Annual European Congress of Rheumatology

14 – 17 June, 2017
Madrid, Spain

Abstracts

The EULAR Journal
Annals of the Rheumatic Diseases publishes original work on all aspects of rheumatology and disorders of connective tissue. Laboratory and clinical studies are equally welcome.
Dear Colleagues,

Welcome to this EULAR Annual European Congress of Rheumatology in Madrid!
Welcome to the 70th anniversary of EULAR!

The annual EULAR Congresses, which began in 2000, are today a major event in the calendar of world rheumatology. This meeting, which marks the 70th anniversary of our very active society, will once again provide a unique occasion for the exchange of scientific and clinical information. It will facilitate interaction between patients, medical doctors, scientists, health professionals and professionals representing the pharmaceutical industry from Europe and from around the world. Participating in the congress is just one element of the annual educational package provided by EULAR: Almost all oral presentations will be available online after signing up and participants will be provided with a complimentary, one-year subscription to the latest developments and publications in the field of rheumatic and musculoskeletal diseases (RMDs). This is in line with a new, exciting event taking place in Madrid this year – the launch of the EULAR School of Rheumatology, which will be unique in providing education in rheumatology throughout the world.

EULAR has grown rapidly in terms of the number of participants and the quality of the submissions. A record number of more than 4'850 abstracts have been submitted to this year's congress in Madrid, and 180 sessions and poster tours are offered. This tremendous success continues to reflect the increasing interest in RMDs; it also reflects the availability of increased information on the size, burden and cost of these diseases for society – and a significantly improved ability to diagnose and treat them. The incorporation of health professional and patient organisations within EULAR has been a considerable stimulus for these advances.

The EULAR Congress 2017 in Madrid will provide a wide range of topics including clinical innovations, clinical translational and basic science. In addition, there will be significant contributions made by People with Arthritis and Rheumatism (PARE), by Health Professionals in Rheumatology (HPR) and by the health care industry. The core science and central activity of the congress will be the poster presentations and poster tours with their highly interactive exchanges between participants. The Madrid meeting will further promote the reputation of the EULAR Congress as a most innovative and informative venue for clinical research for the practising physician and health professionals. Meanwhile, the EULAR EMEUNET organisation of young rheumatologists aims to attract young colleagues to the meeting and will disseminate the message that rheumatology is one of the most attractive and successful disciplines of medicine.

We are back in the vibrant city of Madrid with its remarkable history, architecture, galleries, museums and ambience, all of which will once again provide an excellent background for clinical exchanges, international collaborations and renewal of friendships. “No pierdas tu tren” and in international language “Don’t Delay, Connect Today!” marks the first general EULAR Campaign to be launched in Madrid aiming at early recognition and treatment of RMDs.

It is our great pleasure and a real joy in welcoming medical doctors, patients, health professionals and representatives of the pharmaceutical industry and we hope their stay in Madrid will be delightful, informative, and educational. We wish you a great time, good science, good discussions, good meetings and most of all good memories to take home when you are heading back from Madrid and from our 70th anniversary congress.

Gerd R. Burmester
President of EULAR
EULAR 2017 Abstracts Reviewers

ABISHEK, Abishek (United Kingdom)

Speaker Presentations

Wednesday, 14 June 2017
SP0001–SP0004 Joint EULAR - APLAR session: novel animal models - where no researcher has gone before. . . . 2
SP0005–SP0008 Health professional welcome session ...................................................... 2
SP0009 WIN & HOT session .................................................................................. 3
SP0010–SP0012 Moving towards new criteria in SLE, Sjögren’s and APS ...................... 4
SP0013–SP0016 The differential diagnosis of diffuse skin sclerosis and of Raynaud’s phenomenon and a practical approach to assessment ...................................................... 5
SP0017–SP0018 Controlling the balance between cancer and autoimmunity .................. 5
SP0019–SP0021 Fibromyalgia: a disease of the peripheral or central nervous system .... 6
SP0022 Chondrocyte channels (role in mechanotransduction)or “channeling the chondrocyte” .......... 6
SP0023–SP0024 Wearable technologies in 21st century healthcare .............. 7
SP0025–SP0027 Assessment and management of osteoporosis ....................................... 7
SP0028–SP0030 Systematic literature review: the link from science to clinical practice .... 8
SP0031–SP0033 EULAR Campaign: Don’t Delay, Connect Today ...................................... 8
SP0034–SP0036 Standing Committee session on paediatric rheumatology ................. 9
SP0037–SP0040 Ultrasound basic I & II ....................................................................... 10
SP0041–SP0043 Rehabilitation and modern drug treatment - needs and challenges .......... 10
SP0044–SP0046 Comorbidities: having one RMD is enough - we don’t need anything else ..... 11

Thursday, 15 June 2017
SP0047–SP0049 Cytokines and chemokines .................................................................. 11
SP0050–SP0052 Bringing rheumatology research to the next level: addressing the main challenges of patient partnerships in research and health care service design .................................................. 12
SP0053 WIN & HOT session .................................................................................. 13
SP0054–SP0056 Treat-to-target in axSpA: reality or utopy? ........................................... 13
SP0057–SP0058 Calcium crystal deposition in rheumatic diseases .................................. 14
SP0059–SP0060 Fifty shades of remission in RA ..................................................... 15
SP0061–SP0063 Innate immunity ................................................................................. 15
SP0064–SP0066 To be and to become: transition from paediatric to adult care .............. 16
SP0067–SP0068 Heterogeneity in JIA ........................................................................ 16
SP0069–SP0070 EULAR - EMA session .................................................................... 17
SP0071–SP0073 Barrier free employment for young people with RMDs ......................... 17
SP0074 Epidemiology of rheumatic and musculoskeletal diseases - a critical appraisal ........ 18
SP0075–SP0077 Ultrasound advanced I & II ................................................................. 19
SP0078–SP0079 PsA: an integrated perspective ............................................................. 19
SP0080 Autoinflammatory diseases in children and adults ........................................... 20
SP0081–SP0083 Immunogenicity of biologics; myth or reality? ...................................... 20
SP0084–SP0085 Which target /outcome is more relevant in the management of SLE? ...... 21
SP0086–SP0087 Joint EULAR - EFIS session: Tilting the balance: from disease to tolerance induction 21
SP0088–SP0090 What to do about comorbidity? ............................................................ 22
SP0091 Data visualisation: tables and graphs for publication and presentation I & II ........ 23
SP0092–SP0094 Difficult to reach patient groups .......................................................... 23
SP0095–SP0097 EULAR Projects in musculoskeletal imaging ........................................ 24

Osteoarthritis (OA) is the most frequent joint disease and a leading cause of disability in the Western world. Currently, we do not have a cure for this degenerative disorder and despite a high individual and socioeconomic demand, available therapeutic strategies have not changed substantially within the last 40 to 50 years, largely involving basic symptomatic control using analgesics and NSAIDs, physiotherapy and behavioural changes, and eventual prosthetic replacement in end-stage disease. While prosthetic joint replacement constitutes an effective surgical treatment option for patients whose joints are irreversibly damaged by OA, demographic development together with altered physical activities in our aging society increasingly demonstrate the limitations of joint replacement surgery as the only real treatment modality. There is, therefore, an urgent requirement for disease modifying drugs that aim to halt OA disease progression during the early stages and potentially to kick start cartilage regeneration. This need is contrasted, however, by a sustained “translational roadblock” in OA research with very few conceptually novel therapeutic approaches on the horizon. Amongst others, this “translational roadblock” results from a general lack in our understanding of how articular chondrocytes as the only cells in joint cartilage acquire and maintain their specific and highly specialized phenotype and how this phenotype changes during OA onset and progression. Investigation of this developmental aspect of disease pathology in OA patients and using human samples has many limitations, which is why animal models remain to constitute a key element of cartilage and OA research. This lecture summarizes the relevance of different animal models for understanding fundamental principles of cartilage homeostasis and remodelling in health and osteoarthritic cartilage degeneration. By focusing on the analysis of chondrocyte phenotypic stability, it provides examples for how the use of such models can contribute to understanding OA and to the development of new therapeutic strategies for the disease.

We have previously reported that functional haplotypes of peptidyl arginine deiminase 4 (PADI4) are associated with rheumatoid arthritis (RA). We found that transcripts of the risk haplotype of PADI4 are more stable than those of the non-risk haplotypes, suggesting that increased expression and function of PADI4 (encoded by PADI4 gene) increase the risk of RA. The association has been confirmed by several studies with different ethnicities. Further, we also reported PADI4 polymorphisms highly predispose male smokers to RA. Since PADI4 catalyzes an arginine residue in a protein to citrulline and anti-citrullinated protein antibodies (ACPA) are highly specific in RA, it has been reasonable to speculate that increased PADI4 is associated with increased citrullinated proteins, leading to the initiations of tolerance breakdown or inflammatory arthritis. However, the mechanisms of PADI4 involvement turned out to be more complex than previously thought in animal models. In order to investigate the pathological process in detail, we made PADI4 knockout mice. Decreased severity of experimental autoimmune arthritis was observed in these mice. Further, we found PADI4 regulates the pro-apoptotic fate of neutrophils, and promotes the expression of pro-inflammatory cytokines in macrophages. These actions could result in the pro-arthritic roles of PADI4. Recently, neutrophil extracellular traps (NETs) were reported as an important immune stimulator in RA and SLE, and PADI4 is required for the generation of NETs. Especially, NET-containing immune complex (IC) stimulated plasmacytoid dendritic cells to accelerate the interferon secretion in SLE. Therefore, PADI4 could play several different roles in the immune system and also in the pathogenesis of autoimmune diseases.

The medical treatment of people with rheumatic and musculoskeletal diseases (RMDs) has improved enormously over the past decades. As medical treatment is not completely successful or available for all rheumatic conditions or individual patients, and the demands society imposes on people to participate fully are increasing, there is a substantial proportion of people with RMDs who have functional disabilities. Health professionals (HPs) play an essential role in the management of people with RMDs with disabilities by enabling to reach and maintain their optimal physical, sensory, intellectual, psychological and social functional levels. They provide people with the tools they need to attain independence and self-determination. As such, their contribution is in line with the World Health Organisation definition of rehabilitation [http://www.who.int/topics/rehabilitation/en/]. An important feature of rehabilitation is its multidisciplinarity. Over the past decades, it has been more and more acknowledged that RMDs management involves the whole health care team and concerns a team effort rather than the summation of single interventions by individual HPs or specific professions. This view is reflected in multiple guidelines and standards of care for the clinical management of RMDs, where the need for people with RMDs to have access to a multidisciplinary team of HPs is underlined.
The acknowledgement of the importance of the team of HPs runs in parallel with developments in the organization and activities of HPs within EULAR over the past years. In connection with EULAR, there is a growing network of HPs from multiple professions across Europe. By working together, and collaborating with patients and rheumatologists as partners, EULAR HPs have achieved multiple milestones with respect to the quality of clinical care, education, and research over the past years and are equipped to encounter future challenges.

SP0007
70 YEARS PAST AND A VIEW OF THE FUTURE: LOOKING BACK AND LOOKING FORWARD
H.W. Bijlsma, Department of Rheumatology & Clinical Immunology, University Medical Center, Utrecht, Netherlands

In 1913 the Dutch general practitioner Jan van Breemen, moved by the needs of the many disabled people in his practice, started an international cooperation to fight rheumatic and musculoskeletal diseases. His initiative led to the formation of the International League Against Rheumatism (ILAR), and subsequently to the formation of regional Leagues, such as EULAR in 1947. EULAR has in the following 70 years developed into a unique organisation of rheumatologists, scientists, health professionals and patients, who together are aiming to reduce the burden of rheumatic diseases on the individual and society and to improve the treatment, prevention and rehabilitation of musculoskeletal diseases. To this end, EULAR fosters excellence in education and research in the field of rheumatology. It promotes translation of research advances into daily care and fights for the recognition of the needs of people with RMDs by the governing bodies in Europe (EULAR mission statement 2005).

The first European Rheumatology Congress was held in September 1947 in Copenhagen and was attended by 200 delegates from 16 countries. At the EULAR 2017 May Congress over 14,000 attendees are expected, coming from more than 120 countries.

EULAR is unique in the sense that three pillars work closely together in one organization: rheumatologists, health professionals and patients. Today, I want to focus a bit on the health professionals pillar, since this pillar has its formal 20th jubilee in 2017 as well. At the American celebration of 50 years of non-physician health professionals in Rheumatology (2015), Brady described three science-driven practice paradigm shifts that play an important role in managing patients with RMDs: 1. The widely used “Self-management programs”, that were developed from information giving and ‘patient education’. 2. The positive and intensive use of “Exercise and physical activity”, that were developed from previous acclaimed bed rest and assisted range of motion exercises. 3. The OMERACT initiated definitions and applications of Patient-reported outcome measures, instead of only medical assessment of disease activity.

In addition, she recognized two “evolutions in practice”: 1. Understanding Psychological Factors, from accepting “the arthritic personality” to actively addressing depression, anxiety, coping skills, sense of control and confidence. 2. The development of the important role that nurses and other health professionals can play in the treatment of patients with RMDs.

The EULAR health professionals can be very proud of the important part that Europeans have played in these worldwide developments. My priorities as president-elect of EULAR for the coming two years are:

- Further development of the School of Rheumatology
- Large public awareness campaign: Don’t delay, Connect today
- New EULAR Strategy 2018–2023

I hope and expect that the pillar of health professionals will take an active role in the cooperation that is necessary to reach our common goals.

SP0008
THE FUTURE FOR HEALTH PROFESSIONALS IN RHEUMATOLOGY
A. De Thurah 1, 2, *Department of Clinical Medicine, Aarhus University; 2Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark

In recent years the prevalence of rheumatic diseases has raised leading to increased outpatient activity; at the same time, a general lack of rheumatologists has been described (1). This has created new demands from patients and the health care system towards innovative models of care, e.g. nurse-led follow-up (2), direct access strategies (3) and tele-health interventions (1). In the future this will call for extended and specialized roles for health-professionals within rheumatology, and for future development of compatibility of training of health professionals within the European countries.

Further, the current health-service development is confronting the population with increasing demands to understand and utilize health information and to navigate through this increasingly complex healthcare system. It requires that patients are capable of understanding and managing their health, and calls for a strong focus on health-literate (HL) skills, and the formation of so-called HL organizations (4). In the future, health professionals within rheumatology will have a key role in supporting the development of HL responsive organizations through self-management strategies and patient centered care.

The present presentation will address some of these future demands for health professionals in Rheumatology

WHAT IS NEW (WIN) IN PSORIATIC ARTHRITIS
R. Lories, Skeletal Biology and Engineering Research Center, Dept. of Development & Regeneration, KU Leuven, Leuven, Belgium

Novel therapies and targets have transformed the management of psoriatric arthritis and related skin disease psoriasis. The successful introduction and widespread use of anti-IL17, anti-IL12/23 and anti-PDE4 strategies have joined the ranks of TNF inhibitors. Novel biological insights into specific disease mechanisms are co-emerging with this new wave of treatment options. The different available treatments allow the community to further focus on optimal patient management aiming at remission or minimal disease activity. Yet, the assessment of the patient and his/her satisfaction with current health status remains challenging. Treat to target initiatives are trying to define optimal care and cure adapted to the specific characteristics of the disease. Molecular knowledge of the disease processes remains scattered and insufficient to build a comprehensive view on the disease for the individual patient that would allow the personalized definition of effective strategies.

Moving towards new criteria in SLE, Sjögren’s and APS

SP00010 CLASSIFICATION OF SLE – CHALLENGES AND POTENTIAL SOLUTIONS
M. Aringer on behalf of SLE Classification Criteria Steering Committee. Medicine III, University Medical Center TU Dresden, Dresden, Germany

Systemic lupus erythematosus is characterized by a wide variety of autoantibodies, which, if pathogenic, can lead to inflammation, damage, thrombosis or functional defects of essentially all organ systems. The 1982 American College of Rheumatology (ACR) criteria and their 1997 revision have greatly influenced the disease concept over the last decades. With the at least 4 of 11 criteria to be present, they essentially depict the concept of multiple autoantibodies and multiple organ systems. Putting all items on equal weight made the system relatively easy to use and to memorize, but this approach was not entirely intuitive. Dermatologists have criticized that patients could meet the criteria based on fulfilling all 4 mucocutaneous criteria only. Importantly, sensitivity was felt to be suboptimal, reaching 83% in the cohort of the SLE International Collaborating Clinics (SLICC) group, and lower values in very early disease.

The 2012 SLICC SLE classification criteria introduced two new concepts. First, patients had to be positive for autoantibodies, namely for anti-nuclear antibodies (ANA) or antibodies to double-stranded DNA. Second, if patients are autoantibody positive, classification criteria can be fulfilled by nephritis on histology without any other items. The SLICC groups also introduced large lists of skin and neuropsychiatric symptoms and refined some of the definitions. While many of these ideas are intuitively correct, not all were derived in a pre-defined scientific way. These criteria managed to increase sensitivity to 97% in their own validation data and to a range of 92–99% in other cohorts. At the same time, however, the SLICC set low specificity, falling to 84% as compared to the 96% of the ACR criteria. This set of criteria was therefore rejected by the SLICC group's choice to keep the overall structure the same. Early disease specificity was still not optimal.

In a large transatlantic project jointly supported by EULAR and the ACR, we have over the last years tried to develop (even) better SLE classification criteria. The main goals are to have a relatively intuitive set that helps in teaching, increase sensitivity as compared to the ACR criteria, but maintain specificity in the same range, improve the performance in early SLE, involve the larger SLE community as far as possible, and do this in a strictly scientific way. Given that ANA often are the door to SLE in the diagnostic approach, and that ANA have very high sensitivity, but modest specificity for SLE, we explored whether ANA could be used as an entry criterion. Meta-regression, after compiling ANA data of 13,080 SLE patients from a systemic literature search, gave a sensitivity of 97.8% (CI 96.8–98.5%) for a titer of at least 1:80 on HEp2-ANA immunofluorescence. It was therefore decided that HEp2-ANA of ≥ 1:80 would be used as an entry criterion.

Three different approaches were used to maximize the overview on potential items, namely an SLE expert Delphi exercise involving 123 SLE experts, an international early disease cohort with 389 SLE patients and 227 patients with conditions mimicking SLE, and a patient survey, which 339 SLE patients filled out and mailed anonymously. The resulting 41 items were then reduced in a nominal group technique exercise with 7 international SLE experts, resulting in a list of 20 items plus ANA as an entry criterion. These items were then submitted to multi-criteria decision analysis in a two day conference with 6 international experts together with the steering committee. This approach under the same moderator therefore decided that HEp2-ANA of ≥1:80 would be used as an entry criterion. The revised results are 20 weighted items, which can be additively used within a continuous scale, and a cut-off for classification. Weights for class III or IV lupus nephritis are much higher than for leukopenia or unexplained fever. This candidate classification will now be tested against both the ACR and the SLICC criteria in a large cohort of SLE patients and patients with mimicking conditions. If successful, ANA will now be tested against both the ACR and the SLICC criteria in a large cohort of SLE patients and patients with mimicking conditions. If successful, ANA would represent a factor, consequently the presence of two/three positive diagnostic laboratory tests is a valuable parameter to stratify the patients at highest risk for developing the syndrome/recurrences.

The syndrome displays a protein clinical picture depending on the involved tissue/organ. The majority of the clinical (criteria) manifestations are clearly related to vascular ischemic events. However, some manifestations apparently cannot be supported by a thrombotic mechanism and alternative pathogenic pathways have been suggested. This is the case for thrombocytopenia, central nervous system involvement such as movement disorders and cognitive abnormalities, and APS nephropathy. Heart valve disease, skin ulcers and livedo reticularis are also frequent events in APS patients and their relationship with vascular thrombosis is unclear. Still debated is the suggestion to include these manifestations as additional clinical diagnostic criteria. The possibility to use all these criteria for ranking the patients as having a definite (standard clinical criteria) or probable (non classification criteria) is also debated.

The revised criteria for obstetric morbidity comprise otherwise unexplained pregnancy loss. Some of the obstetric criteria might display low sensitivity/specificity for APS. In particular, the attribution to aPL of a pregnancy wastage early on gestational course requires the exclusion of a myriad of etiologies. Conversely, the rate of late foetal losses is very low, making this criterion rather specific. Placenta-mediated obstetric complications provide another critical field: pre-eclampsia and intra-uterine growth restriction are relatively common. To enhance the specificity for APS, the classification criterion included only cases requiring delivery before 34 weeks of gestation. Medium/high aPL titres and double/triple laboratory tests positivities confer a higher risk for pregnancy complications but recent data seem to suggest that also persistent low aPL titres can be predictive for a negative pregnancy outcome. This finding has been recently explained by the availability of large amounts of b2GPI in tissues of the reproductive system. Even though classification criteria have allowed uniformity in APS diagnosis, there still remain some controversies.

The field of the laboratory classification criteria is even more in progress. Eptope profiling for anti-b2GPI antibodies is quite promising since the characterization of reactivity against the domain 1 of the molecule appears to display a higher specificity for APS and stronger predictive value than the antibodies against the whole molecule. However, anti-domain 1 assay is less sensitive and cannot replace the standard test at the moment. Antibodies against protein C (PT) have been reported to be associated with both the vascular and the obstetric APS, in particular when the antibodies are detectable against a solid phase complex of PT with phosphatidylserine (PS) (the so called anti-PS/PT assay). However, a clear evidence for their usefulness in the clinical diagnosis and risk stratification for APS patients as well as their true pathogenic role is still debated.

SP0011 SJÖGREN’S CRITERIA REVISITED!
S.J. Bowman, University Hospital Birmingham Rheumatology Dept, Birmingham, UK

In clinical practice it is the up to the clinician to use their judgement in making a diagnosis of pSS. In research it is essential to have agreed classification criteria so that there is confidence that participants in a study have the specified condition. During the 1980’s a number of classification criteria were proposed with a major drawback being the advantages and disadvantages of each of these criteria. In 1988 a working group of 29 experts from 12 European countries initiated a study to develop consensus criteria. They published their initial findings in 1993 and in 2002 Vitali et al published the American European Consensus Group Criteria (AECG). The AECG criteria have been the most widely used "gold-standard" criteria for the classification of pSS in research studies. Criteria are never fixed in perpetuity, however, and as new technology such as ultrasound becomes more widely used or new data becomes available further revision is likely. In 2013, an International Collaboration, the Sjögren’s International Clinical Collaborative Alliance (SICCA) funded by the National Institutes for Health in the USA collected data from 151 participants to devise the American College of Rheumatology (ACR) preliminary criteria for SS and in 2016 following a further international consensus group exercise the American College of Rheumatology – European League against Rheumatism (EULAR) consensus criteria for Sjögren’s syndrome have been published.

In this presentation I will go through the development of these criteria, the underlying rationale and by the end of the talk attendees should have a better understanding of how these criteria can be used in research and to support clinical practice.

The differential diagnosis of diffuse skin sclerosis and of Raynaud’s phenomenon and a practical approach to assessment

**SP0013**

**WIDESPREAD CUTANEOUS THICKENING – COULD THIS BE EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS?**

A. Suarez, Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom

A case of diffuse sclerosing skin disease shall be presented. The features that initially led the treating team to consider a diagnosis of systemic sclerosis shall be discussed, alongside subsequent features that emerged that cast doubt over this diagnosis and led the team to undertake additional investigative studies. The presentation shall provide a chronological description of the clinical features, laboratory studies, microvascular imaging and histological studies that helped the team to reach a definitive diagnosis and plan management accordingly.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.7183

**SP0014**

**THE DIFFERENTIAL DIAGNOSIS OF DIFFUSE SCLEROSING SKIN DISEASE AND A PRACTICAL APPROACH TO ASSESSMENT**

J. Pauling, Pharmacy and Pharmacology, University of Bath; J. Hughes, Royal National Hospital for Rheumatic Diseases (Royal United Hospitals), Bath, United Kingdom

The differential diagnosis for sclerosing skin disease is broad but there are clinical and laboratory features that can help guide clinicians to the correct diagnosis. This presentation shall provide a comprehensive review of the spectrum of sclerosing skin disease. A practical approach to integrating the clinical, serological, microvascular imaging and histological features that can help differentiate disease states shall be presented to provide rheumatologists with a practical approach to the assessment of patients with sclerosing skin disease. Case histories shall be used to illustrate the pertinent clinical features and investigative approaches that can help distinguish systemic sclerosis from other sclerosing skin conditions such as scleroderma, pan-sclerotic morphea, lipodermatosclerosis and chronic graft versus host disease. A specific focus shall be placed on the role of autoantibodies in the diagnosis of systemic sclerosis, including recent work reporting the presence of novel systemic sclerosis-specific autoantibodies in patients with antinuclear antibody-negative diffuse cutaneous systemic sclerosis.

**NEW ONSET RAYNAUD’S PHENOMENON – COULD THIS BE EARLY LIMITED CUTANEOUS SYSTEMIC SCLEROSIS?**

M. Hughes, The University of Manchester, Greater Manchester, United Kingdom

A case shall be presented of a patient with Raynaud’s phenomenon and whether this could be early limited cutaneous systemic sclerosis. The presentation shall describe the clinical features and investigative approaches that helped us reach a diagnosis, with a particular focus on the role for microvascular imaging and the detection of SSc-associated autoantibodies.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.7173

**SP0016**

**THE DIFFERENTIAL DIAGNOSIS OF RAYNAUD’S PHENOMENON AND PRACTICAL APPROACH TO ASSESSMENT WITH A FOCUS ON IMAGING**

A.L. Herrick, University of Manchester, Manchester, United Kingdom

Raynaud’s phenomenon is the term used to describes episodic vasoospasm of the digital vasculature in response to cold exposure and/or emotional distress. The majority of people with Raynaud’s phenomenon have primary (idiopathic) Raynaud’s phenomenon which is ‘benign’ in that it does not progress to irreversible digital ischaemia, and is not associated with any underlying disease. Conversely, when Raynaud’s phenomenon is secondary to an underlying disease/condition (for example to a systemic sclerosis-spectrum disorder), it can be severe, sometimes progressing to digital ulceration and/or gangrene. Raynaud’s phenomenon is often the presenting feature of connective tissue disease and therefore provides a window of opportunity for early diagnosis.

