were smokers, 39% had hypertension, 41.5% had hypercholesterolemia and 17.1% hypertriglyceridemia. Most patients had a moderate disease (DAPSA 20.9) at the beginning of treatment and kept a low activity in posterior months (DAPSA 6.8). The results of the Friedman’s test indicate that there are no significant statistic differences on the different measurements of FIB-4 (P=0.575).

In the study can be seen an increasing evolution of the FIB-4 values through the first months that is later stabilized through time. When studying if the evolution of FIB-4 is related to the evolution of BMI, it can be observed that exists a significant statistic relation in the evolution of both measures but being such relation quite weak. The evolution of the classification of the patients FIB-4 at the beginning, at 6 months, at 1 year and at 3 years of treatment with methotrexate does not present significant statistic differences.

Conclusion: In patients with psoriatic arthritis, the treatment with methotrexate does not seem to increase the risk of developing a non-alcoholic fatty liver disease.

Graphics FIB-4 evolution

AB0911 SHORT-TERM RESULTS OF GUSELKUMAB EFFICACY FOR PSORIATIC ARTHRITIS IN REAL LIFE.

M. Navidad Fuentes1, V. Ruiz DEL Valle1, S. Quiriosa Flores1. 1HOSPITAL VIRGEN DE LAS NIEVES, RHEUMATOLOGY, Granada, Spain

Background: Psoriatic arthritis is a chronic immune-mediated disease that mainly affect joints, but is associated with a significant increase in cardiovascular risk and other comorbidities. In the last decades, some pathogenic pathways of these diseases have been identified and have lead to the development of new therapeutic strategies such as biologic drugs. Early treatment and treat-to-target strategies have achieved a great improvement in the management of the disease, but there are still many refractory cases and further research is needed. Gusekumab is a human IgG1, monoclonal antibody that selectively binds to interleukin 23, a regulatory cytokine that affects the activity of T lymphocyte subsets. In this way, blockade of IL-23 normalizes the production of pro-inflammatory cytokines. Gusekumab was approved by FDA for psoriatic arthritis treatment in 2020.

Objectives: To analyze the real-life effectiveness of guselkumab in a cohort of patients with psoriatic arthritis.

Methods: A prospective observational study was conducted in psoriatic arthritis patients who received treatment with guselkumab in a hospital center in the southeastern area of Spain, from April 2020. Patient demographic and baseline data were recorded and response variables such as DAPSA index, presence of enthesis and dactylitis, skin affection by BSA, and drug persistence at 12 and 24 weeks of treatment were analyzed. In addition, adverse events were recorded.

Results: Twenty-nine psoriatic arthritis patients, 20 women, mean age at entry 52 ± 2.47 years, were included in this analysis. The mean of years since psoriatic arthritis diagnosis was 10.14 ± 1.68 years. Demographic and baseline variables of the patients are detailed in Table 1. The mean DAPSA value at the start of treatment was 25.02 ± 2.446. After 12 weeks, it was 17.51 ± 2.655, and after 24 weeks of treatment, it had dropped to 12.37 ± 3.547 points, this difference was statistically significant with p<0.001. The percentage of enthesitis presented a significant reduction, from 37.93% at baseline to 3.84% at 24 weeks of treatment. BSA index had a mean of 12.54 ± 5.94 at baseline, with a significant reduction at 12 weeks (2.136 ± 1.214) and at 24 weeks (0.4167 ± 0.4167). According to their DAPSA index score, patients were classified into disease categories. One third of patients achieved complete remission, and another third achieved low disease activity at 24 weeks, as reflected in Figure 1. Treatment persistence was 89.65% at both 12- and 24-week reviews, as only 3 patients dropped out of treatment at 12 weeks. No drug-related adverse events, including local injection site reactions, were recorded.

Table 1. Demographics and baseline patient characteristics.

Baseline Patient Characteristics guselkumab 100mg/8W (n = 29)

| Age at inclusion, mean (95% CI), years | 52 ± 2.47 |
| Sex | Female, n (%) | 20, 68.9 % |
| Male, n (%) | 9, 31.1 % |
| Disease duration of PsA mean (95% CI), years | 10.14 ± 1.68 |
| DAPSA mean (95% CI) | 25.02 ± 2.44 |
| Enthesitis, n (%) | 22, 75.8 % |
| Dactylitis, n (%) | 3, (10.34 %) |
| BSA mean [95% CI] | 3.1 (10.34 %) |
| Line of treatment | 2.54 ± 0.94 |
| Second, n (%) | 2, (6.89 %) |
| Third, n (%) | 8, (27.58 %) |
| Fourth, n (%) | 8, (27.58 %) |
| Fifth, n (%) | 2, (6.89 %) |
| Sixth, n (%) | 3, (10.34 %) |
| Seventh, n (%) | 5, (17.24 %) |
| Eighth, n (%) | 1, (3.44 %) |

Figure 1. Percentage of patients reaching remission (REM), low disease activity (LDA) or active disease at baseline, 12 and 24 weeks after guselkumab treatment.

Conclusion: Gusekumab is effective and safe for the manifestations of psoriatic arthritis in a real-life cohort of patients.

Disclosure of Interests: None declared

Background: Phase 2 studies have shown that Filgotinib (FIL), a JAK-inhibitor (JAKI), significantly improves signs and symptoms of psoriatic arthritis (PsA) in patients with active disease. PENGUIN 1 and 2 were two phase III trials of FIL in PsA that were stopped. We considered Tofacitinib (TOFA) the best alternative drug for these patients because TOFA is the only JAKI approved so far in Spain. However, data in clinical practice about switching from FIL to TOFA have not been reported.

Objectives: To assess the efficacy and safety of switching FIL to TOFA in patients with PsA.

Methods: Prospective Single-University-hospital study of PsA patients diagnosed according to CASPAR criteria, and previously treated with FIL 100 mg and 200 mg/day in two clinical trials (PENGUIN 1 and 2). Based on a shared decision between the patient and the physician, once the trial was finished, patients receiving FIL were switched to TOFA (5 mg/12h) with a 7 days wash-up period. Analyses were performed on the sub-group of patients who had completed 6 months of treatment. The main outcome was the change in swollen joint count (SJC), tender joint count (TJC) and Enthesitis according to the Enthesitis Index between the patient and the physician, once the trial was finished, patients receiving FIL were switched to TOFA (5 mg/12h) with a 7 days wash-up period. Analyses were performed on the sub-group of patients who had completed 6 months of treatment. The main outcome was the change in swollen joint count (SJC), tender joint count (TJC) and Enthesitis according to the Enthesitis Index.

Results: We included 11 patients (6 women/5 men) with a mean age of 52.5±6.5 years who had received FIL during a mean time of 16.0±9.3 weeks. JAKI was used in monotherapy or combined with sulfasalazine (n=2), methotrexate (n=1) and apremilast (n=1). Disease activity, US scores and laboratory values during the follow-up are shown in Table 1. No significant changes were observed in any case. No adverse events were reported during the 6 month of follow-up except for 1 patient with lymphopenia (500/µL). TOFA was discontinued after 1 month in 1 patient because of lymphopenia and inefficacy and after 3 months in 4 patients for worsening of the joint pain. It was remarkable that in some of the patients who reported a worsening of painful joints we did not observed a higher inflammatory activity in the SJC or US exam, this incongruence could be due to the role that JAK/STAT inhibition plays in pain signaling pathways.

Conclusion: Switching from FIL to TOFA appears to be an effective and safe therapeutic option.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular.3769
Results: We included 113 patients, 62 (54.0% females) with a mean age of 48.1±10.8 years-old at the start of the first bDMARD. Sixty-four patients (56.6%) had symmetric polyarthritis, 19 (16.6%) spondyloarthritis, 25 (22.1%) asymmetric oligoarthritis, 2 (1.8%) distal arthritis and 1 (0.9%) arthritis mutilans. Forty-three percent were under corticosteroid therapy and 75.7% under conventional synthetic DMARD (csDMARD) therapy at baseline (mostly methotrexate, in 45.1% of patients under csDMARD). Enatenec (n=35, 31.0%), adalimumab (n=34, 30.1%), golimumab (n=25, 22.1%), infliximab (n=6, 5.3%), certolizumab (5, 4.4%), secukinumab (n=8, 7.1%) were the bDMARD started in these patients. TSR was categorized into 3 groups, namely low [TSR < 1], moderate [1 ≤ TSR < 2.2] and high [TSR ≥ 2.2], with frequencies 19 (13.3%), 66 (58.4%) and 32 (28.3%), respectively. Whenever the number of tender joints was different from 0 and that of swollen joints equal to 0, patients were included in the group high TSR. All TSR groups, with initiation of bDMARD, showed significantly decreases at 6 months in CDAI (low: p=0.006, moderate: p<0.001, high: p<0.001), SDAI (low: p=0.001, moderate: p=0.001, high: p=0.001) and DAS28- CRP(4) (low: p=0.001, moderate: p=0.001, high: p=0.001). From 6 to 12 months of treatment, the differences were not significant in any of the groups (p>0.05). At baseline, CDAI, SDAI and DAS28-CRP(4) means did not differ between groups (p>0.05). There were also no differences in the means of outcome measures at 6 months as well as at 12 months of treatment (p>0.05). Despite this, patients with low baseline TSR had lower mean values of CDAI, SDAI and DAS28-CRP(4) at 6 and 12 months of treatment, consistent with a low disease activity.

Conclusion: To our knowledge this is the first time studying the TSR on treatment response in samples of patients exclusively with PsA. All patients benefited from bDMARD therapy, regardless of the group, suggesting that TSR might not be a good predictor of treatment response in patients with PsA.

AB0916 ASSESSMENT OF PSORIATIC ARTHRITIS IMPACT OF DISEASE (PSAID-12) QUESTIONNAIRE FOR EVALUATIONS OF 6-YEARS TREAT-TO-TARGET STRATEGY OUTCOMES

P. Tremaskina1, E. Loginova1, L. Vorobyov1, T. Korotaeva1, M. Chamurleva1, S. Glukhova1, A. Lita1, S.V. A. Nasonova Research Institute of Rheumatology, Spondyloarthrits and psoriatic arthritis, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, medical and social problems in rheumatology, Moscow, Russian Federation; 3V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: The 12-item psoriatic arthritis impact of disease questionnaire (PSAID-12) have been found to be a reliable instrument to specifically assess the impact of psoriatic arthritis (PsA) for the patients (pts) as well as predictive of long-term outcomes [1]. There are no data about use of the PSAID-12 for evaluation of long-term outcomes of treat to target (T2T) strategy in PsA pts.

Objectives: to assess the PSAID-12 for evaluations of 6-years outcomes of T2T strategy in PsA.

Methods: 50 (M/F=24/26) PsA pts fulfilling CASPAR criteria were included. Mean age 45±12.1 yrs, median (Me) PsA duration 86 [66;97] month (mos), Me 12 yrs. At the early stage (PsA duration<2 yrs) all pts were treated according to T2T strategy within 24 mos. At 6 years follow-up all pts under went standard clinical examination (tender joint count (TJS), swollen joint count (SJC), patient global assessment disease activity (P-GA), CRP (mg/l), skin psoriasis (PsO) by BSA (%) , presence of nail PsO, enthesis dactylitis, DAPSA and completed PSAID-12. PSAID-12 scores > 4 is considered as a “patient-acceptable status symptoms” (PASS). PSAID-12 > 4 is considered as worse quality of life. DAPSA remission (REM-DAPSA) ≤4 and low disease activity (LDA) ≤14, moderate activity (Mo)>28, high activity >56 were calculated. Me [Q25-Q75], M±SD, Spearman’s correlation, Mann-Whitney test were performed. All p<0.05 were considered to indicate statistical significance.
Results: At 6 yrs follow-up REM-DAPSA were seen in 17 out of 50 pts (34%), LDA in 15 out of 50 (30%) pts. Mean total PsAID-12 score was 2.62±2.1. PASS was seen in 38 of out 50 pts (78%). PsAID-12 significantly associated with the PsA activity parameters: TJC (r=0.72, p<0.01), SJC (r=0.55, p<0.05), PGA (r=0.77, p<0.05), CRP (r=0.55, p<0.05) and DAPSA (r=0.75, p<0.05). PsAID-12 is significantly correlated with presence of dactylitis (r=0.33, p<0.05), skin severity (BSA-3) and presence nails PsO (r=0.41, p<0.38) accordingly. In pts with REM/LDA by DAPSA total PsAID score was significantly lower compared to pts with Mo/High activity - 1.34±0.99 and 4.89±1.84, accordingly (p<0.001). All pts with REM/LDA status is achieved PASS by PsAID.

Conclusion: In our clinical practice PsAID-12 associated with joint and skin severity in PsA pts. PsAID-12 is useful instrument for evaluating of the long-term T2T outcomes, including REM/LDA by DAPSA.

## AB0917

A RANDOMIZED, USUAL CARE CONTROLLED, PARALLEL-GROUP PRAGMATIC CLINICAL TRIAL IN AN INTERDISCIPLINARY COMBINED DERMATOLOGY–GASTROENTEROLOGY–RHEUMATOLOGY CLINIC; PRELIMINARY DATA ON BASELINE CHARACTERISTICS OF 128 PATIENTS AND QUESTIONNAIRE-BASED QUALITATIVE DATA FROM 30 PATIENTS AND 15 HCPs

### Background

Immune-Mediated Inflammatory Diseases (IMIDs), including psoriatic arthritis (PsA), axial spondyloarthritis (AxSpA), psoriasis, hidradenitis suppurativa, and inflammatory bowel disease share both pathophysiological and environmental factors, individuals with one IMID have an increased risk for developing other IMIDs, and are associated with reduced health-related quality of life, increased risk of comorbidities, and reduced socioeconomic status. Unmet needs in care of patients with IMIDs may result from lack of patient-centricity in the usual mono-disciplinary siloed approach to these diseases.

### Objectives

The overall aim of this study is to determine the effectiveness of an interdisciplinary combined clinic intervention compared to usual care in patients with the aforementioned IMIDs.

### Results:

**Statistical Methods and Results**

1. **Methods**: This is a randomized, usual care controlled, parallel-group pragmatic clinical trial. 300 consecutively enrolled participants with co-occurrence of at least two IMIDs are randomly assigned 2:1 to either treatment in the interdisciplinary combined clinic or usual care. The study consists of a 6-month active intervention period and a 6-month follow-up period. Primary outcome is change from baseline to 24-Weeks on the Short-Form Health Survey (SF-36). Additional questionnaire-based qualitative data from 30 patients and 15 health-care professionals (HCPs) is involved in the center are reported.

2. **Results**: Here we report baseline characteristics of the first 128 patients (mean age 45.4 yrs, 18-94 yrs, females 83 (64.8%), All patients had ≥2 IMIDs: Psoriasis (98.77%), PsA (peripheral) (72.56%), AxSpA (34, 26.6%), Hidradenitis (16, 12.5%), Cohn (35, 27.3%), Colitis (20, 15.6%), AxSpA (9, 7.9%), IBD-associated arthritis (10, 7.8%), HS-associated arthritis (1, 0.8%), HLA-B27 was positive in 24 (22.2%) patients.

Advantages, challenges and themes mentioned by the patients are listed in Table 1.

### Table 1. Advantages and Challenges on feedback from 15 HCPs and feedback from 30 patients.

<table>
<thead>
<tr>
<th>Advantages - HCP</th>
<th>Challenges - HCP</th>
<th>Themes mentioned by the patients</th>
</tr>
</thead>
<tbody>
<tr>
<td>Professional development</td>
<td>Culture</td>
<td>Communication between HCPs improved treatment</td>
</tr>
<tr>
<td>Satisfy on high professional level</td>
<td>Large differences between specialties and patient area</td>
<td>Collaboration between HCPs improved treatment</td>
</tr>
<tr>
<td>Improved perspective on diseases</td>
<td>Logistics, physical requirements</td>
<td>Holistic approach – patients felt HCPs cared for all health aspects</td>
</tr>
<tr>
<td>Collaboration – professional, personal, team spirit</td>
<td>Shared goals</td>
<td>Confidence in living with diseases</td>
</tr>
<tr>
<td>Meaning full to work with disease</td>
<td>Time and patience</td>
<td>Coherence</td>
</tr>
<tr>
<td>Effective communication</td>
<td>Optimal use of time and resources</td>
<td>Treatment optimization</td>
</tr>
<tr>
<td>Learning can be brought back to ‘monodisciplinary’ work</td>
<td>Improved treatment in respective departments</td>
<td>Clarification about diet, mastering fatigue and work-related problems</td>
</tr>
<tr>
<td>Broader disease focus</td>
<td>Avoid patient being information carrier</td>
<td></td>
</tr>
</tbody>
</table>

### Conclusion

- **Statement from a patient**: “It gave me much more peace of mind that I should not ‘split’ my health problems and run errands between different departments. Didn’t have to tell the same issues in several places or even try to figure out who to say what to, or who can answer a given question.”

- **Conclusion**: In conclusion, an interdisciplinary combined clinic based on an immunomodulation medicine holistic concept has been successfully established. Preliminary results indicate a high value of an interdisciplinary combined clinic in patients with IMIDs, and HCPs find both advantages and challenges in establishing a combined clinic.

## AB0918

### EVALUATION OF X-RAY PROGRESSION AT 6 YEARS FOLLOW-UP OF TREAT-TO-TARGET STRATEGY IN EARLY PSORIATIC ARTHRITIS

#### Background

In psoriatic arthritis (PsA) patients (pts) persistence inflammation in the peripheral joints leading bone erosions, joint space narrowing and new bone formation. Tight control of PsA disease improved joint and skin outcomes, but the number of pts with erosions increased [1]. Despite of clinical improvement no long-term treat to target (T2T) strategy data on radiographs progression yet [2].

### Objectives

To study X-ray progression in PsA pts treated according to T2T strat-egy at the early stage of disease at 6 years (yrs) follow-up.

### Methods

- **Methods**: 30 (M/F–17/13) PsA pts fulfilling CASPAR criteria, mean age 44.7±11.4 yrs, median (Me) PsA duration 78.5 [86.95] month (mos), Me follow-up 71 [82.68] mos, Me DAPSA 24 [7.45]. All pts was treated according to T2T strategy at the early stage with MTX alone or in combination with IFN within 2 yrs. When T2T strategy was ended all pts were treated according to standard care. All pts underwent standard clinical examination of PsA activity, DAPSA was calculated. Radiographs of the hands and feet were available for 30 pts at baseline and 26 (86.6%) at 6 yrs follow-up. Radiographs of the hands and feet were scored using the modified van der Heijde-Sharp (m-v-d-HS) scoring method for PsA assessing both progression yet.

### Results:

- **Results**: At 6 yrs follow-up Me PsA m-v-d-HS and JSN significantly increased from 4 (0-10) to 50 (6-253) and from 3 (0-97) to 50 (6-127) accordingly (p=0.006 and p=0.011); count of erosion from 0 (0-13) to 4 (0-128), p=0.002. In 19 out of 26 pts significantly negative X-Ray progression in the feet and hands by T2T m-v-d-HS, count erosion, joint space narrowing was seen for all p<0.05. In 7 out of 26 pts X-Ray progression was found. PsA activity by DAPSA was significantly higher in pts with X-ray progression compared to those without progression 14.1 [5.3,33.67] and 2.22 [0.55,13.54] accord-ingly (p=0.04), 6 yrs later the number of pts with erosions significantly increased from 12 out of 26 (46%) at baseline to 22 out of 26 (85%) accordingly (p<0.002).

### Conclusion

At 6 yrs follow-up negative radiographic progressions in the hands and feet found in mostly early PsA pts despite of tight control treatment strategy within 2 yrs.

AB0919
PSORIATIC ARTHRITIS: FACTORS ASSOCIATED WITH THE USE OF BIOTHERAPY
S. Savoy1, N. Akasbi1, B. Bourkhime1, I. El Mezouar1, T. Harzy1, 1Hassan II University Hospital, Department of Rheumatology, fez, Morocco; 2Faculty of Medicine and Pharmacy of Fez, Sidi Mohammed Ben Abdellah University, Laboratory of Biostatistical, Clinical and Epidemiological Research, fez, Morocco

Background: The use of biological treatment in psoriatic arthritis has revolutionized its management with both joint and skin efficacy [1].

Objectives: The goal of our study was to evaluate the use of biological treatment in these patients and to assess the factors associated with it.

Methods: Retrospective study conducted within the rheumatology department of the University Hospital of Fez. Patients were recruited from January 2011 to January 2021. We included patients with psoriatic arthritis according to CASPAR criteria and assessed the use of biotherapy as well as the epidemiological, clinical and biological factors associated with it.

Results: There were a total of 98 patients with psoriatic arthritis, 21 of whom had been put on biological treatment. Of the total of 21 patients, there were 42.9% women and 57.1% men, the average age was 51.1 (± 9.92) years. 20% of patients had a history of tuberculosis, 14.3% had diabetes, 10% had hypertension and 30% had dyslipidemia. 60% of patients had an inflammatory syndrome, 73% had radiographic sacroiliitis and 63.2% had functional repercussions. In bivariate analysis, the value of the initial C-reactive protein CRP (p = 0.04), the initial disease activity score DAS 28 CRP (p = 0.0001) and the value of the initial erythrocyte sedimentation rate ESR (p = 0.02) were significantly associated with the use of biotherapy, there was no significant association with the other parameters. In multivariate analysis, no factor was significant.

Conclusion: An active psoriatic arthritis predicts the prescription of a biological treatment, other studies with a larger sample would be necessary to confirm our results.

AB0920
SAFETY OF APREMILAST IN PSA PATIENTS WITH HISTORY OF MALIGNANCIES OR ACTIVE CANCER: A RETROSPECTIVE STUDY
D. V. A. Sabella1, V. Venerito1, M. Fornaro1, F. Cacciapaglia1, M. G. Anelli1, F. Arezzo1, V. Interbo1, G. Lopalo1, F. Iannone1, 1University of Bari Aldo Moro, D.E.T.Q., Bari, Italy; 2University of Bari Aldo Moro, D.M.I.O., Bari, Italy

Background: One of the most intriguing aspects in the management of patients with inflammatory arthritis is the safety of novel therapies in those with a recent history of malignancy or active neoplasm. In this regard, apremilast (APR), an oral PDE4 inhibitor, is emerging as one of the safest therapeutic options in patients with PsA with comorbid cancer.

Objectives: This retrospective study aims to assess the effectiveness and safety of APR in PsA patients with a recent history of malignancy or active cancer.

Methods: We retrospectively observed patients with a history of neoplasm diagnosed from 1997 to 2021, who underwent apremilast treatment from 2017 to 2021 in a tertiary care centre. We recorded demographic and clinical characteristics at APR baseline and last visit. Furthermore, we recorded the eventual recurrence of primary cancer or the onset of new neoplasms. Paired t-test was used to assess the difference of continuous variables at different follow-ups.

Results: There were a total of 98 patients with psoriatic arthritis, 21 of whom had been put on biological treatment. Of the total of 21 patients, there were 42.9% women and 57.1% men, the average age was 51.1 (± 9.92) years. 20% of patients had a history of tuberculosis, 14.3% had diabetes, 10% had hypertension and 30% had dyslipidemia. 60% of patients had an inflammatory syndrome, 73% had radiographic sacroiliitis and 63.2% had functional repercussions. In bivariate analysis, the value of the initial C-reactive protein CRP (p = 0.04), the initial disease activity score DAS 28 CRP (p = 0.0001) and the value of the initial erythrocyte sedimentation rate ESR (p = 0.02) were significantly associated with the use of biotherapy, there was no significant association with the other parameters. In multivariate analysis, no factor was significant.

Conclusion: An active psoriatic arthritis predicts the prescription of a biological treatment, other studies with a larger sample would be necessary to confirm our results.

AB0921
EFFECTIVENESS OF GUSELKUMAB IN PSORIATIC ARTHRITIS IN DAILY CLINICAL PRACTICE
N. Costas Torres1, I. De la Morena2, D. Bedoya-Sanchis3, J. J. Sammartin Martinez4, E. Montesinos Villasecua5, L. Martinez Casimiro6, S. Porcar Saura7, P. Tenero Larraz2, 1Hospital Clínico Universitario, Reumatología, Valencia, Spain; 2INCLIVA institut d’investigació sanitaria, Reumatología, Valencia, Spain; 3Hospital Clínico Universitario, Dermatología, Valencia, Spain

Background: Gusekumab is a monoclonal antibody against interleukin-23, biological agent approved for the treatment of plaque psoriasis and psoriatic arthritis. There are two randomised, double-blind, placebo-controlled phase III studies (DISCOVER 1 and DISCOVER 2) that evaluated the efficacy and safety of gusekumab versus placebo. Treatment with gusekumab resulted in significant improvements in the measures of disease activity compared to placebo at Week 24.

Objectives: To evaluate the effectiveness of Gusekumab in patients with Psoriatic Arthritis, according to CASPAR criteria, undergoing treatment by dermatology indication.

Methods: This is an observational descriptive retrospective study that includes patients with Psoriatic Arthritis (according to CASPAR criteria) who are being treated with guselkumab. The inclusion criterion is biological indication due to skin involvement. In this study, the epidemiological and clinical characteristics of the patients are assessed: IMC, affected domains, previous treatments, concomitant treatments, PASI before beginning the treatment, at 12 week and 24 week, and joint activity measured by DAPSA at the beginning, after 12 and 24 week.

Results: There are 7 patients included, 5 women and 2 men, the mean age were 50 ± 7.9 years old, with a BMI (body mass index) average of 33.13 ± 6.26. All the patients presented skin involvement: 4 of 7 with plaque psoriasis (2 of them with scalp psoriasis, and one of those two with inverse psoriasis), 3 of 7 with psoriasis on palms and soles (one with scalp psoriasis and inverse psoriasis), and 2 of 7 patients with nail involvement. Regarding joint damage, all the patients presented peripheral joint involvement, 2 of 7 with axial too. For the other domains: 2 of 7 with history of uveitis, 1 of 7 with one episode of dactylitis, and none of them had any episode of enthesitis nor inflammatory bowel disease. All the patients had received at least 1 bDMARD (average of 2.8 ± 2.23, but one of them had used 7 before). All the patients received the standard dose of Gusekumab 100mg sc weekly for 4 weeks) and later on as maintenance treatment to 6 weeks, with a duration of treatment in 2 patients, with an average of 6.3 ± 2.88. At the same time, 1 of 7 patient used Methotrexate concomitantly, 2 of 7 with leflunomide, and 1 of 7 with NSAIDs. The PASI average at the beginning of the treatment with Gusekumab was 9.25 ± 4.99, at 12 week all the patients had obtained a PASI 0, and remained in remission. Regarding joint damage measured with DAPSA, at the beginning of Gusekumab treatment the average was 24.15 ± 22.02, at 12 week 12.19 ± 5.56, at the 24 week 8.86 ± 1.6, of all the patients improved, without any inflammatory flares. Any of them presented uveitis, enthesis nor dactylitis. Drug retention rate of 100%, all the patients are still in treatment with Gusekumab, any side effect was detected.

Conclusion: Gusekumab is a very effective drug for the treatment of psoriasis, and the joint involvement in patients with failure to BIOxARD. We need more real life studies to determine the effectiveness in daily clinical practise.

PSORIATIC ARTHRITIS DISEASE ACTIVITY DIFFERS BY RACE/ETHNICITY

F. Ahmed1, A. Ogdie2, R. Fitzsimmons1, D. Shin1, J. Takeshita1, 1University of Pennsylvania, Department of Dermatology, Philadelphia, United States of America; 2University of Pennsylvania, Department of Rheumatology, Philadelphia, United States of America

Background: Psoriatic arthritis (PsA) affects up to 30% of individuals with psoriasis. Studies have demonstrated that the presenting disease severity and quality of life impact of psoriasis differs by race/ethnicity in patients with and without PsA, but little is known about disease activity among different racial/ethnic groups [1-3].

Objectives: The objective of our study was to evaluate disease activity by race/ethnicity among patients with PsA.

Methods: We performed a cross-sectional study of adult (≥18 years old) patients with PsA who had at least one outpatient visit within the University of Pennsylvania health system between 2010 and 2019. Patients with PsA were identified by the presence of at least two International Classification of Diseases (ICD)-9 or ICD-10 codes for PsA associated with two different healthcare encounters. The primary outcome was disease activity as measured by theRoutine Assessment of Patient Index Data 3 (RAPID3) score. The RAPID3 score is a validated patient-reported measure of physical function, pain, and global status [4]. RAPID3 scores range from 0 to 30, with higher scores indicating greater disease activity. Patients were included if they had at least one documented RAPID3 score. For patients with multiple RAPID3 scores, the median value was used. The primary individual variable was race/ethnicity categorized as White (reference), Black, Asian, Hispanic, or other race. Multivariable linear regression was used to assess the relationship between race/ethnicity and RAPID 3 score.

Results: The study population included 742 patients. Mean (standard deviation) age was 47.2 (13.3) years and 57.4% were female. The racial/ethnic distribution was 79.4% White, 7.0% Black, 5.0% Asian, 3.1% Hispanic, 2.6% other race, and 3.0% missing race/ethnicity. The means of the median RAPID3 scores were statistically significantly different across racial/ethnic groups (p<0.001). White mean (SD) 7.99 (6.02), Black mean (SD) 14.86 (14.86), Asian mean (SD) 9.79 (5.44), Hispanic mean (SD) 15.09 (7.11), other race mean (SD) 10.57 (6.91). In an adjusted multivariable model controlling for other sociodemographic factors, body mass index, treatment history, and medical comorbidity, Hispanic patients had higher RAPID3 scores compared to White patients, indicating greater disease activity (β=3.36; 95% confidence interval [CI] 1.04 – 5.67, p<0.005). In exploratory stratified analyses to evaluate effect modification by sex, among males, Black (β=3.43; 95% CI 0.23 – 6.63, p=0.04) and Hispanic (β=5.94; 95% CI 2.18 – 9.70, p<0.005) patients had higher RAPID3 scores than White patients. Among females, no significant racial/ethnic differences in RAPID3 scores were identified.

Conclusion: Black and Hispanic patients report greater disease activity as indicated by higher RAPID3 scores compared to White patients. Larger studies are necessary to confirm our findings and further understand the causes of racial/ethnic differences in disease activity among PsA patients.

ASSESSMENT OF FOUR SCREENING TOOLS AND RETRIEVAL OF KEY QUESTIONS TO DETECT UNDIAGNOSED PSORIATIC ARTHRITIS IN CHINESE PATIENTS WITH PSORIASIS: A MULTICENTER STUDY

R. Cui1, M. Chen1, S. M. Dai1, 1Shanghai Jiao Tong University Affiliated Sixth People’s Hospital, Department of Rheumatology and Immunology, Shanghai, China

Background: The available data showed great discrepancies in the performance of screening tools in detecting psoriatic arthritis (PsA) in patients with psoriasis, and those including the diagnosed PsA in the validation might exaggerate/oversimplify the performance. The key questions in each tool were unclear and their contributions were not systematically assessed. Here the performance of four different screening tools were validated and compared in detecting undiagnosed PsA, and the key questions with different weights of them were retrieved and evaluated.

Objectives: To compare and validate the performance of the four screening tools in detecting undiagnosed psoriatic arthritis (PsA) in Chinese patients with psoriasis, and to determine the key questions and their weights.

Methods: Consecutive patients with psoriasis but no prior diagnosis of PsA from dermatology clinics and patients with newly diagnosed PsA from rheumatology clinics who were blind to the diagnosis were recruited to complete questionnaires, including early psoriatic arthritis screening questionnaire (EARP), psoriatic arthritis screening and evaluation questionnaire (PASE), psoriasis and arthritis screening questionnaire (PASQ), and psoriasis epidemiology screening tool (PEST). The receiver operator characteristic (ROC) curve with area under curve (AUC) was used to determine sensitivity, specificity and accuracy. The LASSO and logistic regression were utilized to retrieve key questions, and a nomogram was utilized to visualize their weights.

Results: Of 482 psoriasis patients from dermatology clinics, 77 patients were newly diagnosed with PsA. Another 68 patients with newly diagnosed PsA from rheumatology clinics were incorporated in the analysis. ROC analysis indicated that the optimal cut-off values for EARP, PASE, PASQ and PEST were 3, 40, 7 and 3, with corresponding sensitivities of 91.4%, 88.6%, 88.2% and 88.5%, and specificities of 88.6%, 75.2%, 80.2% and 83.6%, respectively. The AUC of EARP (0.925) was higher than those of PASE (0.885), PASO (0.905) and PEST (0.827). A total of twelve key questions were retrieved from these four tools, and their relative weights were scored as 5–100 individually with a nomogram.

Conclusion: To screen undiagnosed PsA, EARP have slightly better balanced sensitivities and specificities. The retrieved twelve key questions may be helpful in proposing a new questionnaire with different scores of each question to screen PsA more efficiently.

INDIVIDUAL DIGIT LEVEL NAIL INVOLVEMENT AND JOINT ASSESSMENT IN PATIENTS WITH NAIL PSORIASIS

C. T. Ritchie1, L. E. Kristensen2, B. Strober3, A. K.avanaugh4, R. Boloe5, J. Lisse6, J. Pustizzi6, N. Somani6, C. Sapin6, J. F. Merola7, 1University of Rochester Medical Center, Allergy, Immunology, and Rheumatology, Rochester, United States of America; 2Bispebjerg and Frederiksberg Hospital, Musculoskeletal Statistics Unit, The Parker Institute, Copenhagen, Denmark; 3Yale University, Yale University, New Haven, United States of America; 4Central Connecticut Dermatological., Cromwell, United States of America; 5University of California San Diego, Department of Rheumatology, Allergy, and Immunology, La Jolla, United States of America; 6Eli Lilly and Company, Corporate Center, Indianapolis, United States of America; 7Birmingham and Women’s Hospital, Department of Medicine, Division of Rheumatology, and Department of Dermatology, Boston, United States of America

Background: The relationship between the evolution of nail disease and the articular features of Psoriatic Arthritis (PsA) is poorly understood. There is a lack of data on the relationship between nail and joint disease, important clinical parameters of disease activity, specifically at the individual digit level.

Objectives: To evaluate the level of association, at digit level, between nail involvement and joint disease at baseline, with a special focus on distal interphalangeal joint (DIP) assessment.

Methods: SPHERE-H2H (NCT03151551) was a 52 week, multicenter, randomised, open-label, parallel-group, assessor-blinded study evaluating the efficacy and safety of IXE vs ADA in PsA. Nail psoriasis was measured using Nail Psoriasis Severity Index (NAPSI) at baseline. The NAPSI assessment was measured using total NAPSI score and total unwollen joint count (TC/JUC) score. Here we examine both baseline tenderness and swollenness at the DIP joint, proximal interphalangeal (PIP) joint and metacarpophalangeal (MCP) joint level for each digit and evaluate the level of association
between nail involvement (NAPSI>0 vs NAPSI=0) and joint assessment using Chi-square tests and/or Fisher's exact test where relevant.

Results: Overall, 368 patients (IXE N=191, ADA N=177) out of 566 had a baseline NAPSI>0. The overall level of nail involvement ranged from 52.7% (n=194) (right 5th finger) to 67.9% (n=250) (right 1st finger). When considering a digit-wide assessment of joints (DIP,PIP, and MCP), in general, no clear association was found between NAPSI >0 and joint involvement. However, there was more frequent DIP joint involvement in patients with nail involvement compared to patients without nail involvement. When taking only the DIP joint into account, nail involvement was found to be statistically associated with tenderness and/or swelling at the DIP level (Figure 1), with differences between patients with nail involvement vs. without nail involvement ranging from 7.9% (p=0.023) (right 5th finger) to 19.4% (p=0.001) (left 3rd finger). These differences are mostly driven by tenderness rather than swelling, irrespective of digit. For tenderness, differences (with vs. without nail involvement) ranged from 70% (right 2nd finger) to 18.0% (left 3rd finger). Differences due to swelling ranged from 5.0% (left 1st finger) to 12.2% (left 3rd finger).

Conclusion: In SPIRIT-H2H, tenderness and/or swelling at the DIP joint was significantly associated with nail involvement in individual digits.

Background: Psoriatic Arthritis (PsA) is a challenging diagnosis both for the absence of specific biomarkers and for its clinical heterogeneity, especially in its initial phases. Early onset of PsA is mostly characterized by mono-oligoarthriti- s, enthesis, dactylitis, onychopathy, modest cutaneous involvement. At least 50% of early-PsA patients initially come at dermatologist’s attention because they carry only few musculoskeletal symptoms such as enthesitis and dactylitis. Rheumatological evaluation and ultrasound (US) demonstration of articular and enthesal inflammation allows to augment the probability of an early diagnosis in a short period of time.

Methods: All patients referred to our derma-rheumatological clinic were considered from July 2017 to July 2019 for suspected PsA. Patients with PsA were considered in the present study. 5% of them were studied with US, according to clinical necessity. All the suspected patients were studied using both B-mode and Power Doppler.

Results: 81 patients, sent to our attention for suspected PsA, were included. In 18 (37%) of them diagnosis was confirmed (Caspar criteria were satisfied). In these patients oligoarthritis (80%), enthesis (40%), dactylitis (23%), sometimes in combination, were the most frequent presentations. In 25% of cases enthesitis was the only clinical feature. Articular disease activity was low to moderate in most of patients (DAPSA 14.83 ± 10.08). Disease duration at the diagnosis was 12 months in 90% of cases and the time occurring between symptoms and the first advanced therapy was 18 months in 50% of cases. US study allowed to redefine disease status in 30% of cases. Arthritis and enthesitis were the main domains where US evaluation gave more diagnostic value.

Conclusion: Literature reports a mean time to diagnosis and to start advanced pharmacological therapy respectively of 1.5 and 5 years. In our report, time to start advanced therapy was much longer than expected, falling in the so-called window of opportunity. US study importantly contributed to reach this target, allowing us to identify as soon as possible sub-clinical and pauci-symptomatic forms (low disease activity, prevailing enthesal domain), which could otherwise be misdiagnosed or have an important diagnostic delay. The attention of dermatologist and integrated evaluation allowed us to optimize our diagnostic-therapeutic work-up in patients affected by early PsA, allowing them to receive sooner advanced therapies, according to recent EULAR and GRAPPA recommendations.

ENTHESIS OF THE HAND IS A DOMINANT LESION IN PSORIATIC ARTHRITIS AND MAY HELP DISTINGUISH IT FROM RHEUMATOID ARTHRITIS: CASE-CONTROL, SINGLE-CENTRE, ULTRASOUND STUDY

D. Esperança Almeida1, A. M. Gomes Correia1, E. Costa1, J. Neves1, J. Silva1, A. R. Ribeiro1, M. Cerqueira1, 1Hospital de Braga, Rheumatology, Braga, Portugal

Background: Enthesitis is the hallmark of psoriatic arthritis (PsA) and may assist in distinguishing PsA from other forms of arthritis (1,2). Its clinical evaluation is hampered by lack of specificity of physical examination (3). Ultrasound (US) may provide information about its presence and response to treatment. Although some previous works have shown that enthesitis of the hand is important in PsA (4), most US studies and scores focused on greater size entheses.

Objectives: To explore the prevalence of enthesitis of the hand in PsA patients as evaluated by US, and compare it with other inflammatory arthritides, namely rheumatoid arthritis (RA).

Methods: Cross-sectional study in which consecutive patients with PsA and RA were recruited for an US protocol evaluating 4 entheses of the hand including: 1. measurement of the extensor digitorum tendon central slip at its insertion at the middle phalanx of the 2nd and 3rd finger bilaterally; 2. search for the presence of power-Doppler (PD) sign; 3. identification of structural lesions. Linear regression models were built to test if diagnosis (PsA vs RA) explained part of the variance of the thickness of tendons insertion while controlling possible influences of age, type of work and body surface area. A ROC curve was built to find a mean thickness cut-off allowing distinction between PsA and RA. The prevalence of PD sign and structural lesions of the entheses was compared between groups.
Results: Fifty-eight patients were recruited (29 with PsA and 29 with RA) and a total of 232 entheses were evaluated. Mean thickness of the interest entheses was superior in PsA patients compared to RA patients (2nd finger – 0.96 ± 0.16mm vs. 0.74 ± 0.09mm; 3rd finger – 0.96 ± 0.25mm vs. 0.76 ± 0.11mm).

Table 1. Multiple linear regression models explaining thickness of the entheses.

<table>
<thead>
<tr>
<th>Linear regression model</th>
<th>PsA vs RA</th>
<th>Diagnosis (PsA vs RA)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2nd finger (mean of both sides)</td>
<td>R²=0.56 p&lt;0.001***</td>
<td>(β=0.587; B=0.203mm) p&lt;0.001***</td>
</tr>
<tr>
<td>3rd finger (mean of both sides)</td>
<td>R²=0.39 p&lt;0.001***</td>
<td>(β=0.483; B=0.182mm) p&lt;0.001***</td>
</tr>
</tbody>
</table>

In our sample, 8 (3.5%) entheses had a measured thickness above mean ± 2 SD, all belonging to PsA patients; 6 (75%) had signs of ongoing inflammatory process as proved by the presence of PD sign (Figure 1). Regarding structural lesions, entheseophytes or bone irregularities/erosions were found in 13.6% of PsA entheses, which compared to 1.7% of RA entheses.

Figure 1. Enthesitis of the central slip of extensor digitorum of the 3rd finger in a patient with PsA: swelling of the 3rd proximal interphalangeal joint (A) due to inflammatory process originating in the enthesis, with no signs of synovitis, as evaluated by US (B).

Conclusion: This work reinforces enthesis as a key lesion in PsA. It also shows enthesis occurs significantly in small entheses, like the ones of the hand and that, in some instances, it may be the dominant lesion in a swollen joint. US may be valuable for establishing a diagnosis in the setting of inflammatory arthritis of unknown etiology.

Disclosure of Interests: None declared.

determining HLA B27 antigen status and X-rays of sacroiliac joints (SIJs) (pelvic radiographs), hands and feet. Bilateral changes in SIJs of grades 2-2, 3-3 and 4-4 were defined as symmetrical SI (sym-SI). Changes in SIJs of grades 2-1, 3-1, 1-2, 2-4 and 3-4 were defined as asymmetrical SI (asym-SI). Skin lesion severity was evaluated in terms of body surface area (BSA) affected and Psoriasis Area Severity Index (PASI). When BSA was ≥ 3%, PASI was calculated. Me [Q25; Q75], Pierson-2 were tested. All p<0.05 were considered to indicate statistical significance.

Results: Sym-SI was found in 187 (65.1%) pts, asym-SI—in 100 (34.8%) pts. In group (gr) of pts with asym-SI there were more females than in the sym-SI gr: 63 (63.0%) vs 77 (41.2%); p = 0.004. Pts with asym-SI had more severe peripheral arthritis as measured by Tender Joint Count (TJC66) and Swollen Joint Count (SJ66). These values were higher in asym-SI gr: 9 (4-16) vs 6 (2-14; p = 0.007) and 5 (2-12) vs 3 (0-9; p = 0.004), respectively. High activity according to DAPSA was found in 53 (54.6%) pts in the asym-SI gr vs 71 (38.8%) in the sym-SI gr (p = 0.01); low activity and remission by DAPSA– in 16 (16.5%) pts vs 51 (28.3%; p = 0.028), respectively. The frequency of enthesitis was higher in the asym-SI gr: 50 (57.5%) pts vs 57 (38.5%) pts (p = 0.005). Pts functional capacity as measured by Health Assessment Questionnaire (HAQ) was worse in the asym-SI gr: HAQ>0.5 values were found in 83 (84.7%) pts vs 130 (72.6%) pts (p = 0.023). No significant differences were found between HLA B27 positivity in sym-SI and asym-SI groups (which were 54.2% and 44.0%, respectively; p = 0.23).

Conclusion: Asym-SI in PsA is associated with female gender, more severe peripheral arthritis, higher activity according to DAPSA, more frequency of enthesitis and reduction of pts functional capacity.

Background: The majority if patients with PsA present with skin manifestations first. Few studies have examined the relationship between severity of skin and joint manifestations, but the results have been variable.

Objectives: To assess the correlation between the extent and severity of skin psoriasis and musculoskeletal manifestations of PsA over time.

Methods: This study is a retrospective analysis of prospectively collected data at a single center cohort study of patients who enrolled within 12 months of PsA diagnosis from 2000-2020. Patients are assessed according to a standard protocol which includes demographics, clinical assessment including skin and joint assessments, laboratory evaluation at 6–12-month intervals and radiographs every 2 years. Skin severity is measured by the PASI score, joint disease severity by the number of tender and swollen joints. Axial disease was defined by the presence of bilateral grade sacroiliac or unilateral grade 3 or 4. The Bath Ankylosing Spondylitis Metrology Index (BASMI) was also measured.

Spearman correlations were calculated between PASI scores and joint counts and BASMI (in patients with axial disease). Multivariable analysis was done using negative binomial model for the joint counts and a linear regression for BASMI. This preliminary analysis includes only the baseline information.

Results: 397 patients were included. Characteristics are shown in the Table 1. There was a correlation significant between PASI score and the active joint count (AJC) (ρ = 0.14, p=0.0095), swollen joint count (ρ = 0.15, p=0.0071). Among the patients with axial disease there was a strong correlation between the PASI and BASMI scores (ρ = 0.58, p=0.0001). Multivariable analysis for AJC revealed traditional DMARDs (0.85 P0.00), PASI score when patients were on no therapy (0.02 p=0.01) and those on biologics 0.04 p<0.05 were associated with higher AJC. Similarly for swollen joints the use of traditional DMARDs (0.85 P0.00), and the PASI score in those taking biologic DMARDs (0.07 p=0.003) were associated with higher swollen joint count. In patients with axial disease Age (0/05, p=0.004), PASI score in patients on no treatment (0.06 p=0.000) or those taking biologics (0.28 p=0.000) were associated with higher BASMI scores.

Conclusion: In patients presenting within 12 months of diagnosis of PsA, there is a correlation between the severity of skin and joint disease. Further studies will assess whether this correlation persists over time.

CHARACTERISTICS ASSOCIATED WITH THE PERCEPTION OF HIGH-IMPACT DISEASE (PSAID ≥4) IN PATIENTS WITH RECENT-ONSET PSORIATIC ARTHRITIS. MODEL BASED ON MACHINE LEARNING

D. Seoane-Mato¹, R. Querol Silva², A. Laiz³, E. Galindez⁴, C. A. Montilla-Martín⁵, B. Joven-Ibáñez³, E. Tonio⁶, J. Ramirez⁷, A. Serrano García⁸ on behalf of Proyecto REAPSER Study Group. ¹Spanish Society of Rheumatology, Research Unit, Madrid, Spain; ²Universidad de Oviedo, Rheumatology Service & the Principality of Asturias Institute for Health Research (ISPA), Faculty of Medicine, Oviedo, Spain; ³Hospital Universitari de la Santa Creu i Sant Pau, Rheumatology and Autoimmune Disease Department, Barcelona, Spain; ⁴Hospital Universitario Basurto, Rheumatology Service, Bilbao, Spain; ⁵Hospital Universitario de Salamanca, Rheumatology Service, Salamanca, Spain; ⁶Complexo Hospitalario Universitario de A Coruña, Rheumatology Service-INITIC, A Coruña, Spain; ⁷Hospital Universitario de Canarias, Rheumatology Service, Sta. Cruz de Tenerife, Spain; ⁸Hospital Universitario 12 de Octubre, Rheumatology Service, Madrid, Spain; ⁹Hospital Universitari Son Llàtzer, Rheumatology Service, Palma de Mallorca, Spain; ¹⁰Hospital Clinic Barcelona, Arthritis Unit, Rheumatology Department, Barcelona, Spain; ¹¹Universidad Autónoma de Madrid, Knowledge Engineering Institute, Madrid, Spain

Background: The Psoriatic Arthritis Impact of Disease (PsAID) questionnaire is the standard tool for evaluating the impact of psoriatic arthritis (PsA) on quality of life [1]. Variables associated with high disease impact were studied in patients with long-standing established disease. The characteristics associated with high-impact PsAID in recent-onset PsA remain unknown.

Objectives: To evaluate which patient and disease characteristics are associated with the perception of high-impact disease (PsAID ≥4) in recent-onset PsA. All patients gave their informed consent. The study was approved by the Clinical Research Ethics Committee of the Principality of Asturias. We conducted a cross-sectional analysis. The dataset was generated using data for the independent variables at the 3 visits (baseline, first year, and second year of follow-up) matched with the PsAID values at each of the 3 visits. PsAID was categorized into two groups, namely, <4 and ≥4 [1]. We trained logistic regression models and a random forest-type machine learning algorithm to analyze the association between the outcome measure and the variables selected in the bivariate analysis (statistical significance defined as p value <0.05). We used a confusion matrix to visualize the performance of the final model. This matrix shows the real class of the data items, together with the class predicted by the machine learning algorithm, and records the number of hits and misses.

Results: The sample comprised 158 patients. 20.9% were lost to follow-up. Of the patients who attended the clinic, 45.8% scored PsAID ≥4 at baseline, 27.1% at the first follow-up visit, and 23.0%, at the second follow-up visit. The variables associated with PsAID ≥4 selected in the logistic regression analysis were HAQ, patient global pain during the previous week, educational level, and level of physical activity in the previous week. The association was positive for the first 2 variables and for level of physical activity and negative for educational level. When physical activity was analyzed as a categorical variable, a possible negative association was observed for a moderate level (although this was not statistically significant) and a positive association was observed for a high level (Table 1).

</tr>
</tbody>
</table>

When the random forest–type machine learning algorithm was trained with these 4 variables, the order of importance (from more to less) attributed by the model was: patient global pain, HAQ, educational level, and physical activity. The percentage of hits in the confusion matrix was 86.14%.

Conclusion: Pain control and control of the disease as a whole, preventing patients from suffering a decrease in their functional capacity, are first-order treatment objectives. PsA patients should take regular physical exercise, but with a moderate or low impact on their joints and entheses.

DEVELOPMENT AND VALIDATION OF A NOMOGRAM FOR PREDICTION OF NONALCOHOLIC FATTY LIVER DISEASE IN PSORIATIC ARTHRITIS

B. C. Li1, R. Su1, H. Yan1, J. Liu1, C. Wang1. 1The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; 2The Second Hospital of Shanxi Medical University, Department of General, Taiyuan, China

Background: Psoriatic arthritis (PsA) has been linked to an increased risk of metabolic syndrome (MetS). Non-alcoholic fatty liver disease (NAFLD), the hepatic manifestation of MetS, is now the commonest liver disease worldwide. About 65% of PsA patients suffer from NAFLD, and chronic systemic inflammation may be an important predisposing factor.

Objectives: The purpose of this study was to establish and validate a diagnostic model nomogram for predicting the occurrence of NAFLD in patients with PsA.

Methods: A total of 127 PsA patients (46 had NAFLD and 81 had no NAFLD) were enrolled in this study. Retrospectively collected clinical and serological parameters of these patients. The percentage and absolute number of lymphocytes and CD4+T cells were determined by Flow cytometry. The independent risk factors for NAFLD were screened in the PsA patients using univariate and multivariate binary logistic regression analyses and were used for construction of the nomogram prediction model. The AUROC (C-index) was used to verify the model discrimination; the calibration curve and Hosmer-Lemeshow test were used to verify the model calibration; and the DCA curve was used to verify the clinical validity of the model.

Results: Univariate and multivariate logistic regression analyses showed that Body Mass Index (BMI) (OR=1.25, P<0.001), serum triglyceride (TG) (OR=3.51, P=0.015) and peripheral blood Th1 cell percentage (OR=1.12, P<0.001) is an independent risk factor for NAFLD in PsA patients, and an individualized nomogram prediction model was successfully established. The prediction model had a good discrimination power with AUROC (C-index) of 0.83 (95% CI: 0.76-0.90); the P value in the Hosmer-Lemeshow test was 0.683, suggesting a high reliability of the predicted probability by the model; the DCA curve indicating a good clinical efficiency of the model.

Conclusion: Our study shows that the establishment of a nomogram prediction model of PsA complicated with NAFLD patients is helpful for early clinical screening and identification of such high-risk patients.

Disclosure of Interests: None declared
Recently, we have reported an increase in the incidence and prevalence of patients with PsA in Germany based on claim data from 65 million people in statutory health insurance during 2009 to 2012 [1].

Objectives: Population-based estimation of long-term projection for incidence and prevalence of patients with diagnosis of PsA until the year 2040.

Methods: Based on prevalence and incidence of PsA, the number of men and women diagnosed with PsA until 2040 is projected using the illness-death model [2]. The mortality and age distribution of the general population is taken from the official population forecasts of the German Federal Statistical Office. Mortality of patients with PsA was considered by using estimates of the mortality rate ratios [3]. Percent change in projected case numbers refer to 2012 (base year).

Results: Starting from 2012, three scenarios about the incidence of PsA after 2012 were found (Graph 1): (A) increase of 5% per year as observed in [1], (B) no trend in incidence and (C) decrease of a similar 5% per year due to a theoretically anticipated early treatment effect. In scenario C, the number of men and women peaks at about 2028 and decreases slightly afterwards. The graph shows the projected numbers of men (left panel) and women (right) with PsA until 2040 in the three incidence scenarios. The projected numbers and the percent changes are given in the Table 1. Different scenario may be considered based on recent population data for the incidence course of PsA until 2040. The most optimistic scenario showed a trend of stabilization of incidence including the anticipated population mortality rates. Thus, it is likely that substantially more medical resources for treating patients with PsA are necessary in the next two decades, whereby approaches to the potential prevention of PsA, for example by very early treatment of psoriasis patients, should be further pursued.

Background: Recent years of progress in conventional and biologic disease-modifying anti-rheumatic drugs development and improved treatment strategies (treat to target) have yield in improved outcome in psoriatic arthritis (PsA) patients. [1,2]. Still, despite modern treatment and clinical monitoring methods, we might miss dimensions of disease burden outside our main focus including quality of life (QoL), which are of high importance from patients’ perspective.

Objectives: Main objective of this study was to explore how clinical aspects of disease activity and QoL measures will change in PsA patients in an ordinary outpatient clinic in Norway, followed for 5 years, in the biological treatment era.

Methods: PsA patients fulfilling the CASPAR criteria visiting an outpatient clinic in Norway between January 2013 and February 2020 were consecutively included in the study. Data collection included variables for demographics, treatment, laboratory assessment of ESR and CRP, joint counts, disease activity score in psoriatic arthritis (DAPSA), global assessments – patient’s (PGA) and investigator’s (IGA), reported joint and global pain, patient reported outcomes (PROMs) regarding different aspects of quality of life (QoL), (MHAQ, RAID, QoLSD) and reported fatigue level. Patients were analyzed at baseline and after 5-year follow-up period. Statistics included paired sample t test and McNemar test.

Results: Among 140 PsA patients included at baseline, 114 (81.4%) were re-examined after 5 years. Mean age at baseline was 52 years (95%CI 50.3-53.7) and percentage of women was 50.7%. Proportion of patients treated with biologics increased from 32.9% to 39.5%, but the difference wasn’t statistically significant. During the 5 year follow up period most clinical disease activity measures decreased and QoL was maintained (Table 1).

Conclusion: In our cohort of PsA patients after 5 years follow up disease activity was reduced and QoL maintained. Our data adds to the evidence that the burden of disease in PsA patients has decreased in the biologic treatment era however is still significant. Further improvement in pharmacological and non-pharmacological treatments in PsA patients is still needed.

and 48 dermatology specialists answered the questions in the second round. At the second tour, the number of questions was reduced from 44 to 22. The distribution of the questions was as follows: Skin and nail involvement n=5, dactylytis n=3, joint question n=2, axial involvement n=2, morning stiffness n=2, enthesis n=1, general questions n=5. A consensus meeting was held to discuss 22 questions determined at the end of the second round within the initial core group. Each question was handled one by one, some of the questions were combined, if necessary, adapted to Turkish. The tool was given its final form. The final version of the questionnaire consists of 6 questions. (Table 1).

Conclusion: A new screening tool targeting different domains in Psoriatic disease was developed in Turkish. While cultural differences play an important role in screening, we believe that the first tool developed in Turkish will be helpful in clinical practice and research settings. Further assessments will be done to understand its validity and reliability within a large cohort of psoriatic patients.

PSORIATIC ARTHRITIS RELATED FATIGUE: WHAT IS THE MAGNITUDE OF THIS PROBLEM AND WHAT ARE THE CORRELATED FACTORS? A CROSS-SECTIONAL STUDY.

A. Martins1,2, D. Santos Oliveira1-3, F. R. Martins4, B. Samões4, R. Nicolau4, F. Oliveira Pinheiro1,2, M. Rato1,2, S. Pimenta1,2, M. Bernades1,2, L. Costa1.

1Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal; 2Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal; 3Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; 4Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal; 5Centro Hospitalar Vila Nova de Gaia / Espinho - Unit 1, Rheumatology Department, Vila Nova de Gaia, Portugal; 6Centro Hospitalar Tondela-Viseu, Rheumatology Department, Viseu, Portugal

Background: Fatigue is a common constitutional feature and has a significant impact on quality of life in patients with chronic inflammatory rheumatic diseases, such as psoriatic arthritis (PsA), It is a complex phenomenon and its pathogenesis remains unclear. Despite being a common symptom, it is largely ignored and rarely assessed in clinical practice.

Objectives: This study aims to evaluate the incidence and severity of fatigue in PsA patients under biological agents and to assess the influence of several clinical and demographic features on PsA related fatigue.

Methods: We conducted a cross-sectional study including patients with PsA, according to CASPAR criteria, treated with biological agents, from our University Hospital and registered in the national database (reuma.pt). Fatigue was assessed by a 13-item self-administered questionnaire (Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F]). Data collected and analyzed included: demographic data, disease activity data, functional status, comorbidities and therapies. Student's t-test, ANOVA and Pearson's correlation were performed to compare data, as appropriate. A p-value <0.05 was considered statistically significant.

Results: 60 PsA patients were included, 61.7% were males, with a mean age at diagnosis of 38.1±10.5 years and a median disease duration of 13.0 (8.75-19.25) years. Most of the included patients had a predominant polyarticular pattern (n=33, 55.0%). The mean FACIT-F score was 34.48±11.61. No differences were found in the FACIT-F score according to gender, pattern of joint involvement, presence or absence of cutaneous involvement, nail dystrophy and/or dactylytis. Patients with depression and enthesis exhibited a lower FACIT-F score (p=0.017 and p=0.007, respectively). Patients treated with tocilizumab had a lower FACIT-F score than patients treated with adalimumab (p=0.025). No differences were found among the other biological agents. Patients in remission (according to EULAR response criteria) had a higher FACIT-T score than patients with moderate disease activity (p=0.032). In patients with a predominant axial involvement, inactive disease (according to ASDAS) was associated with a higher FACIT-T score, when compared to very high disease activity (p=0.02). Also, patients with moderate disease activity had a higher FACIT-T score than patients with very high (p=0.003) and high (p=0.008) disease activity.

Conclusion: We showed a significant correlation with disease activity scores as BASDAI (r=-0.548, p<0.001), DAS 28 CRP (r=-0.506, p<0.001), CDAS (r=-0.672, p<0.001), SDI (r=-0.641, p<0.001) and ASDAS CRP (r=-0.550, p<0.001). FACIT-F was also correlated with BASFI (r=-0.598, p<0.001), HAQ (r=-0.701, p<0.001), BASMI (r=-0.431, p<0.001) and MASES (r=-0.401, p<0.001). The authors found strong correlations between FACIT-F and HADS domains (Depression and Anxiety domains; r=-0.850, p<0.001 and r=-0.788, p<0.001, respectively). A strong correlation was also found between the FACIT-F and the 8 domains of health of the SF36 (p<0.001).

Disclosure of Interests: None declared.

one autoantibody and 21.2% triple negativity after treatment. ANA showed the highest rates of seropositivity among autoantibodies with a rate of 40% before and 55.3% after biologic treatment. Concomitant seropositivity for RF and CCP autoantibodies showed rates of 2.8% and 6.3% before and after treatment, respectively. The most common subtype was AC4-5 before and AC1-4-5 after biologic agent treatment. ANA was tested in 31 patients both before and after biologic treatment showing 6 negative patients became positive after treatment and from 12 positive patients at the baseline 6 of them became negative (p=0.452). The most common biologic agents used in patients with ANA tested after treatment, were adalimumab (ADA) (42.4%), etanercept (ETN) (18.9%), and infliximab (IFX) (18.9%). The only difference was observed in IFX treated patients (n=25) with significantly higher rates of IFX usage in ANA-positive patients (p=0.001).

**Conclusion:** Synovial lymphoid neogenesis rates in PsA are similar to the frequency seen in rheumatoid arthritis (1). Nevertheless, PsA is classified under the group of “seronegative diseases." On the other hand, current reports have started to define specific autoantibodies particularly in psoriatic patients (2). The real-life experience in serology results of PsA patients showed that only 20-30% of the patients were seronegative for all three tests commonly used in practice.

**DISCRIMINATION OF ENTHESIS INFLAMMATORY INVOLVEMENT IN PATIENTS WITH SPONDYLOARTHRITIS THROUGH THE USE OF COMPUTER ANALYSIS OF STATIC ULTRASOUND IMAGES**

C. Guillén-Astete1, Á. Andreu-Suárez2, M. Tortosa-Cabañas1, M. Martinez Aznar2,1. University Hospital Ramón y Cajal, Rheumatology; Madrid, Spain; 2Universidad Europea de Madrid, Faculty of Biological Sciences, Madrid, Spain

**Background:** One of the weaknesses of the ultrasound study of the entheses is the absence of a universal, recognized and replicable ordinal evaluation scale that allows quantifying or semi-quantifying the degree of involvement of these structures.

**Objectives:** To analyze computer analysis of static images of patients with inflammatory enthesopathies differentiation capacity. To determine its ability to discriminate between an affected and a healthy contralateral enthesis in the same individual.

**Methods:** Static images of the Achilles and epicondylar entheses of patients who consulted regarding enthesis pain associated with spondyloarthritides were analyzed. The patients included were from 2016 to 2020. Images were obtained by the same observer under clinical practice routine circumstances and with the same ultrasound equipment (Logiq B®, General Electric, USA). The same settings for each of the two enthesic examinations were used. Image analysis was performed using the ImageJ 1.53e program (Wayne Rasband & contributors – NIH, USA). Imaging records with contralateral studies in patients with recently diagnosed asymmetric enthesopathies (before the start of treatment) were selected. A repository of images from healthy controls, matched by age and sex of the patients, was used as control.

**Results:**

In the non-painful Achilles enthesis, the measurements were 75.3 ±14.71, the DGI 25.93 ±2.52, and the MoGI 72.7 ±15.4. In the non-painful Achilles enthesis the measurements were 83.99 ±27.29, 22.72 ±3.14 and 76.7 ±32.5, respectively. Statistically significant differences were detected in all pairwise comparisons (t =-9.522, P<=.000; t=3.393, P=.004; and t=-2.247, P=.041, respectively). In the epicondylar involvement records, the MoGI on the affected side was 75.3 ±14.71, the DGI 25.93 ±2.52, and the MoGi 72.7 ±15.4. In the non-painful Achilles enthesis the measurements were 82.57 ±16.06, 25.7 ±2.99 and 74.9 ±16.5, respectively. Statistically significant differences between MoGI and MoGi were identified (t=9.849, P=.000; and t=-2.752, P=.022, respectively). The MIN ratio of the affected side and healthy side among patients was 1.18 ±0.047 while the MIN ratio between the dominant and non-dominant sides of the healthy athletes was 0.91 ±0.022 (t=2.81, P=.000).

**Conclusion:** Computer analysis of entheses static images correctly discriminates symptomatic from non-symptomatic entheses in early ultrasound studies. Even in non-symptomatic entheses, it detects differences compared to healthy subjects. This discriminatory capacity could be useful in updating ultrasound enthesis count indices. It may also be interesting as a criterion for evaluating changes over time. As a weakness, it is worth highlighting the potential confounding effect that enthesophytes could have in this type of analysis if specific demarcations of the area studied are not made.

**Disclosure of Interests:** Carlos Guillén-Astete Speakers bureau: Novartis, Janssen, Abbvie, Grunenthal, UCB, Gebro, Paid instructor for: Roche, Novartis, Janssen, Esteve, Menarini, Consultant of: Janssen, Novartis, Roche, Grant/research support from: Pfizer, Grunenthal, Gebro, Novartis, África Andreu-Suárez: None declared, Marina Tortosa-Cabañas: None declared, Miguel Martinez Aznar: None declared

**Figure 1.** Scheme to obtain the analysis area of the Achilles (A) and epicondylar enthesis (B). The enthesis area was considered from the most distal point of the enthesis to the point of emergence or separation of the tendon from the cortex. Case A corresponds to a healthy control. Case B corresponds to a patient with psoriatic arthritis and severe epicondylar pain.
Psoriatic arthritis - clinical aspects (other than treatment)

AB0042 IN INVOLVEMENT OF THE FOOT IN PSORIATIC ARTHRITIS. A REVIEW OF 55 CASES.
F. E. Bennani1, M. M. Pamela Chardene1, A. Mouguil1, I. El Bouchi1,
1CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, RHEUMATOLOGY, Marrakech, Morocco

Background: Psoriatic arthritis (PsA) is a chronic inflammatory rheumatic disease belonging to the spondyloarthropathy family with which shares many clinical and radiographic features. The involvement of the feet with an asymmetric distribution of arthritis is very specific to Psoriasis.

Objectives: The objective of our study is to determine the frequency of foot involvement in a population of psoriatic arthritis by detailing the clinico-radiological aspect of the foot.

Methods: Retrospective descriptive study carried out on the files of patients hospitalized for psoriatic arthritis over a period of 9 years from January 2013 to December 2021. For each file, we collected epidemiological, clinical and radiological data.

Results: 55 patients were included: 41 women (74.5%) and 14 men (25.5%). The mean age was 48.81 ± 17.08 years (20-85 years). Personal and family history of skin psoriasis was noted in twenty and one patients, respectively. The average duration of evolution was about 5.5 years. Inflammatory taliagia was noted in 34 patients (61.8%) and foot joint involvement was found in 13 cases (23.6%). Sausage toe was noted in three cases (5.5%). None of the patients had Bauer’s toe or psoriatic onychopachydermoperiostitis of the great toe. The radiographic workup showed calcaneal in 34.5% (n=30), osteoporosis of the great toe in 6 patients (10.9%). According to the radiological criteria fingers-toes or (CRDO), 3 patients had juxta articular periostitis (5.5%), two cases of phalangeal tuft resorption (3.6%) and one case of osteolyis of an interphalangeal joint (1.8%).

Conclusion: In our context, the involvement of the foot during psoriatic arthritis is dominated clinically and radiologically by the involvement of the hindfoot. The importance of the classification criteria for Psoriasis cannot be underlined, and aim improving their sensitivity and specificity.

AB0043 ASSOCIATION BETWEEN PULSE PRESSURE AND ARTEROSCLEROSIS IN PSORIATIC ARTHRITIS PATIENTS
A. N. Garza-Cisneros1, D. A. Galarza-Delgado1, J. R. Azpiri-López2, N. Guajardo-Jauregui1, A. Cárdenas1, I. J. Colunga-Pedraza1, M. A. Balderas-Palacios1, A. García-Heredia1, D. Flores-Alvaredo1, Universidad Autónoma de Nuevo León, Hospital “Dr. José Eléctorio González”; Rheumatology, Monterrey, Mexico; 2Universidad Autónoma de Nuevo León, Hospital “Dr. José Eléctorio González”, Cardiology, Monterrey, Mexico

Background: Psoriatic arthritis (PsA) is associated with an increased prevalence of cardiovascular diseases due to accelerated atherosclerosis that seems to depend on traditional and non-traditional risk factors (1). There is a positive correlation between pulse pressure (PP) and the progression of atherosclerosis in general population (2). Currently, there are no studies linking PP as an independent risk factor of atherosclerosis in PsA patients.

Objectives: To compare PP between PsA patients with and without carotid plaque (CP).

Methods: This was a cross-sectional study that included patients aged 40 to 75 years with PsA diagnosis according to the 2006 CASPAR criteria. A carotid ultrasound was performed in all patients, and they were divided into two groups, 27 patients with the presence of CP and 27 patients without CP matched by age, gender, and comorbidities. Blood pressure and PP was measured according to current guidelines. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done with Chi-square test for qualitative variables and Student’s t test for quantitative variables. A p value <0.05 was considered statistically significant.

Results: There were no differences regarding demographic characteristics between groups. When comparing the arterial measures, a statistically significant difference was found in the PP, which was higher in patients with CP (48.66 ± 12.04 mmHg vs 41.51 ± 9.10 mmHg, p=0.017) (Table 1). A binary logistic regression was performed, and we found that PP was the only independent factor for the presence of CP in patients with PsA, OR 6.638 (95% CI 0.453-12.823, p=0.036).

Psa, psoriatic arthritis; NS, non-significant; T2DM, type 2 diabetes mellitus; bDMARD, biologic disease-modifying anti-rheumatic drugs; SAP, systolic arterial pressure; DAP, diastolic arterial pressure; PP, pulse pressure.

Conclusion: PsA patients with CP presented higher measures of PP compared with PsA patients without CP. This suggests that PP could be related with an increased risk of subclinical atherosclerosis in PsA patients. It is recommended to consider PP as an important parameter when evaluating cardiovascular risk in PsA patients.