The first step in management of Raynaud’s phenomenon is establishing the diagnosis. Is this primary or secondary Raynaud’s, and if secondary, then to what? While a careful history and examination are always the first steps, different laboratory tests and vascular imaging studies can be used to reach the correct diagnosis. This presentation will provide practicing rheumatologists with a practical approach to the diagnosis and assessment of Raynaud’s phenomenon, focussing on the diagnostic and prognostic role of vascular imaging (including nailfold capillaroscopy and thermography).

**SHARED MECHANISMS IN CANCER AND AUTOIMMUNITY**

A. Rosen, Medicine/Rheumatology, Johns Hopkins University School of Medicine, Baltimore, Md 21205, United States

Some rheumatic disease autoantibodies are powerful markers of subgroups of patients who have distinct disease phenotypes and trajectories. Of particular interest are markers of several disease subgroups in whom cancer and rheumatic disease onset are clustered together in time. For example, a subgroup of scleroderma patients have coincident onset of cancer and scleroderma. This is observed in scleroderma patients with autoantibodies against Polr3a, a ribosomal protein kinase, and more recently with autoantibodies recognizing the minor spliceosome. In autoimmune myopathies, temporal clustering of diagnosis of cancer and myositis is associated with autoantibodies to NXP2 and components of the TFI complex. Interestingly, although the incidence of cancer is higher in patients with these autoantibodies, most patients with these autoantibodies manifest cancer, even with extended periods of follow-up. These observations provide an important opportunity to investigate the potential mechanisms which operate at the cancer-immune interface during development of rheumatic diseases.

We have investigated such mechanisms in scleroderma patients with autoantibodies to Polr3a who also had a cancer diagnosis an average of 2.6 years from scleroderma onset. In cancers from these patients, we found genetic alterations of the Polr3a locus in six of eight patients with antibodies to Polr3a but not in eight patients without these antibodies. 3 antibody-positive patients had somatic mutations in Polr3a; 5 patients had loss of heterozygosity at the Polr3a locus. Analyses of peripheral blood lymphocytes and serum suggested that Polr3a mutations sparked cellular immunity and cross-reactive humoral immune responses. These results offer insight into the pathogenesis of scleroderma, and potentially other autoimmune syndromes. They suggest that somatic mutations in autoantigens in different cancers might initiate an immune response to the mutated autoantigen, which spreads to include the wild type version. Tissues (e.g. blood vessels, regenerating muscle) in which specific autoantigens are expressed at high levels, or potentially play critical functional roles, may be particularly susceptible to immune-mediated dysfunction. The results also provide support for the idea that acquired immunity helps to control naturally occurring cancers in patients with autoimmune rheumatic diseases; it is possible that this immune response may sometimes be fully effective, preventing the emergence of cancer.

Chondrocyte channels (role in mechanotransduction) or “channeling the chondrocyte”

PERIPHERAL PATHOLOGY IN FIBROMYALGIA

The pathophysiology of pain in fibromyalgia is complex. In recent years, an involvement of the thinly myelinated nerve fibers of the A-delta type and the unmyelinated C-fibers has been reported in fibromyalgia patients. Independent research groups have published consistent findings of objective injury to these “small nerve fibers”. These included disturbances in function, electrical properties, and morphological integrity of these nerve fibers. While the reasons for this small fiber pathology and its contribution to FMS pain are still unclear, a new research field has emerged that will focus on uncovering the underlying pathophysiology. In this talk, I will summarize current findings and discuss their significance for the understanding of the fibromyalgia syndrome.

CENTRAL PATHOLOGIES IN FIBROMYALGIA

Fibromyalgia is characterized by widespread, mainly muscular pain that is exacerbated during and following physical activity. Although mechanisms such as muscle ischemia and peripheral nerve fibre pathology have been implicated in fibromyalgia, currently no known peripheral pathology can fully account for the pain. Therefore, the pain in fibromyalgia is most likely explained by a complex interaction between peripheral and central mechanisms. Fibromyalgia patients are characterized by a multimodal, widespread, increase in pain sensitivity and a dysregulation of endogenous pain inhibitory mechanisms. Imaging studies have revealed functional as well as structural cerebral abnormalities in fibromyalgia. During painful stimulation, fibromyalgia patients exhibited an inability to activate cerebral structures associated with the descending pain inhibitory system, i.e., ventral anterior cingulate (VAC) and thalamus.1 There was a significant association between depression or anxiety and cerebral processing of evoked pain, indicating segregated mechanisms for mood and pain processing.2 Furthermore, FM patients had less pain related functional connectivity within the brain’s pain inhibitory network and structural changes such as decreased cortical thickness and reduced brain volumes.3 Longer duration of FM pain was associated with more pronounced functional and structural abnormalities suggesting a time-dependent progress of cerebral pathology, even when controlled for age and mood.4 In addition, FM patients had elevated interleukin-8 in the cerebrospinal fluid indicating neuro-inflammation,5 possibly due to upregulated cell activation. Interleukin (IL) IL-1β is co-localized with translocator protein (TSPO) in glia cells. During glial activation, the production of TSPO is increased and TSPO agonists are involved in the regulation of the expression of IL-8 and its receptor, thus affecting glia to neuron signalling and central sensitisation. We have recently documented that FM patients who are carriers of the genetic functional polymorphism associated with high TSPO binding affinity report higher pain intensity and more severe fibromyalgia symptoms compared to genetically interred TSPO low affinity binders and that this genetic polymorphism also affects cerebral pain processing.6 To our knowledge, this is the first finding of genetic mechanisms associated with symptom severity in FM. Finally, the effect of different treatments on central pathology in FM will be discussed. Short pain duration was predictive of a positive response to a 12 weeks treatment with a serotonin-noradrenaline re-uptake inhibitor (SNRI).7 The degree of symptom improvement and reduced pain sensitivity in SNRI treated FM patients corresponded to the degree of increased pain related activation of cerebral areas associated with pain modulation and the default mode network.8 In contrast, cognitive behaviour therapy did not affect clinical pain or pain sensitivity but increased activations of cerebral regions implicated in executive cognitive control during painful stimulation and thus likely reappraisal of painful stimuli.9 Finally, 15 weeks of physical exercise partially normalized resting state activity in FM.10 The results demonstrated that different treatment modalities affected specific brain mechanisms, indicating that at least some of the cerebral abnormalities in FM are reversible.

CHONDROCYTE CHANNELS IN OSTEOARTHRITIS

TRPA1 CHANNELS IN OSTEOARTHRITIS

Osteoarthritis (OA) has long been viewed as a degenerative “wear-and-tear” disease of cartilage. There is, however, increasing evidence to confirm that inflammation has a critical role in the pathogenesis and symptoms of the disease. Inflammation in osteoarthritis is distinct from that typical for rheumatoid arthritis; it is generally low-grade in its nature but characterized by exacerbations with joint effusions and more severe symptoms. Osteoarthritis shares many features of innate immunity but the inflammatory mechanisms eventually leading to pathological and functional changes are incompletely understood.1,2 Osteoarthritis is not known in detail; but their further understanding is essential for the development of disease-modifying treatments for osteoarthritis. Transient receptor potential ankyrin 1 (TRPA1) is a ligand-gated membrane-bounded cation channel. It has been widely studied in sensory neurons where it acts
as a chemosensor for harmful exogenous compounds and mediates pain and neurogenic inflammation. More recently, TRPA1 has been found to be activated also by endogenous compounds formed in inflammation, such as reactive oxygen and nitrogen species. That prompted us to investigate the role of TRPA1 in inflammatory conditions including osteoarthritis. Monosodium iodoacetate (MIA)-induced arthritis in rats is a widely used animal model of osteoarthritis. We found that MIA evoked acute inflammation, degenerative cartilage changes and joint pain in wild type mice; but interestingly, those responses were significantly attenuated in TRPA1 deficient animals. Furthermore, TRPA1 was found to be expressed and inducible by inflammatory factors including IL-1 and IL-17 in primary human OA chondrocytes, and the TRPA1 channel was shown to be functional based on calcium influx assays. Pharmacological inhibition and genetic depletion of TRPA1 downregulated the production of inflammatory factors and MMP enzymes in mouse cartilage and primary human OA chondrocytes. The present results introduce TRPA1 as a plausible factor involved in the pathogenesis of OA and provide a novel target for analgesic and anti-inflammatory drugs with disease modifying potential in OA. Wearable technologies in 21st century healthcare —

A.M. Clarke-Cornwell, School of Health Sciences, The University of Salford, Manchester, United Kingdom

Working environments have in recent times become less physical with the increase in sedentary, computer-based occupations. Sedentary time is known to be associated with a number of health-related outcomes, including obesity, heart disease, diabetes, cardiometabolic risk factors, some cancers and early mortality, independent of physical activity. There is limited research that has examined sedentary time and physical activity and associations with musculoskeletal conditions, despite these being responsible for the majority of work-related ill health and days absent from work. The validity and practicality of objective and subjective techniques to measure physical behaviour have been widely reported; however, there is no gold standard that is valid, accurate, reliable and also practical. Self-reported methods can be practical and low-cost, but are subject to recall and social desirability bias; whereas objective devices, such as accelerometers, can be expensive, but allow for information on intensity, frequency and duration of activity to be measured. The Health Survey for England 2008 used both subjective and objective measures of physical activity; they found that 39% of men and 29% of women were meeting the recommended levels of physical activity when asked via a questionnaire. In comparison, when physical activity was objectively measured using an accelerometer, it was found that only 6% of men and 4% of women met these targets.

Wearable technologies, including research grade accelerometers (e.g. activPAL™) and consumer wearable devices (e.g. FitBit), are increasingly being used in research, not only to measure physical behaviours but may also be useful in facilitating and monitoring behaviour change. This work will present an overview of wearable technologies used in research, what they can (and can’t) measure, and in particular their application in musculoskeletal research.

NOVEL IMAGING TECHNIQUES FOR ASSESSING OSTEOPOROTIC FRACTURE RISK

R. Chapurlat 1, 2, 3 Université de Lyon; 2 Medicine, INSERM UMR 1033, Lyon, France

The measurement of areal bone mineral density (aBMD) by dual x-ray absorptiometry (DXA) has been the mainstay for the diagnosis of osteoporosis for at least two decades. The sensitivity and specificity of this test, however, remains suboptimal. For example, more than 50% of postmenopausal women with fragility fracture are not identified with DXA. A great deal of research has been performed recently to develop alternative or complementary imaging techniques to overcome DXA predictive limitations. These techniques are based on the non invasive analysis of bone microarchitecture and estimation of bone strength by finite element analysis (FEA).

Texture analysis uses mathematical models based on fractal analysis to evaluate bone microarchitecture using various types of bone images. The trabecular bone score (TBS) has emerged as an approach that may improve fracture risk prediction. The TBS is based on the texture analysis of the DXA lumbar spine image to quantify bone microarchitecture. Several cohort studies have shown that a subset of individuals could be reclassified with TBS. A meta-analysis results have allowed for incorporation of the TBS in the FRAX score, that is widely available.

The measurement of volumetric BMD with quantitative computerized tomography (QCT) at the hip has been shown to predict fracture risk. These images can also be used to perform FEA that may increase the fracture risk prediction. The additional value of this technique compared with DXA remains to be established in a clinical setting.

Bone microarchitecture can also be assessed at peripheral sites such as the distal radius and tibia using high resolution peripheral quantitative tomography (HRpQCT). Numerous cross-sectional and case-control studies have shown a significant association between prevalent fracture and bone microarchitecture and estimated bone strength assessed with FEA. The bone parameters measured at distal sites are also associated with fractures at distant sites, e.g., the vertebrae and the femoral neck. In a recent prospective study, bone microarchitecture at the distal radius - especially the trabecular vBMD - has been associated with incident osteoporotic fractures. The FEA models were also predictive of fragility fracture. The best models and the most appropriate architectural parameters - whether they are trabecular of cortical - remain to be dissected out and their comparative diagnostic value with aBMD by DXA remains to be established.

The measurement of the TBS may allow for reclassification of a subset of individuals for whom DXA is suboptimal.
EMERGING THERAPIES FOR OSTEOPOROSIS
P. Geusens. Rheumatology, MaastrichtUMC and UHasselt, Genk, Netherlands
Currently, anti-resorptive drug therapy is the cornerstone of fracture prevention. Anti-resorptive drugs decrease bone remodelling, allowing the remaining bone to increase secondary mineralisation, and, with denosumab, also allowing periosteal bone modelling. This opens new perspectives in individualised treatment of patients with high fracture risk and for fracture prevention in patients with low bone turnover, multiple previous fractures, and increasing amount of existing literature makes the life of a clinician difficult when trying to search by him/herself for the answer based on the original studies. The effect on non-vertebral fractures was not significant, but geographic interaction was found. When excluding patients from South America, in whom fracture risk was low, one-year treatment with romosozumab significantly decreased the risk of non-vertebral fractures by 42%. Abaloparatide and romosozumab are new bone forming agents, with different effects on bone remodelling and remodelling and early effects on clinical fractures. This opens new perspectives in individualised treatment of patients with high fracture risk and for fracture prevention in patients with low bone turnover, multiple vertebral fractures, very low BMD and fractures or bone loss during anti-resorptive treatment.

BEYOND THE RECOMMENDATIONS: EXAMPLES OF SYSTEMATIC LITERATURE REVIEW IN DAILY CLINICAL PRACTICE
K. Visser 1, 2, 3. 1 VU Medical Center; 2 Academic Medical Center, Amsterdam, Netherlands
Recommendations and guidelines for management and treatment of rheumatic diseases exist to help rheumatologists deliver optimal care for their patients in an evidence-based way. However, not all practical questions and medical difficulties encountered by rheumatologists in daily clinical practice can be addressed using these existing guidelines. Moreover, time in practice is limited and usually does not allow for extensive systematic literature research to find evidence regarding a specific medical question that needs answering in due time. Therefore, an essential skill for doctors and those in training, besides medical knowledge and examination skills, is to be able to search for, withdraw and appraise published evidence applicable to a specific topic. A so called CAT – critically appraised topic – is a compact systematic literature research following a strictly formulated PICO to answer a clinical question encountered in daily practice. Results can be presented in department meetings and stored in a database for education purposes and use in daily practice. This presentation will address the structure of the carrying out, as well as important pros and cons of the CAT. Examples will be given drawn from the experience of young rheumatologists in training in the Netherlands.

HOW COULD GPS ENHANCE THE EARLY DIAGNOSIS OF RHEUMATIC DISEASES
C.D. Mallen. Arthritis Research UK Primary Care Centre, Primary Care and Health Science, Keele, United Kingdom
Primary care and general practice has a key role to play in the early and accurate detection of patients with rheumatoid arthritis. This talk will explore some of the current barriers to best practice, highlighting the workload associated with musculoskeletal problems in primary care and the challenges in making a prompt diagnosis. Possible solutions will be explored, highlighting the importance of strong patient and professional partnerships.

**THE CONTRIBUTION OF PHYSIOTHERAPISTS TO EARLY DETECTION OF INFLAMMATORY ARTHRITIS**

P. Kirwan, 1,2, J. Physiotherapy Dept, Connolly Hospital; 2, School of Physiotherapy, Royal College of Surgeons in Ireland, Dublin, Ireland

Early recognition of inflammatory arthritis is of utmost importance, as failure to do so can delay appropriate treatment and result in permanent joint damage and disability. This presentation will set out to explore the role a Physiotherapist/Healthcare Professional can play in recognition of inflammatory joint disease. Healthcare Professionals/Physiotherapists are often the first point of contact for patients suffering from joint/musculoskeletal pain. They are therefore well-positioned to be the first to identify possible inflammatory sources of pain versus non-inflammatory sources. Useful clinical tools which aid in this decision making process will be discussed. The question as to whether a physiotherapist can recognise inflammatory joint disease versus non-inflammatory joint conditions will be explored with the aim being to highlight the important role a physiotherapist can play in this important diagnostic challenge. With reference to ongoing clinical and research work in this field, this presentation will set out to ask whether or not a Healthcare Professional/Physiotherapist can accurately recognise/diagnose inflammatory arthritis and whether they miss inflammatory arthritis.

**THE EULAR CAMPAIGN “DONT DELAY CONNECT TODAY” AND HOW ORGANISATIONS CAN GET INVOLVED**

J. Church, Arthritis Ireland, Dublin, Ireland

Arthritis is a chronic disease with multiple co-morbidities. With the development of powerful biologic drugs, improvements in care pathways for patients and very effective self-management interventions, early diagnosis and intervention can lead to significant improvements in lifestyle, physical movement, increased well-being and work force participation. Despite its significant impact on the population and the cost to the healthcare system, arthritis still remains undertreated and undiagnosed within the health systems and one that is shrouded in public myth. The EULAR campaign “Done Delay, Connect Today”, aims to promote early intervention by encouraging those with typical symptoms to take action and consult their doctor at the earliest possible opportunity. The campaign which will be adopted and executed across all PARE members also aims to dispel the myths and educate the public about the seriousness of arthritis and the need to take action.

**SHARE RECOMMENDATIONS ON SYSTEMIC VASCULITIDES**

M.W. Beresford on behalf of SHARE Systemic Vasculitis Working Group. Portuguese Rheumatology, Alder Hey children’s NHS Foundation Trust, Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom

Background: Primary systemic vasculitides (PSV) are very rare in children and consequently, little evidence exists. Evidence-based guidelines are lacking; this is an important and unmet need. The European initiative SHARE (Single Hub and Access point for childhood-onset Polyarteritis, Granulomatosis with Polyangiitis, Microscopic Polyangiitis, Eosinophilic Granulomatosis with Polyangiitis, and Takayasu Arteritis) aims to identify best practices for treatment of childhood-onset Polyarteritis, Granulomatosis with Polyangiitis, Microscopic Polyangiitis, Eosinophilic Granulomatosis with Polyangiitis, and Takayasu Arteritis.

Conclusions: European-wide recommendations for the diagnosis and treatment of rare forms of paediatric PSV have been formulated through an evidence-based consensus process. The SHARE project aims to provide international recommendations that will significantly improve the standard of care for children with rheumatic diseases.

**SHARE RECOMMENDATIONS ON JUVENILE DERMATOMYOSITIS**

A. Van Royen-Kerkhof, Wilhelmina Children Hospital, Utrecht, Netherlands

Background: In 2012, a European initiative called Single Hub and Access point for pediatric Rheumatology in Europe (SHARE) was launched to optimise and disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases. Juvenile Dermatomyositis is a rare Pediatric Rheumatic Disease (PRD), associated with significant morbidity. Evidence-based guidelines are sparse and management is mostly based on physicians’ experience. Consequently, treatment regimens differ throughout Europe.

Objectives: To provide recommendations for diagnosis and treatment of JDM based on evidence-informed consensus.

Methods: Recommendations were developed by an evidence-informed consensus process using the European League Against Rheumatism standard operating procedures. A committee was constituted, consisting of 19 paediatric rheumatologists and 2 experts in paediatric exercise physiology and physical therapy, mainly from Europe. Recommendations derived from a validated systematic literature review were evaluated by an online survey and subsequently discussed at two consensus meetings using nominal group technique. Recommendations were accepted if >80% agreement was reached.

Results: In total, 1 overarching principle, 17 recommendations on diagnosis and 13 recommendations on therapy were accepted with >80% agreement among experts. Topics covered include assessment of skin, muscle and major organ involvement and suggested treatment pathways.

Conclusions: The SHARE initiative aims to identify best practices for treatment of patients suffering from PRD and to disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases.

**CONSENSUS-BASED RECOMMENDATIONS (SHARE) FOR THE MANAGEMENT OF JUVENILE SCLERODERMA**

F. Zulian, Department of Woman and Child Health, University of Padova, Padova, Italy

Background: In 2012, a European initiative called Single Hub and Access point for pediatric Rheumatology in Europe (SHARE) was launched to optimise and disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases. Juvenile Scleroderma in its two variety, localized scleroderma (JLS) and systemic sclerosis (JSS) is a rare disease with a growing group of paediatric rheumatic diseases (PRDs) and can lead to significant morbidity. Evidence-based guidelines are sparse and management is mostly based on physicians’ experience. Consequently, treatment regimens differ throughout Europe.

Objectives: To provide recommendations for diagnosis and treatment of both JLS and JSS.

Methods: Recommendations were developed by an evidence-informed consensus process using the EULAR standard operating procedures. A committee was constituted, consisting of 16 experienced paediatric rheumatologists, mainly from Europe. Recommendations derived from a validated systematic literature review were evaluated by an online survey and subsequently discussed at two consensus meetings using nominal group technique. Recommendations were accepted if >80% agreement was reached.

Results: In total, 1 overarching principle, 17 recommendations on diagnosis and 13 recommendations on therapy were accepted with >80% agreement among experts. Topics covered include assessment of skin and major organ involvement and suggested treatment pathways.

Conclusions: The SHARE initiative aims to identify best practices for treatment of patients suffering from PRD. In total, 80% agreement among experts. Topics covered include assessment of skin, muscle and major organ involvement and suggested treatment pathways.

ULTRASOUND BASIC I & II

SP0037 HOW TO ASSESS US ELEMENTARY LESIONS IN CPPD
G. Filippou, University of Siena, Siena, Italy

Ultrasoundography has been increasingly used the last years for the identification of calcium pyrophosphate dihydrate crystal deposition (CPPD) in joints and on 2011 has been considered by the EULAR task force on CPPD as a promising tool for the diagnosis of the disease. However, it is common experience between sonographers that in daily clinical practice CPP identification by US is rather challenging as crystal deposits are not always numerous and diffuse. Furthermore, other conditions can mimic CPP deposition leading to a wrong diagnosis. The recently created OMERACT US for CPPD subtask force has created for the first time a set of criteria for identification of CPP deposition and assessed their reliability trying to address some of the issues that impede a wider use of US for CPPD diagnosis. During this section will be exposed the main US features of CPP deposition according to the new criteria as well as the principal pitfalls that could mislead diagnosis. The scanning technique and some tips and tricks that could help sonographers to identify correctly CPP deposition will also be explained.

SP0038 HOW TO ASSESS CARTILAGE IN RA AND PITFALLS + DEMO
P. Mandi, Rheumatology, Medical University of Vienna, Vienna, Austria

Cartilage damage is a key process in rheumatoid arthritis which appears to be more clearly associated with irreversible physical disability than bony damage. While conventional radiography only allows the evaluation of joint space narrowing, a major feature of cartilage loss, musculoskeletal ultrasound is a reliable tool for evaluating cartilage damage. The presentation will introduce the pitfalls and challenges associated with visualizing cartilage in rheumatic diseases in general and rheumatoid arthritis in particular. It will also review recent studies in the field which have validated sonoanatomy for both the quantitative measurement of cartilage thickness and for the semiquantitative scoring of cartilage change. A practical demonstration will also be provided.

SP0039 HOW TO EVALUATE THE SUBTALAR JOINT
A. Iagnocco, Università degli Studi di Torino, Torino, Italy

The subtalar joint, also known as the talocalcaneal joint, is a synovial joint of the foot, that occurs between the talus and the calcaneus with the talus that is oriented slightly obliquely on the anterior surface of the calcaneus. The two bones articulate at two different sites (i.e. one anteriorly and one posteriorly). The anterior talocalcaneal joint is a convex area of the talus that fits on a concave surface of the calcaneus. The posterior talocalcaneal joint is formed by a concave surface of the talus and a convex surface of the calcaneus. The subtalar joint contributes to the dorsiflexion of the ankle. Three articulating facets (anterior, middle and posterior) are present between the talus and the calcaneus. The sustentacular tunnel forms the floor of middle facet, and the anterior facet articulates with the head of the talus, and sits lateral and congruent to the middle facet. The posterior facet is the largest of the three, and separated from the others by the tarsal canal. The most relevant actions done by the joint are inversion of the foot. The subtalar joint can also be considered a combination of the anatomic subtalar joint discussed above, and the talocalcaneal part of the talocalcaneonavicular joint. When both those joints are accounted together, it allows for pronation and supination to occur. The subtalar joint is frequently involved in arthritis and, particularly in patients with previous sprains, secondary osteoarthritis can also occur. Symptoms of subtalar joint arthritis include pain, loss of motion through the joint’s range of motion, and difficulty walking on uneven surfaces.

Among the imaging techniques that are appropriate for the assessment of the subtalar joint, ultrasound (US) has been increasingly used over the last years. Indeed it is able to image different abnormalities, including both inflammatory and structural changes, and it is helpful in guiding local procedures that can be easily and safely performed with optimal patient’s tolerance. The US scanning technique is quite complex, and the whole joint area should be scanned in the longitudinal (sagittal or coronal) plane with pathology that should be confirmed in the orthogonal (perpendicular) plane. By using a standardised scanning technique and agreed definitions of pathology, US allows an optimal assessment of inflammatory and structural abnormalities, thus filling the gap between clinical and radiographic evaluations of the subtalar joint.

SP0042 THE ART OF JUGGLING - A PATIENT’S PERSPECTIVE
F.M. Catrina, L.R. Bucharest, Romania
Diagnosed with ankylosing spondylitis since 2006, when just turned 24 years old. I was very demoralized and could not understand why I have rheumatic pains bigger than my grandmother 70 years old. I did not understand why I can’t go, just do anything wrong to anyone. Slowly, slowly I began to understand the disease and help doctors started to move again. But my secret to healthy aging, was family. Therefore we understand that positive thinking can help me more than any drug, posterior how you can have a more positive attitude as if in a nice family environment?

SP0043 CURRENT NEEDS FOR REHABILITATION
M. Börk, Department of social and welfare studies, Linköping University, Norrköping, Sweden

New biological medications and earlier multi professional interventions have led to a reduction in the extent of disability for patients with rheumatic diseases. However disability still remains a key problem for many patients and patients may experience participation restrictions even though they are achieving “remission”. To be able to engage in the things we want or need to do is crucial to our health and sometimes a challenge to meet for health professionals. Also, there is an ongoing discussion of whether today’s patients have new rehabilitation needs and if they are met by the health care. This session summarizes both qualitative and quantitative evidence of the disability in today’s patients with arthritis. It will further discuss the current needs of rehabilitation in today’s patient in relation to existing standards and guidelines. Rehabilitation interventions and patient reported strategies in relation to pain, fatigue and affected activity balance will be highlighted since they are common disabilities among today’s patients.

SP0040 HOW TO SCAN THE HIP, NEW APPROACH AND DEMO
I. Möller on behalf of EULAR Working Group Anatomy for the IMAGE. Rheumatology; anatomy; sonoanatomy-sonopathology, Instituto Pobal de Reumatología; University of Barcelona, Hospitalet de Llobregat, Spain

The exploration of the hip includes not only intraarticular findings such as synovitis or lesions of the labrum but also the dynamic exploration of the tendons and muscles surrounding it as well as of the neurovascular bundles of interest. All this is an essential complement in the differential diagnosis of the rheumatic patient. The iliopectos tendon as well as the hip adductors will be demonstrated during the presentation. The anterior and antero internal part of the groin region constitute a relatively frequent consultation and study of the tendinous snapping and its differential diagnosis with the snapping of intraarticular origin can be made by means of the musculoskeletal ultrasound. It requires systematization and knowledge of the regional anatomy.

WORK RETENTION REHABILITATION IN PRACTICE

Y. Prior 1,2 on behalf of Rehabilitation Research Group, University of Salford. 1Health Sciences, University of Salford, Manchester; 2Rheumatology, Mid Cheshire NHS Trust Leighton Hospital, Crewe, United Kingdom

This session aims to meet health professionals’ needs in recognising, examining, and identifying problems that patients with inflammatory arthritis (IA) face at work. We know that one in five people with inflammatory arthritis lose their job within five years of diagnosis and, once work disabled, they are unlikely to return to work. Therefore, preventive interventions targeted at work retention, which aim to help people to stay at work, are needed to avoid the transition from work instability to work disability. Rheumatology health professionals play an important role in identifying patients’ work problems at an earlier stage and helping them to stay at work. Currently, there are no set pathways to outline health professionals’ approach to identifying people with work problems and/or work rehabilitation interventions in the UK. Further, there is a need to train health professionals in the importance of the early recognition of these problems and evidence-based interventions to address work instability.

This session will focus specifically on the rheumatology occupational therapy-led work rehabilitation taken place in a NHS setting in the UK. Using real life case studies, Dr Prior will discuss the standardised assessments used in identifying work problems, collaborative goal setting and work interventions to provide a snapshot of work rehabilitation in the context of clinical practice.

SP0046 PREVENTION AND THE PROTECTIVE ROLE OF EXERCISE AND LIFESTYLE INTERVENTIONS ON COMORBIDITIES IN RHEUMATIC DISEASES

S. Garcia Diaz, Rheumatology, Consorci Sanitari Integral, Hospital Moises Broggi Sant Joan Despi, Sant Joan Despi, Spain

Background: It has been recognised that patients with rheumatic diseases are at increased risk of developing comorbid conditions such as cardiovascular disease (CVD), malignancies, infections and osteoporosis (among others). Lifestyle interventions (non smoking, non alcohol, healthy diet and exercise) may play an important role to reduce comorbidities in these patients.

Objective: To find if lifestyle interventions and especially exercise play a vital role in preventing comorbidities in rheumatic diseases through an extensive review of recent literature.

Screening for Comorbidities in Daily Practice: Who and How?

L. Gossec, Paris 06 University, Pitié-Salpêtrière Hospital, Paris, France

Comorbidities are frequent in RMDs, as in many other chronic diseases. In inflammatory rheumatic diseases, the most frequent comorbidities are cardiovascular diseases, depression, infections and cancers. Some of these diseases are more frequent than in persons without RMDs, some are not more frequent but are more often under-assessed and under-treated. These comorbidities and their risk factors need to be screened for. Screening in daily practice is not so simple since it necessitates time, physician expertise and patient cooperation. In this talk, we will address recent recommendations on how to screen for comorbidities, how often and in which setting this should be performed, and the respective roles in screening of rheumatologists, rheumatology nurses and persons with RMDs.

Do Patient Organisations Have a Role to Play in Preventing Co-Morbidities?

A.M. Bosworth, n/a, National Rheumatoid Arthritis Society, Maidenhead, United Kingdom

My talk will look in detail at how patient organisations can play a role in preventing co-morbidities. NRAS is currently engaged in two major projects which are both directly concerned with the prevention of co-morbidities. During RA Awareness Week in the UK, 19–26 June, NRAS will launch ‘Love your Heart’ an on-line, interactive RA awareness programme to educate people with RA about their increased risk of heart disease and atherosclerosis. This programme explains in simple terms why people with RA are at increased risk of cardiovascular disease. The programme provides the opportunity to appraise individual risk factors, complete a QRISK2 assessment with their GP and provides a cognitive-behavioural framework to empower people to change their behaviours and achieve a healthier lifestyle, thereby reducing risk of heart disease. Baseline and 6 months evaluations are built into the programme. It has been developed with input from a consultant rheumatologist, GP, and other health experts as well as patients. If time permits I will also describe a research study we are undertaking with 3 hospitals in the UK whereby we will randomly assign newly diagnosed patients to receive a targeted support programme or NRAS or be in a control group which does not receive this support for a period of 6 months. Our aim is to show that the group receiving the targeted support has less anxiety and depression, although other outcomes will also be measured.

Targeting of Angiogenesis

S. Tas on behalf of European Synovitis Study Group. AMC Clinical Immunology & Rheumatology, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands

Angiogenesis is de novo capillary outgrowth from pre-existing blood vessels. This process not only is crucial for normal development, but also has an important role in supplying oxygen and nutrients to inflamed tissues, as well as in facilitating the migration of inflammatory cells to the synovium in rheumatoid arthritis, spondyloarthritides, and other tissues in systemic autoimmune diseases. Neovascularization is dependent on the balance of proangiogenic and antiangiogenic mediators, including growth factors, cytokines, chemokines, cell adhesion molecules and matrix metalloproteases. In this lecture I will provide an overview of the various pathways that govern these angiogenic processes and discusses potential approaches to interfere with pathological angiogenesis, and thereby ameliorate inflammatory disease, by targeting these pathways specifically in endothelial cells.

Key Messages:

- In chronic inflammatory diseases, angiogenesis enables increased delivery of oxygen and nutrients to immune cell populations accumulating in inflamed tissues, and contributes to further immune cell infiltration

FROM SCIENCE TO PRACTICE - THE ROLE OF HEALTH PROFESSIONALS IN THE MANAGEMENT AND TREATMENT OF RHEUMATOID ARTHRITIS

S. Preckel, Department of Medicine, Asklepios Klinik am Schauspielhaus, Hamburg, Germany

Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by persistent inflammation of the synovial membrane, which leads to joint destruction, functional impairment, and increased risk for cardiovascular events. Despite advances in the management of RA, individual patient’s disease is often not optimized, as a result of missing information on disease activity of RA, slow transition to treatment, or suboptimal management of comorbidities.

The role of the health-care professionals (HCP) has to be strengthened in the management of RA. At the individual level, self-management is a crucial component to control the rheumatic disease. Educational programs, symptom monitoring, disease management, and self-management education are complex processes that require the input of HCP. The HCP have to be aware of the individual’s situation and needs for the development of an individualized care plan.

At the level of care delivery, HCP have to use the data available to influence the treatment decision process. Furthermore, the HCP have to ensure an effective cooperation between the different care delivery levels (primary care, rheumatologists, specialized inpatient care). Measuring disease activity, quality of care, and joint function and related patient outcomes are crucial tasks for the HCP.

DNA AGGREGATES AS ALARMINS

DNA is a large polymeric molecule that displays powerful immunological activities and operates in the context of multi-component aggregates to alarm the immune system and stimulate innate immunity. Although DNA has important roles in normal host defense, DNA can serve as an autoantigen and autoimmunogen by itself or in association with other immunologically active nuclear molecules. In the setting of systemic lupus erythematosus (SLE), DNA is a key target antigen; while antibodies to pure DNA double stranded DNA serve as important biomarkers, the relevant antigenic form of DNA during disease is the nucleosome in which DNA is bound to histones. Furthermore, nucleosomes can be components of microorganisms which are small membrane-bound structures that are released from dead and dying cells. MPs can stimulate immune responses and serve as a nidus for immune complex formation. In normal immunity, DNA can interact with nucleic acid sensors in the cytoplasm of cells to stimulate responses including production of type 1 interferon. These sensors respond to DNA from intracellular organisms such as bacteria and viruses although damaged DNA and DNA from mitochondria can also interact with these receptors. While these sensors are intracellular, they can interact with extracellular DNA that is introduced or from other molecules. In another facet of host defense, DNA can be released from neutrophils during a process termed NETosis. A NET or neutrophil extracellular trap is a mesh-like structure comprised of DNA as well as granule proteins that have antibacterial activity. NETs can trap and kill bacteria. Thus, in its diverse immunological roles, DNA interacts with other molecules to form aggregates of sub-cellular structures that alarm the immune system, promote host defense or drive critical events in autoimmunity.

only disrupted when I realised that my experience of illness was quite common to other persons with a RMD. I can still remember my fascination, in a Patient Reported Outcomes workshop, by discovering that our experience as patients had a bigger relevance that the one we usually conceive. Then, I felt the need of understanding the research process and specific jargon, so that I could relate the knowledge I had with a RMD. Otherwise any insight on the patient perspective would be "lost in translation", due to an inability to enable a correspondence between the scientific terminology and mindset regarding the disease, and the experience of illness and sickness by the individuals. Training opportunities were also recognised as desirable by the above mentioned EUROLU, in order to increase expertise and understanding of research methods and to promote the patients’ self-confidence on their contribution to research. The Patient Research Partners (PRP) training by EULAR, in 2013, was the first step in discussing the importance of understanding and the role of patients and on how to provide a meaningful input from the patients’ perspective into research processes. It was followed in 2014 by the training provided by European Patients’ Academy on Therapeutic Innovation (EUPATI) for Patient Expert on the Medicines Research and Development Process. This expert-level training was organized in a mixture of independent e-learning coursework and face-to-face training events over a 14-month period. The syllabus involved six modules: Discovery of Medicines & Planning of Medicine Development, Non-Clinical Testing and Pharmaceutical Development, Exploratory and Confirmatory Clinical Development, Clinical Trials, Regulatory Affairs, Medicinal Product Safety, Pharmacovigilance and Pharmacoeconomics, Data management, and audit and practices. Additionally, in 2016, I have attended the 1st EULAR course on Health Economics in Rheumatology. In the meantime, my background as an anthropologist led me to become interested in Medical Anthropology. Between 2007–2015 my academic research (MA Phil. and PhD) was oriented towards a specialization in Anthropology of Health, with a special interest in Anthropology of Pharmaceuticals. Based on my personal experience, on this lecture I will focus on the challenges of the role of the PRP trying to fill the gap between the mindsets and practices of different stakeholders. Navigating through different meanings of symptoms and treatments, the educated patient representative must act like a translator, decoding the biologic impact of the disease and intervention over the experience of illness on the everyday aspects of living with a RMD. The biggest expectation and challenge might be to bring these aspects forward, as relevant for the other stakeholders, since they shape individual values and patient’s preferences. Although recognised as having a pivotal role, patient’s involvement in research may be limited by tokenism or by ineffective patients’ participation. Patients’ involvement is now a requirement and an added value to any project. But, is the project team ready and willing to listen to patients? Are PRP duly involved in the project, or are they just expected to be recipients without any input of their perspectives into the development and implementation of the research? The knowledge and education acquired to perform our task enables us to understand science enough to communicate the patient experience in a meaningful way, improving the research. Our added value is, undoubtedly, our experience with the disease, our understanding of the individual values and preferences shaped by the everyday aspects of living with a RMD. We should be taken more seriously, for the benefit of science and patients. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.7243

**SP0052** BUILDING PATIENT PARTNERSHIP IN HEALTH CARE SERVICE DESIGN AND DELIVERY

H. Lempp, Rheumatology, Kings College London, London, United Kingdom

This paper will present details of the approach to patient and public involvement in health service delivery, health service research and health care education in England. The presentation will be based upon a Logical Framework with the following key elements: inputs, processes, outputs, and outcomes/impacts. Key barrier acting to minimise the impact of building patient partnerships will be discussed, illustrated by examples from our experience with the preparatory stages for our departmental strategy to formalise close Patient Partnership for our research portfolio: (i) establish honorary contracts for patients for the academic Institution and local Hospital Trust; (ii) include patients on the interview panels to appoint project researchers (iii) build in a separate funding within the overall project budget for the costs associated with patient partnership and (iv) manage to appoint project researchers (ii) build in a separate funding within the overall Institution and local Hospital Trust; (ii) include patients on the interview panels for our departmental strategy to formalise close Patient Partnership. The biggest expectation and challenge might be to bring these aspects forward, as relevant for the other stakeholders, since they shape individual values and patient’s preferences. Although recognised as having a pivotal role, patient’s involvement in research may be limited by tokenism or by ineffective patients’ participation. Patients’ involvement is now a requirement and an added value to any project. But, is the project team ready and willing to listen to patients? Are PRP duly involved in the project, or are they just expected to be recipients without any input of their perspectives into the development and implementation of the research? The knowledge and education acquired to perform our task enables us to understand science enough to communicate the patient experience in a meaningful way, improving the research. Our added value is, undoubtedly, our experience with the disease, our understanding of the individual values and preferences shaped by the everyday aspects of living with a RMD. We should be taken more seriously, for the benefit of science and patients. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.7243

**SP0053** HOT SESSION: VASCULITIS TREATMENT

R.A. Lugmani, University of Oxford, Oxford, United Kingdom

The systemic vasculitides are characterized by inflammation of blood vessels, which if untreated, results in tissue or end organ damage or death. Chapel Hill nomenclature is widely used to define different forms of vasculitis according to the size of the predominantly affected vessels. Other forms of vasculitis are not defined by a predominant vessel size (e.g. Behcet’s syndrome). Vasculitis associated with the presence of anti-neutrophil cytoplasm antibody (ANCA), termed AAV, is less common than giant cell arteritis (GCA), but considerable advances have been made in understanding the pathogenesis and evidence based treatment for AAV. AAV is divided into three major forms: granulomatosis with polyangiitis (GPA) (Wegener’s granulomatosis), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) (Churg–Strauss syndrome). ANCA are implicated in their pathogenesis but not all patients with AAV are ANCA positive. We will review recent EULAR guidelines on therapy for AAV, based on careful structured clinical evaluation of patients, with stratification according to severity. Cyclophosphamide or rituximab (plus glucocorticoid) is used for severe disease, followed by maintenance with azathioprine (AZA) or methotrexate (MTX), and reducing doses of glucocorticoids; or maintenance rituximab. Additional plasma- exchanging strategies are advocated for very severe, severe active disease, or after severe disease, MTX or AZA or mycophenolate (plus glucocorticoids) can be used. The evidence for effectiveness is clear for MPA and GPA. A number of studies are underway to improve our use of these existing agents and to test newer, mechanism based treatments such as a inhibition CTLA4 or of the CS complement pathway in GPA and MPA. For EGPA with severe manifestations, cyclophosphamide and glucocorticoids are recommended. A trial of mepolizumab (inhibitor of interleukin 5, a potent driver of eosinophil production) in EGPA has recently been completed. IL-6 inhibition with tocilizumab is a significant advance over glucocorticoid monotherapy at present. We will discuss our experience using these various agents and discuss the current state of the art. This expert-level training was organized in 2014 by the training provided by European Patients’ Academy on Therapeutic Innovation (EUPATI) for Patient Expert on the Medicines Research and Development Process. This expert-level training was organized in a mixture of independent e-learning coursework and face-to-face training events over a 14-month period. The syllabus involved six modules: Discovery of Medicines & Planning of Medicine Development, Non-Clinical Testing and Pharmaceutical Development, Exploratory and Confirmatory Clinical Development, Clinical Trials, Regulatory Affairs, Medicinal Product Safety, Pharmacovigilance and Pharmacoeconomics, Data management, and audit and practices. Additionally, in 2016, I have attended the 1st EULAR course on Health Economics in Rheumatology. In the meantime, my background as an anthropologist led me to become interested in Medical Anthropology. Between 2007–2015 my academic research (MA Phil. and PhD) was oriented towards a specialization in Anthropology of Health, with a special interest in Anthropology of Pharmaceuticals. Based on my personal experience, on this lecture I will focus on the challenges of the role of the PRP trying to fill the gap between the mindsets and practices of different stakeholders. We should be taken more seriously, for the benefit of science and patients. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.7243

**SP0054** THE CONCEPT OF TREAT-TO-TARGET

J. Braun, Rheumazentrum Ruhrgebiet, 44649 Herne, Germany

Many illnesses including most rheumatic diseases have substantial effects on well-being and quality of life, including deterioration of physical and mental function and a reduced life expectancy, since they can cause damage to organs and cells. If healing and regeneration cannot be achieved an impairment of organ function can be expected. In acute diseases this may occur rapidly over hours to days and weeks, while it often takes months to years in chronic disease. However, if treatment is instituted early enough, organ damage may be prevented or diminished. Critical for an optimal management of diseases with potentially severe outcomes is to determine the responsible thresholds for, for example, disease activity or to define the maximum level of a surrogate marker at which damage is unlikely to occur and, thus, will not be harmful in the long term. Although the optimal aim of therapy is cure, and appropriate therapy may even normalize life expectancy, many chronic diseases such as hypertension, diabetes, rheumatoid arthritis (RA) and spinal cord injury (SCI) have remained without curative therapies in the last decades – even though considerable progress has been made. Thus, a strategic therapeutic approach should aim for prevention of future damage, and maximal improvement of compromised organ function. Therefore, a clearly defined threshold of a validated measure that predicts future harm or no minimal harm, is a target of critical importance for chronic diseases with potentially severe outcomes. Treat-to-target strategies have been developed to achieve this have widespread implications. They should be routinely followed - as long as the potential harm from treatment is carefully balanced against its benefit. Clearly, if inappropriately managed, the consequences of diabetes and hypertension in
the long run include, myocardial infarction, stroke, renal failure, blindness, etc. Therefore, target values for biological markers have been determined below which organ damage does usually not occur and life expectancy is normalised. Examples for domains in which such thresholds have been defined are blood pressure, glycosylated haemoglobin (HbA1c), and others. Inflammatory processes lead to organ damage not only in the musculoskeletal system but they may also harm internal organs. A target level of a measure related to its long-term outcome, can be a surrogate measure like the cholesterol level for cardiovascular diseases, or a composite measure of disease activity as used in RA (DAS28) or in AS (ASDAS). The treat-to-target strategy can be reduced to a simple algorithm of, on the one hand measuring activity and on the other hand, in consequence, adapting treatment. Treatment adaptation does not necessarily mean changing a medication or increasing the dosage of a drug but may even also mean lifestyle changes, as long as the therapeutic target is attained or nearly attained – importantly within the specified time frame. Therapeutic adaptations should always take patient factors, including comorbidities, adverse events and patient preferences, into account.

However, the musculoskeletal system can mostly not be assessed by using a simple surrogate or direct “gold standard” measures, since rheumatic diseases with multiple signs and symptoms are mostly rather complex. In RA information derived from physical examination using a quantitative joint count is considered very important. This is different in AS. Additionally, information from the history, which can be collected through patient self-report multifaceted questionnaires, has proven effective in determining patient status and its change. This is even more important in AS, because of its functional impairment. However, the treatment of AS is difficult, but also the assessments should be individualised. Both in the overarching principles and in the recommendation the shared decision between patient and rheumatologist is listed as the basis of the T2T management.

The updated recommendations will be presented.

SP0055 WHAT ARE THE CHALLENGES FOR APPLYING TREAT TO TARGET IN AXIAL SPONDYLOARTHRITIS?
M. Dougados, rheumatology Hopital Cochin, René Descartes University, paris, France

The concept of Treat to Target (T2T) applied in rheumatoid arthritis has been evaluated in psoriatic arthritis and is currently under investigation in two different strategy trials in patients suffering from axial spondyloarthritis (axSpA). Whatever results of these trials will be, the acceptance of this concept and consequently its implementation in daily practice might be challenging for several reasons. The concept of T2T requires 3 different steps: a) the choice of the most relevant outcome measure (e.g. a measure evaluating a domain recognized as predisposing to subsequent clinically relevant damage (either structural damage or important comorbidities such as cardiovascular diseases)), b) the determination of the threshold of the outcome measure to reach (threshold below which the risk of subsequent damage is abolished or significantly diminished) and c) the time to reach the target is usually related to the treatment modality (a few days for NSAIDs and several weeks for DMARDs). A part these different steps, two points have to be considered a) this T2T approach is mostly aimed at minimising the pathologic damage and b) this T2T strategy requires the possibility to adapt/increase the treatment in case the target is not reached after one or several ‘conventional’ treatment modalities. For each of these different points we will consider past ongoing initiatives proposing to resolve the different encountered issues in order to facilitate the elaboration and the implementation of a T2T strategy in axSpA.

SP0056 UPDATE OF THE T2T RECOMMENDATIONS IN SPA
D. Van Der Heijde on behalf of T2T in SpA working group. Rheumatology, Leiden University Medical Center, Leiden, Netherlands

In 2013 the first recommendations for treating spondyloarthritis to target (T2T) were published. These followed the reasoning for the T2T recommendations for rheumatoid arthritis. Although the systematic literature review at that time did not provide evidence to support the recommendations, five overarching principles and 11 recommendations were formulated. There were 9 common recommendations for axial SpA, peripheral SpA and psoriatic arthritis and 2 additional recommendations for each subgroup respectively. In 2017 the T2T working group met again to update the recommendations. This was based on an updated systematic literature review. Data had been published that there is a link between bone density and subsequent long-term outcomes, which is the basis for the T2T principles.

SpA is characterised by musculoskeletal signs and symptoms (arthritis, enthesitis, dactylitis, axial disease) but also extra-articular manifestations (psoriasis, inflammatory bowel disease, anterior uveitis) are important manifestations. Moreover, biomarkers such as osteoporosis, cardiovascular disease. All these manifestations are taken into account in the formulation of the recommendations. The overarching principles were kept largely identical. Some changes in the wording were made for a better understanding, but no fundamental changes were made. A total of 11 recommendations were formulated. These are now for all subgroups of SpA and no specific recommendations are proposed. In principle, the treatment target is remission or inactive disease of musculoskeletal and extra-articular manifestations, and the target should be individualised. It is important that remission/inactive disease should be based on a combination of clinical and laboratory parameters, and disease activity should be measured on the basis of clinical signs and symptoms as well as acute phase reactants. This is important to realise, e.g. in axial SpA as patient reported outcomes only are at best weakly correlated with structural damage. In certain circumstances, low disease activity may be an alternative target. Because of the heterogeneous presentation of SpA, not only the target but also the assessments should be individualised. Both in the overarching principles and in the recommendation the shared decision between patient and rheumatologist is listed as the basis of the T2T management.

The updated recommendations will be presented.

THURSDAY, 15 JUNE 2017
Calcium crystal deposition in rheumatic diseases —

SP0057 CALCIUM CRYSTALS AND THEIR LINK TO OSTEOARTHRITIS
J. Bertrand. Department of Orthopaedic Surgery, Otto-von-Guericke University Magdeburg, Magdeburg, Germany

Calcification of cartilage is a common finding during osteoarthritis (OA). We have shown that it is mainly of the BCP type and not the CPPD type of crystal formation. BCP cartilage calcification is directly linked to the severity of cartilage degradation and, therefore, OA severity. We have also shown that with increasing hypertrophic differentiation of chondrocytes, the amount of calcification increases in vivo and in vitro. This indicates a link between chondrocyte hypertrophy and cartilage calcification. The pyrophosphate pathway is known to be involved in tissue calcification. It functions to keep the sensitive balance of pyrophosphate (PPi) and phosphate (Pi), thereby preventing the generation of calcium-phosphate crystals. One key player in this pathway is the nucleotide pyrophosphatase phosphodiesterase (NPP1), which has been demonstrated to be regulated by inflammatory mediators such as IL-1. In our cohort of OA patients, the expression of collagen X and NPP1, but not ANK and TNAEP, correlated with cartilage calcification and also with the Mankin-Score. NPP1 expression inverse correlated with the calcification, whereas collagen X was upregulated. This finding was confirmed in experimental murine OA using the DMM mouse model. Furthermore, NPP1mut/mut mice (ttw/ttw) exhibit more calcification activity than wild type controls in joints as well as in cartilage of non weight bearing areas, including ear cartilage, suggesting that mechanical stress is not required for the induction of calcification. NPP1mut/mut mice (ttw/ttw) mice developed typical OA-like changes as evaluated by pathologic examinations as well as in vivo histopathological stainings. Intriguingly, calcium was associated with increased expression of the hypertrophic cartilage marker collagen X and the bone marker collagen I. Additionally, BCP crystals are able to activate chondrocyte differentiation via the WNT signaling pathway. NPP1 is an important player in OA-associated cartilage calcification. Pathologic calcification of cartilage resembles in many aspects cartilage transformation into bone. Taken together, the data suggest that OA is characterized by the re-activation of molecular signalling cascades that at least in part resemble endochondral ossification.

SP0058 REVIEW OF THE DIFFERENT IMAGING MODALITIES TO DETECT CALCIUM DEPOSITION DISEASES
P. Omoumi. Lausanne University Hospital, Lausanne, Switzerland

Crystal deposits in and around the joints are common and most often encountered
as incidental imaging findings in asymptomatic patients. However, they can also cause chronic or acute arthropathy, generating symptoms. In the chronic setting, imaging features are usually characteristic and allow the differentiation of the type of crystal arthropathy. In the acute phase and in the early stages of the crystal deposition, the signs are often non-specific, and the finding of a leukocyte-rich synovial fluid is essential for the diagnosis of synovial fluid.

Radiography is the main imaging modality for the workup of these conditions. It can confirm the diagnosis and often characterizes the type of crystal arthropathy. In recent years, US has played an increasingly important role in this setting, and is a useful tool in superficially located crystal-induced arthropathies. CT nicely complements radiography for deeper sites, especially the axial skeleton.

Biomarkers are required for remission: More than clinical...?