AB0044 HIGHER PREVALENCE OF PULSE PRESSURE IN PSORIATIC ARTHRITIS PATIENTS
A. N. Garza-Cisneros1, I. J. Colunga-Pedraza1, D. A. Galarza-Delgado1, J. R. Azpiri-López1, N. Guajardo-Jauregui1, A. Cárdenas1, D. Flores-Alvaredo1, Universidad Autónoma de Nuevo León, Hospital “Dr. José Eléctorio González”; Rheumatology, Monterrey, Mexico; 2Universidad Autónoma de Nuevo León, Hospital “Dr. José Eléctorio González”, Cardiology, Monterrey, Mexico

Background: There is an increased risk of cardiovascular diseases in patients with psoriatic arthritis (PsA) compared with the general population due to higher prevalence of cardiovascular risk (CVR) factors (1). Pulse pressure (PP) is an independent risk factor for cardiovascular morbidity and mortality (2). Currently, there are no studies about PP in PsA patients.

Methods: This was a cross-sectional, observational, and comparative study. A total of 74 PsA patients aged 40-75 years old, who fulfilled the 2006 CASPAR criteria were recruited and matched to 74 controls by age (±5 years), gender, and comorbidities. Patients with history of a previous cardiovascular event or pregnancy were excluded from this study. Blood pressure and PP was measured according to current guidelines. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done with Chi-square test for qualitative variables and Student’s t test for quantitative variables. A p value <0.05 was considered statistically significant.

Results: There were no differences regarding demographic characteristics between groups. When comparing the arterial measures, a statistically significant difference was found in the PP, which was higher in the PsA group [45.00 mmHg (40.00-56.50) vs 42.50 mmHg (38.00-50.00), p=0.024], and in the systolic
arterial pressure, higher in PsA patients (131.06 ± 18.27 mmHg vs 123.02 ± 14.27 mmHg).

SPECIAL FEATURES OF THE LIPID PROFILE IN PATIENTS WITH THE INFLAMMATORY ARTHROPATHIES

S. Spitsin1,2, E. Mozgovaya1, A. Trolifenko1, S. Bedina1, M. Mamus1,3. Federal State Budgetary Educational Institution “Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy”, Clinical Biological Laboratory, Volgograd, Russian Federation; 3Federal State Budgetary Educational Institution of Higher Education “Volgograd State Medical University” of the Ministry of Healthcare of the Russian Federation, Department of hospital therapy, Volgograd, Russian Federation

Background: The main cause of death in patients with the inflammatory arthropathies is involvement of the cardiovascular system, and primarily atherosclerotic lesion with its complications. Initiation and progression of these arthropathies are underlined with similar immune and inflammatory mechanisms and associated with highly atherogenic changes of blood lipoproteins.

Objectives: Identification of particular qualities of the lipid profile in rheumatoid (RA) and psoriatic (PsA) arthritis, anklyosing spondylitis (AS) and their relationship with essential predisposing factors.

Methods: We enrolled 20 patients with RA, 15 with PsA, and 15 with AS, receiving basic anti-inflammatory therapy with methotrexate 10 to 20mg per week for 6 months, in combination with various non-steroidal anti-inflammatory drugs. These diagnoses were verified according to the ACR/EULAR 2010, CAPSAR 2006, ASAS 2009 criteria, respectively. The single exclusion criterion was the presence of a concomitant disease that could affect lipid metabolism. Total cholesterol (TC), HDL cholesterol, and triglycerides (TG) were measured in the plasma samples of all the patients, LDL cholesterol was calculated using Friedewald formula: TC – (HDLLDLTG/2.2)). The atherogenic index was taken as (TC – HDL)/HDL. Results were expressed as arithmetic means ± standard deviations. Differences were considered significant when p<0.05.

Results: The age of all patients ranged from 30 to 67 years, disease duration range was 1.5 to 12 years. All the patients with chronic arthritis had moderate or high disease activity grades. In the subgroup of RA patients average TC value was 5.63±0.16 mmol/l, HDL – 1.09±0.22 mmol/l, LDL – 3.74±1.16 mmol/l. Increased TC levels were detected in 80% of cases, TG - in 40%, LDL - in 80%, and decreased HDL - in 80% patients. There were strong relationships of TC with age, menopause, or overweight. The duration of RA also positively correlated with TC (r=0.189, p<0.05) and LDL (r=0.159, p<0.05). RA (C-reactive protein level) activity was negatively associated with HDL (r=0.168, p<0.05). 80% of PsA patients had increased TC levels, but TG or HDL levels were within reference range. Mean TC in this subgroup was 6.04±1.55 mmol/l. TC values of PsA patients also positively correlated with age, BMI, and duration of PsA. There was an increase in TC, LDL, and the atherogenic coefficient in AS patients. Mean values of TC, TG, LDL, and HDL in this subgroup were 5.65±0.28, 1.28±0.12, 3.86±0.23 and 1.09±0.06 mmol/l, respectively.

Conclusion: Lipid disorders in patients with chronic inflammatory joint diseases may be a source of increased risk of early atherosclerosis and the cardiovascular events. Increased TC and LDL were most pronounced changes in lipid profiles of RA, PsA and AS patients. All these markers were revealed to be associated with both common cardiovascular (age, increased BMI) and the disease-associated factors (arthritis duration, activity of the underlying disease).

AB0946

PELVIS RADIOGRAPHY FINDINGS AND PROGRESSION RATES IN PATIENTS WITH PSORIATIC ARTHRITIS UNDER BIOLOGIC TREATMENT

G. Ayhan,1 A. Sadic2,3, L. Kilic, U. Kalyoncu1,1Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; 2Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey; 3Hacettepe University Medical Faculty, Department of Internal Medicine, ankara, Turkey

Background: Psoriatic arthritits (PsA) is a heterogenous disease that can present with various musculoskeletal manifestations. Several studies have assessed the rate of sacroilitis in PsA population, however data on the involvement of other pelvic structures that could cause symptoms, such as major enthesis or hip involvement, and progression rates during follow-up is scarce.

Objectives: This study aimed to understand overall pelvis radiography findings and progression rates during follow-up in a cohort of patients with PsA under biologic treatment.

Methods: PsA patients from the Hacettepe University biological database (HUR-BIO), were retrospectively analyzed for their pelvis radiographs. All radiographs for individual patient were consecutively scored. Modified New York (mNY) criteria was used to assess sacroilitis and ilium/ iliac wing/ greater trochanter enthesopathy and symphysis pubis osteitis assessments were done using a grade 0, no changes, 1, minimal changes and grade 2 and more counted as significant changes (1). Hip involvement was scored using BASRI-hip score and data on prosthesis were noted (2). All of the assessments were done by an experienced rheumatologist (UK) and in cases with suspicion, another experienced rheumatologist reviewed the cases (LK) and a consensus was reached.

Results: Overall 273 patients (69.6% of females) with the mean (SD) age at the time of first radiography 43.3 (12) years were included. At their initial radiographic assessment, the median (IQR) PsA duration was 2 (7) years. Base-line radiographs showed 10 (%3.7) of the patients had transitional vertebra and 137 (50.2%) patients had sacroilitis according to mNY criteria. From patients without sacroilitis (n=136), 67 patients had following radiographs. After a mean (SD) 471 (37) months, 16 (23.8%) of them progressed to sacroilitis according to mNY criteria. Regarding the major enthesopathies, Regarding significant changes, 26.8 % of the patients had ischium enthesopathy, 19.3% of the patients ad symphysis pubis involvement and 13.2% of the patients had iliac

</table>
*Defined as one unit increase in the grade
Wing entheseopathy. Trochanter major entheseopathy rates were 2.4% and 1.4% at right and left sites respectively. Only one patient had trochanter minor enthesitis on the left site (Table 1). Prosthesis requirement was observed in 4 hip joints and 4 hip joints had prosthesis. There was no correlation between meeting mNY criteria and having iliac, ischium, and pubis involvement ≥ 2. On the other hand, patients with when there is ischium entheseopathy ≥ 2 (17/46 (36.9%) vs 18/96 (18.7%), p=0.013) or iliac wing entheseopathy ≥ 2 above (10/18 (55.5%) vs. 26/129 (20.1%), p=0.001), any syndesmophyte in the spine is more commonly seen.

Conclusion: Half of the patients with PsA requiring advanced treatment modalities, had sacroilitis in a median 2 years of disease duration and the rest may progress to sacroilitis during the follow-up period. Major entheseopathy involvement was also seen in more than half of the patients. Iliac, iliac wing entheseopaties and spinal syndesmophytes may be all a part of the osteoproliferative process. Further assessment is needed to correlate those radiographic changes to clinical symptoms.

AB0947 CORRELATION BETWEEN ENTHESIS AND CLINICAL PHENOTYPE PSORIASIS, NAIL PSORIASIS AND DURATION PSORIASIS IN PATIENTS WITH PSORIATIC ARTHRITIS
L. Vorobeva1, T. Kortaeava1, E. Loginova1, E. Gubaree2, Y. Konsakova3, M. Chamurlieva1, E. Nasonov1, A. Lila1, V.A. Nasonova Research Institute of Rheumatology, Spondyloarthropathies and psoriatic arthritis, Moscow, Russian Federation; 2V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation

Background: Psoriatic arthritis (PsA) is a disease with multidimensional manifestations in patients who have psoriasis (PsO). Enthesitis is an important component of PsA and may be a primary pathological feature driving other manifestations of the disease. [1] Psoriasis and psoriatic nail dystrophy are also important predictors of PsA. Skin and joint disease may indeed arise from the same underlying process at the same time, with patients developing similar inflammatory lesions in the skin and entheses, while the speed of detection of these lesions is different and allows skin changes to be detected earlier. [2]

Objectives: to evaluate correlation between enthesis and clinical phenotype psoriasis, nail psoriasis and duration psoriasis in patients with psoriatic arthritis.

Methods: 187 (M/F=97 (50.2%)/90(48.8%)) PsA pts fulfilling the CASPAR criteria were included. Mean age 45.6±11.7 years (yrs), DAPSA 21.05±21.03, median (Me) PsA duration 88 [16;421] mo. All pts underwent standard clinical examination and after imaging modalities scoring (X-ray or CT -scan).

Results: When 79 (42.3%) pts with enthesitis and 108 pts (57.7%) without enthesitis were compared. In pts with enthesitis had more duration PsO – 275.6±153.4 vs 227.4±139.5, p=0.03. The duration of PsA, both groups were comparable (p=0.9). Also in pts with enthesitis had more nail PsO - 66.6% vs 45% (p=0.005). BSA in both group were comparable, but in pts with enthesitis had more inverse PsO – 6.94% vs 3%, gluttate PsO – 4% in pts without enthesitis with phenotype PsO did not have, and combination plaque and inverse PsO – 51.3% vs 31% (p=0.0056). Moreover, significant but weak positive correlations between the LEI score and duration PsO and nail PsO. Assessment of the correlation modified LEI score and MASES score showed significant positive correlations with duration PsO, nail PsO and phenotype PsO.

Conclusion: In our cohort PsA pts reported that with enthesitis is associated with duration PsO, nail psoriasis and phenotype PsO. These finding should be considered in the turn of improved screening, earlier diagnosis, timely treatment initiation and, eventually, should improve overall disease outcomes.

AB0948 OSTEOPOROTIC SCREENING AND PREVALENCE OF SEVERE OSTEOPOROTIC FRACTURES IN A POPULATION OF PSORIATIC ARTHRITIS INITIATING A BIOLOGIC TREATMENT
M. Lafraye1, M. Caroline3, E. Allado2, E. Bauer1, I. Chary Valkenaere3, D. Loeule1, 1University Hospital, Rheumatology, Nancy, France; 2University Hospital, Center of Sports Medicine and Adapted Physical Activity, Nancy, France

Background: Osteoporosis is a common complication of Rheumatic diseases. The association between osteoporosis and rheumatoid arthritis is clearly demonstrated while this association is still debated as well as for the screening of osteoporosis by Dual-Energy X-Ray Absorptiometry (DEXA) or to demonstrate an increased risk of fracture on radiography in a population of Psoriatic Arthritis (PsA). The prevalence of fragility fractures reported on medical reports ranged between 12% and 40% in PsA patients. Only a few studies evaluated the prevalence of vertebral fracture (VF) on spine radiographs. To our knowledge no study has evaluated the contribution of radiographic or CT assessment of the spine on the prevalence of fragility fracture reported in medical records.

Objectives: To determine Psoriatic Arthritis patient’s characteristics screened for osteoporosis by DEXA in a population initiating a biologic treatment (bDMARD) and to estimate the prevalence of severe osteoporotic fractures on medical reports and after imaging modalities scoring (X-ray or CT-scan).

Methods: Patients with psoriasis should satisfy the CASPAR or ASAS criteria and have been screened during their follow up for a bDMARD. Osteoporotic screening was defined by a BMD testing (DEXA). Vertebral fractures were scored according to Genant’s method on bone X-ray or sagittal CT-scan images. Clinical and demographic data and the presence of previous severe osteoporotic fracture reported in the medical records were collected.

Results: On 417 PsA patients screened for bDMARDS during 2008-2019, 89 patients (21.3%) were assessed for osteoporosis by DEXA. Increased age, female sex, menopause, previous severe fracture, disease duration, presence of inflammatory bowel disease, current and previous corticosteroid and bDMARDs uses were significantly associated with osteoporotic screening. On DEXA, 7 patients (17%) were classified as osteoporotic. The prevalence of severe osteoporotic fracture was 6.7% in medical reports and increased to 23.6% after scoring spine radiographies or TAP-CT images. In univariate analysis the prevalence of severe osteoporotic fractures was associated with age (p=0.013), scanographic bone attenuation coefficient (p<0.005) and Lumbar T-score (p=0.039).

Conclusion: Less than a quarter of PsA patients initiating a bDMARD is screened for osteoporosis. The prevalence of osteoporosis on DEXA and severe osteoporotic fractures on medical records are inferior to 10%. After systematic imaging evaluation, this prevalence increases at 23.6%.

REFERENCES:
Psoriasis and psoriatic arthritis (PsA) are chronic immune-mediated diseases that primarily affect the skin and joints, respectively. A large proportion of patients with plaque psoriasis suffer from psoriatic lesions on the scalp, nails, palmoplantar area and genitals. These locations can also be soley or predominantly affected. Psoriasis in special localizations are often perceived as particularly stigmatizing and significantly reduce quality of life. Involvement of these body parts is associated with an increased risk of PsA.

Objectives: To provide a descriptive analysis of psoriasis in special localizations in patients with psoriasis versus patients with PsA.

Methods: This cross-sectional study was performed in Vega-Baja Hospital (Orihuela-Spain) from May 2021 to December 2021. We prospectively enrolled 77 consecutive psoriasis patients and 76 consecutive patients affected by PsA and followed at the Vega-Baja Hospital (Orihuela-Spain). Sociodemographic data and clinical characteristics were analysed.

Results: One hundred and fifty-three patients were included (77 psoriasis patients and 76 patients affected by PsA). The registry variables used in this study are detailed in Table 1.

Detection of Asymptomatic Enthesal Involvement in Patients with Psoriatic Arthritis: A Case-Control Ultrasound Study

R. Ben Aissa¹, S. Boussaid², S. Rekki¹, S. Jemmali¹, S. Rahmouni¹, H. Ailiani¹, H. Srai Sahl¹, M. Elleuch¹, A. Soussi¹, M. Mokri¹, Rabta Hospital, Department of Rheumatology, Tunis, Tunisia; ²Rabta Hospital, Department of Dermatology, Tunis, Tunisia.

Background: Enthesopathy is one of the major features of psoriatic arthritis (PsA). The clinical screening for entheseal synovitis and enthesitis in patients with psoriasis is nonspecific during the subclinical phase. Ultrasonography (US) has already demonstrated its ability to study entheses and joints in early stages of PsA.

Objectives: To evaluate the prevalence of ultrasonographic subclinical synovitis and enthesopathies in psoriasis patients with no clinical evidence of PsA compared with controls.

Methods: A cross-sectional study conducted on 40 patients with psoriasis and 40 healthy sex- and age- matched controls. The Leeds Enthesitis Index (LEI) and Spondyloarthrits Research Consortium of Canada (SPARCRC) were used to evaluate enthesal involvement. US examination of 18 joints (wrists, metacarpophalangeal, and proximal interphalangeal joints) was performed along with 22 enthesal sites (deep flexor of the fingers, lateral epicondyle, triceps, quadriiceps, patellar and calcaneal tendons and plantar fascia). Inflammatory-score (thickening, hypoechogenicity, bursitis and Doppler signal) and damage-score (calcifications, entheseal erosions and erosions) were calculated (= absent, 1=present for each abnormality). A total score was obtained by adding these two scores.

Results: The mean age of psoriatic patients 51.90±15.90 [19 -76] and the sex ratio of males to females was 3:2. US synovitis were more frequent in psoriatic patients 7/1040 (0.68%) than in controls 3/1040 (0.29%) but this was not significant (p=0.420). Patients with psoriasis had more US enthesopathies 37 (92.5%), comparing to controls 16 (40%) (p < 0.001). The total number of enthesopathies was higher in the psoriatic group 184/880 (20.90%) comparing to controls 42/880 (4.78%) (p < 0.001). Entheses with more US abnormalities in the psoriasis group compared to controls were deep flexor tendons of the fingers entheses (p<0.001), distal patellar tendon entheses (p<0.001) and calcaneal tendon entheses (p<0.001). LEI and SPARCRC scores were positively correlated to higher number of US enthesopathies (p=0.046, p=0.006). SPARCRC was positively correlated to inflammatory-score and damage-score (p=0.009, p=0.024). The mean C-reactive protein level was higher in psoriatic arthritis 5.77±10.10 mg/L than in controls 2.15±3.26 mg/L (p=0.037).

Conclusion: Our results confirm that US enthesopathies and synovitis are more frequent in patients with psoriasis comparing to healthy population. The US screening for subclinical enthesopathies should be object of longitudinal investigations to define its value in predicting the clinical onset of PsA.

Disclosure of Interests: None declared.

inflammatory lesion observed in 4% (n=16) of the entheses, followed by hypoechoegenicity (0.5%, n=2). Enthesophytes were the most frequent chronic damage lesions detected in 1.25% (n=5) of the entheses followed by erosions (0.5% vs. 0.2%). The highest total US scores per enthesis site were observed at the calcaneal enthesis [mean (SD) 0.27 (0.59)], followed by plantar fascia [0.18 (0.50)] and distal patellar tendon origins [0.10 (0.37)]. Age was not associated to higher scores (total, inflammatory, chronic damage; p=0.339, p=0.412, p=0.531). Female participants had higher inflammation scores than males (mean inflammation scores (SD) 0.69 (1.44) versus 0.39 (0.71), p=0.044). The BMI was correlated to higher inflammation score (p=0.020, r=0.368) but not to chronic damage nor to total scores (p=0.478, p=0.104). Intense physical activity was associated to higher chronic damage score comparing to moderate physical activity (mean chronic damage scores (SD) 0.30 (0.67) versus 0.003 (0.00), p=0.058) and to low physical activity (mean chronic damage scores (SD) 0.30 (0.67) versus 0.0018 (0.00), p=0.043). No association between physical activity and inflammation score had been observed.

Conclusion: Our study demonstrates that US changes within the enthesis are associated with higher BMI and physical activity. These results support the effect of biomechanical forces on the entheses that should be considered when differentiating by US pathological from healthy entheses.

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory disease affecting the musculoskeletal system, skin and nails. Therapeutic management in Germany is usually provided by a dermatologist or rheumatologist. The clinical specialization of the treating physician was associated with different treatment and clinical status of patients with PsA. Our analysis showed that patients in the rheumatology setting more frequently had joint affection and lower functional status, whereas skin severity was worse in the dermatology setting, indicating selection effects of health care access. We hypothesize that these differences may be biased due to different diagnostic and therapeutic routines in the specialized health care settings. Psoriatic arthritis should be treated in a multidisciplinary approach to take into account all facets of this complex disease.

**AB0953 LACK OF RACIAL DIVERSITY IN CLINICAL TRIALS OF PSORIATIC ARTHRITIS**

N. Goel1,2, 1Duke University School of Medicine, Internal Medicine, Division of Rheumatology, Durham, NC, United States of America; 2Abcuro, Inc, Newton, MA, United States of America

**Background:** Participant diversity in clinical trials of therapeutics in rheumatology is important to understand how persons of different races and ethnicities might respond differently to therapeutics. Specifically, for psoriatic arthritis (PsA), although people of color (POC) have lower disease prevalence, prevalence still ranges from 0.04-0.19% in Blacks, 0.13-0.19% in Asians, and 0.09-0.30% in Hispanics versus 0.19-0.34% in Whites in the insured population of the US. Literature on the diversity of PsA clinical trials remains limited, though data suggest that minorities are underrepresented in clinical trials. This analysis aims to evaluate the diversity of participants in randomized clinical trials (RCTs) of US Food and Drug Administration approved targeted therapies for PsA.

**Objectives:** To evaluate the reporting of race and ethnicity in published RCTs of PsA targeted therapies approved for use in the US.

**Methods:** Targeted therapies approved for use in the treatment of PsA in the US were identified. Package inserts and ClinicalTrials.gov (CT.gov) were used to

**Disclosure of Interests:** None declared.

**DOI:** 10.1136/annrheumdis-2022-eular.4317

**AB0954**
identify the pivotal double blind, RCTs in PsA which supported the approval of the identified therapeutics in the US. The articles reporting the primary endpoint data were obtained. Race and ethnicity data were extracted from the published data. Countries in which the studies were conducted were identified from the publications or CT.gov. Descriptive analyses were performed.

**Results:** Twenty-nine pivotal RCTs in PsA evaluating targeted therapeutics, published from 2002 – 2022, were identified; 24 reported race; non-White race was reported in only 13 (45%) (Table 1 and Figure 1). In the latter, people of Black race comprised <1% of the overall population in 12 RCTs and 2.7% in the remaining RCT. People of Asian race comprised 6.1% of the overall population reflecting <10% of the population in 11 studies and 11.3% and 19.0% in the remaining 2 studies. Overall, 19 (65.6%) trials recruited participants from Asia Pacific countries. Hispanic/Latinx ethnicity was not reported in any study. Studies published from 2017-2022 reported non-White race (n=7 of 15 [47%]) no more frequently than studies published from 2004-2016 (n=6 of 14 [43%]). Although the 13 RCTs reporting non-White race may not reflect unique individuals, the total number of people included across these RCTs was 7261, of which 48 (0.7%), 441 (6.1%), and 6589 (90.9%) were Black, Asian, and White, respectively.

Figure 1. Pivotal Trials of Targeted Therapeutics Published Between 2004-2022

**Conclusion:** Our data show under-reporting of race and ethnicity in publications of pivotal PsA RCTs, and no evidence of improved reporting over time. Whites were overrepresented in pivotal trials of PsA, especially when considering 72 and 62% of the US population was White in 2010 and 2020 (US Census data), respectively, and the reported prevalence of PsA by race in the insured population of the US1. Improved reporting of race/ethnicity and increased representation of racial/ethnic minorities in PsA RCTs are needed.

CONCORDANCE BETWEEN DIFFERENT COMORBIDITIES SCORES IN PATIENTS WITH PSORIATIC ARTHRITIS

N. D. Popenco1, A. Dima1, I. A. Berza1, G. M. State1, F. Negoi1, M. Panduru2, M. Parvu1, 1Colentina Clinical Hospital, Department of Rheumatology, Bucharest, Romania; 2Colentina Clinical Hospital, Department of Dermatology, Bucharest, Romania

**Background:** Patients with psoriatic arthritis (PA) are more likely to suffer from other chronic medical conditions, associated comorbidities having significant impact upon both quality of life and survival. As disorders like the cardiovascular disease, metabolic syndrome, hepatic or renal pathologies were shown to be more prevalent in PA [1], assessment of comorbidities is important in these patients [2].

**Objectives:** To investigate the concordance of different comorbidities scores in patients with PA.

**Methods:** Prospective inclusion of patients diagnosed with PA according to the CASPAR (Classification criteria for Psoriatic Arthritis) criteria. Associated comorbidities were prospectively assessed using the Psoriatic arthritis comorbidity index (PsACI) with a cut-off of 8 points as previously defined [2]. Also, the following comorbidities scores were completed in all patients: Charlson comorbidity index (CCI), Rheumatoid Arthritis Comorbidity Index (RACI), Rheumatic Diseases comorbidity index (RDCI), Functional comorbidity index (FCI).

**Results:** A total of 56 patients were included: 27 (48.2%) were female, with a median (q1-q3) disease duration of 17.5 (12.7; 26.5) years for the cutaneous disease and 6.0 (4.0; 13.0) years for the articular one. At inclusion, the results of the comorbidities scores assessed were as follow: PsACI 3.2 (2.0; 6.5), CCI 1.0 (0.0; 2.0), RACI 3.5 (1.5; 6.5), RDCI 1.0 (0.0; 2.0), and FCI 2.0 (0.0; 2.0), respectively. According to PsACI, hypertension, hyperlipidemia, osteoarthritis, liver disease, and diabetes mellitus were the most frequent associated comorbidities in PA patients, in 53.6%, 44.6%, 41.1%, 37.5%, and 28.6% cases, respectively (see Table 1).

</table>

In bivariate analysis, we found significant correlations between the results of PsACI and those of the other comorbidities scores used: CCI (p<0.001, rho=0.668), RACI (p<0.001, rho=0.792), RDCI (p<0.001, rho=0.691), and FCI (p<0.001, rho=0.697), respectively. The ability of the comorbidities scores assessed to discriminate a PsACI high value is presented in Figure 1, AUC (95%CI): CCI 0.743 (0.601-0.886) p=0.017, RACI 0.815 (0.634-0.996) p=0.002, RDCI 0.818 (0.657-0.980) p=0.002, and FCI 0.837 (0.725-0.948) p=0.001, respectively.

**Conclusion:** The composite indexes offer the advantage of reducing all associated comorbidities as long with their severity into a single score. We herein
identified good correlations between the results of the comorbidity scores ana-
yzed, PsACI, CCI, RDCI, RACI, and FCI, respectively.

DISEASE ACTIVITY IMPACT OVER THE ANXIETY LEVEL IN PATIENTS WITH PSORIATIC ARTHRITIS

N. D. Popescu¹, A. Dimă¹, I. A. Berza¹, G. M. State¹, F. Negoi¹, M. Panduru²,
M. Parvu³. ¹Colentina Clinical Hospital, Department of Rheumatology, Bucharest,
Romania; ²Colentina Clinical Hospital, Department of Dermatology, Bucharest,
Romania

Background: Psoriatic arthritis (PA) is a complex, systemic, chronic inflam-
matory condition with substantial multisystemic detrimental effects on patients’
health status. In PA patients there was reported increased anxiety occurrence
when compared to general population, even if specific predictors are not
defined yet [1].

Objectives: To characterize disease-related predictors of anxiety in patients
with PA.

Methods: Cross-sectional study with prospective, successive inclusion of
patients fulfilling the CASPAR (CLASsification criteria for Psoriatic Arthritis)
classification criteria for PA. Anxiety level was assessed using the General
Anxiety Disorder-7 (GAD-7) with a cut-off of 10 points as previously defined
[2]. Moreover, disease activity status for PA was defined using also validated
scores, namely the Disease Activity Index for Psoriatic Arthritis (DAPSA), the
Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), the Ankylosing
Spondylitis Disease Activity Score (ASDAS), cutaneous involvement by the
Psoriasis Area Severity Index (PASI), and comorbidities by Psoriatic arthritis
comorbidity index (PsACI).

Results: 56 PA patients were included, 29 (51.8%) males, with mean±SD
age at inclusion of 54.1±13.2years. Regarding the tools for disease activity
assessment, the probability of impact over a high anxiety level as estimated
by area under curve (AUC) was high (> 0.800) for BASDAI [AUC(95%CI)
1.844 (1.198 - 2.839) (see Table 1).

Table 1. Independent predictors for anxiety in psoriatic arthritis patients

Conclusion: Therefore, higher BASDAI results were associated with increased
anxiety in PA and so such results should raise awareness about the need of
search for associated anxiety disorders. On the contrary, the extension of the
cutaneous involvement, the systemic inflammation level or the comorbidities
degree were not identified as predictors for the anxiety occurrence.

TO WHAT EXTEND IS NAIL ULTRASOUND DISCRIMINATIVE BETWEEN PSORIATIC ARTHRITIS
AND HEALTHY SUBJECTS?

I. Mahmoud¹, S. Rahmou², A. Ben Tekaya¹, S. Bouden¹, L. Rouached¹, R. Tekaya¹, O. Saidane¹, L. Abdelmoula¹, C. Charles Nicolle Hospital,
Rheumatology, Tunis, Tunisia

Background: Clinical physical examination can detect superficial nail
changes in psoriatic patients. However, the nail matrix and bed are not
accessible for clinical assessment. Recently, ultrasonography (US) has
emerged as a useful tool to assess nail involvement in psoriatic arthritis
(PsA) patients.

Objectives: To assess the discriminative utility of nail features detected by
B-mode (BM) and color Doppler (CD) ultrasound (US) between patients with
psoriatic arthritis (PsA) and healthy controls (HC).

Methods: This was a cross-sectional study including PsA patients and HC.
All patients and controls underwent an US assessment of the fingernails that
included the study of morphological changes based on Wortsman’s description
[1]: focal hyperechoic involvement of the ventral plate without involvement of the
dorsal plate (type I), loss of definition on both plates (type II), blood
flow disturbances and measurement of the thickness of nail bed (NBT), nail plate
(TNP) and adjacent skin.

Results: A total of 536 nails were examined (PsA:326 nails, HC:210). Patients
with PsA had significantly more morphological changes of the nails than
healthy controls (23% vs 3.33%, p = 0.006). In PsA patients, the most fre-
cently observed aspect was type II (47 nails, 14.4%), followed by type II (40
nails,12.3%) and type IV (38 nails, 11.6%). In HC, the only observed type was
type II, which was observed in 3.33% of nails. NBT and skin thickness were higher
in the HC group than the PsA group (1.90±0.22 mm vs 2.07±0.34 mm, p=0.047
and 2.25±0.69 vs 2.59±0.31 mm, p=0.002, respectively). The power Doppler signal of the nail bed and
matrix was comparable between the groups (54% vs 61%, p=0.603 and 41%
vs 37.1%, p=0.432, respectively). NBT and skin thickness were higher in the
HC group than the PsA group (1.90±0.22 mm vs 2.07±0.34 mm, p=0.047
and 2.25±0.69 vs 2.59±0.31 mm, p=0.002, respectively). While NPT was similar
between the groups (0.38±0.09 vs 0.36±0.07mm, p=0.239).

Conclusion: US detected morphological changes in clinically healthy fingernails
in both PsA patients and healthy controls. However subclinical involvement was
more common in PsA patients. Loosening of the borders of the ventral plate (type
II) was the only aspect observed in HC. This would suggest that this type is not

In bivariate analysis, we found a significant difference regarding a higher anxi-
ety level as assessed by GAD-7 for female gender (28.6% vs. 78.9%, p=0.001),
concomittance of peripheral and axial articular involvement (25.7% vs. 52.6%,
p=0.034), DAPSA (14.8 (7.1; 22.6) vs. 24.6 (12.2; 36.8), p=0.035), BASDAI
(3.1 (1.3; 4.1) vs. 7.1 (5.0; 8.0), p<0.001), and ASDAS-CRP (2.5 (1.1; 3.7)
vs. 3.5 (2.7; 4.0), p=0.038), but not for the other parameters search, namely

age, smoking, alcohol intake, home settle (urban/ rural, living alone, kids),
disease duration, HLA-B27 status, PASI, PsACI, Patient (PsGA) or Physician
(PGA) Global Assessment, ongoing corticosteroid treatment, or inflammation
status (ESR, CRP). In multivariate analysis, the PA disease-related predictor
for increased anxiety was the auto-evaluation by BASDAI, OR (95%CI) 1.844
(1.198 - 2.839) (see Table 1).
a specific feature of psoriatic nail. With regards to nail plate thickness, the measurements were similar between PsA patients and HC as previously reported by Naoum [2]. However, unlike previous studies, we showed that the nail bed and skin thickness were significantly higher in healthy controls than PsA patients [3].

LIMITED GENDER-RELATED DIFFERENCES CHARACTERIZE PSORIATIC ARTHRITIS: DATA FROM A MONOACENTRIC COLLECTION OF 306 PATIENTS

N. Luciano1, G. Roselli1, L. Canziani1, G. M. Guidelli1, M. Caprioli1, M. De Santis1, A. Ceribelli1, G. Seimi1.

Humanitas Research Hospital - IRCCS, Rheumatology and Clinical Immunology, Rozzano, Italy

Background: Psoriatic Arthritis (PsA) is characterized by a wide spectrum of clinical phenotypes which are ultimately driving therapeutic choices. The male-to-female ratio of the disease is approximately even but in the last decades some gender differences have been proposed in terms of clinical expression and therapeutic responses.

Objectives: The aim of this study is to confirm these differences in a real-life cohort of PsA patients.

Methods: A retrospective data collection has been conducted on a cohort of out-patients with PsA attending our Rheumatology Clinics at Humanitas Research Hospital between January 1st and December 31st 2021. All patients were ≥ 18 years old and fulfilled the CASPAR criteria for PsA. For each patient we obtained demographic, laboratory and clinical parameters and registered which domains (peripheral arthritis, axial PsA, skin and/or nail disease, enthesitis, dactylitis) have been involved in the course of the disease. We also collected data regarding any concomitant comorbidities and previous and current therapies. To investigate possible gender specific differences a cross-sectional univariate descriptive analysis was performed.

Results: Our cohort included 306 patients (169 - 55% - women) with PsA. The median age of disease onset was the same for men and women, also when separately considering skin (median 38 years) and articular presentation (median 48 years). No statistically significant differences were observed when comparing the two groups in terms of clinical phenotypes. In both groups peripheral arthritis was referred by the vast majority of patients (95% of women vs. 93% of men) and similar rates of axial involvement (34% in women vs. 37% in men). Considering current or previous therapies, we found a comparable use of non steroidal anti-inflammatory drugs (43% in both groups), systemic glucocorticoids (9% in men vs 10% in women), conventional synthetic DMARDs and biologic DMARDs and in each group the percentages of patients with a history of bDMARDs targeting TNF alpha, IL12-23 or IL17 failure with or without peripheral involvement, and who were treated according to standard clinical practice (EULAR recommendations). Demographic, clinical, analytical and psychological aspect of the disease and it can be measured with the PsaID.

Conclusion: Our cohort demonstrated limited gender-related differences in PsA course and therapeutic choices or duration, reporting only higher prevalence of hypothyroidism, fibromyalgia and neurologic disorders in women.

AB0958

THE RELATIONSHIP BETWEEN THE EXTENSOR TENDON ENTHESIS AND THE NAIL IN DISTAL INTERPHALANGEAL JOINT DISEASE IN PSORIATIC ARTHRITIS: ULTRASOUND STUDY

I. Mahmoud, G. Bahmoun, A. Ben Tekaya, S. Bouden, L. Rouached, R. Tekaya, O. Saidane, L. Abdelmoula, Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia

Background: It has been shown that there is an anatomical link between the distal interphalangeal joint (DIP) extensor tendon enthesis and the nail changes in psoriatic arthritis (PsA) [1].

Objectives: To evaluate the relationship between nail involvement and enthesisopathy at DIP level in PsA patients using ultrasonography (US).

Methods: We included patients with PsA. According to OMERACT, the following elemental lesions were dichotomously (presence/absence) evaluated on greyscale US assessment at extensor tendon insertion at distal phalanges: DIP joints: abnormally hypoechoic, enthesophytes, and erosions. We also measured the tendon thickness. Increased abnormal vascularization at entheseal level was also assessed using PD technique. We also performed an US assessment of the finger nails that included the study of morphological changes and measurement of the thickness of nail bed (NBT), nail plate (NPT) and adjacent skin (ST).

Results: We included 33 PsA patients (323 DIP). Eleven patients (34%) presented psoriatic onychopathy (45 fingernails) with a mean NAPSI 7 (IQR (25.75) [2.18]. US study of the nails revealed dystrophy in 75 nails (23%). At patient level, the mean NPT, NBT and 5K were 1.90±0.22, 0.38±0.09, and 2.33±0.62, respectively. None of the patients had clinical involvement of DIP Using US, we examined 325 extensor tendon. The mean thickness of the tendon was the 0.63mm ± 1.0 mm. The tendon was abnormally hypoechoic in two fingers (0.61%). Erosions were present in 16 DIP (4.9%). We found enthesophytes in 82 DIP joints at insertion of extensor digitorum tendon (25.23%). We did not observe increased abnormal vascularization at entheseal level. At finger level, the extensor tendon thickness was higher in the presence of US nail dystrophy (0.70 mm vs 0.60, p=0.01). Erosions were more common in fingers with US nail involvement (14.6% vs 1.9%, p=0.00). Osteophytes were present in 20% of fingers with US nail involvement and 26.3% of fingers without US nail involvement (p=0.166). The thickness of DIP digital extensor tendons was correlated with the NBT (r=0.412, p=0.00), the NPT (r=0.310, p=0.00), and the thickness of the adjacent skin (r=0.509, p=0.00).

Conclusion: The presence of US nail dystrophy was associated with thicker extensor tendon and more erosions. The thickness of the tendon was correlated with the thickness of the nail parts. This might be explained by the close relationship between nail enthesis and support the theory of the enthesis as an extended organ beyond the tendon bony attachment.

THE ACTIVITY OF PSORIATIC ARTHRITIS WITH AXIAL INVOLVEMENT CORRELATES WITH PSAID12.

Hospital Lucus Augustus, Rheumatology, Lugo, Spain; Hospital Universitario da Coruña, Rheumatology, A Coruña, Spain; Hospital do Meixoeiro, Rheumatology, Vigo, Spain; Hospital Arquitecto Marcide, Rheumatology, Ferrol, Spain; Hospital de Monte Forte, Rheumatology, Monforte de Lemos, Spain; Complejo Hospitalario Universitario de Ourense, Rheumatology, Ourense, Spain; Hospital Lucus Augustus, Rheumatology, Lugo, Spain; Hospital Montecelo (Pontvedra), Rheumatology, Pontevedra, Spain; Hospital Universitario da Coruña, Rheumatology, INIBIC, A Coruña, Spain

Background: Patients with psoriatic arthritis (PsA) show an impact on the physical and psychological aspect of the disease and it can be measured with the PsA Impact of Disease (PsAID) questionnaire, and it is expected that the impact of the disease improves when the patient is in remission or low disease activity. The objective of this study was to determine the rate of low impact of the disease in patients with PsA in daily clinical practice, and to evaluate its relationship with its axial activity.

Methods: A cross-sectional study was conducted in consecutive patients who met the CASPAR criteria, with positive clinical (DLI) and positive axial radiology, with or without peripheral involvement, and who were treated according to standard clinical practice (EULAR recommendations). Demographic, clinical, analytical data, HAQ index (0-3) and PsAID12 (0-10) were also collected. Patients were divided into 2 groups: those with a PsAID above 4 (high impact) or below 4 (low
impact). Continuous variables are shown as median (Q1-Q3) and categorical variables as percentages and frequencies. The analyses were performed using SPSS software. Differences were considered statistically significant if p < 0.05.

**Results:** Of the 269 patients evaluated with PsA, 72 patients with axial involvement were included, 40 men (55.6%), with a median age of 54.1 years (45.0-62.0) and disease duration of 7 years (2-11). Obesity (BMI>29.99) affected 28.3% and serum CRP level was 0.45 mgr/dl (0.08-1.10). The treatments of the patients were: NSAIDs 43.1%, corticosteroids 21.6%, csDMARD 52.9% and biological therapy 51.9%. The BASDAI was 4.2 (2.0-6.2) and the ASDAS-PCR was 2.4 (1.5-3.2), with 39.8% being in low activity or remission. The median PsAID total score was 3.9 (1.6-5.4), evaluated in 61 patients. The patients who achieved a PsAID ≤4 were 63% (see Table 1), more men and with a lower CRP. In addition, the low impact measured by the PsAID2 was associated with a lower BASDAI and ASDAS-PCR.

**Conclusion:** Almost two thirds of patients with PsA with axial involvement in daily clinical practice had a low activity of the disease measured by PsAID2 and correlated with low activity in the BASDAI and ASDAS-PCR.

**UVEITIS IN PATIENTS WITH PSORIATIC ARTHRITIS**

S. Monou1, R. Shummaieva1, M. Sotrova2, D. Monou2, 1Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria; 2Medical Institute - MVR, Department of Ophthalmology, Sofia, Bulgaria

**Background:** Psoriatic arthritis (PsA) is a common disease in Departments of rheumatology, PsA affects from 5 % to 30 % of patients with psoriasis. The arthritis associated with psoriasis follows different patterns, including oligoarticular disease, polyarticular disease, distal interphalangeal disease, arthritis mutilans and axial disease. The axial disease often overlaps with the other four groups. Psoriatic arthritis belongs to the group of spondyloarthropathies in which uveitis is an associated disease. The prevalence of uveitis among PsA patients is not well established.

**Objectives:** The aim of this study is to describe the clinical characteristics of PsA related to uveitis.

**Methods:** Uveitis is described as an inflammation of the tissues that comprise the uveal tract (i.e., iris, ciliary body, and choroid). It can be classified either according to the anatomic parts of uvea that are involved or according to its underlying etiologic cause. Anterior uveitis involves the iris and/or the ciliary body, intermediate uveitis involves the vitreous humor, while posterior uveitis is characterized by inflammation of the uvea and the choroid. A retrospective database study was conducted on 164 (96 female, 68 male, mean age 52,36±16,14 years) adult PsA patients with ocular symptoms. Demographic variables, smoking status, socioeconomic status (SES), body mass index (BMI), presence of selected chronic comorbidities, and medication use, including conventional and biologic disease modifying anti-rheumatic drugs (c/b DMARD) were extracted. We collected data about psoriasis type, uveitis laterality, onset type, human leukocyte antigen types, visual acuity, uveal inflammation localization, anterior segment findings, funduscopy findings, complications, recurrence, intraocular pressure, visual acuity, comorbidities, and medical treatments and outcomes for uveitis and psoriasis, and medical treatments for uveitis and skin diseases. Descriptive statistics was applied as appropriate. Cox proportional hazard regression time dependent models were used to calculate the risk of uveitis given demographic variables, SES, smoking, selected comorbidities, and c/b DMARD. P values of ≤ 0.05 were considered statistically significant.

**Results:** This study included a broad spectrum of ocular inflammation associated with PsA. We found that conjunctivitis was the most common problem, affecting 53 patients (32.32 %). Iritis (anterior uveitis) was found in 10 (6,1%), episcleritis - in 3 (1,83 %) and keratoconjunctivitis sicca - in 5 (3,05 %) patients. 14 patients were with axial involvement, seven of them with anterior uveitis. Patients with PsA and uveitis were more often female (7), of a younger age (48,25±15,4 years). In our cohort of patients uveitis is bilateral in 7 patients, all cases had acute non-granulomatous anterior uveitis. Anterior uveitis is usually accompanied by pain and redness of the eye without vision loss, while intermediate (1 patients) and posterior (2 patients) uveitis are mainly associated with visual symptoms such as floaters or blind spots and may affect central vision. Patients with uveitis had a previous history of uveitis and were more often treated with cDMARDS, monoclonal anti-Tumor Necrosis Factor-α (antiTNF-α) agents and etanercept. No difference in uveitis occurrence was noted regarding demographic characteristics and comorbidities.

**Conclusion:** Uveitis, in particular, is being considered as a relatively rare but very serious ocular complication of psoriasis. Patients with psoriasis should be educated about the increased risk and manifestations of uveitis. An ophthalmological consultation is needed when patients present with eye symptoms.

**PSORIATIC ARTHRITIS WITH POSITIVE ACPA, WHICH FEATURES?**

S. Ghazizadi1, I. EL Harth1, N. Akabi1, I. El Mezouar1, T. Harzy1, 1University Hospital Hassan 2 of Fes, rheumatology, Fes, Morocco; 2medical school of Fes, epidemiology, Fes, Morocco

**Background:** Anti-cyclic citrullinated peptide antibodies (ACPA) have been detected in several patients with psoriatic arthritis (PsA). It is possible that these autoantibodies are associated with particular features of PsA.
Objectives: The objective of our study was to assess the frequency of anti-CCP antibody positivity in psoriatic arthritis, and to identify the factors associated with this positivity in PsA.

Methods: Observational cross-sectional study, carried out in the rheumatology department of the CHU Hassan II of FES between January 2012 and October 2021. Including 67 patients with RF fulfilling the CASPAR criteria. ACPA positivity threshold was >20UI/ml.

Results: Our study included 67 patients, the mean age was 55.3 +/- 15 years, the sex ratio was 0.36M:F, the mean disease duration was 6.61 +/- 9 years. ACPA were positive in 16.4% of cases (11 patients), and negative in 83.6% of cases (56 patients). In bivariate analysis, PsA with positive ACPA was more common in men (278% versus 12%; p=0.049), PsA patients with positive ACPA presented less inflammatory back pain (14% versus 86%) (p=0.049), developed more frequently pulmonary complications (60%) (P=0.001, and presented more often a positive rheumatoid factor (32% versus 7%) (P=0.019). In multivariate analysis, male gender was significantly related to ACPA positivity (p=0.049, OR=22.702, IC=1.05-505). Likewise for lung involvement (p=0.010, OR=6790.3, IC=2.6 -1709.8). Also, ACPA positivity during PsA was significantly related to that of rheumatoid factor (RF) (p=0.05 OR=61.375 IC=0.994-3789). In addition, no statistically significant difference was found between the two groups concerning the activity of the disease, the structural impact, the biological inflammatory syndrome and the use of biotherapies.

Conclusion: In our study, PsA is characterized by a low predominance of a positive ACPA form. This form with positive ACPA is found in our context to be more frequent among men, more often associated with positive RF, and is more complicated by pulmonary damage.

**AB0963** FREQUENCY OF SEXUAL DYSFUNCTION IN PSORIATIC ARTHRITIS, SANTO DOMINGO, DOMINICAN REPUBLIC

Background: Psoriatic arthritis (PsA) is an inflammatory joint disease that cause structural damage, disability, and an impairment of quality of life 1. Sexual function is a neglected area of quality of life in patients with PsA, with a high prevalence of dissatisfaction. 2 It has been described that there is no relationship between the orgasm/completion domain proved to be the most dysfunctional in both sexes. A statistically significant linear association of sexual dysfunction and disease activity was evident.

**AB0964** PSORIATIC ARTHRITIS (PSA) WITH POSITIVE RHEUMATOID FACTOR (RF) VERSUS PSORIATRIC ARTHRITIS WITH NEGATIVE RF

S. Ghazaali, I. EL Harchi, N. Akasbi, I. El Mezouna, T. Harzy, University Hospital Hassan 2 of Fes, Rheumatology, Fes, Morocco; University Hospital Hassan 2 of Fes, epidemiology, Fes, Morocco

Background: Rheumatoid factor (RF) has been detected in several patients with psoriatic arthritis (PSA). It is likely that its positivity is linked to a very specific clinical, biological and/or evolutionary profile of PsA.

Objectives: The objective of our study was to evaluate the frequency of positive rheumatoid factor during PsA, and to define the characteristics and factors related to this positivity.

Methods: Monocentric observational cross-sectional study including 84 patients with PsA, fulfilling the CASPAR criteria, and hospitalized in our rheumatology department in University Hospital Hassan II of Fez, on the period lying between January 2012 and October 2021. A threshold greater than 20UI/ml of defines RF positivity.

Results: Our study included 84 patients, the average age was 57 +/- 13 years. The sex ratio was 0.35 M:F, the average duration of disease progression was 6 years +/- 8 years. 47.6% of patients had a positive RF (40 patients) while 52.4% of patients had a negative RF (44 patients). In bivariate analysis, PsA with positive RF had an earlier age of the disease onset (p=0.017), was more frequent in chronic smokers (p=0.045), and showed more enthesis damage (p=0.046). Also, patients with PsA and a positive RF had a higher biological inflammatory syndrome (p=0.013) in particular CRP (p=0.007), higher Basdaï and DAPSA (p=0.021) (p=0.021) respectively In multivariate analysis, enthesis damage involvement was significantly linked to RF positivity (p=0.039, OR=3, IC=1.059-8.496), as was the biological inflammatory syndrome (p=0.010, OR=3.875, IC=1.382 -10.766).

Conclusion: In our study, PsA with positive RF is found to be earlier and more severe in comparison with PsA with negative RF, and more frequently adopts the peripheral enthesitic form.

**AB0965** SERIAL SEROLOGY TESTING IN PATIENTS WITH PSORIATIC ARTHRITIS: SHOULD IT BE DONE?

S. Sundanam, D. Veale,* C. Orr,* L. O’Neill,* F. Young,* Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, University College Dublin, Rheumatology, Dublin, Ireland

Background: The diagnosis of psoriatic arthritis (PsA) is largely based on clinical phenotype due to the heterogeneity of the presenting features, which can include synovio-enthesal disease, dactylitis, skin and nail disease, uveitis and axial involvement. (1) In contrast to rheumatoid arthritis (RA), PsA is a seronegative inflammatory arthropathy. Rheumatoid factor (RF) and Anti-CCP antibodies are usually absent in PsA, and if patients do have positive serological findings for RF or CCP, the titres tend to be low. (2) Seronegativity for RF has a significantly high discriminant value in the Classification Criteria for Psoriatic arthritis (CASPAR), such that a negative RF forms one of the five possible criteria; thus serological testing is often done once at the initial diagnostic appointment. (3) A previous study in the context of RA has shown that there is a tendency for
repeated serological testing with as much as 70% of patients having RF tested more than once. (4) Repeated testing amounts to additional expense and is rarely needed in PsA. The literature on the frequency of repeated serology testing in PsA patients is absent.

Conclusion: As opposed to RA, PsA has not been associated with the presence of circulating antibodies. The presence or absence of RF in PsA patients has for long been a subject of debate. (3) In cases of peripheral polyarticular PsA, which may be difficult to distinguish from RA, serological testing can be useful to identify RA. However, studies have found that RF can be present in 5-13% of PsA patients. (5) In the context of RA, serological conversion from negative to positive is infrequent and repeat testing is not recommended. (6) Over half of the patients in our PsA cohort had repeated RF testing. Certainly this is unlikely to be helpful or cost effective and serial serology measurements in PsA patients should be avoided.

ARE CURRENT PATIENT REPORTED OUTCOMES TOOLS OPTIMIZED TO CAPTURE THE ENTIRE PATIENT EXPERIENCE?

P. J. Mease1, V. Strand2, D. Furst3, E. Siegel4, M. McIlraith5, M. E. Husni6, M. C. Hay7. 1Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, Washington, United States of America; 2Stanford, Rheumatology, Palo Alto, California, United States of America; 3University of California Medical Center/Provider St. Joseph Health and University of Washington, Rheumatology, Seattle, Washington, United States of America; 4Georgetown University School of Medicine, Rheumatology, Washington DC, United States of America; 5Mmc Consulting, Research, Dallas, Texas, United States of America; 6Cleveland Clinic, Rheumatologic and Immunologic Disease, Cleveland, Ohio, United States of America; 7Miami University, Anthropology, Oxford, Ohio, United States of America

Background: Psoriatic Arthritis (PsA) affects multiple attributes of patient health; to assess treatment effectiveness a compilation of Patient Reported Outcomes (PRO) have been utilized. While useful, most of these were originally created for other diseases and only later validated or adapted for use in PsA. More recent efforts have focused on development of PsA specific PRO tools, with inclusion of patient input and relevance for use in both clinical research and clinical care (1).

Objectives: To subject a broad set of currently used PROs to patient assessment, giving insight into usefulness in the clinic and informing efforts for optimization of PsA PROs.

Methods: Four focus groups were conducted across three regionally-diverse areas in the United States from March 2016 to October 2016. Patients represented a range of disease history, symptoms, and severity. After trained facilities encouraged open conversation about PsA, including symptoms, challenges and feelings about disease and treatment, patients reviewed 13 currently utilized PROs and rated relevance of these instruments to reporting their disease experiences on a 3 point scale of Relevant, Somewhat Relevant, and Irrelevant. Verbal discussion followed on the merits and challenges of each rated PRO.

Results: PRO instruments ranged from overall global assessments to disease specific assessments (Table 1). The PROs received a variety of ratings, with Functional Assessment of Chronic Illness Therapy - Fatigue (FACT-F) and Psoriatic Arthritis Impact of Disease (PsAID) judged as Very Relevant by the largest number of patients, followed by Health Assessment Questionnaire-Spondyloarthropathies (HAQ-S) and Pain VAS (Figure 1). Instruments receiving the most assessments of Not Really Relevant were Pt Global and PsA Quality of Life (PsAQOL). In the qualitative portion of the research, major patient critiques across PROs were the time frames listed on the questionnaires; some were too restrictive and disallowed reporting important recent disease activity. Preferences were for questions asked "since your last visit," Multiple participants also agreed that a visual tool allowing patients to circle specific joints to indicate pain would be useful.

</table>

Conclusion: Currently utilized PROs in PsA evaluating domains of fatigue, function, pain, and disease specific manifestations were all important regarding new therapeutic agents. However, some are more relevant than others to patients, most notably FACT-F and PsAID, the latter being an important example of a patient-led and disease-specific development effort. Allowing reporting of items of concern without restrictive time periods is important to patients. These preferences and comments can be utilized to better understand the value of PROs in clinical settings to optimize patient-therapistcommunications.

Background: Carpal tunnel syndrome (CTS) and hand osteoarthritis (HOA) are common diseases that can coexist in the same patient. Only one recent study showed that CTS was associated with a significant decrease in strength and performance of the OA-affected hand [1]. This observation suggested that CTS-induced neuropathic disorders may have effects on the surrounding joints symptomatically supporting the role of nerve-joint axis in OA pain.

Objectives: Our work aimed to study the impact of CTS on the symptoms and structural severity of HOA in the DIGICOD (DIGital Cohort Design) cohort.

Methods: DIGICOD is a single-center prospective hospital cohort which includes 426 patients over 35 years of age with symptomatic HOA [2]. Patients in our study were those in the DIGICOD cohort at inclusion for whom the dominant hand and lateral aspect of CTS involvement were known. The analysis was based on the study of the dominant hand. We compared the demographic, clinical and radiographic characteristics (notably by the sum of the Kellgren Lawrence (KL) score) between patients with CTS and those without CTS. In case of comparison test, Chi-square or Fisher exact test were performed. Then, we investigated whether CTS was associated with grip strength, pinch strength and KL score by linear regression model and with numbers of joints painful pressure with negative-binomial model, after adjustment for age and sex.

Results: 417 patients including 39 with CTS were included in our study. Obesity and metabolic syndrome were more frequent in patients with CTS than in those without CTS (obesity: 29.7% vs 10.2%, p<0.01; metabolic syndrome: 51.4% vs 35.1%, p<0.05). The same was true for dysthyroidism (38.5% vs 18.5%, p<0.01) and thyroid hormone replacement therapy (30.8% vs 15.4%, p<0.05). At the level of the dominant hand, clinical signs of HOA (painful, swollen, or nodal joints), sum of Kellgren Lawrence (KL) score, number of joints with a KL score ≥ 2, and the presence of erosive HOA (defined by the presence of at least 1 erosive joint defined as phase “E” or “R” in the Verbruggen scoring) were comparable between HOA patients with and without CTS. After adjustment for age and sex, the presence of CTS in the dominant hand was not statistically associated with grip strength disturbances (measured with the Jamar dynamometer), pinch strength (thumb index, finger pinch), number of joints painful pressure, and KL score.

Conclusion: The risk factors for CTS in HOA are those known in the general population. Hypothyroidism, obesity and metabolic syndrome. However, our study did not find any impact of CTS on the clinical signs and structural severity of HOA.

AB0967 FACTORS INFLUENCING THE RESULT OF LOCAL INJECTION THERAPY WITH HYALURONIC ACID PREPARATIONS IN OSTEOARTHRITIS OF THE KNEE JOINT

V. Biakie1, S. Makarov2, E. Biakie2, V. Nesterenko1, M. Nurmukhametov1, M. Makarov1, I.V. Nasonova Research Institute of Rheumatology, Rheumorthopaedics and Rehabilitation, Moscow, Russian Federation

Background: Local injection therapy (LIT) with hyaluronic acid (HA) preparations is one of the methods of conservative treatment of the knee joint osteoarthritis (KO). However, the factors affecting the effectiveness of such treatment require clarification.

Objectives: to study the influence of age, body mass index (BMI), stage of KOA, the presence of deformity of the knee joint and enthesitis on the results of LIT with HA preparations in KOA.

Methods: From September 2017 to June 2019, intra-articular injections of HA were performed in 160 patients with primary and posttraumatic KOA stage I-II. For the analysis, the patients were divided into groups depending on the factor studied: by age into young - 36 (22.5%), middle age - 51 (31.3%), elderly - 61 (37.8%) and old age - 12 (7.5%); by BMI: on patients with normal values - 32 (20%), obesity - 56 (35%), I - 43 (26.9%), II - 16 (10%) and III - 13 (8.1%) degrees of obesity; by stages of KOA: I - 37 (23.1%), II - 91 (56.8%), III - 32 (20.1%); by the presence of deformity: varus deformity <10° - 83 (51.8%), >10° - 23 (14.4%), valgus deformity >22 (13.8%), no deformity - 32 (20%); and also depending on the presence (44 (27.5%)) or absence (116 (72.5%)) of enthesitis. To assess the results, the pain intensity was determined using a visual analogue scale and the knee injury and osteoarthritis outcome score before treatment, 1, 3, and 6 months after the course of LIT.

Results: 1 month after the course of LIT, the best results were obtained in young patients (p=0.001), as well as stage 1 of KOA (p=0.0001) and normal BMI values.
Methods: The patients with knee disorders scheduled to undergo knee arthroplasty at our hospital between July 2020 and May 2021 were included. They were assessed for baseline attributes, clinical assessment including Knee Society Score (KSS), degree of pain on walking by visual analogue scale (VAS), range of motion (ROM), and also leg skeletal muscle mass index (SMI; whole-body mode DXA), quadriceps strength by dynamometer with written consent (UMIN ID: 000040940). And Japanese Cardiovascular Health Study criteria for frailty, and sarcopenia by Asian Working Group for Sarcopenia 2019 criteria were evaluated.

Results: Demographic data of 83 patients (65 women, mean age 74.9 years) included in this study was shown in Table 1. The distribution in frailty is 38.2% and that in sarcopenia is 7.3%. Most of the patients with pain without knee disorder did not suffer from sarcopenia. A multivariate analysis was conducted with walking speed as the objective variable and the dependent variables as age, gender, pain VAS on walking, KSS, leg SMI, quadriceps strength, and ROM. The results showed that age and ROM in flexion were significantly and independently associated with walking speed (P<0.01, 0.03). Gender, pain VAS on walking, KSS, leg SMI, quadriceps strength, and ROM in extension were not significantly associated with walking speed (P=0.92, 0.11, 0.11, 0.52, 0.85, 0.52).

Conclusion: Among the patients with knee disorders immediately before arthroplasty, frailty was not caused by sarcopenia. Age was found to be the most correlated factor with walking speed, and walking speed became slower with age. In addition, poor flexion angle was also the factor for delayed walking speed, but it did not correlate with lower limb skeletal muscle mass or quadriceps strength. In this study pain on walking was not significant factor for walking speed, because it was observed in most of all cases.

Disclosure of Interests: None declared

Patients were divided into 2 groups according to BMI: BMI<24.9 kg/m², n=22 (no obesity); BMI≥30kg/m², with signs of grade 1-2 obesity, n=50.

Results: OA patients with obesity had higher WOMAC and Lequesne index values than OA patients with normal weight (5.8±1.2 cm and 13.8±1.1 points, respectively, p<0.05). WOMAC parameters in overweight patients were significantly higher than in non-obese patients (31.2±5.9 vs. 9.7±2.7, respectively, p<0.05 for the above parameters). There was a direct correlation (p<0.05) between the severity of OA and increased BMI. Radiological changes of the joints in patients without obesity were stage I (60.6%) in 14 (60.6%), stage II in 7 (34.8%) and stage III in 1 (4.5%) patient. Grade I obesity was noted in 8 (16.0%), Grade II in 22 (44.0%), Grade III in 18 (36.0%), Grade IV in 2 (4.0%) patients. Inadequate joint function (NFS) grade I was in 16 (72.7%), II in 4 (18.2%), III in 2 (19.1%) patients with normal body weight, with NFS grade II (26-52%) and III (18-36%) predominating with obesity, grade I in 6 (12.0%). Synovitis was diagnosed in 37 (74.0%) with elevated BMI, significantly higher than in non-obese patients in 7 (31.8%). On the course, rapid progressive OA was seen more frequently in 11 obese patients (22.0%) than in non-obese patients (4.5%); there was a direct correlation between the VAS pain index, Lequesne index and WOMAC index (r=0.5, p<0.05; r=0.4, p<0.05 respectively).

Conclusion: Overweight in patients with OA was associated with greater joint destruction and functional impairment of OA joints, progressive course and pain syndrome, including secondary synovitis.

AB0973 LONG TERM EFFICACY OF INTRA-ARTICULAR VISCOSUPPLEMENTATION WITH HYALURONIC ACID IN HIP OSTEOPOROSIS SECONDARY TO SYSTEMIC RHEUMATIC DISEASES: A PRELIMINARY EVALUATION

F. Cumbo1,2, O. De Lucia1, A. Murgo1, C. Artusi1, R. Caporali1,2
1Università degli studi di Milano, Dipartimento di Scienze Cliniche e di Comunità, Milano, Italy; 2Asst Pini-CTO, UOC Reumatologia Clinica, Milano, Italy

Background: Few studies have assessed response to intra-articular HA viscosupplementation in patients affected by hip osteoporosis secondary to systemic rheumatic diseases (SOA). From in vitro studies we know that the synovial environment in these diseases presents different molecular characteristics in comparison to primary osteoporosis (POA) in terms of pro-inflammatory activity and therefore in degradation of hyaluronic acid.

Objectives: To evaluate differences in efficacy and safety of treatment with US-guided intra-articular HA viscosupplementation within a cohort affected by POA and one affected by SOA, with regard to pain assessment and time to arthroplasty.

Methods: We conducted this observational retrospective study on consecutive patients treated with US-guided hip intra-articular injections with Hylan G-F 20 2 ml at the Rheumatology Unit of ASST-Pini-CTO, Milano (Italy) from 2013 to 2021. Joints with active synovitis detected by US examination weren't treated. VAS pain at baseline and at the end of October 2021 was registered as well as time to the event of hip arthroplasty and adverse reactions. Patients treated had hip pain at least 6 months before treatment and radiological OA assessed by standard hip X-rays no more than 6 months before baseline. Patients included in the SOA group had a diagnosis of rheumatic systemic disease, POA patients had osteoporosis and any further rheumatological condition was ruled out. Additional clinical features recorded for the SOA patients were clinimetric assessment of disease activity according to SDAI for RA, clinical judgment for PMR, DAPSA for PsA, ASDAS for SpA and medical treatment at baseline.

Results: We included 55 primary OA patients and 16 systemic rheumatic diseases patients (5 JIA, 1 periperal SpA, 2 PMR, 1 Axial-Spa, 1 PsA, 2 RA) who had received hip intra-articular HA injection with Hylan G-F 20 ml once a month for three consecutive months and then every six month. Mean duration of follow up was 51.1 (±27.1) months. We observed significant longer treatment survival and lower VAS pain in POA patients at follow up (in absence of significant difference of VAS pain at baseline). In both cohorts we observed a reduction in VAS pain similar to that reported in literature: in the POA a mean reduction of 29.7 (95% CI 23.8-35.6), while in the SOA was noticed a mean reduction of 12.8 (95% CI 18.2-23.7) in absence of significant clinimetric variations over time. We observed higher incidence of local adverse reactions in SOA group (2 cases of post-injection synovitis in the SOA cohort only (12.5%), p 0.001).

Conclusion: According to our results symptomatic hip SOA patients respond less and with a slightly higher degree of adverse reactions to intra-articular visscosupplementation when compared to POA patients, even if the incidence of these adverse events was similar to that observed in previous studies. We can infer that synovial pro-inflammatory environment in rheumatic systemic diseases can reduce efficacy of intra-articular viscosupplementation with hyaluronic acid.

AB0974 ASSOCIATION BETWEEN DIABETES MELLITUS AS PART OF METABOLIC SYNDROME AND OSTEOPOROSIS (PRELIMINARY DATA)

L. Alekseeva1,2, E. Taskina1, N. Kashevarova1, D. Kusevich1, K. Telyshev2, E. Strekova1, E. Sharapova1, D. Kudinsky1, O. Alekseeva1, N. Demin1, O. Tenkova3, E. Kharlamova3, A. Abolyoshina5, 1V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation; 2Russian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation; 3VA. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; 4VA. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation; 5VA. Nasonova Research Institute of Rheumatology, Diagnostic Department, Moscow, Russian Federation

Background: There are more evidence that diabetes mellitus (DM) aggravates the course of osteoarthritis (OA).

Objectives: At multicenter study to evaluate impact of DM as part of metabolic syndrome on course of knee OA.

Methods: The enrolled patients had knee OA based on ACR criteria with x-ray confirmation with stage I-II (Kellgren and Lawrence (K&L). Mean disease duration was 5 (2-10) years. Patients were evaluated by report form, using the anthropometric parameters, questionnaires, disease history and comorbidity, clinical examination data, assessment of knee joints pain, standard X-ray, ultrasound signs of OA, DXA three sites the L1-L4 lumbar spine, femoral neck, and total hip. All participants were signed an informed consent form.

Results: At prospective study were enrolled 253 women with mean age 58.3 ± 9.5 years (40-75) years, with knee OA. Compensated DM type 2 was diagnosed in 26 (10.3%) patients with knee OA. All patients with knee OA were divided into two groups:1st group was with DM and 2nd group without DM (Table 1). Patients with DM were older, had higher weight and BMI. In patients with DM was harder course of OA based on clinical and instrumental data: higher pain by WOMAC score; at X-ray were more frequent confirmed III stage (K&L) (OR=3.1, 95%CI 1.1-8.7, р=0.01). At X-ray investigation narrow of medial joint space and at ultrasound thickness of the cartilage were also more expressed in 1st group. More often comorbidity at 1st group was DM and DM was harder course of OA based on clinical and instrumental data: higher pain by WOMAC score; at X-ray were more frequent confirmed III stage (K&L) (OR=3.1, 95%CI 1.1-8.7, р=0.01). At X-ray investigation narrow of medial joint space and at ultrasound thickness of the cartilage were also more expressed in 1st group.

Conclusion: DM was harder course of OA based on clinical and instrumental data: higher pain by WOMAC score; at X-ray were more frequent confirmed III stage (K&L) (OR=3.1, 95%CI 1.1-8.7, р=0.01). At X-ray investigation narrow of medial joint space and at ultrasound thickness of the cartilage were also more expressed in 1st group.

In the Spearman correlation analysis are confirmed positive associations between DM and the difficult and prolonged course of OA. We found out that higher WOMAC pain subscale (r=0.18), total hip BMD at DXA (r=0.25), smaller size of medial joint space (r=-0.24) and thickness of the cartilage at ultrasound (r=-0.13) are associated with DM (p<0.05 for all parameters). Positive relationships also are indicated with BMI (r=0.21), hypertension (r=0.15), MS (r=0.24), (r=-0.13) are associated with DM (р<0.05 for all parameters). Positive relation-

AB0976 DETERMINATION AND CHARACTERIZATION OF PATIENT SUBGROUPS WITH DIFFERENT PAIN PROGRESSION IN HAND OSTEOARTHRITIS

C. Van der Meulen1, L. Van de Stadt1, F. Rosendaal2, J. Runhaar3, M. Kloppenburg1,3 Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; 2Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands; 3Erasmus MC, Department of General Practice, Rotterdam, Netherlands

Background: Hand pain is common in hand osteoarthritis (OA). Previous cohort studies reported stable average pain levels on the short to midterm. Subgroups with different pain trajectories have been found in knee OA. Similar subgroups of hand OA patients may exist. Knowledge of such subgroups in hand OA patients may help inform decisions for pain treatment.

Objectives: To determine and characterize subgroups with different hand pain trajectories over four years in hand OA patients.

Methods: Data from the ongoing HOSTAS (Hand OSTeoArthritis in Second-

ary care) cohort were used, collected from consecutive patients at the LUMC Rheumatology outpatient clinic with primary hand OA followed for four years. Hand pain measurements were collected annually starting at baseline with the AUSCAN pain questionnaire (range 0-20). Development of pain over time was modelled using latent class growth analysis (LCGA), dividing the cohort into subgroups based on differences in pain development. The optimal model was selected based on the AIC, BIC, entropy and likelihood ratio test for models with n vs n-1 classes. LCGA requires ≥2 measurements per case, so patients with less were excluded. Associations of LCGA classes with baseline demo-
graphics and factors associated with hand pain were analyzed using multino-
minal logistic regression.