For both, it is clear that we are defining a very good, perhaps even the best concept adequately defined in RA, but less so in many other rheumatological diseases. To even begin with answering the question, we must first agree on a clear conceptual definition of remission. When we started on the development of the ACR-EULAR definition of remission in RA, we used dictionary sources and discussions to settle on this:

“The state of absence of disease activity in patients with a chronic illness, with the possibility of return of disease activity” [1] It is clear that choices are made from the beginning, especially with the concept “disease activity”, and the possibility that disease activity returns (as opposed to “healing”, where this possibility does not exist). Disease activity is a tangible concept adequately defined in RA, but less so in many other rheumatological diseases. Also, disease activity is conceptually separate from (mostly irreversible) consequences of the disease, such as damage. Finally, note that the above concept does not contain the elements “duration” or “treatment”.

If we continue with the above concept, why do we want to proceed to operationalize the remission definition? The two main reasons are research and patient care. From both is clear that we are defining a very good, perhaps even the best state a patient can be in, given that we are talking about chronic disease, i.e. the root cause of the disease cannot be taken away to heal the patient. Being in such a good state has immediate benefits (minimal disease impact) and probably also future benefits, of lack of disease activity translates to less consequences (damage etc). In both research and patient care, we want a definition that is both valid (favorable test characteristics; links to prognosis) and feasible (time, costs, interpretability). Validity and feasibility oppose each other to a certain extent (e.g. definitions with better sensitivity and specificity are usually more expensive). Research and patient care differ in their use of the definition. In research, validity and feasibility can be lower than in patient care, because research is about groups, and cost and interpretability are less of an issue than in patient care. Most of the people criticizing the current ACR-EULAR remission definition of RA are confused over its purpose: whereas it was intended for use in trials, they criticize it for lack of validity in the clinic. For instance, it is felt that the patient global criterion is too strict, so that patients with no apparent inflammatory activity but a patient global score of 2 or higher (scale 0–10) are “unjustly” not classified as in remission. Also, the lack of a duration or treatment criterion is felt to be a problem, but this is not an issue in research.

In the following pro-con debates, please consider the following:

Proposals to change existing criteria for remission must also be held to the following:

1. Conceptually, remission is thought of as a state where the disease is absent. As we approach a better understanding of the underlying pathophysiological process of a disease, it becomes more and more relevant to include in a definition of remission appropriate biochemical markers of that process.

2. From a practical point of view, definitions of remission in RA have been built upon clinical parameters of disease activity, supplemented in some cases with a single biomarker. However, it is clear that in practice these definitions are insufficiently precise: held against a gold standard of expert opinion, they perform at around 80–90%, misidentifying one or two out of every ten patients. And while there is an understandable and in many ways desirable development of more patient-reported emphasis in outcomes, it has consensually practical value to be able to objectively an important disease state such as remission.

3. There is convincing evidence to show that biomarkers can be employed successfully to predict some aspects of RA. In the day-to-day care of patients with this disease, the most important prediction may be whether the effective drug can be tapered or not. Current evidence indicates that biomarkers may be invaluable at helping clinicians and their patients make this important decision.

Fifty shades of remission in RA

M. Boers, Epidemiology & Biostatistics; Amsterdam Rheumatology and Immunology Center, VU University Medical Center, Amsterdam, Netherlands

This session is about defining remission. Most examples will be about rheumatoid arthritis (RA) because most experience has been gathered in that disease. But the concept of remission should be viewed from a wider perspective than one disease. The session includes two pro-con debates (on the utility of including imaging biomarkers in a definition of remission).

As in all things, when embarking on a scientific project, one must ask: “Why are we doing this?”

To even begin with answering the question, we must first agree on a clear conceptual definition of remission. When we started on the development of the ACR-EULAR definition of remission in RA, we used dictionary sources and discussions to settle on this:

“The state of absence of disease activity in patients with a chronic illness, with the possibility of return of disease activity” [1]

It is clear that choices are made from the beginning, especially with the concept “disease activity”, and the possibility that disease activity returns (as opposed to “healing”, where this possibility does not exist). Disease activity is a tangible concept adequately defined in RA, but less so in many other rheumatological diseases. Also, disease activity is conceptually separate from (mostly irreversible) consequences of the disease, such as damage. Finally, note that the above concept does not contain the elements “duration” or “treatment”.

If we continue with the above concept, why do we want to proceed to operationalize the remission definition? The two main reasons are research and patient care. From both is clear that we are defining a very good, perhaps even the best state a patient can be in, given that we are talking about chronic disease, i.e. the root cause of the disease cannot be taken away to heal the patient. Being in such a good state has immediate benefits (minimal disease impact) and probably also future benefits, of lack of disease activity translates to less consequences (damage etc). In both research and patient care, we want a definition that is both valid (favorable test characteristics; links to prognosis) and feasible (time, costs, interpretability). Validity and feasibility oppose each other to a certain extent (e.g. definitions with better sensitivity and specificity are usually more expensive). Research and patient care differ in their use of the definition. In research, validity and feasibility can be lower than in patient care, because research is about groups, and cost and interpretability are less of an issue than in patient care. Most of the people criticizing the current ACR-EULAR remission definition of RA are confused over its purpose: whereas it was intended for use in trials, they criticize it for lack of validity in the clinic. For instance, it is felt that the patient global criterion is too strict, so that patients with no apparent inflammatory activity but a patient global score of 2 or higher (scale 0–10) are “unjustly” not classified as in remission. Also, the lack of a duration or treatment criterion is felt to be a problem, but this is not an issue in research.

In the following pro-con debates, please consider the following:

Proposals to change existing criteria for remission must also be held to the question: “Why are we doing this?”

Innate immunity

A. Hidalgo, Cell & Developmental Biology, Fundación CNIC, Madrid, Spain

Immunity is essential for life, yet the strength of immune responses are not constant throughout the day. This oscillatory immunity reflects an adaptation of organisms to environmental changes that occur through day-night cycles, so as to optimize and concentrate effective responses to the times of maximal environmental threat. In my talk I will discuss our ongoing efforts to uncover the mechanisms by which neutrophils, the most abundant and aggressive of all immune cells, orchestrate temporal immunity. These mechanisms are reflected in diurnal changes in phenotype and function of neutrophils, which we refer to as neutrophil aging. We propose that the existence of a timed response of neutrophils governed by cell-intrinsic and –extrinsic mechanisms suggests that inflammatory disease co-opts ancestral processes to damage tissues.

Differential scavenging of apoptotic cells and bacteria

G. Krönke, Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany

During inflammation and infection, we are simultaneously confronted with both self and non-self in form of dying cells and microbes, respectively. Mechanisms that facilitate the non-immunogenic clearance of self-antigens derived from apoptotic and necrotic cells and that, in parallel, allow the initiation of an immune response against invading pathogens are incompletely understood. Recent data from our laboratory show that the immune system actively sorts apoptotic cells (ACs) and bacteria into distinct subspecies of phagocytes thereby enabling a segregated processing of self and non-self as well as a differential immune response against these two entities. During inflammation, ACs were cleared by tissue resident macrophages (resMϕ) that performed a non-immunogenic disposal of self antigens, whereas bacteria were preferentially ingested by monocyte-derived inflammatory macrophages. We identified the enzyme 12/15-lipoxygenase and the nuclear receptor Nrf4, both specifically expressed by resMϕ, as key factors that control the coordinated and non-immunogenic phagocytosis of ACs by these specialized macrophage subset. Incorrect sorting and aberrant uptake of AC-derived self-antigens by pro-inflammatory and immunocompetent phagocytes, however, resulted in the break of self-tolerance and autoimmunity. Our data thus demonstrate the importance of a sorted clearance of ACs for the maintenance of immunologic self-tolerance.

The role of muscle in innate immune responses

P. Rovere-Querini, Immunology, Transplantation and Infectious Disease, San Raffaele Scientific Institute and Vita-Salute San Raffaele University, Milano, Italy

The skeletal muscle represents a unique site from the immunological point of view. Leukocytes are virtually absent in healthy conditions. However they are quickly recruited upon muscle injury, persist during the regenerative phases to disappear again after tissue healing. Thus, it represents and ideal scenario to study the
involvement of the innate immune system in the homeostatic response either to the conventional programmed death of multinucleated myofibers and to the parallel occurrence of "non-canonical" cell death and survival programs, including necrosis and autophagy. Recruited phagocytes are responsible of the clearance of damaged myofibers and of dying muscle stem/progenitor cells, striomal cells and cardiomyocytes in particular are endowed with remarkable plasticity throughout regeneration and healing, switching from activated cells that generate inflammatory cytokines to reparative assets, that play a non redundant role during the resolution phases of the damage and regulate the termination of the inflammatory responses. This dynamic transition between is increasingly felt to be the key to muscle homeostasis. Conversely defects in the process favour maladaptive remodeling with deposition of collagen and fat accumulation and in predisposed individuals autoimmunity leading to inflammatory idiopathic myopathies. A specialized population of regulatory T (Treg) cells, which control the immune system by promoting the M1-to-M2 switch, and the activation of the muscle stem cells, satellite cells is receiving increasing attention for their central role in tissue homeostasis. Thus, the immunologic perception of muscle cell death and regeneration – in turn influenced by environmental cues, including mitophagy and alteration of the redox balance - determines whether these events foster successful tissue healing or persisting inflammatory myopathies. The insights that are progressively become available on this original scenario hold promises to develop new approaches for disease treatment. Thus, immunologic perception of death and regeneration of muscle cells determine whether these events promote healing of tissues or persistent inflammatory myopathies. The impacts that are becoming increasingly available on this original scenario hold promise for the development of new approaches to the treatment of persistent human muscle disease.

To be and to become: transition from paediatric to adult care

W. Olde, YOUTH-R-WELL.COM, Groningen, Netherlands

The importance of successfully transitioning pediatric patients to adult care is increasingly recognized across a wide range of health care providers. However, there are still many challenges occurring during the transition phase. This presentation will contribute to these challenges by sharing the journey of a young person with arthritis on the transition to adult care. As a young patient with arthritis, I made the journey from pediatric care to adult care a couple of years ago. I am diagnosed with arthritis since I was 14 years old. In this presentation, I will show the experiences of my own transition. Furthermore, as the chair of Youth-R-Well.com, an organization for young people with RMDs in the Netherlands, I will share some of the main points around transition I learned from other young patients. For every person, the transition to adult care is experienced differently. Therefore, I will try to give some main answers from personal journeys on the questions: How is the transition experienced by a young patient? What are the current challenges faced by a young patient during the transition? What should be the role of the parents during the transition? What are best practices for the transition to adult care?

ARE WE ASKING THE RIGHT QUESTIONS IN TRANSITION RESEARCH?

K. Minden,1,2, Epidemiology unit, German Rheumatism Research Centre; 1Charte Universitätsmedizin, Berlin, Germany

Already in 1991 Robert Blum pointed to the diverse set of issues of which the clinicians need to be cognisant to successfully care for youth with chronic illness. Since then, the special health care needs of adolescents and young adults with chronic diseases, including rheumatic diseases, have been on the agenda. Despite efforts to develop holistic services and programmes for youth, there are still inconsistencies in service delivery and practice standards. This revealed a survey among paediatric rheumatologists from 115 centres in 22 European countries in 2016. A minority of European paediatric rheumatology centres have written transition policy, follow a standardised, structured approach in transitioning patients and measure the success of their interventions with evaluated instruments. To overcome these deficits and existing practice variation, key elements of transitional care, frameworks and pathways to implement and assess transition programmes have been recommended by EURAL and PRES. However, as long as we don't have robust evidence upon best practices for transition, on the best metrics for measuring "success" and "outcome" of transitional care services and on the impact of interventions on the young people with rheumatic diseases will the service planning and delivery for transition aged youth remain suboptimal and result in adverse long-term outcomes.

The literature about transitional care is exponentially increasing each year and comprises among others assessments of experience of care and clinical outcomes, evaluations of different services and processes of care. What we have learned so far from transition research in the field of rheumatology, which research priorities are currently set on the agenda by health care providers and whether they meet those of young people will be in the focus of this lecture.

IMPLEMENTATION OF A BRIEF TRANSITION PROGRAMME FOR ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

L.R. Knudsen, Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark

Background: It is well described that adolescents and parents find transition between the children’s and adult ward challenging (1–2) because they feel inadequate prepared, and find communication and cultural differences between child and adult care challenging. Thus, transitional care programmes becomes essential for a successful process (3).

Objectives: We aimed to develop a brief transition programme for adolescents with juvenile idiopathic arthritis (JIA), suitable for daily clinical practice in the children’s and adult ward of rheumatology at Aarhus University Hospital, Denmark.

Methods: The development was based upon studies of transitional care programmes and qualitative studies of the patient, parent, and health professionals perspective in the transition process. Needs in the transition process from the perspective of both adolescents and parents were further investigated through semi-structured interviews. We used studies by Janet McDonagh and colleagues (3) as a theoretical framework for the programme development.

Results: The programme focuses on the final part of the transition process by including the adolescent from the children’s ward at the age of 14. It runs for two years in the children’s ward and continues the first year in the adult ward. The programme focuses on preparing the adolescent and parents for transition by bringing attention to the adolescent’s knowledge and skills in coping with JIA. The programme further focuses on the relation between the adolescents and parents by bringing attention to the need for a gradually separation, and to placing more self-dependence on the adolescents. A guideline, describing the programme, containing concrete instructions to health professionals has been developed. The programme was primarily initiated by the adult ward, but nurses and physicians in both wards have been involved throughout the process. The programme consists of the following elements:

• Assigned contact persons.
• Information leaflets about transitional care, transfer to adult care and differences between the children’s and adult ward, i.e. in ways of working and treatment procedures.
• Independent consultations with health professionals.
• Materials for educational sessions.
• Educational sessions dealing with JIA and treatment, dialogue on adherence and challenges in adolescence.
• Arrangements of visits to the adult ward before transfer.

Conclusions: Our experiences with the programme practice are generally positive. However, we have noticed that successful implementation calls for good collaboration and continuous involvement of the health professionals involved in the programme on a daily basis. Hence, ongoing meetings and communication have been essential to promote collaboration between the children’s and adult ward.

Heterogeneity in JIA

W. de Jager, Pediatric Immunology, University Medical Center Utrecht, Utrecht, Netherlands

The importance of cytokines in the pathogenesis of inflammatory diseases is highlighted by the success of therapeutic approaches directed against cytokines and cytokine receptors. Cytokines are characterized by their redundancy and pleiotropy: multiple cytokines can target the same receptor, while on the other hand a single cytokine can have multiple, even contradictory immunological effects.
Linking a cytokine/protein biomarker signature with clinical outcome may help to identify and classify patient cohorts. Thus “intelligent” cytokine signatures can be used as biomarkers in human inflammatory diseases. There are however various risks associated with this approach; often it is impossible to obtain material from the site of inflammation and there are various often not well-known technical aspects that can lead to unreliable results. Although standards for regulators are prominent in day to day clinical practice, standardization of sample collection and laboratory assessments remains suboptimal. Inconsistency in sample collection can affect the results of biological assays and thus several characteristics require thorough evaluation and standardization. This standardization is not limited to assay validity and reproducibility but also pre-analytical treatment and appropriate specimen types.

SP0068 CLINICAL INSIGHTS INTO JIA HETEROGENEITY
A. Consolaro on behalf of EPOCA Study Group. Istituto Giannina Gaslini, Genova, Italy

Several epidemiologic surveys have documented a remarkable, yet unexplained, disparity in the prevalence of juvenile idiopathic arthritis (JIA) subtypes among different geographic areas or ethnic groups. Moreover, the therapeutic approach to JIA is not standardized and the availability of the novel and costly biologic medications is not uniform throughout the world. This disparity may have significant impact on disease outcome. The multinational study of the EPIdemiology, treatment and Outcome of Childhood Arthritis (EPOCA) study is aimed to obtain information on the variability of JIA phenotypes in different geographic areas, the therapeutic approaches of pediatric rheumatologists practicing in diverse countries, and the disease status and outcome of children with JIA currently followed worldwide. Participation in the study was proposed to all pediatric rheumatology centers that are part of the Pediatric Rheumatology International Trials Organization (PRINTO), and to several centers in the US and Canada. Each center was asked to enroll 100 consecutive JIA patients or all consecutive patients seen within 6 months. Each patient received a retrospective and cross-sectional assessment. Parent- and child-reported outcomes were recorded through the administration of the Juvenile Arthritis Multidimensional Assessment Report (JAMAR). Participating countries were grouped into 6 geographic areas. Patients were then grouped according to their country’s gross domestic product per capita (GDP) and the total expenditure on health per capita (HE) (source www. who.org). Currently, 8,325 patients from 44 countries have been entered in the web database. Comparison of main epidemiology, treatment, and outcome features across the different geographic areas was performed. Patients living in countries with GDP or HE below the median had lower frequency of remission, higher median cJADAS, higher frequency of damage, and were less frequently prescribed biologic DMARDs. These results were confirmed when analyses were conducted only in oligoarthritis or polyarthritis patients. These results provide further evidence of the wide difference of JIA characteristics across geographic areas in terms of age at disease onset, subtype prevalence, and frequency of anterior uveitis. Overall, patients living in non-Western countries had higher levels of disease activity and cumulative damage than patients followed in North America and Western Europe. This disparity in disease outcomes may be partially due to differences in the availability or affordability of biologics, as confirmed by the evidence of worst outcomes in countries with lower GDP or HE.

EULAR - EMA session

SP0069 REGISTRIES IN MUSCULOSKELETAL DISEASES AND THEIR REGULATORY USE
R. Vesely, Rheumatology, Respiratory, Gastroenterology and Immunology Office, European Medicines Agency, London, United Kingdom

Patient registries collect information about individuals sharing health-related characteristics, for example, a particular disorder, a treatment or a procedure. While randomised controlled trials typically provide the primary evidence supporting marketing authorisations for new medicines, the patients studied may not be fully representative of everyone ultimately receiving the medicine and the trials may provide limited information about the natural history of the disorder. Information collected in patient registries is potentially of value for filling these evidence gaps in certain situations and for providing post-marketing safety and effectiveness information. Multiple stakeholders stand to benefit from using registry information in this way including patients, healthcare providers, policy makers, manufacturers and healthcare regulators.

In 2014, the EMA commenced a Registry Initiative aiming to optimise the use of registries in supporting medicines authorisations. Establishing a strategy of early engagement between marketing authorisation applicants and registry holders and a task force to support activities, a pilot phase was undertaken aiming to understand the barriers and enablers in using registries to support marketing authorisation applications and to inform the development of recommendations to optimise their use.

On 28 October 2016 the Agency organised Patient Registries Workshop to collect and discuss the information about experience from different patient registries in various therapeutic areas. The topics included:
- Benefits of registries for HTA and payers
- Benefits for industry
- Benefits for clinicians and researchers
- Benefits for patients
- Challenges in collaboration between registries
- Technical challenges
- Governance
- Sustainability

Conclusions of the pilot and the workshop have been utilised in the following activities including workshops to support registries in individual diseases.

There are multiple advanced registries in RA and JIA. Utilisation of outcomes of these and other existing or newly planned registries in other musculoskeletal diseases for regulatory purposes current environment offers new opportunities that require further analyses and collaboration.

SP0071 YOUNG PATIENTS: READY, BRILLIANT AND ABLE TO WORK!
L. Kullamaa, European Patients’ Forum, Brussels, Belgium

In May 2016, European Young Patients Group, an initiative representing young patients from the European Patients’ Forum (EPF) and the European Multiple Sclerosis Platform (EMSP), organised a workshop in the framework of the European Youth Event (EYE) 2016 in Strasbourg that corresponded with one of the five main programme themes titled, Exclusion or Access: Crackdown on Youth Unemployment.

The physical and emotional symptoms of chronic conditions, together with social stigma and attitude, create significant barriers to young patients in the job market. With appropriate support, they, like all enthusiastic young people, can be assets for employers. Through interactive discussion, creative expression, education and open dialogue, the workshop aimed to challenge expectations and inaccurate perceptions about the abilities of young people with chronic conditions, tackle societal beliefs and stereotypes of individuals with chronic conditions, stimulate discussion to explore concrete solutions and develop practical actions for young people and their allies accessing employment and steer change to ensure young patients benefit from equal opportunities and treatment at work. By addressing these specific objectives, the workshop was to help to reduce the extra burdens faced by young people with chronic conditions transitioning from education to employment, as well as bringing public attention to the stigma and discrimination that exists at both the recruitment stage and in relation to employees disclosing their health conditions. It also was to compliment and
strengthen the EPF and EMSP’s wider initiatives on tackling the multiple forms of discrimination faced by patients with chronic conditions.

The workshop demonstrated how many issues surrounding young people with chronic conditions transitioning into the labour market are still prevalent. The expectation of discrimination and stigma in the workplace, along with the unwritten attitudinal condition of being a liability, is still very much present. When applying for a job, fear of rejection is not unknown, and the consequences are compounded by young people’s experiences of negative employer attitudes. Moreover, the concept of quota systems and giving people with chronic conditions and/or disabilities preference among applicants for certain jobs probably suggests that they are employed because they have a chronic condition and/or disability, not because of their abilities. This unambiguous form of positive discrimination also affects how young people manage information about their health. They feel forced to share about their condition to get an interview, however by doing so they risk being subjected to negative reactions in the interview or at the workplace.

Youth with chronic conditions frequently have a great deal to contribute to the workplace and more action should be taken to encourage and support employers with hiring them. Training and resources should be provided to managers and employees to raise awareness of the impact that chronic conditions can have on an individual, and how they can be assisted through small adjustments or specific care requirements. Employees should not assume what someone can or cannot do and how their condition affects them, therefore a place for an open discussion should be created. In addition, where quota systems apply, they should be re-evaluated and designed to recruit young patients on merit, in competition with other workers without a chronic condition and/or disability.

CHALLENGES AND POTENTIAL SOLUTIONS ABOUT STAYING IN WORK AS A YOUNG PERSON WITH AN RMD

J. Andersen1,2, 1Lupus Europe, Romford, Essex, United Kingdom; 2EULAR Young PARE, Zürich, Switzerland; 3Lupus Dk, Gigtforeningen, Copenhagen, Denmark

Introduction: A lot of young people with RMDs experience difficulties when it comes to staying in work after diagnosis. Some employers see a young person with an RMD-diagnosis as a liability. They are afraid it will cause a lot of difficulties with sick leaves and less work effort and in the end cost them a lot of money. Often the young person hasn’t worked in the company for that many years (because of the age) and hasn’t had the chance to make themselves indispensable/a valued work force yet, which makes it easy/obvious for the employer to terminate their employment.

The process of getting a diagnosis can often cause long periods of sick leave in the beginning and many employers don’t understand that this will get better over time as the person gets used to having the disease and the medication has a chance to work properly.

Some young people choose not to tell their employer, that they have an illness at the beginning and many employers don’t understand that this will get better over time as the person gets used to having the disease and the medication has a chance to work properly.

ULTRASOUND AND MAGNETIC RESONANCE IMAGING FUSION OF IMAGES EVALUATION OF TENOSYNOVITIS – A PILOT STUDY ON A NEW IMAGING TECHNIQUE IN RHEUMATOID ARTHRITIS PATIENTS

M.A. Danielsen 1,2, 1Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup; 2Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

Background/Purpose: Image fusion is an advanced imaging technology, which enables fusion of ultrasound (US) and magnetic resonance imaging (MRI). This fusion gives for each US probe position an exact projection of the corresponding anatomical area on a previously obtained MR image, during a live US assessment. This study is the first to address image fusion of US and MRI tenosynovitis. The aim of this study was to assess and compare US and MRI visualisation of tenosynovitis using image fusion technique.

Methods: Fifteen rheumatoid arthritis patients with US verified tenosynovitis in the wrist or hand had an MRI performed of the affected wrist or hand. A subsequent image fusion was performed, i.e. the MR images and a live US assessment of one tendon sheath were fused. In order to compare the two imaging modalities quantitatively, the area of the tendon and tendon sheath in the transverse axis was measured on US and MRI for each image fusion. Due to partial volume artefacts (voxel containing two different tissues and therefore possessing a signal average of tendon and tendon sheath) on MRI two measures were performed; area 1) the circumference of the black tendon, i.e. excluding voxels containing two types of tissue 2) the circumference of the grey line that surrounds the black tendon, i.e. including voxels containing two types of tissue. Tenosynovitis was assessed using the proposed OMERACT semi-quantitative scoring system for US and MRI. US scoring was therefore based on both grey scale and Doppler, whereas MRI scoring was based only on post-contrast tenosynovial enhancement, measured as distance from the tendon to end of the enhanced tendon sheath.

Results: The median circumference area of the tendons and tendon sheaths on US and MRI 1 and 2 were respectively 0.16 (25.75 pct; 0.10;0.25), 0.9 (0.06–0.18) and 0.13 of (0.10;0.25) for the tendons and 0.18 (0.13–0.26), 0.27 (0.20–0.45) and 0.23 (0.16–0.40) for the tendon sheaths. Statistically significant differences were found for all measured areas between US and MRI, except for the US tendon area and the MRI tendon area 2 (Wilcoxon’s test; p=0.47). Overall agreement between US and MRI tenosynovitis scoring systems was good (see table 1).

Conclusion: In conclusion, we found that US and MRI have good agreement for quantitative assessment of tendons and scoring of tenosynovitis, when comparing the two modalities using image fusion, if the partial volume artefacts on MRI are included in the measure.

HOW AND WHEN TO ASSESS THE CERVICAL FACET JOINTS + DEMO

D.A. Borge 1 on behalf of EULAR Working Group Anatomy for the IMAGE.
1Instituto Paol de Reumatologia; 2University of Barcelona, Barcelona, Spain

At any given time, 10% of the adult population will be affected by neck pain. Although similar in incidence to low back pain, it has less of a socio-economic impact and uncommonly progresses to neurologic deficit. Pain may result from degenerative, traumatic or inflammatory processes involving the diarthrodial facet (zygapophysial) joints and/or the facet (medial branch of the dorsal dorsal ram) nerves. Although routinely evaluated by radiography, magnetic resonance imaging and computed tomography, high-resolution musculoskeletal ultrasound (MSKUS) imaging and guidance has become increasingly popular, particularly among pain management specialists, in the evaluation and treatment of these structures owing to its safety, portability, superior resolution and direct real-time visualization. This presentation will discuss the unique anatomy and sonoanatomy of the cervical spine and its innervation/vascularization with particular focus on the facet joints and nerves and the use of MSKUS in the evaluation and treatment of the facet joint/nerve with review of available evidence. Examination technique and sonoanatomy findings will be demonstrated.