Results: Of 538 participants, 484 completed the AUSCAN at ≥2 timepoints. Data of excluded patients were missing at random. Included and excluded patients were comparable. Of included participants 86% were women, mean (SD) age was 60.8 (8.5), 29% had erosive disease, median (IQR) symptom

Figure 1. LCGA trajectories. Trajectories of AUSCAN pain identified by latent class growth analysis. Least pain to most pain, named class 1 (pink), class 2 (red), class 3 (brown), class 4 (blue) and class 5 (green).
duration was 5.2 (1.9-12.2), 91.0% fulfilled the ACR criteria for hand OA. Mean AUSCAN pain score was 9.3 (4.3). LCGA yielded five classes (Figure 1). Classes were characterized by different pain levels at baseline; mean level of pain remained stable over time. Classes with more pain were associated with more erosive disease, higher tender joint count, longer symptom duration, more comorbidities, worse AUSCAN function scores and worse SF-36 and HADS scores (Table 1).

Multinomial logistic regression of variables associated with LCGA classes adjusted for baseline AUSCAN pain, age, sex and BMI. Class 1 = least pain, class 5 = most pain. SF-36 = Short Form-36. MICS = Mental component scale. PCS = Physical component scale. HADS = Hospital anxiety and depression scale. SF-36 scores are standardized on age, sex and nationality with mean 50 and SD 10.

Conclusion: Latent class growth analysis showed five subgroups with different pain trajectories in hand OA patients, with differing baseline pain and stable pain over time. These subgroups were associated with disease characteristics, number of comorbidities, psychological distress and health-related quality of life. This knowledge can help develop treatment for hand OA patients and inform them about the disease course.

AB00977 THE RELATIONSHIP OF OVERWEIGHT AND CONCOMITANT METABOLIC DISORDERS WITH THE FEATURES OF THE COURSE OF PRIMARY OSTEOARTHRITIS OF THE KNEE JOINTS

I. Bashkova1,2, I. Madyanov1,3, K. Misko1. 1Chuvash State University named after I.N. Ulyanov, Department of Hospital Therapy, Cheboksary, Russian Federation; 2Federal Center of Traumatology, Orthopedics and Endoprosthetics, Consultative Polyclinic, Cheboksary, Russian Federation; 3Republican Clinical Hospital, Department of Endocrinology, Cheboksary, Russian Federation

Background: There are two theories of the relationship between osteoarthritides (OA) and obesity: biomechanical and metabolic.

Objectives: To study the prevalence of overweight and obesity and concomitant metabolic disorders in patients with OA and to assess their impact on the features of the course of primary OA of the knee joints.

Methods: Patients with primary OA with a lesion of the knee joints (n=90, including 22 men) were examined. The age of the patients was 29-69 years, the duration of the disease is 15-20 years. The control group (n=114, including 26 men) was formed by random sampling of the population from practically healthy people, it is representative by gender and age. Anthropometric examination, determination of lipid metabolism parameters, levels of dehydroepiandrosterone sulfate (DHEA-S) and cortisol in the blood, X-ray and arthrosonographic examination of joints were performed. The functional state of the knee joints was analyzed by the Lequesne gonarthrosis severity index and the WOMAC algofunctional index.

Results: Average Body Mass Index (BMI) in patients, OA was 28.6±5.8 kg/m² and was slightly higher than in the control group (27.6±4.5 kg/m², p<0.05). Overweight and obesity were detected, respectively, in 40.7% and 33.0% of patients with OA, and in 43.0% and 29.8% of the control group. An increase in BMI in patients with OA, despite the absence of a significant difference in age and duration of the disease, is accompanied by an increase in the total values of the WOMAC index (p=0.042) and Lequesne (p=0.038). According to arthrosonography, the increase in BMI is directly related to an increase in the size of osteophytes (r=0.403, p=0.003) and inversely correlates with the width of the articular gap of the medial knee joints (r=-0.37, p=0.014). Knee synovitis was detected in 5 patients out of 24 people (20.8%) with normal body weight, in 11 patients out of 37 people (29.7%) who were overweight, and in 13 patients out of 30 people (43.3%) who are obese varying severity (p<0.05). Synovitis of the knee joints in most cases was detected in patients with OA with an abdominal type of fat distribution. The negative influence of the abdominal type of fat distribution on the course of knee joint OA was revealed: positive correlations between waist circumference and the total Lequesne index (r=0.443, p=0.027), and the radiological stage of OA (r=0.467, p=0.019). In patients with OA with abdominal type of fat distribution, the severity of joint pain during exercise exercise was 33.3% higher than in patients with gluteofemoral type (p=0.001), the total Lequesne and WOMAC indices were 27.2% (p=0.028) and 20.1% (p=0.041), respectively. In patients with OA, a significant increase in the blood content of cholesterol (HC) of low-density lipoproteins (LDL) was found (p=0.039) and a decrease in high-density lipoprotein (HDL) cholesterol (p=0.046). Disorders of lipid metabolism of atherogenic orientation were more pronounced in patients with III-IV radiological stages of gonarthrosis. In patients with OA who are overweight or obese, the serum DHEA-C content was lower than in patients with OA with normal body weight (2.31±0.98 mg/cm² vs 2.63±1.68 mg/cm², p<0.05). As the radiological changes in the joints progress, there is a clear decrease in the concentration of DHEA-C. In women with OA, a significant relationship was found between waist circumference and the concentration of DHEA-C in the blood (r=-0.321, p=0.045). There was an increase in the concentration of cortisol in the blood of patients with OA. The inverse correlation relationship between the number of swollen joints with the blood content of DHEA-C (r=-0.269, p=0.012) and cortisol (r=-0.232, p=0.028) was revealed.

Conclusion: The mechanisms of the negative effect of overweight and obesity on the course of OA are lipid disorders (high concentrations of LDL cholesterol, low HDL cholesterol), hormonal changes (low DHEA-C, elevated cortisol levels) and the production of proinflammatory cytokines by adipose tissue.

AB00978 EFFECT OF ATORVASTATIN ON SKELETAL MUSCLES OF PATIENTS WITH KNEE OSTEOARTHRITIS: POST-HOC ANALYSIS OF A RANDOMISED CONTROLLED TRIAL

Y. Lim1, F. Cicuttini1, A. Wluka1, G. Jones1, C. Hill1,2, A. Forbes1, A. Tonkin1, S. Berezhkovskaya1, L. Tan1, C. Ding2, Y. Wang1, 1Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia; 2University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia; 3University of Adelaide, The Queen Elizabeth Hospital, South Australia, Australia; 4University of Adelaide, Adelaide, Department of Medicine, South Australia, Australia; 5The Alfred, Alfred Hospital, Melbourne, Australia; 6Southern Medical University, Clinical Research Centre, Zhuhai Hospital, Guangdong, China

Background: Statins are often discontinued due to muscle-related side effects. The effect of statin on skeletal muscles in populations with osteoarthritis is unknown.

Objectives: This study aims to examine the effect of atorvastatin on skeletal muscle biochemistry, strength, size and symptoms in patients with symptomatic knee osteoarthritis.

Methods: This is a post-hoc analysis of a multicentre randomised, double-blind, placebo-controlled trial over 2 years in which participants with knee osteoarthritis who met the American College of Rheumatology clinical criteria received atorvastatin (n=151) or placebo (n=153). Outcomes included muscle biochemistry, strength, size and symptoms in patients with symptomatic knee osteoarthritis.

Results: 304 participants [mean age 55.7 (SD 7.8) years, 55.6% female] were randomised. There were no significant differences in CK and AST levels between atorvastatin and placebo groups at 4 weeks (CK median 107 vs 110, p=0.76; AST 22 vs 21, p=0.014), 6 (CK 109 vs 105, p=0.37; AST 21 vs 20, p=0.45), 12 (CK 103 vs 103, p=0.93; AST 22 vs 21, p=0.99), and 24 (CK 103 vs 93.5, p=0.17; AST 22 vs 21, p=0.34) months. The atorvastatin group had higher ALT levels than the placebo group at 4 weeks [26 vs 21, p=0.004] and 6 months [25 vs 22, p=0.007] but no between-group differences at 12 [24 vs 21, p=0.08] and 24 [24 vs 21, p=0.05] months. Muscle strength significantly increased in the atorvastatin group but not the placebo group over 24 months with no between-group differences [mean 8.5% (95% CI 2.6,14.4) vs 5.6 (0.3,11.5), p=0.50]. Change in vastus medialis CSA over 24 months showed between-group differences favouring the atorvastatin group (+0.12 [-0.09,0.34] vs

14Astellas Pharma, Cambridge, UK.

Background: There is an unmet need for new treatments for hand osteoarthritis (OA). Symptomatic hand OA is more common in women and its incidence increases around the age of menopause. Pre-clinical, epidemiological and post hoc studies in Hormone Replacement Therapy (HRT) trials implicate estrogen deficiency as of likely importance in OA aetiology. No clinical trials of HRT have been carried out in hand OA to date. The licensed HRT Duavive (conjugated estrogens + SERM bazedoxifene) was selected on its potential for efficacy and tolerability.

Objectives: We set out to determine the feasibility and acceptability of this form of HRT in post-menopausal women with hand OA, to generate proof of concept data and refine methods for a full study.

Methods: ISRCTN21196200. Females aged 40-65 y and 1-10yrs after final menstrual period with hand OA fulfilling ACR criteria and ≥2 painful hand joints were recruited. Eligibility incorporated best practice for HRT prescription but did not require menopausal symptoms. Recruitment was at 3 sites in primary/secondary care, including directly from the community. Design was parallel group, double-blind: 1:1 randomisation of Duavive or placebo, orally once daily for 24 weeks, then weaning for 4 weeks before stopping. Routes and rates of recruitment and the acceptability of randomisation, medication (compliance, retention), and proposed outcomes were measured, and the likelihood of blinding. Measures related to hand pain and function, menopausal symptoms and joint appearance. Patient and Public Involvement actively informed study rationale, design and materials. An end of study questionnaire and 2 participant focus groups provided further acceptability data.

Results: Recruitment was for 18 months. Estimated 15% loss to follow up. However, small adjustments made to study design to reduce drop out. Overall recruitment was possible 18 months, interrupted due to COVID-19. Some study procedures were modified to allow reopening whilst collecting all primary outcomes. 434 enquiries/referrals were received, leading to 96 telephone screen, of which 33 gave written informed consent and attended face to face screening. 28/33 screened (85%) were eligible and randomised. The highest number of randomisations was from study web presence (n=7) followed by SMS text from GP surgeries (n=5). Of 401 not proceeding, 250 (62%) were ineligible, most commonly due to contraindications to enrolment or no interest. A total of 13 AEs were experienced. One death from metastatic ovarian cancer not considered related to treatment. 4 serious AEs were reported. 4 participants withdrew due to treatment group, whilst 5 (14%) decided not to take part, for reasons including not wanting to take a hormone-based drug or difficulty attending study visits. Retention and compliance were excellent. All 28 participants completed all study follow ups, with only 3 withdrawals from treatment due to AEs, 2 of these at week 24 and all in the placebo arm. There were no serious AEs. High levels of completeness of all study outcome measures were achieved. Bang’s blinding index suggested that participants/investigators were well blinded. There were overall high/good levels of satisfaction with taking part in the study. 26/28 (92%) would recommend taking part to others with hand OA (irrespective of study arm). Many found the flexibility

RECOMMENDATIONS FOR WEIGHT MANAGEMENT IN OSTEOARTHRITIS: A SYSTEMATIC REVIEW OF CLINICAL PRACTICE GUIDELINES

Y Lim1, J. Wong1, S. M. Hussain1, M. Este2, L. Zoloi1, M. Page1, C. Harrison3, A. Wluka1, Y. Wang4, E. Cicuttini5,1, Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia; 2The Alfred, Alfred Hospital, Melbourne, Australia; 3Monash University, Monash Centre for Health Research and Implementation, School of Public Health and Preventive Medicine, Melbourne, Australia.

Background: Weight loss interventions are often recommended to target overweight and obesity in the clinical practice guidelines (CPGs) for the management of osteoarthritis. This is despite evidence from meta-analyses of clinical trials that significant weight loss results in modest improvements in symptoms and minimal effects on disease progression1,2. There is evidence that weight gain is associated with increase in knee pain3,4. In countries such as USA, adults gain on average 0.5 to 1 kilogram per year from early to middle adulthood Preventing weight gain is easier to achieve and sustain than losing weight.

Objectives: Given that weight loss is accepted as fundamental to osteoarthritis management, we systematically reviewed the recommendations and approaches for weight management in all current osteoarthritis CPGs.

Methods: Nine databases were searched (1st January 2010 to 30th September 2021) to identify guidelines informing the non-pharmacological management of osteoarthritis. Three reviewers appraised guidelines according to the AGREE II instrument, and independently extracted data on their characteristics. One author extracted and summarised guideline recommendations on weight management. This systematic review is registered on PROSPERO (CRD42021274195).

Results: Fifteen CPGs from developed and developing countries were included. Weight loss was recommended for knee OA by the American College of Rheumatology and Australian and New Zealand College of Physicians (2018) and hip (10 of 11 guidelines) but not hand osteoarthritis (0 of 4 guidelines). Combination approaches of diet and/or exercise were recommended for overweight or obese individuals (knee: 8 of 12; hip: 4 of 10), with 2 guidelines specifying ≥5% weight loss for knee and hip osteoarthritis. One of 15 guidelines specified strategies for weight loss and maintenance of lost weight. Two of 15 guidelines recommended controlling body weight for osteoarthritis, regardless of obesity status.

Conclusion: Most CPGs for knee and hip osteoarthritis include recommendations for weight loss in those with overweight or obesity as key to managing osteoarthritis, despite evidence of modest at best effect of weight loss on symptoms and no effect on joint structure.2. Given obesity is a major risk factors for osteoarthritis, the prevention of weight gain may be more effective and practical in improving clinical outcomes for osteoarthritis, and hence should be considered as part of the key management in osteoarthritis.

REFERENCES:
offered by a combination of remote and face to face visits (due to the pandemic) attractive. Additional insights from focus groups were to include hand stiffness as well as pain measures but to reduce the overall number of questions. 

Conclusion: Despite COVID-19 and a reduced recruitment period, this study recruited sufficient numbers to assess feasibility outcomes. Randomisation of eligible people and retention rates were high. A mixture of remote and face to face visits due to COVID-19 probably improved recruitment and retention and was supported by participants, who were generally satisfied with the study design and medication. The study provided useful insight and improvements that would be incorporated into a future study. Overall, this feasibility study showed that with clear messaging on eligibility and a defined recruitment strategy, recruitment and retention to a study testing this treatment is possible.

DYNAMICS OF PAIN ACCORDING TO THE VAS SCALE, FUNCTIONAL ACTIVITY ACCORDING TO THE WOMAC INDEX AND QUALITY OF LIFE ACCORDING TO THE EQ-5D QUESTIONNAIRE IN ELDERLY AND SENILE PATIENTS WITH KNEE JOINT OSTEOARTHRITIS AFTER COVID-19

M. Letaeva1, M. Koroleva1, O. Malysheenko1, J. Averkieva1, T. Raskina1.

1Kemerovo State Medical University, Department of Propaedeutics of Internal Diseases, Kemerovo, Russian Federation

Objectives: To evaluate the dynamics of pain on the VAS scale, functional activity according to the WOMAC index and quality of life according to the EQ-5D questionnaire in elderly and senile patients with knee joint osteoarthritis (OA) after COVID-19.

Methods: A total of 32 elderly and senile male patients with an established diagnosis of knee joint OA (according to the criteria of ACR, 1986) stage I–III according to Kellgren–Lawrence, with pain ≥40 mm on a visual analog scale (VAS), who needed non-steroidal anti-inflammatory drugs (NSAIDs), were included in the study. The median age of the patients included in this study was 72.6 (66.0; 79.3) years. All patients had been ill with COVID-19 for the last 6 months. Pain dynamics was assessed on the VAS scale, functional activity - on the WOMAC index, quality of life - on the EQ-5D questionnaire.

Results: When analyzing the clinical picture, it was found that the majority of patients - 22 people (68.8%) - had moderate COVID-19, 4 people (12.5%) - in mild form, 6 patients (18.7%) - in severe. The average duration of hospitalization was 14.0 (9.0; 17.0) days. The majority of patients were discharged with recovery - 30 people (93.75%), 2 people died (6.25%). The most frequent manifestations of postcovid syndrome in elderly and senile patients with OA: weakness – in 18 (56.2%) patients, arthralgia – in 17 (53.1%) and memory loss – in 14 (43.8%). During the study, there was a slight increase in the pain index on the VAS scale after COVID-19, statistically significant differences in the WOwAMC index and pain on the VAS scale after COVID-19 was registered.

RESULTS OF A PROSPECTIVE 6-YEAR OBSERVATIONAL STUDY OF THE EFFICACY AND SAFETY OF A BIOACTIVE CONCENTRATE OF SMALL MARINE FISH IN SENILE PATIENTS WITH KNEE OSTEOARTHRITIS AND MULTIMORBIDITY

T. Raskina1, J. Averkieva1, M. Letaeva1, O. Malysheenko1, M. Koroleva1.

1Kemerovo State Medical University, Department of Propaedeutics of Internal Diseases, Kemerovo, Russian Federation

Background: According to the updated ESCEO, 2019 guidelines for the management of the knee osteoarthritis (OA), SYSDAODA, which includes bioactive concentrate small sea fish (BCCSF), is a mandatory component of OA therapy. There are few studies evaluating the efficacy and safety of BCCSF in elderly patients with knee OA and a high level of multimorbidity, which served as the basis for this work.

Objectives: To evaluate the efficacy and safety of BCCSF therapy in elderly patients (75–90 years old) with knee osteoarthritis (OA) and multimorbidity based on the results of a prospective 6-year follow-up.

Methods: The study included 38 elderly women with OA of the knee (according to the criteria of ACR, 1986) stage II–III according to Kellgren–Lawrence, with pain ≥40 mm on the visual analog scale (VAS), who needed non-steroidal anti-inflammatory drugs (NSAIDs). BCCSF was administered as 1 ml intramuscular injections 20 consecutive days with a 6-month interval (12 courses). The impact of comorbidity on long-term prognostic was assessed using the Charlson comorbidity index. The effectiveness of therapy was assessed by VAS and WOMAC index. All patients during V0, V4 (36 months), V5 (72 months) underwent radiography of the knee joint. The safety of therapy was monitored throughout the observation period. The duration of the study was 6 years, the number of visits (V) - 6: V0 - day 1 (inclusion in the study and initiation of therapy), V1 - 21st day of therapy, V2, V3, V4, V5 - 12, 24, 36 and 72 months after the start of treatment, respectively.

Results: The 29 (76.3%) patients completed the full course of BCCSF treatment. 9 (23.7%) patients withdrew from the study due to the inability to visit the treatment site (for reasons not related to the study). Elderly patients with OA of the knee showed a
high level of multimorbidity - an average of 5 comorbidities. The prognosis of 10-year mortality according to the Charlson index was 1-2% (26%) in 2 (5.3%) patients, 3-4% (52%) in 26 (68.4%) patients, ≥5 points (85%) - in 10 (28.3%) respectively. There was a significant decrease in pain according to VAS (95%; p<0.001) by v1 - in 76.3%, by v2 - in 71.0%, by v3 - in 68.4%, by v4 - in 63.1% and v5 - in 55.2% of patients. There was a significant decrease in the total WOAC index at all visits compared with baseline: V0: 112.5±13.5 mm, V1: 64.7±22.9 mm, V2 - 64.2±22.4 mm, V3: 594±216.0 mm, V4 - 609±183.0 mm, V5 - 669±141.0 mm (p<0.001 for all cases). The reduction in OA symptoms resulted in a signifi- cant improvement in the scored for NSAIDs. By v1, 31.6% of patients did not need to take NSAIDs, by v2 - 47.4%, by v3 - 44.7%, by v4 - 50.0% and by v5 - 44.7%. After 12 months of therapy, the number of days of taking NSAIDs significantly decreased to 5 (0, 10) days per month versus 14 (7, 15) days per month at the beginning of the study (p = 0.005). This rate remained relatively stable through- out the follow-up. X-ray progression of OA ≥1 stage according to Kellgren-Law- rence during BCSSF therapy after 36 months was recorded in 10.5% of patients, after 72 months - in 50.0%. During the entire period of observation, no serious adverse events were registered, including new cardiovascular accidents and allergic reactions.

Conclusion: The results of a 6-year prospective study demonstrate the high efficacy and safety of BCSSF in elderly patients with knee OA and high multimorbidity.

AB0984

CHANGES IN PLASMA VOLUME WHEN MEASURING BIOCHEMICAL MARKERS OF JOINT TISSUE TURNOVER IN RELATION TO ACUTE PHYSICAL ACTIVITY

J. Bjere-Bastos 1, 2, C. Sejersen 2, H. B. Nielsen 2, N. Secher 2, C. C. Kitchen 3, C. P. Miller 1, A. Mackey 1, A. R. Bihlet 2, 1 Department of biomedical Sciences, Copenhagen, Denmark; 2NBCD A/S, NBCD, Herlev, Denmark; 3Rigshospitalet, Niels Secher Lab, Department of Anaesthesiology, Copenhagen, Denmark; 4Roskilde Hospital, Department of Anaesthesiology, Roskilde, Denmark

Background: Physical activity can induce acute changes in plasma volume (PV) and thereby influence concentration of plasma constituents, such as biochemical markers. 2 However, it remains undocumented to what extent PV changes occur during physical exercise in osteoarthritis (OA) patients.

Objectives: Investigating the direct course and magnitude of PV changes during and after weight-bearing (WB) and non-weight-bearing (NWB) exercise, adrena- line-induced cardiovascular stress and resting in an OA population.

Methods: Data originates from the EFEX-OA-02 study (Reg. no.: NCT04542668), which explored biomarker changes in knee OA patients dur- ing and after running, cycling, adenalin infusion and resting on separate days. Blood samples were obtained before, during, at five time points after and again 24 hours post exercise/infusion. Hemoglobin (Hgb) and derived hema- tocrit (Hct) were measured at all time-points to monitor PV fluctuations. Main inclusion criteria: Cumulative Kellgren-Lawrence (KL) radiographic grade of the left and right knee of ≥ 2, 40-75 years of age, bodyweight 50-100 kg and BMI 18.5-35.0 kg/m². Active interventions consisted of 4x5-minute intervals each progressing from low intensity and peaking at ≥80% of the heart rate reserve (HRR). For the adenalin infusion, 0.06 mg/kg of adrenalin was pre- pared in 50 mL saline and administered intravenously. At rest, blood samples were collected at time points similar to the other study interventions, however the 24-hour follow-up sample was omitted. Hgb was measured on a ABL800 blood gas analyzer and converted to Hct using the formula: Hct (%) = (0.0485 x cHb/mL + 0.0083) x 100. Estimated PV change (% ΔPV) was calculated as: % ΔPV = ([Hct Post - Hct Baseline] / Hct Baseline) x 100, where % ΔPV = % change in PV. By v1, Hct decreased to 50% of baseline. By v2, Hct decreased to 30% of baseline. By v3, Hct decreased to 20% of baseline. By v4, Hct decreased to 10% of baseline. By v5, Hct decreased to 5% of baseline. By v6, Hct decreased to 2.5% of baseline. By v7, Hct decreased to 1% of baseline. By v8, Hct decreased to 0.5% of baseline.

Results: Forty subjects were included. Mean age was 60.4 years (Standard deviation (SD): 8.7), 16 (40%) were male, mean BMI was 27.2 kg/m² (SD: 3.5), and mean score in the nine item pain domain of the Knee Injury and Ostearthri- tis Outcome Score (KOOS) at baseline was 67.5 (SD: 15.2) out of 100 (0 and 100 corresponding to max pain and no pain, respectively). Baseline Hgb was 9.05 mmol/L (SD: 0.68) and Hct was 44.7% (SD: 2.9%). All subjects were able to reach the defined peak cardiovascular intensity or higher during exercise, while reaching on average 70% (SD: 8.7%) of that during the adenalin infusion. Cycling, running and adenalin infusion led to acute reductions in PV compared to rest: Cycling -14.3% (95%CI: -10.0 to -18.7%), running -13.9% (95%CI: -10.9 to -17%), adenalin -7.8% (95%CI: -4.2 to -11.5%). The reductions in PV induced by both cycling and running were greater compared to adenalin (p<0.001). There was no difference in PV changes after cycling vs. running (p=0.99). Thirty minutes after both modes of exercise, PV had returned to baseline. After completion of the adenalin infusion, PV returned to baseline at 30-60 minutes, but was lower than baseline levels at 120 minutes by -3.9% (95%CI: -0.7 to -7.1%), at 240 minutes by -5.3% (95%CI: -2.1 to -8.6%), and at 24-hour by -5.9% (2.0 to -9.9%). During seated rest, PV initially increased (3.1%, 95%CI: 0.75-3.4%) (Figure 1).

Conclusion: Moderate-high intensity running, cycling and cardiovascular stress led to rapid reductions in PV of knee OA patients. Adjustment for PV changes should be considered when measuring biochemical markers in relation to physical activity.

PREDICTIVE VALUE OF ULTRASOUND IN HAND OSTEOARTHRITIS

S. Abdelalouf 1, S. Lefki 1, Issad Hassanii Beni messous hospital, Rheumatology, Algiers, Algeria

Background: Hand osteoarthritis (HOA) is a complex degenerative pathology with sometimes noisy joint manifestations that can mimic inflammatory rheuma- tosis. The osteocarticular ultrasound, is a valuable addition to the clinical examina- tion, remains little used for diagnosis and monitoring HOA.

Objectives: The objective of our study is to analyze the ultrasound characteristics of arthritic hands OA in order to know the lesions and to better correlate the clinical data with the sonographic results.

Methods: We performed an ultrasound study of 38 patients (76 osteoarthritis hands) suffering from finger osteoarthritis meeting the ACR criteria. SPSS.20 Software was performed to data analysis

Results: There were 38 patients: 84% women and 16% men, mean age was 61.5 years. 47.36% had had a manual profession, 39.47% had associ- ated osteoporosis, 66% had reported the presence of finger nodules in the mother in family history. 60.52% of patients presented with Heberden's nod- ules, 34.21% with Bouchard nodules, 63.15% an adductus inch and 13.15% an inch in “M” deformation. Impairment of Metacarpo-phalangeal (MP), Proximal inter-phalangeal (PIP) and Distal inter-phalangeal (DIP) (PIP, Distal Inter-phalangeal (DIP) and Trapeziometacarpal (TM) were found respectively: clinically in 24%, 58%, 87% and 76% of cases, and in 8%, 37%, 74% and 92% after ultrasound examination. The impairment was more severe from side of the dominant hand in 39.47% of cases clinically vs 52.63% after an ultrasound analysis. Regarding “erosive” HOA, 36.84% of patients presented at least one clinical and / or sonographic criterion suggesting an erosive form. 7.89% of patients had radiology, 13.15% erythema, 34.21% swell- ing and 60.52% paresthesia. According to ultrasound, 28.94% showed an ero- sion / reconstruction aspect. 28.94% of the patients had presented an erosion of the PIP, 47.36% an erosion of the DIP, grade 1 Doppler signal was found in 15.78% with a strong clinical correlation and positive ultrasound signs in 65.78% of cases, no synovitis was reported.
Conclusion: Hand osteoarthritis is a very heterogeneous disease, the added value of ultrasound appears to be of interest in the diagnosis and monitoring patients with this pathology.

RISK OF SARCOPENIA IN THE WOMEN WITH OSTEOARTHRITIS

N. Gruporina1, N. Zaverukha1, A. Musiienko1, M. Bystrytska1, D. F. Chebotarev

Institute of Gerontology, NAMS of Ukraine, Clinical Physiology & Pathology of Locomotor Apparatus, Kyiv, Ukraine

Background: Recently, physicians all over the world have been focusing on the relationship between sarcopenia and osteoarthritis (OA) [1, 2]. This connection is considered from different positions: as coexisting conditions, sarcopenia as a risk factor for the progression of OA, or OA as a risk factor for sarcopenia.

Objectives: The aim of this study was to determine the risk of sarcopenia (according to the SARC-F Questionnaire) and the level of probable sarcopenia in Ukrainian women with (hip and knee) OA.

Methods: The study included 271 women aged 50-84 years old (mean age 65.6 ±8.0 years, mean height 162.2±5.6, mean body weight 76.7±14.2, mean BMI 29.1±5.1). All subjects were divided into 2 groups: the group of healthy women (group I, n=176), a group of patients with hip or knee osteoarthritis (OA) (group II, n=95). The risk of sarcopenia was determined by the SARC-F Questionnaire.

The probable sarcopenia was determined due to muscles strength (handgrip strength using spring hand dynamometer σ 16(kg)) and physical performance (5-time chair stand test > 15 s), the fall risk – by Desмонд Fall Risk Questionnaires and function – according to the assessment of IADL scale.

Results: In 20.3% of females without musculoskeletal pathology and in 34.7% of women with OA was detected high risk of sarcopenia. The probable sarcopenia was practically 2 times higher in patients with OA and was equal to 42.1% compared to 21.5% in healthy women. According to the Desмонд Fall Risk Questionnaire, 27.5% of healthy subjects and 49.3% with OA had increased fall risk. Low function (according to the assessment of the IADL scale) was detected in 36.4% of females without pathology of the musculoskeletal system and in 57.2% of women with OA.

Conclusion: Our results demonstrated that the incidence of probable sarcopenia was 2 times higher in women with hip and knee OA, as well as the risk of sarcopenia – 34.7%, compared to healthy subjects – 20.3%. Also, the risk of falls and the need for outside help were higher in patients with hip and knee OA but their function (by IADL scale) was significantly lower.

KNEE RESERVE: ULTRASONOGRAPHIC FEATURES OF KNEES IN PATIENTS WITH ASYMPTOMATIC KNEE OSTEOARTHRITIS

M. A. Mortada1, Y. A. Amer1, Zagazig University, Rheumatology, Zagazig, Egypt

Background: Symptoms of knee osteoarthritis (KOA) vary according to many factors mainly degree of KOA and degree of inflammatory features. The primary goal of treatment the patients with KOA is to maximize long-term health-related quality of life through control of symptoms. Understanding ultrasonographic characteristics of KOA in asymptomatic patients may help in management of knee osteoarthritis. Zagazig scale is a newly validated and feasible tool for KOA assessment.

Objectives: To understand the ultrasonographic features of the patients with asymptomatic knee osteoarthritis

Methods: Among 245 patients with knee OA diagnosed according to ACR criteria and recruited in a previous ultrasonographic study (1), data of patients with no or mild pain (VAS ≤ 2) was recorded and studied in a separate section. All patients were subjected to clinical assessment WOMAC scale Western Ontario and McMaster Universities Index of Osteoarthritis, global visual analogue scaleVAS, and functional assessment through the use of health assessment questionnaire-II (HAQ-II). Ultrasound assessment was conducted following ZAGAZIG scale comprising five domains: (1) Severity of knee OA grades (0-5) according to severity scale published by Mortada et al. 2016, (2) Effusion: 4 grades (0-3) no, mild moderate and severe effusion respectively, (3) synovitis: 4 grades (0-3) using the combined EULAR/OMERACT score of grey scale synovitis and Doppler activity, (4) Pes Anserine tendinitis/bursitis: 3 grades (0-2) normal, mild inflammation and severe inflammation (5) Baker cyst: 3 grades (0-2), grade 0: normal, grade 1: small and simple cyst and grade 2: large/and complicated cyst. Each grade in all domains takes one point into score with the total score of all domains ranging from 0 to 15.

Results: At cut-off point of >5, total US score distinguishes between knee osteoarthritis patients with no or mild pain 87.2% specificity and 87.2% sensitivity.

FREQUENCY OF OSTEOGENIC SYNDROME AND LOW-ENERGY FRACTURES IN POSTMENOPAUSAL WOMEN WITH OSTEOARTHRITIS OF THE KNEE JOINT

E. Usova1, T. Raskina1, O. Malyshenko1, M. Leteava1, M. Koroleva1, J. Averkova1

1. Federal State Educational Institution of Higher Education ‘Kemerovo State Medical University’ Ministry of Health of the Russian Federation, Department of Internal Medicine Prophylactics, Kemerovo, Russian Federation
Background: The impact of knee osteoarthritis on the risk of low-energy fractures remains an open question in recent times. Some cohort studies show that OA of the knee joint is associated with increased risk of fractures [1-3]. Other studies do not support this finding [4,5].

Objectives: to compare the incidence of osteopenic syndrome and low-energy fractures in postmenopausal women with osteoarthritis (OA) of the knee joint.

Methods: The study includes 98 women, of whom: 51 (median age 63.0 [93.6:39.8] years) are diagnosed with OA of the knee joint according to the ACR criteria (1991) and 47 without OA of the knee joint (median age 65.0 [61.7:75.0] years). The bone mineral density (BMD) was measured by DXA method (standard deviation, CO) of the femur neck and lumbar spine (L-LIV) were evaluated by the two-energy X-ray absorption (DXA) method ( Lunar Prodigy Primo, USA). The DXA data of the femoral neck and the lumbar spine were interpreted using the following reference intervals: normal BMD - T -criterion -1 CO, osteopenia - T-criterion from -1 to less CO. Low-energy fractures were considered to have occurred with minimal trauma (falling from a height of own height to the same surface or an even smaller injury) and were found in the anamnesis.

Results: In the group of patients with OA of the knee joint, normal BMD was found to be statistically significantly more frequent than the control group (15.7% vs. 4.3%) p=0.033. It is shown that in women with OA of the knee joint, low-energy fractures were statistically less recorded than in the control group; in 29.4% and 5.0% of women respectively (p=0.002). The chances of having low-energy fractures in the group of patients with OA of the knee joint were statistically lower by a factor of 2.64 compared to the control group (OR = 0.378; 95%CI: 0.230 - 0.703).

Conclusion: The low frequency of low-energy fractures and the lower the chances of them in women with OA of the knee joint compared to the control group are probably associated with lower prevalence of the osteopenic syndrome among these patients.

PLANTAR FASCIITIS IN PATIENTS WITH KNEE OSTEOARTHRITIS

S. Bouzid1, S. Miladi2, A. Fazaaz1, H. Bousaa1, K. Ben Abdelghani1, A. Laatar1.
1Mongi Slim Hospital, Rheumatology, La Marsa, Tunisia

Background: Knee osteoarthritis (OA) is a highly prevalent disease, it shares with plantar fasciitis similar risk factors including aging, occupation, obesity, and inappropriate footwear. The association between knee OA and heel pain caused by plantar fasciitis has received limited attention to date.

Objectives: to determine the association between knee OA and plantar fasciitis.

Methods: We conducted a cross-sectional study including 30 patients with symptomatic knee OA. Health status was evaluated using the Western Ontario and McMaster Universities Osteoarthritis (WOMAC) index. The functional impairment of knee OA was determined by the Lequesne index. Ultrasound evaluation of heels was performed in all patients examining signs of plantar fasciitis (measure thickness, echogenicity, enthesisopathy, calcification, erosion, doppler).

Results: The study included 30 patients. Mean age was 62.09 +/- 6.7 years. Patients reported lower back pain and heel pain in 67% (n=20) and 47% (n=14) respectively. Knee symptoms were evaluated by the WOMAC index: mean score for pain, stiffness, and physical function was 9.68 +/- 4.25, 4.18 +/- 3.75 and 2.72 +/- 1.63, respectively. Mean Lequesne index for the knee OA was 11.4 +/- 4.57.

Physical examination revealed limited range of motion in knees in 33 % (n=10) with a genu flexum in two patients. Patella tap was positive in 20 % (n=6).

Conclusion: Our study showed that half of our knee OA patients have plantar fasciitis confirmed with ultrasound. More studies with larger cohorts are needed to explain the correlation between the two lesions.

Disclosure of Interests: None declared.

AB0990

CORRELATION OF CLINICAL PARAMETERS WITH URINARY COLLAGEN TYPE II-C-TELOPEPTIDE AND KNEE CARTILAGE THICKNESS MEASURED WITH ULTRASOUND IN PATIENTS WITH KNEE OSTEOARTHRITIS

D. Iarlenko1, D. Fedkiv2, M. Saluflinig1, K. Iarlenko2.
1Bogomolets National Medical University, Department of internal medicine N3, Kyiv, Ukraine;
2Olexandrivska City Hospital, Central Laboratory Department, Kyiv, Ukraine

Background: Although knee osteoarthritis (KOA) incidence is one of the highest among chronic diseases, no effective biomarkers are known for its management [1].

Objectives: To estimate the relationship between the sensitive marker of matrix metalloproteinase-dependent cartilage degradation - urinary collagen type II-C-telopeptide (uCTX-II) levels, patient-reported outcomes (PRO), and knee cartilage thickness measured using ultrasound (US) in patients with knee OA.

Methods: WOMAC questionnaire and Leken’s functional index, VAS pain by pts, knee joints US, uCTX-II levels (ng/ml; ELISA) were evaluated in 46 pts (71.7% female) with KOA, who hadn’t received any medical treatment except paracetamol or NSAIDs the last 12 weeks. The mean age was 62.6±6.2, mean disease duration – 10.2±6.3 years, 63% and 27% of pts had Kellgren-Lawrence grade II and III, respectively. The knee cartilage thickness (mm) in three compartments (lateral, middle, medial) of the patellofemoral region was evaluated using a linear L50 sensor in standard sensor positions, frequency 5-12 MHz. Calculation of average thickness for each knee joint and both joints was performed. The Spearman correlation coefficient was utilized to detect the association of uCTX-II, PROs and knee cartilage thickness.

Results: The mean values (M±SD) of WOMAC and Leken’s indices were 39.13±6.5 and 12±4.18, respectively. The mean value of VAS pain by pts was 57.7±16.5. The mean concentration of uCTX-II was 0.18±0.12. The mean thickness of cartilage were: 1.7±0.33 for the right, 1.7±0.36 for the left, and 1.7±0.31 for both knee joints. The mean value of both knee joints cartilage thickness had significant negative moderate correlation with Leken’s index (r=-0.354, p<0.01). According to VAS following tertile groups were detected: 1 group: mean interval less than 50mm; 2 group: mean interval 50-64 mm; 3 group: more than 64 mm. There were negative moderate correlations between cartilage thickness of the left knee joint and Leken’s index (r=-0.513, p=0.03) and WOMAC (r=-0.535, p=0.024) only in group 1. Also, pts were divided into three groups according to disease duration: 1 group: mean interval less than 7 years; 2 group: mean interval 7-10 years; 3 group: more than 10 years. There were negative correlations between uCTX-II and medial, middle compartments of left knee cartilage thickness (r=-0.474, p=0.03; r=-0.592, p<0.01, respectively). WOMAC negatively correlated with cartilage thickness of the left (r=-0.517, p=0.02) and right (r=-0.435, p=0.046) knee joints. Leken’s index negatively correlated with cartilage thickness of the left knee joint (r=-0.590, p<0.01). All correlations were moderate and found in group 2. There were negative moderate correlation between uCTX-II and the mean value of middle compartments of both knee joints cartilage thickness (r=-0.538, p=0.04) and positive moderate correlation between uCTX-II and Leken’s index (r=0.561, p=0.036) in men. There were no correlations between uCTX-II and cartilage thickness of each knee joint and both joints in patients with KOA.

Conclusion: Cartilage thickness measured with US associated with PROs in KOA pts. At the same time, the association between uCTX-II and cartilage thickness was less pronounced, only in men and in pts with disease duration 10-70 years. In pts with VAS pain less than 50 mm and in the group of pts with KOA disease duration - WOMAC and Leken’s indices negatively correlated with the thicknesses of the cartilage of the knee joints. In control pts, correlations didn’t represent the expected relationship between uCTX-II level and clinical, instrumental characteristics of KOA. This may be because the current level of uCTX-II characterizes only the state of cartilage metabolism at the time of examination of the patient and doesn’t show the cumulative results of previous anabolic/catabolic changes in articular cartilage.

The aim of this study was to determine the prognostic factors related to clinical response to PRP injections in knee osteoarthritis, in order to better select candidates for this therapy.

Methods: This was a single-center, prospective observational study including patients treated by PRP injections for knee osteoarthritis, from a university hospital. The PRP was leukocyte-poor, obtained by an ARTHREL® kit, and was injected into the joint at one-month intervals. They were assessed at 4 months (M4) and 7 months (M7) after the first injection. Pains on a Visual Analog Scale (VAS) and function with Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Knee injury and Osteoarthritis Outcome Score (KOOS) – Physical Function Shortform (KOOS-PS) were collected. Patients were then classified as responders if they met the OMERACT-OARSI criteria at M7. Univariate and multivariate analysis was performed to compare the two groups.

RESULTS: Among 197 patients, 210 knees were treated. The mean age was 59.8±10.8 years. Body mass index (BMI) was 31.0±6.5. Patellofemoral osteoarthritis was found in 34.3% of the patients, the distribution according to Kellgren and Lawrence stages I, II, III, IV was 11.8%, 33.5%, 40.4% and 14.3% respectively. A majority of patients had failed viscosupplementation (62.4%). At 7 months, 43.8% were classified as responders. Total WOMAC was 49.4±16.1 at M0, 43.6±17.9 at M1, 31.1±19.0 at M4 and 31.9±19.8 at M7, with significant improvement at M4 and M7 versus baseline (p<0.0001). The VAS was 58.5±19.7, 51.6±21.7, 43.7±23.2 and 43.5±23.5 at M0, M1, M4 and M7 respectively (p<0.0001 at all 3 times versus baseline). Regarding treatment satisfaction, 70% of patients considered the treatment effective or very effective at M7. Physical therapy and a heel-buttock distance greater than 35 centimeters were the two criteria associated with a poorer response at M7 on multivariate analysis. The pain VAS at M7 appeared to be lower in patients whose osteoarthritis had been evolving for less than 24 months. Tolerance was good. There was an increase in joint effusions between M0 and M1 (17% vs. 41%, p<0.0001), but no increase in pain.

Conclusion: PRP treatment in knee osteoarthritis appeared to be effective and well tolerated, and this response was not associated with the radiographic stage or the type of knee osteoarthritis. In accordance with the recommendations of a group of French experts, this treatment should be proposed in case of failure of drug and rehabilitation treatment, at the same level as hyaluronic acid injections.

PROGNOSTIC FACTORS RELATED TO CLINICAL RESPONSE IN 197 PATIENTS WITH KNEE OSTEOARTHRITIS TREATED BY PLATELET RICH PLASMA (PRP)

C. Chopin1, M. Geoffrey1, C. Dorleau2, B. Lois1, A. Hittinger1, I. Charlot2, L. Kanagaratsan1, J. H. Salmon1, CHU Reims - Hôpital Maternel Blanche, Service de Rhumatologie, Reims, France; CHU Reims - Hôpital Maternel Blanche, Unité d’aide méthodologique, Reims, France

Background: The European League Against Rheumatism (EULAR) [1] and the Osteoarthritis Research Society International (OARSI) [2] recommend a combination of non-pharmacological and pharmaceutical treatment in the management of knee osteoarthritis. New therapies have emerged such as Platelet Rich Plasma (PRP) injections. Many studies have shown the effectiveness of this treatment, and even its superiority over Hyaluronic Acid.

Objectives: The objective of this study was to determine the prognostic factors related to clinical response to PRP injections in knee osteoarthritis, in order to better select candidates for this therapy.

Methods: This was a single-center, prospective observational study including patients treated by PRP injections for knee osteoarthritis, from a university hospital. The PRP was leukocyte-poor, obtained by an ARTHREL® kit, and was injected into the joint at one-month intervals. They were assessed at 4 months (M4) and 7 months (M7) after the first injection. Pains on a Visual Analog Scale (VAS) and function with Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Knee injury and Osteoarthritis Outcome Score (KOOS) – Physical Function Shortform (KOOS-PS) were collected. Patients were then classified as responders if they met the OMERACT-OARSI criteria at M7. Univariate and multivariate analysis was performed to compare the two groups.

RESULTS: Among 197 patients, 210 knees were treated. The mean age was 59.8±10.8 years. Body mass index (BMI) was 31.0±6.5. Patellofemoral osteoarthritis was found in 34.3% of the patients, the distribution according to Kellgren and Lawrence stages I, II, III, IV was 11.8%, 33.5%, 40.4% and 14.3% respectively. A majority of patients had failed viscosupplementation (62.4%). At 7 months, 43.8% were classified as responders. presarcopenia (p<0.050). The BMD in the femoral neck in patients with sarcopenia was 0.908 [0.817; 0.977] g/cm², which corresponds to -0.95 [-1.35; 0.425] CO according to the T-criterion, while in the groups of patients without sarcopenia and with sarcopenia, statistically significantly higher BMD values were recorded: 0.988 [0.953; 1.09] g/cm² and 0.995 [0.94; 1.04] g/cm² (p=0.009 and p=0.027), which corresponds to -0.30 [-0.80; 0.225] and -0.30 [-0.70; 0] CO according to the T-criterion (p=0.013 and p=0.024), respectively. When comparing the BMD and T-score in the lumbar spine, there were no statistically significant differences in the studied groups of patients.

Conclusion: Sarcopenia is associated with low BMD in the neck and proximal femur in general elderly and senile male patients with knee joint OA.

EXPLORING KNEE OSTEOARTHRITIS PAIN TRAJECTORIES AND MOVEMENT-EVOKED PAIN CHANGES DURING A 24-WEEK OUTDOOR WALKING PROGRAM (WALK)

S. Drummen1, S. Balogun2, L. Scheepers1, I. Murugodua, A. Lahtham2, K. Bennett1, R. Himman1, M. Callissaya1, C. Gai1, P. Othal1, T. Winsenberg1, Z. Wang1, B. Antony1, J. Martel-Pelletier6, J. P. Pelletier6, F. Abram7, S. Drummen1, S. Balogun1,2, L. Scheepers1, I. Munugodaa, A. Lahtham3, D. Aitken1, University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia,1Australian National University, College of Health & Medicine, Canberra, Australia,2Monash University, Respiratory Care group, Melbourne, Australia,3The University of Melbourne, Medicine, Dentistry and Health Sciences, Melbourne, Australia,4Monash University, Medicine, Nursing and Health Sciences, Melbourne, Australia,5University of Montreal, Hospital Research Centre (CRCHUM), Montréal, Canada,6Medical Imaging Research & Development, ArthroLabInc., Montreal, Canada

Background: Exercise therapy is recommended as first line treatment for knee osteoarthritis (OA), but it remains to be sub-optimally applied (1). Movement-evoked pain is a potential barrier to exercise adherence, but recent evidence suggests that such pain can be improved by training (2). Walking programs are low-cost, easily adopted and can be performed outdoors which can minimize the risk of SARS-CoV-2 transmission when in a group (3).

Objectives: To explore the acute pain trajectories of individuals with knee OA during a 24-week outdoor walking intervention. In addition, to explore the effect of pain trajectories and/or baseline characteristics on retention and adherence.

Methods: Individuals with clinical knee OA and bone marrow lesions (BMLs) on magnetic resonance imaging (MRI) were asked to follow a 24-week walking program. Every week consisted of two one hour supervised group sessions at various outdoor locations and one unsupervised session. At the start and end of every supervised group walk, knee pain was self-reported by participants to their trainer using a numerical rating scale (NRS) (0-10). The difference between the NRS pain values was considered as an acute pain change evoked by that walk. At baseline, the most affected knee of each participant was assessed using the Visual Analogue Scale (VAS) pain, the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain, stiffness and function, wellbeing (3 questionnaires) and the Osteoarthritis Research Society International (OARSI) recommended strength and performance measures.

Results: In total, N = 24 participants started the program of whom N = 7 (29%) withdrew. Pain at the start of each walk decreased from NRS 2.5 (SD 1.6) at the first walk (N = 24) to NRS 0.9 (SD 0.8) at the final walk (N = 17). This pain was estimated to decrease on NRS by -0.04 (95% CI -0.05 to -0.02) per supervised session, p = 0.001 during the first 12 weeks and -0.01 (95% CI -0.02 to -0.004), p = 0.004 during the second twelve weeks of the program. The number (%)

Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Knee osteoarthritis (OA) is not an age-related condition but it can be a consequence of metabolic factors. Systemic characteristic biochemical and imaging features of metabolic phenotype of knee OA are needed. The aim of the present study was to identify characteristic biochemical and imaging features of metabolic phenotype of knee OA in a multicenter prospective study.

Methods: 284 female patients with knee OA (according to the ACR criteria) aged 40-78 were included in this prospective multicenter study. OA radiologic stages in the study group varied from I to III (Kellgren & Lawrence) and all the patients signed an informed consent. Mean age was 58.5 ± 9.5 years, disease duration was 5 (2-10) years. BMI was 29.6 ± 5.6 kg/m², with hip (HC) – 109.3 ± 10.4 cm and waist circumference (WC) – 92.5 ± 12.5 cm. Physicians filled out individual case report forms containing demographic and physical assessment data. All patients performed lab tests, ultrasonography and x-ray of the knee, as well as proximal femur and lumbar spine DEXA.

Results: Metabolic phenotype was diagnosed in 52.4% of patients. Participants were then divided in two groups. Patients with metabolic phenotype of osteoarthritis were older (61 [57-68] vs 52 [43-58], respectively, p<0.0001), had higher BMI (31.6 [28.6-35.5] vs 26.4 [23.4-30.3], p<0.0001) and had more intense VAS knee pain while walking on flat surface (50 [40-60] vs 35 [10-50], p<0.0001). There were also statistically significant differences when we analyzed the imaging results (Table 1). Patients with metabolic phenotype of knee OA had higher chances of grade III K&L (OR=4.4, 95% CI 1.3-14.2, p=0.01) and more significant mediolateral joint space narrowing, bigger tibial osteophytes; knee ultrasound revealed thinner cartilage and thicker synovium. DEXA showed higher total hip BMD. Patients with metabolic phenotype had higher levels of CRP, HbA1c, uric acid, cholesterol, LDL, triglycerides, ALT, AST, glucose, leptin and COMP.

Spearman correlation analysis showed positive correlations (p < 0.05) between the metabolic phenotype and OA radiologic stage (r = 0.44), size of tibial osteophytes (r = 0.31), synovium thickness (r = 0.28), hsCRP (r = 0.44), HbAlc (r = 0.45), cholesterol (r = 0.29), DLGL (r = 0.3), triglycerides (r = 0.36), uric acid (r = 0.46), IL-6 (r = 0.38). A significant correlation was found between the M1/MR phenotype and OA with higher levels of hsCRP, leptin, IL-6, COMP, which possibly demonstrate a more active form of low-grade inflammation (the underlying mechanism of OA pathogenesis) and more significant cartilage damage.

Disclosure of Interests: None declared.

AB0997 PREDICTORS OF DISEASE PROGRESSION AND CLINICAL OUTCOMES IN OSTEOARTHRITIS A. Tyurin1, R. Khushainova1, 2 Bashkir State Medical University, Internal Medicine, Ufa, Russian Federation; 1 Institute of Biochemistry and Genetics, Human molecular genetics, Ufa, Russian Federation

Background: Osteoarthritis (OA) is one of the most common joint diseases, often causing persistent pain and immobilization [1]. The genetic contribution to OA varies from 40% to 65%, depending on the presence of the pathology in the immediate family, the location of the affected joint, sex, and ethnicity of the patients [2]. The study of miRNA target sites is a new promising direction in molecular diagnostics [3].

Objective: The aim of our work was to study the miRNA binding sites of COL1A1, COL11A1, ADAMT5, MMP1, MMP13, SOX9, GDF5, FGF2, FGFRL1 genes in patients with OA of different localization.

Methods: A total of 417 women (mean age 51.6±11.5) from Ufa (Republic of Bashkortostan, Russia) participated in the study between January 2013 and August 2017. The patients were examined and diagnosed for osteoarthritis according to the criteria of the American College of Rheumatologists (1990) with X-ray confirmation. Overall, 356 women with OA were recruited and divided into 3 groups as follows: subgroup 1 included 84 women affected by generalized OA, subgroup 2 included 197 women affected by knee OA, subgroup 3 included 75 women affected by hip OA. For genotyping, RT-PCR analysis using KASP technology was used. Selection of the miRNA target site was carried out using the database of the National Center for Biotechnology Information (https://www.ncbi.nlm.nih.gov), Ensemble Genome Browser (www.ensembl.org), and the base of polymorphisms of microRNA target sites (http://compbio.uthsc.edu/mirNPS). As a calculation tool, Statistica v6.2 (StatSoft) software packages were used. Considering the type I error caused by multiple testing, p values were adjusted by calculating the FDR value using the Benjamini-Hochberg method (https://tools.barcation.com/FRD).

Results: The T allele of the rs9650300 (COL11A1) was associated with the generalized OA (p = 0.019; OR = 2.0; 95% CI 1.1 to 3.62), the TT genotype was associated with all patients (p = 0.026; OR = 1.95; 95% CI 1.05 to 2.31), and OA of the hip (p = 0.016; OR = 2.3; 95% CI 1.14 to 4.36). With respect to rs229069 (ADAMTS5), a significant association was found between the C allele and the incidence of total OA (p = 0.018; OR = 1.43; 95% CI 1.06 to 1.89), as well as with the knee OA (p = 0.042; OR = 1.43; 95% CI 1.01 to 2.03) and hip OA (p = 0.026; OR = 2.039; 95% CI 1.08 to 3.85). The CC genotype was also found to be associated with total OA (p = 0.037; OR = 1.53; 95% CI 1.2 to 2.82) and hip OA (p = 0.026; OR = 2.039; 95% CI 1.08 to 3.85). The T allele of rs13317 (FGFRL1) was strongly associated with the total OA (p = 0.001; OR = 1.67; 95% CI 1.2 to 2.3), knee OA (p = 0.003; OR = 1.74; 95% CI 1.19 to 2.55) and generalized OA (p = 0.044; OR = 1.67; 95% CI 1.01 to 2.73). After Benjamini-Hochberg correction, rs13317 remained statistically significant in the following groups: the T allele in control vs total patients (adjusted p = 0.01) and in control vs OA of the knee (adjusted p = 0.03). Neither the genotype nor the allele frequencies of rs1061347 (COL1A1), rs229077, rs9978597 (ADAMTS5), rs5854, rs702151 (MMP1), rs1042840 (MMP13), rs1042673 (SOX9), rs5469740 (FGFRL1) were significantly different between the affected individuals and normal controls.

Conclusion: The current study demonstrated an association between the T allele of rs13317 in FGFRL1 and incidence of the total OA and knee OA in women from Volga-Ural region of Russia.

AB0998 DIET AND JOINT SYMPTOMS: A SURVEY OF MOROCCAN PATIENTS WITH OSTEOARTHRITIS R. Bensaid1, T. Fatima Zahrae1, N. El Mansouri1, A. Anas1, L. Berrichi1, B. Khadja1, F. Abourazak1

1 CHU Tangier, Rheumatology, Tangier, Morocco

Background: The question of diet is frequently asked by patients with osteoarthritis. Beyond the effect of weight on the aggravation of their symptoms, patients

Disclosure of Interests: None declared.

often ask whether certain foods, described as inflammatory or anti-inflammatory, can improve or worsen their disease.

**Objectives:** The objective of our study is to investigate whether Moroccan patients report a relationship between certain foods and their symptoms and also to study whether they adopt specific dietary behaviors in an effort to alleviate their symptoms.

**Methods:** This is a survey based on a questionnaire, that included any patient followed for osteoarthritis who presented to the rheumatology department. The questionnaire consisted of 3 parts:
1) Socio-demographic data, comorbidities, and information on osteoarthritis location, duration of evolution, functional impact and treatments.
2) Beliefs and attitudes of patients regarding diet in relation to osteoarthritis.
3) A list of 24 foods for which patients were asked to indicate whether they aggravated, improved or left their joint symptoms unchanged.

**Results:** At this time we included 120 patients. The mean age was 57.1 ± 11.8, 88.3% of the patients were women, 41.2% had comorbidities, 62.5% were illiterate. The median duration of osteoarthritis was 4 years [2; 7]. 64.2% of the patients were followed for gonarthritis, 25% for discarthrosis and 10.8% for digital osteoarthritis. The average BMI was 27.8 ± 5.2. 8.3% of the patients thought that diet influenced their osteoarthritis. 9.5% of the subjects stated that food had an effect on their symptoms, 9.2% of them reporting an improvement and 8.3% an aggravation. Fish (1.7%), garlic (1.7%), and olive oil (1.7%) were the foods most often cited as improving joint symptoms, while red meat (3.3%), and sweetened soft drinks (2.5%) were the most often cited as worsening symptoms. 6.7% of the patients had food avoidance behaviors, 10.8% adopted certain diets and 5.8% had tried fasting in order to relieve joint symptoms. In univariate and multivariate analysis, education level (OR: 0.165; 95% CI [0.046-0.592]; p=0.006) and experience with a food that improves symptoms (OR: 46.8; 95% CI [1.798-1222.5]; p=0.021) were associated with reporting that food influence OA symptoms.

**Conclusion:** Our study showed that associations between certain foods and worsening or improving joint symptoms were reported by a minority of patients and appeared to be mostly associated with patients' education level and experience of a food improving symptoms.

**OSTEARTHritis. PHARMACoeconomics: ASPECTS OF SYMptom-MODIFYING THERAPY IN REAL CLINICAL PRACTICE.**

I. Kryakova1,2,*, V. Kryakova1,2,*, V. Ermaikova2,3,*, N. Shostak2,*, and Pravdyuk2.
1Institute of Clinical and Economic Assessment and Pharmacoeconomics; 2Raschichi, Russian Federation; 3Federal State Budgetary Educational Institution of Higher Education “A.I. Yevdokimov Moscow State University of Medicine and Dentistry” of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation; 4Moscow State University of Food Production, Medical Institute of Continuing Education, Moscow, Russian Federation; 5FSAEI HE I.M. Sechenov First Moscow MOH Russia (Sechenov University), Moscow, Russian Federation; 6Prokhorov Russian National Research Medical University, Nesterov Department of Faculty Therapy, Moscow, Russian Federation

**Background:** Treatment of osteoarthritis (OA) is a significant medical and social problem worldwide. Modern therapeutic approaches include both pharmacological and non-pharmaceutical methods aimed at reducing pain, improving joint function, and preventing disease progression. A wide variety of symptomatic slow-acting drugs for osteoarthritis and their usage dictate the necessity for a clinical and economic analysis to select the most economically feasible treatment regimen for OA.

**Objectives:** To conduct a clinical and economic assessment of OA therapy using drugs of the SYSADOA group.

**Methods:** The search for publications for the period 2011-2022 on the clinical efficacy and safety of SYSADOA (bioactive concentrate of small marine fish containing chondroitin sulfate, amino acids, peptides, sodium, calcium, magnesium, iron, copper and zinc ions) was conducted using available sources (Medline, eLIBRARY.ru). The research selection methodology was in compliance with the PRISMA criteria (Preferred Reporting Items for Systematic Reviews and Meta-analysis), 124 sources were analyzed. To collect data on the costs for managing patients in a real-life therapeutic practice, a literature data showed that bioactive concentrate of small marine fish, produced by Biotehnos S.A. is a modern original SYSADOA for the initial therapy of knee joint OA with proven efficacy and safety. The estimated course cost of SYSADOA therapy ranges from 36.961 to 92 euros. The median exchange rate of all drugs in the sample was 50.2; for SYSADOA drugs with oral administration - 85.82 euros; injectable drugs - 47.76 euros. The median amount of direct costs for injectable SYSADOA was 388,012 euros. Cost minimization analysis showed that the use of an alternating mode of administration of the drug (2 ml every other day intramuscularly - 10 injections) in patients with knee joint OA is the most cost-effective method for the treatment of OA and allows to reduce direct costs up to 64% per patient by reducing the number of medical services provided.

**Conclusion:** The analysis proved rationality of the established medical practice in prescribing of the injectable SYSADOA (bioactive concentrate of small marine fish was a leader among injectable SYSADOA according to HWC and IQVIA marketing analytical data for the period 2020-2021). Choosing the most economically feasible drug for the treatment of patients with OA will reduce the costs of the healthcare system and reduce the overall economic burden of OA.

**AB1000 RELIABILITY AND VALIDITY OF THE Cone EVASION WALK TEST IN PATIENTS WITH TOTAL KNEE ARTHROPLASTY: A PILOT STUDY**

K. S. Kaczm1,*, B. Unev2,*, V. Karatosun2,*, 1izmir katip celebi university, physical therapy and rehabilitation, izmir, Turkey; 2dokuz eylul university, physical therapy and rehabilitation, izmir, Turkey; 3dokuz eylul university, orthopaedics and traumatology, izmir, Turkey

**Background:** Total knee arthroplasty (TKA) is the gold-standard procedure for end-stage knee osteoarthritis, however, some residual problems may still continue and cause a variety of dysfunctions, such as impaired strength, proprioception, gait balance, postural instability, and, impaired ability to avoid obstacles while walking. Tripping over an obstacle is the most frequent cause of falls 1 and falls can limit daily activities and induce post-fall syndromes, such as dependence, loss of autonomy, immobilization, and depression 2. The Cone Evasion Walk test (CEW) to assess fall risk by the ability to evade obstacles, (ICF-code d455), which requires attentional, perceptual, and several neuromusculoskeletal and movement related functions 3. However, there is no study investigating the reliability and validity of the CEW in TKA patients.

**Objectives:** The aim of the study is to investigate the reliability and validity of the CEW in patients with TKA.

**Methods:** Twenty patients with TKA included in the study. The CEW, the Timed Up And Go Test (TUG) and the Hospital for Special Surgery (HSS) Knee Score administered to the patients. Patients rested between the tests for an hour.

**Results:** Mean age was 68.1 ± 5.59 years and the mean HSS Knee Score was 85.43a ± 3.47a The relative (ICC coefficient) and absolute (SEM and SRD95) reliability values were 0.98, 1.01, and 2.75 respectively. The Spearman correlation coefficient of the CEW with the TUG was 0.72.

**Conclusion:** Based on the current findings, the CEW has excellent reliability, high validity and responsiveness in evaluating dynamic balance and obstacle avoidance in patients with TKA. The minimal clinically important difference of CEW in TKA patients is 2.57 a and it may be concluded that the fact that this value is low, indicates the sensitivity of the test. Therefore, the CEW can identify even small alterations in the functional status, can be reliably used for post-operative surveillance of TKA to observe patient results, and the usage of the CEW for assessing the fall risk and mobility in the community maybe a better predictor of the patients' current condition.

OSTEOARTHRITIS AND OBESITY: RELATIONSHIPS AND EFFICACY OF THERAPY.

E. Strekova1, L. Alekseeva1,2, V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation; 2Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Rheumatology, Moscow, Russian Federation

Background: Osteoarthritis (OA) is the most common joint disease. The most important factor not only in the development but also in the progression of OA is obesity. Higher incidence of OA in obese patients is associated with several factors. One of them is a large volume of fat mass, which increases the mechanical load on the joints. On the other hand, in obesity, hyperexpression of pro-inflammatory mediators (cytokines, adipokines) is observed, which negatively affect joint tissues, as well as provoke the development of low-level metabolic inflammation. Thus, the problem of OA and obesity is very relevant in modern rheumatology.

Objectives: To determine features of clinical manifestations of OA in obesity and evaluate the effectiveness of obesity therapy in OA.

Methods: The study included 73 patients (women) with knee OA (according to the ACR criteria) II-III X-ray stage by Kellgren-Lawrence: obese 50 (30%) and non-obese 23 (30%) control group. Obese patients were divided into 2 groups: 1 group (n = 25) - received orlistat 120mg 3 times a day for 6 months in combination with non-pharmacological methods of controlling body weight and 2 group (n = 25), whose patients were recommended a diet and did the exercise for 6 months. Monthly visits evaluated anthropometric measures, articular status, WOMAC. Initially and after 6 months, laboratory scores were evaluated in obese patients (determination of leptin, TNF-α, IL-6, CRP, in peripheral blood).

Results: In patients with OA and obesity, a more severe course of OA is determined compared to the control group (Table 1).

After 6 months of drug therapy of obesity in patients of group 1, a significant decrease in body weight by 10.07% (p < 0.05) was achieved. In patients of group 2, body weight decreased by 8.8% (p > 0.05). In patients of group 1, the indicators of the WOMAC index improved: pain decreased by 52.5% (p < 0.05), stiffness by 47.98% (p < 0.05), functional insufficiency by 51.55% (p < 0.05). In patients of group 2, there was also a decrease in the WOMAC index, however, these changes were worse than in patients with greater body weight loss. Analyzing laboratory data, in group 1 there was a significant decrease in the level of leptin (p = 0.05) and IL-6 (p < 0.05), in contrast to patients of group 2 (p = 0.64; p = 1.0, respectively). In the study of TNF-α, no significant changes in the two groups were determined. CRP level in group 1 decreased by 23.7% (p > 0.05) compared to baseline data, in group 2 (p = 0.64; p = 0.01, respectively). In the study of TNF-α, no significant changes in the two groups were determined. CRP level in group 1 decreased by 23.7% (p > 0.05) compared to baseline data, in group 2 (p = 0.64; p = 0.01, respectively). In the study of TNF-α, no significant changes in the two groups were determined. CRP level in group 1 decreased by 23.7% (p > 0.05) compared to baseline data, in group 2 (p = 0.64; p = 0.01, respectively). In the study of TNF-α, no significant changes in the two groups were determined. CRP level in group 1 decreased by 23.7% (p > 0.05) compared to baseline data, in group 2 (p = 0.64; p = 0.01, respectively).

Conclusion: The results of our study demonstrated a more severe clinical course of OA in obese patients. Drug therapy for obesity in patients with knee OA and obesity not only leads to a decrease in the presentation of clinical symptoms of OA, but also entails changes at the metabolic level: a decrease in leptin, IL-6 and CRP, which indicates a decrease in the intensity of metainflammation in obese patients. Thus, therapeutic interventions aimed at reducing body weight should be an integral part of knee OA therapy.

CLASSIC VERSUS AQUATIC REHABILITATION IN GONARTHROSIS: WOMAC SCORE

R. Maouli1, M. Hlaidi1, K. Ben Amor1, N. Mouhil1, H. Rahali1, I. Kebi1, M. Slouma1, L. Ben Ammar2, L. Metoui2, R. Dhahir2, I. Gharsallah2, I. Maaoui1, M. Hfaidh1, K. Ben Amor1, N. Mouhil1, H. Rahali1, I. Kebi1, M. Slouma1, L. Ben Ammar2, L. Metoui2, R. Dhahir2, I. Gharsallah2, I. Maaoui1, M. Hfaidh1, K. Ben Amor1, N. Mouhil1, H. Rahali1, I. Kebi1, M. Slouma1, L. Ben Ammar2, L. Metoui2, R. Dhahir2, I. Gharsallah2

1The Military Hospital of Tunis, Physical Medicine and Rehabilitation Departement, Tunis, Tunisia; 2The Military Hospital of Tunis, Rheumatology Department, Tunis, Tunisia

Background: Gonarthrosis is the most frequent and common condition of the lower limb, responsible for goniaxia, stiffness, leading sometimes to major functional impotence. The WOMAC with its three domains (pain, stiffness and function) is a valid index for the evaluation of lower limb osteoarthritis [1]. The management of gonarthrosis is multidisciplinary with rehabilitation as the mainstay. Currently, aquatic gymnastics is more and more prescribed in the management of this pathology.

Objectives: The objective of our work was to compare the contribution of aquatic rehabilitation to classical one in patients with gonarthrosis through the WOMAC score.

Methods: This is a prospective, comparative study conducted over a period of 15 months, between September 2016 and December 2017, including 120 patients recruited at the Physical Medicine and Functional Rehabilitation Department of The HMPIT, in whom the diagnosis of gonarthrosis was made according to the ACR criteria. The patients were randomly divided into 2 groups of 60 patients each. The first group, called G1, received a conventional rehabilitation program. The second group, called G2, received aquatic rehabilitation. Two evaluations were made, the first (T1) before the beginning of the rehabilitation and the second (T2) at the end of the eight weeks of treatment.

Results: The average age of the general population was 54.85 ± 9.5 years [40–81 years]. The average age of G1 was 59.07 ± 10.2 years versus 50.63 ± 6.4 years for G2. Among the 120 patients, 28 were male (23%) and 92 were female (77%). There were 6 males and 54 females in group 1 versus 22 males and 38 females in group 2. Initially, the average WOMAC pain was 15.1 ± 3.9 in G1 and 12.3 ± 1.22 in G2. There was a statistically significant difference between the 2 groups (p < 0.01). After rehabilitation, there was an improvement in the WOMAC pain score of 17% in G1 and 50% in G2 with a statistically significant difference between the 2 groups (p < 0.001). The average WOMAC score for stiffness was initially 5.4 ± 2 in G1 and 3.2 ± 2 in G2 with no statistically significant difference between the 2 groups (p = 0.076). After rehabilitation, an improvement of this score was noted in both groups, it was 18% in G1 and 50% in G2 with a statistically significant difference between the 2 groups (p < 0.001). After rehabilitation, the score had improved by 10% and after hydrotherapy, the improvement was 46% with a statistically significant difference between the 2 groups (p < 0.001).

Conclusion: These results were aligned with the literature and confirmed the effectiveness of functional treatment whether aquatic or classic with better outcome for aquatic rehabilitation. The best would be to combine the different methods according to the needs of the patient and their functional capacities in order to ensure a better adherence.