HOW TO EVALUATE JOINTS IN JUVENILE IDIOPATHIC ARTHRITIS (JIA)

J. Vojinovic. Pediatric Rheumatology, Clinical Centre, Medical Faculty, University of Niš, Niš, Serbia

Ultrasound (US) has numerous advantages when used to examine joints in children compared to other imaging modalities. This include non-invasiveness, rapidity of performance, easy repeatability, high patient acceptability and lack of exposure to ionizing radiation. In addition, it does not require sedation for scanning in younger children. US is more sensitive than physical examination and examination of early disease that is not evident on physical examination. Lack of standardized precise definitions of grey scale (GS) and Power Doppler (PD) US findings in different age groups was the biggest limitation for its use. Additional difficulty is age dependent variability of normal sonoanatomy, due to maturation and ossification in children. That is why acquisition, interpretation and comparison of US images are completely different than in adults and had to be addressed specifically. All this may affect the validity of the technique, and without defined standardized examination technique, US can be a challenge in the childhood population. On the other hand, US as an imaging technique is considered to be examiner and equipment dependent. Studies resulting in good intra and inter-reader reliability and validity, based on specific definitions, are essential for its application as a diagnostic tool. Recently developed standardized image acquisition methodology, definitions of joint components in healthy children, as well as, definitions for synovitis components and its grading in GS and PD in children will be presented in details. US allow precise and thorough visualization of inflammatory and destructive joint abnormalities, including synovial hyperplasia, joint effusion, cartilage damage, bone erosion, tenosynovitis and enthesisopathy. In JIA ultrasound is considered particularly useful for its ability to detect subclinical synovitis and improve classification of JIA patients into the subtypes. Current evidences about application of ultrasound in JIA can improve definition of remission necessary to optimize treatment strategies. Due to peculiarities of US examination and image acquisition in children additional educational efforts among pediatric rheumatologists are required for expanding this imaging modality in daily practice.

PsA: an integrated perspective

CAN IMAGING BE A PREDICTOR OF PSORIATIC DISEASE?

M. Østergaard. Copenhagen Center for Arthritis Research, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark

Early detection of inflammatory joint diseases is very important to allow prompt initiation of effective therapies. Identifying patients with early arthritic disease can be challenging by conventional clinical, laboratory and radiographic methods, and more advanced imaging modalities such as computed tomography (CT), magnetic resonance imaging, ultrasonography (US) and various nuclear medicine techniques can provide additional information.

This talk describes the current knowledge on the value of different imaging modalities for 1) predicting development of psoriatic disease in undifferentiated patients 2) predicting development of psoriatic arthritids (PsA) in patients with psoriasis with and without musculoskeletal pain and 3) predicting the disease course in patients with PsA.

DOI: 10.1136/annrheumdis-2017-eular.7188

PATHOLOGIES ACROSS THE TISSUES IN PSA

The psoriatic disease concept includes the skin disease psoriasis and joint disease psoriatic arthritis. Increasingly, prevalent comorbidities such as obesity and cardiovascular disease are considered to be an integral part of the psoriatic disease concept in many patients. Within this disease concept, accumulating evidence indicates molecular and cellular cross talk between affected organs and tissues. Skin inflammation affects the bone; nail disease is associated with specific types of arthritis; inflammation links to cardiovascular disease; skin or joint disease may contribute to depression. Novel therapeutic strategies are reaching psoriatic disease patients as never before. Their global impact could be envisioned from a holistic perspective, optimizing the strategy chosen as determined by the active molecular and cellular network that triggers and sustains disease.

Thus, linking the joints with the skin and other organs involved is proposed as an entry point towards personalized medicine in a complex disease.

**SP0080** RECURRENT EPISODES OF FEVER AND ARTHRITIS IN ADULT PATIENT

C. Deacu. Department of Rheumatology and Internal Medicine, Stanta Maria Hospital, Bucharest, Romania

Background: Familial Mediterranean Fever (FMF) is a relatively rare condition that belongs to the more recent group of autoinflammatory diseases (AiDs)\(^1\). It primarily affects patients with Mediterranean or Middle Eastern origins and its clinical setting includes short, recurrent episodes of fever, serositis, skin rash and a high risk of amyloidosis\(^2\). FMF is an autosomal recessive transmitted disease and several mutations of the Mediterranean fever gene (MEFV) on chromosome 16 have been identified\(^3\). Patients respond well to colchicine therapy or if necessary, biological therapy with anti-IL1, IL6 or anti-TNF could be initiated\(^4\). Establishing the right diagnosis might raise difficulties for rheumatologists who are not fully accustomed to this condition.

**Objectives:** To evaluate the clinical course, specific features and treatment difficulties of a male patient diagnosed with FMF in adulthood, based on the diagnosis (LE) of a case reported in the literature.

**Methods:** Case-description using patient’s medical records and investigations.

**Results:** This is the case report of a 37-year old male patient currently admitted for right knee arthritis and high grade fever (39.1°C). His medical history dates back to age 16 when he presented in the Pediatric Department with recurrent episodes of prolonged fever (up to 40°C), diffuse abdominal pain together with myalgia, arthralgia accompanied by increased acute phase reactants; after various sources of infection and hematological malignancies were excluded, physicians noted positive low titer ANA (1/20) but normal complement fractions, absent lupus (LE) cells. Further medical investigations showed a negative rheumatoid factor, ACPA, negative antibodies’ panel (dsDNA, Sm, Ro, U1-RNP) and absent cryoglobulins but a positive HLA B27. No signs of sarcoidosis were detected on the x-ray. Patients’ repeated complaints of knee or ankle arthritis together with later finding of positive anti-Salmonella and anti-Shigella antibodies led to establishing the diagnosis of reactive arthritis. Due to symptoms’ persistence and reoccurrence under non-steroidal anti-inflammatory drugs, he was prescribed high dose corticosteroids and sulfasalazine. At age 20 the patient presented with recurrent arthritis of the knees and ankles, fever (38.5°C) and abdominal pain with markedly elevated inflammatory markers. The abdominal ultrasound highlighted a splenomegaly and peritonitis. Colchicine treatment was initiated and his favorable response led to MEFV genetic testing that revealed a mutation of the assay locations.

**SP0081** THE T CELL RESPONSE TO THERAPEUTIC ANTIBODIES

B Mailleer, Institute Frederic Joliot, CEA, gif sur Yvette, France

Therapeutic antibodies (TMabs) are part of the best successful therapeutic products of the last decades. They are currently used to treat many inflammatory diseases such as rheumatoid arthritis (RA) and bowel diseases and represent worldwide a market of several billions of dollars. However the therapeutic potential of these intrinsically powerful biologicals is tempered by a drawback to be potentially immunogenic and therefore might elicit anti-drug antibodies (ADA). ADA could dramatically reduce the efficacy of the drugs or might provoke allergic reactions. Because generally self-proteins are less immunogenic than foreign proteins, the sequence in which antibodies have been humanized. However humanization even at the highest level does not fully guarantee the lack of immune responses demonstrating the important need to know more about ADA response. Because T cells are known to initiate the ADA response, we are currently investigating the T cell response to immunogenic therapeutic antibodies. With the perspective of immunogenicity prediction, we quantified the number of very rare T cells specific for therapeutic antibodies in the blood of normal donors and found a good concordance between the number of T cells specific to them and their respective clinical immunogenicity level.

We then identified the CD4 T cell epitopes of four immunogenic TMabs with different levels of humanization and therapeutic potential. This is the case report of a 37-year old male patient currently admitted for right knee arthritis and high grade fever (39.1°C).

**Disclosure of Interest:** None declared

**SP0082** IMMUNOGENICITY OF BIOLOGICS IN INFLAMMATORY BOWEL DISEASES

A. Gils. Dept of Pharmaceutical Sciences, KU Leuven, Leuven, Belgium

Anti-tumor necrosis factor-alpha and anti-integrin monoclonal antibodies show great benefits for inducing and maintaining remission, healing the mucosa and restoring the quality of life of patients with inflammatory bowel diseases. The therapeutic potential of these intrinsically powerful biologicals is tempered by a high variability in clinical response. Whereas primary non-response is defined as the lack of clinical response to treatment, assessed for up to 8–12 weeks after initiation, secondary loss of response is defined as loss of clinical benefit after initially responding which can be attributed to disease-related or drug-related factors. Assays have been developed to determine the concentration of the therapeutic antibody in serum of the treated patient. The trough concentration is the concentration just before the next administration and for practical reasons therapeutic drug monitoring is mainly based on measurement of these trough concentrations. Several studies have reported correlations between trough concentration of infliximab, adalimumab, golimumab, vedolizumab and clinical outcome. Optimal therapeutic windows have been defined for both infliximab and adalimumab. A panel of prospective studies in which dosage regimens are adapted in order to achieve target trough infliximab concentrations that correlate with beneficial therapeutic outcomes have been initiated.

Immunogenicity is the capability of biologics to elicit an unwanted immune response that results in the formation of anti-drug antibodies. Anti-drug antibodies can be non-neutralizing or neutralizing. Non-neutralizing antibodies do not impair the drug-target interaction but may increase clearance of the drug resulting in lower serum concentrations. Neutralizing anti-drug antibodies compete with the target antigen and may antagonize the biologic’s effect. As a result, in addition to the enhanced clearance of the drug, a number of anti-drug antibody assays to quantify the immunogenicity of biologicals have been developed. Most of the assays quantify the total amount of anti-drug antibodies but comparing anti-drug antibody concentrations between different assays is hampered by the...
use of different calibrators and by the fact that drug tolerance differs among assays ranging from extreme drug sensitive over various forms of drug tolerant to drug resistant anti-drug antibody assays. The clinical relevance of the different type of anti-drug antibody assays remains to be proven.

Combining therapeutic drug concentrations and anti-drug antibody concentrations with relevant patient, disease and drug information will lead to optimal dosing of patients aiming at optimal clinical, biochemical and endoscopic outcomes.

**SP0083** AS A RHEUMATOLOGIST, DOES IT HAVE ANY CONSEQUENCE IN MY DAILY PRACTICE?

J.W. Blijisma, Rheumatology & Clinical Immunology, UMCG, Utrecht, UTRECHT, Netherlands

It is nearly inevitable that when we administer foreign (even humanned) proteins intravenously or subcutaneously to a person, that said person will develop antibodies to that (foreign) protein. This happens to most of our patients when we administer biologicals; depending on the sensitivity of our methods, we can measure these anti-bodies either not or not at all. These antibodies start becoming a problem when they are actually binding the administered biological, thus making the active drug less available for its targeted function. We can evaluate this by measuring the actual drug-level, so called trough level. Numerous reports have been published, showing that there is indeed a negative correlation between e.g. anti-tumor necrosis factor (TNF) drug antibodies and the efficacy of anti TNF in the treatment of RA. It has also been shown that adding methotrexate (MTX) to the anti-TNF treatment improves its efficacy and reduces the level of anti-drug antibodies. Probably only 10 mg MTX weekly would be enough to obtain this effect.

So what do I do as a clinician when I observe that a patient, who originally did very well, loses response to her biological? Do I measure possible anti-biologic antibodies? This activity measured on trough level shows no cross-reactivity to other biologicals (even from the same class of action), except to its biosimilar (underscoring that it is a real biosimilair). In case there is doubt whether a patient is actually using the biological we could better measure the drug-trough level; but –in my practice- this question seldom arises in patients with active arthritis, being treated with a biological.

Measuring drug-trough levels is a completely other item, and perhaps more relevant. Biologicals are in general given in a standard fixed dosage, while there are clear differences in patients characteristics, that could influence biavailability of the biological. In addition when the disease is more active, it could be that more biological is needed to temper the inflammation compared to low disease activity, where perhaps a lower dosage would be more effective. To guide physician and patient in personalizing and optimizing treatment with biologicals measuring drug-trough levels might be helpful. Different studies have been performing trying to use through level of the drug in adapting the dosage, and even in predicting possibility to stop the drug treatment. This area is still being evaluated and it is too early to make firm statements, but with a look at cost-effectiveness this will certainly become relevant.

Coming back to the original question: do I use anti-drug antibodies in my daily practice to guide treatment: no, it doesn’t influence my decisions. Will I use in the future drug trough levels to guide treatment decisions: this could well be, but it is too early to make a final decision yet.

Which target/ outcome is more relevant in the management of SLE?

---

**SP0084** BIOLOGICAL TARGETS IN SLE

C. Chizzolini on behalf of Swiss SLE Cohort Study and PRECISESADS Consortium, Immunology & Allergy, Geneva University Hospital, Geneva, Switzerland.

SLE is a prototypical condition characterized by the complete subversion of immunological tolerance and the generation of autoantibodies directed against a wide array of ubiquitous and tissue-specific antigens. This is possible because the joint dysregulation of the innate and adaptive arms of the immune system; which results from multiple gene polymorphisms, each contributing marginally, deregulating the immune system. Alteration of certain cells, i.e. activating naïve and T and B cells, enhanced responses of antigen-presenting cells resulting from the altered disposal of apoptotic cells, as well as dysregulation of cytokine circuitries including regulatory networks.

Pathogenic mechanisms resulting in clinically overt SLE very likely are heterogeneous among individuals. Thus, the identification of biological targets in SLE goes also with the identification of selected modules of gene activation in distinct individuals. Very strong signals indicate that type I interferon (IFN) may contribute to autoimmunity in a large proportion of SLE individuals and therapeutic trials targeting IFN signaling suggest the clinical relevance of this mediator. B cells/plasmablasts are also relevant and obvious targets. Refinements in our understanding in B cell sub setting and/or the timing in disease development in which they play a relevant role should result in defining the appropriate targets specific to this cell lineage. Gene modules activated during flares suggest that neutrophils in a subset of individuals may also be relevant targets. Cytokine affecting T cell differentiation, in particular T follicular helper cells, represent additional relevant targets.

Within the last several years a number of novel biological targets have been identified in SLE. However, a single biological agent has been approved for SLE treatment in the last five years. This underscores the difficulties encountered when translating validated targets in efficacious therapeutic agents. This stress the need for careful preclinical evaluation. It further emphasizes the need of small phase II clinical trials based on stringent inclusion criteria aiming at precisely identifying individual groups more likely to respond to validate the target. Current progress made in the identification of molecular signatures in individuals with SLE will offer the tools for the requested accurate selection.

**SP0085** PATIENT REPORTED OUTCOMES

M. Schneider, Policlinic & Hiller Research Unit for Rheumatology, HHUD, Düsseldorf, Germany.

In SLE as in other rheumatic diseases, the most relevant target of intervention should be a status with controlled disease process assuring no further accrual of damage. If actual expert discussions like DORIS define the frame of such a status as validated lupus disease activity instrument, serologic activity and therapy – because of harm - are the dimensions of remission with its duration as additional factor for outcome. Patient reported outcomes (PROs) were not included. Otherwise, if payers and reimbursement system decide about relevance, patient outcomes are clear of highest importance as target.

Looking on the evidence of PROs for outcome in SLE, PROs were never used as primary endpoint in clinical trials. In RCTs, PROs were often collected and mostly explorative analysed. There is no evidence that PROs can validly define the above described status of controlled disease. But from systematic analyses in RA, we know that pure PRO like VAS of general health status and semi PRO like tender joints are at least as relevant as more ‘objective’ criteria like swollen joints or CRP as clearly exhibited by the ACR/EULAR remission criteria for RA.

The challenge in SLE is that the discrepancies between patients’ and physicians’ perception and perspectives are even more distinct than in RA. Sometimes, there is the expression that physicians and patients are describing different diseases. The burden of illness in lupus is better defined by pain than by organ manifestations; the overall survival in SLE is more related to lupus nephritis than to fatigue. It is obvious that physicians should analyse the actual clinical symptoms and integrate the future consequences of their actual management in their decision, and patients are more focused on release of their actual burden.

Until today, these different and divers perspectives are no integrated, neither in RCTs nor in daily care. But such integration is mandatory, because no side imagines the complete picture of lupus, which may also produce to the poor results of clinical trials. In routine care, this behaviour causes frustration and mental distress, optimal results are prohibited.

So, the answer to what is more relevant in the management of SLE patients - clinical targets, biological targets or PROs – is the integration of all important aspects of lupus. This implies more than the statistical evaluation of the best items of all three aspects, it is the active involvement of patients in their care: patient empowerment in SLE, a fruitful process, in which both sides have to learn a lot and find about each other.

**JOINT EULAR - EFIS SESSION: TILTING THE BALANCE: FROM DISEASE TO TOLERANCE INDUCTION**

H.-D. Chang, German Rheumatism Research Center Berlin, Berlin, Germany

While conventional state-of-the-art immunosuppression can lead to significant...
improvement for patients suffering from rheumatic diseases, only in rare cases a therapy-free remission is achieved. In most cases stopping of treatment results in disease relapse. Apparently, components of the immune system are refractory to conventional immunosuppression and can drive the inflammation. Experimental and clinical evidence suggests that cells of the immunological memory contribute to disease perpetuation via immunosuppression and if pathogenic play a major role in the chronication of the disease. In particular long-lived memory plasma cells secreting autoantibodies represent a major therapeutic challenge. Once generated, they are not subject to physiological and even conventional therapeutic immune regulation. Their elimination may be prerequisite to curative therapies. A detailed understanding the lifestyle of long-lived memory plasma cells will be important to address this cell type therapeutically.

DOI: 10.1136/annrheumdis-2017-eular.7257

A number of groups have developed methods to generate “tolerogenic” antigen presenting cells (APCs) that mimic the cells which regulate self-tolerance in health. It is hypothesised that administration of such cells, loaded with autoantigens, to patients with autoimmune disease should be able to overcome autoreactivity and re-establish immune regulation. Our group has developed a therapeutic approach based upon autologous tolerogenic dendritic cells, which we derive from dividing peripheral blood monocytes. Unlike conventional mature DC, which produce IL-12p70 and other pro-inflammatory cytokines, tolDC produce no IL-12p70 but high levels of IL-10. They deviate naïve T-cells towards an IL-10-producing, anti-inflammatory phenotype and induce hyporesponsiveness in memory T-cells. In mixed cultures they mature, pro-inflammatory DC and down-regulate T-cell activation. Their phenotype is stable in the presence of pro-inflammatory stimuli. Equivalent murine tolDC switch off collagen-induced arthritis, with immune deviation from IL-17 to IL-10 production by CD4+ T cells and a reduction in type II collagen-specific T cell responses. In a phase I trial (AutoDeCRA), we demonstrated that these cells are safe when administered into a recently inflamed target knee joint of patients with inflammatory arthritis. However, in that safety study we were unable to demonstrate a tolerogenic effect in vivo. Furthermore, we have reason to believe that administered cells may remain in the target joint, whereas a disease-modifying effect is likely to require migration to secondary lymphoid tissues. Moving forwards we are designing a study that will address the optimal administration route for tolDC, based on a technique to track the cells in vivo and to measure their effect on auto-reactivity.

What to do about comorbidity?

The comorbidity paradigm views comorbid conditions in patients with rheumatic diseases as “extra” conditions that negatively affect disease control and outcomes. This view is well supported by the prevalence of comorbidity, which is extremely high in these patient populations and increases with age. Comorbidity is frequent in rheumatoid arthritis and/or cervical spondylosis, osteoarthritis, psoriatic arthritis, and lupus. The impact of comorbidity on disease activity and on the efficacy of drugs is an important question for clinicians.

Data visualisation: tables and graphs for publication and presentation I & II

SP0091 DATA VISUALISATION: TABLES ANDGRAPHS FOR PUBLICATION AND PRESENTATION
M. Boers
Epidemiology & Biostatistics; Amsterdam Rheumatology and Immunology Center, VU University Medical Center, Amsterdam, Netherlands

This workshop (held both on Thursday and on Friday) is an introduction to the principles of good graph and table design as pioneered by Cleveland1 and Tufte2 and updated by Few3 so that the participant can better answer the following questions:

Which of the messages in my research results requires a graph or table? Recognizing how graphs improve on simple statistics and convey much more information. Knowing when a table is better, or keeping the data in the body text.

How can I best convey the message? Striving for clear vision by choice of graph, scaling, discrimination of data series, minimizing non-data ink, avoiding chart junk. Striving for clear understanding through a balance between data and explanation. Using order, subheadings, formatting and rules to guide your reader through your table data.

Is my graph/table truthful? Creating a direct proportion between graph and data quantities, avoiding forms prone to misinterpretation, labels to prevent ambiguity; keeping data in context, avoiding more dimensions in the graph than in the data. This year’s course will extend introductory material available via YouTube clips on the ARD website (ard.com)!

Direct link: https://www.youtube.com/playlist?list=PLXU14EQbU_V9JpmolAKsaCC0VjJzbxzAN

Note that you can also sign up for a special lecture followed by a poster tour after the session, devoted to poster design!

Difficult to reach patient groups

SP0092 THE VICIOUS CIRCLE OF EDUCATIONAL LEVEL AND RISK OF POVERTY IN RHEUMATOID ARTHRITIS - RESULTS OF A CROSS-SECTIONAL MULTICENTER STUDY IN GERMANY
M. Zaenker 1,2, *; 1Rheumatology Dept., Immanuel Klinikum Bernau & Heart Center Brandenburg, Bernau; 2Brandenburg Medical School, Neuruppin, Germany

This lecture will provide an overview on the dimensions of poverty in general and describe methods of assessing the risk of poverty in patients with rheumatoid arthritis (RA).

Based on results of a cross-sectional multicenter study of RA-patients from outpatient-clinics in Brandenburg and Saarland, Germany, this talk will give a rationale for how patients with RA are threatened by poverty due to treatment-related expenses, disability and early retirement compared to the general population.

It will be highlighted, that the equalized disposable income of RA patients is significantly lower than in general population and RA patients share a doubled risk of poverty, even in social-welfare well-secured countries such as Germany. Further, the talk will demonstrate that both lower educational level and socioeconomic state are associated with more severe disease course of RA and various underlying mechanisms will be discussed.

THE SWEDISH EXPERIENCE - HOW A PATIENT ORGANISATION COULD REACH OUT TO IMMIGRANTS AND DEVELOP THROUGH INTEGRATION

T. Diao. The Swedish Rheumatism Association (SRA), Stockholm, Sweden

Background: in the early years of the new millennium many European countries faced an increased number of immigrants due to the second Iraqi war that affected the whole sub region. Some of these immigrants reached the Swedish shores and many of them have RMDs.

In an attempt to help integrate them to the Swedish society, the SRA reached out to these immigrants. The SRA decided to act together with other actors to facilitate the inclusiveness of these minorities into the society.

Methods: To achieve this giant task the SRA applied and received financial support from the Swedish General inheritance fund and collaborated with several health providers, the employment office, some Folk High Schools, ABF (Adult Liberal Education Association) and our local chapters and joiners in 5 of the biggest cities: Stockholm, Örebro, Gothenburg, Norrköping and Umeå.

Results: This experience was a breakthrough for the SRA. The SRA was the first patient organisation that walked this new path. The iconoclastic experience enriched the SRA and gave it a great knowledge of how to reach out to minority groups and giving them the tools to be a fully part of the society despite the burden of the RMDs.

Conclusion: The SRA increased its knowledge, capacity and flexibility during this experience. Today the SRA is cited as a reference in Sweden when it comes to reaching out to different minorities suffering of RMDs. Many organisations are now lining up to work with the SRA in these matters. In 2007 the SRA received the price for best project from the Swedish General Inheritance Fund.

EULAR Projects in musculoskeletal imaging

EULAR RECOMMENDATIONS FOR THE USE OF IMAGING IN THE DIAGNOSIS AND MANAGEMENT OF LARGE VESSEL VASCULITIS IN CLINICAL PRACTICE

C. Dejaco 1,2 on behalf of Taks force to develop the EULAR recommendations for the use of imaging in LVV.

1Rheumatology, Medical University Graz, Graz, Austria; 2Rheumatology Service, Hospital of Bruneck, Bruneck, Italy

Large vessel vasculitis (LVV) is the most common form of primary vasculitits comprising giant cell arteritis (GCA) and Takayasu arteritis (TA).

Although temporal artery biopsy and conventional angiography are still the gold standard diagnostic tests for GCA and TA, respectively, modern imaging methods including ultrasound, magnetic resonance imaging, computed tomography (CT) and 18F-FDG positron emission tomography - CT are increasingly used. In clinical practice however, these methods are inconsistently applied and rheumatologists and other specialists are still uncertain about the specific value of these modalities. This project has been conducted with the aim to provide user-friendly, evidence-based recommendations for the use of modern imaging methods for diagnosis, monitoring and outcome prediction of primary LVV. Specifically, we give advice on 1) when to use these imaging techniques, 2) what specialists might conclude from imaging results and 3) what technical standards are required to achieve high quality imaging results.

These recommendations aim at an early and specific diagnosis as well as an improved assessment of LVV, thus ultimately leading to better outcomes of patients with LVV.

THE IMPORTANCE TO DIFFERENTIATE NORMAL FROM ABNORMAL CAPILLAROSCOPIC IMAGES FOR AN EARLY DIAGNOSIS OF DISEASE

P. Collado. Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain

Musculoskeletal ultrasound (MSUS) is a readily available and suitable imaging technique to asses the immature skeleton of paediatrics in different musculoskeletal rheumatic diseases (MSRD). Besides the potential operator–dependent feature of this technique, the age-related variation of normal sonoanatomy due to the child’s growth makes more difficult acquisition, interpretation and comparison of images than in adults. Hence, to use MSUS as a valid technique for diagnosis of MSRD, it is needed to develop specifically evidence-based recommendations for paediatrics. Additionally, the variability in background and experience of ultrasonographers in different countries requires an international multidisciplinary contribution for an optimal standardization of MSUS performance in paediatric MSRD.

Reflecting the perceived need for developing recommendations on the standardization of procedures for performing MSUS examination in MSRD, a collaborative international EULAR/PReS task force was convened. In the talk, it is going to summarize the original proposed specific aims and update on work for each aim previously mentioned. A systematic literature search was performed in Medicine and Embase from databases inception to 1st June 2016 as the first step. One hundred and eighty-eight articles were finally included after reviewing 6059 records identified. The scanning for the knee and the ankle joint was the most common reported, whereas the paediatric wrist was uncommon.

THURSDAY, 15 JUNE 2017 EULAR Projects in musculoskeletal imaging

EULAR RECOMMENDATIONS FOR THE USE OF IMAGING IN THE DIAGNOSIS AND MANAGEMENT OF LARGE VESSEL VASCULITIS IN CLINICAL PRACTICE

C. Dejaco 1,2 on behalf of Taks force to develop the EULAR recommendations for the use of imaging in LVV.

1Rheumatology, Medical University Graz, Graz, Austria; 2Rheumatology Service, Hospital of Bruneck, Bruneck, Italy

Large vessel vasculitis (LVV) is the most common form of primary vasculitits comprising giant cell arteritis (GCA) and Takayasu arteritis (TA).

Although temporal artery biopsy and conventional angiography are still the gold standard diagnostic tests for GCA and TA, respectively, modern imaging methods including ultrasound, magnetic resonance imaging, computed tomography (CT) and 18F-FDG positron emission tomography - CT are increasingly used. In clinical practice however, these methods are inconsistently applied and rheumatologists and other specialists are still uncertain about the specific value of these modalities. This project has been conducted with the aim to provide user-friendly, evidence-based recommendations for the use of modern imaging methods for diagnosis, monitoring and outcome prediction of primary LVV. Specifically, we give advice on 1) when to use these imaging techniques, 2) what specialists might conclude from imaging results and 3) what technical standards are required to achieve high quality imaging results.

These recommendations aim at an early and specific diagnosis as well as an improved assessment of LVV, thus ultimately leading to better outcomes of patients with LVV.

Disclosure of Interest: C. Dejaco Grant/research support from: Pfizer, MSD, Esaote, Speakers bureau: Pfizer; MSD, AbVie, Celgene, UCB, Roche, BMS, GSK, Novartis, Sanofi, Sano.

THE IMPORTANT TO DIFFERENTIATE NORMAL FROM ABNORMAL CAPILLAROSCOPIC IMAGES FOR AN EARLY DIAGNOSIS OF DISEASE

P. Collado. Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain

Musculoskeletal ultrasound (MSUS) is a readily available and suitable imaging technique to asses the immature skeleton of paediatrics in different musculoskeletal rheumatic diseases (MSRD). Besides the potential operator–dependent feature of this technique, the age-related variation of normal sonoanatomy due to the child’s growth makes more difficult acquisition, interpretation and comparison of images than in adults. Hence, to use MSUS as a valid technique for diagnosis of MSRD, it is needed to develop specifically evidence-based recommendations for paediatrics. Additionally, the variability in background and experience of ultrasonographers in different countries requires an international multidisciplinary contribution for an optimal standardization of MSUS performance in paediatric MSRD.

THURSDAY, 15 JUNE 2017 Capillaroscopy I & II

THE IMPORTANCE TO DIFFERENTIATE NORMAL FROM ABNORMAL CAPILLAROSCOPIC IMAGES FOR AN EARLY DIAGNOSIS OF DISEASE

V. Smith, Department of Rheumatology, Faculty of Internal Medicine, Ghent University Hospital, Ghent University, Gent, Belgium

Medical doctors frequently get patients with Raynald’s phenomenon (RP), a frequent symptom in the general population, referred. The importance of distinguishing normal capillaroscopic findings from (pathomomonic) abnormal (pathological) findings, lies in the fact that this distinction allows the differentiation between a primary RP (not connected to any connective tissue disease [CTD]) from a secondary RP due to systemic sclerosis (SSc) and diseases of the scleroderma spectrum. What is normal in primary RP? A normal capillaroscopic pattern, by qualitative assessment, is characterized by a homogeneous distribution of hairpin shaped capillaries as a “comb-like structure”, with a density of between 9–14 capillaries per mm. Yet, there exists a wide intra- and inter-individual variety in a normal population which will be discussed in this session. What is pathomomonic abnormal in patients with RP due to SSc? Patients with the RP who have an underlying clinically recognizable (~ with skin involvement) SSc show a very characteristic combination of capillary abnormalities in the nailfold, which can easily be assessed through qualitative assessment (~ pattern
WHY CAPILLAROSCOPY CAN PREDICT DISEASE SEVERITY

DIAGNOSTIC AND THERAPEUTIC ULTRASOUND-GUIDED

HOW TO PERFORM A QUICK AND EFFICIENT PHYSICAL EXAMINATION

W. Herman, Department of Rheumatology and Clinical Immunology, Kerckhoff-Klinik, Bad Nauheim, Germany

One of the most important indications for performing capillaroscopy is to differentiate between primary and secondary Raynaud’s syndrome. Different kinds of microscopes are at hand and generally vary in terms of picture quality or price. Before purchasing a microscope and capillaroscopy software, several considerations about the required standards of examination should be made; some of which are summarized as follows:

- The region of interest (ROI). Normal capillaries have a mean diameter of about 8 μm. For an accurate assessment a magnification of 100–200x is recommended, for an overview the magnification of 50x is sufficient.
- Measurement. Beside qualitative measures like changes in vessel architecture, there should be the possibility of quantifying the number of capillaries/mm or vessel diameters.
- Documentation. All parts of the examination have to be stored and assigned to patient and case.
- Practical aspects and handling of the device.
- Different kinds of microscopes are on the market of which three will be discussed in detail. Briefly summarized:
  - Stereo microscopes.
  - Advantages: Very good image quality, zooming in and out without problems, relatively easy to use.
  - Disadvantages: device is not mobile, in patients with finger contractures examinations are difficult to perform, relatively high costs.
  - Videocapillaroscopes:
    - Advantages: Very good image quality, easy to use, “gold standard” for capillaroscopy.
    - Disadvantages: No overview, zooming in and out not applicable (change of lenses required), relatively high costs.
- USB microscopes:
  - Advantages: low costs, zooming in and out without problems, easy to use.
  - Disadvantages: limited picture quality, documentation laborious.

Selecting a capillaroscopic device depends on the conditions of use (“quick look” vs. “academic evaluation and follow up”), which should be clarified before buying a device. The price range is significant and usually differs between 100€ for USB microscopes and up to 10,000€ for stereo and videocapillaroscopes.

HOW TO ASSESS US COMPETENCY SKILLS

H.B. Hammer
Dept of Rheumatology, Diakonhjemmet Hospital, OSLO, Norway

To optimize and standardize musculoskeletal ultrasonography education for rheumatologists, there is a need for competency assessments addressing the required training and practical and theoretical skills. Because of the increasing use of MSUS in rheumatology, there has been a focus over the past years on training.

A minimum training requirements are described by The European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB) where a 3 levels competency assessment (COMPASS) has been developed for rheumatologists, including an in-detail description of what theoretical and practical competencies to be acquired at each level with a related log book (1). The rheumatology-COMPASS levels are closely related to the levels of the EULAR MSUS courses, thereby ensuring that the content is supported by already provided courses such as the EULAR and EULAR-endorsed MSUS courses to facilitate the implementation of the rheumatology-COMPASS. In COMPASS level 1 the course contents resemble the EULAR MSUS basic and intermediate courses, level 2 resembles the EULAR MSUS advanced course whereas level 3 requires attendance in a “teach-the-teachers course” or experience as a teacher in at least 2 international MSUS courses. Level 3 also includes an academic level requiring research activity and acceptance of level 1 and 2 sonographers for training.

The EULAR MSUS courses have been organized since 1998 and the interest in these courses has been increasing. In 2007, the first 3 level EULAR MSUS course was established and the 3 level courses (basic, intermediate and advanced) have been running ever since in relation to the EULAR congress, focusing mainly on the relevant content on the individual levels and the distribution between practical and theoretical skills.

EULAR has developed the following competence levels: level 1 and 2. The EULAR level 1 includes the performance of EULAR Online MSUS course and attendance to basic, intermediate and advanced MSUS courses, where attending the intermediate and advanced courses require a certain number of US examinations (however, if already reached COMPASS level 1, 2 or 3, there is no need of repeating EULAR courses), and the advanced course requires in addition to pass a practical examination. The EULAR level 2 competency is organized to ensure a minimum level of US knowledge for teachers in MSUS courses (2). This level includes the EULAR Teach the Teachers course as well as passing a theoretical and practical examination. Since there is a growing number of EULAR endorsed MSUS courses, it is of highly importance that the teachers in these courses have equal qualifications thereby providing comparable training and competencies beneficial for the clinical use of US.

Information about the competence requirements is found at the EULAR website (http://www.eular.org).

FRIDAY, 16 JUNE 2017 Comorbidities in rheumatoid arthritis

SP0108 HERPES ZOSTER: HOW TO PREVENT, TO DIAGNOSE AND TO TREAT L. Calabrese, Rheumatology, Cleveland Clinic, Cleveland, United States

Herpes Zoster is a major public health problem and is an infection that results from re-activation of latent varicella infection acquired most commonly naturally or more recently through immunization. The incidence of HZ is approximately twice that of the general population in patients with immune mediated inflammatory diseases (IMIDs). Underlying mechanisms are largely those which compromise cell mediated immunity and epidemiologic risks largely follow immunosenescence patterns (i.e. aging). Rheumatologists use a large variety of immunosuppressive drugs which further increase the risk of HZ and are obliged to recognize the clinical syndrome, its complications, apply effective therapy and be actively engaged in strategies to maximize immunization and prevention. This discussion will focus on recent advances in each of these areas highlighting newly described complications of HZ such as stroke and advances in vaccine development.

FRIDAY, 16 JUNE 2017 Life-threatening presentation of rheumatic diseases

SP0109 ACUTE RESPIRATORY FAILURE, MACULAR-PAPULAR RASH, INDURATIVE EDEMA OF THE EXTREMITIES AND CERVICAL LYMPHADENOPATHY IN A 6-WEEK-OLD INFANT C. Birolo, Pediatric Rheumatology Unit, Department for Woman and Child Health, University of Padua, Italy, Padua, Italy

Case report: A previously healthy 40-days-old male infant, from non-consanguineous parents from Morocco, presented in a peripheral hospital with fever for 48 hours, associated with rhinorhea, mild diarrhea and progressive irritability during the last 24 hours. Initial laboratory studies revealed elevating acute phase reactants (CRP 116 mg/L), mild neutrophilia, elevated liver enzymes (AST 315, ALT 174 U/L), direct hyperbilirubinemia, dissecoagulopathy. Cerebral spinal fluid analysis and microbiology cultural workup resulted negative. A wide-spectrum antibiotic and antiviral therapy was initiated. On the 6th day of illness he developed diffuse macular-papular rash, indurative edema of the extremities, right cervical lymphadenopathy and bilateral conjunctival injection. On the basis of a certain clinical diagnosis of Kawasaki disease and the infant was treated with IVIG 2 g/kg. An echocardiography performed prior to the IVIG infusion showed homogeneous dilated coronary arteries (left coronary artery 3.2 mm, right coronary artery 2.2 mm). Twelve hours after the end of IVIG infusion, the child presented a rapidly progressive, severe respiratory failure requiring endotracheal intubation and was transferred to our ICU. On admission (day 7th), physical examination revealed a feverish, critically ill infant with hepatomegaly (5–6 cm below the right costal margin), diffuse macular-papular rash, “sock-like” erythema and swelling of the feet, chellitis, bilateral conjunctival injection and right cervical adenopathy. The urine output was markedly decreased; he rapidly developed hemodynamic instability with hypotension and tachycardia. Complete blood count showed anemia (6.8 g/dL), thrombocytopenia (16,000/mm3), elevated CRP (240 mg/L), hypalbuminaemia (18 g/dL) and hypofibrinogenemia (0.83 g/L); liver enzymes were normal. Intensive ventilatory and hemodynamic support therapy were started, in addition to a massive transfusional regimen. Given the clinical and hematologic picture, the diagnosis of MAS was considered and eventually confirmed on the next day from very high levels of IL2-R above the normal value (61 U/L) and hypertriglyceridemia (181 mg/dL) [2]. The clinical suspicion was supported by persistent cytopenia despite daily transfusions, low erythrocyte sedimentation rate (3 mm/h) with concomitant rising CRP, elevated IL2-R level (28.320 KUL) and decreased NK function. The patient was treated with high dose methylprednisolone pulse therapy (25 mg/kg) for 3 consecutive days 12–14), followed by a maintenance of 1 mg/kg/daily. By day 15th, a progressive decline in inflammatory markers and a concomitant improvement of general conditions was observed, with the possibility to discontinue inotropic support on day 12th and invasive ventilation on day 25th. Since day 17th, a diffuse cutaneous desquamation was noted. The fever settled on day 35th. Echocardiography follow-up revealed an increasing, irregular dilation of left (max 5 mm) and right (max 3.5 mm) coronary arteries, with a progressive left ventricular apex hypokinesia, but a stable ejection fraction (55%). ECG showed persistent repolarization abnormalities. Of note, Adenosinuric-PCR was found positive in the bronchoalveolar washing performed on admission. The differential diagnosis included: Kawasaki disease complicated by respiratory distress syndrome and MAS, familiar hemophagocytic lymphohistiocytosis, autoimmune lymphoproliferative syndrome, cryopyrinopathies and immunodeficiencies. The child presented a rapidly progressive, severe respiratory failure requiring intensive support. These two complication are rarely associated to KD. In this particular case, respiratory failure can probably be explained by a combination of causes: fluid overload, systemic vasculitis and the concomitant and probably triggering Adenosinuric infection.

Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.7176
gent surgery. These may be observed in polycystitis nodosa, cryptogulbiniculovasculars, erosinophilic granulomatosis with polyangiitis and other AAV. High-dose glucocorticoids and cyclophosphamide are usually applied. Children with IgA vasculitis may develop bowel intussusception.

Deep venous thrombosis and pulmonary embolisms are significantly more frequent in AAV and pregnancy than in the general population, especially during active disease. Anti-coagulation may be needed in AAV, although this approach is controversial in Behçet's disease. By contrast, aneurysm formation is typical in polycystitis nodosa and Behçet's disease and may be occasionally seen in AAV. Massive bleeding derived from aneurysm rupture usually requires arterial embolization.

It is important to keep in mind that during the early course of diagnosed vasculitis, intense immunosuppressive therapy may favor life-threatening infections including opportunistic infections such as pneumocystis jiroveci pneumonia or disseminated SLE. In summary, systemic vasculitis may present with a variety of severe complications and other may develop during follow-up. These complications are heterogeneous, vary according to the size of vessels involved, and usually require specific procedures or treatments in addition to immunosuppressive therapy. Due to the life-threatening nature of these complications their immediate recognition and management are crucial to patient survival.

AxSpA: From bug to gut and to disease phenotype...

SP0111 INHIBITING BONE FORMATION IN THE CLINIC. ARE WE THERE YET?
R. Landewe, Rheumatology & Immunology, Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands

One of the most characteristic features of axial spondyloarthritis (axSpA) is bone formation in the spine (syndesmophytes). Syndesmophytes may occur at any time during the course of the disease, are more frequent in patients with radiographic axSpA (AS) than in those with non-radiographic axSpA, and are best seen on conventional X-rays of the spine. Currently, it is suggested that (low-radiation) CT-scanning of the spine provides a better (more sensitive) picture of developing syndesmophytes than conventional X-rays. Syndesmophytes matter in that they interfere with spinal mobility and physical function independent of inflammation. As such, it makes sens to try and prevent their occurrence or to inhibit their progression.

It is a matter of debate whether current available treatments are able to inhibit syndesmophyte growth or occurrence. Part of the debate is the methodological challenges related to measuring syndesmophyte progression properly.

In this lecture I will address current issues related to inhibition of syndesmophyte formation in patients with axial SpA.

Pregnancy meets rheumatic patients

SP0112 WHICH DRUGS IN PREGNANT PATIENTS?
M. Østensen, Department of Rheumatology, St.Olavs Hospital, Trondheim, Norway

Management of rheumatic disease during pregnancy starts with prepregnancy counselling. Assessment of maternal and fetal risks is necessary for adjusting therapy to the current stage of pregnancy. The ultimate goal is to keep the disease in remission or at least at low activity throughout pregnancy.

Immunosuppressive drugs requiring withdrawal before conception are methotre- ate, cyclophosphamide, and mycophenolate which are known teratogenic drugs. Other drugs like leflunomide, tocilizumab and several biological should be discon- tinued because pregnancy experience is at present insufficient and safety for the fetus has not been proven. Flares of rheumatic disease showing be treated immediately and with pregnancy compatible drugs. For patients with inflammatory arthritis like rheumatoid arthritis, spondyloarthritis and juvenile idiopathic arthritis disease activity during pregnancy can be controlled with antimalarials, sul- fasalazine and TNF inhibitors. Women with systemic lupus erythematosus should continue basic therapy with hydroxychloroquine, and azathioprine, ciclosporine or tacrolimus added when needed due to organ manifestations. Severe flares during pregnancy may require biologics like rituximab, abatacept, tocilizumab or Anakinra. In case of infected pulsed or, if life threatening, intravenous gamma globulin or cyclophosphamide.

Treatment during pregnancy demands balancing suppression of maternal disease and no harm to the child. Selecting the adequate type, the right dose and the right timing of medications for optimal care of pregnant patients remains a challenge.

SP0113 PREGNANCY IN SLE: STILL CHALLENGING FETAL AND MATERNAL ISSUES
R. Fischer-Betz, Rheumatology, Heinrich-Heine-University, Duesseldorf, Germany

Patients with SLE are mostly young women diagnosed during the childbearing years. Despite the so-called “unmet need” in knowledge of reproductive health issues, management are crucial to patient survival. Because of earlier recognition of disease and advances in medical treatment, family planning has gained greater importance. Concerns include the effect of pregnancy on maternal disease, the risk of flare following delivery, and the safety of medications during pregnancy and breastfeeding. Preconception counselling and risk stratification (including life style, disease activity, autoantibody profile, previous vascular and pregnancy morbidity, hypertension and the use of drugs with emphasis on benefits from hydroxychloroquine and antiplatelet/anticoagulants) are essential for prevention of unwanted complications during pregnancy. Recommendations for the management of family planning and antihypertensive treatment during pregnancy and lactation have been published recently by EULAR. However, many lupus patients still do not feel that their family planning concerns are adequately addressed in current clinical practice and report that they receive inconsistent advice from the various healthcare professionals. There is a clear need for provision of up-to-date and consistent information/support to our patients.

SP0114 CHILDREN OF PATIENTS WITH RHEUMATIC DISEASES: ISSUES RELATED TO MATERNAL DISEASE AND TREATMENT
L. Andreoli, Rheumatology and Clinical Immunology, University of Brescia, Brescia, Italy

A major source of anxiety for women with systemic autoimmune diseases (SADs) who wish to become pregnant is the possible impact of maternal disease and medications on the offspring, in terms of physical and mental development. A recent multicenter survey conducted in 24 Italian Rheumatology Centers showed that more than 50% women affected by SADs restricted their family size mainly because they were afraid that children could get an autoimmune disease or could be harmed by intrauterine exposure to maternal autoantibodies and anti-rheumatic drugs (Dall’Ara, ACR abstract, Arthritis Rheumatol 2016: 68, suppl 10). Therefore, the long-term follow-up children born to mothers with SADs is a topic of major importance for the counselling on family planning.

First of all, it should be emphasized that preterm birth and other fetal complications, such as low birth weight and babies small for gestational age, are more common in patients with systemic autoimmune diseases as compared to the general population. These conditions carry themselves an increased risk for poorer physical and neuropsychiatric development. Therefore, the prevention of foetal complications should be operated by means of close obstetrical monitoring and tight control of maternal disease activity, which would be detrimental for foetal wellbeing. In this context, the use of “safe” anti-rheumatic drugs is of paramount importance for pregnant women with SADs.

Recently, a dedicated EULAR Task Force has released points to consider for the use of anti-rheumatic drugs during pregnancy and lactation (Gotestam Skorpen, Ann Rheum Dis 2016). The work of this Task Force was focused on updating the information about the use of “conventional synthetic” (cs) DMARDs but also to provide for the first time evidence-base indications on the use of “biologic” (b) DMARDs, mainly anti-TNFalpha agents.

No significant impact in the maturation and functioning of the child’s immune system has been observed for several csDMARDs, supporting their safety of use during pregnancy (Andreoli, J Autoimm 2012).

Turning to bDMARDs, a case-control study on the long-term follow-up of children exposed in utero to anti-TNFalpha showed the safety of use either until the positive pregnancy index or during the second and third trimester of gestation (Dall’Ara, EULAR abstract, Ann Rheum Dis 2016: 75, Suppl 2:493). No differences between exposed and non-exposed children were found in terms of congenital defects, developmental milestones, response to vaccinations and major health problems. No particular problems were also observed in children who were breastfed while maternal anti-TNFalfa intake. The use of anti-TNFalfa agents during breastfeeding had been proposed to women who were strongly motivated based on the following considerations: 1) these drugs are poorly or absolutely excreted into breast milk as recently demonstrated for certolizumab pegol (Cioisse, ACR abstract. Arthritis Rheumatol 2016: 68, suppl 10); 2) even this was the case, the drug will be degraded in the baby’s gastrointestinal tract and absorption could not be possible.

Regarding maternal disease, major concerns are linked to fetal exposure to mater- nal autoantibodies, mainly anti-Ro/SSA (for the development of neonatal lupus) and antiphospholipid antibodies (aPL). Therefore, the evaluation of these autoanti- bodies with potential negative impact on pregnancy and neonatal outcome should be part of the preconception work-up of women with SADs in order to provide ad- equate counselling and preventative strategies (Andreoli, Ann Rheum Dis 2017).
The transplacental passage of maternal aPL does not generally produce any thrombocytic complication in the neonate. The registry of infants born to mothers with APS, started by the European Forum on aPL in 2003, is collecting precious information for the assessment of neonatal outcome and subsequent development. The exposure to maternal aPL was linked to learning disabilities (LD) in children born to both mothers with SLE and with APS, based on the experimental observation that aPL can affect neural cells functioning. A recent study on the long-term neurodevelopment of children exposed in utero to aPL was reassuring for a normal neurological functioning and intelligence level, but found a higher rate of LD as compared to the general population (19% vs 3%) (Nail, Lupus 2017). These affected children were all born at term to triple aPL positive mothers.

Although systemic autoimmune diseases are not hereditary, newborns may receive from the mother a genetic background that may predispose to the establishment of autoimmune processes. However, the incidence of autoimmune diseases in the offspring was rather low (1%) among 269 children with a mean age of 15 years investigated in the previously cited study of Italian Rheumatology Centers.

Neuronal and hormonal alterations in arthritis

SP0115 NEUROTRANSMITTERS AND INNERVATION IN SYNOVIUM

R.H. Straub. Dept. of Internal Medicine, University Hospital, Regensburg, Germany

The synovial tissue is innervated by nociceptive sensory nerve fibers and sympathetic postganglionic nerve fibers. While sensory nerve fibers have afferent (by transmitting pain to the CNS) and efferent functions (by local release of neuroactive substances, mainly neuropeptides), sympathetic nerve fibers exert mainly efferent vasoregulatory, energy-regulating and immunomodulating roles. In synovial tissue of patients with rheumatoid arthritis (RA), the major proinflammatory neuropeptide of sensory nerve fibers is substance P, which is upregulated relative to anti-inflammatory calcitonin gene-regulated peptide (CGRP). In addition, sensory nerve fibers undergo a sprouting response leading to sensory hyperinnervation of RA synovial tissue. Removal of sensory nerve fibers exerts anti-inflammatory effects, and it is thought that this elimination is beneficial during hemiplegia, which can spare the paralytic limb from developing RA. Therapeutic neutralization of substance P was not successful, most probably due to vast receptor redundancy. Furthermore, the sensory nervous system undergoes a sensitization response (aggravation of pain and inflammation) in the synovial tissue, the dorsal root ganglion, the spinal cord, and more central in the brain. Chemical sympathectomy or suppression of adrenergic signaling significantly reduce inflammatory processes in the initial acute state of inflammation whereas the same procedures may increase inflammation at later stages. These findings indicate that the sympathetic nervous system supports the development of inflammation but can reduce inflammation at more chronic stages. During chronic inflammation, the density of sympathetic nerve fibers in synovial tissue is reduced but other tyrosine hydroxylase-positive cells secreting noradrenaline appear in the inflamed joint. In addition to local vascular effects in the joint, the sympathetic nervous system influences numerous immune processes in the joint and in lymphoid organs. Hence the net effect of the sympathetic nervous system on inflamed tissue results from local sympathetic effects in the joint as well as from sympathetic influences on major systemic immune processes and energy regulation. This lecture summarize the central aspects of the two nervous systems.

SP0117 OSTEOPOROTIC FRACTURES IN EUROPE: ARE WE DOING ENOUGH

J.A. Kanis, University of Sheffield & Australian Catholic University, Melbourne, Cobham, Surrey, United Kingdom

The past 30 years has seen significant milestones in assessment and management of osteoporosis. These include the development of DXA and FRAX to identify individuals at high risk of fracture fracture and the development of interventions that have been shown to significantly decrease the risk of fracture in well-designed clinical trials. A major challenge has been how to apply these treatments. Measurements of bone mineral density (BMD) are used for diagnosis and for fracture risk prediction. Facilities for BMD testing are patchy and many European countries have inadequate resources to service the societal needs. In addition, BMD has poor sensitivity for the prediction of fracture so that the majority of fractures occur in individuals with T-scores ≤−2.5 SD. The development of FRAX has improved the sensitivity of fracture risk prediction and is now adopted in many assessment guidelines. Despite these advances, there are a number of challenges to be faced. Of paramount importance is that few patients with a prior fracture and even less with osteoporosis alone actually receive treatment. In Europe, there is wide inter-country variation in the treatment of women at high risk for osteoporotic fractures. The treatment gap varies from 25% in Spain to 95% in Bulgaria. Large treatment gaps were identified in countries with populations all of the same ethnic origin. Moreover, the treatment gap is increasing in many countries. Thus the disease is under-recognised by the medical community. Urgent action is required to address the under-recognition of osteoporosis and fragility fracture. Simple measures include:

• The development of country-specific guidelines,
• Piloting screening strategies in the elderly,
• Identifying the determinants of imminent risk,
• The development of fracture liaison services.