EFFECTIVENESS OF CLASSIC VERSUS AQUATIC REHABILITATION IN GONARTHROSIS: LEQUESNE SCORE

R. Maouli1, K. Ben Amor1, M. Hlaidi1, N. Mouhil1, H. Rahali1, I. Kebi1, M. Slouma1, L. Ben Ammar2, L. Metoui2, R. Dhahir2, I. Gharsallah2

1The Military Hospital of Tunis, Physical Medicine and Rehabilitation Departement, Tunis, Tunisia; 2The Military Hospital of Tunis, Rheumatology Department, Tunis, Tunisia

Background: Gonarthrosis is a benign knee condition, but it can become disabling if poorly managed. The evaluation of the functional impact of gonarthrosis is based on Lequesne’s algofunctional index [1], thus judging the effectiveness or failure of the proposed treatment. Water gymnastics is increasingly prescribed in the management of this pathology.
**Objectives:** The main aim of our work was to compare the efficacy of aquatic gymnastics with conventional rehabilitation in patients with gonarthrosis using Lequesne's algofunctional index.

**Methods:** This is a prospective, comparative study conducted over a period of 15 months, between September 2016 and December 2017, in 120 patients recruited from the outpatient department of the Physical Medicine and Functional Rehabilitation Department of The HMPIT, in whom the diagnosis of gonarthrosis was made according to the ACR criteria. The patients were randomly divided into 2 groups of 60 patients each. The first group, called G1, received a conventional rehabilitation program. The second group, called G2, received water gymnastics. Two evaluations were made, the first (T1) before the beginning of the rehabilitation and the second (T2) at the end of the eight weeks of treatment.

**Results:**
- The mean age of the general population was 54.85 ± 9.501 years (40-81 years).
- An improvement in pain triggers between the 2 groups (p=0.02).
- After rehabilitation, 23% of the patients in G1 and 30% in G2 noted an improvement in pain with a statistically significant difference between the 2 groups (p=0.001). Pain was awakened by squatting in 93% of cases in G1 versus 97% of G2. There was no statistically significant difference between the 2 groups (p=0.554). After rehabilitation, 13% of the patients in G1 and 30% in G2 had a noted complete disappearance of pain with a statistically significant difference between the 2 groups (p=0.001).
- All patients in G1 and 92% of patients in G2 reported pain when climbing/descending stairs. There was no statistically significant difference between the 2 groups. An improvement in symptomatology was noted in both groups with disappearance of pain in 18% of G1 and 27% of G2. An adjustment on the parameters by which the 2 groups differed was made without impact on the results obtained.

**Conclusion:** Rehabilitation has an important role in the control of pain triggers by ensuring, in addition to analgesic means, good muscle balance, joint gain and good proprioception. Balneotherapy has proven to be more effective.

**CONTRIBUTION OF DRY REHABILITATION VERSUS BALNEOTHERAPY IN THE CONTROL OF PAIN TRIGGERS IN GONARTHROSIS**

R. Maaou1, M. Hfaidi1, G. Wechteti1, L. Ben Ammar2, L. Metoui2, R. Dhaïni2, I. Garsalalti2, M. Slouma2, L. Ben Ammar2, L. Metoui2, R. Dhaïni2, I. Garsalalti2. The Military Hospital of Tunis, Physical Medicine and Rehabilitation Department, Tunis, Tunisia

**Background:** Gonarthrosis is a very common condition and a real public health problem [1]. One of the pillars of its management is pain management. In addition to drug treatment, rehabilitation is part of the therapeutic arsenal.

**Objectives:** The main objective of our work was to compare the contribution of balneotherapy versus dry rehabilitation in the control of pain triggers.

**Methods:** We carried out a prospective, comparative study carried out over a period of 15 months, (September 2016-December 2017), in 120 patients recruited from the outpatient department of the Physical Medicine and Functional Rehabilitation Department of HMPIT in whom the diagnosis of knee osteoarthritis (KOA) was made according to the criteria of the ACR [2]. The patients were randomly divided into 2 groups of 60 patients each. The first group, called G1, received a conventional rehabilitation program. The second group, called G2, received water gymnastics. Two evaluations were made, the first (T1) before the beginning of the rehabilitation and the second (T2) at the end of the eight weeks of treatment.

**Results:**
- The mean age of our patients was 57.2 ± 12.5 years in G1 vs 54.3 ± 7.1 years in G2 (p = 0.012). The sex ratio was 0.2 in G1 versus 0.37 in G2 (p = 0.011). The duration of KOA was 63.4 ± 4.5 months in G1 vs 56.2±7.5 months in G2 (p=0.172). Pain was triggered by standing in 92% of cases in G1 versus 85% in G2 with a mean delay of 1.72 min for G1 and 20.1 min for G2. There was no statistically significant difference between the two groups (p=0.452).
- After rehabilitation, 22% of the patients in G1 and 43% in G2 noted an improvement in pain with a statistically significant difference between the two groups (p=0.001). Prolonged sitting in 62% of cases in G1 versus 38% in G2 with a mean delay of 6.2 min for G1 and 52.3 min for G2 awakened pain. There was a statistically significant difference between the two groups (p=0.02).
- After rehabilitation, 23% of the patients in G1 and 30% in G2 noted an improvement in pain with a statistically significant difference between the 2 groups (p=0.001).

**Conclusion:** Rehabilitation has an important role in the control of pain triggers by ensuring, in addition to analgesic means, good muscle balance, joint gain and good proprioception. Balneotherapy has proven to be more effective.

IMPACT OF OSTEOARTHRITIS ON THE QUALITY OF LIFE IN PATIENTS WITH KNEE PAIN

A. Chaidou1, K. Veliou1, M. Gianniki1, M. Migkos1, F. Prits1, D. Giotis2, N. Tsifetaki3, 1General Hospital of Ioannina, Rheumatology Department, Ioannina, Greece; 2General Hospital of Ioannina, Orthopaedic Department, Ioannina, Greece

Background: Knee osteoarthritis is a common disease which mainly concerns aged population and impairs the quality of life in all aspects. Apart from causing pain or other related biomechanical comorbidities, osteoarthritis might affect psychological and social aspects of life.

Objectives: The purpose of the study was to investigate the impact of knee osteoarthritis on the quality of life and whether certain factors are related to this impact.

Methods: In a cross-sectional study, performed in our Hospital from January 2016 to December 2016, 150 patients (127 females and 23 males) with a mean age of 61.8 ± 8.07 years were examined. The sample included outpatients of the Rheumatology Department diagnosed with osteoarthritis and patients displaying knee pain. Individuals who had undergone previous knee surgery, and those with other osteoarthritic, rheumatic diseases or chronic degenerative disorders that could interfere with the quality of life, were excluded from the study. All participants, who gave their informed consent, answered the identification questionnaire and were interviewed with the Western Ontario and McMaster Universities Arthritis Index (WOMAC), The World Health Organization Quality of life (WHoQoL) questionnaire, the IPQ and the PHQ-9. All instruments used, were standardized in the Greek context.

Results: The effect of certain variables including patient associated characteristics, demographics, medical history, drug intake and symptomatology related to osteoarthritis, were evaluated with each of the WHO QoL measurements, the IPQ total score and the WOMAC scale. The regression analysis results demonstrated common significant correlations regarding the presence of injuries, the depression, the increased body mass index (BMI) and occasional crepitus. However, no significant difference was observed between patients with osteoarthritis and patients without osteoarthritis, concerning any of the examined parameters.

Conclusion: It was demonstrated that quality of life indices were related to agents that are not exclusively met in patients with osteoarthritis which implies that patients’ quality of life does not depend on the specific diagnosis but on patient’s psychological aspect (depression), presence of pain (injury) and overall health status (BMI).

</tbody>
</table>

In Cox regression analysis, the presence of prevalent MOF (p-MOF), fall-ability, lifestyle-related diseases (LSD), chronic kidney diseases (CKD) ≥ Grade3a, and higher Cys/Cr had significant higher risk ratios with univariate models. In these, the presence of LSD and fall-ability had significant higher risk ratios with multivariate model. All the binary factors had COI as the presence of each event such with 0.626, 0.703, 0.612, and 0.685 of area under the curve for LSD, Fall-ability, CKD, and pr-MOF, respectively. Cys/Cr also had COI (1.345) with 0.614 of the area under the curve. In the Kaplan-Meier survival analysis, Cys/Cr > COI, Fall-ability, pr-MOF, LSD, CKD ≥ Grade 3 were significantly higher in ascending order of Hazard ratio (6.32, 4.83, 4.81, 3.60, 2.56, respectively) (Table 1).

Conclusion: These results suggest that Cys/Cr may be a predictor of MOF or a risk factor if it exceeds the COI. This value is the reciprocal of Cr/CysC, and if Cr/CysC reflects muscle mass, Cys/Cr is assumed to reflect low relative muscle mass. It is supposed that this is also affected by sex difference and age. There seems to be a correlation between MOF and Cys/Cr. Early measurement of Cys/Cr facilitates screening for fractures. For a result, it may be easier to implement fracture prevention programs such as drug interventions such as OPD and exercise habit guidance.

AB1008  CHARACTERIZATION OF THE RISK OF OSTEOPOROSIS IN A COHORT OF RHEUMATIC PATIENTS DURING 10 YEARS OF FOLLOW-UP.

L. Dulcey1, J. Theran1, D. Villamizar1, E. Espinoza1, R. Cattagrine1, H. Gonzalez2, J. Lopez2, A. Quintero2, R. Parales3, M. Aguas3, Los Andes University, Internal Medicine, Bucaramanga, Colombia; 2Bucaramanga University, Medicine, Bucaramanga, Colombia; 3Industrial University of Bucaramanga, Medicine, Bucaramanga, Colombia; 4Santander University, Medicine, Bucaramanga, Colombia; 5Metropolitan University, Medicine, Bucaramanga, Colombia; 6Santander University, Medicine, Bucaramanga, Colombia

Background: Osteoporosis is the most common cause of fractures. The lifetime risk of fracture after age 50 is 40% for women and 13% for men.

Objectives: Patients with rheumatological diseases are at greater risk for the development of osteoporosis, either due to the natural history of their disease or due to the side effects of the medications used. We propose to carry out this study.

Methods: Retrospective study aimed at determining the presence of risk factors in patients over 50 years of age who attend the Rheumatology service of a hospital in Venezuela during a follow-up from January 2010 to December 2020 in order to know these risk factors and thus generate strategies that allow better orienting the care of these patients.

Results: The main group of patients was constituted by the female gender and the ages between 50 and 65 years. The main rheumatological pathology was rheumatoid arthritis, followed by Lupus, Osteoarthritis in 3 place and finally in the last box other entities other than those indicated.

AB1009  EXERCISE IS ASSOCIATED WITH HIGHER BONE MINERAL DENSITY IN PATIENTS WITH POLYMYALGIA RHEUMATICA AND VASCULITIDES

A. Palmowski1, E. Wiebe1, S. Herrmann1, B. Mucic1, F. Buttgereit1, 1Charité - Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany

Background: Exercise is an effective non-pharmaceutical intervention for osteoporosis (OP). However, it has not yet been explicitly validated whether it is associated with bone mineral density (BMD) in patients suffering from polymyalgia rheumatica (PMR) and vasculitides.

Objectives: To assess whether exercise is associated with BMD in PMR and vasculitis patients.

Methods: We evaluated baseline visits of patients enrolled in the monocentric, prospective “Rh-GIOP” cohort. Patients were included when having PMR or any kind of vasculitis. Simple and multiple linear regression models with minimum T-score (lumbar spine or hip, whichever was lowest) as the dependant variable were constructed. A dose-response analysis (frequency of exercise per week) was conducted in patients who were doing any kind of exercise. In multiple regression, we adjusted for potential confounders associated with minimum T-scores in an analysis of the overall cohort (manuscript in preparation): age, sex, menopause, body mass index, bisphosphonate use, denosumab use, current glucocorticoid dose, proton-pump inhibitor use, history of vertebral fractures, health assessment questionnaire scores, alkaline phosphatase levels, and gamma-glutamyltransferase levels. Multiple imputation by chained equations was used to handle missing data.

Results: 198 patients were included. The mean age was 68 ± 11 years, 68% were females, and the most common diseases were PMR (36%), giant cell arteritis (26%), and granulomatosis with polyangiitis (17%). The mean minimum T-score was -1.74 ± 0.9. Five patients had a disease duration of less than three months. In both unadjusted (Figure 1) and adjusted analysis, exercise was positively associated with minimum T-scores (unadjusted: β = 0.36; 95% CI 0.09 to 0.63; p = 0.01; adjusted: β = 0.30; 0.04 to 0.56; p = 0.02). In exercising patients, there was no association between frequency and minimum T-scores (p(ANOVA) = 0.66).

Conclusion: In PMR and vasculitis, exercise is positively associated with BMD. We adjusted for several covariates, including health assessment questionnaire scores, so it is unlikely that the association between exercise and BMD is only caused because generally healthier patients have a higher likelihood of exercising. However, we found no dose-response relationship by looking at exercise frequency. This is probably due to confounding caused by different kinds of exercises. E.g., weight-bearing exercise is thought to be more effective in elevating BMD. Furthermore, our analysis might have been underpowered (too few patients) to assess differences within the group of exercising patients. Our findings underpin the general advice given to most patients suffering from low bone mass or OP irrespective of their underlying disease, which is to start or to continue exercising within the scope of personal possibilities. Of note, this study is of cross-sectional nature and must be interpreted accordingly as residual confounding cannot be fully ruled out. We plan for the future longitudinal analyses.

Background: Rheumatoid Arthritis (RA) is a long-term inflammatory disorder affecting the joints. It is associated with osteoporosis, possibly linked to inflammation around affected joints and glucocorticoid medication. To our knowledge, longitudinal analysis of a UK based cohort of patients with RA has not been carried out. The impact of average tissue thickness on bone mineral density (BMD) has not been studied longitudinally in RA.

Objectives: This study aimed to identify factors that affect the rate of BMD change in patients with RA in a UK based cohort.

Methods: RA patients referred for multiple routine DEXA scans at the Royal Lancaster Infirmary from 2004-2019 were studied. Demographic and physical data such as sex, weight and height were collected. BMD in grams/centimetre² and average tissue thickness were collected from DEXA images of the left and right hip (femoral neck and total femur), and the spine (L1-L4). BMD was modelled at the region of the hip and spine using mixed-effects linear models. Age, sex, average tissue thickness and weight were used as explanatory variables.

Results: 1135 scans from 496 patients (80.4% female) with more than one scan were included, mean age was 64.1 (standard deviation 12.5). Fixed effect size and confidence intervals for each variable are shown in the Table 1. Female sex had a negative fixed effect at the hip but no significant effect on BMD change at the spine. Average tissue thickness had a significant positive fixed effect at the hip but no significant effect at the spine.

Conclusion: This study demonstrates that in RA patients, sex is associated with an increased rate of BMD loss at the hip but not at the spine. It also shows that weight and average tissue thickness are associated with lower BMD loss over time. This could be due to increased inflammation at the hip compared to the left and right hip, and no significant effect at the spine. Weight showed a significant positive fixed effect with BMD at the hip but no significant effect at the spine.

AB1011 FACTORS RELATED TO GLUCOCORTICOID-INDUCED OSTEOPOROSIS AND FRAILITY FRACETURES IN YOUTH SUBJECTS.

1Hospital Clinic, University of Barcelona, Metabolic Bone Diseases Unit, Department of Rheumatology, Barcelona, Spain; 2University of Barcelona, Biostatistics, Department of Basic Clinical Practice, Barcelona, Spain; 3University of Barcelona,., Barcelona, Spain; 4Hospital Clinic, University of Barcelona, Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Vascularis Research Unit, Department of Autoimmune Diseases, Barcelona, Spain; 5Hospital Clinic, University of Barcelona, Department of Nuclear Medicine, Barcelona, Spain

Background: Glucocorticoid (GC) treatment is the most frequent cause of osteoporosis (OP) in young subjects. However, the factors related to the development of glucocorticoid-induced osteoporosis (GIOP) and fragility fractures (FF), and consequently, the therapeutic approach to GIOP in young populations is not well established.

Objectives: Analyze the prevalence of GIOP and FF in GC-treated patients and compare the risk factors related to their development according to age (< and ≥50 years).

Methods: 127 patients (62±18 years) receiving chronic GC treatment were included (<5mg/day of prednisone, >3 months). The clinical data collected included: dose and duration of GC treatment, disease activity, previous FF, anthropometric data, bone metabolism parameters (including bone turnover markers and the presence of hypogonadism), bone mineral density (BMD) by DXA; defining densitometric OP: T-score ≤-2.5 or Z-score ≤-2, depending on the age of the patient), trabecular bone score (by DXA), and vertebral fractures (X-ray). GIOP was defined as densitometric OP and/or FF. Results were compared between subjects < and ≥50 years old.

Results: The prevalence of GIOP was similar in both age groups: <50 (n=36) 44.4% vs. 46.1% ≥50 years (n=91). Four subjects <50 (13.8%) and 30 ≥50 (33%) presented FF (p=0.05). Young subjects with FF tended to be >40 years, have a higher body mass index (BMI) (25.4 vs. 23.3, p=n.s.), and higher inflammatory disease activity (CRP 0.90 vs. 0.06mg/dL, p=0.06). When analyzing the different risk factors related to FF depending on age, a higher body mass index (BMI) (29.63 vs. 26.95, p=0.04) and inflammatory disease activity (PCR -0.87 vs. -2.51 [log scale], p=0.03) were observed in young subjects, while low lumbar T-scores (-1.08 vs. -0.06, p=0.003) and higher cumulative GC-doses (9.11 vs. 8.56, p=0.03) were differential factors in subjects over 50. Hypogonadism was a risk factor independent of age (OR 4.89, 95%CI 1.36-17.39), being associated with the presence of FF in both age groups.

Conclusion: More than 40% of the patients receiving GC developed GIOP; with a similar prevalence in both age groups (< and ≥50 years); however, FF are less common in young subjects. Hypogonadism is a determining risk factor for FF independent of age. In addition, young subjects with FF tend to be older, with a higher BMI and disease activity, and, thus, evaluation of these risk factors can improve the identification of subjects at increased risk of fracture.

SCHOOL FOR DOCTORS ON THE PROBLEM OF OSTEOPOROSIS - "START WITH YOURSELF"

V. Polyakova1, L. Seewordova1. 1Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Treatment and Prevention of Joint Disease Laboratory, Volgograd, Russian Federation

Background: Observing in practice the attitude of the medical community to the problem of OP, we decided to conduct a course of training lectures for doctors within the framework of the program “Start with yourself” on the basics of diagnosis and treatment of this disease. After the lecture material, the fracture risk was calculated using the FRAX (Fracture Risk Assessment Tool) in the audience before and after the two-energy X-ray absorptiometry (DXA). If necessary, additional examination and treatment were prescribed.

Objectives: To evaluate the frequency of decrease in bone mineral density in doctors, to raise awareness about the frequency of decrease in bone mineral density (BMD), to assess the attitude to therapy.

Methods: The risk of fractures according to FRAX was calculated for doctors of therapeutic specialties, DXA was performed at the Center for Osteoporosis of the A.B. Zborovsky Research Institute of KIER, Volgograd. Bone mineral density (BMD) was determined on the Lunar DPX (GE) apparatus.

Results: The average age of 59 trainees was 54 ± 10.55 (M±σ) years, 36 women were aged 50 years and older, 23 were under the age of 50, the average body mass index (√BMI) was 26.51 ± 4.8 kg/m². 47 (79.6%) of 59 showed a decrease in bone mineral density (BMD) below the norm (according to the T/Z criterion, according to age) in at least two positions. 15 (25.4%) of them showed a decrease in BMD according to the T criterion by -2.5 SD or lower, which corresponds to the diagnosis of "Osteoporosis". Of these 15 people, 9 had previously undergone DXA, were diagnosed with OP, and drug therapy was prescribed. Only 3 students are constantly taking medications.

Background: Osteoporosis consists in the reduction of bone mineral density and increased fracture risk. Age is a risk factor for osteoporosis. Although many treatments are available in osteoporosis, there is limited data regarding their efficacy in older people.

Objectives: We aimed to evaluate the efficacy of osteoporosis treatments in patients over 75 years old.

Methods: We reviewed all published studies in MEDLINE, COCHRANE and EMBASE including patients over 75-year-old treated by osteoporosis drugs and focused on vertebral fractures or hip fractures.

Results: We identified 4393 records for review. 4216 were excluded after title/abstract review. After full text review, 19 records were included in systematic review. Most of the studies showed a reduction of vertebral fracture with osteoporosis treatments but non-significant results were observed for hip fractures. Meta-analysis of 10 studies showed that osteoporosis treatments significantly reduced the occurrence of vertebral fractures at one (OR=3.67; 95%CI=2.50-5.38) and three years (OR=2.19; 95%CI=1.44-3.34) as well as those of hip fractures at one (OR=2.68; 95%CI=1.09-6.29) and last 2-3 years (OR=1.31; 95%CI=1.12-1.53).

Conclusion: Osteoporotic treatments showed to be effective in the reduction of vertebral and hip fractures in older people. However, majority of data derived from post hoc and pre-planned analyses or observational studies.

Disclosure of Interests: None declared

TABLE 1 Percentage BMD changes

<table>
<thead>
<tr>
<th>BMD trend (n=25)</th>
<th>sp BMD (LSC – 2.6%)</th>
<th>hip BMD (LSC – 3.6%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>a-b BMD</td>
<td>5.22%</td>
<td>4.13%</td>
</tr>
<tr>
<td>b-c BMD</td>
<td>5.39%</td>
<td>2.93%</td>
</tr>
</tbody>
</table>

sp BMD - Mean of L2, L3 & L4 Spine BMD, hip BMD - Mean of Right and Left Hip BMD, a-b BMD - Percent change in BMD from before treatment to 6 months of PTH & Dmab, b-c BMD - Percent change in BMD from before 6 months of PTH & Dmab to next 6 months Dmab alone and LSC – Least significant change from a single DXA machine.

Conclusion: These findings suggest that a short term combination of Dmab and PTH for 6 months followed by Dmab alone shows sustained synergistic effect on the BMD trend which was more profound in the spine than the hip. This would help in judicious and cost effective utilisation of the limited period of PTH use.

Disclosure of Interests: None declared.

Objective: This study investigated the efficacy of a 12-month ROMO treatment in patients with OP and explored the efficacy predictors of increased BMD.

Methods: Our study included 52 patients with OP, who were started on ROMO treatment between June 2019 and August 2020. The following information was collected: 1) baseline characteristics, 2) time-course of BMD (lumbar spine [LS] and total hip [TH]) and bone turnover markers (BTM; bone-specific alkaline phosphatase [BAP], type I procollagen-N-propeptide [P1NP], type I procollagen-N-propeptide [NTX], and tartrate-resistant acid phosphatase-5b [TRACP-5b]).

Results: 1) The mean age of the participants was 72.9 years (48 female and four male). Of the 52 understudied patients, 78.8% had past insufficiency fractures, whereas 21.2% had been treated with concomitant prednisolone. Furthermore, 21 patients had primary OP, 20 had rheumatoid arthritis, nine had glucocorticoid-induced OP, and two had other conditions. Pretreatments for OP were bisphosphonate (33 patients), vitamin D (6), none (5), selective estrogen receptor modulator (4), and denosumab (3). 2) Both mean LS- and TH-BMD significantly increased in the patients for whom ROMO administration was continued for 12 months. The average percentage changes of LS- and TH-BMD were 7.1% and 1.6% at six months and 11.7% and 3.0% at 12 months, respectively (Figure 1). However, BAP and P1NP increased steeply at one month, followed by a gradual decrease. As observed, the average percentage changes of BAP and P1NP were +70.1% and +166.8% at one month, +50.3% and +91.7% at six months, and +24.4% and +41.5% at 12 months, respectively. The results also showed that TRACP-5b decreased from one to 12 months, with the average percentage changes being −22.9% at one month, −13.8% at six months, and −17.7% at 12 months. Moreover, NTX, a bone-resorptive marker, was slightly increased during ROMO treatment. 3) Multiple regression analysis results revealed that the baseline BAP and percentage calcium changes at 12 months were significant factors positively correlated with the percentage change of LS-BMD at 12 months. As observed, the baseline T-score of LS-BMD was a significant factor negatively correlated with the percentage change of LS-BMD at 12 months. The standardized partial regression coefficient values were +0.68, +0.28, and −0.40, respectively. Moreover, the multiple regression analysis results revealed no significant factor that was correlated with the percentage changes of TH-BMD at 12 months.
Objectives: The aim of this study was to compare the performance of the REMS BMD assessment with dual-energy X-rays absorptiometry (DXA) in a cohort of patients affected by end-stage renal disease undergoing peritoneal dialysis (PD).

Methods: Consecutive patients referring to the PD clinic of our hospital were enrolled. Lumbar spine and proximal femur REMS scans were performed, and lumbar spine (anteroposterior and laterolateral) and proximal femur DXA scans were performed as well. Clinical data were extracted from medical records. The risk assessment outputs of two fracture risk algorithms (FRAX and DeFRA), calculated upon the worst BMD obtained from either technique were compared as well. Analysis of variance (ANOVA) with post hoc analysis (Bonferroni) and a two-sided Student’s t-test were used to estimate the absolute differences between groups. Written informed consent was obtained from all participants included (protocol 1483 CESC).

Results: 41 total patients were enrolled (Table 1). No significant differences were documented between the BMD T-scores measured through DXA or REMS at the proximal femur. At the lumbar spine, the DXA laterolateral T-score was not significantly different from that of REMS, while the DXA anteroposterior T-score was significantly higher than both the anteroposterior DXA and the REMS measurements (Figure 1, panel A and B). When either DXA or REMS was adopted, no significant difference in the fracture risk estimate was found for both algorithms (Figure 1, panel C and D).

Figure 1. comparison of the mean T-scores (error bars represent 95%CI) measured with DXA and REMS at the lumbar spine (panel A), and at the femur (panel B). Comparison between the DeFRA DXA and REMS-derived outputs (panel C) and FRAX DXA and REMS-derived outputs (panel D) raw and after correction for TBS. DeFRA, Fracture Risk Assessment tool; FRAX, Fracture Risk Assessment tool; AP, anteroposterior; LL, latero-lateral; TH, total hip; FN, femoral neck; TBS, trabecular bone score.

Conclusion: Our data showed a good agreement, in a real-life PD setting, between the DXA and REMS-derived BMDs and in the consequent fracture risk assessment obtained with the FRAX or DeFRA tools.

AB1018 RELATIONSHIP BETWEEN AORTIC CALCIFICATIONS AND DXA AND RADIOFREQUENCY ECHOCOGRAPHIC MULTI-SPECTROMETRY (REMS) ACQUISITIONS

A. Fassio1, S. Andreola1, D. Gatti1, M. Gatti1, G. Gambaro2, O. Viapiana1, V. Messina1, G. Zanetti1, F. Pistillo1, M. Rossini1, G. Adam1, 1University of Verona, Rheumatology Unit, Verona, Italy; 2University of Verona, Nephrology Unit, 37134, Italy

Background: Data on the relationship between peritoneal dialysis (PD), BMD and aortic calcifications (AOC) are lacking.

Objectives: to study the relationship between the degree of AOC and DXA and Radiofrequency Echographic Multi-Spectrometry (REMS) acquisitions.

Methods: Consecutive patients referring to the PD our clinic were enrolled. Lumbar spine (LS) and proximal femur REMS scans were performed, and LS (anteroposterior and laterolateral) and proximal femur DXA scans were performed as well. The degree of AOC was assessed through the semiquantitative score described by Kauppila et al, and applied to the laterolateral LS DXA scans. To test for correlations between different variables, we used the Pearson’s correlation for continuous variables and Spearman’s rho for discrete variables. Multiple regression analysis was performed to adjust for age and body mass index (BMI) the correlation between BMD and the CKD duration. Written informed consent was obtained from all participants (protocol 1483 CESC).

Results: 41 total patients were enrolled (29 males, 19 females). Median disease duration of CKD [IQR]: 132 months [48-140]. 15% had vertebral fractures at the lumbar spine (anteroposterior and laterolateral) and proximal femur DXA scans were performed as well. The degree of AOC was assessed through the semiquantitative score described by Kauppila et al, and applied to the laterolateral LS DXA scans. To test for correlations between different variables, we used the Pearson’s correlation for continuous variables and Spearman’s rho for discrete variables. Multiple regression analysis was performed to adjust for age and body mass index (BMI) the correlation between BMD and the CKD duration. Written informed consent was obtained from all participants (protocol 1483 CESC).

Conclusion: Our data showed a good agreement, in a real-life PD setting, between the DXA and REMS-derived BMDs and in the consequent fracture risk assessment obtained with the FRAX or DeFRA tools.

**Conclusion:** Our study confirmed that the overestimation of DXA BMD assessed with the anteroposterior scan is indeed influenced by AOC. Furthermore, our data suggest that REMS might be an interesting tool for the investigation of bone changes in CKD.

**Method:**

- **Background:** The effect of cholecalciferol supplementation on the regulation of inflammatory cytokines is still unclear.
- **Objectives:** This is a preliminary analysis on exploratory outcomes the DIBA/11 RCT [1,2] and aimed to compare the effects on serum inflammatory cytokines of three different regimes of cholecalciferol supplementation in vitamin D deficient subjects.
- **Methods:** We evaluated, in healthy subjects affected by vitamin D deficiency (defined as 25OHD<20ng/mL), 16 to 60 years of age, the efficacy of three different oral supplementation regimens: daily 10,000iu administered for 8 weeks (group A), weekly 50,000iu (group B) for 12 weeks and biweekly 100,000iu (group C) for 12 weeks. Serum TNFα, interleukin-6 (IL6), interleukin-17 (IL17) and interleukin-10 (IL10) were assessed. The study was approved by the institutional review committee (protocol identification: DIBA/11, EuDrAC Number:2017-000198-36). Supported by Abiogen Pharma, Italy.

**Results:** A total of 75 subjects were randomized to receive one supplementation regimen. The descriptive of the sample at baseline and relative cytokines levels at each site after adjustment for age and BMI, BMI, body mass index; β, standardised coefficient.

DOI: 10.1136/annrheumdis-2022-eular.22316

**REFERENCES:**

**Methods:** This is a descriptive and analytical retrospective study of 126 osteoporotic patients with breast cancer under aromatase-inhibitors, collected during a period of 4 years (2017 to 2021). Statistical data analysis was performed using SPSS version 20 software. The bivariate study was performed by ANOVA test.

**Results:** All the patients were treated for breast cancer and received systemic hormone-modulating anti- aromatase type therapy. All the patients had densitometric osteoporosis confirmed by a T score < −2.5, of which 31.7% had a T score < −3.5. The average age was 62.29 (40−92) years. 16% had an osteoporosis family history and 0.8% had an osteoporosis's fracture family history, 77% had a personal history of fracture. 54.8% were overweight, 14.3% had a metastasis. 88.1% had insufficient vitamin D levels (<20 ng/L). 15.9% had high blood pressure. The average duration of anti-osteoporotic treatment was 2.31 years. 77% of patients were on Residronate, 8.7% on Zoledronate, and 14.3% on Alendronate. The study of bone gain involved osteoporotic patients with breast cancer under aromatase-inhibitors and to evaluate the factors associated with bone gain in this population.

**Background:** Breast cancer is the first female cancer, especially after meno-pause. In Morocco its prevalence is estimated at 35.8%. Its hormone-dependent aspect requires the use of hormone-modulating treatments, in particular aromatase-inhibitors responsible for hypogonadism, bone loss and osteoporosis (OP) with increased fracture risk.

**Objectives:** The aim of this study is to determine the epidemiological, clinical and densitometric profile of osteoporotic patients with breast cancer under aromatase-inhibitors and to evaluate the factors associated with bone gain in this population.

**Methods:** This is a descriptive and analytical retrospective study of 126 osteoporotic patients with breast cancer under aromatase-inhibitors, collected during a period of 4 years (2017 to 2021). Statistical data analysis was performed using SPSS version 20 software. The bivariate study was performed by ANOVA test.

among which 12% were previously unknown and in women who were fully symptom-free. The vertebral fractures were mainly located at the dorsal-lumbar region; the L1 and T11 vertebrae were fractured in 3 patients and the T12 vertebra in 3 patients.

Conclusion: Our study showed that nearly half of patients with BMD-objecfied osteoporosis had a VF detected on standard X-rays, most of which were previously unknown. It is plausible to speculate the place of this method combining BMD with spinal X-rays in the diagnosis of asymptomatic VFs.

CHARACTERISTICS OF PATIENTS REFERRED FOR FIRST BONE DENSITOMETRY TO A RHEUMATOLOGY FLS, WITH NORMAL RESULTS IN THE LUMBAR SPINE

J. Rosas1, J. C. Fortés-Quiróz2, C. Raya-Santos3, C. Cano7, A. Pons7, M. Lorente Betoret4, J. M. Senabre-Gallego5, G. Santos Soler6, J. A. Bertran4, X. Barber1, J. A. García-Gómez7on behalf of AIRE-MB. 1Hospital Marina Baixa, Rheumatology, 03570, Spain; 2Hospital Marina Baixa, Rheumatology; Villajoyosa, Spain; 3Hospital Marina Baixa, Rheumatology; Villajoyosa, Alicante, Spain; 4Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain; 5 Miguel Hernández University, CIO, Elche, Spain; 6Miguel Hernández University, CIO, Elche, Spain

Objectives: To analyze the characteristics of postmenopausal women referred for the first bone densitometry (BMD), with normal results in the lumbar spine.

Methods: Retrospective study of postmenopausal women, for a first BMD, at a rheumatology FLS, during February/2010-December/2021. General patient data (age, gender), osteoporosis (OP) risk factors were collected: age at menopause, parental hip fracture, body mass index (BMI), smoking and alcohol habit, drugs and potentially osteopenizing diseases, low-impact fractures in adulthood (fractures of osteoporotic origin included: vertebral, hip, humeral head and distal radius and pelvis), current treatment for OP and FRAX index.

Results: 2,930 postmenopausal women with normal lumbar BMD are included: 505 (17%) had suffered an OP fracture: mean age (SD): 63.2 years (8.5) and of menopause 48 years (10). Among the OP risk factors: early menopause: 814 (28) years; osteopenic, n (%) 247 (49); 734 (30); among osteopenia: OP fracture: 47 (2%); hip: 47 (2%). 808 (28%) patients were receiving treatment for OP: oral bisphosphonates: 518 (18%), SERM: 136 (5%), strontium ranelate 75 (3%) 20 (4%) 55 (2%) 1; humeral head: 46 (2%) and hip: 47 (2%).

The group with OP fractures, are significantly (Table 1): older (p<0.0001), with lower mean age of menopause (p=0.0001), receive more treatment (p=0.0001), especially oral bisphosphonates (p=0.02), have worse results in hip BMD (p<0.0001), with a higher percentage of osteopenia (50% vs 30%, p=0.0001) and worse result in FRAX of major fracture (p<0.0001) and of hip (p=0.001).

Conclusion: Among the patients referred to BMD, although the result of lumbar spine is normal, 17% have suffered an OP fracture, presenting this group: 1) Older age, 2) Osteopenia in hip BMD 50%, with high risk of fracture due to FRAX and they followed treatment for OP, especially oral bisphosphonates. 3) It is advisable to simultaneously perform BMD at the lumbar and hip levels, especially in older subjects.

SECONDARY PREVENTION OF VERTEBRAL FRACTURES SUSTAINED EFFICACY OVER TIME

J. E. Oller Rodríguez1, E. Grau García2, S. Leal Rodriguez3, P. Muñoz Martínez4, L. Mas Sánchez5, C. Riesco Barcena6, A. V. Huaylla Quispe7, C. Pávez Perales1, J. C. Cortés-Quiroz1, C. Raya-Santos3, C. Cano7, A. Pons7, M. Lorente Betoret4, J. M. Senabre-Gallego5, G. Santos Soler6, J. A. Bertran4, X. Barber1, J. A. García-Gómez7on behalf of AIRE-MB. 1Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain; 2Hospital Marina Baixa, Rheumatology; Villajoyosa, Spain; 3Hospital Marina Baixa, Rheumatology; Villajoyosa, Alicante, Spain; 4Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain; 5 Miguel Hernández University, CIO, Elche, Spain; 6Miguel Hernández University, CIO, Elche, Spain

Background: Vertebral fractures entail a notorious social and health problem, and their presence is the greatest risk factor for the appearance of a new vertebral fracture. Despite the availability of different drugs for secondary prevention, there are few comparative studies in real clinical practice.

Objectives: Our aim is to evaluate the appearance of new vertebral fractures depending on the strategy chosen as secondary prevention.

Methods: We performed a retrospective descriptive study with patients who had suffered their first vertebral fracture between 2010 and 2018, in whom we checked the subsequent appearance of new vertebral fractures.

We selected only those patients who had completed a minimum of 18 months of secondary prevention with antiresorptive drugs, or a sequential scheme (anabolic treatment followed by at least 1 year with an antiresorative drug). Those patients who had presented new fractures in the first 6 months of treatment were excluded. Finally, we adjusted efficacy by treatment time.

Results: A total of 452 patients were included, out of an initial baseline pool of 1,184 patients. We found female predominance (83%) of the total. The mean age of the first vertebral fracture was 69.2 years, with a mean latency to fracture of 51.4 months. A new vertebral fracture happened in 4.7% of these patients. The different secondary prevention strategies were classified according to the different therapeutic options, as we can see in Table 1.

</tr>
</tbody>
</table>

No statistically significant differences between different treatments were observed, but we found a lower probability of a new fracture in patients treated with sequential treatment with teriparatide followed by denosumab. Finally, the Kaplann-Meier survival analysis showed a lower probability per year of new fractures in patients treated with teriparatide followed by denosumab, being this probability greater in patients treated with teriparatide followed by oral bisphosphonate.

Conclusion: A lower probability of refraction was observed in patients who received sequential treatment with teriparatide followed by denosumab.

No statistically significant differences between different treatments were observed, but we found a lower probability of a new fracture in patients treated with sequential treatment with teriparatide followed by denosumab. Finally, the Kaplann-Meier survival analysis showed a lower probability per year of new fractures in patients treated with teriparatide followed by denosumab, being this probability greater in patients treated with teriparatide followed by oral bisphosphonate.

Conclusion: A lower probability of refraction was observed in patients who received sequential treatment with teriparatide followed by denosumab.

Disclosure of Interests: None declared

ty-nine patients (56.5 %) had osteoporosis. Nine patients (13%) had moderate to severe VFs with predominance at the thoracic spine (77.8%). There was a negative correlation between MOF-FRAX score and lumbar spine BMD ($r = -0.473; p < 0.001$), and also hip BMD ($r = -0.530; p < 0.001$), while there was no correlation between MOF-FRAX score, HF-FRAX and TBS. The areas under curves were $0.824$, $0.800$, $0.792$, and $0.443$ for the FRAX-MOF score with BMD, FRAX-MOF score, FRAX-MOF score adjusted for TBS, and TBS, respectively.

Conclusion: In this study, MOF-FRAX score showed a better correlation with BMD than TBS. It was also superior to TBS and adjusted FRAX in identifying prevalent VFs in RA patients.

AB1027  CLINICAL EFFICACY OF SEQUENTIAL TREATMENT AFTER ROMOSOZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS FOR 18 MONTHS

Y. Kanayama1, 2, Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan

Background: Romosozumab (ROMO), a monoclonal antibody that binds sclerostin, increases bone formation and decreases bone resorption. And although it is a novel therapeutic agent for osteoporosis, which has shown high effects of increasing bone density and inhibiting fragile fracture in overseas clinical trials. However the clinical efficacy for rheumatoid arthritis complicated with osteoporosis (RA-OP) is unknown.

Objectives: To evaluate the clinical efficacy of ROMO for 12 months and denosumab (DMB) 6 months in patients with RA-OP for 18 months.

Methods: RA patients diagnosed according to the 2010 ACR/EULAR criteria. All patients met at least one of the following criteria were eligible: a bone mineral density T score of -2.5 or less at the lumbar spine or total hip and either one or more moderate or severe vertebral fractures or two or more mild vertebral fractures. All patients were initiated ROMO from between April, 2019 and March, 2020. The total number of patients was 12 cases. The ROMO dose was 210mg at once every 1 months. After 12 months of ROMO, all cases were changed to DMB. In all cases native or activated vitamin D has been used. We reviewed the results for 12 months about the increase and decrease of bone mineral density (BMD) of lumbar spine (LS) and total hip (TH) by DEXA and bone turnover markers, intact n-terminal propeptide type I procollagen (PINP) and tartrate-resistant acid phosphatase form 5b (TRACP-5b).

Results: He was all female. The mean age was 72.8 ± 7.0; disease duration was 17.7 ± 16.5 years; the body mass index was 19.4 ± 3.1 and the FRAX was 36.0 ± 14.9. Clinical findings related to RA-OP at baseline were as follows; CRP 12.5 ± 17.5; DAS28-CRP 3.45 ± 0.99; HAG 1.56 ± 0.99 and, bone turnover markers and bone mineral density at baseline were as follows; PINP 62.4 ± 36.2; TRACP-5b 485 ± 262; LS-BMD and T-score 0.79 ± 0.14g/cm² and -0.47 ± 0.14g/cm². The rate of increased PINP from baseline to 1, 3, 6, 12 and 18 months were each 116.3 ± 68.7% at 1 month, 135.0 ± 131.3% at 3 month, 126.1 ± 177.0% at 6 month, 83.7 ± 179.1% at 12 month and -45.1 ± 35.7% at 18 month and decreased TRAC-p5b were -13.0 ± 181.4% at 1 month, 6.9 ± 38.6% at 3 month, 20.0 ± 63.4% at 6 month, 14.8 ± 64.5% at 12 month and -11.4 ± 95.9% at 18 month. The rate of increased LS-BMD from baseline to 6, 12 and 18 months were 10.8 ± 8.0%, 15.2 ± 9.5% and 18.9 ± 10.4% and TH-BMD were 4.1 ± 4.5%, 5.7 ± 6.3% and 8.4 ± 8.1% (Figure 1, 2).

Conclusion: Clinical efficacy of treatment with ROMO for 12 months and DMB for 6 months for RA-OP was extremely effective and has the high potential to be an important option in the treatment of RA-OP.

AB1028  REGRESSIVE BONE MINERAL DENSITY TRENDS SEEN WITH DELAY IN FOLLOW UP OF DENOSUMAB TREATMENT DUE TO THE PANDEMIC INDUCED LOCKDOWN - A SINGLE CENTRE INDIAN EXPERIENCE.

A. K. Aggarwal1, N. Aggarwal2, H. Sharma3, 1Institute of Rheumatology & Pain, Rheumatology, Ghaziabad, India; 2Institute of Rheumatology & Pain, Administration and Research, Ghaziabad, India; 3Institute of Rheumatology & Pain, Pharmacy, Ghaziabad, India

Background: Denosumab (Dmab), a fully human monoclonal antibody that inhibits receptor activator of nuclear factor kappa-β ligand (RANKL), which selectively inhibits osteoclastogenesis can be used for a long period unlike the relatively short period with Teriparatide. However the effects of Dmab can quickly regress if the treatment is delayed.

Objectives: The pandemic led to multiple prolonged lockdowns since March 2020 to Jan 2022 in India. This resulted in follow up Dmab treatment delays. The retrospective study was aimed to look for the effect of the delays.

Methods: A retrospective study was aimed to look for the effect of the delays.

Results: A p>0.05 was considered statistically significant. Table 1 shows the BMD changes.

Conclusion: These findings suggest that regressive trend in BMD are seen when the treatment with Dmab is delayed even as early as 10 to 12 months. It was seen much faster in the spine compared to the hip. It is therefore advised that short term treatment with Dmab without follow up could lead to loss of all gains and may also worsen the osteoporosis.

AB1029  CLINICAL AND RADIOLOGICAL OUTCOMES AFTER VERTEBROPLASTY AND KYPHOPLASTY FOR OSTEOPORTIC VERTEBRAL FRACTURES

A. Ben Tekaya1,2, E. Hannech1,2, M. Bellil2,3, M. Ben Salah2,3. 1Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; 2Faculty of Medicine of Tunis, University Tunis El Manar, Tunisia, Tunisia; 3Orthopedic Department, Charles Nicolle Hospital, Tunis, Tunisia

Background: Vertebral Fractures are among the most frequent osteoporotic fractures. Pain and spinal deformation cause loss of autonomy and predispose to a higher risk of morbidity and mortality. Vertebroplasty and Kyphoplasty are an efficient therapeutic alternative in the management of these fractures [1,2].

Objectives: The aim of our study was to evaluate functional and radiological outcomes of Vertebroplasty and Kyphoplasty for osteoporotic vertebral fractures.

Methods: It was a retrospective study including patients treated with Vertebroplasty or Kyphoplasty for osteoporotic vertebral fractures with no spinal cord injuries. Clinical, functional, and radiological data were collected. Pain assessment was evaluated by the Visual Analogue Scale (VAS) and the Denis pain scale. Oswestry Disability Index (ODI) was used to evaluate the functional impairment. The measurement of the vertebral height pre and postoperatively was assessed by the Beck’s index on the spine lateral X-ray.

Results: There were 36 patients: 26 female and 10 male. The mean age was 65 years (41-74). The follow-up period was about 17 months. The thoracolumbar hinge was the most affected region (70%). Twenty two patients were treated by kyphoplasty and 14 by Vertebroplasty. The mean percentage trend change between a-b, b-c, and c-d BMD was -2.38% and 4.52% in the sp BMD & hip BMD respectively. A p>0.05 was considered statistically significant. Table 1 shows the BMD changes.
mean VAS pain improved from 5.28 preoperatively to 2.92 postoperatively (delta VAS pain was 2.36, p<10^-3). The improvement in the VAS pain was by 3.42 (p<10^-7) in the last follow-up. There was no difference between the two technics regarding the pain improvement (p=0.06). On preoperatively, the mean Denis pain scale was 4. It was 2.19 after kyphoplasty and 2.27 after Vertebroplasty with no significant difference between the two technics (p=0.6). The mean ODI at the last setback was fourteen: 95% of patients had minimal to moderate disability, 5% had severe disability. There was no difference between Kyphoplasty and Vertebroplasty regarding the functional impairment (14.87 vs 12.36, p=0.05). Kyphosis on the level of the fractured vertebra improved from 16.8° preoperatively to 9.5° postoperatively with a significantly mean reduction of 7.3° (p<10^-3).

Regional kyphosis improved from 12.1° to 7.4° with a significantly mean reduction of 4.3° (p<10^-7). Beck’s index went up from 0.66 to 0.8 post-operatively (p=0.05). The improvement of kyphosis on the level of the fractured vertebra (angular gain) was more important for the group treated with Kyphoplasty (8.45° vs 5.5°, p=0.01). A significant association was found between the Beck’s index losses with the ODI at the last setback (p=0.02). Complications were cement leakage in five patients without clinical symptoms. We had noted one anterior vascular leak without any clinical implication. Surgical site infection was noted in one case and was managed by medical treatment without any general complication.

Conclusion: Our study showed that Vertebroplasty and kyphoplasty were both effectively for the pain reduction and for restoration of autonomy in osteoporotic patients. They also allowed an improvement of the kyphosis necessary for an appropriate spinal static's.

**Prevalence of Glucocorticoid-Induced Osteoporosis in African Adult Patients with Chronic Rheumatic Diseases: A Systematic Review and Meta-Analysis.**

**Hammouch1,2, P. Paruk, S. A. A. Tabra, K. Maatallah2, A. Bouziane1, R. Abouqal1,2, Y. El Miedany1, A. E. Maghraoui2, A. A. Kalla2, Mohammed V University Rabat, Laboratory of Biostatistics, Clinical Research and Epidemiology (LBRC), Faculty of Medicine and Pharmacy, Rabat, Morocco; Temara Hospital, Rheumatology Unit, Temara, Morocco; University of Kwa-Zulu Natal, eThekwini, Department of Rheumatology, Insko Albert Luthuli Central Hospital, School of Clinical Medicine, College of Health Science, Durban, South Africa; Tanta University, Lecturer of Rheumatology & Rehabilitation Department, Faculty of medicine, Tanta, Egypt; University Tunis El Manar, Rheumatology Department, Kassab Orthopedics Institute, Faculty of Medicine of Tunis, Tunis, Tunisia; Mohammed V University in Rabat, Department of Periodontology, Faculty of Dental Medicine, Rabat, Morocco; Ibn Sina University Hospital, Academic Medical Unit, Rabat, Morocco; Canterbury Christ Church University, Rheumatology Department, Canterbury, United Kingdom; Mohammed V University Rabat, Private Medical Office, Rabat, Morocco; University of Cape Town, Department of Medicine, Cape Town, South Africa

**Background:** Glucocorticoid (GC) use is well established in the treatment of rheumatic diseases, particularly rheumatoid arthritis (RA). The use of low dose GC has been endorsed by EULAR recommendations for the management of rheumatic and musculoskeletal diseases even if it is the context of SARS-CoV-2, but long-term use is generally discouraged.

**Objectives:** To estimate the prevalence of glucocorticoid-induced osteoporosis (GIOP) on bone mineral density (BMD) in African adult patients with inflammatory rheumatic diseases.

**Methods:** For this systematic review and meta-analysis, PubMed, Google Scholar, Scopus, and African index medicus were systematically searched up to December 2020 without language restrictions. We included studies as follows: population-based or hospital-based study, study with sufficient information to estimate the prevalence of GIOP and osteoporotic fractures in African patients with rheumatic disease. Searches were limited to peer-reviewed full text articles. A standardized data extraction form was used to collect information from eligible studies. A random-effects meta-analysis was conducted to obtain the pooled prevalence of GIOP in these studies. The meta-analysis was stratified by geographical region. The study is registered with PROSPERO, number CRD42021256252.

**Results:** Our search identified 8571 studies, of which 8 studies were included in the systematic review from only four African countries and 7 studies in the meta-analysis. The pooled prevalence of osteoporotic fractures in our study was 47.7% (95% CI 32.9–62.8) with 52.2% (95% CI 36.5–67.6) in North Africa and 15.4% (95% CI 19.4–45.4%) in South Africa (SA). There was no evidence of publication bias, although heterogeneity was high (p=0.018). There was no data from sub-Saharan Africa apart from the two studies from SA.

**Conclusion:** The overall prevalence of GIOP in African adult patients with inflammatory rheumatic diseases was high at 47.7% (95% CI 32.9–62.8). Meta-analysis calculation revealed patient geographic origin as possible confounding factors of the proportion outcomes and further studies are required.

**AB1032**

**Predictors of Increasing Number of Fractures in a Large Cohort of Patients Receiving for Dual-Energy X-ray Absorptiometry Scan.**

**Z. Sultan, M. Bukhari, Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom**

**Background:** Osteoporosis has been described as a global epidemic(1), it is the most common disease affecting bones (2). Incidence of osteoporosis is estimated to double by 2034(2) and osteoporotic fractures are expected to cost the US healthcare system around $50 billion by 2040(1), this is more than that for either chronic lung disease, breast cancer, diabetes, or stroke (1). Thus, it is vital to define the risk factors and characteristics associated with fractures to aid early prophylaxis.

**Objectives:** To identify risk factors and predictors associated with fractures.

**Methods:** 31546 patients presented to a district general hospital in North West England for dual energy X-ray absorptiometry scan between 1996 and 2017. Demographics, risk factors and incidence of fractures were recorded. This data was retrospectively analysed to identify patients who had sustained at least one fracture. Patients were divided into three groups – group 1 had one fracture, group 2 had two fractures and group 3 had three or more fractures. STATA was used for statistical analysis. One way ANOVA with a Tukey post-hoc test and chi-squared test were used to compare the three groups.

**Results:** 11839 patients were identified to have sustained at least one fracture, this included 9993 females and 1846 males (Table 1). Group 1 contained 9390, group 2 contained 2050 and group 3 contained 399 patients. A statistically significant increase in the proportion of females within in each group was observed as the number of fractures increased (chi squared=13.99, p<0.001). There was a significant reduction in average height, weight and BMI between the 3 fracture groups with an increasing number of fractures (f(2)=31.67, p=0.0000, f(2)=23.71, p=0.0000 and f(2)=8.14, p=0.0003 respectively). Group 3 had the oldest mean age and group 1 the youngest (f(2)=44.36, p=0.0000). A significant reduction in fat percentage of the spine was identified as number of fractures increased (f(2)=4.92, p=0.0073). A significant increase in the proportion of patients with a history of smoking and alcohol excess within each group was observed as number of fractures increased (chi squared=7.48, p<0.024 and chi squared = 23.12, p<0.0000 respectively). Mean T score in the lumbar spine, total femur and femoral neck were significantly lower between the 3 fracture groups with increasing fractures (f(2)=60.54, p=0.0000, f(2)=156.44, p=0.0000 and f(2)=115.86, p=0.0000 respectively).

</table>

**Conclusion:** Some important risk factors and characteristics in patients sustaining fractures have been identified. Increased height, weight and BMI are associated with sustaining fewer fractures. Increasing age is associated with having sustained more fractures, in line with what is expected with the reducing T-scores and the ageing process. A reduced spine fat percentage is associated with higher number of fractures suggesting that fat provides a protective effect to bone. Finally, a history of smoking and excess alcohol consumption are shown to be important risk factors in sustaining increasing numbers of fractures.

**REFERENCES:**

**Disclosure of Interests:** None declared

**DOIs:** 10.1136/annrheumdis-2022-eular.4354
Background: Bone mass reaches the peak during the third decade of life. By this age, men reach an increased bone mass that starts declining in their fifties, however less rapidly than women after menopause. However, men and women lose bone mass at the same rate by age 65-70, becoming fragile and more likely to have fracture.

Objectives: This study aimed to evaluate the diagnostic accuracy in osteoporosis diagnosis of Radiofrequency Echographic Multi Spectrometry (REMS) technology applied on the proximal femur in an adult male population in comparison with the Dual-energy X-ray Absorptiometry (DXA).

Methods: A cohort of Caucasian males was enrolled in the study. Inclusion criteria were: age between 30 and 90 years, body mass index (BMI) less than 40 kg/m², no significant walking impairments and proximal femur DXA medical prescription. All the enrolled patients underwent proximal femoral scans with both DXA and REMS. The agreement between REMS and DXA-measured BMD was expressed by Pearson correlation coefficient and Bland-Altman method. The classification into patients “with osteoporosis” or “without osteoporosis” was carried out considering the conventional threshold of T-score (<-2.5) for both techniques independently. The accuracy was evaluated by the assessment of sensitivity and specificity considering the DXA outcome as reference.

Results: A total of 219 men were included in the analysis, with mean age of 55.5 (± 15.3) years. The Pearson correlation coefficient between REMS- and DXA-measured BMD values was r=0.94. At Bland-Altman analysis, Bias ± 1.96 Standard Deviation were -0.004 ± 0.04 g/cm². The REMS capability to discriminate osteoporotic patients from non-osteoporotic ones was very high: a sensitivity of 90.0% and specificity of 91.8% was detected.

Conclusion: REMS, applied to the proximal femur site, is a reliable technology for the diagnosis of osteoporosis also in men, thus confirming the diagnostic performance already observed in studies carried out in female populations.

FRACTION RISK BY FRAX WITH AND WITHOUT BONE MINERAL DENSITY. COMPARISON OF FACTORS AFFECTING CONCORDANCE

A. Y. Luiano Negrete1, C. M. Skinner Taylor2, L. Pérez Barbosa1, M. C. Rodriguez-Pluiz1, A. Aguilar-Leal1, L. G. Espinosa Banuelos1, A. Cárdenas1, D. A. Galarza-Delgado1, 2Hospital Universitario “Dr. José Eleuterio González”; Rheumatology, Monterrey, Mexico

Background: The Fracture Risk Assessment Tool (FRAX) estimates the 10-year probability of hip (FXC) and major osteoporotic fractures (FXOM) fractures in patients aged 40 to 90 years using important clinical factors, such as bone mineral density (BMD), optional input variables. (1) There is convincing evidence that with or without the use of BMD it provides a well-validated instrument and may be useful in clinical practice for identifying patients at high risk of fracture and informing treatment decisions. (2)

Objectives: This study aims to determine the concordance between the treatment decision, calculated using FRAX scores with and without BMD, and to identify the risk factors associated with the discordance in patients with autoimmune rheumatic diseases.

Methods: A cross-sectional study was carried out in patients with autoimmune rheumatic diseases who had undergone osteoporosis detection (OP) using dual bone densitometry in the Rheumatology service of the University Hospital “Dr. José Eleuterio González” during the period August 2020 - August 2021. The FRAX questionnaire was applied to determine risk factors for OP and the results of the instrument with and without BMD were calculated, the patients were classified as low, intermediate, and high risk.

A Student’s t-test, a Wilcoxon rank-sum test, and a Chi-square or Fisher’s exact test were used to compare variables between groups and calculate P-values.

Results: A total of 88 patients were included. Based on FRAX questionnaire responses, 82 (93.18%) patients had at least one risk factor for OP. The FRAX result with or without densitometry resulted in a treatment decision in 48 (54.5%) and 28 (31.8%) patients, respectively. The results were concordant in 65 (73.9%) of the cases. It was found that patients with osteopenia due to BMD had a greater agreement between both measurements (93.3%, p=0.003) than patients with normal BMD (82.5% p=0.001). Likewise, patients with secondary osteoporosis had lower concordance than patients without this diagnosis (25% and 72.5%, respectively, p=0.006).

Conclusion: The results of FRAX with and without densitometry were mostly agreeable in predicting the need for treatment according to the 10-year probability of hip fracture, however, this concordance decreased in patients with a previous diagnosis of secondary osteoporosis, no significant difference was found between the risk factors for the concordant and discordant groups. More studies are required to determine the variables that cause a decrease in the concordance of the tests.

Table 1. Factors that affect the results between the discordant groups.

AB1035
END STAGE RENAL DISEASE IN PATIENTS WITH GOUT AND CONTROLS. ETOLOGICAL DIFFERENCES?
L. Höpex1, U. Lindström1, H. Herlitz2, M. Dehlin1. 1 Sahlgrenska Academy at University of Gothenburg, Rheumatology and Inflammation Research, Gothenburg, Sweden; 2 Sahlgrenska Academy at University of Gothenburg, Molecular and Clinical Medicine/Nephrology, Gothenburg, Sweden

Background: The association between gout and renal disease is well known. However, whether hyperuricemia causes renal disease, or if the association is explained by comorbidities, is still up for debate. Studies on the effects of urate and gout on chronic kidney disease (CKD) show conflicting results. There is a lack of data on the underlying causes of CKD in gout patients.

Objectives: To compare causes of end stage renal disease (ESRD) in patients with gout and population controls.

Methods: This is a population-based and register-based case-control study. Gout cases, aged 18 years or older, were identified by at least one visit to a physician either an in- or outpatient clinic with a registered ICD-10 code for gout (M10) in the Western Regional Healthcare Contact Register (VEGA), between January 1st 2001 through December 31st 2018. For each case five controls without gout were matched by sex, age, and county/place of residence at year of first diagnosis. Cases and controls were excluded if they prior to the first recorded ICD-10 code for gout, had a record of end stage renal disease, defined as codes for renal transplantation or dialysis either in VEGA or the Swedish Kidney Register (SNR). In this cohort, all cases and controls developing ESRD during the follow-up period (2001 to 2018) were identified, and the registered causes of ESRD were compared across the groups.

Results: In total, 48594 gout cases (mean age 68.4 years; 67% male), and their 150618 matched controls (mean age 63.3 years; 67% male) were included. Of the cases and controls, 529 (1.1%) and 128 (0.1%) developed ESRD, respectively. At the time-point of active uremia treatment start (as in start of dialysis or beginning had significantly less gout flares compared to those without hypouricemic treatment since hemodialysis mic treatment. Patients on hypouricemic treatment since hemodialysis without hypouricemic treatment and 22 patients (45%) with hypouricemic treatment presented at least one gout flare during the follow-up: 42 patients (65%) with a male/female sex ratio of 2.7:1. Sixty-four/182 patients (35.16%) presented at least one gout flare during the follow-up: 42 patients (65%) without hypouricemic treatment and 22 patients (45%) with hypouricemic treatment. Patients on hypouricemic treatment since hemodialysis beginning had significantly less gout flares compared to those without hypouricemic treatment at the initiation of hemodialysis (p = 0.0009) (graphic 1). There was no significant KT/V ratios difference between the 2 populations at the time of gout flares. Hypouricemic treatment was a protective factor for the occurrence of gout attacks (HR: 0.42, 95% CI 0.25 – 0.71) (Table 1).

Conclusion: Therefore hypouricemic treatment at the initiation of hemodialysis seems to be a protective factor against gout flares, which may persist in dialysis patients. Prospective studies should be performed to confirm these results for this particular gouty population.

AB1038  PEGLOTICASE URATE-LOWERING RESPONSE FOLLOWING COVID-RELATED GAP IN THERAPY: EXPERIENCES OF ONE RHEUMATOLOGIST

D. Mandel1, P. Scott1, B. Lamoreaux2, 1David R. Mandel, M.D. Rheumatology & Osteoporosis, Rheumatology, Mayfield Village, United States of America; 2Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America

Background: When uncontrolled gout cannot be managed with oral urate-lowering therapies, pegloticase is one of the few remaining treatment options. Patients receiving infusions therapies experienced treatment interruptions due to the COVID-19 pandemic. As with other biologic therapies, patients can develop anti-drug antibodies (ADAs) against pegloticase, and longer infusion intervals can result in higher rates of pegloticase immunogenicity.1 The literature suggests that co-administering an immunomodulator with pegloticase can markedly decrease the proportion of patients who develop ADAs, increasing the proportion with sustained urate-lowering response.2

Objectives: This case series reports one rheumatologist’s experience with a gap in pegloticase therapy during the COVID-19 pandemic.

Methods: Uncontrolled gout patients who underwent pegloticase treatment during 2019/2020 and had a gap in therapy of ≥28 days were identified. Patient, clinical, and treatment (number post-gap infusions, immunomodulation co-therapy) characteristics were retrospectively examined, along with urate-lowering response following therapy interruption. Patients who had a serum urate (SU) <6 mg/dL after the last post-gap pegloticase infusion were considered to have recaptured response.

Results: 7 patients (5 men, 64.3±13.5 years, pretherapy SUA: 7.76±2.47 mg/dL, 6 had tophi) were included with 2 remaining on therapy at data collection. Eleven gaps were noted with an average gap duration of 11.4±9.3 weeks (median: 9 weeks). For the last gap in therapy, patients received 13.9±7.0 infusions (range: 4-22) before the gap and 7.0±4.1 infusions (range: 2-14) after (Figure 1). Four patients (57%): Patients 1, 2, 5, 7, had recaptured urate-lowering at last pegloticase infusion, all of whom began immunomodulation (3 methotrexate, 1 mycophenolate mofetil/hydroxychloroquine) prior to resuming pegloticase. Of the 3 patients without response capture, 2 initiated MTX after resuming pegloticase. Of the 3 patients without response recapture, 2 patients (67%) experienced ≥1 AE, including mild infusion reaction (n=1), acute gout flare (n=2), clinically meaningful decrease in eGFR (14.8±1 min/1.73m², n=1), heart attack (n=1), and anemia (n=1).

Conclusion: These cases suggest that it may be possible to recapture urate-lowering response to pegloticase in some patients, particularly in the presence of immunomodulation. These preliminary findings are important to this vulnerable patient population, particularly during the COVID-19 pandemic. Further study is needed to confirm our findings.

REFERENCES:
Gout affects more than 9 million Americans,[1] with some suffering so severely that everyday life becomes painful and difficult. Pegloticase is an infused uricase-based medicine that significantly reduces serum uric acid (sUA) levels in patients suffering from treatment-resistant gout,[2] but the direct effect of treatment on quality of life (QoL) by response status has not yet been reported.[3]

Background: Gout outcomes more than 9 million Americans,[1] with some suffering so severely that everyday life becomes painful and difficult. Pegloticase is an infused uricase-based medicine that significantly reduces serum uric acid (sUA) levels in patients suffering from treatment-resistant gout,[2] but the direct effect of treatment on quality of life (QoL) by response status has not yet been reported.[3]

Methods: This analysis utilized results from two parallel 6-month randomized phase 3 registrational clinical trials in which subjects were treated with 8 mg of pegloticase or placebo biweekly. Responders were those who maintained sUA levels <6 mg/dL for >80% of the time during Months 3 and 6 combined. Multiple QoL measurements were taken throughout the 6-month treatment period, including the Health Assessment Questionnaire (HAQ; Pain, Disability Index [DI], and Health), the 36-Item Short Form Health Survey Questionnaire (SF-36), and the Limitations of Daily Activities (LIDA). HAQ was assessed at baseline and Week 25. The SF-36 and LIDA were assessed at baseline, Weeks 3, 6, 12, 24, and 25.

Results: A total of 36, 49, and 43 patients were included in the treatment responders, treatment non-responders, and placebo-treated groups, respectively. Significant differences in the change from baseline to Week 25 in HAQ-Pain, HAQ-DI, HAQ-Health, and SF-36 PCS was not significantly different between any of the 3 groups examined.

Conclusion: In the Phase 3 registration trials of pegloticase used as monotherapy for uncontrolled gout, QoL parameters improved among pegloticase-treated patients regardless of response status.

Disclosure of Interests: Jacy Sparks: None declared, Katie Obermeyer Shareholder of: Horizon Therapeutics., Employee of: Horizon Therapeutics, Brian LaMoreaux Shareholder of: Horizon Therapeutics plc, Biostatistics, Deerfield, United States of America; Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America

homozgyous CC genotype and CA or AA genotypes did not differ: 17 (33%) and 11 (35%) cases, respectively. It turned out that CA and AA pts required a significantly higher dose of allopurinol (365±102 mg/day) than CC pts (290±85 mg/day), p=0.02. Of 54 pts treated with febuxostat who did not achieve the target sUA level, 30 (56%) pts had the CC genotype and 24 (44%) pts had the CA genotype. The opportunity of the target sUA level achievement was comparable (p=0.22).

Conclusion: The opportunity of achieving the target sUA level in pts with gout taking allopurinol is not associated with the C→A polymorphism of the ABCG2 gene, but the presence of the CA and AA genotypes is associated with the need to prescribe large doses of allopurinol.

AB1041 REAL-WORLD REPORTING OF GOUT FLARES IN UNCONTROLLED GOUT PATIENTS CO- TREATED WITH PEGLOTICASE AND METHOTREXATE
J. Alberi, L. Padnick-Silver, B. Lamoreaux1. Rheumatic Disease Center, Rheumatology, Milwaukee, United States of America; 2Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America

Background: Acute gout flares are a known result of urate-lowering in gout patients1 and are also the most common adverse event in patients treated with pegloticase.2 Fortunately, the proportion of pegloticase-treated patients who experience flares and the number of flares/patient decrease over time.3,4 Though well-studied in the clinical trial setting, little has been published on the rate of acute gout flares during pegloticase therapy in a real-world, rheumatology setting. This retrospective study examined one community practice’s findings on gout flares in uncontrolled gout patients co-treated with pegloticase and methotrexate.

Objectives: This retrospective chart review examined acute gout flare occurrence and characteristics in patients undergoing pegloticase-methotrexate co-therapy. Patients with and without gout flares were also compared to investigate potential factors that may have influenced gout flare occurrence.

Methods: All patients who underwent pegloticase plus methotrexate co-therapy between January 2017 and March 2021 at a community rheumatology practice were included. Patient, treatment, and flare characteristics were extracted from the medical record and compiled into a de-identified data set.

Results: 29 patients treated with pegloticase and methotrexate (28 subcutaneous, 1 oral) were included. Mean patient age was 59.9±17.0 years and 72% were male. Gout duration was 11.7±10.8 years, pre-therapy serum uric acid (sUA) averaged 9.4±1.8 mg/dL, and 97% had visible tophi. Patients had received 12.8±1.3 pg/ml pegloticase infusions over 25.9±9.7 weeks, with pre-infusion sUA±6mg/dl in 27/29 patients (93%) at last pegloticase dosing. 23 gout flares were noted in 12 patients (41%, 19.9±18 flares/patient), 59% of which were noted as severe and 50% involved a single joint. Acute gout flare was most common in the first 4 weeks of therapy, with first flare occurring on average 1.6±2.9 weeks after first pegloticase infusion. Demographic and treatment characteristics were similar between flaring and non-flaring patients. However, patients with ≥1 flare were older (65.8±15.4 years vs. 55.6±17.8 years), more often obese (83% vs. 47%), and had a higher overall comorbidity burden.

Conclusion: This retrospective study of real-world pegloticase use suggests that gout flare rates may be lower in a real-world setting (41%) than that reported in clinical trials (76%–86%6-7), which have different gout flare criteria. Consistent with clinical trials, a flare rate was highest during the first 4 weeks of pegloticase treatment, progressively decreasing over time. Interestingly, these data suggest that patients who experience gout flares on pegloticase may have more obesity and a higher comorbidity burden than those who do not experience flares. Further examination of gout flares during real-world pegloticase use is warranted.

AB1043 IDENTIFICATION OF UNUSUAL TOPHI ANTERIOR TO THE THYROID CARTILAGE USING DIFFERENT IMAGING METHODS
Y. Jiang1, X. Wu1, Z. Liao1, J. Qi1, J. Gu1. 1Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China

Background: Inadequately treated gout patients could develop tophi. However, tophi could appear as atypical mass, leading to difficulty in differential diagnosis.

Objectives: The objectives of the study were to describe an unusual case with tophi anterior to the Thyroid Cartilage using different imaging methods.