Whereas osteoporosis is recognized, worldwide, as a major Public Health issue, with one in two women and one in five men over the age of 50 years presenting...
a fragility fracture, a vast proportion of women at high risk remain untreated. Case-finding strategies prioritizing assessment of men and women with prior fracture are required to alleviate this problem.

**SP0118 ESTABLISHING AND IMPLEMENTING A FRACTURE LIAISON SERVICE**

S. Stephenson on behalf of National Osteoporosis Society, Service Development - Operations, National Osteoporosis Society, Bath, United Kingdom

**Objectives:** The objective of the National Osteoporosis Society (NOS) is to establish a Fracture Liaison Service (FLS) in every NHS Trust in the United Kingdom. The NOS Delivery Manager supports sites to implement and develop a new FLS, as well as to improve the quality of existing services. The FLS model enables secondary fracture prevention through identification of fragility fractures in every person who breaks a bone aged over 50 using dedicated case-finding, with assessment and appropriate management of osteoporosis where necessary. The object of FLS is to prevent secondary fractures, in particular expensive hip and vertebral fractures, thereby providing both clinical and cost effectiveness for patients and payers. The NOS has developed a unique service to support FLS across the UK.

**Developments:** A team of specialist development managers with clinical and commissioning experience support providers and payers in the process of establishing new FLS’s by offering consultation and guidance at every step of the process from pathway development to successful funding of services. This model has been replicated across the UK since April 2015 with the support and expertise of the NOS. Once an FLS is established the NOS provides support with service improvement, whether through additional commissioning of funds, Peer review or Gap analysis.

**Results:** Results from a range of analyses show that FLS has a positive impact on the World Health and in particular hip fractures. At the time of writing, the NOS is currently supporting 166 sites across the UK, 83 sites are improving the quality of their service; 58 sites are developing new services. 13 new services have been commissioned since commencement of the work programme, delivering new FLS provision to an additional 1.6 million people over 50, preventing 1,482 hip fractures over a 5-year period. Figures have been calculated from the NOS FLS Benefits Calculator https://benefits.nos.org.uk

**Challenges:** The primary challenge in establishing an FLS is identifying a clinical champion - this maybe a nurse, an allied health professional, rheumatologist or ortho-geriatrician in the hospital, or a representative from Public Health or from a Clinical Commissioning Group (CCG). The champion can lead and take the FLS from an idea to implementation.

To support the establishment and implementation of FLS the NOS has developed the FLS Implementation Toolkit as well as the Clinical Standards for FLS. The Clinical Standards will shortly be supported with a supplementation - New Clinical Guidance on the identification of Vertebral Fractures. Furthermore, the Charity has developed the Fracture Prevention Practitioner (FPP) training for those wishing to implement an FLS. This is backed by the Competency Framework for Nurses, allied health professional and doctors to ensure best practice in fracture prevention.

**Conclusion:** The NOS service development model of support is successful in driving the establishment, implementation and improvement of FLS across the UK. This is tough in an economic climate where health budgets are constrained. However, there is strong evidence that investment in FLS improves the quality of care as well as illustrating financial savings in health and social care. NHS England recommends that every patient with/or at risk of osteoporosis and fragility fractures should have access to a commissioned service.

**SP0120 PREDICTING THE RISK OF FALLS AND PROMOTING BALANCE IN OLDER ADULTS**

D. Rose, Kinesiology, California State University; Fullerton, Fullerton, United States

Falls are the leading cause of injury and death due to injury among the older adult population in the United States. Of those who fall, 24% will sustain serious injuries and 6% will experience fractures. In addition to injury, older adults who fall may experience decreased functional ability, loss of independence, a poorer quality of life, or premature mortality. At a global level, these statistics are similar among developed countries.

It is important to first identify the intrinsic and extrinsic risk factors that contribute to falls and then intervene appropriately once the level of fall risk has been identified. It is important to understand that there is no one size suits all fall risk reduction program and that the type of program will vary as a function of the level of risk. Core components of successful fall risk reduction programs include exercise, environmental modifications, and behavior change techniques aimed at fostering long-term adherence to engaging in fall risk reducing behaviors. The purpose of this presentation will be to describe appropriate methods for identifying fall risk, and intervention strategies that have been shown to significantly reduce fall risk and/or fall incidence rates across the continuum of fall risk.

**SP0119 PREDICTING FRACTURE RISK: ACCURACY AND FEASIBILITY OF TOOLS**

A.A. Marques, Rheumatology; Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal

Several therapeutic options and screening strategies are available to effectively decrease fracture risk. However the main clinical challenge still consists in accurately identifying and selecting individuals for bone densitometry and for pharmacological treatment, in order to increase efficiency and minimize individual and societal costs.

The World Health Organization provided an operational definition of osteoporosis as a bone mineral density (BMD) that lies 2.5 or more standard deviations below the average value for young healthy women of the same gender and ethnic background [T-score ≤ -2.5]. However, BMD has limited sensitivity and specificity in the prediction of fracture. In fact, a large number of conditions have been firmly established as risk factors for the occurrence of fragility fractures, independently from BMD. These have been combined into prediction algorithms to estimate fracture probability and are currently available for calculate the risk of fractures. However, the existing tools differ in many relevant aspects: from their own feasibility, to the number and availability of clinical risk factors included, the accessibility of BMD measurements and, finally, their performance in different settings.

With this session we aim to identify and synthesize the best available evidence on the accuracy and feasibility of the currently available tools designed to predict fracture risk.

**SP0121 LONG TERM SIDE EFFECTS OF BIOLOGICAL AGENTS IN JIA**

J.F. Swart on behalf of Pharmachild and Foreum (Comorbidity in JIA), Pediatric Rheumatology, UMC Utrecht, Utrecht, Netherlands

In the last years, the interest in the concept of comorbidity and its societal as well as individual impact has increased. Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disease starting in childhood which often persists into adulthood. Clinicians are facing an aging population with multiple morbid conditions occurring in one individual. Long term outcome studies show the high prevalence and the potential interaction of coexisting diseases. For JIA recent studies reported that uveitis, asthma/atopic diseases and diabetes mellitus are prevalent comorbidities in JIA with 11.6–30%, 10.8% and 3.5% respectively, followed by cardiovascular disease, malignancies and inflammatory bowel diseases. Childhood long term outcome studies and Pharmacovigilance registries already revealed associations of co-existing diseases and the role of used medication (especially biologicals).

It is important to plan preventive and screening strategies in order to prevent or early detect and treat comorbidities and integrated follow up once comorbidity exists.

AUTOIMMUNE PHENOMENA ASSOCIATED WITH BIOLOGICAL AGENTS

P. Quartier 1,2, P. Chevret 3, P. Pauwels 4, C. Clavel 5, B. Fautrel 6, S. Auvray 7, A. Nijenhuis 8, R. van den Hoogen 9

1. Pediatric Rheumatology, Université Paris Descartes, APHP, Hôpital Necker-Enfants Malades, Paris, France
2. INSERM, UMR 1145, Necker-Enfants Malades Hospital, Paris, France
3. IMAGINE Institute, Paris-Descartes University, Paris, France

Biologic agents are being increasingly used in pediatric rheumatology, particularly TNF antagonists but also abatacept, tocilizumab, interleukin (IL)-1 antagonists and some other drugs. In juvenile idiopathic Arthritis (JIA) and some autoinflammatory diseases, data from phase 3 and extension trials or from cohorts such as Pharmachild allow to prospectively collect information on adverse events of "special interest", including autoimmune complications. A few patients develop autoimmune/dysimmune features while on biologics, as seen in adults, including central nervous system lesions, inflammatory bowel disease or psoriasis. In addition, in patients with systemic-onset JIA, anti-IL-1 treatment is usually associated with the appearance of a type 1 interferon signature (gene expression analyses) which might in some cases favour lupus-like autoimmune features.

On the other hand, among patients with early-onset arthritis, vasculitis, recurrent fever or other inflammatory manifestations, an increased number of children are diagnosed with complex monogenic diseases resulting in auto-inflammation, immune deficiency and autoimmunity. In such cases, biologics might not be responsible for the occurrence of autoimmune features that may sometimes be diagnosed on treatment. This distinction is important as biologics are useful treatments in some of these patients, as was shown in a patient with a diagnosis of Systemic-onset JIA and ANCA-associated glomerulonephritis in whom anti-IL-1 treatment was beneficial. It was also more recently shown in patients with lipopolysaccharide-responsive beige-like anchor (LRBA) mutations associated with autoimmunity and inflammation, including polyarthritides: as LRBA is a partner of cytotoxic-T lymphocyte antigen-4 (CTLA4), abatacept has been used as a targeted treatment and shown efficacy.

We hence aim to discuss the way to explore patients who develop autoimmune features while on biologics in order to take the right decisions regarding treatment maintenance, withdrawal or modification and regarding patients follow-up.

Health equity and economy - a vital relationship

UNCOVERING THE EQUITY GAP IN RHEUMATIC AND MUSCULOSKELETAL DISEASES

P. Putrik, R. Peiro, P. Gendre, I. Pham, J. Crews, D. Le Page, M. Bonnafous, N. Grenier, E. Choy

Maastricht University Medical Center (MUMC), Maastricht, Netherlands

The aim of this lecture is to discuss the current evidence on the socio-economic inequities in disease outcomes in RMDs. Socio-economic determinants at the individual and country level will be considered, as well as the interplay between these factors. Special attention will be given to the role of different socio-economic factors in the access to biologic DMARDs in rheumatoid arthritis.

HEALTH ECONOMICS AND HEALTH EQUITY: TWO COMPLEMENTARY DISCIPLINES

B. Fautrel, E. Choy

1. Rheumatology, AHPH - CHU Pitié Salpêtrière; 2. Rheumatology, UPMC - Pierre et Marie Curie University; 3. CRI-IMIDATE Clinical Research Network, FORCIN Clinical Research Infrastructure Networks, Paris, France

Health equity in the one hand refers to the absence of systematic disparities in health between different social or demographic groups in a country or a group of country. Health inequity thus corresponds to a situation in which health services are not similarly available to all people with the same health conditions and health needs, due to individual personal or socioeconomic characteristics. Health economics in the other hand focuses on how to allocate health budgets in order to maximize the general health of the population as a whole. With regards to this, no specific attention is dedicated to socially disadvantaged subgroups. In addition, the most visible action in the field of health economics was the valorization of therapeutic innovation, i.e., the determination of its price not on production cost but on value associated with this innovation. Economic evaluation – i.e., determination of incremental cost-effectiveness ratio – has lead during the last 20 years to substantial financial pressure on health care systems with dramatic increase in health expenditures mainly due to the costs of therapeutic innovation. Several studies have shown that such a process may increase health inequities within a country. Specific actions are not taken to maintain or improve treatment availability and access to care to all the population members whatever their social, educational and economic characteristics.

BIOMARKERS IN CARDIOVASCULAR RHEUMATOLOGY – RELEVANT METABOLIC BIOMARKERS

E. Choy, Section of Rheumatology, Cardiff University, Cardiff, United Kingdom

Patients with RA have increased mortality compared with the general population due to higher cardiovascular disease (CVD), which is up to 50% more frequent [1]. Even after adjusting for traditional cardiovascular risk factors such as smoking, diabetes and hypertension, the risk for CVD is increased by up to twofold compared with the normal population [2]. Whilst traditional cardiovascular risk factors, contribute to the increased risk of mortality in RA patients, they do not fully explain increase in cardiovascular risk [3,4]. European League Against Rheumatism (EULAR) recommend regular assessment of cardiovascular risk in patients with RA [5]. Since traditional cardiovascular risk factor assessment equations, such as Framingham and the Systematic Coronary Risk Evaluation Score (SCORE) models, underestimate cardiovascular risk in RA, EULAR recommend multiplying such traditional cardiovascular risk scores by 1.5 for patients with RA. Such adjustment operates at the population level. Ideally, cardiovascular biomarkers that can predict future cardiovascular event in the individual patient will improve screening and management.

Biomarkers of cardiovascular disease can be divided into five major categories: lipids, inflammation, endothocrine, vascular and prothrombotic [7]. HDL and LDL are used in routine clinical practice. However, they do not predict future cardiovascular events in patients with RA as the levels of HDL and LDL are suppressed during inflammation [8]. The ratio of HDL/LDL or total cholesterol/HDL is less affected by inflammation and might be considered. Other lipid biomarkers include apolipoprotein A-1, apolipoprotein B, cholesterol ester transfer protein lipoprotein-associated phospholipase A2, small dense LDL and paraoxonase-1. They have been measured in patients with RA but their precise value in predicting cardiovascular risk in RA has not been determined.

High level of inflammation as measured by ESR and CRP is associated with increased cardiovascular risk in patients with RA. EULAR recommended adequate suppression of inflammation as a key strategy to reduce cardiovascular events [5]. Disease flares increased cumulative cardiovascular risk [9]. Many inflammatory mediators are elevated in RA and might add to traditional cardiovascular risk score to improve individual risk prediction should be evaluated. The vascular biomarker of cardiovascular disease, VCAM-1, has also been shown to be elevated in patients with RA. High level of VCAM-1 was associated with high cardiovascular risk score [10].

Metabolic syndrome is common in patients with inflammatory arthritis. Insulin resistance is a feature of metabolic syndrome. Fibrinogen and other prothrombotic molecules are part of the acute phase response, their levels are elevated in RA. Neither endocrine nor prothrombotic factors have been studied systematically in RA.

THE VESSEL WALL IN IMDS – NEW EMERGING VASCULAR MARKERS

Z. Szekanecz, Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

Cardiovascular disease dependent on inflammatory accelerated atherosclerosis
leads to increased mortality in rheumatoid arthritis (RA). In addition to traditional, Framingham risk factors, several immune-inflammatory cells, mediators and molecules may link atherosclerosis to arthritis. Among immune cells, primarily TH1 cells, as well as endothelial cells play a crucial role in syndical and vascular inflammation. Various cell surface molecules, such as adhesion receptors, CD40-CD40L interaction with members of the RANK-RANK ligand-osteoprotegerin system, as well as soluble pro-inflammatory cytokines, chemokines, autoantibodies and proteins have been implicated in RA and vascular damage. The early assessment of atherosclerosis and early intervention would decrease cardiovascular risk in RA.

SP0127 TAPERING BIOLOGICS INDUCES A PROTHROMBOTIC STATE IN RHEUMATOID ARTHRITIS?

M.T. Nurmohamed on behalf of M. Heslinga, J. Meijers & M. Nurmohamed. Rheumatology, Amsterdam Rheumatology Immunology Center | VUMc & Reade, Amsterdam, Netherlands

In addition to the "traditional" risk factors for venous thrombo-embolism (VTE), like age, trauma and immobilisation, inflammation could also be regarded a risk factor for VTE. For example, patients with acute inflammatory conditions (sepsis), but also patients with chronic inflammation, like inflammatory bowel disease (IBD), and rheumatoid arthritis (RA), have an increased risk of thrombo-embolism. Inflammation can lead to activation of coagulation, and vice-versa, coagulation also has considerable effects on overall inflammatory activity. First, the inflammatory cytokine network induces several pro-thrombotic conditions including insulin resistance, dyslipidaemia, endothelial dysfunction and alteration of coagulation and fibrinolysis. Second, activation of the extrinsic coagulation system and impairment of the fibrinolytic pathway may contribute to amplify and perpetuate the inflammatory response. Previous studies have reported several blood parameters that reflect a pro-thrombotic state in RA. These include increased levels of thrombin-antithrombin complex, prothrombin fragment F1+2, von Willebrand factor, plasmin-alpha2-antiplasmin complex and D-dimer, as well as an increased platelet count. Impaired fibrinolysis combined with increased antithrombin levels have also been reported in RA. An important mediator in the inflammatory pathway is tumor necrosis factor-α (TNF-α). In the general population, TNF-α induces a disbalance between clotting and fibrinolysis, resulting in a hypercoagulable state. Since TNF-α is the key player in RA, RA is an ideal "human model" to study the interplay between inflammation and coagulation. Hence, RA can be considered as a pro-thrombotic state, which explains partly why patients with RA are at increased risk of thrombo-embolic cardiovascular events. (1)

Only one small study suggested that TNF-inhibitors (TNFi) is accompanied with normalization of thrombotic biomarkers: an improvement of clinical and laboratory parameters as well as a reduction in the activation of coagulation and endothelial dysfunction was found in RA patients treated with a TNFi. In addition, we previously demonstrated that combination therapy with corticosteroids improves the procoagulant state that exists in early RA. (2) Nowadays, tapering of biological therapies is becoming more and more standard of care. However, the effects on the coagulation status in RA are unknown. In light of the growing evidence of an increased cardiovascular morbidity and mortality in RA, mostly independent of traditional risk factors, treatment strategies in RA should not only aim at relieving symptoms and inhibiting joint destruction but should have a beneficial effect on the vasculature and haemostasis to reduce cardiovascular events. Although modest, there is evidence suggesting a beneficial effect of TNFi on the haemostatic status in RA. Unfavourable changes in haemostatic markers, such as TAT, F1+2, VWF, PAP, D-dimer and thrombin generation, which indicate a pro-thrombotic state, may therefore (re)occur when RA patients stop with TNFi treatment. We first assessed arterial wall inflammation with 18F-FDG PET scans in RA patients in remission under TNFi therapy or DMARD therapy versus controls. The FDG uptake in the aorta in DMARD remission patients was similar to the controls, whereas the uptake in RA patients in remission under antiTNF was significantly higher than in controls either when looking at the overall aortic uptake or the thoracic dissected segment. Theoretically, stopping TNFi blockade in these patients might lead to increased inflammation and thus coagulation activation. Therefore, we are presently investigating it and to what extent tapering/ stopping TNFi therapy induces a pro-thrombotic state in RA patients.

DOI: 10.1136/annrheumdis-2017-eular.7143
Epidemiologic studies have shown that not only fracture risk, but also mortality is increased after fracture, and that adequate therapy can not only decrease fracture risk but also increase survival. Fracture risk is not constant over time. It is highest the years following a fracture, and immediately increases in some instances, such as after starting glucocorticoids or androgen deprivation therapy. This has raised the concept of “imminent” fracture risk, in contrast to long-term fracture risk as included in FRAX. In this context, we present the the EU&LAR initiative, in collaboration with EFORT, that published recommendations for multidisciplinary acute fracture care, including orthogeriatric care after hip fracture, and subsequent fracture prevention at the Fracture Liaison Service. The presence, number and severity of vertebral fractures contribute to fracture risk, independent of BMD. Most vertebral fractures are subclinical and can therefore only be diagnosed by imaging of the spine. The role of vertebral fracture assessment (VFA) using DXA will be discussed. New treatment insights will be reviewed, including for glucocorticoid users, combined and sequential treatments with anti-resortive and bone forming drugs, real world data and the role of fall prevention.

Prescription of and adherence to treatment are still major issues. In patients adherent to therapy, new insights and recommendations will be reviewed on the need for early treatment, duration of treatment and the clinical approach when considering stopping drug therapy.

What is behind vasculitis?__

**SP0131**

**AUTOIMMUNE ATHEROSCLEROSIS**

Z. Szekanecz, Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

Arthritides have been associated with accelerated atherosclerosis to increased vascular disease risk. Traditional risk factors, as well as the role of systemic inflammation including cytokines, chemokines, proteases, autoantibodies, adhesion receptors and others have been implicated in the development of these vascular diseases. Accelerated atherosclerosis and increased cardio- and cerebrovascular morbidity and mortality have been observed in rheumatoid arthritis (RA) and spondyloarthropathies (SpA).

Endothelial dysfunction, overt atherosclerosis and vascular stiffness may be indicated by brachial artery flow-mediated vasodilation (FMD), common carotid intima-media thickness (cIMT) and aortic pulse-wave velocity (PWV), respectively. These abnormalities have been described in most inflammatory rheumatic diseases. While cIMT and stiffness are relatively stable, FMD may be influenced by many confounding factors.

In addition to traditional vasculoprotection, immunosuppressive agents including corticosteroids, traditional and biologic DMARDs may have significant vascular and metabolic effects. The official EULAR recommendations on the assessment and management of cardiovascular disease in arthritis have been published.

**VIRUSES DRIVING VASCULITIS**

L. Calabrese, Rheumatology, Cleveland Clinic, Cleveland, United States

Viruses have long been associated with varying forms of vasculitis in both pre-clinical models and human diseases. Immuneopathogenic mechanisms have varied and include direct vascular invasion, immune complex mediated and more recently novel mechanisms which include autoinflammatory like responses. This discussion will review major advances in the field of medical virology as it applies to rheumatic diseases, especially vascular inflammatory disease, including and introduction to the human and more specifically vascular microorganisms. Major forms of virally mediated vasculitis will be discussed with an emphasis on new viral vasculitis syndromes largely defined by next generation sequencing and their potential clinical impact.

**ANCA AND THEIR ENVIRONMENT**

R.A. Luqmani, University of Oxford, Oxford, United Kingdom

The association between antibodies to neutrophil cytoplasm (ANCA) and systemic vasculitis has transformed our understanding of granulomatosis with polyangiitis (EGPA) and eosinophilic granulomatosis with polyangiitis (EGPA). ANCA undoubtly played a major role in their pathogenesis. There are different forms of ANCA, but only two of direct clinical relevance: cytoplasmic c-ANCA (usually directed against proteinase 3, PR3), and perinuclear p-ANCA (usually directed against myeloperoxidase, MPO). P-ANCA can also be directed against other antigens including bacterial/permeability-increasing protein, lactoferrin, human neutrophil elastase, cathespin G and azurocidin, but their clinical significance is not clear.

Transfer of MPO ANCA in humans (maternal-fetal route) and animal models (necrotizing pauci-immune glomerulonephritis after passive transfer of purified antibodies or soluble micromolecules from murine MPO) has resulted in features of MPA. By contrast, the pathogenicity of anti-PR3 antibodies is less well-established. There is a significant genetic predisposition to disease in patients with AAV. Patients with PR3-ANCA have a strong association with HLA-DP and genes encoding alpha-1-antitrypsin and proteinase 3; by contrast, patients with MPO-ANCA have an association with HLA-DQ. Other factors that could interact with ANCA include: loss of B cell and T cell tolerance; direct involvement by neutrophils and their mediators in vascular injury and damage, degranulation and cytokine production; environmental exposure to silica or other bacteria like Staphylococcus aureus, coupled with a lack of effective T cell regulation to prevent inflammation. Neutrophils spontaneously release of neutrophil extracellular traps (NETs), which directly cause endothelial cell damage and complement activation. NETs retain proteinase 3 and myeloperoxidase, helping to break immune tolerance and inducing antibody formation.

The alternative complement pathway plays a crucial role in the pathogenesis of AAV. Activated neutrophils produce C5a, which in addition to recruitment, primes additional neutrophils for further activation by ANCA. C3a, C5a, soluble C5b-9 are elevated in active disease and plasma levels of complement factor H, a regulator of the alternative complement pathway is significantly lower in patients with active AAV.

Central to the pathogenesis of AAV is a dysregulated immune response to ANCA and aberrant expression of their target autoantigens, MPO and PR3. Environmental exposure to silica may inactivates α1-antitrypsin, whilst activating monocytes and macrophages releasing cytokines such as interleukin-1 and TNF-α, oxygen radicals and lysosomal enzymes (such as PR3 and MPO). Other environmental interactions include Cpg-ODN, a short synthetic DNA containing unmethylated Cpg and several drugs, especially propylthiouracil and levamisole-adulterated cocaine. Some of these associations could provide a better insight into the development of ANCA associated disease.

ANCA play a central role in the pathogenesis of systemic vasculitis, supported by a dysregulated immune system, with significant interactions with micro-organisms, environmental toxins and drugs, all of which can contribute to the development and severity of disease.

Cytokine taxonomy: reflection in the therapy of arthritides and other IMIDs

**SP0134**

**INTERLEUKIN-2 THERAPY IN SLE**

J.Y. Humrich, Department of Rheumatology and Clinical Immunology, University Hospital Schleswig-Holstein, Campus Lübeck, Lübeck, Germany

There is an unmet need for more effective and selective therapeutic strategies in severe autoimmune diseases such as systemic lupus erythematosus (SLE). A deeper understanding of the pathogenic mechanisms in the past has led to the clinical translation of low-dose interleukin-2 (IL-2) therapy which primarily aims to restore the activity of regulatory T cells. First results from phase III clinical studies are promising by proving the selective expansion of regulatory T cells in vivo and by providing first evidence for the clinical efficacy of low-dose IL-2 therapy in SLE. Here we will summarize key findings which led to the development of this novel therapeutic concept and will highlight the main rationales for the clinical translation of low-dose IL-2 therapy in SLE.

Regulatory molecules in connective tissue

**SP0135**

**MYOSTATIN, SCLEROSTIN, SYNDECAN AND MORE**

T. Pap, Institute of Experimental Musculoskeletal Medicine (IEMM), University Münster, Münster, Germany

Rheumatoid arthritis (RA) is the prototype of an inflammatory arthritis that is characterized by chronic inflammation, progressive cartilage destruction and bone proliferation. Development of RA is marked by the hyperplasia of the synovial membrane as caused by an infiltration and accumulation of inflammatory cells such as macrophages and lymphocytes as well as an increase in the number of resident mesenchymal cells. These fibroblast-like synovocytes (FLS) are a key part of the local immune system in the joints and integrate signals...
form different sources into a pathological tissue response. Resorption of the juxtaarticular bone is part of this pathological tissue response and is denoted as focal bone erosion which occurs early in this disease and over time is associated with significant morbidity. Focal bone erosions are observed at the interface of pannus and bone tissue both marginally, where pannus invades cortical bone adjacent to an intermediate subchondral bone, where the pannus invades the marrow space. Many of the cytokines and growth factors implicated in the inflammatory processes are secreted by FLS and have also been demonstrated to impact directly or indirectly on osteoestal and/or osteoclast differentiation and function. However, research of the last years has also identified some novel pathways by which i) osteoclast- mediated bone resorption is regulated and fine-tuned under inflammatory conditions such as in RA and that ii) link inflammatory bone resorption to other features of systemic autoimmunity such as the activation of developmental pathways or muscle weakness. This lecture will review some of these novel mediators and pathways, including members of the Wnt- signalling pathway (e.g. sosterolin), members of the GDF- family of growth differentiation factors (e.g. myostatin) and cells surface anchored proteoglycans (e.g., syndecans). Focusing on the role of these molecules in the FLS-mediated regulation of osteoclast bone resorption, the lecture will point to general principles of inflammatory bone remodelling and discuss potential therapeutic implications for RA.