Methods: Clinical information of the case was presented. Ultrasound, dual energy Computed Tomography (DECT) and CT scan were compared to describe the tophi.

Results: A 66-year-old man with a 30-year history of gout was admitted. He received 8-year urate-lowering drugs intermittently over the past few years. Physical examination revealed multiple tophi on the hands, feet, and other acral surfaces. Moreover, there was a subcutaneous mass above the thyroid cartilage (Figure 1A). Ultrasound revealed hyperechoic nodule anterior to the thyroid cartilage, 11*7 cm in size, with uneven internal echo, no blood flow signal inside, and a close relationship between the barrier of the nodule and the thyroid cartilage (Figure 1B). DECT of the neck confirmed that the mass anterior to the thyroid cartilage were tophi (Figure 1C-D). A plain radiographic evaluation demonstrated

REFERENCES:

soft-tissue swellings and para-articular erosions involving hands (Figure 1E-F). The serum creatinine and uric acid levels were elevated as follows, creatinine, 562 µmol per liter (normal range, 31.8 to 116); and uric acid, 621 µmol per liter (normal range, 90 to 420).

Conclusion: DECT has more advantages over ultrasound and CT for detection of atypical tophi in gout patients.

AB1044 RISK FACTORS OF DIABETES MELLITUS IN PATIENTS WITH GOUT (RESULTS OF A PROSPECTIVE STUDY)

O. Sheliabina1, M. Eliseev2, S. Glukhova3, 1VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation; 2VA Nasonova Research Institute of Rheumatology, Laboratory of Axial Spondyloarthritis, Moscow, Russian Federation

Background: It is assumed that the risk of developing diabetes mellitus (DM) is due not only to generally accepted risk factors (RF), but also to RF related to gout.

Objectives: To evaluate the influence of various RF for DM in pts with gout.

Methods: 444 pts aged ≥18 years with a crystal-verified diagnosis of gout without DM were included in the study. The average duration of observation was 5.66 (2.69; 7.4) yrs. To identify the RF associated with developing of DM in patients with gout, multivariable logistic regression was used. There were included: gender; DM in relatives; insufficient physical activity; unbalanced diet; age ≥45 yrs; ≥4 exacerbation of arthritis per yr; presence of tophi; BMI ≥30 kg/m²; presence of subcutaneous tophi; sUA ≥600 µmol/l; age ≥45 yrs; presence of hypertension; allopurinol, febuxostat, GC, diuretics, metformin or colchicine intake; GFR <60ml/min/1.73 m²; serum uric acid (sUA) level ≥420 µmol/l; UA ≥480 µmol/l. Statistica 12.0 package was used for statistical data processing.

Results: The opportunity of achievement of the target serum UA (sUA) level in pts with gout, stratified by renal function, is not studied. The frequency of arthritis exacerbation in pts who achieved the target sUA level was decreased from 3.1±1.6 cases per year to 0.9±1.1 cases per year (p=0.0001); in those who did not achieve - from 3.1±1.9 cases per year to 2.4±1.6 cases per year (p=0.047).

Conclusion: The risk of developing diabetes in pts with gout is associated with the frequency of exacerbations of arthritis, sUA level ≥480 µmol/l, hypertension and diuretics intake. Therapy with febuxostat or metformin is associated with descended risk of DM.

Disclosure of Interests: Olga Sheliabina Speakers bureau: Berlin Chemie Menarini Group, Maxilis Eliseev Speakers bureau; Berlin Chemie Menarini Group, Sobi, EGIS, CSC, MosFarma, Alium Group, Svetlana Glukhova: None declared

AB1045 QUALITY OF LIFE IN PATIENTS WITH GOUT TAKING URATE-LOWERING DRUGS, DEPENDING ON THE ACHIEVEMENT OF THE TARGET LEVEL OF SERUM URIC ACID

M. Chikina1, O. Sheliabina1, M. Eliseev1, 1VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation

Background: Intake of urate-lowering drugs (ULD) leads to an improvement in the quality of life (QoL) in pts with gout. However, it is not clear to what extend the QoL is changed in pts who did not achieve the target level of serum uric acid (sUA).

Objectives: To evaluate the dynamics of the QoL in pts, taking ULD, who have achieved and have not achieved the target sUA level.

Methods: 98 pts with gout were included in the prospective study. The follow-up period was 24 months, allopurinol or febuxostat at doses sufficient to achieve the target sUA level (>360 µmol/l) were used. The maximum daily dose of allopurinol was 900 mg/day, febuxostat - 120 mg/day. Pts who did not achieve the target sUA level continued taking ULD at the maximum dosages. The values of the QoL in dynamics were calculated using the SF-36v2 questionnaire. The assessment of the QoL was carried out separately in pts who achieved and did not achieve the target level of sUA. The frequency of exacerbations of arthritis was also assessed. Statistica 12.0 package was used for statistical data processing.

Results: Of 98 (70%) pts achieved the target sUA level, whereas allopurinol was taken by 46 pts, febuxostat - 34 pts. Pts who achieved the target level of sUA after 6 mo. of ULD usage, demonstrated a significant improvement in the physical health (PH), including physical functioning (PF), role limitations due to physical functioning (RP), general health (GH), as well as vitality (V) (p<0.05 for all). After 12 and 24 mo. improvement was achieved in RH, GH and PF (p<0.01), PF, role-emotional functioning (RP) and VT (p<0.05). General mental health (MH), role-emotional functioning (RE) and social functioning (SF) were unchanged throughout the study. Pts who did not achieve the target sUA level after 6 and 12 mo. significantly improved. PF, RP (p<0.05 for all). For 24 months, for all QoL parameters, the values did not differ from the initial ones. The frequency of arthritis exacerbation in pts who achieved the target sUA level decreased from 3.1±1.6 cases per year to 0.9±1.1 cases per year (p=0.0001); in those who did not achieve - from 3.1±1.9 cases per year to 2.4±1.6 cases per year (p=0.047).

Conclusion: The QoL in gout pts who achieved target sUA level continues to improve during the first year of ULD intake. Even if the target sUA level is not achieved, the QoL of patients with gout treated with ULD remains stable for at least 2 years of therapy. This predetermines the need to use maximum daily doses of ULD, even if the target serum UA level is not achieved.

level: baseline 2.13[0.22; 2.8] mg/l vs at th end of study period 3.06 [0.39; 3.68] mg/l, p=0.627. A decrease in mean values of calMT was noted in 5 of 6 (83%) pts took hydroxychloroquine, in 6 of 9 (67%) pts took colchicine, in 4 of 7 (57%) pts took methotrexate.

Conclusion: Therapy with colchicine, methotrexate and hydroxychloroquine in pts with CPPD leads to regression of early signs of atherosclerosis. This result can be achieved by suppressing chronic inflammation.

Discussion of Interests: Maxim Eliseev Speakers bureau: Berlin Chemie Menarini Group, Sobi, EGIS, CSC, Mosfarma, Alum Group, Olga Shelibabina Speakers bureau: Berlin Chemie Menarini Group, Maria Chikina: None declared.
Conclusion: In this retrospective real-world review of a limited number of cases, MTX-pegicotide co-therapy resulted in sustained uAUL lowering in uncontrolled gout patients with and without CKD. Close monitoring of renal function indicated stability or improvement during therapy in 86% of uncontrolled gout patients with CKD. Further study is needed to better understand therapy tolerance and treatment response rates of uncontrolled gout patients with CKD undergoing MTX-pegicotide co-therapy.

Disclosure of Interests: John Albert Speakers bureau: Horizon Therapeutics, Consultant of: Horizon Therapeutics, Aaron Broadwell Speakers bureau: Horizon Therapeutics, Consultant of: Horizon Therapeutics, Karim Masri Shareholder of: Horizon Therapeutics, Speakers bureau: Horizon Therapeutics, Consultant of: Horizon Therapeutics, Lissa Padnick-Silver Shareholder of: Horizon Therapeutics, Employee of: Horizon Therapeutics, Employee of: Horizon Therapeutics, Amod Athavale Grant/research support from: Horizon Therapeutics, Bally several anti-inflammatory, and some oral urate-lowering therapies (ULTs). This unique patient population has not been well characterized using real-world data. Objectives: This retrospective chart review study of patients with coincident gout and CKD was conducted to better understand patient characteristics and treatment patterns of this population. This study is unique in that patient data were obtained from nephrologists, allowing a glimpse of how they view gout and its management.

Methods: 111 nephrologists provided de-identified medical record data of their most-recently seen advanced (stage 3–5) CKD patients. Patients met study criteria for gout if any of the following were true: gout listed as a comorbidity, ULT use, or visible tophi or gout flares documented. A patient’s gout was determined to be uncontrolled if they had serum uric acid ≥6 mg/dL in addition to ≥1 visible tophus, ≥2 gout flares in the past year, or gouty arthritis (≥1 tender or swollen joint). Only characteristics of this unique population were examined, along with gout management patterns. Differences between patients with controlled and uncontrolled gout were also investigated using data from patients’ most recent evaluation.

Results: 173 patients with stages 3-5 CKD and who met study criteria for gout were included. Mean age was 56.3±12.9 ± 1 years and BMI averaged 32.0 ± 11.9 kg/m². A higher than expected proportion of patients was female (47%). The most common comorbidities were hypertension (85%), diabetes mellitus (47%), anemia of CKD (42%), CKD-mineral bone disorder (41%), ischemic heart disease (23%), and congestive heart failure (21%). Mean CKD duration was 4.1 ± 5.5 years, mean estimated glomerular filtration rate (eGFR) at most recent visit was 32.3 ± 13.9 ml/min/1.73 m², and 62% were using a ULT. 23 patients (13%) had uncontrolled gout (48% female, 63.1 ± 16.4 years, mean eGFR 32.0 ± 14.6 ml/min/1.73 m²), all of whom had been prescribed a ULT. Compared with controlled gout patients, uncontrolled patients had higher rates of pulmonary hypertension (14% vs. 4%), gout-related chronic pain in the 12-months prior to data collection (83% vs. 42%), and joint involvement (joint swelling, tenderness, flexibility loss, and/or damage/lesions on x-ray; 26% vs. 9%). Colchicine was also used more frequently in uncontrolled gout patients (26% vs. 7%).

Conclusion: The coincident with advanced CKD population described here shows unique differences from the general gout population, including a high proportion of females (47%). Given that women have a lower likelihood of developing gout at the same serum uric acid level, this finding was particularly surprising (general gout population: 67% male). Importantly, nearly 40% of included patients were not utilizing a ULT, leaving them susceptible to developing the painful and debilitating sequelae of uncontrolled gout. Additionally, 41% of the study population had a CKD-related mineral bone disorder, indicating that patients with coincident gout and CKD may have bones that are more vulnerable to gout-related bone damage. Our study confirms a high prevalence of gout and its associated comorbidities in patients with advanced CKD and suggests another nephrology education opportunity to highlight the potential benefits of gout monitoring, earlier intervention, and management.

Clinical outcomes and healthcare resource utilization of uncontrolled gout prior to pegloticase therapy

R. Morlock, V. Divino, M. Dekoven, B. Lamoneaux, A. Powers, N. Barreto, R. Holt, S. Taylor,

Background: By definition, uncontrolled gout (UG) cannot be managed with oral urate lowering therapies (ULTs) and is associated with substantial morbidity, UG, also known as refractory gout, results in escalated treatment and management. Recent American College of Rheumatology guidelines recommend treating gout to serum uric acid targets; if targets are not achieved or patients continue to have symptoms, pegloticase is recommended. There is a paucity of data documenting the clinical and economic burden of UG patients.

Objectives: Assess clinical outcomes and healthcare resource utilization (HCRU) of UG prior to pegloticase initiation.

Methods: A retrospective observational database analysis was conducted among patients initiating pegloticase between April 1, 2011 and August 31, 2020 using the PharMetrics Plus database. Eligible subjects had ≥1 pegloticase claim (first claim = index date) and continuous enrollment for 24 months prior to index. Relevant clinical and economic (HCRU) outcomes were evaluated over a 24-month pre-index period and compared between two different time periods prior to index: time interval 1 (Day -720 to Day -361) and time interval 2 (Day -360 to Day -1).

Assessment of comorbid disease burden included Charlson Comorbidity Index (CCI) and relevant health conditions. Dependent pairwise comparisons were conducted to compare clinical and economic outcomes between time periods prior to pegloticase initiation. To assess statistical differences, paired t-tests (continuous variables) or McNemar’s tests (categorical variables) were used.

Results: Of the 408 eligible subjects, most were male (88.5%), with an average age (SD) of 55.2 (11.3) years, 66.9% were between the ages of 45-64 years and 78.2% had a preferred provider organization (PPO) health plan. Most often (34.8% of patients), a rheumatologist was associated with initiation of pegloticase therapy, while primary care physicians accounted for 23.8% of initiations.

Mean (SD) CCI score was 2.4 (2.4) with 37.3% of subjects having a CCI score of ≥3. Prevalence of relevant health conditions over the 24-month pre-index period included tophi (62.5%), uric arthritis (8.6%), chronic kidney disease (34.6%) and chronic pain/fibromyalgia (76.5%), all of which significantly increased from time interval 1 (Day -720 to Day -361) to time interval 2 (Day -360 to Day -1) prior to pegloticase initiation (Table 1). Of patients initiating pegloticase, 57.4% had ≥1 ULT (excluding probenecid), 11.3% had ≥2 ULT (excluding probenecid), and 10.3% UG patients had ≥1 probenecid claim over the 24-month pre-index period. Most patients (98.3%) had ≥1 physician office visit, 27.2% had ≥1 hospitalization and 45.3% had ≥1 emergency room (ER) visit over the 24-month pre-index period. HCRU significantly increased from time interval 1 to time interval 2, prior to pegloticase initiation (Figure 1).

Conclusion: Overall, these data demonstrate the progressive nature of UG as confirmed by significant increases in gout-related conditions and healthcare resource utilization prior to pegloticase initiation. Further research is needed on healthcare resource utilization among patients with UG post-pegloticase use.

Association between body mass index and health-related quality of life in patients with gout

I. Orlowa, I. Vovk, M. Stanislavichuk

Background: Gout is an inflammatory disease that may cause decreased function and health-related quality of life (HRQoL). [1] In a few studies, it was demonstrated a negative relationship between body mass index (BMI) and HRQoL in individuals with gout, in the others, it was not confirmed.

Objectives: This study aimed to assess the BMI and quality of life in patients with gout and to value the association between these variables.

Methods: All 151 patients were male with mean age (M±SD) 52.4±9.2 years. Diagnosis of gout was based on the ACR/EULAR 2015 criteria [2]. Tophi were present in 51 (33.7%), and the median duration of gout was 7 years (25th to 75th interquartile range (IQR), 4 to 14.0). The mean uric acid in serum was (M±SD) 477.2±120.5 µmol/l. HRQoL was evaluated by the SF-36 and calculated summary physical (PCS) and mental component (MCS) scores of the SF-36.

Results: About 67.5% of the surveyed patients had BMI > 30 kg/m2, while the average index was 31.9±3.4. The overall median SF-36 PCS score was 33.9 (IQR 28.8 to 38.4), and the overall median SF-36 MCS score was 41.1 (IQR 34.2 to 47.4). Among the eight subscales of SF-36, there was a correlation between BMI and role physical functioning (RP) r = -0.22 (p<0.01), general health (GH) r = -0.17 (p<0.05), but others were statistically not significant (P>0.05). Our analysis showed negative associations between BMI and physical and mental HRQoL.

Conclusion: This analysis provides further evidence to support the injurious effects of obesity on different aspects of health patients with gout and underline the importance of weight loss.

Cardiovascular risks and mortality in Korean patients with gout

K. W. Moon

On behalf of ULTRA cohort group. 1Division of Rheumatology, Department of Internal Medicine, Kangwon National University School of Medicine, Chuncheon-si, Korea, Rep. of (South Korea)

Background: Gout is associated with an increased risk of cardiovascular comorbidities and premature mortality. Many epidemiological studies support an association between gout and increased risk of diverse cardiovascular diseases. There has been no study on cardiovascular risks and mortality in Korean patients with gout with large scale data. Therefore, we intended to investigate the risk of each specific cardiovascular disease and mortality in Korean patient with gout with the national insurance database. The purpose of this study is to investigate cardiovascular risks and mortality in Korean patient with gout.

Objectives: The purpose of this study is to investigate cardiovascular risks and mortality in Korean patient with gout.

Methods: Using Korean National Health Insurance Service data, we conducted a cohort study on gout patients. Gout patients were defined as those aged ≥ 20 years who were diagnosed as gout between 2009 and 2010, and control patients were matched with gout patients (1:1 ratio) after frequency matching for age, sex and index year. Primary outcomes were ischemic heart disease (IHD), acute myocardial infarction (AMI), congestive heart failure (CHF), cerebrovascular disease (CVD), cerebral infarction, cerebral hemorrhage, or transient ischemic attack (TIA). Secondary outcomes were all-cause mortality and cardiovascular mortality. We calculated hazard ratio (HR) in Cox regression, adjusting potential confounders.

Results: This study included 3,306 gout patients and an equal number of matched controls. Multivariate Cox regression analysis showed that gout patients showed increased risks of IHD (HR 1.860, 95% CI 1.446-2.392), AMI (HR 3.246, 95% CI 1.460-7.217), CVD (HR 1.552, 95% CI 1.177-2.036) after adjusting age, sex, laboratory findings, comorbidities, and medication (Table 1). However, statistical differences were not found in the risks of CHF, cerebral infarction, cerebral hemorrhage, TIA, all-cause mortality, and cardiovascular mortality.

AB1054 FERRITIN LEVELS IN PATIENTS WITH GOUT AND COMORBID PATHOLOGY

G. Kuzmina1, O. Lazarenko1. 1Zaporizhzhya State Medical University, Department of Therapy; Cardiology and Family Medicine Faculty of Postgraduate Education, Kryvyi Rih, Ukraine

Background: Gouty arthritis is the most common type of inflammatory arthritis among the working-age population. In patients with gout, the following comorbidities are often recorded: hypertension, diabetes mellitus, and heart failure. The issue of the relationship between ferritin levels in patients with gout and comorbid pathology remains relevant, as well as establishing the nature of this relationship.

Objectives: The aim of this study was to determine the frequency of hyperferritinemia in patients with gout and comorbid hypertension.

Methods: 122 patients with hypertension, middle age of whom amounted to 56.0 (10.29) years, had been surveyed, 104 (85.2 %) men and 18 (14.8 %) women. All women were divided into three groups: the main group – 72 patients with hypertension in combination with gout, comparison group – 50 patients with hypertension without gout, control group – 20 patients with gout. Standard clinical examination and laboratory evaluation including ferritin, uric acid levels were performed.

Results: The following ferritin values were determined in the main group 344.0 (196.5; 389.0) ng/ml, comparison group 130.9 (68.0; 143.3) ng/ml and control group 276.5 (257.0; 354.5). The ferritin level were significantly higher in the main group - 2.6 (p <0.01) times than in the comparison group. The ferritin level were significantly higher in the control group - 2.1 (p <0.01) times than in the comparison group. There is no significant difference the ferritin levels between main and control groups (p>0.05), which indicates the important role of this marker in gout and requires further study of hyperferritinemia in gout and comorbid pathology.

Conclusion: The combination of hypertension with gout in patients was associated with a higher ferritin levels, which should be considered not only in the context of chronic inflammation, but as part of the disease with the possibility of further determining the cause and diagnostic value of hyperferritinemia in this category of patients.

AB1055 GENDER DIFFERENCES IN TAKING XANTHOXIODASE INHIBITORS IN GOUT

M. Gromova1, V. Tsurko1. 1Pirogov Russian National Research Medical University, Department of Faculty Therapy of the Medical Faculty, Moscow, Russian Federation

Background: There is little evidence of a possible difference between men and women in response to urate-lowering therapy (ULT).

Objectives: To compare the clinical characteristics of the gout course and evaluate the differences in response to ULT with allopurinol and febuxostat in men and women.

Methods: The retrospective cohort study included 279 men and 83 women diagnosed with gout (ACR/EULAR, 2015). The comparative analysis of the clinical characteristics of gout and responses to taking xanthoxidase (XO) inhibitors in representatives of different genders was conducted. We compared the gender characteristics of obtaining a positive response to ULT, defined as achieving a target serum uric acid (sUA) level of <360 μmol/l within 6 months of treatment with allopurinol and febuxostat.

Results: By the age when gout manifested women were older than men, the duration of their disease was shorter. Men showed a shorter duration of the first arthritic attack. Chronic arthritis was diagnosed in 56% of men and 35% of women (p<0.05). The process involved the joints of the lower and upper extremities. More often the joints of the lower extremities were affected in men, and in the upper extremities in women. Tophus were detected in 35% of patients: 30.3% – men, 4.7% – women (p<0.05). Allopurinol was prescribed to 216 men and 54 women, febuxostat – to 63 men and 29 women. After six months the proportion of women who achieved the target sUA was 57.5% and 65.8%, the proportion of men – 60.4% and 76.2% for allopurinol and febuxostat, respectively.

Conclusion: The clinical manifestations of gout in men and women differ. Due to the marked acid release in the low-acid level, men develop more severe joint damage because of the tendency to chronicity. However, the study did not reveal gender differences in the response to XO inhibitors, which indicates that there is no need to choose therapy depending on the patient's gender.

AB1056 CHARACTERISTICS OF METABOLIC SYNDROME IN PATIENTS WITH GOUTY ARTHRITIS AND NON-ALCOHOLIC FATTY LIVER DISEASE

K. Zhigulina1, S. Spitsina1,2. 1Federal State Budgetary Educational Institution of Higher Education “Volgograd State Medical University” of the Ministry of Healthcare of the Russian Federation, Department of Hospital Therapy, Volgograd, Russian Federation; 2Federal State Budgetary Institution “Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy”; Clinical Biochemical Laboratory, Volgograd, Russian Federation
Background: Gouty is an inflammatory and metabolic disease. Hyperuricemia can contribute to inflammation, hypertension and cardiovascular disease, adipogenesis and lipogenesis, impaired insulin and glucose metabolism, and liver disease. In turn, allopurinol is a fava liver disease (NAFLD) monitored. The primary outcome uric acid worldwide; is closely associated with obesity; type 2 diabetes mellitus, dyslipidemia, and other metabolic risk factors included in the metabolic syndrome (MS).

Problem of MS exists for many years, due to its extremely rapid spread in the world. Lipidemia, and other metabolic risk factors included in the metabolic syndrome (MS). In contrast, non-alcoholic fatty liver disease (NAFLD) is the most common chronic liver disease in combination with NAFLD, to identify the main traditional and disease-associated risk factors.

Methods: A cross-sectional descriptive study was conducted in the rheumatology and endocrinology departments of Farhat Hached University Hospital of Tunisia over a period of 6 months. Patients diagnosed with T2D according to the 2021 guidelines of the American Diabetes Association were included. A cut-off of uric acid ≥ 360 μmol/L in females and ≥ 420 μmol/L in males was used to define HU. Background: Recombinant uricase such as pegloticase are indicated for chronic gouty arthritis who have failed to achieve serum urate level <300μmol/L even though receiving conventional urate-lowering drugs. Rasburicase which is currently approved at a dosage of 0.2mg/kg/d for 5 days for the prevention of tumor lysis syndrome in pediatric patients with hematological tumors, is the only available uricase in China at present.

Objectives: To study the frequency and structure of MS in patients with gouty arthritis in combination with NAFLD, to identify the main traditional and disease-associated risk factors.

Methods: The study included 70 patients with gouty arthritis. The diagnosis was made based on the criteria of S. Wallace et al. All patients were examined with general clinical and biochemical blood tests (determination of uric acid, transaminases, glucose, glycosylated hemoglobin, insulin, lipid spectrum), physical examination (measurement of blood pressure, body mass index in kg/m²), calculation of the HOMA index. An ultrasound examination of the liver was performed as the instrumental diagnostic method.

Results: Among the surveyed, men and women accounted for 60% and 40%, respectively, with an average age of 52 years, with an average disease duration of 8.2±3.5 years. The debut of gouty arthritis was observed at 35.6 years. 25 patients had a family history of gouty arthritis, 64 patients had arterial hypertension, of 8.2±3.5 years. The debut of gouty arthritis was observed at 35.6 years. 25 patients had a family history of gouty arthritis, 64 patients had arterial hypertension, as well as hyperuricemia. All identified factors are higher risks of developing insulin resistance and dyslipidemia, abdominal obesity and arterial hypertension, as well as hyperuricemia. All identified factors of the metabolic syndrome directly correlated with the duration of gouty arthritis.

Efficacy and Safety of Low-Dose Rasburicase in Refractory Chronic Gouty Arthritis: A Pilot Study in

W. C. Zeng1,2, Q. H. Li1, A. J. Tang1,2, H. G. Li1, L. F. Chen1, X. N. Wei1, J. L. Jiang1, D. H. Zheng1, L. Dai1, Y. Q. Mo1,2,3,4,5 Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Department of Rheumatology, Guangzhou, China; 2Shenshan Medical Center, Memorial Hospital of Sun Yat-sen University, Department of Rheumatology, Shanwei, China

Background: Recombinant uricase such as pegloticase are indicated for chronic gouty arthritis who have failed to achieve serum urate level <300μmol/L even though receiving conventional urate-lowering drugs. Rasburicase which is currently approved at a dosage of 0.2mg/kg/d for 5 days for the prevention of tumor lysis syndrome in pediatric patients with hematological tumors, is the only available uricase in China at present.

Objectives: To evaluate the efficacy and safety of low-dose rasburicase in refractory chronic gouty arthritis.

Methods: We retrospectively collected data of 17 patients with refractory chronic gouty arthritis who were treated with rasburicase from January 2021 to September 2021 at Sun Yat-sen Memorial Hospital, Sun Yat-sen University. The refractory chronic gouty arthritis was defined as serum urate level was still more than 300μmol/L and dual-energy CT showed the volume of urate more than 10 cm³.

Results: Seventeen patients were recruited with 16 males (94%) and mean age 47±15 years old. The median gout course was 11 (6.5, 15) years with gout flares number 20 (11, 36) times in the previous year. At week 0 before the rasburicase add-on treatment, the mean serum urate was 652±94μmol/L and the median urate volume was 44 (21, 251) cm³ (Table 1). At urate level after the rasburicase add-on treatment was significantly decreased than that before the treatment either at week 0, week 4, or week 8 (Figure 1A, all p<0.001). The median reduction of serum urate was 585 (446, 821) at week 4, 214 (57, 373) at week 8, and 118 (21, 185) at week 12 (all p<0.017). Five cases (29%) showed serum urate lower than 300μmol/L at week 12. (Figure 1B–D). The median volume of urate reduction was 24 (12, 60) cm³ (p<0.001) and the median percentage of urate reduction 42% (25%, 66%). Urate reduction volume was positively correlated with baseline urate volume (r=0.890, p<0.001), while the percentage of urate reduction volume negatively correlated with baseline urate volume (r=−0.689, p=0.002). (3) Rasburicase was generally well tolerated. No gout attack occurred on the basis of intravenous methylprednisolone 20mg before each rasburicase add-on treatment and oral colchicine 0.5mg/d to 1mg/d. No hypersensitive reaction occurred during the treatment. Phlebitis occurred in a patient (6%), while dizziness and nausea occurred in two patients (13%). One patient (6%) who was suffering chronic kidney disease of stage 3 developed acute kidney injury after rasburicase injection at week 0 and week 8, but the serum creatinine spontaneously returned to the baseline level during follow-up.

Conclusion: This pilot study shows rasburicase is well tolerated in patients with refractory chronic gouty arthritis and may be a reasonable option to effectively lower the urate burden of these patients, although this is an off-label use. Further prospective randomized controlled studies to verify the efficacy and safety are needed.

Funding: This study was funded by Yat-sen Clinical Research Project.

AB1058

IS HYPERURICEMIA ASSOCIATED WITH TYPE 2 DIABETES DEGENERATIVE COMPLICATIONS?

F. Fhima1, N. El Amri1, D. Khalifa1, A. Ben Abdellah2, B. Ben Abdallah2, S. Latou1, K. Baccouche1, E. Bouajina1, K. Ach2, Farhat Hached Hospital, Rheumatology Department, Sousse, Tunisia; 2Farhat Hached Hospital, Endocrinology and Diabetes Department, Sousse, Tunisia

Background: Prevalence of hyperuricemia (HU) is constantly increasing around the world and HU is now identified as an independent cardiovascular risk factor.

Objectives: To determine the prevalence of HU in patients with type 2 diabetes (T2D) and to identify degenerative complications of T2D associated with HU.

Methods: A cross-sectional descriptive study was conducted in the rheumatology and endocrinology departments of Farhat Hached University Hospital of Tunisia over a period of 6 months. Patients diagnosed with T2D according to the 2021 guidelines of the American Diabetes Association were included.

Results: One hundred fifty-one patients were included. Sex ratio F/M was 1.4. The median of age was 61 years. The prevalence of HU was 17.2%. Only 6% of patients had gout. Degenerative complications of T2D were encountered in 74.2% of cases. Diabetic neuropathy was the most common (51.7%) and was significantly associated with HU (p=0.049). Diabetic nephropathy was reported in 38.4% of patients and was also associated with HU (p=0.008). HU was associated with renal failure (p<0.01), microalbuminuria (<0.01), proteinuria (<0.001) and history of ischemic stroke (p=0.048). Diabetic feet problems were reported in 16.9% of patients and were associated with HU (p=0.008).
were examined at an outpatient appointment. Against the background of treatment with allopurinol and meloxicam.

**Conclusion:**
The course of treatment with allopurinol and meloxicam.

**POSSIBILITIES OF COMBINED THERAPY FOR TREATMENT OF HYPERURICEMIA AND ARTICULAR SYNDROME EXACERBATIONS IN PATIENTS WITH GOUT**

V. Tsurko1, M. Gromova1, O. Kisliak1, N. Malyheva1; 1Pirogov Russian National Research Medical University (Pirogov Medical University), Department of Faculty Therapy of the Medical Faculty, Moscow, Russian Federation

**Background:**
Throughout the year 69 per cent of patients with gout experienced repeated exacerbations during therapy aimed at reducing urate levels. Prevention of arthritis exacerbations with low-dose NSAIDs should be done in the first 3-6 months of urate-reducing therapy.

**Objectives:**
To assess the frequency of exacerbations and quality of life in patients with gout after a 12 weeks course of urate-reducing therapy with allopurinol in combination with the anti-inflammatory drug meloxicam for the prevention of gout exacerbations.

**Methods:**
Physical examination, clinical blood, urine tests, biochemical blood tests, instrumental diagnostics were performed in all patients. Information about concomitant diseases was entered, drug therapy was recorded at the time of observation. Allopurinol was administered orally, once a day. Every 3 weeks under the control of serum uric acid levels (sUA), the allopurinol dosage was increased by 50 mg, up to 300mg per day. The total daily dose of meloxicam administered in different dosage forms was 75-15mg. After 3, 6, 9 and 12 weeks, the clinical efficiency of treatment was assessed using the EuroQol-5D-5L questionnaire, physical examination, joint pain dynamics at rest, during movement and palpation, as well as the Likert scale and visual analog scale (VAS) in mm. Factors such as the presence of anxiety or depression, self-care ability, normal daily activities of daily living were taken into account, as well as their rating of their level of satisfaction with the treatment on a scale of 1 to 5. Where 1 is not an improvement but a deterioration and 5 is a very good result. Both the period of remission and the time before the onset of a recurrence of gouty arthritis were taken into account, as well as adverse events (AEs) were recorded.

**Results:**
143 patients with an established diagnosis of gout (ACR/EULAR, 2015) were examined at an outpatient appointment. Against the background of treatment with meloxicam 7,5mg per day, more than two-thirds of the patients did not experience a worsening of the joint syndrome with an increase in the dose of allopurinol to 300mg per day. By the 12th week of follow-up, it was found that the characteristic features of gouty arthritis significantly began to differ in improving mobility, self-care, habitual daily activities, reducing soreness, reducing anxiety and depression (p <0.05). Moreover, the initial ESR and sUA levels were significantly different from the follow-up endpoint (p < 0.05), indicating a positive effect on the inflammatory process. A three-month course of combination therapy did not cause a significant increase in blood pressure or change in serum creatinine clearance in the patients. From the gastrointestinal tract there were no adverse events. 90.9% of patients assessed the treatment efficiency as very good. AEs in the form of an allergic skin rash were observed in one patient. But there was no need to interrupt the treatment, as the rash completely disappeared without consequences after completing the course of treatment with allopurinol and meloxicam.

**Conclusion:**
A 12-week combination therapy with allopurinol, a urate-reducing drug, and meloxicam, an anti-inflammatory drug, prevents exacerbation of joint syndrome and improves quality of life in patients with gout.

**LONG-TERM DISABILITY SECONDARY TO CRPS-1: RETROSPECTIVE MONOCENTRIC STUDY ON 106 CASES.**

C. Criotl1, F. Zucchi1, M. Manara1, R. Caporalil1, M. Varenna1; 1ASST Gaetano Pini-CTO, Department of Rheumatology, Milan, Italy; 2University of Milan, Department of Clinical Sciences & Community Health, Milan, Italy

**Background:**
Complex regional pain syndrome type-1 (CRPS-1) is a severely disabling pain syndrome characterized by sensory and vasomotor disturbance, swelling, and functional impairment. Persistence of signs and symptoms has been observed in up to 64% of cases until 5.8 yrs after the onset of manifestations. Long-term disability, such as irreversible functional limitation, has been reported in up to 28% of cases with severe consequences on workability. No scores are validated to evaluate residual disability. Bisphosphonates have the best efficacy profile, compared with other therapeutic approaches, but data on long-term effectiveness are lacking.

**Objectives:**
To retrospectively evaluate long-term residual disability in patients with CRPS-1 of hand or foot after treatment with IV Neridronate (IVNer). To identify predictors of residual disability. To quantify disease outcomes, such as patient’s subjective perception and residual pain. To assess long-term safety profile.

**Methods:**
We retrospectively collected data of patients affected by CRPS-1, treated with IVNer, referred to a tertiary Rheumatology Centre between Feb 2013 and Dec 2020. Visual analogue scale (VAS) and McGill Questionnaire (McGQ) were used for pain assessment. Disabilities of the Arm, Shoulder and Hand (DASH) and American Orthopaedic Foot and Ankle Society’s (AOFAS) ankle-hindfoot scale for hand and foot involvement, respectively, were administered to explore disability through a phone survey. This kind of investigation was preferred for Covid pandemic.

**Results:**
106 patients with definite diagnosis of CRPS-1 were included, mean age ±standard deviation 55.6±13 yrs, 67% females, mean follow up duration 56.3 months (range 14-94), 46.2% with hand involvement. The mean VAS score before treatment onset was 55.8±23.4mm, while the McGQ was 12.9±6.7 in the sensory domain, 4.9±3.3 in the affective domain and 17.8±9.2 on the total score. Based on the patient’s subjective perception and the proposed semi-quantitative scale, 77.4% described themselves as fully recovered (FR), 15% partially recovered (PR), and 7.6% with persistent disease (PD). Comparison between baseline and follow-up VAS shows a significant reduction (55.8±23.4 vs 15.1±26.4, p<0.0001). Pain assessment by McGQ showed a significant improvement in global score (baseline vs follow-up 17.8±9.2 vs 3.9±7.8, p<0.0001), sensory (12.9±6.7 vs 2.7±5.7, p<0.00011) and affective (4.9±3.3 vs 1.2±2.3, p<0.00001) domains. According to DASH score, 79.2% of the patients were FR, 3.8% had some difficulties, but with overall preserved use of the upper limb, and 17.0% had permanent functional disability. According to AOFAS ankle-hindfoot scale 76.4% of patients were FR, 16.0% had partial recovery, and 7.6% had severe functional impairment. Percentages of DASH and AOFAS scores showed a complete accordance with patients’ subjective perception (Figure 1a and b). The only predictor of long-term functional impairment for CRPS-1 in the hand was a delayed treatment compared to symptoms onset (p=0.02). No predictors were found for foot localization. No patients reported the occurrence of osteonecrosis of the jaw or atraumatic fractures/atypical fracture features.

**Figure 1.**

**Conclusion:**
IVNer maintained a good long-term effectiveness and safety profile in the treatment of CRPS-1. The effectiveness of IVNer is maintained on both pain symptoms and function, in terms of reductions in the VAS, McGQ and in hand and foot disability scores.

**DOI:**
Background: Hypertrophic osteoarthropathy (HOA) is characterized by several clinical findings, including arthralgia/arthritis, periostitis, and digital clubbing. It can occur as a congenital condition called pachydermoperiostosis, and more commonly, as a secondary manifestation of pulmonary or extrapulmonary diseases or malignancy. Genomic studies support the role of prostaglandin E2 (PGE2) in the pathogenesis of primary HOA, with mutations in the 15-hydroxyprostaglandin dehydrogenase encoding gene resulting in increased PGE2 levels.

Objectives: To analyse the clinical characteristics, comorbidities, and the potential role of PGE2 in primary and secondary forms of HOA and/or clubbing and also evaluate the clinical evolution of these patients.

Methods: Eighteen patients (10 men/8 women) aged 15 to 78 years (49.9 ± 15.6) diagnosed with clubbing and/or HOA were attended in our Rheumatology Department over an 11-year period. We reviewed the clinical characteristics of the patients, including associated comorbidities, image findings, bone turnover markers (BTM), and serum and urinary levels of PGE2, among others. Additionally, we evaluated the treatment and the clinical evolution of these subjects.

Results: Most patients presented associated clinical conditions for HOA and/or clubbing, with only one, the youngest (15 years old), having primary HOA (pachydermoperiostosis). Pulmonary disorders were the most frequent associated conditions, with interstitial lung disease (4 cases), COPD (3 cases), and lung cancer (4 cases) being the most frequent, followed by liver diseases including primary biliary cirrhosis (1 patient), liver cirrhosis (2 patients) and chronic hepatitis C virus (2 patients). All the subjects evaluated (15/18) presented increased urinary PGE2 levels (the highest being observed in primary HOA), with most also presenting increased serum PGE2 values. BTM were evaluated in most subjects (17/18) showing increased values in most (11/17), particularly in PNP and Ctx. 4 patients were treated with selective inhibitors of cyclooxygenase-2 (COX-2) presenting, when evaluated, a small decrease in urinary PGE2 titers and partly improving their symptoms, which clearly improved after treating the associated cause when possible.

Conclusion: In the present series, all subjects with primary or secondary HOA and/or clubbing presented markedly increased PGE2 values, particularly in urine, supporting the role of this agent in the etiopathogenesis of this disorder. Pulmonary disorders, including malignancy and liver diseases, constituted the most frequent associated conditions. The use of COX-2 seems to be an effective symptomatic therapeutic approach in this entity.

**EVALUATION OF THE EFFECTIVENESS OF GOUT THERAPY IN OUTPATIENT PRACTICE**

A. Sarapulova1, O. Teplyakova2, 1USMU Outpatient Therapy, Yekaterinburg, Russian Federation; 2USMU Outpatient Therapy, Yekaterinburg, Russian Federation

Background: gout is a socially significant pathology, as it affects men of working age and is associated with the development of cardiovascular diseases. Meanwhile, according to studies, most patients with gout do not reach the target values of uric acid (UA).

Objectives: to evaluate the effectiveness of gout therapy in real clinical practice and to identify factors that improve this indicator.

Methods: the study included patients with an established diagnosis of gout (according to ACR/EULAR criteria). Depending on the stage of the disease, patients were prescribed symptomatic anti-inflammatory therapy, and urate-lowering therapy (UST) - allopurinol or febuxostat - to reduce the level of UA. The dosage of allopurinol in the first 2 months of admission was 300 mg/day and then adjusted depending on the level of UA, the dosage of febuxostat was 80 mg, adjusted to 120 mg if necessary. To prevent exacerbation, all patients were prescribed colchicine 0.5-1.0 mg/day for up to 6 months. After 2 and 6 months of therapy, the effectiveness of it was assessed. All patients had a conversation about the correction of risk factors (diet, alcohol intake) and recommendation to watch online educational school for patients with gout.

Results: Twenty-one of 60 patients included in the study were 46.9±9.9 years, the duration of the disease was 8.5±5.4 years, of which 96.7% were men. The mean number of exacerbation per year prior to therapy was 7.8±3.5. After 6 months of therapy, 46.7% of patients noted the absence of gout attacks, the rest - a decrease in the duration of attacks (from 10.4 to 1.6 days on average) and their intensity (the average pain during an attack on the VAS scale decreased from 7.8 points up to 3.9). The average level of UA decreased over 2 months from 541.3±146.8 to 387.4±146.9 µmol/l, and after six months of admission it was 299.6±85.5 µmol/l. The creatinine level did not change significantly and amounted to 104.7±34.9 µmol/l before therapy and 97.3±26.7 µmol/l after 6 months. None of the patients discontinued therapy due to side effects or intolerance; one of the patients experienced a slight leukopenia while taking febuxostat, which did not lead to discontinuation of the drug. It should be noted that the majority of the subjects - 56.7% - had previously consulted a rheumatologist, but most of them did not receive permanent therapy. Patients highlighted qualitative information and the effect of treatment as the most important reasons for continuing therapy.

Conclusion: This study proves that achieving the target level of UA is possible in most patients with gout, leads to a significant reduction in the number of attacks and their severity, requires educational work and patient monitoring. It is important that this work is part of a planned 2-year follow-up of patients with gout in order to determine the long-term effectiveness of therapy.

HYPURURICEMIA IN PATIENTS WITH PRIMARY HYPERTENSION: PREVALENCE AND ASSOCIATED FACTORS
N. El Amri1, F. Phima1, D. Khalfia1, A. Ben Abdelkrim2, B. Ben Abdallah2, S. Latou1, K. Baccouche1, E. Bouajina1, K. Acht2. 1Farhat Hachid Hospital, Rheumatology department, Sousse, Tunisia; 2Farhat Hachid Hospital, Endocrinology and Diabetes Department, Sousse, Tunisia

Background: Hypertension and hyperuricemia (HU) are both cardiovascular risk factors. HU is frequently associated with hypertension even without the use of treatments that potentially cause elevations of uric acid levels.

Objectives: To determine the prevalence of HU in patients diagnosed with primary hypertension and its associated factors.

Methods: A cross-sectional study was conducted in the rheumatology and endocrinology departments of Farhat Hachid Hospital of Tunisia over a period of 6 months. Patients diagnosed with primary hypertension were included. HU was defined by uric acid levels ≥ 360 µmol/L in women and ≥ 420 µmol/L in men.

Results: One hundred patients were included. Study population was mainly made up of women (65%). The median age of 63 years (min:34, max:89). The prevalence of HU was 26%. HU was more common in women (19%) compared to men (7%) without statistical significance (p=0.315). The median values of systolic and diastolic blood pressure values were 140 mmHg and 80 mmHg, respectively. Elevated diastolic blood pressure was associated with HU (p=0.043). All patients presented other comorbidities. Type 2 diabetes was the most common one (83%) followed by obesity (56.7%). Forty three percent of patients had dyslipidemia, 21% renal failure, 16.9% proteinuria, 9% gout, 8% hypothyroidism and 30% osteoarthritis. HU was significantly associated with systolic (p=0.02), diastolic (p=0.039) and proteinuria (p=0.02). HU was not associated with disturbance of lipid and glycemic status. High uric acid levels were associated with the use of thiazide diuretics (p=0.048) and ACE inhibitors (p=0.037). Nonetheless, no association was found with the use of low dose aspirin (p=0.412) nor other antihypertensive treatments.

Conclusion: Prevalence of HU is high in patients diagnosed with primary hypertension and is associated with hypothyroidism, obesity, renal failure, proteinuria and diastolic hypertension. HU is also associated with the use of thiazide diuretics and ACE inhibitors.

EARLIER ONSET OF ARTERIAL HYPERTENSION IS A RISK FACTORS FOR SEVERE COURSES OF GOUT
F. Markelova1, E. Ilinykh2, D. Karateev2, E. Luchkhina1. 1FM Vladimirov Research Clinical Institute of the Moscow Region, Rheumatology Department, 612, Shchepkina Street, Moscow, 129110, Russian Federation; 2VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, Rheumatology Department, Moscow, Russian Federation

Background: Comorbidities cardiovascular disease such as arterial hypertension (AH) are common in people with gout and complicate its management and treatments that potentially cause elevations of uric acid levels.

Objectives: Our purpose was to evaluate the effect of AH on the severity of gout.

Methods: We included data of 286 male patients with gout: median (Me) age 51.2 [interquartile range (IR) 42.6;59.4] years (ys), disease duration – Me 6.2 [IR 3.8;12.1] ys, number of joints involved during disease course – Me 7 [IR 4;12], subcutaneous tophi – in 35% pts, intraosseous tophi – in 44% pts. All pts were made of women (65%). The median of age was 63 years [min:34, max:89]. The prevalence of HU was 26%. HU was more common in women (19%) compared to men (7%) without statistical significance (p=0.315). The median values of systolic and diastolic blood pressure values were 140 mmHg and 80 mmHg, respectively. Elevated diastolic blood pressure was associated with HU (p=0.043). All patients presented other comorbidities. Type 2 diabetes was the most common one (83%) followed by obesity (56.7%). Forty three percent of patients had dyslipidemia, 21% renal failure, 16.9% proteinuria, 9% gout, 8% hypothyroidism and 30% osteoarthritis. HU was significantly associated with systolic (p=0.02), diastolic (p=0.039) and proteinuria (p=0.02). HU was not associated with disturbance of lipid and glycemic status. High uric acid levels were associated with the use of thiazide diuretics (p=0.048) and ACE inhibitors (p=0.037). Nonetheless, no association was found with the use of low dose aspirin (p=0.412) nor other antihypertensive treatments.

Results: One hundred patients were included. Study population was mainly made up of women (65%). The median age of 63 years (min:34, max:89). The prevalence of HU was 26%. ASYMPTOMATIC HYPERURICEMIA AND ASSOCIATED FACTORS IN MALE PATIENTS VISITED HANOI MEDICAL UNIVERSITY HOSPITAL

T. Pham1, H. T. Pham1, T. H. Pham1, G. Trân1, T. Nguyễn1, T. Đỗ1, 1Hanoi Medical University Hospital, Rheumatology Unit - Internal Medicine Department, Hanoi, Vietnam

Background: Asymptomatic hyperuricemia prevalence in Vietnamese men has rose over the past several years. This leads to gout and increase cardiovascular risk. 

Objectives: To assess the prevalence of asymptomatic hyperuricemia and associated factors in male patients who had medical check-ups in Hanoi Medical University Hospital.

Methods: All asymptomatic hyperuricemia male patients over 18 years old, had medical check-ups in outpatient clinics from January 2020 to May 2021. Exclude criteria included patients having medicine which affected serum uric acid (allopurinol, probenecid, sulfinpyrazone, salicylate, phenylbutazone, ascorbic acid, ethambutol, pyrazinamide, etc.), had acute diseases, diabetes type 1, chronic kidney disease and malignancies. All patients were tested for serum uric acid, total Cholesterol, Triglyceride, HDL-C, LDL-C and fasting serum glucose using Roche Cobas 6000 analyzer. Age, body mass index, alcohol consuming, physical activities and comorbidities were identified.

Results: 798 male patients over 18 years old were included in the study. Mean age was 39.5 ± 11.2, overweight and obesity rate was 31.5% and 29.8%, respectively. 41.4% patients had hyperuricemia with mean serum uric acid was 405.2 ± 81.2 μmol/l (highest was 820 μmol/l). We found that the factors associated to hyperuricemia in men were: the presence of hypertension (OR 1.64, 95% CI 1.12-2.4), obesity (OR 2.16, 95% CI 1.6-2.6). We did not find association between smoking, physical activities, impaired glucose tolerance with hyperuricemia.

Conclusion: Alcohol consuming, dyslipidemia and hypertension were associated with higher risk of incident asymptomatic hyperuricemia in Vietnamese men.

HIGH FREQUENCY OF STRUCTURAL DAMAGE IN THE LOWER SPINE OF PATIENTS WITH CHONDROCALCINOSIS

K. Klavdianou1, J. Kasfeld1, M. Fruth2, S. Tsiarni1, J. Braun1, P. Sewerin1, D. Kiefer1, X. Baralakos1, 1Rheumazentrum Ruhrgebiet Heme, Ruhr-University Bochum, Heme, Germany; 2Asklepieion General Hospital, Department of Rheumatology, Volua, Athens, Greece; 3Bilik, Radiologie, Heme, Germany

Background: Calcium pyrophosphate dihydrate crystal deposition disease (CPPD, chondrocalcinosis) is known to affect fibrocartilaginous tissue in the large and smaller peripheral joints. The affection of similar structures in the axial skeleton is unclear.

Objectives: To assess the frequency and severity of structural changes in the lower spine in patients with established CPPD in comparison to degenerative disc disease (DDD).

Methods: In a retrospective study, patients with CPPD or DDD as a main diagnosis with available spinal conventional radiographs (CR) performed during 2014 – 2020 were included. Define other inflammatory conditions affecting the spine were excluded. The CR segments T7-L5/L6 were evaluated for the occurrence of disc calcification, intradiscal vacuum phenomena, disc height (normal, narrow, complete loss), endplate erosion, osteophytes and spondylolisthesis. When lumbar spine MRIs of the same time point were available, discovertebral units were evaluated for the occurrence of vacuum phenomena, endplate erosion, Modic changes and disc dehydration (Pfirrmann). Follow up CR were assessed if available. All available images were evaluated by 2 independent readers and discrepancies were solved by consensus.

Results: CR of 140 patients (1.171 discovertebral units) with CPPD and 99 DDD (803 discovertebral units) were evaluated (mean age 74.4±9.7 and 71±6.2; 20% vs. 20.2% males, respectively). MRIs of the spine were available from 48 CPPD and 44 DDD patients. Vacuum phenomena, disc calcification, osteophytes and erosion were significantly more frequently seen in patients with CPPD compared to DDD (Table 1) with no differences between the thoracic and the lumbar spine. Follow-up CR were available for 29 patients with CPPD and 48 DDD. Both groups presented statistically significant progression of endplate erosions and osteophytes (p=0.001 - 0.02 for both groups). Notably, even though CR follow-up times in the CPPD group were, compared to DDD (median (IQR) 1.9 (2.4) vs 3.0 (3.1) years, p=0.033, respectively), shorter, radiographic progression was noted more frequently in CPPD vs. DDD for erosive changes (6.8% vs. 0.6%, p=0.018) and disc calcification (9.8% vs. 0.6%, p=0.007), respectively. When comparing MRIs, a higher number of discovertebral units was affected by vacuum phenomena (34 vs 13, p=0.04) and endplate erosions (L4/S 45.5% vs 24.4%, p=0.04), L5/S 1(40.4% vs 19.5%, p=0.03) in patients with CPPD vs. DDD, respectively.

Table 1. Frequency of affected discovertebral units on conventional radiographs

CPPD: calcium pyrophosphate dihydrate crystal deposition disease DDD: degenerative disc disease

Conclusion: Patients with chondrocalcinosis showed more severe and progressive degenerative findings in the lower spine as assessed by both, CR and MRI, even more in comparison to established DDD. This data shows that disease manifestations of CPPD in the axial skeleton are clinically relevant.

Disclosure of Interests: None declared

URIC ACID LEVELS IN RELATION TO FASTING BLOOD GLUCOSE AND HBA1C

F. Fhima1, N. El Amri1, D. Khalfi1; A. Ben Abdedkrim2, S. Latoula1, B. Ben Abdallah1, K. Baccouche1, E. Bouajina1, K. Ach1, 1Farhat Hached Hospital, Rheumatology Department, Sousse, Tunisia; 2Farhat Hached Hospital, Endocrinology and Diabetes Department, Sousse, Tunisia

Background: Hyperuricemia is reported to be a risk factor for the development of type 2 diabetes (T2D) and prediabetes.

Objectives: To determine the prevalence of HU and gout in T2D and prediabetes and to study the relationship between HU, gout, T2D and prediabetes.

Methods: A cross-sectional study was conducted between January 2021 and June 2021 in the Rheumatology and endocrinology departments of Farhat Hached Hospital. Patients who fulfilled the diagnosis of diabetes or prediabetes according to the American Diabetes Association guidelines of 2021 were included. Uric acid levels were also assessed and HU was defined as uric acid levels ≥ 360 μmol/l in women and ≥ 420 μmol/l in men. Diagnosis of gout was based on the ACR/EULAR 2015 classification.

Results: One hundred fifty-one patients having T2D and 46 prediabetic patients were included. The mean age of both groups was 61 and 54 years respectively. Prevalence of HU was 26.1% in prediabetic while it was 17.2% in the group of T2D with no statistical relevance (p=0.182). No difference related to gender was observed in both groups. The prevalence of gout was higher in the prediabetes group (15.2%) compared to the T2DM group (6%) but without significant difference (p=0.082). Uric acid levels were remarkably higher in prediabetic patients (mean=324.3 μmol/l) compared to patients having T2D (median=278 μmol/l) with a significant statistical difference (p=0.022). No association was identified between HU, fasting blood glucose and HbA1C in the two groups. However, uric acid levels are inversely proportional to fasting blood glucose (p=0.001) and HbA1C (p=0.001) in both patients.

Conclusion: Individuals with moderately elevated HbA1C and fasting glucose levels (prediabetes) may be at a higher risk of HU, whereas individuals with diabetes or elevated HbA1C levels may have a normal uricemia. This could be explained by the GLUT-9 transporter regulation in the renal proximal tubule that blocks the absorption of uric acid when glycosuria is present.

Infection-related rheumatic diseases

**AB1070** INFECTIOUS SACROILIITIS: A RARE ENTITY IN RHEUMATOLOGY!

S. Rekić1, O. Hamdi1, S. Bousaid2, S. Rahmouni3, S. Jemmali1, H. Sahli1, M. Elleuch1, 1La Rabta hospital, Rheumatology, Tunisia, Tunisia

**Background:** Infectious sacroiliitis (ISI) is a rare disease, with misleading clinical symptoms that often delay the diagnosis.

**Objectives:** The aim of this study was to describe the clinical, microbiological, therapeutic and radiological characteristics of ISI.

**Methods:** This descriptive, retrospective study included all ISI patients that were hospitalized in our rheumatology department over an 11-year period [2010 - 2021].

**Results:** Overall, 25 cases of ISI were identified, comprising 15 men (60%) and 10 women (40%), with a mean age of 48.7±10.5 years [21-67]. ISI was caused by pyogenic microorganisms in 12 cases (70.5%), mycobacterium tuberculosis in 7 cases (41.2%), and brucella spp in 6 cases (35.3%). The mean symptoms duration in pyogenic, brucellar and tuberculous ISI was 42 days, 67 days, and 255 days, respectively. The onset was brutal in 88% of pyogenic ISI, while it was progressive in 66% of brucellar ISI and in all cases of tuberculous ISI. Lumboischialgia pain was the most common symptom (80%). The involvement of the sacroiliac joint was always unilateral, and inflammatory in 92% of cases. The other most common symptoms included: fever (80%), impotence (68%), and lumbago (52%). An infectious source was found in 17 patients: 41.2% pulmonary (tuberculosis, n=7), 29.4% urinary, 17.6% gynecological (postpartum, n=3), and 11.7% septicemic (n=2). Fifteen patients (60%) had a biological inflammatory syndrome. Leukocytosis was found in 11 cases (64.7%). Pelvic x-ray showed a narrowing of the sacroiliac joints in 52% of cases. CT of the sacroiliac joints showed erosions in 60% of cases. Sacroiliac MRI showed erosions (45%), joint effusion (32%), and psosas abscess (14%). A second infectious site was found in 20% of cases: psosas abscess (n=2), and a collection of the soft tissues facing the joint (n=1). A pathogenic agent was isolated by means of blood culture (48%); staphylococcus aureus 56%, streptococcus 28%, and staphylococcus with negative coagulase 16%), articular biopsy (40%), cytobacteriological examination of urine (20%), Wright serology (20%), and Tuberculin skin test (6.2%). All patients received germ-adapted antibiotics. No patients have had surgical treatment. Evolution was favorable in most cases (n=11). Four patients complained of residual pain in the sacroiliac region. None of the patients relapsed.

**Conclusion:** Although ISI is rare, it remains an emergency diagnosis. A rigorous physical examination is essential in order to detect this infection early. Antibiotics often lead to clinical improvement, making thus the need for surgery exceptional.

**DOI:** 10.1136/annrheumdis-2022-eular.177

**AB1071** INFECTIONS IN RHEUMATOLOGIC PATIENTS IN A LATIN AMERICAN HOSPITAL: A 10-YEAR COHORT STUDY.

L. Dulcey1, J. Theran2, R. Callagrione1, H. Moreno1, J. Pineda1, R. Parales2, M. Aguas3, 1Los Andes University, Internal Medicine, Bucaramanga, Colombia; 2Bucaramanga University, Medicine, Bucaramanga, Colombia; 3Santander University, Medicine, Bucaramanga, Colombia

**Background:** Infections have been indicated to be the cause and / or consequence of the calving and decompensation of some Connective Tissue Diseases and, in principle, both the immunological disorder and the immunosuppressive action of medications contribute to this.

**Objectives:** To describe the frequency of infections associated with the various rheumatological pathologies in patients admitted to hospitalization and to know their associated factors.

**Methods:** A descriptive study was carried out in which 3328 medical records belonging to the patients of the Rheumatology service were reviewed during a follow-up period from January 2010 to December 2020, measures of central tendency such as mean, mode, median and applied the Chi square test to appreciate statistical value between the various variables to be correlated.

**Results:** Most of the patients were female. The main rheumatological pathology was Rheumatoid Arthritis, followed by Systemic Lupus Erythematosus, Osteoarthritis in 3 place and finally in the last box other entities other than those indicated. The main infectious were those of the urinary tract, in the second instance those of skin and soft tissues, in third place the respiratory ones and lastly those not included in the previous categories. The 2 main therapies related to infections were the use of steroids followed by biological therapy (p 0.001).

**AB1072** HERPES ZOSTER IN INDIVIDUALS WITH AUTOIMMUNE DISEASES AND RECOMBINANT HERPES ZOSTER VACCINE AS A PREVENTATIVE STRATEGY

K. Winthrop1, F. A. Ferraye2, K. M. Sullivan3, D. O. Miller4, P. Vink5, F. Tavares-Da-Silva6, 1Oregon Health and Science University, Portland, OR, United States of America; 2Inflammatory Bowel Disease Center Division of Gastroenterology and Hepatology, Mayo Clinic, Jacksonville, FL, United States of America; 3Duke University Medical Center, Durham, NC, United States of America; 4GSK Vaccines, Mississauga, ON, Canada; 5GSK
Vaccines, Rockville, MD, United States of America; 2GSK Vaccines, Wavre, Belgium

Background: Individuals with autoimmune diseases (AIDs) are particularly vulnerable to herpes zoster (HZ) and its related complications. Although the live attenuated HZ vaccine is contraindicated in many of these individuals, the two-dose non-live recombinant zoster vaccine (RZV) can be used in immunosuppressed individuals. Based on accumulating data from RZV studies within specific immunosuppressive conditions, recently updated guidelines recommend RZV not only in immunocompetent adults aged ≥50 years, but also in adults aged ≥18 years (EU)/≥19 years (USA) at risk of HZ due to immunodeficiency or immunosuppression.1

Objectives: To evaluate the burden of HZ in individuals with AIDs and the use of RZV as a preventive strategy.

Methods: We reviewed PubMed for available data on HZ incidence, summarised RZV data (effectiveness and safety) and the current recommendations for RZV in individuals with AIDs. The latest search was conducted in September 2021.

Results: HZ incidence in the general population is 4–7/1000 person-years (increases with age) and 8–15/1000 person-years in individuals with AIDs. Common immunosuppressive and immunomodulatory therapies can predispose individuals to HZ, as shown by large meta-analyses of interventional and observational studies. No published randomised controlled trial data of RZV in AID populations were found in our search. In two retrospective cohort studies in patients with inflammatory bowel disease (IBD),1,2 RZV demonstrated high vaccine effectiveness (OR 0.84; 95% CI 0.44, 0.77).2 In a real-world observational study investigating RZV in beneficiaries of the Medicare national health insurance program in the USA, individuals with AIDs achieved vaccine effectiveness of 68.0% (95% CI 62.3%, 72.8%), which was similar to the overall population (70.1% [95% CI 68.6%, 71.5%]).3 In two single-centre, retrospective studies of RZV in individuals with AIDs, including rheumatoid arthritis (RA), adverse events after the first RZV dose were mild to moderate, with a flare at the first RZV dose was significantly associated with an increased risk of a flare at the second dose (hazard ratio 3.9; P=0.005).4 In addition, glucocorticoid use during vaccination was significantly associated with flares (odds ratio [OR] 2.31; P=0.004; Lenfant, 2021).5 In a study of individuals with IBD, receiving ≥1 RZV dose was associated with a low flare rate.6 Current RZV guidelines vary by country and will be revised as new data emerge. Ongoing studies include phase 4 studies of individuals with RA and IBD receiving immunotherapies, and a study investigating the immunogenicity and safety of RZV in individuals with stable systemic lupus erythematosus.

Conclusion: Individuals with AIDs are at increased risk of HZ and its related complications, which may be due to either or both of their underlying condition and the treatment(s) they are receiving. The developing collective scientific evidence from the published literature on RZV in individuals with AIDs demonstrates a favourable benefit:risk profile for RZV in this population which contributed to the recent USA ACIP recommendation. Further studies are warranted to evaluate potential effects of individual conditions and immunotherapies on vaccine efficacy and methods to optimise vaccine use.

Conclusion: As a complementary approach to conventional methods, mNGS could help improving the identification of infection in CTD patients. The incidence of viral infection is high in patients with connective tissue disease and close attention should be paid to it in clinical works.

PNEUMOCYSTIS JIROVECCI PNEUMONIA (PJP) IN PATIENTS WITH AUTO-IMMUNE INFLAMMATORY RHEUMATIC DISEASE (AIIRD) IN ONE YEAR.

A. Escudero Siosi1, M. Andersson2, C. Woodrow3, S. Dubey1.1Oxford University Hospitals NHS Foundation Trust, Infection Disease & General Medicine, Oxford, United Kingdom; 2Oxford University Hospitals NHS Foundation Trust, Rheumatology, Oxford, United Kingdom; 3Oxford University Hospitals NHS Foundation Trust, Infectious Diseases and Microbiology, Oxford, United Kingdom

Background: Pneumocystis jirovecii pneumonia (PJP) is an uncommon but frequently fatal fungal infection, which can affect patients with rheumatic diseases treated with immunosuppressants or high doses of steroids. There are no clear guidelines on when to prescribe primary prophylaxis and available agreements differ depending on the disease or immunosuppressant.

Objectives: To raise awareness about this preventable infection and to highlight the urgent need to create a tailored probability scoring, before starting any immunosuppression so that the risk benefit of prophylaxis can be objectively assessed.

Methods: This is a retrospective case series of six patients who developed definite or probable PJP known to the Rheumatology Department at Oxford University Hospitals NHS FT since the beginning of 2021. These patients were identified through the microbiology and infectious disease teams, and notes were reviewed to collate data regarding the clinical characteristics. Of these, five were being treated for large vessels vasculitis (LVV) whilst the other one had seropositive rheumatoid arthritis (RA). The diagnosis of PJP was made on clinical picture, laboratory results, bronchoscopy and CT findings.

Results: In this series, the median age was 78 years (range 55-93) with equal gender distribution. In three LVV patients, the diagnosis was confirmed on ultrasound, one had a positive PET-CT whilst the other case had a high probability clinical diagnosis. Comorbidities included chronic kidney disease and hypertension in three patients, diabetes, or previous underlying malignancy in other two. Smoking history was present in four patients, while five patients had lymphopenia with counts <1x10^9/L. Four of the six cases were on combined therapy with disease modifying anti-rheumatic therapy drugs (DMARDs) and prednisolone, only one was exclusively on prednisolone and the patient with RA was on Methotrexate and Humira. The chronology of the infection was variable, still most of the patients developed PJP infection during the first three months of starting either a biological or corticosteroids. The median steroid dose by the time of PJP infection was 30mg and unfortunately three of the patients died. None of the patients who developed PJP had been given antibiotic prophylaxis prior to infection. Some proposed scoring systems for serious infection risk in patients with AIIRD exist, however they focused on RA or biologics use rather than patients with vasculitis or connective tissue disorders who might be on high dose corticosteroids. Additionally, PJP prophylaxis is not recommended in any of the current guidelines for LVV management (BSR, EULAR, ACR). Cochrane review suggests reduction of risk by 85% in patients given prophylaxis.

Conclusion: Pneumocystis jirovecii pneumonia (PJP) prophylaxis is not current practice for patients with large vessel vasculitis. Consideration needs to be given to PJP prophylaxis for patients on high dose steroids for a prolonged period, particularly in the presence of other risk factors. More data will be needed to help establish guidelines on PJP primary prophylaxis.

Conclusion: Disease inflammatory cascades along with ongoing usage of immunosuppressive agents could affect results of QFT-plus assay in rheumatic diseases. TB2 tubes stimulating CD8(+) T lymphocytes have additional impact in detecting latent TB infection in patients with RA and SpA.

**AB1078** SPECTRUM OF INFECTIONS DURING RHEUMATOID ARTHRITIS

S. Rekik¹, S. Boussaid¹, H. Thini¹, S. Rahmouni¹, S. Jemmali¹, K. Zouaoui¹, H. Sahli¹, M. Elleuch¹.¹Tunis, Department of Rheumatology, La Rabta hospital, Tunis, Tunisia

**Background:** Immunosuppression during rheumatoid arthritis (RA) induced by the disease but especially immunomodulatory treatments, is responsible for an increased frequency of infections in these patients.

**Objectives:** The purpose of this study is to assess the incidence of infections during RA and to determine their nature and management.

**Methods:** A retrospective study over a period of 10 years, including 150 patients with RA. We identified 33 patients who had at least one infectious episode during their follow-up.

**Results:** There were 19 women and 14 men. The mean age was 51 years old [39-63]. RA was immunopositive and erosive in all cases. The average disease duration was 8 years. A comorbidity was associated with RA in 14 patients (42%): diabetes in 7 cases, hypertension in 3 cases, ethylism in 2 cases and history of pulmonary tuberculosis in 2 cases. As an extra-articular manifestation, 15% of patients had Sjogren's syndrome and 18% had uveitis associated or not with radiculalgia. Inflammatory pain was reported in 13 cases, pain associated or not with radiculalgia. Inflammatory pain was reported in 13 cases, pain associated or not with radiculalgia.

**Conclusion:** Elderly patients with infectious spondylodiscitis have fewer clinical symptoms leading to a delayed presentation. Increasing morbidity and mortality make rigorous monitoring necessary.

**AB1080** BRUCELLAR SPONDYLODISCITIS: EPIDEMIOLOGICAL, CLINICAL AND BIOLOGICAL ASPECTS

S. Rekik¹, S. Boussaid¹, H. Thini¹, S. Jemmali¹, S. Rahmouni¹, K. Zouaoui¹, H. Sahli¹, M. Elleuch¹.¹Tunis, Department of Rheumatology, La Rabta hospital, Tunis, Tunisia

**Background:** Brucellosis is a systemic infection characterized by significant clinical polymorphism and non-specific manifestations. The spine is a common location for brucellosis.

**Objectives:** The aim of this study was to describe the epidemiological, clinical and biological characteristics of brucellar spondylodiscitis.

**Methods:** A retrospective study over a period of 15 years, including 18 patients diagnosed with brucellar spondylodiscitis on clinical, biological and/or imaging data.

**Results:** Eighteen cases were collected (13 men and 5 woman). The mean age was 52 years [19-76]. The main symptom was unifocal or diffuse spinal pain associated or not with radiculargia. Inflammatory pain was reported in 12 cases. Thirteen patients consumed raw milk, eleven had contact with farm animals or professional exposure. The average duration of symptoms was 5.7 months [0.5-12]. The disease had a progressive onset in 13 patients. The general signs were frequent: deterioration of general condition (13 cases), fever (12 cases) and night sweats (6 cases). All patients had a biological inflammatory syndrome. Wright’s serology, performed in 17 patients, was positive in 15 cases. The Rose Bengal test was positive in 13 of the 15 patients tested. Diagnosis by indirect immunofluorescence, performed in 11 patients, was positive in nine cases. However, the blood cultures, carried out in 13 patients and the disco-vertebral biopsy, carried out in 9 patients, did not find the causal agent.

**Conclusion:** The diagnosis of brucellar spondylodiscitis must be based on epidemiological, clinical arguments and biological examinations. Immunological examinations, however, seem to be more contributory and should be performed in case of diagnostic doubt and negative bacteriological investigation.

COVID-19

FLARES OF RHEUMATOID ARTHRITIS FOLLOWING CORONAVIRUS VACCINATION

R. Hayward 1, Z. Farah 1. 1Northwick Park Hospital, Rheumatology Department, Harrow, United Kingdom

Background: With the emergence of the Coronavirus vaccine and the clear and important role it provides in maintaining the health of individuals and the population (1), it is important that our patients receive or are recommended the vaccine. We here document a case series of patients who have long-term quiescent rheumatoid arthritis who then experienced a flare of disease activity after receiving a vaccine. This information is important to understand as it allows informed discussions regarding the side effect profile of the vaccine and also the influence this may have on the patient’s disease control and future management options.

Objectives: To understand the changes to control of rheumatoid arthritis in those experiencing a flare of disease after receiving the coronavirus vaccine.

Methods: Patients were reviewed in clinic as part of standard care. Individuals with Rheumatoid Arthritis who had experienced a flare defined as a self-reported disease activity score of >5.1 in otherwise stable disease were noted and their response to treatment reviewed. This was a review of usual clinical practice and did not alter the treatment undertaken or monitoring of the patient. Information obtained was through the consultation with a rheumatologist and the data was collected retrospectively through review of clinical notes and clinic letters.

Results: The table below outlines the patient details and treatment responses. All flares occurred within two weeks of receiving the vaccine. Of the patients who flared, two required short term steroid treatment; three an increase in the usual medications and one who had been in disease remission to re-start previous therapy. More patients in the Pfizer vaccine group required an escalation of usual care compared to the AstraZeneca vaccine group.

Table 1

<table>

<td>Re-start methotrexate, Sulfasalazine</td>
</tr>
</tbody>
</table>

Conclusion: We report 6 cases of rheumatoid arthritis flare soon after receipt of the coronavirus vaccine. In all, disease control was returned with minimal changes to treatment, 42% of those requiring either no treatment or an intra-muscular steroid injection alone. Therefore, we recommend that clinicians should counsel patients of this potential effect, but continue to advocate the vaccine, as the risk of complications to their underlying arthritis is very low and seemingly easily treatable.

AB1083 MUSCULOSKELETAL MANIFESTATIONS AND POSTCOVID SYNDROME IN HOSPITALIZED PATIENTS INFECTED WITH COVID-19

Ö. Küçülmez1, G. Genççoğ1. 1Baskent University Alanya Education and Research Hospital, Physical Medicine and Rehabilitation, Antalya, Turkey; 2Baskent University Alanya Education and Research Hospital, Nephrology, Antalya, Turkey

Background: Covid-19 may cause musculoskeletal manifestations or postcovid syndrome (1-3). Molecular mimicry, precursor activation, and immune activation are held responsible for the development of autoimmunity (4). It has been suggested that SARS-CoV-2 infection can cause blockage of lymph vessels since the virus can infect lymph endothelial cells branching to the nasal cavity and may cause postcovid syndrome (5).

Objectives: The aim of this study was to characterise the prevalence of musculoskeletal complaints, postcovid syndrome in hospitalized COVID-19 patients and relationship between clinical features and laboratory parameters.

Methods: A single-centre retrospective cohort study was conducted of patients at Baskent University between March 1 and December 31, 2020. The study protocol was approved by the Ethics Committee. Hospitalized patients aged above 18 years, diagnosed with COVID-19 via RT-PCR are included the study. Pregnant patients, those with severe end-stage disease or with missing documentation were excluded. Data were obtained from electronic health records. Information was collected about patient demographics, history and duration of complaints, history of postcovid syndrome, fever or anosmia, respiratory problems, length of stay, history of intensive care and COVID-19-related biochemical parameters and rheumatologic tests. The correlation between musculoskeletal manifestations, postcovid syndrome and laboratory and clinical parameters were observed. P value<0.05 was considered statistically significant.

Results: Totally 109 patients included to the study. %39.45 of patients were female (n=66), %60.55 of patients were male (n=43). %34.86 (n=38) of patients complained about arthralgia, %1.83 (n=2) had arthritis and %41.28 (n=45) described fatigue. Postcovid syndrome was determined in %32.11 (n=35) of patients. Positive otoantibody was determined in one patient and arthritis due to paraneoplastic syndrome was detected in a case. There was significant correlation between fever, length of stay and control CRP (p<0.05).

Conclusion: As there was no correlation between musculoskeletal manifestations, postcovid syndrome and laboratory and clinical findings. There should be further studies for understanding mechanisms of musculoskeletal manifestations and postcovid syndrome in SARS-CoV-2 infection.

AB1085 COVID-19 VACCINATION INTENTION AMONG TUNISIAN HEALTH CARE WORKERS

O. Hamel1, M. Boudokhame2, Z. Teyeb2, I. Abdellaït3, T. Jomni2, S. Belakhal2, M. H. Drogui2. 1La Rabta Hospital, Rheumatology, Tunis, Tunisia; 2FSI hospital, Internal Medicine, Tunis, Tunisia

Background: Health care workers (HCW) are the soldiers in the forefront of the fight against the coronavirus (COVID-19) pandemic. It is therefore a priority target group in the COVID-19 vaccination process.

Objectives: Our purpose was to assess the COVID-19 vaccination intentions of Tunisian HCW and the reason for fear in case of hesitancy.

Methods: We conducted an anonymous online questionnaire in the months of May and June 2021 among HCW via social networks. The data collected included demographic characteristics, vaccination intentions, and reasons of hesitancy.

Results: Five-hundred HCW were included in the study. Participants were divided as follows: 74% doctors (15% seniors, 37% juniors, 22% interns), and 26% nurses. The mean age was 34 ± 5 years [24 – 58]. Seventy-three percent of participants were female. A history of chronic illness was noted 150 HCW (30%). A psychiatric disease was noted in 105 participants (21%): anxiety disorder (62%), depression (33%), and bipolar disorder (5%). A treatment was prescribed in 63% of cases: anxiolytics (84.2%), antidepressants (16.6%), and neuroleptics (10%). Psychotherapy was prescribed in 47% of cases. A personal and family history of COVID-19 infection was noted in 50.4 and 55% of cases, respectively. The infection was mild in 91.2% of cases. Four-hundred and five HCW (81%) had the intention to get vaccinated against COVID-19. Twenty participants (4%) refused the vaccine, and 75 (15%) were still hesitant. Vaccination hesitancy was linked to concerns about the safety of a rapidly-developed vaccine in 92% of cases: adverse reactions (95.8%), tolerance (75%), and efficacy (25%). Sixteen percent of hesitant respondents expressed...
VACCINE HESITANCY AGAINST COVID-19 VACCINES IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES AND EFFECT OF SPECIALIST COUNSELLING ON VACCINE HESITANT PATIENTS WILLINGNESS TO TAKE VACCINE

K. Kunalachandwar@gmail.com1, K. Kishor1, J. Dixit1, P. Dogga1, D. Ekbot1, P. Kumar1, U. Dhakad1. 1King George’s Medical University, Clinical Immunology and Rheumatology, Lucknow, India

Background: Vaccination is one of the most significant public health achievements; however, the success has been marred with vaccine hesitancy. The reasons for vaccine hesitancy are neither singular nor straightforward and arise from a complex interplay between scientific, religious and political beliefs. This study aims to understand the possible reasons for vaccine hesitancy in patients with autoimmune rheumatic diseases and the effectiveness of Specialist counselling on vaccine-hesitant patients willingness to take the vaccine.

Objectives: 1. To assess causes of Vaccine hesitancy against COVID-19 vaccines in patients with autoimmune rheumatic diseases. 2. To study the effect of specialist counselling on vaccine-hesitant patients willingness to take vaccine.

Methods: Study design: We conducted an observational survey-based in person cross-sectional study. Patients attending a tertiary care hospital’s outpatient department were asked about their vaccination status. Those unvaccinated were asked reasons for vaccine hesitancy. The vaccine-hesitant patients were counselled by the treating rheumatologist and asked regarding their willingness to take the vaccine after the counselling. The patient responses were recorded. Sample: Convenience sampling was used, so the sample size was not calculated. Inclusion and exclusion criteria: All adults (>18yrs) with AIRD coming to the rheumatology OPD. Those vaccinated, recently infected (within 6 weeks), and non-AIRD patients were excluded. Data collection: The questionnaire included patients’ demographic details, Diagnosis, medication details, and response to the reason for vaccine hesitancy. Statistical analysis: Descriptive statistics were performed by calculating measures of central tendency for quantitative variables and using counts and percentages for qualitative and nominal variables.

Results: A total of 322 patients participated in the study with a mean age of 40 years (18-76), with 73% (234) females and 27% (88) males. Most patients had Rheumatoid Arthritis (40%) followed by SPA (27%), SLE(13%) and others (18%). Significant proportion of patients (60%) had more than one reason for vaccine hesitancy. Almost 60% of the respondents feared their disease might flare post-vaccination, while almost half (44.4%) were hesitant to take the vaccine due to the fear of vaccine side effects and more than one third (35%) feared vaccine may not be effective on them as they were on immunosuppressive medications. Other major causes of vaccine hesitancy were the inability to get a chance to get vaccinated (18%), doubts about vaccine efficacy (15%), and fear of injections (10%). Most patients (91%) were willing to take the vaccine after specialist counselling and only 28 of the 322 (9%) were unwilling even after specialist counselling.

Conclusion: Vaccine hesitancy can be multifactorial. Major reasons for vaccine hesitancy in patients with autoimmune rheumatic diseases were fear of vaccine side effects and doubts whether the vaccine would work in patients taking immunosuppressive medications. Most patients were willing to take vaccine after counselling by a rheumatologist.

Background: Considering the concerns regarding COVID-19 vaccine safety among patients with rheumatic diseases due to a lack of data, an urgent need for studies evaluating safety profiles of vaccines emerged.

Objectives: Vaccination against the coronavirus disease-2019 (COVID-19) started in March 2021 in the same group using biological therapy in our country. In this study, post-vaccine real-life data of patients with spondyloarthritides (SpA) followed up with biological therapy were analyzed.

Methods: Adult patients diagnosed with SpA who were followed up under biological therapy and vaccinated with CoronaVac inactivated SARS-CoV-2 (bNTT162b2 messenger RNA (mRNA) COVID-19 (Pfizer-BioNTech) vaccine were included in our observational, multicenter, prospective study.

Results: A total of 287 patients (58.2% male; mean age: 47) were included in the study. 202 (%70.4) of patients were being followed up with the diagnosis of AS, 40 (%13.9) of them with PsA, 32 (%11.1) of them with nr-axSpA, 11 (%3.8) of them with entropic arthritis, and 2 (%0.7) of them with uSpA. The
most common comorbidities were found to be HT (n=65; 22.6%) and DM (n=38; 13.2%). While 221 (77%) of the patients were receiving biological therapy alone, 27 (9.4%) patients were using methotrexate, 25 (8.7%) patients were using sulphasalazine, and 12 (4%) patients were using infliximab. The median duration of biological therapy was 40 weeks (19-75 IQR). The most commonly used treatment was infliximab (26.8%), adalimumab (23.3%) was the second (Table 1).

It was determined that 207 (72.1%) of the patients preferred inactivated virus vaccine, while 80 (27.9%) preferred mRNA vaccine. When the time between the biological treatment and the day of vaccination is examined, detected median time between biological treatment and the first dose of vaccination is 11.5 days (5-19 IQR), between the first dose of vaccination and biological treatment is 14 days (7-21 IQR), between treatment and the second dose of vaccine is 14 days (5-23.5 IQR), and between the second dose of vaccine and the next biological treatment is 12.5 days (7-15 IQR). While 25 (8.7%) of the patients had COVID-19 infection before vaccination, 7 (2.4%) patients were found to have COVID-19 after vaccination (p<0.001). While two of the patients who had COVID-19 infection in the pre-vaccination period required hospitalization, none of the patients who had COVID-19 in the post-vaccination period required hospitalization.

The rate of patients who developed side effects after the first dose of the vaccine was 20.6%. The side effects seen, respectively, were detected as pain-redness at the injection site (16%), fatigue (11.6%), headache (8.4%), muscle-joint pain (73%) and fever (5.6%). The rate of patients reporting side effects after the second dose of the vaccine was 17.1%. The incidence of side effects after mRNA vaccine was found to be statistically significant compared to inactivated virus vaccine in terms of both doses (p=0.011, p<0.001). Major side effects such as myocardiitis, anaphylaxis-angioedema, myocardial infarction, and thrombosis were not observed in any of the patients included in the study. There was no evidence of disease activation in the median follow-up of 209 days (145-280 IQR) after vaccination.

Conclusion: During the follow-up of the patients during the study, no major vaccine-related side effects, post-vaccine disease activation and the need for treatment change were not detected. In order to more accurately evaluate the efficacy of the vaccination program in the patient population using biologic agents, larger-scale studies including unvaccinated individuals are needed.

AB1089 PSYCHOSOCIAL IMPACTS OF THE COVID-19 PANDEMIC ON ETHIOPIAN AND CANADIAN RHEUMATOLOGY PATIENTS

1University of Manitoba, Internal Medicine, Winnipeg, Canada; 2McGill, Medicine, Montreal, Canada; 3Addis Ababa University, Medicine, Addis Ababa, Ethiopia; 4University Laval, Medicine, Quebec, Canada; 5Jefferson University, Medicine, Philadelphia, United States of America

Objectives: To describe COVID-19 related illness and psychosocial impact in Ethiopian (ET) rheumatology patients attending the only public rheumatology clinic in Ethiopia (Tikur Anbessa Specialized Hospital (TAH) in Addis Ababa), and to compare findings in ET with findings in Canadian (CA) rheumatology patients.

Methods: Between May 1 and Oct 31 2021, 130 patients attending the TAH rheumatology clinic answered questions related to COVID-19 infection, symptoms and testing, and psychosocial impacts of the COVID-19 pandemic. We compared findings in ET with findings in Canadian (CA) rheumatology patients from Quebec1.

Result: ET patients were mainly female (71%) with a mean (SD) age of 47 (16), and resided in the capital city (Addis Ababa) (72%). Half had RA or lupus. A quarter of patients had moderate to severe rheumatic disease severity despite good medication adherence (MAS4 score of 3(2.4)). Most (89%) reported no COVID-19 symptoms since the beginning of the pandemic, were not tested for COVID-19 and reported few risk factors for COVID-19 exposure. Eight (6%) ETs were diagnosed with COVID-19, 2 required hospitalization. Diagnosed patients reported a median of 2 COVID-19 symptoms (range 0-8; mainly cough, fever and malaise). Within the entire cohort, depression (PHQ9=10 or above) and anxiety (GAD7=10 or above) were more frequent in ETs than CA (depression 30% vs 3%; anxiety 16% vs 1%) yet nearly half (47%) of ETs had normal or high resilience levels. The most common COVID-19 stressors were risk of contracting COVID illness personally (ETs vs CA stress risk ratio*95% confidence limits: CA: 0.5; 0.5, 0.99) or of loved one (0.11). More ETs reported COVID-19 related stress related to difficulty obtaining food, medicine or other essentials [1.74, (1.0-3.0)].

Conclusion: During the COVID-19 pandemic, depression was more common in ETs compared to CAs with rheumatic disease. COVID-19-related stressors due to insecurity in obtaining the basic essentials and support were more pronounced in ETs. Differences between ETs and CA in these stressors may reflect local public health and economic supports. There were no differences in coping strategies.

AB1090 IMPACT OF THE COVID19 PANDEMIC ON THE SOCIAL BEHAVIOR OF PATIENTS WITH RHEUMATIC DISEASES

L. Cano García1, S. Manrique Arija1, M. Vera Rodríguez2, R. Redondo3, C. M. Romero-Barco4, N. Mena-Vázquez5, 1Instituto de Investigación biomédica de Málaga (IBIMA); Hospital Regional Universitario de Málaga, UGC de Reumatología, Málaga, Spain; 2Universidad de Málaga, Medición, Málaga, Spain; 3Instituto de Investigación biomédica de Málaga (IBIMA); Hospital Universitario Virgen de la Victoria, UGC de Reumatología, Málaga, Spain.

Background: Depression in rheumatic diseases negatively influences the support network and the perception of company of these patients (1).

Objectives: To describe how the COVID-19 pandemic affects the social activities of patients with chronic rheumatic diseases such as Rheumatoid arthritis (RA), Systemic Lupus Erythematosus (SLE) and Spondyloarthritis (SpA).

Methods: Observational, longitudinal study of a series of patients. Patients: RA (ACR/EULAR 2010 classification), SpA (ASAS/EULAR 2010 criteria), and SLE (ACR 1997 criteria) patients, age ≥ 18 years. Questionaries for the evaluation of participation in social activities is the Patient Reported Outcomes Measurement Information Systems (PROMIS) v2.0 Short-Form (8 items, PROMIS-APS) at baseline (OCT to DEC 2019) and after 18 months of pandemic (SEP to DEC 2021) were performed. Variables evaluated were: social activities in terms of various factors, such as satisfaction with social roles mobility, depression, companion social isolation, emotional support, instrumental support, support via information and ability to participate in social activities. All the variables were evaluated using the PROMIS questionnaire with quantitative scores. We also recorded demographic, clinical, and comorbidity data. Statistical analysis: Multivariate Linear Regression (Dependent variable: PROMIS ability to participate in social activities 18 months COVID19) was performed.

†Severe stress = score 2 (moderately) to 5 (extremely)

Conclusion: During the COVID-19 pandemic, depression was more common in ETs compared to CAs with rheumatic disease. COVID-19-related stressors due to insecurity in obtaining the basic essentials and support were more pronounced in ETs. Differences between ETs and CA in these stressors may reflect local public health and economic supports. There were no differences in coping strategies.
Results: We recruited 91 patients, 31 (34.1%) RA, 30 (33%) SpA y 30 (33%) SLE. The 3 groups were well balanced in terms of clinical-epidemiological characteristics, except that patients with SpA were younger (mean 45 years) than patients with RA (53 years) and SpA (55 years) (p = 0.004) and because most of the patients with RA and SpA were women (97%) compared to those with SpA (60%) (p < 0.001). There was a worsening after 18 months of the COVID-19 pandemic in the mean scores of the PROMIS for: satisfaction of the social role (26.9 ± 8.7 vs 25.3 ± 8.4; 0.046), depression (14.7 ± 7.6 vs 16.1 ± 8.4; p = 0.044) and for the ability to participate in social activities (27.7 ± 7.2 vs 26.1 ± 6.8; p = 0.020). By diagnoses, the ability to participate in social activities was very similar between the different groups except for worse mobility in patients with RA and SpA compared to SLE, both at baseline and at 18 months of the pandemic. SLE patients worsened more after 18 months of the COVID-19 pandemic in social role satisfaction, depression, instrumental support and ability to participate in social activities. In the multivariate analysis, the ability to participate in social activities at 18 months of the COVID-19 pandemic was inversely associated with the diagnosis of SLE compared to the rest (95% CI), -2.60 [-4.62 - 0.58]; p = 0.012) and depression (95% CI), -0.23 [-0.39 - 0.08]; p = 0.004) and directly with social role satisfaction (95% CI), 0.18 [0.10-0.33]; p = 0.031), mobility (95% CI), 0.13 [0.07-0.20]; p = 0.001) and company (95% CI), 0.32 [0.11-0.60]; p = 0.023).

Conclusion: Our aims are to evaluate whether altering our delivery of care has impacted on the impact of rheumatic disease. After 18 months of the COVID-19 pandemic, patients with RA and SpA remain stable but SLE patients significantly worsened their social role and depression.

AB1092
INFLAMMATORY ARTHRITIDES IN POST-COVID-19 PATIENTS: AN ALBANIAN EXPERIENCE.
A. Pecani1, J. Tula1, L. Karaiu2, A. Islami3, S. Bala4
1Rheumatology Unit, Department of Internal Medicine, University Hospital Centre “Shefqet Ndroqi”; Tirana, Albania; 2Rheumatology Unit, Department of Internal Medicine, University Hospital Centre “Shefqet Ndroqi”; Tirana, Albania; 3Pulmonology Clinic, Department of Pulmonology, University Hospital Centre “Shefqet Ndroqi”; Tirana, Albania; 4University Hospital Centre “Shefqet Ndroqi”, Department of Pulmonology, Tirana, Albania

Background: COVID-19 is a disease caused by the new pathogen SARS-CoV2 (severe acute respiratory syndrome coronavirus 2) typically presenting with pneumonia but also other systemic manifestation has been reported worldwide [1]. Different reports have described the appearance of inflammatory arthritis (IA) after resolution of acute infection from COVID-19 [2].

Objectives: To observe the frequency of inflammatory Arthritis in an Albanian cohort of post-COVID-19 patients.

Methods: Post-COVID-19 patients, having two consecutive negative PCR (real-time reverse transcription polymerase chain reaction), discharged from the Pulmonology Department (January – July 2021) were invited to enter in a 6 (six) month multidisciplinary observational study. Data regarding post-COVID-19 inflammatory arthritis are presented in this study. Descriptive statistical analysis was used to express data.

Results: From 154 post-COVID-19 patients (F/M = 62/92) enrolled, 14 (9.9%) patients didn’t follow regularly the dedicated ambulatory thus were excluded from this study. Considering the remaining 140 patients (F/M = 58/82), only 21 (15%) patients were diagnosed with IA where the most common were, respectively: Reactive Arthritis (ReA) 11 (52.3%) patients; Rheumatoid Arthritis (RA) 4 (19.09%) patients; Ankylosing Spondylitis (AS) 3 (14.2%) patients; Gout Arthritis (GA) 3 (14.2%) patients. All rheumatic conditions were more frequent in male than in female post-COVID-19 patients. Data summarized in Table 1. All patients that developed a post COVID-19 IA, had fever during the period of SARS-CoV2 infection. Arthralgia was a typical symptom that have been reported by patients that have developed RA and AS. All RA post-COVID-19 patients reported having had even symptoms like cough, dispnea and fatigue. None of the AS patients neither GA reported symptoms of dysguesia or anosmia. Only 9% of ReA patients reported having had abdominal pain during acute infection with SARS-CoV2. Data summarized in Figure 1.

</table>

Conclusion: IA is another manifestation that follows acute infection from COVID-19. In this regard increased awareness and further investigations are needed.
in order to better understand weather SARS-CoV2 infection can accelerate the development of a rheumatic autoimmune disease.

AB1093
SAFETY OF COVID-19 VACCINES IN PATIENTS WITH RHEUMATOID ARTHRITIS (PRELIMINARY DATA).

A. Kulikov1, N. Muravyeva1, B. Belov1.1V.A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccinoprophylaxis, Moscow, Russian Federation

Background: Patients with rheumatoid arthritis (RA) are at high risk of developing COVID-19. Vaccination should be an effective method of preventing this disease. However, vaccination may be unsafe in RA patients. At present, data on the safety of vaccines against COVID-19 in RA patients are few and relate to foreign vaccines that are not licensed in Russia.

Objectives: To study the safety of COVID-19 vaccines in patients with RA in real clinical practice.

Methods: The study included 131 RA patients (120 women, 11 men, age 53.8±13.9 years, duration of disease 11.5±9.2 years) - the main group and 121 people without any immuno-inflammatory rheumatic diseases (87 women, 34 men, age 39.8±14.2 years) - the control group. 103 patients received disease-modifying antirheumatic drugs (54 - methotrexate, 30 - leflunomide, 10 - hydroxychloroquine, 8 - sulfasalazine, 1 - methotrexate and sulfasalazine), 68 - biological drugs (58 - rituximab, 5 - TNF-inhibitors, 4 - abatacept, 1 - tocilizumab), 6 - immunosuppressants (58 - rituximab, 5 - TNF-inhibitors, 4 - abatacept, 1 - tocilizumab), 66 - corticosteroids, 10 - did not receive therapy. In the main group, 92 patients were vaccinated with Gam-COVID-Vac (Sputnik V), 21 with Sputnik Light, 16 with CovVac; 2 with EpiVacCorona (110 patients received two components of the vaccine). In the control group, 91 were vaccinated with Sputnik V, 16 with CovVac, 5 with BNT162b2, 5 with Sputnik Light, 2 with EpiVacCorona, 1 with mRNAb1273 (114 participants received two components of the vaccine). All patients were interviewed by a research doctor with a unified questionnaire, additional information was obtained from medical documentation.

Results: Local and systemic adverse events (AEs) were observed both in the main group and in the control group. After the introduction of the first component of the vaccine, local AEs (pain/hyperemia/edema) were noted in 12.2% of RA patients and in 10.7% of the control group, after the introduction of the second component of the vaccine - in 9.1% and 11.4% of respondents, respectively (in both groups p>0.05). There was a significant difference between the main group and the control group in the frequency of injection pain at the injection site without restriction of movements both after the first (24.4% and 40.5%, p=0.007) and after the second component (18.2% and 31.6%, p=0.021). The most frequent systemic AEs were weakness, fever, muscle or joint pain, chills, which were observed in both groups after administration of both the first and second components of the vaccine. There was a significant difference between the main group and the control group in the frequency of fever (16.8% and 39.7%, p<0.001), weakness (26.0% and 38.8%, p=0.029), muscle and joint pain (9.2% and 25.6%, p<0.001) after administration of the first (but not the second) component of the vaccine. A significant difference was revealed between the main group and the control group in the number of patients with local and systemic AEs both after the introduction of the first component of the vaccine (19.1% and 43%, p<0.001) and after the second (15.5% and 30.7%, p=0.007). After administration of the two components of the vaccine, a higher number of patients without any AEs were detected in the main group compared to the control group (32.7% and 18.4%, p=0.014). Exacerbation of RA and the emergence of new autoimmune phenomena in main group are not marked.

Conclusion: According to preliminary data, the tolerance of vaccines against COVID-19 in RA patients is satisfactory. Further studies are needed to study the safety, immunogenicity and clinical efficacy of immunization against COVID-19 in patients of this cohort.

AB1094
SAFETY AND EFFICACY OF VACCINES FOR SARS-COV-2 IN PATIENTS WITH RHEUMATIC AND IMMUNE-MEDIATED INFLAMMATORY DISEASES: DATA FROM THE ARGENTINEAN REGISTRY SAR-COVAC

Background: Currently there is little information on the efficacy and safety of SARS-CoV-2 vaccination in patients with immune-mediated diseases and/or under immunosuppressive treatment in our country, where different types of vaccines and mix regimens are used. For this reason, the Argentine Society of Rheumatology (SAR) with the Argentine Society of Psoriasis (SOARPSO) set out to develop a national register of patients with rheumatic and immune-mediated inflammatory diseases (IMIDs) who have received a SARS-CoV-2 vaccine in order to assess their efficacy and safety in this population.

Objectives: To assess SARS-CoV-2 vaccine efficacy and safety in patients with rheumatic and IMIDs.

Methods: SAR-Covac is a national, multicenter and observational registry. Adult patients with a diagnosis of rheumatic or IMID who have been vaccinated for SARS-CoV-2 were consecutively included between June 1st and September 17th, 2021. Sociodemographic data, comorbidities, underlying rheumatic or IMIDs, treatments applied and their modification prior to vaccination and history of SARS-CoV-2 infection were recorded. In addition, date and place of vaccine (SARS-CoV-2) infection were documented in patients of this cohort.

Results: A total of 1234 patients were included, 79% were female, with a mean age of 57.8 (SD 14.1) years. The most frequent diseases were rheumatoid arthritis (41.2%), osteoarthritis (14.5%), psoriasis (12.7%) and spondyloarthritids (12.3%). Most of them were in remission (28.5%) and low disease activity (41.4%). At the time of vaccination, 21% were receiving glucocorticoid treatment, 35.7% methotrexate, 29.7% biological (b) Disease Modifying Anti-Rheumatic Drugs (DMARDs) and 5.4% JAK inhibitors. Before vaccine application 16.9% had had a SARS-CoV-2 infection. Regarding the first dose of the vaccine, the most of the patients (51.1%) received Gam-COV-ID-Vac, followed by ChAdOx1 nCoV-19 (32.8%) and BBIBP-CorV (14.5%). In a lesser proportion, BNT162b2 (0.6%), Ad26.COV2.S (0.2%) and CoronaVac (0.2%) vaccines were used. Almost half of them (48.8%) completed the scheme. 12.5% were mix regimes, the most frequent being Gam-COV-ID-Vac / mRNA1273. The median time between doses was 51days (IQR 53). More than a quarter (25.9%) of the patients reported at least one AE after the first dose and 15.9% after the second. The flu-like syndrome and local hypersensitivity were the most frequent manifestations. There was one case of mild anaphylaxis. No patient was hospitalized. Altogether, the incidence of AE was 246.5 events/1000 doses. BBIBP-CorV presented significantly lower incidence of AE in comparison with the other types of vaccines. (118.5 events/1000 doses, p<0.002 in all cases) Regarding efficacy, 63 events of SARS-CoV-2 infection were reported after vaccination, 19% occurred before 14 days post-vaccination, 57.1% after the first dose (>14 days) and 23.8%
after the second. In most cases (85.9%) the infection was asymptomatic or had an outpatient course and 2 died due to COVID-19. Conclusion: In this national cohort of patients with rheumatic and IMIDs vaccinated for SARS-CoV-2, the most widely used vaccines were Gam-COVID-Vac and ChAdOx1 nCoV-19, approximately half completed the schedule and in most cases homologously. A quarter of the patients presented some AE, while 5.1% presented SARS-CoV-2 infection after vaccination, in most cases mild.

AB1095

POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME IN A PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS AFTER COVID-19 VACCINATION: A CASE REPORT

D. Abdel Mohsen1, R. A. Elziaty1, A. A. Abdalkader1. 1Ain Shams University, Internal Medicine Department, Division of Rheumatology, Cairo, Egypt

Background: The COVID-19 pandemic has infected millions of people around the world and there has been a new surge of virulent strains in many parts of the world[2]. Patients with Systemic Lupus Erythematosus (SLE) were reported to be at higher risk of SARS-CoV-2 infection and worse outcomes from COVID-19, possibly due to their intrinsic immune dysfunction, demographics, disease activity, medications, associated organ damage, comorbidities and as such, have been among the first to receive the vaccines [3]. The most common reason for vaccine refusal in patients with SLE is fear of SLE disease flare. Additionally, SARS-CoV-2 mRNA vaccines could potentially induce interferon production, associated with increased SLE disease activity[1].

Objectives: we report a case of SLE presented with lupus flare after receiving the 1st dose of Pfizer vaccine.

Methods: A 30-year-old female patient, kown case of SLE since 2011 well controlled on low dose steroids, hydroxychloroquine and azathioprine. Upon receiving her 1st shot of Pfizer-BioNTech COVID-19 Vaccine, she developed high grade fever associated with generalized papulovesicular skin eruption mainly on the back of the trunk and the outer surface of both thighs, then she developed generalized tonic-clonic convulsions and transferred for Intensive Care Unit (ICU), intubated, mechanically ventilated and received intravenous anti-epileptic medications. During her admission, Cerebrospinal fluid (CSF) examination and Magnetic Resonance Imaging (MRI) brain were done.she regained her consciousness, extubated after 48 hours.

Results: The initial laboratory investigations revealed COVID19-PCR: negative,ESR: 35 mm/hr, CRP: 78, C3: 70 mg/dL (90-180) and C4: 8 mg/dL (10-40). CSF examination revealed proteins: 116.9 mg/dL (15 – 45), glucose: 46.3 mg/dL (50-60% of serum),LDH: 49.1 U/L (10% of serum) and no cells. Emergency MRI brain was performed revealed multiple bilateral symmetrical mainly cortical and subcortical abnormal signal with cortical swelling are seen mainly involving both occipito-temporo-parietal lobes with patchy enhancement of left cerebellar hemisphere, cerebellar white matter and left thalamus, medulla and pons.Picture suggestive of Posterior Reversible Encephalopathy Syndrome (PRES).Accordingly the patient received pulse steroid therapy for 3 days under cover of oral acyclo-visor.She also received levetiracetam and Oxcarbazepine.the condition markedly improved and discharged from the hospital for follow up for one month.

Conclusion: 1)The mRNA COVID Vaccine may rarely cause CNS affection, or even SLE flare so, SLE patients must be well controlled before giving the Vaccine. 2) SLE patients must be monitored closely by clinical examination and laboratory investigations after taking mRNA COVID Vaccine.

AB1097

FEATURES OF THE COURSE AND CLINICAL AND DEMOGRAPHIC CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO UNDERWENT COVID-19

E. Aronov1, G. Gridneva1, B. Belov1. 1V.A.Nasonova Research Institute of Rheumatology, Department of Comorbid Infections and Vaccine Prevention, Moscow, Russian Federation

Background: COVID-19 remains a serious problem almost two years later, despite the ongoing active search for effective tools to control it. To date, it is known that COVID-19 not only proceeds as an acute respiratory illness, but also leads to a systemic inflammatory response and hypercoagulability through activation of both the innate and adaptive immune systems. Patients with rheumatic conditions receive immunosuppressants prescribed to control RMD increase the risk of infections. And finally, RMD is often combined with comorbid conditions from the group of risk factors for severe forms of COVID-19 such as arterial hypertension, diabetes mellitus and obesity.

Objectives: to characterize the features of the course of COVID-19 in patients with rheumatoid arthritis.

Methods: We studied the material of questionnaires filled out by patients of the hospital of the V.A. Nasonova Research Institute of Rheumatology who underwent COVID-19, verified by RT-PCR to SARS-CoV-2 RNA, for the period from 05/15/2020 to 12/15/2021. The information was supplemented with data from discharge summary after inpatient treatment of COVID-19. Statistica software (version 12) was used for statistical processing. The results of the correlation analysis were considered reliable at p<0.05.
Patients with higher RA activity more often noted increased arthralgia. Symptoms associated with COVID-19 did not correlate with RA activity. However, treatment in 12.5% - COVID-19 proceeded with complications. The number of patients and acute respiratory failure in 2 more patients.

Conclusion: Patients with higher RA activity more often noted increased arthralgia during COVID-19 and RA activity. On average, median, each patient reported 13.5 [9.75; 19.25] symptoms associated with COVID-19. There was no significant correlation between the number of COVID-19 symptoms and RA activity. During COVID-19, CT scan was performed in 19 patients: CT-0 - in 1 patient (5.3%), CT-1 - in 9 (47.4%), CT-2 - in 5 (26.3%), CT-3 - in 3 (15.7%), CT-4 - in 1 (5.3%). There was no correlation between the CT stage and RA activity. 12 patients (37.5%) were hospitalized, of which 8 needed oxygen support. Rituximab treatment was not associated with hospitalization rates. Complications were reported in 4 cases (12.5%): venous thrombosis in 2 patients and acute respiratory failure in 2 more patients.

Disclosure of Interests: None declared

AB1098 DEVELOPMENT OF INFLAMMATORY MYOPATHY AFTER COVID-19

I. Menshikova1, A. Shilina1, N. Nikolaeva1, 1I.M.Sechenov First Moscow State Medical University (Sechenov University), Rheumatology, Moscow, Russian Federation

Background: It has been more than a year and a half since the WHO announced a pandemic of a new coronavirus infection caused by SARS-CoV-2. The virus belongs to the respiratory group, but it can damage various organs and tissues of the body. COVID-19 infection is characterized by pathological activation of immunity, violated synthesis of pro-inflammatory, immunoregulatory, anti-inflammatory cytokines, and other factors. Such as acute respiratory distress syndrome (ARDS), liquid food, rash on the face, neck, chest and arms. In August 2020 she had a mild case of COVID-19. A month later, flaky erythematous papules got through the skin on her abdomen and upper extremities. These features contribute to the development of rheumatic diseases and syndromes in people who have had COVID-19. Cellular and humoral immune responses are also of primary importance in the pathogenesis of inflammatory myopathies.

Objectives: Description of a case of severe dermatomyositis after COVID-19. Methods: The 34-year-old female patient complained of pain and weakness in the proximal muscles of the upper and lower limbs, fatigue, dizziness, fever, and cough. On admission to the hospital, she had a mild case of COVID-19. A month later, flaky erythematous papules appeared on the legs. Echocardiography and electrocardiogram showed normal results. The duration of the course of RA was 8 [4; 14.5] years. The most common comorbidities were disorders of the cardiovascular system (in 20 patients), diseases of the gastrointestinal tract (in 7 patients), diabetes (in 4 patients) and obesity (in 5 patients). The median number of comorbid diseases was 2 (IQR 3).

A patient was noted: swallowing normalized, the severity of myopathy decreased, after 10 days CK decreased to 2049 IU/l. After 6 months during the control examination: there are no skin rashes, muscle strength is restored, CK 300 IU/l. The dose of methylprednisolone is reduced to 10 mg per day, the patient continues injections of methotrexate 15 mg per week.

Conclusion: COVID-19 may be a trigger for the development of inflammatory myopathy. In this clinical case there are features of the course and therapy of inflammatory myopathies in patients after coronavirus infection.

PREVALENCE OF LONG COVID IN RHEUMATIC DISEASE PATIENTS: ANALYSIS OF SAR COVID REGISTRY

C. A. Gonzalez Gomez1, M. Cosatti1, V. V. Castro Coello2, M. Haye3, Y. Tissena4, A. A. Reyes2, J. A. Albiero2, S. Ornelia5, P. Alba2, C. Gobbi2,

1CEMIC, Centro de Educación Médica e Investigaciones Clínicas Norberto Quintero, Rheumatology Section, Ciudad de Buenos Aires, Argentina;
2on behalf of SAR COVID Registry, SAR Research Unit, Ciudad de Buenos Aires, Argentina

Background: Persistent symptoms after acute COVID have been described previously. Main symptoms reported are fatigue, arthralgias, myalgias and mental sickness. Definition and methods vary widely.1

Objectives: To assess prevalence and related factors to long COVID in a retrospective cohort of patients with rheumatic diseases from Argentina.

Methods: A total of 1915 patients were registered from August 18th, 2020 to July 29th, 2021. Patients > 18 years old, with rheumatic disease and confirmed infection by SARS-CoV-2 (antigen or RT-PCR) were included. Those dead, with unknown outcome, without date or missing data were excluded. Demographic data, comorbidities, rheumatic disease, and characteristics of SARS-CoV-2 infection were recorded. Long COVID was defined according to NICE guidelines (persistent symptoms for more than 4 weeks, without alternative diagnosis). Long COVID symptoms were defined by rheumatologist. Severe infection was classified according to WHO ordinal scale. We used descriptive statistics, univariate model (Student's test, chi square test, ANOVA) and multivariate logistic regression analysis.

Results: 230 (12%) had long COVID. Median age was 51 (IQR 40-61) years, 82% were females, 51% were not caucasian. Median of education was 13.3 years (IQR 12 – 16), 79 % had private health insurance and 55 % were employed. Nearly half (n=972, 46%) had comorbidities, the most prevalent was hypertension (n=396, 24%). The most frequent rheumatic diseases were rheumatoid arthritis (n=719, 42%) and systemic lupus erythematosus (n=280, 16%). Most were in low activity/remission (79%), used treatment for COVID-19 5 months after complete VAC and died. Conclusion: There is very high number of VAC (98.1%) in a real life setting of a rheumatological OC. Many patients (95%) developed low to high AB levels after 2 VAC, independently which agent was used. Otherwise, we must be aware of the small group of patients (5%) without developing any AB. Unfortunately, our group was too small to find significant risk factors (RF). But RF seems to be the age, therapy with RTX, ABA and P. This is in line with reported RF in clinical studies (1). Furthermore, we see lower levels in elderly patients who get vaccinated with C. This could be biased by the fact that, in the first months of the VAC campaign, C was used in patients with higher age and the 2nd VAC was given 3 weeks after 1st VAC. Retrospectively, this interval seems to be too short. Thus now, the 2nd VAC is given 4-6 weeks after 1st VAC. In conclusion it is still unclear, which levels of AB make VAC effective and which patients will develop AB levels. AB levels should be evaluated to pick out patients with VAC gap, since the levels of AB make VAC effective and which patients will develop AB levels. Many patients (95%) developed low to high AB levels 5 months after complete VAC and died.

To asses prevalence and related factors to long COVID in a retrospective cohort of patients with rheumatic diseases from Argentina.

Methods: A total of 1915 patients were registered from August 18th, 2020 to July 29th, 2021. Patients > 18 years old, with rheumatic disease and confirmed infection by SARS-CoV-2 (antigen or RT-PCR) were included. Those dead, with unknown outcome, without date or missing data were excluded. Demographic data, comorbidities, rheumatic disease, and characteristics of SARS-CoV-2 infection were recorded. Long COVID was defined according to NICE guidelines (persistent symptoms for more than 4 weeks, without alternative diagnosis). Long COVID symptoms were defined by rheumatologist. Severe infection was classified according to WHO ordinal scale. We used descriptive statistics, univariate model (Student's test, chi square test, ANOVA) and multivariate logistic regression analysis.

Results: 230 (12%) had long COVID. Median age was 51 (IQR 40-61) years, 82% were females, 51% were not caucasian. Median of education was 13.3 years (IQR 12 – 16), 79 % had private health insurance and 55 % were employed. Conclusion: There is very high number of VAC (98.1%) in a real life setting of a rheumatological OC. Many patients (95%) developed low to high AB levels after 2 VAC, independently which agent was used. Otherwise, we must be aware of the small group of patients (5%) without developing any AB. Unfortunately, our group was too small to find significant risk factors (RF). But RF seems to be the age, therapy with RTX, ABA and P. This is in line with reported RF in clinical studies (1). Furthermore, we see lower levels in elderly patients who get vaccinated with C. This could be biased by the fact that, in the first months of the VAC campaign, C was used in patients with higher age and the 2nd VAC was given 3 weeks after 1st VAC. Retrospectively, this interval seems to be too short. Thus now, the 2nd VAC is given 4-6 weeks after 1st VAC. In conclusion it is still unclear, which levels of AB make VAC effective and which patients will develop AB levels. AB levels should be evaluated to pick out patients with VAC gap, since the high risk of fatal course of COVID-19 disease. The booster campaign and 3rd VAC will change the current state again, therefore revaluation will be necessary.

A RARE CASE OF ACUTE INFLAMMATORY DEMYELINATING POLYRADICULOPATHY FOLLOWING THE SECOND DOSE OF Pfizer COVID-19 VACCINE

V. Courant1, M. Silva2, S. Grewal1. 1Mount Sinai Morningside, Internal Medicine, New York, United States of America

**Background:** We present a case of a 36-year-old female who developed Acute Immune-mediated Demyelinating Polyneuropathy (AIDP) after receiving the second dose of Pfizer COVID-19 vaccine.

**Objectives:** To report a rare auto-immune complication of COVID-19 vaccination. To educate and inform physicians about the approach to diagnosing AIDP and narrowing down its etiology.

**Methods:** Case report and literature review

**Results:** A 36-year-old female with no significant past medical history presented to the hospital with progressive bilateral paresthesia. She started to experience numbness and tingling sensation in her extremities 1 week after receiving the second dose of Pfizer COVID-19 vaccine. Following 5 days of symptoms onset, she was no longer able to hold onto objects and experienced difficulty ambulating without assistance. Physical exam was notable for decreased distal sensation to touch and pain in all 4 limbs, otherwise, the rest of her neurological and musculoskeletal evaluation was normal. MRI-head showed small scattered foci of increased FLAIR signal in the white matter, suggesting an underlying inflammatory process. Electromyography (EMG) was performed and showed evidence of acute diffuse sensorimotor neuropathy with mixed axonal and demyelinating features. These results along with the clinical features allowed us to diagnose the patient with Acute Immune-mediated Demyelinating Polyneuropathy (AIDP). Extensive autoimmune workup, including anti-GM1, GD1b, Gq1b, ANA, DS-DNA, RF, CCP, and C/P ANCA, were unremarkable. She had positive anti-Ro atb but did not have any clinical or physical features that would suggest Sjogren’s Syndrome. Vitamin levels (B12, folate, thiamine) were found to be normal. Infectious workup of serum and CSF which included hepatitis serology, other infectious workup, and narrowing down its etiology.

**Conclusion:** The possible etiology of her disease was attributed to Pfizer COVID-19 vaccine given to be normal. Infectious workup of serum and CSF which included hepatitis serology, other infectious workup, and narrowing down its etiology.

**AB1103**  
THE EFFECT OF COVID-19 PANDEMIC IN A LARGE SERIES OF PATIENTS WITH TAKAYASU ARTERITIS

A. Karakas1, T. Yuce Inel1, F. Onen1, I. Sari1. Dokuz Eylul University Faculty of Medicine, Rheumatology, Izmir, Turkey

**Background:** Patients with inflammatory rheumatic diseases faced several challenges during the COVID-19 pandemic. Uncertainties such as the lack of evidence regarding the use of immunosuppressive (IS) therapies and deferred patient care because of limited health resources impacted negatively on many aspects of treatment decisions and routine follow-up of the patients.

**Objectives:** We aimed to investigate the prevalence and severity of SARS-CoV-2 infection, the impact of the pandemic on delays in routine clinical follow-up, changes in IS treatment, and COVID-19 vaccination status of patients with Takayasu arteritis (TAK).

**Methods:** The study was performed between July and September 2021. TAK patients who registered in our database were investigated with regards to the COVID-19 infection and vaccination status, delays in routine clinical visits, changes in IS treatment, and flares during the pandemic. Physical examination, laboratory tests, and imaging of the patients were performed and ITAS2010 scores were calculated.

**Results:** There were 56 adult TAK patients (87.5% female and median age 47 years). 14 (25.8%) patients experienced a delay with routine follow-up visits to their physicians and about 20% of patients stopped their antirheumatic treatments without consulting their physicians. Compared to the pre-COVID-19 pandemic, 16 (28.5%) patients were flared. 13 (23.2%) patients had a mild COVID-19 infection. Pneumonia was reported in five patients, two of them required hospitalization, and all patients recovered completely. In the total group, about 90% of the patients had received the COVID-19 vaccine (Table 1).

**Table 1. Effects of COVID-19 pandemic on patients with Takayasu arteritis**

<table>

</tr>
</tbody>
</table>

**Conclusion:** COVID-19 disease in TAK patients were in mild severity and IS therapy seem not affecting the COVID-19 course. A substantial number of patients who stopped their medications flared and its long-term consequences need to be assessed by large-scale studies. New approaches are required to maximize healthcare access for patients who have chronic diseases during pandemic.

occur even in patients who have experienced mild or moderate COVID-19 and includes long-term symptoms that may be associated with residual inflammation, organ damage, non-specific effects of hospitalization or prolonged ventilation, so-called COVID-19 sequelae, or comorbid diseases. In October 2021, the WHO defined PCS as a condition that occurs in individuals with a history of probable or confirmed infection with the SARS-CoV-2 virus, usually within 3 months of the onset of COVID-19, and is characterized by the presence of symptoms for at least 2 months, as well as the impossibility of explaining them with an alternative diagnosis.

Objectives: To conduct a comparative assessment of clinical and demographic indicators in groups of patients with rheumatoid arthritis who underwent COVID-19, with and without PCS.

Methods: The material of the questionnaires filled in by patients of the V.A. Nasonova Research Institute of Rheumatology, who underwent COVID-19, verified by RT-PCR for SARS-CoV-2 RNA. The information was supplemented with data from discharge records after inpatient treatment for COVID-19. Statistica program (version 12) was used for statistical processing. The results of correlation analysis were considered significant at p<0.05.

Results: The study included 23 adult patients (over 18 years of age) with a reliable diagnosis of rheumatoid arthritis (ACR/EULAR). Of these, 11 (47.8%) patients noted the development of PCS (Group 1), and 12 patients underwent COVID-19 without consequences (Group 2). Both groups were represented predominantly by women (90.9% and 91.7%, respectively). The average age in both groups did not differ significantly and amounted to 56.7±14.79 years in group 1, and 48.1±19.95 years in group 2. The median number of comorbid diseases was 2 [1;4] in group 1 and 0.5 [0;2.5] in group 2. PCS was presented by the following symptoms: weakness, increased fatigue – in 6 patients, problems with attention, concentration – in 7, memory impairment – in 6, steep disturbances – in 7, increased pain in the joints – in 7, shortness of breath during exercise – in 6, fluctuations in blood pressure – in 5, tachycardia – in 4. On average (median), each patient noted 10 [6.5;12] symptoms of PCS at a time. When assessing the number of symptoms in the infectious phase, in group 1, patients reported 20 [16;23], and in group 2, 10 [7;12] symptoms of COVID-19. At the time of development of COVID-19, the severity of RA symptoms, assessed by VAS, was 5.6±4.3±26 in group 1 and 4.7±5.2±99 in group 2. In group 1, 5 (45.5%) patients needed hospitalization, 3 of them needed oxygen support. In group 2, 4 (33.3%) patients were hospitalized, two of them needed oxygen support. 3 patients in group 1 suffered COVID-19 again on average 9.3±3±2.52 months after the first illness. One of them has been vaccinated. All patients in this group were treated as outpatients, while the first case of COVID-19 required one hospitalization and oxygen support. Statistical assessment of significant differences (p<0.05) between groups in terms of sex, age, number of comorbid diseases, number of COVID-19 symptoms in the infectious phase, severity of RA symptoms, and hospitalization rate was not revealed.

Conclusion: Even though when assessing the socio-demographic characteristics, no statistically significant differences were found between the study groups, the average age, the number of comorbid diseases, and the severity of RA symptoms at the time of COVID-19 were higher in the group of patients with RA and PCS. Patients with PCS reported higher rates of hospitalizations and severe RA (VAS > 5) symptoms. There were also more treated cases of COVID-19 in this group. It is necessary to continue the study on a larger cohort.

PSEUDOPERNIOSIS AS A LATE MANIFESTATION AFTER SARS2-COD19 INFECTION. A PURPOSE OF A SERIES OF 19 CASES

F. J. Navarro Blasco1,1 Hospital General Universitario de Elche, Rheumatology, Elche, Spain

Background: In winter, you can usually see a picture of Perniosis and / or chilblains. Painful, often itchy, red-to-purple lesions that affect the acrid surfaces of the fingers and toes after contact with the cold, resembling vasculitis, characterize them. Chilblains can be idiopathic and self-limiting or associated with systemic diseases. The diagnosis is usually clinical, but in some circumstances, analytical and microscopic studies of a biopsy sample may be necessary. We present a series of 19 consecutive cases of Pseudoperniosis associated with probable past INFECTION by SARS-CoV-2.

Methods: During the winter 2020-21, an unexpected number of cases referred as “acute arthritis/vasculitis” have been received in our rheumatology section and the main problem is pain along with edema of the tissues of the hand that leads to make it impossible to use. Similarly, asymmetric lesions similar to perniosis were observed in patients who presented skin manifestations of SARS-CoV-2 infection in a study conducted in Spain (1). We are following these patients to assess if there is any relationship with any other factor that facilitates this unusual incidence, and at the same time indicate the transience of the clinical picture that evolves favorably in a few weeks.

HOW HAS THE COVID-19 PANDEMIC AFFECTED OUR RHEUMATOLOGY PATIENTS USING BIOLOGICAL/ TARGETED DMARDS?

S. Gulle1, Y. Erez1, A. Karakas1, T. Yüce İne1, S. B. Koca1, T. Demirci Yıldırım1, G. Can1, I. Sarı1, M. Birlik1, F. Önen1, 1Dokuz Eylül University School of Medicine, Rheumatology, Izmir, Turkey

Background: Bioinformatics data, which are becoming more detailed day by day, show that male gender, advanced age, smoking, and comorbidities are associated with poor outcome of COVID-19. However, it is well known that the active disease state that may occur as a result of discontinuing the drugs also increases the susceptibility to infection.

Objectives: It was aimed to investigate the effects of the COVID-19 pandemic on the course and treatment of rheumatic disease in patients with inflammatory rheumatic musculoskeletal disease (iRMd) using biological or targeted synthetic DMARDs (b/tsDMARDs).

Methods: The study was carried out in two stages: while investigating the delay of b/tsDMARD treatment in the first 3 months of the pandemic with the fear of infected SARS-CoV-2 in the first stage, in the second stage, it was investigated whether all patients who decided to continue treatment after interruption in the 12-month period.

Results: A total of 521 patients were included in the study. It was seen that the iRMd diagnosis was listed as SpA (54.3%), RA (25.7%), PsA (8.4%), vasculitis (6.1%), and others (5.4%). The overall 12-month drug retention rate was 92.3%. Concurrent use of hydroxychloroquine (HCQ) (HRI=1.49), iv bDMARD use (HRI=1.34), and a history of discontinuation of drug in the first 3 months of the pandemic (HRI=1.19) were determined as factors that reduced 12-month drug retention rates. During a total of 12 months, 34 (6.5%) of patients had COVID-19. COVID-19 was severe in 7 patients and 5 of these patients died. The use of GC (HRI=3.81) and having a diagnosis of ILD/COPD (HRI=4.98) were found to increase the risk of infected by SARS-CoV-2.

Targeted DMARDs?
Conclusion: The results of this study with a long follow-up period suggest that the retention rates of b/tsDMARD treatment increased with good communication with IMD patients during the COVID-19 pandemic.

AB1107 COVID-19 INFECTION MAY BE TRIGGER FOR DEVELOPMENT OF IMMUNE-MEDIATED DISEASES (IMDS) 

N. Manukyan1, V. Vardanyan1, K. Ginosyan2, A. Sangpyan2, S. Mardoyan1. 
1Yerevan State Medical University, Rheumatology, Yerevan, Armenia; 2“Mikayelyan” University Hospital, Rheumatology, Yerevan, Armenia

Background: As considerable evidence indicates viruses play an important role in the pathogenesis of inflammatory rheumatic diseases as environmental factors. The most prominent pathogenic viruses which have been proposed to trigger autoimmune responses, it is also likely to induce clinical autoimmunity2.

Aim of the study: To determine the possible association between COVID-19 infection and development of IMDs.

Methods: We analyzed data of 21 patients (Male 4/19% , female 17/81%; mean age 45.5 ± 13.9 years), who were admitted to Rheumatology department of “Mikayelyan” University Hospital after Covid-19 infection with newly diagnosed IMDs from June till December 2021. All patients had never had such kind of disorder before. EULAR/ACR criteria were used for diagnosis and assessment of disease activity.

Results: After SARS-CoV-2 infection some patients presented with preserved fever, high levels of CRP and ESR, rash and arthritis. Particularly, 3 (14.3%) developed systemic lupus erythematosus, 3 (14.3%) – antiphospholipid syndrome, 4 (19%) – rheumatoid arthritis, 2 (9.5%) - spondyloarthritis, 3 (14.3%) – systemic juvenile idiopathic arthritis, 1 (4.8%) - undifferentiated arthritis, and 1 (4.8%) - juvenile idiopathic arthritis. 52.4% of patients the course of disease was mild. We’ve found a significant association between severe course of Covid-19 and development of erythema nodosum. (p< 0.05). Also an association between female gender and severe course of Covid-19 was determined (p<0.05).

Conclusion: In acute progression of the COVID-19 along with development of antiviral immunity, a dysregulated response of immune system may occur, represented by the marked cytokine release syndrome, macrophage activation, and systemic hyperinflammation.3 We analyzed the data of patients who didn’t have any typical symptom of rheumatic diseases before coronavirus infection, therefore, on our opinion, virus played an important role to induce clinical autoimmunity and autoinflammation and subsequently – IMDs. Possibly, Covid-19 infection may be included in the group of trigger viruses for IMDs.

AB1108 IMPACT OF THE FIRST WAVE OF THE COVID 19 PANDEMIC ON HEALTHCARE ACCESSIBILITY, DISEASE BEHAVIOUR, ANXIETY, AND PHYSICAL ACTIVITY IN RHEUMATIC DISEASE PATIENTS: AN ONLINE SURVEY AND POTENTIAL SOLUTIONS 

S. Yadav1, R. Samant1. 1P. Hinduja National Hospital & Medical Research Centre, Rheumatology, Mumbai, India

Background: Coronavirus Disease (covid 19) negatively impacted psychosocial health, health care accessibility and exercise regimen but problem’s scope and potential solutions remain elusive. We conducted a patient based online survey to understand these impacts and discussed potential solutions.

Objectives: Assess impact of Covid 19 on rheumatological disease status, accessibility to health care, patient anxiety and behavior and continuation of physical activity during pandemic.

Methods: Google form (18-question) based questionnaire was sent via SMS/WhatsApp in Aug 2020, at height of first pandemic and responses were collected over next month.

Results: Only 339 /2700 patients (12.5 %) responded to the survey. Other authors (1)(2) have observed a similar low response rate to online surveys. We recognise questionnaires with fewer questions tend to generate more responses, which should be considered critical in constructing future health-related surveys. Patients’ global assessment of their disease score was 7/10, with 0 representing the worst disease status and 10 representing best disease status, also 1/3 patients not felt need for rheumatological consultation during six months (March 2020- Aug 2020) of lockdown. These may imply adequate rheumatic disease control over long periods and during subsequent waves of pandemic, rheumatology patients can be shielded by avoiding non-urgent hospital follow up visits. Significant number of patients (20%) were unable to contact their rheumatologist, implying a significant impact of covid 19 and lockdown on rheumatology care, as suggested by other authors (1). As expected, there was switch to teleconsultancy mode of communication, with 22% per cent of patients already using it within 3 months of its introduction, which appears to be a good indicator of future adaptability and feasibility of teleconsultation.

Identifying specific profile of patients during physical consultation who can be easily managed via teleconsultation, may reduce unnecessary hospital visits while also improving healthcare delivery. 1/3 of our patients had anxiety about disease flare, and 41% were concerned about increased risk of covid 19 infection as they were on immunosuppressive medications as noted by other authors (3). Improving access to health care and increasing public awareness could help alleviate this anxiety. Reaching out to isolated rheumatology patients through SMS / educational video may improve the sense of health security. Contrary to our expectations, overall medication adherence was reasonable, likely due to be management of supply chains by local authorities, 15% completely stopped exercising and 25% reduced their exercise regimen by 50%. Shifting to home-based exercise, educational videos on physical therapy and online teleconsultation with physiotherapists could overall have positive impact.

Conclusion: Covid 19 has significantly impacted rheumatological patients in terms of increased anxiety, decreased healthcare accessibility and decreased exercise and physical activities. Modifications in teleconsultation methodology are needed in the future. Patients’ anxiety can be alleviated by educating them through digital and social media platforms and enrolling them in online patient support groups.

AB1109 EVALUATION OF THE POTENTIAL INDUCTION OF AUTOANTIBODIES AFTER THE ANTISARS-COV2 VACCINATION IN A COHORT OF PATIENTS WITH TRIPLE POSITIVITY FOR ANTIPHOSPHOLIPID ANTIBODIES 

P. Semeraro1, S. Bortolchi2, S. Piantoni2, L. Andreoli2, F. Franceschini2, E. Garatta1, A. Tincani1. 1University of Brescia - ASST Spedali Civili di Brescia, Clinical and Experimental Sciences, Brescia, Italy; 2University of Brescia - ASST Spedali Civili di Brescia, Molecular and Translational Medicine, Brescia, Italy

Background: Anti-SARS-CoV2 vaccines showed a good efficacy in prevention of severe COVID-191. Their potential in induction of autoantibodies (abs) has not been well established2. One recent study demonstrated an increase of ab’s titre after anti-SARS-CoV2 vaccination only in patients with already pre-existing positivity2.

Objectives: To evaluate the potential induction of abs after anti-SARS-CoV2 vaccination in a triple positive antiphospholipid antibody (APL) patient.

Methods: 18 subjects were enrolled [M/F= 17/1; median age=52 years; 5 Primary Antiphospholipid Syndrome (PAPS), 5 Systemic Lupus Erythematosus...
Background: SARS-CoV-2 infection had a major impact on patients with inflammatory rheumatic diseases. Spondyloarthritis (SpA) patients were one of the most affected groups of these patients.

Objectives: To assess the impact of Covid19 in spondyloarthritis patients under biological disease-modifying anti-rheumatic drugs (bDMARDs).

Methods: A retrospective observational study was conducted using registry data of patients with SpA under bDMARD therapy, followed at a tertiary level hospital, that have been diagnosed with COVID19 from March 2019 to December 2021. At least one evaluation previous (T0) and two evaluations after SARS-CoV-2 infection (T1, T2) were included in our analysis. Sociodemographic, clinical, disease activity, therapeutic response, function and general health status data were collected. Statistical analysis (significance at p < 0.05) was performed using paired t-test, Wilcoxon test and McNemar tests for paired samples. Linear and logistic regression models were performed to assess direction and strength of association.

Results: Thirty-two patients with SpA under bDMARD had COVID19, mostly women (20, 62.5%), with a disease course time averaged 18.65 (± 9.69) days, mainly with axial involvement (19, 59.4%) and positive for HLA-B27 antigen (11, 64.7%). The majority were under TNF inhibitors (30, 93.75%), with golimumab being the most common (9, 28.1%), and with a median bDMARD persistence of 2.63 (5.09) years. Seven (21.9%) were under a cDMARD, 3 (9.4%) under NSAID and 18 (56.3%) under corticosteroids. Three (9.4%) were already vaccinated against SARS-CoV-2, 2 (66.6%) with the mRNA-1273 vaccine, presenting a medium time since inoculation of 240 (± 234.01) days. Arterial hypertension was the most common comorbidity (5, 15.6%) and one patient (3.1%) had a previous diagnosis of type 2 diabetes. Most were never-smokers (17, 53.1%) and never-drinkers (29, 90.6%). The average age at infection was 40.97 (± 6.15) years and the most common symptom was cough (22, 68.8%), followed by headache (20, 62.5%) and myalgia (19, 59.4%). Event tree analysis didn't show association with SpA subtype, education level, work status, tobacco or alcohol consumption. Only one patient needed hospital admission but without needing of oxygen, therapy, ventilator or ECMO. Only one patient had an overlaid bacterial infection and no thromboembolic complications were observed. Two patients needed specific SARS-CoV-2 infection treatment, one with hydroxychloroquine and another with azithromycin. Twelve (37.5%) patients suspended bDMARD at the time of infection, with only 2 (6.3%) maintaining suspension at the time of the first post-infection visit. When comparing clinical variables, higher disease activity was seen at T1 only for BASDAI mean values, without statistical significance. Higher all domains VAS scores were also observed at T1, but not at T2, also without statistical significance; moreover, physical function didn't change significantly. No differences were observed according to gender or SpA subtype, nor with the use of cDMARD, NSAIDs or corticosteroids. The only statistically significant difference concerned MASES score between T0 and T1 (1 ± 4 vs. 2 ± 6, p=0.04), but not between T0 and T2. Higher baseline tender joint score (p < 0.01) and higher baseline LEI (p=0.03) negatively correlated with MASES score variation. Several baseline variables correlated positively with MASES at T1, including female gender (p < 0.01), corticosteroid use (p = 0.04), BASDAI (p < 0.01), ASDAS-ESR (p < 0.01), ASDAS-CRP (p < 0.01), DAS28 (p < 0.01), SPARCC (p = 0.04), physician VAS (p = 0.03) and total spine VAS (p = 0.01). Working status varied significantly after SARS-CoV-2 infection (at least part-time - 29, 90.6% vs. 22, 68.8%, p= 0.016).

Conclusion: SpA patients on bDMARD had a mild course of SARS-CoV-2 infection, with slight changes in enthesisis score in the short term, the latter particularly in those with higher disease activity in the pre-infection period. Long-term effects on work status could represent confounding factors related to the economic constraints of the pandemic.

AB1112 NO INCREASED RISK OF ADVERSE EVENTS OF THE WHO-VALIDATED COVID-19 VACCINES IN PATIENTS WITH RHEUMATIC DISEASES TREATED WITH BIOLOGICS  
M. Yasmine1, W. Triki1, H. Ferjani1, D. Ben Nessib1, K. Maattaïlah1, D. Kaffel1, W. Hamdi1, 1Kassab Institute of Orthopedics, Rheumatology; Tunis, Tunisia  
Background: The COVID-19 pandemic is a major concern for the management of patients with rheumatic diseases (RD). Indeed, an increasing risk of coronavirus infection has been demonstrated in these patients, explained on the one hand by the chronic inflammation and on the other hand by the immuno-modulating treatments used [1]. In this context, vaccination represent an efficient mean to prevent infections and should be included in the management of these patients.  
Objectives: The objective of our study was to determine the peculiarity of vaccination against SARS-CoV-2 in patients with RD treated with biologic therapies.  
Methods: We conducted a cross-sectional study during August 2021, including patients with RD: rheumatoid arthritis (RA) and spondyloarthritis (SpA). Sociodemographic data as well as disease characteristics were recorded. Patients were asked to answer a self-questionnaire about SARS-CoV-2 vaccination: modalities, time between doses, type of vaccine, adverse events, and time to biologic injection. We compared these results between the two groups: group 1 patients on biologics and patients on conventional disease-modifying antirheumatic drugs (DMARDs). A significance level was set for p<0.05.  
Results: The study included 102 patients with RD: RA (65.3%) and SpA (34.7%). The mean age was 52.4 ± 13 years [19-77]. There was a female predominance (71 women and 31 men) with a gender ratio of 0.4. The mean duration of disease progression was 7.8 ± 5 years [1-35]. Fifteen percent of patients were on corticosteroids with a mean dose of 6.7 mg [2-20] of prednisone equivalent.  
Conclusion: Our work demonstrated that patients treated with biologics adhered to vaccination and did not have more SARS-CoV-2 infections or adverse events compared to patients on conventional treatment.

AB1113 AUTOINMUNE DISEASE-ASSOCIATED INTERSTICIAL LUNG DISEASE  
A. García Studer1, M. Rojas-Giménez2, M. Veloso Feijoo3, C. M. Romero-Barco3, F. Godoy-Navarrete4, N. Mena-Vázquez1, 1Instituto de Investigación Biomédica de Málaga (IBIMA), UGC de Reumatología, Hospital Regional Universitario de Málaga (HRUM), Málaga, Spain; 2Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), UGC de Reumatología, Hospital Universitario Reina Sofia de Córdoba, Córdoba, Spain; 3Hospital Universitario Virgen de Salamanca, Servicio de Reumatología, Salamanca, Spain; 4Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Universitario Virgen de la Victoria, Málaga, Spain; 5Hospital Universitario de Jaén, Servicio de Reumatología, Jaén, Spain  
Background: Interstitial lung disease (ILD) is a common condition in patients with systemic autoimmune diseases (SAI) that is characterized by increased morbidity and mortality. Coronavirus disease 2019 (COVID-19), caused by SARS-CoV-2, has posed huge challenges worldwide and previous studies suggest that ILD patients experience a more severe clinical course.  
Objectives: To analyze COVID-19 infection effects in patients with ILD associated systemic autoimmune disease (ILD-SAI) and to describe their vaccination status.  
Methods: Design We performed a multicenter, retrospective, observational study from 6 teaching hospitals in Andalusia, Spain. Study protocol We included ILD-SAI patients: rheumatoid arthritis (RA), systemic sclerosis (SS) and inflammatory myopathies (IM), assisted in rheumatology consultations in 2021. Variables COVID-19 infection was the main variable that we collected and it was confirmed by a positive result on a PCR test. Secondary variables: (1) COVID-19 severity defined as hospitalization or death; (2) vaccination status; (3) temporary relationship between infection and vaccination. Other variables included: clinical, epidemiological characteristics, treatments received, type of ILD (UIP/NSIP), pulmonary function testing and high-resolution computed tomography.  
Statistic analysis Two multivariable logistic regression analysis to indentify the "COVID-19" and "severe COVID-19" associated factors.  
Results: We included 176 ILD-SAI, of whom: 105 (59.7%) had RA, 49 (27.8%) had SS and 22 (12.5%) had IM. The main baseline characteristics for the overall sample and te 3 subgroups are shown in Table 1.  
Table 1. Clinical and epidemiological characteristics of 171 ILD-SAI patients.

</table>

We recorded 22/179 (12.5%) SARS-CoV-2 infections, 7/22 (31.8%) of them were severe and 3/7 (42.85%) died. As to the vaccination, 163/176 (92.6%) patients received the complete dosis. Among those correctly vaccinated 18/163 (11%) had the SARS-CoV-2 infection, 4/18 (22%) after the vacciniation date and 14/18 (77%) when they still dount have the complete vacci- nation. From the 13 not vaccinated patients, 4/13 (30.7%) had COVID-19. As to frequency, COVID-19 severity and vaccination, there were no difference over subgroups of CTD-ILD patients. The risk factors associated with the COVID-19 infection were the last FVC (OR [CI 95%], 0.971 [0.944-0.998]; p=0.046), the vaccination (OR [CI 95%], 0.185 [0.049-0.891]; p=0.012) and the Rituximab treatment(OR [CI 95%], 3.172 [1.028-6.785]; p=0.045). Moreover, the only variable associated independently with the severe COVID-19 was the protective effect of vaccination (OR [CI 95%], 0.020 [0.003-0.119]; p<0.001).  
Conclusion: A total of 12.5% ILD-SAI patients were COVID-19 infected, most of them without the complete vaccine. Rituximab and a deterioration of FVC were risk factors for the COVID-19 wehreas the vaccination was a protective factor for the mild and severe infection.

AB1113 THE IMPACT OF SARS-COV-2 INFECTION ON DISEASE ACTIVITY AND CLINICAL RESPONSE TO BIOLOGICAL DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS  
B. Sambe1, A. Martins2, D. Santos Oliveira1, F. R. Martins1, R. Nicola1, M. Rato1, F. Oliveira Pinheiro1, M. Bernardez2, L. Costa1, 1Centro Hospitalar Vila Nova de Gaia / Espinho – Unit 1, Rheumatology Department, Vila Nova
VACCINATION OF PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: AN ANALYSIS OF BARRIERS AND FACILITATORS IN A PROSPECTIVE COHORT

I. Andreica, I. Roman, X. Baralakos, J. Braun, U. Kitz, Rheumazentrum Ruhrgebiet and Ruhr-Universität Bochum, Rheumatology, Herne, Germany

Background: Patients (pts.) with chronic inflammatory rheumatic diseases (CIRD) are often not adequately protected against infectious diseases. As shown in an earlier study, less than 50% of CIRD pts. were vaccinated against pneumococci and influenza before the SARS-CoV-2 pandemic started. High vaccination rates are critical to achieve herd immunity. Knowledge on barriers and facilitators of vaccine uptake in CIRD pts. is limited.

Objectives: The aim of this study was to characterize barriers and facilitators towards vaccines in general and specifically against pneumococci, influenza and SARS-CoV-2 in adult CIRD pts.

Methods: In early 2021, consecutive CIRD pts. completed a structured questionnaire including knowledge on vaccination, attitudes, and perceived barriers and facilitators towards vaccination. A total of 12 facilitators and 11 barriers towards vaccination was assessed in general, and specifically for vaccination against pneumococci, influenza and SARS-CoV-2. The Likert scales had 4 response options, ranging from 1 (completely disagree) to 4 (completely agree). Patient and disease characteristics, their vaccination history and attitudes towards vaccination against SARS-CoV-2 were assessed.

Results: Of 514 prospectively recruited pts., 441 responded (85.8%) to the questionnaire (table 1). Self-reported vaccine uptake was 48.8% against pneumococci and 66.2% against seasonal influenza. The majority (82.2%) was willing to be vaccinated against SARS-CoV-2. The majority (70%) had decent knowledge about vaccination, and only <10% doubted its effectiveness. The level of knowledge did not differ between the studied 3 vaccinations. Pts. were more likely to rate statements about facilitators favorably compared to statements about barriers. Facilitators for SARS-CoV-2 vaccination did not differ from vaccination in general (Figure 1). Societal and organizational facilitators such as public vaccine campaigns or protection for high-risk pts. were more commonly named compared to inter- or intrapersonal facilitators. Protection of high-risk pts. was by far the most frequently cited facilitator. Most pts. indicated that they were likely to receive a vaccine if their health care professional would recommend it – without preference for GP or rheumatologist. The frequency of barriers was much lower compared to facilitators and more barriers towards SARS-CoV-2 vaccination were reported in comparison to vaccination in general or pneumococci and influenza, respectively. However, pts. frequently cited intrapersonal issues as barriers against vaccination. Importantly, the major barrier was an inadequate risk perception between the severity of COVID-19 and the potential adverse events of the vaccine.

Table 1. Patient and disease characteristics

|       | Age, y | Women, No. (%) | Men, No. (%) | CRP, mg/L, n=440 | CDAI, n=194 | HADS-D, n=436 | HADS-A, n=436 | DAS28, n=371 | BASDAI, n=118 | BASFI, n=118 | HAQ score, n=317 | Employment status, No. (%) | Work status, No. (%) | PSQ score, n=337 |
|-------|-------|----------------|-------------|------------------|-------------|---------------|---------------|---------------|---------------|---------------|-------------------|----------------------|------------------|
|       | 54.1 (12.6) | 272 (54.4) | 256 (52.8) | 0.4 (0.7) | 11.1 (9.0) | 5.8 (4.3) | 6.6 (4.0) | 3.8 (2.2) | 4.1 (2.5) | 6.6 (4.0) | 6.6 (4.0) | 7.8 (4.0) | 8.3 (4.0) |

Variables as mean (SD)

Figure 1. Facilitators of vaccine uptake in general and for SARS-CoV-2

Conclusion: A relatively high number of pts. was vaccinated against pneumococci and influenza, a relatively high campaign success during the last year. In addition, more than 80% of pts. were willing to be vaccinated against SARS-CoV-2. Facilitators were of greater significance than barriers in this scenario. The high number of societal and organizational facilitators enables the implementation of effective strategies to increase future vaccination rates.

[AB1115] COVID-19 VACCINE HESITANCY AMONG RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGICS

E. Hanneche1,2, S. Boussaid1,2, S. Reki1,2, S. Jemmali1,2, S. Rahmouni1, H. Aji2, H. Sahli2, M. Elleuch1,2. RHEUMATOLOGY Department, La Rabita Hospital, Tunis, Tunisia; 3Faculty of medicine of Tunis, University Tunis El Manar, Tunis, Tunisia

Background: Vaccine hesitancy is defined by the OMS as “a delay in acceptance or refusal of vaccines despite availability of vaccination services” [1], and it is considered as one of threats to global health. This hesitancy emerges around Covid-19 vaccination. Patients on biologic Disease-Modifying Anti-Rheumatic Drug (bDMARD) are vulnerable to Covid-19 infection and their perception to vaccination is unknown.

Objectives: The aim of our study was to identify Covid-19 vaccine hesitancy among rheumatoid arthritis (RA) patient on bDMARD.

Methods: We conducted a monocentric, cross-sectional study, including patients with RA who met the ACR/EULAR 2010 criteria. All patients were on bDMARD with or without conventional synthetic (Cs) DMARD for at least 3 months. Disease activity was assessed using the Disease Activity Score (DAS) 28 (CRP) and the functional impairment using the Health Assessment Questionnaire (HAQ). A structured interview was done using a prepared questionnaire evaluating their vaccine hesitancy behavior.

Results: We enrolled 60 patients: 10 male (16.7%) and 50 females (83.3%). Their average age was 58.16±9.04 years [34-80]. For the education level: 38.5% of patients were illiterate, 34.6% had primary education, 23.1% had secondary education, and 3.8% have a university degree. Forty-four patients (73.3%) had no occupation, 13 patients (21.7%) were employed, and 5% were retired. The majority of patients lived in urban areas (85%) and 98.2% with their secondary education, and 3.8% have a university degree. Forty-four patients (73.3%) had no occupation, 13 patients (21.7%) were employed, and 5% were retired. The majority of patients lived in urban areas (85%) and 98.2% with their families. The average duration of RA was 15.23±8.8 years [2-39]. The average DAS28 (CRP) and the average HAQ were 4.05±1.22 [1.5-7.2] and 0.7±0.4 [0-2.4], respectively. Fifteen patients (25%) had a high disease activity and seven (11.7%) were in remission. When asking patients about their Covid-19 infection and vaccination status; 15% had caught the virus and 61.7% have already received the vaccine. One third (35.6%) believed that they had enough information about vaccination. Their main sources were their family, friends, and the media. More than half of the asked patients (68.3%) reported vaccine hesitancy. Reasons of vaccine hesitancy were divided into three categories: lack of confidence (66.7%, p<0.005) (63.3% fear related to side effects, 10% conspiracy theory, 6.7% lack of confidence in the provider), complacency problem (16.7%, p=0.01) and lack of convenience (8.6%). There was no association between vaccine hesitancy and sociodemographic data. The existence of comorbidities had no influence on vaccine hesitancy (p=0.4). This hesitancy was not associated with DAS28 (CRP) (p=0.6) and with HAQ (p=0.7). Patients with moderate to high disease activity were more likely to deny the usefulness of Covid-19 vaccination (p=0.09). Regarding to the therapeutic data, there was no association between corticotherapy and vaccine hesitancy (p=0.1). There was no influence on the type of the current bDMARD (p=0.3) or of the rate of administration (p=0.4). The route of administration was associated with hesitancy (53.65% intravenous vs 46.34% subcutaneous, p=0.04).

Conclusion: Our study showed that Covid-19 vaccination coverage among RA patients on bDMARDs was not optimal with a high percentage of hesitancy. The reasons are complex and they may be related to a lack of awareness. Rheumatologists should play a key role in the vaccine company.

[AB1116] RESULTS OF PRESCRIBING BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS AND JANUS KINASE INHIBITORS FOR RHEUMATOID ARTHRITIS DURING THE COVID-19 PANDEMIC: DATA FROM A TELEPHONE SURVEY OF 254 PATIENTS.

A. Potapova1, A. Karateev2, E. Pogozheva1, E. Matianova1, A. Bobkova1, A. Semashko1, E. Filatova1, V. Amirdzhanaeva1, E. Zotkin1, A. Lilia1, 1VA. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow; Russian Federation

Background: Prescribing biologic disease-modifying antirheumatic drugs (bDMARDs) and Janus kinase (JAK) inhibitors during the global pandemic of coronavirus disease 2019 (COVID-19) requires a balanced approach and rigorous monitoring of patients’ condition.

Objectives: To evaluate the effect of bDMARDs and JAK inhibitors on the condition of patients with rheumatoid arthritis (RA), taking into account the outcomes assessed by the patients themselves, as well as the incidence of COVID-19 in these patients.

Methods: A telephone survey was conducted of 254 patients with RA (age 49.8 ±13.7 years, 83.5% women, RF + 64.4%, DAS28 5.4 ± 1.6), who in the period from January 2020 to June 2021 by decision of the medical commission of the V.A. Nasonova Research institute was first prescribed bDMARDs or JAK inhibitors: rituximab (RTX) - 148 (58.3%), TNF-a inhibitors - 57 (22.4%), JAK inhibitors - 20 (7.9%), IL 6 inhibitors - 17 (6.7%), abacetab - 12 (4.7%).

Results: At the time of the survey, 204 (80.3%) patients continued to take the prescribed drugs. The main cause discontinuation of treatment was for non-medical reasons. Synthetic DMARDs (mainly methotrexate and leflunamide) were received by 68.0%, glucocorticoids - 45.3%, non-steroidal anti-inflammatory drugs - 44.5% of respondents. Among the patients who took bDMARDs or JAK inhibitors, 68.1% noted the “state of symptoms acceptable to the patient”; the absence of frequent joint pain - 65.3%, increased fatigue - 14.3%. The incidence of COVID-19 and hospitalization associated with this disease didn’t differ between individuals who continued and discontinued the use of bDMARDs or JAK inhibitors: 41.2% and 44.6%; 13.7% and 14.0% respectively, p=0.80884. There was no significant difference in the incidence of COVID-19 and hospitalization associated with this disease in patients taking various biologics or JAK inhibitors.

Conclusion: Despite the COVID-19 pandemic, rituximab remains one of the most popular bDMARD. About a third of patients receiving bDMARDs and JAK inhibitors aren’t satisfied with their condition. More than 40% of patients treated with these drugs experienced COVID-19, and 14.0% required hospitalization.

[AB1117] THE IMPACT OF THE COVID-19 PANDEMIC ON HEALTH AND LIFESTYLE IN INDIVIDUALS WITH KNEE PAIN, A HALLOSA STUDY

E. Sunesson1, C. Sylwander1,2, E. Haglund3,4, M. Andersson1,3, I. Larsson1,2,3. 1Spenshult Research and Development Centre, Halmstad, Sweden; 2Halmstad University, School of Health and Welfare, Halmstad, Sweden; 3Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden; 4Halmstad University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmstad, Sweden

Background: Covid-19 has affected everyday life, health and lifestyle among the general population and vulnerable groups. Individuals with knee pain are recommended an active lifestyle to reveal pain but find it difficult to maintain health and lifestyle compared to the general population due to the cause of chronic pain, impaired physical function and a diminishes quality of life. This adds to the importance of exploring how to preserve health and lifestyle among individuals with knee pain during the pandemic.

Objectives: The aim of this study was to explore the impact of the covid-19 pandemic on the health and lifestyle in individuals with knee pain. A second objective was to assess if current knee pain and disability had changed during the pandemic.

Methods: Nineteen participants with current knee pain, and with no earlier diagnosed radiographic osteoarthritis, and no rheumatologic disorder or cronic ligament injury. were recruited from The Halland Osteoarthritis (HALLOA) Cohort Study, twelve female and seven males, between 41-62 (median 51) years of age. Data were collected through individual interviews with open-ended questions: What impact have you experienced with your health and lifestyle during covid-19? What activities or changes have you changed to maintain your health and lifestyle during covid-19? Qualitative content analysis was used, where two categories and five sub-categories emerged (Table 1).
Table 1. Categories, and sub-categories exploring the impact of the covid-19 pandemic on health and lifestyle in individuals with knee pain

<tr>
<td>Valuing life due to covid-19</td>
<td></td>
</tr>
</tbody>
</table>

**Results:** The results from this study explored how behaviour and attitude towards valuing life have been adjusted to maintain health and lifestyle among individuals with knee pain during covid-19. The categorical analyses emerged with the sub-categories: spending more time at home, becoming digitally, and spending more time outdoors. These sub-categories determine how a more reclusive behaviour was adopted to maintain health and lifestyle, as well as their supporting others maintain their health and lifestyle. The result may in the future contribute to alternative ways of maintaining health and lifestyle in different vulnerable groups and may be used in situations other than the pandemic.

**AB1118 INVESTIGATION OF THE EFFECT OF THE HISTORY OF COVID-19 ON COGNITIVE LEVEL, PAIN CATASTROPHIZATION, AND PHYSICAL ACTIVITY LEVEL IN INDIVIDUALS WITH CHRONIC LOW BACK AND NECK PAIN**

A. Ailiyucu1, O. Ulger2,1, Ankara, Physical Therapy and Rehabilitation, Ankara, Turkey; 1Hacettepe University, Physical Therapy and Rehabilitation, Ankara, Turkey

**Background:** Low back and neck pain is one of the most common health problems in society, and one of the top reasons for admission to the hospital (1). Studies show that the level of physical activity decreases in individuals with chronic pain, and the cognitive level and quality of life are negatively affected (2). There are studies examining the effects of the Covid-19 pandemic process on the level of physical activity and cognitive level in various groups. However, the number of studies on how the history of Covid-19 affects individuals with low back and neck pain is limited.

**Objectives:** The aim of this study is to examine the effect of Covid-19 history on cognitive level, pain catastrophize and physical activity level in individuals with chronic low back and neck pain in individuals.

**Methods:** A total of 25 individuals with chronic pain, including 16 with low back pain and 9 with neck pain, were included in the study. Demographic data such as age, gender, and body mass index (BMI) were obtained from all individuals. The education levels of the individuals were recorded. Cognitive level was assessed by the Montreal Cognitive Assessment (MoCA)(3), pain severity was assessed by the Visual Analog Scale (VAS), pain catastrophization was assessed by the Pain Catastrophizing Scale (PCS)(4), and physical activity level was assessed by the International Physical Activity Questionnaire-Short Form (IPAQ-SF)(5).

**Results:**

| Primary school n (%)                | 0 (0%) must, 11 (44.0%) High school n (%) 11 (44.3%) Bachelor's degree n (%) 5 (21.4%)
| Moca                                | 0.01* (p = 2.3) Moca 0.01* (p = 2.3) Moca 0.01* (p = 2.3) Moca 0.01* (p = 2.3)
| VAS                                 | 0.01* (p = 2.3) VAS 0.01* (p = 2.3) VAS 0.01* (p = 2.3) VAS 0.01* (p = 2.3)
| PSC                                 | 0.01* (p = 2.3) PSC 0.01* (p = 2.3) PSC 0.01* (p = 2.3) PSC 0.01* (p = 2.3)
| IPAQ-SF                             | 0.01* (p = 2.3) IPAQ-SF 0.01* (p = 2.3) IPAQ-SF 0.01* (p = 2.3) IPAQ-SF 0.01* (p = 2.3)

Demographic data, VAS, MoCA, PCS, and IPAQ-SF scores are given in Table 1. 7 of the participants had history of Covid-19, 18 did not. The MoCA scores and education levels of individuals with Covid-19 were higher than individuals without history of Covid-19 (p<0.05). There was no difference in physical activity, pain and pain catastrophization levels between the 2 groups (p> 0.05).

**Conclusion:** Surprisingly, individuals who had a history of Covid-19 had higher cognitive levels than individuals without a history of Covid-19. In addition, there was no difference between physical activity and pain catastrophization levels. This may be due to the higher education level of individuals with a history of Covid-19. There is a need for further studies in which education levels are similar, and hospitalization and the Covid-19 positivity process are examined in more detail.

PSYCHOLOGICAL ASSESSMENT IN PATIENTS WITH CHRONIC RHEUMATIC, SYSTEMIC AUTOIMMUNE, OR AUTOINFLAMMATORY DISEASES PRESENTED WITH COVID-19: THE MENTOCVRMD STUDY.

M. M. Farhat1,2, M. Horn3,4, G. Vaiva5,6, E. Drumez5,6, R. Sero7,8, V. Gaudin9,10, V. Devauchelle-Pensec11,12, S. Guillaume-Czitrom11,12, N. Hamamouche16, S. Morell-Dubois13,14, E. Hachulla1,17, on behalf of FAI2R/SFR/SNFMI/SMFH.

AB1120

BACKGROUND:

The COVID-19 pandemic has raised concerns about its psychological impact on patients with chronic rheumatic, autoimmune and/or autoinflammatory diseases, due to immunosuppression, are at risk of severe forms of infection. Currently, there is little information on psychological impact of the pandemic on the mental health of these more vulnerable patients.

METHODS:

In the present study, we included 59 patients with chronic rheumatism, systemic autoimmune disease, or autoinflammatory diseases who presented with COVID-19 infection between March and September 2020, first wave of French pandemic, and patients with same diseases who did not presented with infection to date.

RESULTS:

Between February and December 2021, 60 cases (46 (76.7 %) women), median age 52.0 (39.0; 63.0) were included, of which 15 (25 %) had been hospitalized during infection, and 169 controls (148 (87.6%) women), median age of 52.0 (38.0; 63.0). There were more smokers in the group of cases (12 %) than controls (14 (9.1 %) (p=0.028) as well as more cases on ARA2 treatment (8 (13.3 %)) than controls (7 (4.5 %) (p=0.035) with no statistically significant difference in others comorbidities or treatments. There was no statistically difference concerning the ISCI scores between cases (11.6 ± 7.31) of which 60% had sleep disorders and controls (11.64 ± 6.82) of which 70.4% had sleep disorders. There was no statistically significant difference in PTSD scores of 15.5 (5.0 to 28.0) for cases and 18.0 (8.0 to 35.0) for controls, of which respectively 12 (20 %) had values indicating possible PTSD for cases and 50 (29.6 %) for controls. There was no statistically significant difference in PHQ-9 scores (5.5 (1.5 to 11.0)) of which 50% had depressive symptoms and controls (6.0 (2.0 to 11.0)) of which 54.5% had symptoms. There was no statistically significant difference in GAD-7 scores (3.5 (0.0 to 8.0)) of which 40% had anxiety symptoms and controls (4.0 (0.0 to 8.0)) of which 43.2% had symptoms. There was no statistically significant difference in PHQ-15 scores (11.4 ± 6.7), 85% of whom reported presence of symptoms, and controls (10.9 ± 6.2), 82.3% of whom reported symptoms. There was no statistically significant difference in SSD scores between cases (17.7 ± 10.5) and controls (18.4 ± 10.9). There was a statistically significant difference in reported VAS scores of pain related to inflammatory rheumatism in cases with a median of 4.5 (3.0 to 6.0) compared to controls with a medium of 4.0 (1.0 to 6.0) (p=0.011). There was no statistically significant difference in any of the psychological assessment scores between the inpatient and outpatient groups.

CONCLUSION:

There was no statistically significant difference between COVID cases and controls in the evaluation of these psychological parameters. Prevalence of all these variables were high in the whole study population, testifying to the need to manage these psychological aspects for patients with chronic rheumatisms, autoimmune and/or autoinflammatory diseases.

HOW FEARS AND HOPES HAVE EVOLVED IN PATIENTS WITH RMSD THROUGH THE COVID-19 PANDEMIC? RESULTS FROM THE REUMAVID STUDY (PHASE 1 AND 2)

M. Garrido-Cumbre1,2, H. Marzo-Ortega1,4, E. Mateus1,2, L. Grange5,6, D. Webb7, C. Jacklin11, S. Irwin12, S. Mingolla13, K. Antonopoulou14, S. Makri15, V. Navarro-Compañ16 on behalf of REUMAVID working group.

AB1121

BACKGROUND:

The COVID-19 pandemic has raised concerns about its psychological effects. Sleep disturbances, anxiety and/or depressive symptoms, post-traumatic stress symptoms have been reported in general population. Patients with chronic rheumatism, systemic autoimmune disease or auto-inflammatory disease, due to immunosuppression, are at risk of severe forms of infection. Currently, there is little information on psychological impact of the pandemic on the mental health of these more vulnerable patients.

OBJECTIVES:

To compare psychological assessment between patients with chronic rheumatism and/or autoinflammatory diseases who presented with COVID-19 infection between March and September 2020, first wave of French pandemic, and patients with same diseases who did not presented with infection to date.

METHODS:

The MENTOCVRMD study was a multicenter descriptive study. Cases were patients with chronic rheumatic, autoimmune and/or autoinflammatory diseases from the French RMSD cohort who presented COVID-19 infection between March and September 2020. Controls were patients with same diseases who did not develop infection. The study is registered in Clinical Trials under number 2020-A02058-31. For participants, following criteria were collected: demographics (age, gender, smoking status), psychological assessment questionnaires: Insomnia Severity Index (ISI); Post-traumatic stress disorder (PTSD) checklist; Patient Health Questionnaire (PHQ9) Depression; Generalized Anxiety Disorder (GAD7) Anxiety; Patient Health Questionnaire-15 (PHQ-15) and Somatic Symptom Disorder (SSD)-12.

RESULTS:

Between February and December 2021, 60 cases (46 (76.7 %) women), median age 52.0 (39.0; 63.0) were included, of which 15 (25 %) had been hospitalized during infection, and 169 controls (148 (87.6%) women), median age of 52.0 (38.0; 63.0). There were more smokers in the group of cases (12 %) than controls (14 (9.1 %) (p=0.028) as well as more cases on ARA2 treatment (8 (13.3 %)) than controls (7 (4.5 %) (p=0.035) with no statistically significant difference in others comorbidities or treatments. There was no statistically difference concerning the ISCI scores between cases (11.6 ± 7.31) of which 60% had sleep disorders and controls (11.64 ± 6.82) of which 70.4% had sleep disorders. There was no statistically significant difference in PTSD scores of 15.5 (5.0 to 28.0) for cases and 18.0 (8.0 to 35.0) for controls, of which respectively 12 (20 %) had values indicating possible PTSD for cases and 50 (29.6 %) for controls. There was no statistically significant difference in PHQ-9 scores (5.5 (1.5 to 11.0)) of which 50% had depressive symptoms and controls (6.0 (2.0 to 11.0)) of which 54.5% had symptoms. There was no statistically significant difference in GAD-7 scores (3.5 (0.0 to 8.0)) of which 40% had anxiety symptoms and controls (4.0 (0.0 to 8.0)) of which 43.2% had symptoms. There was no statistically significant difference in PHQ-15 scores (11.4 ± 6.7), 85% of whom reported presence of symptoms, and controls (10.9 ± 6.2), 82.3% of whom reported symptoms. There was no statistically significant difference in SSD scores between cases (17.7 ± 10.5) and controls (18.4 ± 10.9). There was a statistically significant difference in reported VAS scores of pain related to inflammatory rheumatism in cases with a median of 4.5 (3.0 to 6.0) compared to controls with a median of 4.0 (1.0 to 6.0) (p=0.011). There was no statistically significant difference in any of the psychological assessment scores between the inpatient and outpatient groups.

CONCLUSION:

There was no statistically significant difference between COVID cases and controls in the evaluation of these psychological parameters. Prevalence of all these variables were high in the whole study population, testifying to the need to manage these psychological aspects for patients with chronic rheumatism, autoimmune and/or autoinflammatory diseases.

DISCLOSURE OF INTERESTS:

None declared.
Background: The COVID-19 pandemic has generated uncertainties and concerns among patients with rheumatic diseases throughout the two phases of RÉUMAVID.

Methods: RÉUMAVID is an international cross-sectional study collecting data through an online survey in seven European countries led by the Health & Territory Research Group of the University of Seville, together with a multidisciplinary team including patient representatives, rheumatologists, and health researchers. Data were collected in two phases: Phase 1 (P1) between April-July 2020 and Phase 2 (P2) between February-April 2021. Demographics, health behaviours, employment status, access to healthcare services, disease characteristics, WHO-5 Well-Being Index and Hospital Anxiety and Depression Scale (HADS). Participants rated a series of fears (infection, medication consequences, lack of medication, impact on healthcare, lost job, civil disorder) on a scale from zero ("no concern at all") to five ("extremely concerned") and hopes (treatment/vaccine availability, going outside, travel, economic situation, treatment continuation, health status) on a scale from zero ("no hope at all") to five ("extremely hopeful"). Descriptive analysis and Mann-Whitney test were used to explore fears and hopes in both phases of RÉUMAVID.

Results: A total of 3,802 participants were recruited across both phases in RÉUMAVID with comparable demographic characteristics: mean age 52.6 (P1) vs. 55.0 years (P2), 80.2% female (P1) vs. 83.7% (P2), 69.6% married (P1) vs. 68.3% (P2), and 48.6% university educated (P1) vs. 47.8% (P2). Most prevalent RMD was axial spondyloarthritis in P1 (37.2%), and rheumatoid arthritis in P2 (53.1%). In P1 and P2 the major concern was the impact on healthcare in the future (3.1 and 3.2 out of 5, p = 0.051). Compared to P1, patients in P2 had less fears about RMD medications not reaching the country (2.4 vs. 1.9, p < 0.001), civil disorders (2.0 vs. 1.8, p = 0.001), or losing their jobs (1.4 vs. 1.5, p = 0.003). Comparing hopes with P1, patients in P2 had greater hopes about availability of treatments or vaccines suitable for COVID-19 (3.2 vs. 3.9, p < 0.001), to be able to go out as before the pandemic (3.1 vs. 3.5, p < 0.001), to be able to travel as before the pandemic (2.8 vs. 3.3, p < 0.001), maintain and even improve the current economic situation after the pandemic (2.6 vs. 3.0, p < 0.001), and to be able to continue their treatment as usual (3.8 vs. 3.9, p = 0.049; Table 1).

Conclusion: During the first phase of RÉUMAVID at the beginning of the pandemic, patients with RMDs were more fearful and less hopeful compared to the second phase. These fears were notable in terms of lack of medication for their RMD, while during the second phase, patients were hopeful of a treatment or vaccine against COVID-19, and of being able to go out and travel as before.

Acknowledgements: This study was supported by Novartis Pharma AG. AB1112
EFFICACY AND SAFETY OF SARS-COV-2 THIRD VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO DID NOT RESPOND AFTER PRIMARY TWO-DOSE REGIMEN

Background: Vaccination for COVID-19 is an essential tool to fight the pandemic. Evidence suggests that patients with immune mediated inflammatory diseases (IMIDs) have less response. The application of a booster shot is a strategy that has been implemented in this population, however there is scarce information about its efficacy.

Objectives: To assess the humoral and cellular immune response after a third dose of SARS-CoV-2 vaccine in patients with rheumatoid arthritis (RA) with undetectable antibodies titers after primary regimen of two doses.

Methods: Observational study. Patients with RA (ACR/EULAR 2010 criteria) from two rheumatology centers, ≥18 years old, with no seroconversion after two doses of SARS-CoV-2 vaccine, who received a third dose of either mRNA or vector-based vaccines (BNT162b2 or ChAdOx1 nCoV-19) were included. Anti-SARS-CoV-2 IgG antibodies, neutralising activity and T cell responses were assessed between 21 and 40 days after the third dose. Sociodemographic data, comorbidities, treatment, vaccine applied and the presence of adverse events (AE) were recorded. Statistical analysis: descriptive analysis. Chi² or Fischer test and T test. Results: Total of 99 patients were evaluated. 76 (76.8%) patients were females with a mean age of 63.7 years (SD 11.6) and mean disease duration of 15.8 years (SD 8). Most of them (81%) reported comorbidities, being the most frequent arterial hypertension, obesity and dyslipidemia. At vaccination time, 6 (6.1%) patients were taking methotrexate and ABT and the other one RTX. Compared to other treatments, ABT and RTX was associated with no neutralizing activity in 4 (80%) patients and lower titers of neutralizing antibodies (median 1/3 (IQR 0-1/20) vs median 1/1 (IQR 14-1/128), p=0.197). A T-cell response was present in 41.2% of all patients after the second dose, increasing to 75% after the third dose. The use of ABT was associated with a lower frequency of T-cell response (80% vs 20%, p=0.014). Sixteen (76.1%) patients reported at least one AE, 66.7% injection site reaction and 25% flu-like syndrome.

Conclusion: In this RA cohort who failed to seroconvert after two doses of SARS-CoV-2 vaccine, 90.5% presented detectable anti-SARS-CoV-2 IgG and 75% T-cell response after a third dose. The use of ABT was associated with a lower frequency of T-cell response. This data highlights the importance of a third vaccine in this group of patients.

AB1124
IMPACT OF COVID-19 ON PATIENTS WITH RHEUMATIC DISEASES IN A SECOND LEVEL HOSPITAL

Background: Covid-19 has generated a change in society and in people's daily lives. Patients with rheumatic diseases have suffered physically and mentally, both due to mobility restrictions and to the impact on personal, family, work and social life that COVID-19 has brought.[1-4]

Objectives: To examine the impact of the pandemic COVID-19 on patients with rheumatic diseases.

Methods: Cross-sectional descriptive study in patients with rheumatic diseases. Data collection was done through an online questionnaire to assess the impact of COVID-19, adapted for this purpose and made up of 5 scales of the 9 of the Coronavirus Psychological Impact Questionnaire [3]. This instrument is divided into two parts: 1) sociodemographic variables and 2) Experience with Coronavirus (ECOVI); Preventive Behaviour Use (UCP); Fear against coronavirus Scale (EMC); Interference with the coronavirus Scale (EIC) and positive psychological aspects (EPAP). This questionnaire was accessed through a QR code (provided to all patients both in consultations and in the day hospital) by the rheumatology team for two weeks between November-December 2021. In addition, this code was sent by the nurse via WhatsApp to all patients registered in our database.

Statistical analysis: SPSS 24.0 and Pearson Chi-square, T-Student and ANOVA tests.

Results: n=362 online surveys; 72% women with a mean age of 63 years ± 14.21 (22-70 years). The most frequent rheumatic diseases were Rheumatoid Arthritis (50%) and Spondyloarthritids (31%). 83.2% had only one rheumatic disease (mean 1.26 ± 0.66) and 90% self-completed survey. In experience with the Coronavirus (ECOVI), 89% patients had not had symptoms or confirmed diagnosis of coronavirus, 98% were not hospitalized, 91% had confidence in our health system; Regarding the Use of Preventive Behaviors (UCP), 93% used a mask outside the house and 78.5% kept a safe distance; In relation to the most common fears associated with the Coronavirus (EMC), 40% were a little afraid of getting infected (34% quite a bit) and 50% were almost nothing afraid of losing their job; Regarding the interference that the coronavirus has caused in these patients (EIC), 73% had not had serious work problems and 74% had not had difficulties in their studies. In reference to the positive psychological aspects (EEPA), 48% had discovered new hobbies, 19% had become more religious, 83% had learned to value personal relationships more. It was significant that women were more afraid of infecting themselves or a loved one or family member and/or dying from coronavirus than men (p=0.02; p=0.011 and p=0.002 respectively). Regarding age, younger patients (45y) were more concerned that they could lose their job compared to older patients (61y), p=0.

Conclusion: The COVID-19 disease has impacted patients with rheumatic diseases. In our sample, women have been more concerned about being infected and dying themselves and their closest relatives/friends, and younger people more concerned about job loss and economic income than older people. It has to be considered that the majority of this population has not been hospitalized or diagnosed with COVID-19 and also has great confidence in our health care system. More studies are necessary to examine the impact of the COVID-19 after the 6th wave of the pandemic.

REFERENCES:
Background: A novel viral infection known as COVID-19 (Coronavirus-19 disease) spread up in Wuhan (China) in December 2019, but rapidly diffused worldwide and nowadays it remains an international health problem. Because of its impact on immunologic system, immunomodulating therapies have been studied as possible treatments for severe cases of COVID-19. In that context, patients affected by of rheumatic musculoskeletal disorders (RMD) under disease-modifying anti-rheumatic drugs (DMARDs) have been observed in several studies to impact of COVID-19 on these subjects, well known to be at higher risk of infection.

Objectives: The primary objective of this study is to assess prevalence and severity of COVID-19 in patients with RMD under treatment with biologic (b-DMARDs) or targeted synthetic (ts-DMARDs) DMARDs, before the vaccination campaign. The second aim is to compare those data with that in general population of the same Area (Province of Udine, Friuli Venezia Giulia Region, Italy).

Methods: A cohort of RMD patients treated with b-DMARDs or ts-DMARDs was observed from September 2019 to November 2020. Both pandemic waves have been considered, until the start of vaccination (since current variants can overcome vaccine protection), between February 2020 and April 2020 (first wave) and between September 2020 and November 2020 (second one).

Results: Among 1051 RMD patients treated with b- or ts-DMARDs COVID-19 prevalence was 3.5% (37 cases) without significant differences compared to general population of the same Region (Table 1). Infected patients were 18 men and 19 women, with a median age of 60 years (IQR 49-68). Notably, the infection rate of RMD patients was significantly lower compared to the general population of the same province, particularly during the second wave (p<0.001, Table 1). Almost all patients reported fever (70%), Gastro-intestinal symptoms (nausea, vomit and diarrhoea) have been recorded in 10 subjects (27%) and resulted significantly associated with longer swab positivity (p<0.05) (Figure 1). Only a small percentage of patients with COVID-19 infection was receiving corticosteroids (8%), and the doses were low (3.5 or 5 mg per day of prednisone equivalents). The most used b-DMARDs were anti-TNFs (24/37, 65%), while just 4/37 (11%) employed JAK inhibitors. A small percentage of patients (6/37, 16%) continued ongoing treatment, with some risk factors and only 9 patients needed to be hospitalized (24%). After COVID-19 infection, 12 subjects (32%) had RMD flare and 5 of them subsequently needed to change the immunosuppressive drug.

Objectives: To evaluate basic demographics, clinical features and outcomes of COVID-19 infection in patients with SRD from a tertiary rheumatology centre in West Malaysia.

Methods: A retrospective observational study of 77 patients with SRD diagnosed with COVID-19 between 1st December 2020 to the 31st of December 2021 was performed. Demographic details, type of SRD, number and type of disease-modifying antirheumatic drugs (DMARD), dose of glucocorticoid, comorbidities, SARS-CoV-2 vaccine (type and number of doses) hospitalisation, oxygen requirement, type of COVID-19 related complication and death were recorded.

Results: A total of 55 (71%) patients were hospitalised and 9 (12%) died. Mean age at time of COVID-19 diagnosis was 51±14. Amongst these patients, 32 (42%) were Chinese, 30 (39%) Malays and 15 (19%) Indians. Majority of these patients had inflammatory arthritis (56%) which included rheumatoid arthritis and spondyloarthritis. The most common DMARDs used was methotrexate (51%), hydroxychloroquine (46%), sulfasalazine (22%), leflunomide (13%), azathioprine and mycophenolate mofetil (5% each). Two patients were on Janus Kinase (JAK) inhibitors and 3 on biologic DMARDs (tumour necrosis factor inhibitor, IL-6 inhibitors and IL-17 inhibitors). There were 38 patients (49%) vaccinated with two doses of SARS-CoV-2 vaccine (Pfizer n=29, CoronaVac n=7 and AstraZeneca n=2) prior to admission and amongst those unvaccinated, 15 (20%) contracted COVID-19 before the vaccine was released in Malaysia. Among hospitalised patients, those more than 60 years and those with more than one comorbid had a higher chance of admission (n=21, 88%; p=0.036 and n=28, 88%; p=0.001) and death (n=8, 33%; p=0.001 and n=7, 22%; p=0.001). Comorbidities associated with higher risk of hospitalisation was diabetes mellitus (85%, p=0.06), hypertension (82%, p=0.001) and coronary artery disease (100%, p=0.03) and those associated with death was obesity (33%, p=0.01) and hypertension (22%, p=0.007). Use of conventional DMARD, JAK, biologics and glucocorticoid were not associated with hospitalisation or morbidity. However, we found that patients who developed acute respiratory distress syndrome secondary to COVID-19 were mostly on sulfasalazine compared to other DMARDS (35%, p=0.01).
**Conclusion:** In our multiethnic cohort of patients with SRD we found that age and multiple comorbidities such as diabetes mellitus, hypertension, obesity and coronary artery disease were associated with hospitalisation and morbidity. Disease activity and glucocorticoid use which have been shown to be associated with morbidity[1] was not seen in our cohort. The association between sultasalazine and poor outcomes have been reported[2] however further studies are still needed to investigate the causal relationship between the two.

**ANTIOSTEOPOROTIC TREATMENT AND COVID-19: RISK: IS THERE AN ASSOCIATION?**

N. Grupeniewa1, M. Bystrytska1, N. Zaverukha1, A. Musienko1, D. F.Chebotarev Institute of Medical Genetics, NAMS of Ukraine, Clinical Physiology/Pathology of Locomotor Apparatus, Kyiv, Ukraine

**Background:** Nowadays, the COVID-19 and its complications are considered an important medical issue with aggravated medicosocial outcomes, both at the worldwide scale and of various individual countries. Despite the recent ASBM, AACE, Endocrine Society, ECTS and NOF recommendations according to osteoporosis management in the era of COVID-19 the influence of antiosteoporotic drugs on disease incidence and severity continue to be studied[1,2].

**Objectives:** The purpose of this study was to assess the COVID-19 risk for the patients receiving the parenteral bisphosphonate or Denosumab treatment, and the severity of its course in the systemic osteoporosis patients.

**Methods:** We performed the phone survey and studied the results of 195 patients (92 % women; mean age – 62.7±10.8 years, height – 161.0±8.0 cm, body weight – 68.9±12.3 kg) with systemic osteoporosis depending on the current use of parenteral antiresorptive drugs (Zoledronic acid, Ibandronic acid, or Denosumab, n=125) and compared the results with patients with osteoporosis who did not use any antiosteoporotic drugs previously (n=70).

The mean duration of antiosteoporotic treatment did not vary across the groups, accounting for 15 [9-27] months. Prior to the beginning of the antiosteoporotic therapy, all the patients had a confirmed diagnosis of osteoporosis at the Ukrainian scientific-medical Center of osteoporosis.

**Results:** We did not reveal any significant differences in the COVID-19 frequency and severity depending on the presence and type of parenteral antiosteoporotic therapy. Additionally, there were no differences depending on patients’ age of sex, obesity presence, and other osteoporosis risk factors. The risk of COVID-19 in the patients with systemic osteoporosis did not differ depending on antiresorptive drug use, amounting (Odd Ratio (OR) 95 % CI) to 1.1 (0.6-2.0), or on the use of the definite antiosteoporotic drug (for the Zoledronic acid - 0.9 (0.4-2.0), the Ibandronic acid - 1.1 (0.5-2.3), and for the Denosumab - 1.6 (0.5-6.2).

**Conclusion:** Our study did not reveal any significant differences in the COVID-19 frequency and severity depending on the presence and type of parenteral antiosteoporotic therapy. We conclude that parenteral antiosteoporotic drugs (Zoledronic acid, Ibandronic acid, or Denosumab) do not have an influence on COVID-19 frequency and severity and can be recommended for the continuation of treatment of patients with osteoporosis.

**MAINTENANCE THERAPY FOR PATIENTS WITH RHEUMATIC DISEASES DURING THE COVID-19**

D. Ben Nessib1, M. Yasmine1, H. Ferjani1, W. Triki1, K. Maatallah1, D. Kaffel1, 1V .A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccinoprophylaxis, Moscow, Russia

**Background:** The Covid-19 pandemic has been raging for more than a year in a pandemic mode. Since then, many questions have been raised regarding the management of patients with rheumatic diseases (RD). In this context, the maintenance therapy of conventional, biologic and targeted synthetic disease-modifying anti rheumatic drugs (Cs DMARDs, SDMARDs and tsDMARDs respectively) during the Covid-19 infection remains a subject of debate given their immunosuppressive effects as well as their potential generation of lung fibrosis. While the EULAR 2020 guidelines emphasize that discontinuation or maintenance should be discussed on a case-by-case basis, the ACRP guidelines advocate discontinuation of all therapies except for the anti-interleukin-6[1,2].

**Objectives:** The objective of our work was to report our real-life experience of therapeutic maintenance during the covid-19 pandemic.

**Methods:** We conducted a cross-sectional study of patients with RD: rheumatoid arthritis (RA) and spondyloarthritis (SpA) recruited from the rheumatology department of the Kassab Institute of Orthopedics. All the patients were asked to complete a questionnaire about their disease management in the era of the Covid-19. The questionnaire included sociodemographic data, treatment modalities, as well as data related to the infection with the Covid-19 (severe forms defined by the need for oxygen therapy or hospitalization), and changes in treatment during the infection.

**Results:** The study included 102 patients with RA (65.3%) and SpA (34.7%). The mean age was 52.4 ± 13 [19-77] years. There was a female predominance with a sex ratio of 0.4. The mean duration of the disease was 7.8 ± 5 years [1-35]. Fifteen percent of patients were on corticosteroids with a mean dose of 6.7±4.5mg/L [2-20] of prednisone equivalent. CsDMARD was prescribed in 36.3% of cases and combined with a biologic in 16% of cases. A Covid-19 infection was occurred at least once in 25.5% of cases, of which 19.2% had a severe form (hospitalization (15.4%), oxygen therapy (19.2%)). No deaths were observed. The treatments received during the covid-19 infection were: corticosteroids (n=5), heparin therapy (n=6) and antibiotic therapy (n=10). No patient tapered treatment dosage of DMARDS but discontinuation was reported by 4 patients with a mean time between discontinuation and resumption of 2.1 ± 2 months [0.5-5 months]. The cessation of the treatment was dictated by the treating physician in 2 cases and involved csDMARD in 3 cases (Methotrexate (n=2), Lefunomide (n=1)) and biologics in only one patient. There were no cases of clinical pulmonary worsening upon resumption of the treatments. We found no statistically significant association between severe forms of the infection and the type of RD (p=0.925), as well as the presence of comorbidities (p=0.825). Similarly, the presence of severe forms was not associated with the use of long-term NSAIDs (p=0.29), corticosteroids (p=0.85), or biological treatment (p=0.7). However, maintenance therapy was significantly associated with a lower risk of severe forms (p=0.013).

**Conclusion:** Our work showed that the maintenance of conventional treatment during Covid-19 infection was associated with a lower risk of severe forms. Our results, along with those of other studies in the literature, support the maintenance of antirheumatic treatments.

**SAFETY OF VACCINES AGAINST COVID-19 IN PATIENTS WITH SPONDYLOARTHRITIS (PRELIMINARY DATA).**

A. Kulikov1, N. Muraveyva2, B. Beloy1, 1V.A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccinoprophylaxis, Moscow, Russia

**Background:** Patients with spondyloarthritis (SpA) probably have a high incidence of COVID-19. Vaccination remains one of the most effective methods of preventing infectious diseases. However, data on the safety of vaccines against COVID-19 in patients with SpA are few and relate to foreign vaccines that are not licensed in Russia.

**Objectives:** To study the safety of COVID-19 vaccines in patients with SpA in real clinical practice.

**Methods:** The study included 47 SpA patients (25 - ankylosing spondylitis, 13 - psoriatic arthritis, 9 - undifferentiated SpA, 19 women, 28 men, age 42.3±11.6 years, duration of the disease 11.8±9.2 years) - the main group and 97 people without any immuno-inflammatory rheumatic diseases (67 women, 30 men, age 43.7±13.1 years) - the control group. 20 patients received disease-modifying antirheumatic drugs (12 - methotrexate, 8 - sulfasalazine), 10 - biological drugs (8 - TNF- u inhibitors, 2 - IL-17 inhibitors), 6 - glucocorticoids, 1 - tocilizumab, 12 - only nonsteroidal anti-inflammatory drugs, 8 - did not receive therapy. In the main group, 40 patients were vaccinated with Gam-COVID-Vac (Sputnik V), 3 – CovitVac and Sputnik Light, 1 – EpiVacCorona (both components of the vaccine were received by 44 patients). In the control group 69 were vaccinated with Sputnik V, 15 - CovitVac, 5 - Sputnik Light and BNT162b2, 2 - EpiVacCorona, 1 - mRNA-1273. (91 participants received both components of the vaccine). All participants
were interviewed by a research doctor with a unified questionnaire, additional information was obtained from medical documentation.

Results: The data obtained are reflected in the Table 1. Local adverse events (AEs) occurred relatively less frequently in patients with SpA than in the control group. After the introduction of the first component of the vaccine, there was a significant increase in the frequency of pain without restriction of movement and edema/hyperemia in the control group (p<0.001 and p=0.049, respectively), while after the introduction of the second component, a significant difference was registered only for the first indicated symptom (p>0.001). The most frequent systemic AEs were weakness, fever, arthralgia or myalgia, headache, and chills, which were significantly less common (p>0.008) in the main group after immunization with the first component. The proportion of SpA patients without any reactions was significantly higher after the introduction of the first component of the vaccine (59.6% and 29.9%, p<0.001), while after immumity with the second component there were no differences (59.1% and 44.0%, p>0.05). After complete immunization, the percentage of patients without any AEs was significantly higher in the main group than in the control (50.0% and 17.6%, p<0.001). There was no exacerbation of SpA or development of new autoimmune phenomena in the main group after full vaccination.

Table 1. The frequency of AEs in SpA patients and in control

A REDUCTION IN NEW REFERRALS FOR RHEUMATOID ARTHRITIS, OSTEOARTHRITIS AND CRYSTAL ARTHRITIS COMPARED TO GCA DURING COVID19 PANDEMIC

M. Tormo-Ratera 1, M. Mirza 2, R. Lugmann 2, 1Hospital Universitari de Bellvitge, Rheumatology, L'Hospitalet de Llobregat, Spain; 2Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom

Background: The COVID-19 pandemic has had profound effects on the Rheumatology department; we wanted to see if consequently referrals for Rheumatoid arthritis (RA), Crystal Arthritis (CA), Osteoarthritis (OA) and Giant cell arteritis (GCA) were affected. A greater understanding of the impact may enable adequate number of clinics and resources to be made available where needed.

Objectives: To evaluate the impact of COVID-19 pandemic on volume of new referrals to the Rheumatology department for RA, CA, OA and GCA.

Methods: A retrospective analysis of data was conducted from the period of January 2016 to December 2021. The Rheumatology department database was closely analysed and information about new referrals for GCA, RA, OA and CA were evaluated. Statistical analysis was conducted using t-test to compare the mean value pre and during the COVID19 outbreak (2020).

Results: From 2016 to 2021 a total number of 9998 new patients were referred to the Rheumatology department. There were 2768 new referrals for GCA (15%), RA (34%), OA (40%) and CA (11%) made during this period. In 2020, there was a significant decrease in OA, RA and CA referrals (p value 0.00004, 0.00017, 0.0042 respectively) but an insignificant decrease in GCA referrals (p value 0.243).

Conclusion: During COVID19 pandemic in 2020 there was a significant reduc-

Background: Patients with autoimmune/inflammatory rheumatic diseases (AIRD) were suspected to be an at-risk population of severe COVID-19. However, whether this higher risk is linked to the disease or to its treatment is difficult to determine.

Objectives: To identify, among AIRD patients, factors associated with occurrence of moderate-to-severe COVID19 infection and to evaluate if having an AIRD was associated with an increased risk of severe form of COVID19 infection (defined by hospitalization in ICU or death), compared to general population.

Methods: Data source: The “Entrépôt des Données de Santé (EDS)“ collect data from electronic health records of all patients hospitalized or followed in the AP-HP (39 hospitals in Paris area, France). The French RMD COVID19 cohort is a national multi-center cohort that included patients with confirmed AIRD and diagnosed with COVID-19. All AIRD patients diagnosed with COVID-19 before September 2020 from both cohorts were included.

We identified factors associated with severe COVID-19 was made in a combined analysis of the 2 cohorts.

- Then, we compared COVID-19 infection severity in the EDS-COVID database in AIRD patients and controls, by a propensity score (PS)-matched case-control (1:4) study.
MUSCULOSKELETAL MANIFESTATIONS AMONG PATIENTS WITH COVID-19 INFECTION

S. Thawra1, N. M. Shaban2, M. K. Nassar3. 1Faculty of Medicine, Mansoura University, Mansoura, Egypt; Rheumatology & Immunology Unit, Department of Internal Medicine, Mansoura, Egypt; 2Mansoura Manchester Programme for Medical Education, Faculty of Medicine, Mansoura University, Mansoura, Internal Medicine; Rheumatology & Immunology Unit, Mansoura, Egypt; 3Faculty of Medicine, Mansoura University, Mansoura, Egypt, Mansoura University Nephrology and Dialysis Unit, Internal Medicine Department, Mansoura, Egypt

Background: Coronavirus disease-2019 (COVID-19) is declared as a global pandemic [1]. It is caused by a novel coronavirus with structural similarities to the virus that causes severe acute respiratory syndrome (SARS) [2]. While the pulmonary consequences have received a lot of attention, the impact of the disease extends far beyond the respiratory system and affects other organs of the body such as heart, kidney or liver [3]. Although different musculoskeletal (MSK) manifestations have been linked to COVID-19 infection, a systematic approach to outline these manifestations is still lacking [4].

Objectives: The aim of this study was to determine the prevalence, distribution and determinants of MSK manifestations in patients with COVID-19 infection.

Methods: Patients with a history of confirmed COVID-19 infection were asked to answer a web-based survey. The survey consisted of multiple questions centered around demographics, clinical and COVID-19 infection data in addition to MSK discomfort form based on the Nordic MSK Questionnaire. The inclusion criteria included age of ≥18 years, Patients who had malignancies or any chronic rheumatic, neurological disease were excluded.

Results: There was a total of 110 participants, mostly females (72.7%), with mean age 37.7 years, only 9 (8.2%) were current smokers while 31 (28.2%) had comorbidities such as hypertension (n=74), coronary artery disease (n=74), cancer (n=5), chronic obstructive pulmonary disease (n=4), chronic kidney disease (n=3). The patients were interviewed by a research doctor, additional information was obtained from medical documentation.

Results: The most common symptoms of COVID-19 were fever - 67.7%, weakness/drowsiness - 53.7%, cough - 48.4%, as well as anosmia and dyspnea - 35.5% each, headache - 20.4%, body aches - 16.1%, congestion nose - 8.6%, chest pain - 7.5%, dysgeusia - 5.4%, diarrhea/vomiting - 3.2%. According to CT scan, 8 patients had 0% of lung damage, 31 - 25%, 32 - 50%, 12 - 75%, in other cases the study was not carried out (n=9) or data are not available (n=1). In 2 patients the course of COVID-19 was complicated by bacterial pneumonia, in 1 - bacterial-fungal. An asymptomatic course was noted only in 2 patients (PCR+/IgM+, CT 0, close contact with a confirmed case of COVID-19). Recovery was noted in 90 patients, fatal outcome - in 3. Exacerbation of IIRDs after COVID-19 was noted in 48.4% of patients, which required intensifying antirheumatic therapy.

Conclusion: Preliminary data indicate that COVID-19 is characterized by moderate and severe course in elderly patients with IIRDs. Further studies are required to identify risk factors for severe course and complications in order to provide timely qualified care.

Disclosure of Interests: None declared

Conclusion: MSK manifestations are prevalent among patients with COVID-19 infection. They are usually associated with more severe COVID-19 infection and longer disease duration.

BIBLIOMETRIC NETWORK ANALYSIS ON TOCILIZUMAB TREATMENT FOR COVID-19 PATIENTS

L. Cascella1, F. Monaco2, D. Nocerino2, A. Infermuro2, V. Cascella1, F. Del Prato2, S. Cascella1, M. Cascella1on behalf of Study Group on AI in medicine. 1School of Medicine. University Federico II. Naples, Italy. Medicine, Naples, Italy; 2Istituto Nazionale Tumori, IRCCS Fondazione G. Pascale, Division of Anesthesia and Pain Medicine, Naples, Italy; 3School of Medicine. University of Pavia, Medicine, Pavia, Italy; 4Istituto Nazionale Tumori, IRCCS Fondazione G. Pascale, Scientific Directorate, Naples, Italy

Background: Tocilizumab is a humanized monoclonal antibody that provokes inhibition of the proinflammatory signals by binding to IL-6 receptors [1]. Due to these properties, it is used in inflammatory arthritis conditions and in cytokine release syndromes [2]. Notably, given its ability to intersect proinflammatory cascades, tocilizumab is an important option for patients with critical forms of COVID-19 [3]. Nevertheless, several aspects about the use of tocilizumab in this clinical setting should be better explained [4].

Objectives: This bibliometric analysis is aimed at dissecting the developed research in the subject. It could provide useful findings for predicting the direction of future studies, implementing corrective measures, and enhancing research networks.

Methods: The global literature on tocilizumab treatment for COVID-19 was scanned in the Web of Science (WOS) online database. The search terms applied to identify the closest matching articles included “tocilizumab” and “COVID-19”. All data were acquired on January 29, 2022. The information for the documents that met the requirements were extracted. The source was Journal Citation Reports™ 2020 (Clarivate Analytics). The literature analysis and knowledge visualization software tool VOSviewer (version 1.6.17) was used to analyze the co-occurrence of keywords (interconnection), co-citation (bibliographic coupling), co-citation analysis for sources, and countries, and analysis of the most productive organizations and networks.

Results: A total of 1019 articles on tocilizumab treatment for COVID-19 patients were published from 2020 to January 2022. In WOS, Of those: 462 in 2020, 546 in 2021. On January 29, 2022. About article types, 697 were research articles, 322 reviews. The analysis of keywords provided by authors showed that of 50 keywords, 17 met the threshold (interconnection 2). The most frequent keywords were EFFICACY, and OFF-LABEL USE (Figure 1).

Conclusion: This bibliometric network analysis on tocilizumab treatment for COVID-19 patients can be useful for planning future research. It highlights the strength of representative scholars and core research teams. Additional networks should be built, and high-value clinical studies are needed.
lower for patients on combination DMARD therapy compared to all other groups (81% compared to 95% for monotherapy, and 100% for both no DMARD therapy and/or b/tsDMARD combination therapy). Considering effects of individual compounds, mycophenolate mofetil in mono- or combination therapy led to lower antibody titers after the 2nd dose as compared to HC or patients receiving no DMARDs (2 BAU/ml versus 1673 BAU/ml and 2500 BAU/ml respectively, both p<0.0001).

*dermatopoliomyositis (n=4), mixed connective tissue disease (n=2), primary Sjögren’s syndrome (n=6), undifferentiated connective tissue disease (n=3)*

**Conclusion:** Patients with SARD showed a good response after the 2nd vaccination compared to the mRNA vaccine. However, the choice of immunosuppressive regimen has a marked effect on both seroconversion rate and overall antibody titer.

**Disclosure of Interests:** We thank Sylvia Taxer and Zoltan Vass for their support.

**Figure 1.** Seroconversion rate (A) and anti-SARS-CoV 2 S antibody levels (B) after the 1st and 2nd vaccination between the healthy control (HC) group and patients according to therapy

**Figure 1.** A: Forest map of a meta-analysis of COVID-19 prevalence in SLE patients. B: Forest map of a meta-analysis of hospitalization rates among patients treated with hydroxychloroquine. C: Forest map of a meta-analysis of the rate of adverse outcomes in patients using hydroxychloroquine. D: Forest map of a meta-analysis of the prevalence of patients treated with hydroxychloroquine throughout the course of disease.

**Figure 2.** A: Forest map of a meta-analysis of the rate of adverse outcomes in patients using hydroxychloroquine as part of a treatment regimen. D: Forest map of a meta-analysis of the prevalence of patients treated with hydroxychloroquine throughout the course of disease.

**Results:** A total of 14 studies comprising 5365 patients were identified (Table 1). Overall prevalence of COVID-19 in SLE patients was 1.5% (95% CI: 1.2%-1.8%). Eight of the studies included patients who used hydroxychloroquine as part of their treatment regimen, with 29.8% (95% CI: 25.8%-33.8%) hospitalization rates and 14.6% (95% CI: 11.5%-17.8%) adverse outcome rates. Among patients treated with hydroxychloroquine throughout the course of disease, the prevalence was 0.7% (95% CI: 0.4%-1.0%, Figure 1).

**Conclusion:** Patients with SLE had a higher risk of COVID-19. Hydroxychloroquine might benefit to reduce the overall hospitalization rate and prevalence rate of COVID-19, and alleviate inflammatory damage in the chronic stage of viral infection, inhibiting over activation of the immune system.

AB1137 USE OF TOCILIZUMAB IN CRITICALLY ILL SARS-COV-2 PATIENTS: CARE-PROGNOSTIC FACTORS OF TREATMENT EFFECTIVENESS AND TREATMENT RESULTS

Z. Kardos 1, 2, M. Szabó 2, Z. Báthi 1, Á. Mikó 1, A. Kozmán 3, G. A. József 2, Z. Székanecky 1, 2, 4, 5

1. Borsod County Teaching Hospital, Rheumatology, Miskolc, Hungary; 2. University of Miskolc, Medical Faculty, Miskolc, Hungary; 3. Borsod County Teaching Hospital, Pharmacy, Miskolc, Hungary; 4. University of Debrecen, Rheumatology, Debrecen, Hungary

Background: The treatment of COVID-19 caused by SARS-CoV-2 poses serious challenges to health care systems. In 8-10% of patients with severe COVID-19, there is a cytokine storm syndrome, highlighting the importance of host immune response in pathogenesis.

Objectives: Our aim was to evaluate the effect of tocilizumab treatment in COVID-19 patients with severe cytokine storm who were refractory to standard care therapy. To determine the prognostic factors that indicate the success of treatment in these patients.

Methods: Fifty-three patients were treated with tocilizumab during waves 2 and 3 of the pandemic due to a cytokine storm associated with SARS-COV-2 infection. All patients underwent physical examination, saturation monitoring, laboratory examination, blood gas analysis and chest CT examination. Deteriorating clinical status, elevated IL-6 and other acute phase protein levels observed in patients treated with standard therapy suggest cytokine storm syndrome. The treatment of these patients was supplemented with 8mg/kg (max. 800mg) tocilizumab (1 or 2 times within 24 hours). We assessed the clinical and laboratory response of these patients to IL-6-R inhibitor therapy, the need for ventilation, the need for intensive care and mortality.

Results: Immunological consultations were performed in 31 patients, of whom 21 (68%) were successfully treated. Eleven patients of them (22%) died. In the 22 non-consulted patients, this rate was reversed: 7 (22%) were successful and 15 (68%) were treatment failures. The success of the treatment was mainly influenced by the well-established indication, the recognition of concomitants, and the condition that did not require invasive ventilation method. The 29 tocilizumab therapies initiated in the non-intensive care unit avoided intensive care unit treatment in 18 patients. Eleven patients were admitted to the intensive care unit, but 7 patients required temporary respiratory support and recovered, 4 patients required invasive mechanical ventilation and later died (14%). In contrast, 24 treatments initiated in the intensive care unit saved the lives of only 3 patients, and 21 patients were lost (87.5%). The effectiveness of treatment was not affected by age, with survival rates of 40%, 44%, 57% and 55% for the 40-49, 50-59, 60-69, 70-79 age groups, respectively. Interestingly, the extent of lung involvement also did not show a significant difference. Although it was a prerequisite for initiating tocilizumab treatment to have fresh alveoli on the CT image of the chest. Conclusion: Use of tocilizumab is most effective in patients with COVID-19 who have high levels of inflammatory activity and IL-6, who are at an early stage of lung involvement and who do not respond to high-dose corticosteroid therapy, who have no bacterial superinfection and require not invasive mechanical ventilation. It is also important that specialist who has immunological approach and routine with biological treatment be also involved in the care of patients with severe COVID-19 disease.

AB1138 SAFETY OF SARS- COV- 2 VACCINES IN PATIENTS WITH AUTOIMMUNE DISEASES

S. Monov1, R. Shurmaliieva1, D. Monova1, 2, 3, 4, 5
1. Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria; 2. Medical University - Sofia, Medical Institute, Department of Internal Medicine, Sofia, Bulgaria

Background: Patients (pts) with autoimmune diseases are at higher risk of infections, including those by SARS-COV-2. There is no general agreement regarding priority criteria for anti-COVID vaccine access for pts with autoimmune rheumatic diseases (ARD). Few studies have addressed the issue of anti-COVID vaccination in these pts, but many are available on the safety, immunogenicity, efficacy, and possible contraindications of traditional vaccines in pts with ARD. These studies may represent the basis on which to recommend the anti-COVID-19 vaccines.

Objectives: Patients (pts) with autoimmune diseases are at higher risk of infections, including those by SARS-COV-2. There is no general agreement regarding priority criteria for anti-COVID vaccine access for pts with autoimmune rheumatic diseases (ARD). Few studies have addressed the issue of anti-COVID vaccination in these pts, but many are available on the safety, immunogenicity, efficacy, and possible contraindications of traditional vaccines in pts with ARD. These studies may represent the basis on which to recommend the anti-COVID-19 vaccines.

Methods: A telephone survey investigating the AE of SARS-CoV-2 vaccinations on pts with systemic lupus erythematosus, systemic sclerosis, inflammatory arthritis (rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis), idiopathic inflammatory myopathies, ANCA-associated vasculitis was administered. Data extraction included diagnosis, disease activity status, demographics, disease duration, therapy, comorbidities, and laboratory tests. Vaccinated participants are asked to report whether they experienced any local or systemic AE following vaccination, and if so, to report on the severity and duration of the AE. Mild AE were defined as unpleasant reactions that did not limit daily activities, moderate AE as those that limited daily activities, and severe AE - required medical attention. Serious AE were defined as reactions that resulted in hospital admission.

Results: ChAdOx1 nCoV-19 and BNT162b2 are the most common vaccines in our pts. 98 (38.84%) of 246 pts received the BNT162b2 vaccine, 95 (38.62%) - ChA-DOx1 nCoV-19 vaccine, 47 (19.10%) - CX-024144 and 6 (2.44 %) were vaccinated with Ad26.COV2-S. 127 (51.63%) pts had at least one mild AE and 51 (20.73 %) pts reported moderate AE. Severe AE were rare - 4 (1.63%) pts and no serious AE were reported. The most commonly reported AE is pain (40.24%), redness (30.49 %), swelling (18.7%) at the injection site, which was consistent across all vaccines for both first and second doses. Systemic AE occurred in 104 (43.27 %) pts, most frequently fatigue (29.67 %), headache (27.13 %) and muscle ache (24.39 %). The symptoms started mostly during the first day post-vaccination and lasted for no more than two days. Joint complaints were reported in 8.94 %, but only a small proportion of pts (2.84 %) reported a deterioration of their autoimmune disease up to 3 months after COVID-19 vaccination. Age was a significant effect modifier in the association between autoimmune status and the risk of moderate or severe AE. Vaccination with ChAdOx1 nCoV-19, female sex, age between 35 - 50 years were independently associated with an increased likelihood of reporting any AE. The current results

support the safety of different COVID-19 vaccines in pts with ARD. This information can help fight vaccine hesitancy in this population.

Conclusion: Our data indicated that COVID-19 vaccines are well tolerated by pts with ARD. We did not observe any serious AE, but the number of pts included in our study is too low to draw conclusions about rare serious events. Additionally, our data suggest that COVID-19 vaccinations do not seem to trigger autoimmune disease flares, which is in accordance with data from previous small studies that assessed consequences of vaccines in pts with ARD.

Disclosure of Interests: None declared.

AB1139
SARS-COV2- INFECTION AFTER VACCINATION AGAINST COVID-19 IN PATIENTS WITH RHEUMATIC DISORDERS IN A REAL LIFE SETTING OF A RHEUMATOLOGICAL OUTPATIENT CENTER

S. G. Werner1, L. Moll1, A. Uhlenberg-Moll1, S. Mettler1, H. E. Langer1. 1RHIO (Rheumatology, Immunology, Osteology) Düsseldorf, RHIO Research Institute, Düsseldorf, Germany

Background: Coronavirus SARS-CoV-2 and its associated disease COVID-19 have become a worldwide pandemic since its first case in 12/2019. Since approval of the first vaccines against COVID-19 in Europe in 12/2020 a large vaccination campaign started. Our patients with inflammatory diseases (ID) were given priority for an early vaccination. Many of our patients used the possibility and got vaccinated. Until now, there is few knowledge about the efficacy and safety of vaccination in patients with rheumatic disorders. There are some reports of less vaccination response in patients with ID (1). First reports of those patients with rheumatological disorder and infection with SARS-CoV2 are available (1,2). Nevertheless, there is few knowledge about SARS-CoV2-infection in patients with ID after vaccination against COVID-19, yet.

Objectives: The aim of our study was to evaluate, how many patients got infected with SARS-CoV2 after vaccination against COVID-19 and the course of the disease.

Methods: All consecutive patients of the routine follow up visits from 07/2021 to 01/2022 in our rheumatological outpatient center were questioned for SARS-CoV2-infection. In case of infection, they were questioned for vaccination status and the course of the disease.

Results: N=1206 patients could be evaluated. N=1183/1206 (98.1%) vaccinations were documented. N=12/1183 (1%) patients got infected with SARS-CoV2 after at least 2 doses of vaccination against COVID-19. N=1/12 (8.3%) patient got infected after 3 doses of vaccination. N=3/12 (25%) received 2 doses Vaxzevira (AstraZeneca), n=2/12 (16.7) patients 1st dose Vaxzevira, 2nd dose Comirnaty (Biontech), n=7 (58.3%) patients two doses Comirnaty. In n=8/12 (66.7%) patients antibody levels were available. N=7/8 (87.5%) patients developed high antibody levels after 2 vaccinations. N=1/8 (12.5%) patient developed any antibodies against SARS-CoV2 after 2 doses of Comirnaty, measured ≥4 months after 2nd vaccination dose. This patient was treated with Abatacept. This patient came down with COVID-19 5 months after complete vaccination and died after long-standing highly intensive care. All other patients developed a mild to moderate course of COVID-19, without need of hospitalizing.

Conclusion: There is a very high number of patients (98.1%), who got vaccinated in a real life setting of our rheumatological outpatient center. We have seen only a low number of SARS-CoV2-infections (1%). Most patients developed high antibody levels after vaccination and fortunately had a mild to moderate course of COVID-19 in case of SARS-CoV2-infection, independently from the different vaccination agents. Nevertheless, 1 patient came down with COVID-19 5 months after complete vaccination and died after long-standing highly intensive care. This patient did not develop any antibodies after vaccination. In conclusion, vaccination seems to be effective in patients with rheumatological disorders. However, we must be aware of the small group of patients without antibody development, since they are at risk to have a fatal course. Yet, antibody testing is not recommended in routine clinical care by official recommendations, largely because it is still unknown which level of antibodies predicts protection (3). The booster campaign and 3rd vaccinations will change the current state again, but a reevaluation and further studies will be necessary.

AB1140
IMPACT OF COVID-19 NEWS SOURCES ON RHEUMATOID ARTHRITIS PATIENTS’ LIFESTYLE AND THEIR DISEASE ACTIVITY FROM NINJA 2020 COHORT STUDY

A. Iihata1, T. Matsui2, S. Tohma3 on behalf of NinJa registry. 1National Hospital Organization Yokohama Medical Center, Department of Rheumatology, Yokohama, Japan; 2National Hospital Organization Sagamihara National Hospital, Department of Rheumatology, Sagamihara, Japan; 3National Hospital Organization Tokyo National Hospital, Department of Rheumatology, Kiyose, Japan

Background: One of the problems with the COVID-19 epidemic is infodemic. Insufficient and inaccurate information can be confusing and hinder treatment. In Japan, tabloid TV show might be an easily accessible source of information, but its reliability is low and it has a harmful effect on patients’ mental status and lifestyle. There are no reports to examine what is the source of COVID-19 news for patients with rheumatoid arthritis and how these information affect patients’ daily lives and disease activity. By using NinJa, Japanese largest database of rheumatoid arthritis, it may be possible to examine them in detail.

Objectives: To investigate the impact of the COVID—19 news sources on rheumatoid arthritis patients’ disease activity using NinJa 2020 cohort study.

Methods: At the timing of collection of patients’ data of NinJa2020, questionnaire about their lifestyle and news source of COVID-19 was given. Questionnaire includes questions about frequency of scheduled visit, going out and exercise, weakness and news source.

Results: 6877 patients out of 15553 patients answered questionnaire. Most patients did not change the interval of scheduled visit. The frequency of hospital visits was “unchanged” in 85.8%, “longer” in 13.6%, and “shortened” in 0.6%. The chances of going out were “unchanged” at 14.4%, “significantly decreased” at 57.5%, “slightly decreased” at 27.8%, and “increased” at 0.3%. 42.6% answered that the amount of exercise did not change, 30.2% answered that it decreased considerably, 26.1% answered that it decreased a little, and 1.1% answered that it increased. Regarding muscular strength and physical strength, 46.0% answered “no change”, 19.9% answered “significantly dropped”, 33.5% answered “slightly dropped”, and 0.6% answered “increased”.

The media used as information sources are “newspaper (86.4%)”, “tabloid show (54.5%)”, “family, acquaintance and friends (43.7%)”, and “official web of Ministry of Health, Labor and Welfare and academic societies (9.4.%)”.

Respondents often referred to multiple media and 30.6% of them listed three sources (Figure 1). There was a positive correlation between the decrease in frequency of going out and the number of information sources, and a negative correlation between age and the number of information sources. We also found a negative correlation with age for muscle weakness. No correlation was found between the number of information sources and SDAI, CDAI, HAQ-DI, EQ-SD, HADS (A), HADS (D).

Figure 1.

Conclusion: The more sources of information, the less chance of going out. About 80% of the patients refrained from going out, the opportunity for exercise decreased in more than 50% of the patients, and the decrease in physical fitness was also noticed in nearly 50% of the patients. Newspapers, tabloid shows, and acquaintances were the most common sources of medical information, and relatively few patients used official sources. He provision of accurate information about COVID-19 was important to avoid infodemic. From this questionnaire, more practical information delivery system was required in Japan.

Disclosure of Interests: None declared.

Background: According to the recent medical literature, COVID-19 disease can lead to a constellation of clinical syndromes lasting well beyond the first 30 days of infection. The most common post COVID sequelae includes pulmonary, nervous system and neuropsychiatric, mental, metabolic, cardiovascular, gastrointestinal and several other clinical manifestations. Regarding joint involvement and particularly reactive arthritis (ReA), literature data is limited and describes case reports or series of cases of patients diagnosed with this condition following COVID-19 disease.

Objectives: To describe the pattern and the management of post-COVID reactive arthritis.

Methods: We have conducted a descriptive study of consecutive adult patients who presented to rheumatology outpatient clinic for joint or peri-articular pain/ swelling/stiffness and received a diagnosis of post-COVID 19 reactive arthritis, by excluding other types of rheumatological conditions. The assessed clinical variables were: visual analogue scale (VAS) pain, swollen joint count (SJC), tender joint count (TJC), duration of morning stiffness, presence of enthesitis/tennisitis and axial involvement. Biochemistry and serology was performed: rheumatoid factor, ACPA, ANA, HLA B27, antiChlamydia Trachomatis, Ureaplasma Urealyticum and Mycoplasma Hominis Ab, anti HBs and Hbc Ab, and anti HCV. COVID-19 disease prior to diagnosis of ReA was confirmed by PCR test.

Results: In the study were included 16 patients with confirmed post COVID-19 ReA. The mean age of the study group was 43.5±10.8 (range 21-60), the female: male ratio was 4:1 and the duration of joint symptoms was 10.4±11.8 (range 1-42) weeks. The severity of COVID-19 disease was mild in 68.7% cases, moderate in 18.7% and severe in only 6.2% of the cases. The duration between COVID-19 diagnosis and ReA varied between cases, with a mean value of 4.3±4.2 (range 1-12) weeks. In 43.7% of the cases patients had peripheral joint involvement (spondyloitis), in 37.5% - periarticular involvement (enthesitis), 6.25% - isolate axial involvement (sacrolarian joints), 6.25% enthesitis and axial involvement (cervical spin) and 6.25% synovitis and enthesis. In patients with peripheral joint pattern, the distribution of pain was symmetric (71.4%). The pattern of synovitis was determined by a TJC of 6.25±5.25 (range 1-16) joints and SJC 1.6±2.4 (range 0-7) joints. Both TJC and SJC correlated positively with the duration of morning stiffness (r=0.9 and r=0.6), but did not correlate with the VAS pain scale.

Conclusion: Reactive arthritis represents a post COVID-19 sequelae. The time of onset of ReA varied between 1 and 12 weeks after COVID-19 diagnosis. The clinical pattern of the disease was expressed by joint or periarticular involvement, mainly affecting the hand, feet and knee symmetrically. Cases of axial manifestations were less common. Most of the patients responded well to NSAIDs, only in a few particular cases, low doses of corticoids and/or Methotrexate were recommended.

AB1144
COGNITIVE AND PSYCHOSOCIAL OUTCOME IN CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME FOLLOWING SARS-COV-2 INFECTION

D. Goso\¹, M. Zajc Avramovi\², N. Emenisci\³, M. Šušteri\³, M. M. Šom\³, D. Osredkar\³, T. Avcin\³.
\¹University Medical Center Ljubljana, \²University Children's Hospital, Department of Child, Adolescent and Developmental Neurology, Ljubljana, Slovenia; \³University Medical Center Ljubljana, University Children's Hospital. Departament of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia; \⁴University of Ljubljana, Department of Psychology, Ljubljana, Slovenia

Background: Despite the low rate of neurological deficits following the SARS-COV-2 infection in the pediatric population, children and adolescents who develop multisystem inflammatory syndrome (MIS-C) after being infected with SARS-COV-2 are at a higher risk for neurological abnormalities and brain injury, increasing the risk of adverse cognitive and psychiatric outcome.

Objectives: Given the increased risk of central nervous system impairment we chose to conduct a prospective study looking at the cognitive and psychosocial outcome of patients with MIS-C.

Methods: Our study included 27 of the 29 patients between 2 to 18 years of age (M = 11.1, SD = 4.4) who were treated for MIS-C from the onset of the SARS-COV-2 pandemic until the beginning of May 2021 at the only tertiary care pediatric neurology center in Slovenia. We assessed these patients 6 months after diagnosis using the age-appropriate Wechsler intelligence scales and a battery of neuropsychological test measuring attention, executive function, memory and fine motor skills. We also asked parents to report on patients' psychosocial outcome using the Achenbach Child Behavior Checklist.

Results: By using Bayesian statistics to take into account parental education and any potential pre-morbid learning difficulties we found no evidence of impairment on measures of intelligence. However, the posterior distribution of scores on neuropsychological tests measuring attention, executive function, memory and fine motor skills was skewed. This means that although their average did not rise to a clinically significant level, the extent did not rise to a clinically significant level.

Conclusion: The findings from our cohort suggest that the cognitive and psychosocial outcome of patients with MIS-C is generally favorable, although up to 35% may experience specific neuropsychological deficits more than 6 months after diagnosis. The most commonly injured cognitive domains seem to be attention, executive function and visual memory.

AB1145
EVALUATION OF THE HUMORAL IMMUNE RESPONSE SECONDARY TO VACCINATION AGAINST SARS-COV IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES

P. M. Corbalán\¹, M. Pera\¹, G. V. Espasa\¹, M. L. Leguizamón\¹, A. L. Barbaglia\¹, L. González Lucero\¹, H. R. Suelto\¹, M. C. Bertolacini\¹, R. N. Chehin\¹, R. H. Tomas-Grau\¹, D. Pliper\¹, E. Vera Pinguito\², B. Socías\³, C. L. Ávila\³, S. I. Cazorla\³, C. Maldonado Galdeano\³, V. I. Bellomio\³, \¹Hospital Ángel C. Padilla, Rheumatology Unit, San Miguel de Tucumán, Tucumán, Argentina; \²IMCA (CONICET - UNIT - SIROPSA). Instituto de Investigación en Medicina Molecular y Celular Aplicada, San Miguel de Tucumán, Tucumán, Argentina; \³CERELA (CONICET), Centro de Referencia para Lactobacilos, San Miguel de Tucumán, Tucumán, Argentina

Background: Several trials have reported lower seroconversion rates in patients with autoimmune rheumatic diseases than in healthy patients. In Argentina, the vaccines that were available during the development of this study were: Sputnik V (Gam-COVID-Vac), Astrazeneca (ChAdOx1 nCov), Sinopharm (BBIBP-CorV) and Moderna (mRNA-1273). Limited information is available about vaccines against SARS-CoV2 with inactivated virus or viral vector in autoimmune patients.

Objectives: To evaluate the humoral immune response to vaccines against SARS-CoV2 in patients with autoimmune rheumatic diseases; to compare the humoral response among patients with Systemic Lupus Erythematosus (SLE) and other autoimmune diseases and to analyse the variables associated.

Methods: We included patients with autoimmune rheumatic diseases (Rheumatology Unit of Padilla Hospital, Tucumán, Argentina), who received vaccination against SARS-CoV2 from June 2021. Sociodemographic, comorbidities, related to rheumatic disease, vaccination and SARS-CoV2 infection were the variables recorded. To evaluate the humoral immune response, the neutralizing anti-S-RBD IgG antibody titres were determined by ELISA “In House” test with a cut-off titre of 200 (IMMCA). The times established for the serological determinations were: T0 or baseline: 1\⁴th vaccine dose, T1: 14 ± 2 days after the 1\⁴th dose, T2: 2\⁴th dose, T3: 21- 45 days after the 2\⁴th dose, T4: 30 days after the 3\⁴th dose, T5: 6 months and T6: 12 months after the 3\⁴th dose.

Results: 66 patients were included, 91% women and 92.4% Amerindians. The mean age was 40.7 ± 11.4 years; 53% with SLE, 15.2% Rheumatoid Arthritis, 7.6% Systemic Sclerosis, 7.6% Juvenile idiopathic Arthritis, 7.6% Systemic Vasculitis and 9% other diagnoses; mean disease duration was 12.05 ± 7.5 years; 63.6% had at least one comorbidity (57% HBP, 31% overweight or obesity). At baseline, the treatments received were: corticosteroids (37.3%), prednisone mean dose 4.12 ± 8.9 mg/day), cDMARDs (75.7%), bDMARDs (18.2%); Rituximab (58.3%) and anti TNF (25%). Sixteen patients (24.2%) had previous COVID19 (75% mild symptoms). The vaccines applied were: AstraZeneca 38.2%, Sinopharm 31.7%, Sputnik V 19%, and combined schedule Sputnik V/ Moderna in 11%. At baseline, 28.8% had detectable anti-S-RBD IgG antibodies. This frequency increased to 48.4% at 1\⁴th dose and 70.2% at 2\⁴th dose. The variables that were associated with lower seroconversion rates and lower antibody titre were vaccination with Sinopharm (p 0.028) and treatment with bDMARDs (p 0.02), none of the 5 patients with Rituximab showed seroconversion. There were no significant differences in the levels of anti-S-RBD IgG antibodies between patients with SLE and the other rheumatic diseases. Patients who had SARS-CoV2 infection prior to vaccination had higher antibody titres in both T1 (p 0.006) and T2 (p 0.002) but after the two doses this difference was not significant (p 0.67). In the regression analysis, the variables that were independently associated with serocconversion were the type of vaccine applied at the 1\⁴th dose and the hypertensive disease. The chance of responding to vaccination was 13 and 9 times higher for those who received Sputnik V (OR 12.78; 95% CI 1.46 - 315.9) or AstraZeneca (OR 8.61; 95% CI 1.63 - 72.5) respectively, than Sinopharm in the 1\⁴th dose. The chance of being a responder was 88% lower for hypertensive patients (OR 0.12; 95% CI 0.02 - 0.58).

Conclusion: In this preliminary analysis, a seroconversion rate of 70.2% was associated with two-dose vaccination for SARS-CoV2 in patients with autoimmune rheumatic diseases. There were no differences in the serological response between patients with SLE and other rheumatic diseases. The humoral immune response was lower in patients with bDMARDs and null in those who received Rituximab. Seroconversion and antibody titre levels were associated with the type of vaccine applied, being Sinopharm who presented the lowest response. The follow-up will provide more knowledge about the behaviour of the humoral response in our patients.

SARS-COV2 VIRAL LOAD IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASE, A RETROSPECTIVE COMPARATIVE STUDY

O. Alsa\¹, Y. A. Y. Alrimawi\¹, R. Saleh\¹, M. Chapouda\¹, P. Coyle\¹, K. Becetti\¹, H. Ashour\¹, E. Elsayed\¹, M. Hamed\¹, F. Alam\¹, B. Awadh\¹, M. Hammoudeh\¹, S. Al Emadi\¹.
\¹HAMAD Medical Corporation, Medicine/Rheumatology, Doha, Qatar; \²HAMAD Medical Corporation, Medicine/Infectious disease, Doha, Qatar; \³HAMAD Medical Corporation, Laboratory Medicine and Pathology, Doha, Qatar

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) viral load and its impact on disease outcome in patients with autoimmune rheumatic disease (ARD) are lacking. Also, whether patients with ARD receiving immunomodulators have different viral loads compared to the general population is unknown.

Objectives: To compare the viral load of SARS-CoV-2 and its trend between patients without and with ARD.

Disclosure of Interests: None declared
Methods: Retrospectively, patients with ARD infected with SARS-CoV-2 were matched by age and sex at a ratio of 1:2 to patients without ARD and not receiving immunosuppression or immunomodulator drugs. Viral load was determined by the cycle threshold (CT) value measured by a number of platforms: (a) Automated Platforms - the Roche Cobas 6800 system using the Cobas SARS-CoV-2 Test targeting the E and orf1a/b genes (Roche, Switzerland) and the Xpert Xpress SARS-CoV-2 targeting the E and N genes (Cepheid, USA); (b) Manual platforms - EZ1 (QIAGEN, USA), QIAxSystem (QIAGEN, USA), and Bioneer ExiPrepTM 96 Virus DNA/RNA kits Catalogue No K4614 (Bioneer, South Korea) extraction with thermal cycling using TaqPath™ PCR COVID-19 Combo Kit targeting the N, S and orf1a/b genes (Thermo Fisher Scientific, USA) on ABI 7500 thermal cyclers. Independent samples t-test was used to compare the mean CT values of the study groups at baseline and at 5 subsequent intervals (1 - 5.9, 6 - 11.9, 12 - 17.9, 18 - 23.9 and 24 - 30 days).

**Results:** Mean age (SD) of 197 cases and 420 controls were 45.2 (11.8) and 44.1 (12.3) years, respectively. Females were predominant in both groups 60% vs. 52%, P=0.053. The most common ARD was rheumatoid arthritis in 82 cases (41.6%), followed by spondyloarthropathy in 33 (16.8%) and systemic lupus erythematosus in 31 (15.7%). Of the cases, 67% were on conventional synthetic disease modifying anti-rheumatic drugs (DMARDs), 15.2% on biological DMARDs and 4.6% patients were on rituximab. The mean CT values was significantly lower in the ARD group at baseline and persisted till day 24.

</tbody>
</table>

Conclusion: Compared to patients without ARD, the viral load of SARS-CoV-2 in patients with ARD is significantly higher at baseline testing and persists till day 24. This finding may indicate that patients with ARD are at higher risk of severe SARS-CoV-2 infection and prolonged potential transmission. Clinical outcome correlation is needed.

**AB1147 COVID 19 INFECTION IN PATIENTS WITH RHEUMATIC IMMUNE-MEDIATED DISEASES IN A SINGLE UNIVERSITY HOSPITAL. MATCHED CASE-CONTROL STUDY.**

1Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander (SPAIN), Spain; 2Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander (SPAIN), Spain; 3Servicio Cántabro de Salud, Epidemiology, Santander, Spain

**Background:** COVID19 may present different degrees of severity. It is generally thought that viral infections in patients with rheumatic inflammatory diseases (R-IMID) or receiving immunosuppressive treatment tend to present more severe disease. However, data comparing the severity of the disease between R-IMID and the general population are scarce.

**Objectives:** To assess the predisposing factors, clinical-analytical features and severity of COVID-19 infection in R-IMID compare to patients without R-IMID.

**Methods:** Case-control study in a single University Hospital. We included all consecutive patients with a diagnosis of a R-IMID and a positive test for COVID-19 up to March 31st, 2021. A total of 274 controls were selected for each case, and matched by sex, age (+5 years), and without previous diagnosis of R-IMID or use of immunosuppressive therapy. Confirmed infection was defined if the patient had a positive nasopharyngeal swab for SARS-CoV-2. COVID-19 case severity was divided into mild, moderate, severe and critical according to the United States National Institute of Health (NIH) COVID-19 guidelines (1). Mild/moderate COVID19 was compared with critical.

**Results:** We included 274 patients (185 women/89 men), mean age 59.1 ± 18 years. More frequent R-IMID were: Rheumatoid arthritis (RA) (n=87, 31.8%), Axial spondyloarthritis/ Psoriatic arthritis (SpA/Psa) (n=90, 32.8%), Polymyalgia Rheumatica (PMR) (n=22, 8%) and Systemic Lupus Erythematosus (SLE) (n=22, 8%). We also included 274 age and matched controls. Main characteristics of patients with R-IMID and controls are shown in Table 1.

CRP: C-reactive protein.

Concerning comorbidities, hypertension and dyslipidemia were more frequent in patients with R-IMID (p< 0.05). COVID-19 symptoms distribution is shown in Figure 1.

**Figure 1. Symptoms in R-IMID patients and matched controls**

*p< 0.05

Cough and dyspnoea were more frequent and headache, odynophagia and diarrhoea were less frequent in the R-IMID group. The only analytical difference was D-Dimer that was significantly higher in patients with R-IMID. Although most of the cases were mild, critical cases and deaths were more frequent in R-IMID (p<0.05).

**Conclusion:** Most of the patients present a mild COVID-19. However, a more severe syndrome was observed in R-IMID.

AB1149
EVALUATION OF THE EFFICACY AND SAFETY OF THE SARS-COV-2 VACCINE IN PATIENTS WITH CHRONIC INFLAMMATORY DISEASES TREATED WITH BIOLOGICAL THERAPY.

J. Calvo Gutierrez1, 2, C. López-Medina3, M. C. Ábalos-Aguirera1, A. B. Pérez Jiménez2, D. Ruíz-Vilchez1, F. U. Pilar1, R. Ortega Castro1, A. Escudero Contreras1, E. Collantes Estevez1, Reina Sofia University Hospital; Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC); Córdoba University (UCO), Rheumatology Department, Córdoba, Spain. Reina Sofia University Hospital; Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC); Córdoba University (UCO), Microbiology Department, Córdoba, Spain

Background: In the current situation of the SARS-CoV-2 pandemic, the Spanish Society of Rheumatology recommends vaccination of patients with chronic inflammatory diseases (CID) under treatment with biological DMARDs (bDMARDs). However, the data regarding the generation of protective antibody titers after mRNA vaccines in patients with CID is limited.

Objectives: To determine the seroconversion rate and safety after the SARS-CoV-2 vaccine in patients with CID under treatment with bDMARDs

Methods: Cross-sectional observational study of 81 patients with CID from the HURS in Córdoba, who have received full vaccination for SARS-CoV-2 (without having previously suffered from COVID-19 disease) according to national guidelines. A determination of specific IgG-type antibodies against the trimeric spike protein of SARS-CoV-2 was performed on all of them. The chemiluminescence technique with the kit was used in serum samples taken 4-5 weeks after administration of the second dose of the vaccine. Information about sociodemographic characteristics, disease, type of bDMARDs, concomitant treatments and adverse effects after the second dose of the vaccine were collected in each patient.

Results: 81 patients were included (mean age 59.5, 72.8% females). 50.6% of patients had RA, 17.3% SpA, 11% PsA and 18.5% other CID. 23.5% were under treatment with Rituximab, 38.8% antiTNF, 13.6% Tocilizumab, 9.9% abatacept, 5% anti-JAK and 14.2% under other treatments. Anti-SARS-CoV-2 antibodies and neutralizing activity were detected in 80% of study participants. Rituximab treatment was significantly associated with negative seroconversion in comparison with patients under antiTNF treatment (OR 84.0 (95%CI 11.9-1708.2)). No interaction was found between the bDMARDs treatment and the type of vaccine with regard to the seroconversion, nor between bDMARDs and concomitant synthetic DMARD. When we evaluated IgG titers against the spike protein of SARS-CoV2, we found that patients under treatment with Rituximab showed the lowest titers levels in comparison with patients with other treatments (Figure 1, Table 1). In addition, patients who received AstraZeneca vaccine developed lower titers of antibodies in comparison with patients who received Pfizer (Table 1).

Figure 1. IgG titers against the spike protein of SARS-CoV2 with regard to the bDMARD

AB1148
POST COVID-19 RHEUMATIC AND MUSCULOSKELETAL DISEASES

N. Varghes1, N. Loghin-Oprea1, V. Sadovici-Bobeica1, Nicolae Testemitanu State University of Medicine and Pharmacy, Internal Medicine, Chișinău, Moldova, Republic of Moldova, Republic of Moldova, Republic of Moldova

Background: Recent data suggests that SARS-Cov-2 can alter self-tolerance and trigger autoimmune responses through cross-reactivity with host cells; therefore it can lead to late autoimmune and inflammatory manifestations. With regard to rheumatic and musculoskeletal diseases (RMDs), medical literature displays sporadic case reports describing a variety of conditions diagnosed after COVID-19, but it remains unclear what are the most common problems in patients presenting to rheumatology clinic following COVID-19 disease.

Objectives: To describe the pattern of post-COVID-19 RMDs in a consecutive group of patients from rheumatology outpatient clinic.

Methods: We have performed an observational descriptive study of a group of adult patients who received a new diagnosis of RMD within a timeframe of 12 weeks after the confirmation of COVID-19. Data was collected based on clinical presentation, paraclinical pattern and radiological examinations.

Results: The study included 23 patients who were consulted in rheumatology outpatient clinic and had post COVID-19 new onset joint, periarticular, bone or inflammatory syndrome manifestations. The general characteristics of the study group were as follows: mean age 45.5±11.3 (range 21-63) years and female to male ratio of 1.8:1. The majority of subjects consulted for joint symptoms (91.4%), in other cases reason for consultation was persistent low grade fever and fatigue (4.3%) and skin rash with dyspnea (4.3%). The mean duration of symptoms was 9.8±10.5 (range 1-42) weeks, and the time of onset after COVID-19 diagnosis was 4.9±4.1 (range 0-12) weeks. Concerning COVID-19 severity, it was established that in 60.9% it was mild, 17.4% - moderate and 21.7% - severe. After clinical and paraclinical examination, the following diseases were diagnosed: ReA, lupus like syndromes, avascular necrosis, new onset RA and new onset PsA. In 69.7% of patients were diagnosed with ReA, the clinical pattern being joint or periarticular involvement of the hand, knee and feet. In 13.0% cases patients had multisystemic involvement (myocarditis, pericarditis, skin rash, inflammatory arthritis and/or low grade fever) and positive ANA and or dsDNA Ab, these cases were diagnosed as lupus like syndromes and followed a severe form of COVID-19. In 8.7% of patients who presented with non-inflammatory hip pain, avascular necrosis was diagnosed, in both cases femoral head being the affected part. No be noted that patients with avascular necrosis had a severe form of COVID-19 disease and joint pain started later after COVID-19 diagnosis (10-12 weeks). In 4.3% of cases each, new onset RA and PsA were identified.

Conclusion: In the present study we have found that COVID-19 can be followed by a variety of RMDs. The most common symptom of patients presenting with RMD was joint pain. The most common disease was post-COVID-19 ReA (69.7%). Avascular necrosis (8.7%) and lupus like syndromes (13.0%) were found in patients who experienced a severe form of COVID-19. More rarely, patients had new onset of rheumatoid arthritis (4.3%) or psoriatic arthritis (4.3%). Our findings suggest that during the COVID-19 recovery period patients might experience onset of RDMs; therefore, in the presence of joint symptoms or other manifestations suggesting an autoimmune disease, patients should be referred to a rheumatologist for careful clinical examination.

REFERENCES:

Disclosure of Interests: None declared.

Interestingly, among patients with anti-TNF treatment, AstraZeneca was associated with lower IgG titers in comparison with Pfizer and Moderna [405.9 (553.0) vs. 1084.1 (79.12) vs. 1264.0 (1012.6), p=0.016, respectively]. No differences between vaccines were found in patients with the other type of bDMARDs. Only 18.9% presented mild adverse effects. No serious adverse effects were observed and no patient experienced a disease flare after vaccination.

**Conclusion:** Our results show that SARS-CoV-2 mRNA vaccines produce seroconversion in most patients with CID, except in the case of patients with rituximab. No severe adverse effects or CID reaction were found. Despite the small number of patients included, this study suggests the need for revaccination in the group of patients treated with rituximab or vaccinated with AstraZeneca.

**DOI:** 10.1136/annrheumdis-2022-eular.3971
response in volunteers vaccinated with BNT162b2 showing a 2S≥1 poly-
epitope response.

**Results:** Twenty-eight patients (25 women, 3 men; mean age 59.1±17.8) with various ISD were investigated. These patients suffered from lupus (n=14), vasculitis (n=4), myositis (n=2), sarcoidosis (n=2), primary immunodeficiency (n=3), Sjögren’s syndrome (n=2) and pericarditis (n=1). Three patients had received 4 doses, 16 three doses, and 8 two doses of vaccine (Pfizer; n=25; Moderna n=1, Astra-Zeneca n=1). One patient refused the vaccination. The tests were performed 86.7 (±60.5) days after last vaccine dose. Ten patients were on prednisone (mean dose: 11.8mg, median 7.75mg, range: 5-40). Among those patients, 6 had only prednisone, 1 was also treated with belimumab, 3 with methotrexate (MTX) and 1 with azathioprine (AZA). Following COVID19 vaccination, humoral (100% in healthy vs 84.6% in ISD patients) and IGRASpike T cell (96% in healthy vs 59.7% in AI patients) responses took place with lower response reported among the ISD disease group (Figure 1). Humoral and cellular COVID19 vaccine responses significantly decrease after 100 days post vaccine.

**Figure 1.** SARS-CoV2 humoral and T cell responses in non-vaccinated healthy individuals (n=103), SARS-CoV2 infected individuals (n=9), and 104 samples from individuals having received COVID19 vaccine including 28 non-Sars-cov2 infected patients with ISD diseases. A- Anti-SARS-CoV2 Spike total IgM/IGG antibodies (Ab) titer (BAU/mL) tested by ELISA. B- Whole blood IFN-γ release assay (IGRA) response to the full-length Spike recombinant protein (IGRA-Spike). C- Whole blood IGRA response to the nucleocapsid recombinant protein (IGRA-Nuc). Positivity cut-off (dotted line) p values <0.05 are indicated when significant (ANOVA).

5/5 vaccinated patients on CS alone, 2/5 vaccinated patients on corticosteroids with MTX/ZA/Beclomumab and 3/17 other vaccinated patients (all being primary immunodeficiency patients) had no cellular response. Humoral and T cell responses were independent from sex and age.

**Conclusion:** Altogether, this ongoing study confirms the utility of the IGRA-Spike-nucleocapsid assay coupled with serology in COVID19 vaccinated individuals and in particular in ISD patients treated with steroids, who may be at risk when the humoral protection decreases.

COVID-19 MRNA VACCINE BOOSTER IN PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES

C. Cardelli1,2, T. Caruso1,3, C. Tani2, F. Pratesi1,3, R. Talarico2, F. DI Cianni1,2, N. Italiani1,2, E. Laurino1,2, M. Moretti1,2, M. Diomedi1,2, L. Gualtieri1,2, R. D’urzo2, P. Migliorini1,3, M. Mosca1,2.

**Background:** Patients with systemic autoimmune diseases (SADs) are often treated with drugs that interfere with the immune system and previous data showed a reduced seroconversion rate after anti-SARS-CoV2 vaccine in these subjects compared to healthy controls1. Administration of a booster dose of the vaccine could be particularly important in these patients, but data available to date are still scarce.

**Objectives:** To evaluate the antibody response to the booster dose of mRNA SARS-CoV2 vaccine in patients with SADs and to compare it to the response after completion of the first vaccination course. Secondly, to find possible correlations between a low antibody titre and patients’ clinical features, with special regard to ongoing immunosuppressive therapies.

**Methods:** Consecutive patients with an established diagnosis of SADs undergoing SARS-CoV2 vaccine were prospectively enrolled from January 2021; among them, we selected the patients who received the third vaccination dose between September and December 2021 Demographic and clinical data were collected at enrolment (sex, age, diagnosis, disease duration, ongoing therapies, previous SARS-CoV2 infection, presence of hypogammaglobulinemia); the last three elements were reassessed at each follow-up visit. Blood samples were collected 4 weeks both after the second (W4a) and the third (W4b) dose of the vaccine; a minority of patients was also tested 12 weeks after the second dose (W12).

IgG antibodies to SARS-CoV2 receptor-binding domain (RBD) and neutralizing antibodies inhibiting the interaction between RBD and angiotensin converting enzyme 2 were evaluated. IgG anti-RBD were detected by solid phase assay on plates coated with recombinant RBD, while neutralising antibodies by using the kit SPIA (Spike Protein Inhibition Assay). Cut-off values were defined as the 97.5% percentile of a pre-vaccine healthy population. Statistical analysis was performed using IBM SPSS Statistics 20 and GraphPad Prism statistical packages. P values<0.05 were considered significant.

**Results:** Forty-five patients (95.6% female; mean age ±SD 55.6±14.1 years; mean disease duration 12.9±10.6 years) were enrolled. Diagnosis was in most cases connective tissue disease (31/45, 68.9%), followed by inflammatory arthritis (11/45, 24.4%) and systemic vasculitis (3/45, 6.7%). Two patients (4.4%) had a previous SARS-CoV2 infection and three had hypogammaglobulinemia (6.7%). At the time of the second dose, 18/45 patients were treated with glucocorticoids (GCs) (mean daily 6-methylprednisolone (6MP) dose 3.9 mg). At the third dose administration, 19/45 patients were treated with GCs (mean daily 6MP dose 4.1 mg (min. 1.5, max. 10)), 18/45 with csDMARDs and 13/45 with bDMARDs. Anti-RBD IgG were positive in 42/45 patients (93.3%) at W4a, in 16/16 (88.9%) at W12 and in 42/45 (93.3%) at W4b. Neutralizing antibodies were present in 36/45 patients (84.4%) at W4a, in 14/18 (77.8%) at W12 and in 42/45 (93.3%) at W4b. Both anti-RBD IgG titers and neutralizing antibody titers significantly increased after the third dose if compared to W4a (p<0.0001 both) (Figure 1). Interestingly, of the 7 patients who had not developed an adequate neutralizing antibody response after the first vaccination course, 5 mounted an adequate titer after the booster. Two non-responder patients were both on combination therapy (one with low dose of GCs plus mofetil, the other with methotrexate and infliximab).

**Conclusion:** Our data suggest that in patients with SADs there is a decline in the antibody titers developed after COVID-19 vaccination, however the booster dose is effective in restoring an adequate antibody titre. These data consolidate the importance of a booster dose of COVID-19 vaccination in patients with SADs to aid in the generation of an immune response.

HYPEREOSINOPHILIC SYNDROME FOLLOWING THE BNT162b2 (BIONTECH/ PFIZER) VACCINATION

A. Hoza1, T. Tomaselii, G. Minicucci2, G. Scanneli3, D. Zardo3, L. Naiei3. 1San Bortolo Hospital, Internal Medicine Unit, Department of Medicine, Vicenza, Italy; 2San Bortolo Hospital, Department of Neurosciences, Vicenza, Italy; 3San Bortolo Hospital, Department of Pathology, Vicenza, Italy; 4San Bortolo Hospital, Department of Dermatology, Vicenza, Italy

**Background:** Some reports of small vessel vasculitis following nSARS-CoV2 vaccination are reported in the literature (1, 2).

**Objectives:** We purpose to report the case of small-medium vessel vasculitis after BNT162b2 (BioNTech/Pfizer) vaccination.
Methods: We present the case of a 48 years old man with an unremarkable history who underwent BNT162b2 vaccination.

Results: Five days after the first shot of BNT162b2 vaccine, the patient refer the onset of left inguinal adenopathy, and erythematous dermatitis of the trunk. Ultrasound of the groin found increase bilateral inguinal lymph nodes with reactive characters. Contextually, erythematous, itchy and painful nodular lesions appear in the lower and upper limbs as well as acrocyanosis and paresthesia in the right hand and foot. The tests performed showed thrombocytopenia and eosinophilia. While, CRP, search for fecal parasites, pANCA, cANCA, ANA, RAST test, serum tryptase were all absent. Haematological evaluation, bone marrow biopsy, karyotype and molecular biology (FIP1L1/PDGFRα) were performed, all results negative. The patient was admitted in Internal Medicine ward for worsening of skin lesions and of acrocyanosis with gangrenous lesions at the tips of the fourth finger of the right hand. An angio-CT showed an occlusion of the right ulnar artery. At electromyography an axonal sensory neuropathy was found. The skin biopsy showed fibrinoid necrosis of vessels of the superficial vascular plexus associated with numerous eosinophils, lymphocytes and karyorrhetic debris (Figure 1). High-resolution CT scan described diffuse minimal accentuation of the interstitial texture with micronodular aspects and some ground glass appearance. The diagnosis of hypereosinophilic syndrome was made. Therapy with Methylprednisolone 500mg/day for 3 days then Prednisone 1 mg/kg daily in association with IL-5 inhibitor (mepolizumab) with good clinical response, in addition to antiocoagulation with warfarin was started.

Figure 1.

Conclusion: To our knowledge this might be the first case of (HES) following COVID vaccine. As our experience, due to the short commercialization of anti- nSARS-CoV2 vaccines, is limited further studies are needed to explore the possible effect on small-medium vessels.

HUMORAL AND CELLULAR RESPONSE TO A THIRD BOOSTER DOSE SARS-COV-2 VACCINATION IN PATIENTS WITH AUTOIMMUNE DISEASE: A CASE SERIES

T. Dimitriou1, A. Tychala2, K. Deftarou3, E. Katispourli2, E. Sidropoulou2, M. Papachristou4, A. Fylaktou, L. Skourà2, Aristotle University of Thessaloniki, Greece; Aristotle University of Thessaloniki, Department of Microbiology, Ahepa University Hospital, Thessaloniki, Greece; Papanikolaou General Hospital, Department of Immunology, Thessaloniki, Greece; Hippokration General Hospital of Thessaloniki, Immunology Departments, National Peripheral Histocompatibility Center, Thessaloniki, Greece

Background: Patients with systemic rheumatic diseases (SRD) are at increased risk for viral infections and successful vaccination is crucial to combat COVID-19 pandemic in this population. However, reduced antibody responses have been described in a proportion of SRD individuals on immunosuppressant agents including mycophenolate (MMF).

Objectives: We aimed to assess humoral and cellular response of SRD patients who received a booster SARS-CoV-2 vaccination.

Methods: Twenty patients without history of COVID-19 infection (11 men, median age 58 years (range:38-74) on treatment with MMF (2g daily) due to systemic sclerosis (n=6), inflammatory myositis (n=4) and systemic lupus erythematosus (n=2) and on tumor necrosis factor-alpha inhibitors (anti-TNF) due to spondyloarthritis (n=5), rheumatoid arthritis (n=2) and Bechet disease (n=1) were included. All were on monotherapy with anti-TNF except patient with Bechet. Patients on MMF discontinued treatment for 1 week after the booster dose while no treatment modification was implemented in anti-TNF group. Serological response to vaccination was assessed using the Abbott SARS-CoV2- IgG II Quant assay. Cellular immunity was estimated via interferon-γ produced by CD4+ and CD8+ T-lymphocytes in response to a SARS-CoV2- peptide cocktail, with the SARS-CoV2- ELISA Kit.

Results: Nineteen patients (95%) demonstrated positive serological response following booster vaccine dose (Table 1). Only one female patient in MMF group failed to develop adequate levels of antibodies. The median antibody titers of patients under MMF and anti-TNF was 647.90 BAU/mL (range: 0.71-4795.32 BAU/mL) and 542.98 BAU/mL (range: 4.32-1391.33 BAU/mL) respectively. No statistically significant difference was found between the two groups. Regarding cellular immunity a T-cell response was present in all patients on monotherapy with anti-TNF but only in 7/12 under MMF including the one with negative humoral response.

Conclusion: We report sufficient immunogenicity following a third booster vaccine in patients with RSD on immunomodulatory measures coupled by a strong cellular immune response particularly in patients on anti-TNF monotherapy. Percivaccination management of immunosuppressive therapy represents an important parameter of vaccine administration in patients with RSD.

AB1155

PAUSING METHOTREXATE IMPROVES IMMUNOGENICITY OF COVID-19 VACCINATION IN PATIENTS WITH RHEUMATIC DISEASES

1Charité University Hospital, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 2Charité University Hospital, Department of Rheumatology and Clinical Immunology, Berlin, Germany; 3Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), Berlin, Germany; 4Charité University Hospital, Institute of Virology, Berlin, Germany

Background: Several research groups have recently described a reduced vaccination response to COVID-19 vaccination under methotrexate (MTX) (1,2). The increase in humoral immune response when pausing MTX two weeks after vaccination has already been described for influenza vaccination (3). However, data regarding MTX-hold during COVID-19 vaccination are still lacking.

Objectives: To study the effect of MTX and its discontinuation on the humoral immune response after COVID-19 vaccination in patients with autoimmune rheumatic diseases (AIRD).

Methods: In this retrospective study, neutralising SARS-CoV-2 antibodies were measured after second vaccination in 64 rheumatic patients on methotrexate therapy, 31 of whom temporarily paused medication without a fixed regimen. The control group consisted of 21 AIRD patients without immunosuppressive medication.

Results: MTX patients showed a significantly lower mean antibody response compared to AIRD patients without immunosuppressive therapy (71.8 % vs 92.4 %, p<0.001). For patients taking MTX, age correlated negatively with immune response (r=-0.49; p<0.001). All nine patients with antibody levels below the cutoff were older than 60 years. Patients who held MTX during at least one vaccination showed significantly higher mean neutralising antibody levels after second vaccination compared to patients who continued MTX therapy during both vaccinations (83.1 % vs 61.2 %, p=0.001). This effect was particularly pronounced in patients older than 60 years (80.8 % vs 51.9 %, p=0.001). The impact of the time
period after vaccination was greater than of the time before vaccination with the critical cut-off being 10 days.

**Conclusion:** MTX reduces the immunogenicity of SARS-CoV-2 vaccination in an age-dependent manner. Our data further suggest that holding MTX for at least 10 days after vaccination significantly improves the antibody response in patients over 60 years of age.

**CLINICAL CHARACTERISTICS OF PATIENTS WITH RHEUMATIC DISEASES AFTER COVID-19 IN THE REPUBLIC OF TATARSTAN**

S. Lapshina1, N. Shamsutdinova2, V. Mukhamadieva1, R. Abdrikapov2, E. Sukhorukova2, L. Kupkovenova2, D. Abdulganieva2, Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation; 2Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation; 3Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation; 4Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation

**Background:** The management of patients with rheumatic diseases (RD) who have undergone a new coronavirus infection (NCI) is an urgent and significant problem.

**Objectives:** To study the course of the NCI and its influence on the course of RD in the Republic of Tatarstan.

**Methods:** From June 2020 to January 2022, 159 cases of NCI with a confirmed SarsCoV2 PCR result and/or X-ray computed tomography (CT) of the lungs in patients with RD were analyzed. The study included 104 patients with RA, 36 patients with AS, 18 patients with PsA. RD activity before NCI was low in 56 (35.2%) patients, moderate in 91 (57.3%), and high in 12 (7.5%) patients. Distri-

**Disclosure of Interests:** None declared

**DOI:** 10.1136/annrheumdis-2022-eular.4311
RD were followed up. The study included 100 patients with RA, 36 patients with AS, 18 patients with PsA. RD activity before NCI was low in 56 (36.4%) patients, moderate in 90 (58.4%) patients, and high in 4 (5.2%) patients. Among the patients, 110 (71.5%) were female, 44 (28.5%) were male, the average age was 58 [46; 64]. 28% (43) of patients had asymptomatic or mild NCI, 66.2% (102) had moderate NCI, and 5.8% (9) of people had severe NCI. Bilateral polysegmental pneumonia was detected in 111 (72.0%) patients. The results of clinical and laboratory examinations for RD were assessed before and 3 and 6 months after NCI. Patients underwent an in-depth survey 3 and 6 months after undergoing NCI for the presence of various symptoms, including manifestations of asthenia. Additionally, the severity of depression and anxiety was assessed using the Hospital Anxiety and Depression Scale (HADS) and the Hamilton Scale.

Results: 90.3% of patients noted the persistence or appearance of symptoms after undergoing NCI, and all of them had a combination of at least 3 different groups of symptoms. The most common asthenic manifestations were in the form of a decrease in the quality of life and manifestations of asthenia. Additionally, the severity of depression and anxiety was assessed using the Hospital Anxiety and Depression Scale (HADS) and the Hamilton Scale.

After 3 months, a decrease in the quality of life, manifestations of depression and anxiety were noted by 30.5% of the respondents, while there was no connection with the severity of NCI, and half of the patients had a mild course of COVID-19. The appearance/intensification of chest pain and/or palpitations was noted by 20.8% of patients. After 3 months, a decrease in the quality of life, manifestations of depression and anxiety were revealed: 32.2% of people had a mild depressive disorder of moderate severity, 22.3% had clinically expressed anxiety and depression. Six months after the NCI, no abnormalities were detected on the Hamilton scale, and significantly expressed anxiety/depression on the HADS scale.

Conclusion: In most patients with RD, post-covid manifestations persist, primarily due to general constitutional, articular and cognitive symptoms. Manifestations of NCI itself in the form of respiratory and cardiovascular manifestations persist in less than a third of patients.

**HYDROXYCHLOROQUINE SHORTAGE AND ITS RELATION TO ANXIETY LEVEL AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS DURING COVID-19 PANDEMIC**

M. H. Abu-Za'id, H. Elta, A. Mohshif, D. Abdeldaim, N. EL Ghobashy

1Tanta University, Rheumatology, Tanta, Egypt; 2Al-Azhar University, Rheumatology, Cairo, Egypt; 3Al-Azhar University, Rheumatology, Assiut, Egypt; 4Tanta University, public health, Tanta, Egypt; 5Cairo University, Rheumatology, Cairo, Egypt

Background: Concerns of hydroxychloroquine (HCQ) shortage for patients with rheumatic diseases are growing during the era of COVID-19 pandemic, as it was associated in some treatment protocols. HCQ nonavailability may impact the disease management especially in patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA).

Objectives: To evaluate the shortage of HCQ in patients with RA and SLE and its impact on patients anxiety and disease activity.

Methods: 219 RA patients (according to 2010 ACR/EULAR criteria) and 200 SLE patients (according to 2012 SLICC criteria) were recruited in the study. Demographic and clinical features of the patients together with the current disease activity parameters (CDAI and SLEDAI) were prospectively collected. Previous disease activity measures were collected from the patients records before hydroxychloroquine shortage. Patient's anxiety was measured using Hamilton anxiety rating scale.

Results: A total of 416 patients divided into two groups, Group (1): 219 RA patients with mean age 45.6±9.6 years, disease duration 45.5±32.8 months with female prevalence (63 %). Group (2): 200 SLE patients with mean age 33.8±7.9 years, disease duration 612±39.2 months with female prevalence (84%). 168 (76.7%) of the RA patients and 128 (64%) of SLE patients reduced or stopped the dose of HCQ due to nonavailability. Despite HCQ shortage, there was no significant change in RA disease activity (p=0.063 and 0.04 respectively). All participants suffered from different levels of anxiety which was positively correlated with HCQ shortage (p<0.001 and 0.005 for RA and SLE respectively).

Conclusion: COVID 19 pandemic caused hydroxychloroquine shortage in the majority of patients with RA and SLE with no significant impact on their disease activity. Anxiety was found correlating to HCQ shortage in both diseases more significantly in SLE patients.

**IMPACT OF COVID-19 TREATMENTS ON PERIPHERAL CAPILLARY DENSITY EVALUATED BY NAILFOLD VIDEOCAPILLAROSCOPY**

E. Gotelli1, A. Sulli1, P. F. Bica2, I. Schiavetti1, T. Aloe3, M. Grosso3

1University of Genova, IRCCS Sant Martino Polyclinic Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, Genova, Italy; 2University of Genova, Department of Health Sciences, Genova, Italy; 3IRCCS Sant Martino Polyclinic Hospital, Interventional Rheumatology Unit, Genova, Italy; 4Ghent University Hospital, Department of Rheumatology, Ghent, Belgium; 5Ghent University Hospital, Department of Internal Medicine, Ghent, Belgium; 6VIB Inflammation Research Center, Unit for Molecular Immunology and Inflammation, Ghent, Belgium

Background: Human SARS-CoV-2 infection can induce a wide spectrum of organ dysfunctions, including microvascular impairment [1]. S. subunit of viral receptor-binding domain links to the angiotensin-converting enzyme 2 receptor on endothelium and Sβ subunit allows the virus to enter endothelial cells. The resulting breakdown of barrier integrity drives a cascade of inflammatory and thrombotic events, that aggravate the course of COVID-19 together with other risk factors [2-4]. Up to date, a lower capillary density has been reported in several distinct body districts, using sublingual video microscopy, ocular optical coherence tomography, skin function tests and videocapillaroscopy [5-6]. NVC examination has been performed in adult COVID-19 patients, however, without a control group [8].

Objectives: To confirm the statistical significance of the reduction in capillary density per linear millimeter evaluated by NVC in comparison with primary Raynaud’s phenomenon (PRP) patients and control subjects (CNT) and to evaluate the impact of an aggressive therapy against COVID-19 on the sparing in the number of capillaries.

Methods: Sixty-one COVID-19 survivors, thirty-one PRP patients and thirty CNT age and sex-matched underwent NVC analysis. Demographic and clinical data of COVID-19 survivors were collected with special regard to concomitant therapies, that included antivirals, antibiotics, anti-coagulants and anti-inflammatory immunomodulating drugs (glucocorticoids, hydroxychloroquine, IL-6 receptor antagonist). COVID-19 survivors were divided in two subgroups according to the severity of the active infection: thirty-four survivors with past mild-moderate disease (either unneedy for oxygen supplementation or need for Venturi mask) and twenty-seven survivors with past severe disease (need for Continuous Positive Airways Pressure and/or mechanical ventilation). The same Rheumatologist performed NVC evaluations in all patients and controls, using an optical probe, equipped with a 200x magnification lens and connected to a picture analysis software (Videocap, DS Medica, Milan, Italy). Absolute capillary number per linear millimeter was counted.

Results: COVID-19 survivors underwent NVC examination after a mean period of 126±53 days from the disease onset. Multivariate analysis showed differences in absolute capillary number per linear millimeter (p=0.001) after adjusting for age, sex, body mass index, comorbidities and concomitant drugs. The mean (± standard deviation) absolute nailfold capillary number per linear millimeter was significantly lower in severe (8.2±1.15) and mild-moderate (8.4±0.75) COVID-19 survivors than in both PRP (8.7±0.68) and CNT subjects (9.3±0.53) (p<0.001). The analysis of the impact of treatments on capillary density in the severe COVID-19 patients showed a positive correlation (p<0.005) between the capillary number (p=0.001) and antivirals (no: 7.8±1.53; yes: 8.5±0.64; p=0.35) and anti-L16 receptor antagonist administration (no: 7.8±1.36; yes: 8.6±0.74; p=0.16), while none of the other drugs was shown to be effective (glucocorticoids p = 0.46; antibiotics = 0.52; anti-coagulants not evaluable as they were used in all COVID-19 patients).

Conclusion: SARS-CoV-2 infection seems associated to a significant capillary loss as distinctive NVC feature and data concerning the comparison of capillary density pre COVID-19 and post COVID-19 are desirable to reinforce this observation. The positive trend in saving the number of capillaries induced by aggressive anti-inflammatory therapies in COVID-19 patients needs larger cohorts of patients.

COVID-19 IN MY RA CLINIC: DATA FROM QUESTIONNAIRE, VACCINATION, INFECTION AND FRAILTY FROM THE RA LOUVAIN BRUSSELS COHORT

V. Pirson1, T. Sokolova1, X. Theunssens1, S. Bricman1, E. Sapart1, S. DE Montjoye1, S. Dierckx2, A. Avramovska1, P. Durez1. 1Division of Rheumatology, Department of Medicine, Udine, Italy; 2Division of Rheumatology, Rheumatology, Brussels, Belgium; 3CHU Mont-Godinne, Rheumatology, Mont Godinne, Belgium

Background: Over 5 million deaths from the COVID-19 disease have been reported in the world. Patients (pts) living with rheumatoid arthritis (RA) affecting the immune system or under immunosuppressive agent are considered as a high risk population for a SARS-CoV-2 infection. Since no antiviral treatment is available, the vaccination is a major option.

Objectives: The aim of this study is to evaluate in our RA cohort a questionnaire about the COVID-19 vaccination willingness, to analyse the vaccination rate, the number of COVID infection, the RA frailty and the side effects.

Methods: We included pts with RA from the UCLouvain Brussels cohort who met the ACR/EULAR 2010 classification criteria. A simple and standard questionnaire about the vaccine willingness was distributed in 2020 before the vaccination. From January to December 21, the rate of vaccination was calculated. The number of Covid infections, RA frailty, therapy switches and side effects were also collected. All patient and RA characteristics were analyzed.

Results: 605 eligible RA pts were included. The average age of the population is 58.21 years. 72% of the patients are women. 21% are smokers and 65% are positive for anti-citrullinated protein antibody (ACPA) with a mean DAS28-CRP of 2.39 and a mean HAQ of 0.821. In 2020, 460 pts filled the questionnaire and 61% indicated they would receive the vaccine as soon as it is available. For the 179 pts (39%) who decline, the reasons for not having vaccine were no trust in the vaccine at this time (33%), fear of side effects (28%), opposition to vaccine (4%), previous SARS-CoV-2 infection (2%) and unknown (5%). Pts under the age of 50, women, low education grade, smokers, presence of RF/ACPA and treatment with a bioDMARD were less willing to receive the vaccine. In 2021, 538 pts were vaccinated and only 67 pts (11.1%) not. The majority received a mRNA vaccine (81.8%). 72 and 21 pts developed a SARS-CoV-2 infection before and after the vaccination, respectively. Among them, 5 were admitted to intensive care unit leading to 4 deaths. Only, 7 RA frailties were observed and 17 pts switched the therapy. 101 adverse events were reported. All of them were mild and transient except 2 cases with pulmonary embolism and one case with Herpes Zooster infection.

Conclusion: The SARS-CoV-2 global pandemic is responsible of many medical dramas. In our RA cohort, we observed first hesitation followed by a high rate of vaccination. The safety was reassuring with a minimal number of RA frailties and serious adverse events including only 4 deaths.

AB1162
THE LINK BETWEEN INFLAMMATION AND THROMBOSIS: CLINICAL AND IMMUNOHISTOCHEMICAL CHARACTERIZATION OF PULMONARY ARTERIAL THROMBOSIS IN COVID-19 PATIENTS

L. Quartuccio1, A. Sonaglia1, L. Casarotto2, D. Mogenaglie3, C. Di Loreto2, E. Pogolo2. 1Division of Rheumatology, Department of Medicine, Udine, Italy; 2Institute of Anatomic Pathology, Department of Medicine, Udine, Italy; 3Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM), National Institute for Health Research (NIHR), Leeds Biomedical Research Centre (BRC), Leeds, United Kingdom

Background: Coronavirus-19 disease (COVID-19) has been responsible, to date, for more than 5 million of deaths. Immunothrombosis may be a major factor contributing to mortality in COVID-19 and pulmonary arterial tree involvement that mimics multiple pulmonary embolism could be a major contributor to disease course. Immunomodulatory drugs are of some benefit but mechanism not completely clear. We investigated pulmonary arterial tree clots to better appreciate their immunothrombotic nature, in contrast to the pathological characteristics of non-inflammatory thrombi (1).

Objectives: The primary objective was to study in depth the arterial thrombosis in COVID-19, by characterizing the immunohistochemical nature of thrombi, performing macroscopic and microscopic analyses, and by comparing clinical, laboratory and anatomical-pathological data of these patients with other patients died for COVID-19 but without evidence of pulmonary arterial thrombosis.

Methods: Autopsies were performed in patients (cases) who died for COVID-19 with evidence of pulmonary arterial thrombosis at autopsy finding but without pathological signs of bronchopneumonia or peripheral venous thrombosis. COVID-19 positive patients without pulmonary arterial thrombosis were selected as control group. Hematoxilin and eosin stained slides were reviewed choosing those with visible pulmonary thrombi. Further histochemistry and immunohistochemical staining were performed in selected paraffin blocks. Each component of the thrombus was evaluated with the software application QuPath in terms of fibrin, red blood cells, platelets and immune cells percentage after scanning the slides with Aperio System. Laboratory tests were recorded at 2 points: at hospital admission and at Intensive Care Unit transfer.

Results: We included 13 patients (cases) and 14 controls, matched for age, gender and time from diagnosis to death. Twenty arterial thrombi were studied. By immunohistochemistry, arterial thrombi were composed by white blood cells (WBC) [median, IQR range: 10% (5-12.25), mainly neutrophils [58% (35.2-64.5)], red blood cells [12%, (6-34.25)], fibrin [19% [14.5-42.25]], platelets [39%, (31.75-48)] (Figure 1). Three cases had a history of previous thrombosis. All cases had received anticoagulant treatment during hospitalization, low molecular weight heparin in 12/13 (therapeutic regimen in 4/12, prophylactic in 8/12) while 1/13 continued oral anticoagulants for comorbidity. By comparing laboratory findings between cases and controls, cases showed significantly higher levels of platelet count [median, IQR range: 195000/mmc (157750-274500) vs 143500 (113000-173520), p=0.011], LDH (854 U/L (731-1315) vs 539 (391.5-660), p=0.003) at hospital admission, and D-dimer at ICU transfer [25072 FEU (6951-50531) vs 1024 (620-5501), p=0.003].

Conclusion: Pulmonary arterial thrombosis in COVID-19 is a type of immune-mediated inflammatory thrombosis, since the amount of WBC is 6-times more than normal value seen in non-inflammatory thrombi. Some markers of inflammation, necrosis and coagulation are much more increased in this subset of patients. Chest CT angiography rather than simple CT scan at hospital admission could be more useful in this setting, and treatments with antiplatelet agents or anticoagulants, eventually in combination with immunotherapy, might positively affect the outcome.

Sofia, Clinic of Internal Medicine, Varna, Bulgaria; "Sputnik Light" , other 65 pts received 2 doses of Gam-COVID-Vac (Sputnik V). 2 pts - Systemic sclerosis. Extraglandular manifestations of SjS were detected in out of 70 were women. The mean age was 52.5±14.6 years, the average duration

AB1165 THE ROLE OF MOLECULAR MIMICRY IN SARS-COV-2 RELATED AUTOIMMUNE RHEUMATIC DISEASES

C. Liaskos1, E. Patrikiou1, L. Komorowski2, C. Tsagaliou1, A. Tsirgianni1, L. Sakka1, D. Bogdanos1.

Faculty of Medicine, University of Thessaly University General Hospital of Larissa, Department of Rheumatology and Clinical Immunology, Larissa, Greece; 2AG Euroimmun, Immunology Experimental of Institut, Lübeck, Greece; 3Democritus University of Thrace, Alexandroupolis, Greece, Laboratory of Microbiology,Alexandroupolis, Greece; 4Evangelismos General Hospital, Athens, Greece, Department of Immunology-Histocompatibility, Athens, Greece

Background: Several studies suggested that SARS-CoV-2 infection may induce autoantibodies related to autoimmune rheumatic diseases (ARD). Objectives: To determine whether polyclonal antibodies from SARS-CoV-2 uninfected patients with ARDs co-react with SARS-CoV-2 and vice versa. Methods: 90 sera positive at high-titres for 23 common autoantibodies (all sera stored before 2018), were tested for reactivity against proteins of SARS-CoV-2 (spike protein S1, nucleocapsid NC etc) by ELISA and CMIA. 10 monoclonal antibodies against S1 protein (most of them against RBD) were tested for autoantibody reactivity by indirect immunofluorescence, ELISA, immunoblot and dot/line immunosassays coated with different antigens. Ten post-COVID sera with high titers of anti-Spike abs were tested by ELISAs for reactivity against various autoantigens related to ARDs.

Results: 88 out of 90 samples (%), were totally unreactive to SARS-CoV-2 proteins; 2 sera, one anti-CCP and one anti-CENP reacted against S protein. All sera tested negative for neutralized abs against SARS-CoV-2. None of 10 sera from SARS-CoV-2-infected patients reacted with different autoantigens by molecular assays. None of the 10 monoclonal abs against S1 protein reacted with 23 different self-antigens. On HEp2 cells as substrate for IIF, 3 of the 10 monoclonal abs against S1 protein (most of them against RBD) were tested for autoantibody reactivity by indirect immunofluorescence, ELISA, immunoblot and dot/line immunosassays coated with different antigens. Ten post-COVID sera with high titers of anti-Spike abs were tested by ELISAs for reactivity against various autoantigens related to ARDs.

Conclusion: Our data suggest that there are still possibilities to influence rheumatic patients on their decision to vaccinate against SARS-CoV-2 in Bulgaria. Raising the awareness of the safety and efficacy of the SARS-CoV-2 vaccines and spending more time on the education of patients with rheumatic diseases may positively affect their attitude towards vaccination.

AB1164 EFFICACY AND TOLERABILITY OF THE VACCINE AGAINST SARS-COV-2 IN PATIENTS WITH SJOGREN’S SYNDROME RECEIVING VARIOUS TYPES OF THERAPY.

A. Torgashina1, E. Sokol1, B. Chalcev1, J. Khvan1, M. Kireeva1, V.A. Nasonova Research Institute of Rheumatology, Rare Rheumatic Disease and Sjogren’s Syndrome, Moscow, Russian Federation

Background: there are some concerns among patients (pts) with rheumatic diseases regarding the tolerability and efficacy of SARS-CoV-2 vaccination. The impact effect of vaccination on the course of Sjogren’s syndrome (SjS) is not entirely clear. Objectives: to evaluate the efficacy and tolerability of the heterologous recombinant adenovirus (AdV)-based vaccine Sputnik in pts with SjS receiving various types of therapy.

Methods: single center observational retrospective study. Diagnosis of SjS was based on ACR/EULAR 2016 criteria. Rituximab (RTM) was administered in two 1000mg infusions 14 days apart for the 1st course, then 500mg every 6 months.

Results: 70 pts with a definite diagnosis of SjS were included in the study. Four, 36 and 30 were women. The mean age was 52.5±14.6 years, the average duration of the SjS was 72 (36-120) months. Three pts had concomitant RA, 3 pts - SLE - 2 pts - Systemic sclerosis. Extraglandular manifestations of SjS were detected in 35 cases. Five pts received single-dose Ad26 vector-based COVID-19 vaccine “Sputnik Light”, other 65 pts received 2 doses of Gam-COVID-Vac (Sputnik V).

Eighteen pts did not receive any immunosuppressive therapy and were vaccinated before RTM therapy. One patient of them just diagnosed with lymphoma, 8 pts had extraglandular manifestations of the SjS (hypergammaglobulinemic purpura, cryoglobulinemic vasculitis with polyneuropathy, interstitial lung disease). 20 pts at the time of vaccination received various immunosuppressive drugs: 1 - cyclophosphamide (CYP), 1 - leflunomide, 1 – Azathioprine, 3 – methotrexate, 2 - mycophenolate mofetil (MMF), 10 – hydroxychloroquine, 13 - low doses of methylprednisolone. Thirty-two pts received anti B-cells therapy with RTM. The duration of RTM therapy before vaccination was 18 (12-36) months, the period of time between the last injection of the RTM and the vaccine was on average 6 (5-8) months. B-cells level was determined in 18 pts immediately before vaccination and it was normal only in 10 pts. The level of neutralizing antibodies after vaccination was monitored in 44 pts. The level of IgG antibodies against SARS-CoV-2 was positive in 15 of 22 pts who did not receive RTM and in 10 of 22 pts who received the RTM (p<0.05). Neutralizing antibodies did not develop in 4 pts despite complete recovery of B cells. It is important that none of the vaccinated pts was infected COVID-19 within at least 6 months after vaccination. Various types of adverse reactions were observed in 8 pts. The most common was flu-like syndrome. In one case this syndrome required the prescription of dexamethasone. In 3 cases disease exacerbation occurred after vaccination. These pts had extraglandular manifestations of SjS and received immunosuppressants (CYP, MMF or RTM), 2 of them required treatment intensification, in one case the exacerbation was self-limiting.

Conclusion: vaccination against SARS-CoV-2 infection was well tolerated by pts with SjS even in the absence of immunosuppressive therapy. In most cases, there were no exacerbation of the SjS and pts could continue immunosuppressive therapy without becoming infected COVID-19.

Disclosure of Interests: None declared
Background: Since the development of COVID-19 vaccines, more than 300 million people have been immunized worldwide. Soon after vaccinations were initiated, reports on cases of myocarditis following the second vaccine dose have emerged.

Objectives: This study aims to report our experience with nine patients with post-COVID-19 vaccine myocarditis, and to compare them to a cohort of patients who presented with paediatric inflammatory multisystem syndrome (PIMS / PIMS- TS) post COVID-19 infection.

Methods: We collected all reported cases of patients who developed myocarditis following COVID 19 vaccination (Pfizer mRNA BNT162b2), from all pediatric rheumatology centers in Israel, and compared them to the cohort of patients previously diagnosed with PIMS.

Results: Nine patients with myocarditis post-vaccination were identified and compared to 78 patients diagnosed with PIMS. All patients with post-vaccination myocarditis were males who developed symptoms following their second dose of the vaccine. Patients with myocarditis post-vaccination had a shorter duration of stay at the hospital (4.4±1.9 vs. 8.7±4.7 days), less myocardial dysfunction (11.1% vs. 61.5%), and all had excellent outcomes as compared to chronic changes among 9.2% of patients with PIMS.

Conclusion: The clinical course of vaccine-associated myocarditis appears favorable, with resolution of symptoms in all the patients in our cohort. The risk–benefit decision for vaccination remains highly favorable, given the potential morbidity of patients with COVID-19, especially those with PIMS.

AB1167 THE USE OF ORAL AMINO-BISPHOSPHONATES AND CORONAVIRUS DISEASE 2019 (COVID-19) OUTCOMES

P. Pistillo 1, M. Rossini 2, A. Fassio 3, C. Benini 4, D. Gatil 5, G. Adami 6

University of Verona, Rheumatology Unit, Department of Medicine, Verona, Italy

Background: The determinants of the susceptibility to SARS-CoV-2 infection and severe Coronavirus Disease 19 (COVID-19) manifestations are yet not fully understood. Amino-bisphosphonates (N-BPs) have anti-inflammatory properties and have been shown to reduce the incidence of lower respiratory infections, cardiovascular events and cancer.

Objectives: We conducted a population-based retrospective observational case control study with the primary objective of determining if oral N-BPs treatment can play a role in the susceptibility to the development of severe COVID-19.

Methods: Administrative ICD-9-CM and ATC data, representative of Italian population (9% sample of the overall population), were analyzed. Oral N-BPs (mainly alendronate and risedronate) were included in the analysis. Patients treated with bisphosphonates (controls), with a random match (1:1 ratio) for age, sex and for other clinically relevant variables (presence of treatments other than bisphosphonates and hospitalizations) with all the health-assisted population without this treatment (controls).

Results: Incidence of Covid-19 hospitalization was 12.32 [95%CI 9.61-15.04] and 11.55 [95%CI 8.91-14.20], of ICU utilization due to COVID-19 was 1.25 [95%CI 0.38-2.11] and 1.42 [95%CI 0.49-2.36] and of all-cause death was 0.06 [95%CI 2.50-5.61] and 3.96 [95%CI 2.41-5.51] for oral N-BPs users and non-users, respectively (Figure 1A). Figure 1B Incidence and 95% CI of COVID-19 related events in N-BPs treated and untreated subjects with anti-osteoporotic drugs and without corticosteroids. C. Incidence and 95% CI of COVID-19 related events in N-BPs treated and untreated without previous vertebral or hip fragility fractures. D. Incidence of COVID-19 related events in bisphosphonates treated and untreated patients without previous vertebral or hip fracture without corticosteroid prescriptions.

Conclusion: In conclusion, we found that the incidence of COVID-19 hospitalization, intensive care unit (ICU) utilization and COVID-19 potentially related mortality were similar in N-BPs treated and non-treated subjects. Similar results were found in N-BPs versus other anti-osteoporotic drugs. We provided real-life data on the safety of oral N-BPs in terms of severe COVID-19 risk on a population-based cohort. Our results strongly support national and international guidelines that advocate against the discontinuation of oral bisphosphonates only for the fear of COVID-19.

AB1168 CLINICAL AND SEROLOGICAL EVOLUTION OF RHEUMATIC PATIENTS INFECTED BY SARS-COV-2

Hospital Universitario La Fe, Reumatología, Valencia, Spain

Background: SARS-CoV-2 infection is a public health problem due to its high contagiousness and mortality. Spectrum of symptoms ranges from no symptoms to interstitial pneumonia. Patients with rheumatic disease present an increased infectious risk, especially those treated with immunosuppressants or biologic therapy. Since the beginning of the pandemic, risk of contagion and development of complications in these patients has been questioned.

Objectives: To describe hospitalization prevalence, seroconversion, and symptoms in patients under follow-up by the rheumatology department of a tertiary hospital.

Methods: Observational, cross-sectional study conducted by phone interview including patients with different diagnosis of rheumatic diseases. Data about symptoms, hospital admission, serology by ELISA (when >15 days of evolution), diagnosis and baseline treatment, from March 2020 to February 2021 were collected.

Results: Eighty-six patients with different rheumatic diseases and positive COVID-19 PCR were included (82.35% women) in Table 1. Mean age was 49.30 years (16.16). The 48.71% received biological therapy, JAK inhibitors or apremilast, with a median of 3.11 years (Q1 1.08; Q3 3.17), Secukinumab was the biological therapy most often used (24.32%), followed by Tocilizumab (13.51%). The 34.18% received DMARDs or immunosuppressors, with a median of 5.09 years (Q1 12.25; Q3 11.09). The most frequent symptoms were asthma (72.15%), headache (66.23%) and cough (59.49%). Nine patients (11.25%) were admitted to hospital, eight of them (10%) for pneumonia. Three of them were admitted to intensive care and one died.

Seroconversion occurred in 53.25%. low IgG titers were present in 2.94% and IgM persisted positive in 56.25% of this group. In 6.45% the result was indeterminate.

Conclusion: Hospitalization and mortality rate obtained was low and the most frequent symptoms were mild. Seroconversion occurred in more than 50% of patients and the result of 6.45% was indeterminate. It's important to highlight that since March 2020 to May 2020 IgG positive prevalence was 25%, while since September 2021 to February 2021, this prevalence increased until 57.45%.

This difference is due to a modification of autoantibody detection technique since summer 2020.

**AB1169**

**IMMUNODIMODULATORY EFFECTS OF SARS-COV-2 VACCINATION: INCREASE OF REGULATORY T CELLS AFTER MRNA VACCINE**

P. La Gualiana1, F. Villani1, G. Cusano1, L. Gragnani2, L. Stefanini3, S. Santini2, S. Basili1, M. Casato1, M. Fiorilli1, M. Visentini1, Sapienza University of Rome, Department of Translational and Precision Medicine, Rome, Italy; University of Florence, Department of Experimental and Clinical Medicine, Rome, Italy; Catholic University School of Medicine, Department of Basic, Clinical, Intensive and Perioperative Biotechnological Sciences, Rome, Italy.

**Background:** Besides the ability to induce antigen-specific responses, vaccines can be endowed with immunomodulatory properties including the capacity to induce or downregulate regulatory T cells (Treg) that suppress adaptive and autoreactive immune responses (1).

**Objectives:** We asked if an anti-SARS-CoV-2 mRNA vaccine could also induce an accumulation of Treg cells in patients with mixed cryoglobulinemia vasculitis (MCV), who have a deficiency of Treg cells (2) and in healthy individuals. We also investigated immunologic variables possibly associated with a low immunogenicity of SARS-CoV-2 mRNA vaccine in patients with MCV (3).

**Methods:** We analyzed peripheral blood lymphocyte subpopulations and anti-SARS-CoV-2 serological response in 24 patients with MCV and 9 Healthy donors (HD) before and after 2 weeks after the second dose of the Pfizer/BioNTech vaccine.

**Results:** Among MCV patients we found 15 serological responders and 9 non-responders. All 5 seronegative patients treated recently with rituximab had <5 B cells/μL, whereas the absolute B cell count was increased in 2 of 4 untreated patients due to monoclonal B cell lymphocytosis, with monoclonal cells representing more than 90% of B cells, associated with non-Hodgkin lymphoma. The percentage of pathologic CD21low B cells was significantly increased in seroreactive patients. Before receiving the Pfizer/BioNTech vaccine, patients with MCV had a significantly reduced frequency of Treg cells among CD4+ T cells compared to HD. After the second dose of the vaccine, there was in MCV patients a significant increase in the percent and absolute count of Treg among CD4+ T cells Concerning the pre-vaccination distribution of T cells subpopulations, including the percentages and absolute counts of total CD3+, CD4+, CD8+, HLA-DR+ activated, Treg or CD56+ natural killer T cells, we could not reveal any pattern significantly associated with lack of serological response to vaccine.

**Conclusion:** Our findings show that lack of immunoreactivity in patients with MCV may be associated with expansion of pathologic B cells and that anti-SARS-CoV2 mRNA vaccine may induce an increase of Treg cells.

**IMPACT IN PRENATAL EVALUATION OF PREGNANT WOMEN WITH RHEUMATIC DISEASES BY THE SARS-COV2 PANDEMIC**

A Y. Luiano Negrete1, M. E. Corral Trujillo1, C. M. Skinner Taylor1, L. Pérez Barbosa1, A. Aguilar-Leal1, D. C. Rodriguez-Ruiz1, L. G. Espinosa Banuelos1, A. Cárdenas1, D. A. Galarza-Delgado1. Hospital Universitario “Dr. José Eleuterio González”, Rheumatology, Monterrey, Mexico

**Background:** Due to the SARS-CoV-2 pandemic, an increase in stress, anxiety, and depression has been seen, as well as greater use of substances and a decrease in prenatal care in pregnant women. (1) Women of childbearing age with autoimmune rheumatic diseases (ARDs) experience greater psychological stress, which can negatively influence behavior. (2)

**Objectives:** This study aims to compare changes in prenatal laboratory and ultrasound tests by trimester, as well as the detection of anxiety and depression in pregnant women with ARDs due to the SARS-CoV-2 pandemic.