SP0136 MULTIFACTORIAL TISSUE GROWTH FACTORS

C.P. Denton, Centre for Rheumatology, Royal Free Hospital and Ucl Medical School, London, United Kingdom

Connective tissue is a critical component of all organs and has special importance in the musculoskeletal system. In specialist tissues, such as bone, cartilage of muscle an in vascular structures and internal organs there is a mixture of less specialized connective tissue together with the specific tissue and organ specific cellular and cellular organelles. In addition to physiological function there are two other areas in which it plays a central role. Normal embryonic and postnatal growth and development, and tissue repair in response to injury. It has emerged that there are shared pathways, mediators and mechanisms in these different processes and that multifactorial tissue growth factors have an important role. In this way, these proteins can have a profound influence on multiple cell types and provide a mechanistic link in many complex chronic diseases. It is notable that pathways that are perturbed in one chronic disease, such as atherosclerosis or osteoarthritis may be similarly disrupted in different context in conditions such as lung fibrosis or scleroderma. In addition to physiological function there are two other examples of this class of protein. This included TGFbeta isoforms and also the related bone morphogenous (BMP) and activin family of proteins. They share chemical structure and an ability to regulate multiple cell types in a context specific way. In addition, there is remarkable complexity in their regulation with intrinsic inhibitory mechanisms to protect from inappropriate biological activity. Their role in repair means that activation of preformed protein may regulate biological effects. Proteins regulated by the TGFbeta family, such as the CCN family of matricellular proteins and some for the cardinal growth factors and cytokines share properties. There is functional redundancy and cross talk. Conceptually it is interesting to envisage dysfunctional networks of cytokines in disease that may be attenuated by extracellular blocking or antigen. Insights for many areas of developmental biology and pathology have informed about this challenging area of molecular medicine.

SP0137 FROM GLYCOSYLATION TO INFLAMMATION

M. Herrmann, University Hospital Erlangen, Erlangen, Germany

One of the best studied posttranslational modification of immunoglobulin G (IgG) is the addition of a complex glycan to asparagine 297, which is required for IgG to bind to Fc-receptors and for the activation of complement via the classical activation pathway. In the absence of the glycan the IgG usually behave like a lame duck unable to execute its effector functions. The sugar tree is polymorphic and there are several functional consequences related to the glycan. The terminal sialylation, the presence of galactose, the core fucosylation and the insertion of a bisecting third sugar chain all reportedly modify the biological and functional activities of IgG.

As examples for the impact of Asp-297 associated glycans to the activity I will present (I) the sialylation of anti-histon autoantibodies in patients with systemic lupus erythematosus (II) the exposure of sugar epitopes by random IgG isolated from patients with rheumatoid arthritis (III) the molecular analysis of the glycan of random IgG isolated from patients with inflammatory diseases and controls and (IV) and finally the glycosylation of IgG-anti-phospholipid autoantibodies in healthy children.

(I) The autoantibodies are mainly found in the non-sialylated fraction of the anti-histon autoantibodies which can be considered inflammatory IgG.

(ii) The circulating random IgG from patients with rheumatoid arthritis show an increased exposure of the Asp-297 associated glycans.

(iii) The molecular analysis of the glycan of random IgG isolated from patients with systemic lupus erythematosus, rheumatoid arthritis, sepsis showed disease-specific glycans.

(iv) The non-pathogenic IgG-anti-phospholipid autoantibodies isolated from healthy children displayed an increased sialylation when compared to the pathogenic autoantibodies from adults with anti-phospholipid syndrome.

The examples point to a strong impact of IgG glycosylation in the etiopathogenesis of chronic inflammatory rheumatic diseases. One should consider to include IgG glycan analyses into the diagnostic repertoire for autoantibodies.

Patient engagement in research: best practices, benefits, and challenges

SP0138 THE CHALLENGES OF PATIENT INVOLVEMENT IN SCIENTIFIC RESEARCH. HOW TO ACHIEVE TRUE REPRESENTATION OF THE PATIENTS’ VOICE?

M. De Wit on behalf of the EULAR Working group for Collaborative Research. Dept. Medical Humanities, EMGO+ research institute, VU University Medical Centre, Amsterdam, Netherlands

There is a strong call in the western world for collaborative research. Rheumatology is one of the disciplines that has explored best practices and paved the way to implement lessons learned. Although good methodologies for evaluating the impact of patient participation stay behind, we have been able to develop expert-based recommendations for collaboration. They are helpful for both researchers and patient representatives, but they do not address all concerns that occur in daily practice. In this lecture current challenges of integrating the perspectives of patients in clinical research will be discussed: 1. Defining the role and complementary value of patient research partners; How can patients in the role of collaborative partner contribute to research in addition to the data that patients provide as respondent or study participant? 2. Facilitating and guiding researchers in collaborative research; We have experience in preparing and educating patient representatives for their role in research, but how should researchers be trained and supported? 3. Preserving the patients’ voice throughout the research process; Qualitative research may elicit patients’ experiences with health care or health interventions, but what is needed to guarantee that these findings are not lost in the rigorous process of producing scientific knowledge? 4. Demonstrating impact of collaborative research to funders and the public; Despite many case studies reporting a great variety of patient participation methods, there are no clinical trials nor consensus on a validated methodology for assessing the outcomes of patient involvement in research. For each challenge we will try to propose a way forward. These challenges will also be discussed at the newly established EULAR working group for collaborative research.

SP0139 MEANINGFUL PATIENT AND PUBLIC INVOLVEMENT IN PLANNING RESEARCH

A. Redmond, Leeds Institute for Rheumatic and Musculoskeletal medicine, University of Leeds, Leeds, United Kingdom

Historically, services providing care for people with long term conditions (LTCs), together with any associated research agendas, have been driven entirely by clinicians. In many cases this is well meaning and is done with some consideration of what patients need, but almost always the end result relies on the clinicians’ interpretation of what patients need.

Recently it has become more usual to involve patients in planning research projects and service changes directly. Initial attempts to give patients genuine input were ad hoc in nature and so patient contributions could be lacking, ignored or misinterpreted.

In many cases having poor patient input is worse than no input at all as it tends false credibility to the process. Lately a range of formal requirements, arrangements and methods have become adopted and this presentation will focus on how these can be brought to bear to ensure meaningful patient and public involvement in planning research. From national guidance such as the UK’s INVOLVE initiative, to local standard operating procedures we will share experiences and lessons learned.

The session will close with a practical summary of how to make PPI contributions genuine and meaningful, and some insights into possible future developments as this aspect of the research process matures and consolidates.

**SP0140** PATIENT ENGAGEMENT IN RESEARCH: A PCORI EXEMPLAR

**J. Pooe.** Occupational Therapy Program, University of New Mexico, Albuquerque, United States

This session will discuss patient and stakeholder involvement as members of the research team on a grant funded by the Patient Centered Outcomes Research Institute (PCORI). Patients with a rare chronic disease, systemic sclerosis, and members from key stakeholder organizations were involved in evaluating, revising and testing the effectiveness of an internet self-management program. They participated at several levels of engagement including planning the study, conducting the study, and disseminating the results. This session will discuss how engagement occurred at each of these levels through different opportunities such as creating interventions, identifying outcomes, recruiting, presenting findings, and planning dissemination efforts. The benefits and challenges for both researchers and patient research partners will also be described.

**RA treatment in patients wanting to become pregnant - interactive session**

**SP0141** NEW RA, BUT WHAT ABOUT A NEW BABY?

A. Willemsen. Rheumatology, LUMC, Leiden, Netherlands

Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease affecting women often in their childbearing years. In this case presentation a 35 year old female patient is illustrated with a recently diagnosed rheumatoid arthritis with active disease and a wish to conceive in the nearby future. Management of disease activity in patients who wish to conceive or during pregnancy might be a challenge due to limited treatment options. How should we treat this patient taking into account her wish to conceive in the nearby future? Should the patient postpone her wish to conceive because of active disease?

**SP0142** FOREPLAY AND FINALE: FACTORS AFFECTING FERTILITY, BIRTH AND LACTATION IN RHEUMATOID ARTHRITIS PATIENTS. CLINICAL CASE

P. Nero. Rheumatology, Hospital CUF Desobertas, Lisboa, Portugal

We present the clinical case of a 38 year old woman diagnosed with rheumatoid arthritis at the age of 32. She went into remission of her disease during treatment with subcutaneous methotrexate (25 mg/week) for 2 years. She decided to become pregnant and stopped treatment. RA relapses 4 months later and she has no response to classic DMARD’s (sulphasalazine and hydroxychloroquine) and starts etanercept (50mg/week). She gets pregnant and achieves remission at 16 weeks of gestation. At week 36 she is still in remission and stops etanercept. 2 months after giving birth the disease relapses but she wants to breastfeed and would like to restart etanercept. We agreed and 3 months after restarting anti-TNF RA is again in remission. In January 2017 her RA is in remission for 15 months and keeps her medication with etanercept every other week because she plans another pregnancy.

**SP0143** A NEW DAY FOR PEOPLE WITH PSORIATIC ARTHRITIS—A HETEROGENEOUS DISEASE THAT CAN BE TREATED WELL?

L.C. Coates. Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

This talk will summarise recent advances in research around the treatment of psoriatic arthritis (PsA). Firstly there will be an update on research that shows the importance of treating patients promptly when they are diagnosed. Then results from studies of new therapies for both psoriasis and psoriatic arthritis will be shown to highlight the drugs that have recently become available in the clinic or are likely to be available in the next few years. This will include new biologic disease modifying drugs with different targets including those that target interleukin 17 and interleukin 23 as well as new oral medications that are part of a family called small molecules. The role of these new therapies and how they compare to existing therapies in the clinic will be addressed. Finally there will be a summary on the research of how to use the existing and new therapies in the clinic including the use of the “treat to target” strategy.

**From pre-RA to established RA**

**SP0145** PATHOPHYSIOLOGIC PROCESSES LEADING TO THE DEVELOPMENT OF AUTOIMMUNITY

R. Toes. Rheumatology, Leiden University Medical center, -Leiden, Netherlands

Rheumatoid arthritis (RA) is a common complex disease characterized by chronic inflammation which results in joint destruction and significant disability in those affected. According to the World Health Organisation, within 10 years of onset, at least 50% of patients in western countries are unable to sustain a full-time job and about 25% develop mental consequences to patients as well as extensive societal costs. The cause of RA remains unknown. Human genetic studies have provided valuable insight with over 100 genetic risk factors identified to date. Genetic variants at the human leucocyte antigen (HLA) locus remain the most prominent genetic risk factor. Smoking is the best known environmental factor to contribute to the development of RA.

Gene-environment interactions are likely since the development of RA is determined by both genetic and environmental factors. A prominent example of AMPA is Anti-Citrullinated Protein Antibodies (ACPA). ACPA are highly disease-specific biomarkers of important diagnostic and prognostic value, with ACPA-positive patients being at risk for rapidly progressive, destructive and systemic disease. The strongest genetic risk factors for RA, the so-called HLA-shared epitope (SE) alleles, are strongly associated with CDRA positive patients. SE alleles define a specific disease entity within the complex group of symptoms clinically defined as RA. Current concepts of RA pathogenesis hold that a sequence of events leads to the development of ACPA-positive disease. Environmental factors are thought to cause an initial break of tolerance leading to the generation of ACPA-specific immune responses resulting in the development of RA. This talk will summarise recent advances in research around the treatment of RA.
of ACPO. This initial development of auto-immunity appears to be independent of the disease-predisposing HLA-molecules. In most patients, this early event generates a polyclonal yet limited, mostly low-level autoantibody response that can be present for many years in the absence of clinical symptoms. Upon a putative second trigger, the ACPO epitrace recognition repertoire broadens, mostly isohaemolysin using, and ACPO serum levels rise. This is followed by precipitation of disease and is likely associated with the presence of the predisposing HLA-molecules. While the nature of this second trigger is presently unknown, the second event that initiates the broadening of the auto-immune response, in particular the citrulline-specific immune response, could mark a crucial moment upon which the auto-immune response becomes self-perpetuating and, potentially, irreversible.

Despite the many facets of ACPO revealed in the past two decades summarized above, it is not known how a breach of tolerance towards citrullinated proteins is mediated, or how ACPO-producing B-cells emerge. Provision of T-cell help is crucial to convey the ability to B-cells to modify the B cell receptor through somatic hypermutation. At present, it is unknown how ACPO- or other Anti-Modified Protein Antibody (AMPA)-producing B cells are “helped” by CD4+ T-helper cells, but it is often speculated that an auto-reactive T-cell response is crucial for their appearance. Our recent data show that such help could be provided by T-cells recognizing foreign proteins that may have undergone a post-translational modification. In mice, AMPA-responses recognizing modified self-proteins are readily induced by immunization with modified proteins of non-self origin. This is explained by the observation that the murine AMPA-response works both at the monoclonal- and polyclonal level, highly cross-reactive towards multiple modified proteins, including proteins of self- and foreign origin. A similar observation was made analyzing the AMPA response in sera from RA patients. These data are important as the cross-reactive nature of AMPA could explain how auto-reactive B-cell responses against PTM self-proteins can be induced by exposure to PTM foreign proteins thereby providing new insights on the breach of autoreactive B-cell tolerance. Taken together, the analysis of the fine-specificity and recognition pattern of antibodies against modified proteins in RA during different phases of disease, together with detailed studies on the identification, isolation and phenotypic characterization of auto-reactive B cells that express AMPA starts to shed light on the earliest phases of autoimmunity in RA.

SP0146 CAN WE PREDICT WHO IS GOING TO DEVELOP RHEUMATOID ARTHRITIS?
D. Van Der Woude. Rheumatology, Leiden University Medical Center, Leiden, Netherlands

To accurately predict disease development can be considered the “holy grail” of risk factor research. It holds the potential to employ preventive treatment thereby nipping RA in the bud.

This presentation will review familial risk in RA and the underlying genetic risk factors, as well as environmental risk factors for disease. Autoantibodies are a potent prognostic marker when it comes to the risk of developing RA, and play a key role in current pathophysiological hypotheses. The newest players in the autoantibody field, and latest concepts of how the various risk factors contribute to disease onset will be discussed.

SP0147 CAN WE PREVENT THE ONSET OF RHEUMATOID ARTHRITIS IN HIGH RISK INDIVIDUALS?
K.D. Deane. Division of Rheumatology, University of Colorado Denver, Aurora, United States

Multiple studies have demonstrated that rheumatoid arthritis (RA) related biomarkers can identify individuals without inflammatory arthritis who are at high-risk for the future development of clinically apparent synovitis and classified RA. These findings have led to the development of several prevention trials in RA that have either been completed, or are underway. With these exciting developments as background, this lecture will discuss multiple aspects of RA prevention including the role of biomarkers and other factors in developing robust prediction models for future RA, and methods to identify individuals before they develop RA. In addition, this lecture will discuss specific preventive approaches to RA such as clinical trial design and choice of preventive interventions that are based on our growing understanding of the mechanisms of RA development.

Laboratory course - from the clinic to the lab and back II

SP0149 NEW TRENDS IN BIOMARKERS IN INFLAMMATORY JOINT DISEASES
E. Feist. Rheumatology, Charité University Hospital, Berlin, Germany

This lecture provides an overview on new developments in biomarker research and standardization in inflammatory joint diseases. The presentation includes an introduction of established and new biomarkers in serum and synovial fluid as well as methods for their detection. Furthermore, an overview on different modifications of auto-antigens (including citrullinated and carbamylation) and their role in immune response and pathogenesis of disease will be given. The diagnostic performance of new and established biomarkers will be discussed including antibodies against modified antigens also illustrated by difficult to diagnose cases. In this context, special attention will be attributed to the predictive value of biomarkers for diagnosis of disease and treatment response.

Switching T on and off: how T cells drive and regulate chronic inflammation

SP0149 TH17 CELLS DRIVE AND REGULATE TISSUE INFLAMMATION
V. Kuchroo on behalf of Basic and Translation Science, Evergrande Center for Immunologic Diseases, Harvard Medical School, Boston, United States

Recently a subset of interleukin (IL)-17-producing T cells (Th17) distinct from Th1 or Th2 cells was described and shown to have a crucial role in the induction of autoimmune tissue injury. Accumulating data suggests that there are three distinct steps in Th17 differentiation: Induction, Amplification and Stabilization mediated by distinct cytokines. Whereas TGF-β + IL-6 or IL-1 + IL-6 induces them, IL-21 amplifies Th17 cells, IL-23 stabilizes the phenotype of Th17 cells. Loss of any of the cytokines (TGF-β, IL-1, IL-6, IL-21 or IL-23) in the pathway results in a defect in generation of Th17. However not all Th17 cells are pathogenic and induce autoimmunity, IL-23 is a key cytokine that induces pathogenicity in Th17 cells (Lee et al., 2012). Using expression profiling at high temporal resolution, novel computational algorithms and innovative nano-wire based “knock-down” approaches, we have developed a regulatory network that governs the development of Th17 cells. In addition to high-density temporal microarray analysis, we have performed single-cell RNA-seq of Th17 cells in order to characterize cellular heterogeneity, identify subpopulations, functional states and learn how gene expression variation affects Th17 effector functions. We have identified novel regulators of Th17 cells both in vivo and in vitro that do not affect Th17 differentiation but affect pathogenic vs. non-pathogenic functional states of Th17 cells. Some of the regulators that make Th17 cells non-pathogenic are also utilized by CD6+ T cells to induce T cell “exhaustion” or “dysfunction”. These novel inhibitors cooperate with other known “check-point” co-inhibitory receptors to suppress anti-tumor immunity.

SP0151 SWITCHING OFF UNWANTED IMMUNE RESPONSES: THE MECHANISM OF ANTIGEN-SPECIFIC IMMUNOTHERAPY WITH T CELL EPITOPIES
D.C. Wraith. Institute of Immunology & Immunotherapy, University of Birmingham, Birmingham, United Kingdom

Control of autoimmune and allergic conditions can be reinforced by tolerance induction with peptide epitopes; this presentation will focus on the mechanisms involved. Peptides must mimic naturally processed epitopes. Peptide induced peripheral tolerance is characterised by the generation of anergic, IL-10 secreting CD4+ T-cells with regulatory function. CD4+ T-cells become anergic following their first encounter with peptide. The loss of proliferative capacity correlates with a cytokine switch from a pro-inflammatory to a phenotype characterised by secretion
of the anti-inflammatory cytokine IL-10. IL-10 Treg/Th1 cells suppress dendritic cell maturation, prevent Th cell differentiation and create a negative feedback loop for Th driven immune pathology. Tolerance induction involves upregulation of transcription factors controlling IL-10 and inhibitory receptors limiting T cell signalling. Results from clinical trials of peptide immunotherapy will be discussed.

Reverse translation - learning from clinical trials in SLE, Sjögren’s and APS

LEARNING FROM CLINICAL TRIALS IN SYSTEMIC LUPUS ERYTHEMATOSUS

D.A. Isenberg, University College London/University College Hospital London, London, United Kingdom

An enormous sense of frustration has surrounded the results of clinical trials in patients with systemic lupus erythematosus (SLE). A steady stream of trials involving those studying the effects of Epratuzumab, Abatacept, Rituximab, Tabalumab and Silfalimumab have failed to meet their endpoints. Even though Benlysta (which blocks the B-cell activating factor BAFF) did meet its endpoints, it only demonstrated a difference of around 10% between the Benlysta-treated and placebo-treated arms in trials involving over 800 patients.

However, there are some bright spots on the horizon. Trials comparing the use of interferon-alpha with other classic immunosuppressive drugs clearly showed it to be as good as Cyclophosphamide in getting patients into renal remission and demonstrated its superiority in maintaining that remission compared to Azathioprine(1). The use of Atacicept which blocks two B-cell activating factors has shown some extremely promising results(2) as have trials of both Rontalizumab and Anifrolumab(3) (which block interleukin-alpha).

Some key messages learnt from the running of the lupus trials include the importance of minimising the concomitant steroids and immunosuppression; ensuring the quality of those assessors participating in the clinical trials and the utility of employing an independent peer-review panel to monitor data as it is collected from the participating centres during the course of the trial. It is also evident that selecting patients who are more serologically active is likely to be of benefit both in clinical trials and in the clinic. However, we still need better biomarkers to help guide us; the identification of individuals expressing a high interferon alpha signature (and who thus might better benefit from an interferon alpha blocker) is one such example.

It remains ironic that Rituximab, the most widely used monoclonal antibody in SLE, failed its endpoint in two clinical trials. However, detailed analyses of data from those trials have shown some encouraging trends including falls in DNA abnormalities and improvement in some clinical parameters.

LESSONS FROM APS TRIALS

M. Khamashta, 1, 2, 3 Rheumatology Dept, Dubai Hospital, Dubai, United Arab Emirates; 4 Lupus Research Unit, St Thomas Hospital, London, United Kingdom

Prevention of thrombosis in patients with APS remains a vexing clinical problem. In patients with a history of thrombosis, there is considerable risk of recurrence, and long-term anticoagulation treatment with warfarin is effective in most cases. Existing evidence suggest that the use of DOACs for secondary thromboprophylaxis for APS patients with previous VTE is promising. Until new data from ongoing clinical trials are available, there is not enough evidence to consider using DOACs in patients with APS and previous arterial events. The efficacy of heparin and low-dose aspirin in APS patients with previous pregnancy losses is supported by 3 meta-analysis available on the topic. In patients with antiphospho-lipid antibodies but without a previous thrombotic event, most physicians in the field recommend thromboprophylaxis with low-dose aspirin. Given the diversity of clinical presentations and medical specialties involved, it is not surprising that treatment of APS has been subject of intense debate. Due to the difficulty in conducting trials in the setting of a relatively rare condition, well designed multicenter studies (such as registries) using actual classification criteria and standardized tests should be performed in the future to answer all the opened questions regarding management of APS.

Genomic imprinting and post-translational modifications

RATIONALIZE TO TARGET IMMUNE MEMORY RESIDING IN INFILLED TISSUES

H.-D. Chang, German Rheumatism Research Center Berlin, Berlin, Germany

T helper (Th) lymphocytes play a major role in the regulation of immune responses and are thought to initiate and drive chronic rheumatoid inflammation. Memory Th lymphocytes persist in the inflamed tissue and are refractory to therapy. Inflammation in Th lymphocytes have undergone molecular adaptations, such as the upregulation of Twist1 and the microRNA miR-148a, which are not found in circulating Th lymphocytes, and support the survival of the Th cells within the inflamed tissue. Within the inflamed tissue, the Th lymphocytes constantly recruit and activate inflammatory cells, such as monocytes/macrophages and granulocytes through the secretion of particular chemokines and interleukins. The monocytes/macrophages in turn can recruit more Th cells into the inflamed tissue. Disrupting this vicious circle by specifically targeting the memory Th cells resident in the inflamed tissue by interfering with their molecular adaptations could be an interesting therapeutic option.

THE ROLE OF POST-TRANSLATIONAL MODIFICATION AND AUTOREACTIVITY

R. Toes, Rheumatology, Leiden University Medical Center, -Leiden, Netherlands

Rheumatoid arthritis (RA) is a prototype autoimmune disease, with the hallmark signs of synovial inflammation and the presence of autoantibodies. Of the different autoantibody systems present in RA, rheumatoid factors (RF) are probably the best studied. Their presence was first detected > 70 years and it was in the late 1950s when it was realized that RF reacted to gamma globulins. Since the discovery of RF several other autoantibody systems have been discovered in RA, many of them directed against post-translationally modified protein antigens. The most prominent example of such autoantibodies are anti-citrullinated protein antibodies (ACPAs), which are directed against a wide array of citrullinated proteins. Now RF and ACPA determination are the two major diagnostic laboratory tests for RA and part of the EULAR and ACR criteria for RA.

In the past few years, it has become clear that the autoantibody response present in RA extends towards several other modified proteins, such as proteins modified by acetylation or carboxylation. As all these auto-antibodies recognize Post-Translationally Modified (PTM) proteins, these antibodies are collectively called Anti-Modified Protein Antibodies (AMPA). In the context of this presentation, I will focus on the auto-antibody response against citrullinated, carbamylated and acetylated proteins.

Carbamylations lead to the formation of homocitrulline. Structurally, homocitrulline greatly resembles citrulline but is one methylene group longer. Citrulline is generated when PAD enzymes modify the amino acid arginine. In contrast, the amino acid homocitrulline is generated by a chemical reaction in which cyanate reacts with the amino acid lysine. Arginine and lysine are located at different positions in the amino acid sequence of proteins, and therefore these modifications occur at different positions in proteins with different flanking amino acids. Intriguingly, although homocitrulline residues can also be recognised by auto-antibodies, these auto-antibodies often do not crossreact with citrulline.

Acetylation is a process where acetyl groups are added to free amines of lysine residues by acetyl transferases. Acetylated lysine does not resemble citrulline but bears similarity to homocitrulline except at the side chain terminal amine, which is replaced by a methyl moiety.

By now it is clear that AMPA consist of different auto-antibody families that are largely distinct, but that they also display a certain degree of cross-reactivity. Therefore, the notion is emerging that, although cross-reactivity exist, different classes of AMPAs are generally seen as distinct auto-antibody families that target different antigens, but intriguingly often co-occur. As the AMPA-responses in RA are often found together, it indicates that –somehow- AMPA-reactivity has a commonality that is currently not understood.

Although, the reason why an immune response starts against PTM proteins is not known, it appears crucial to obtain understanding on the break of tolerance towards PTM proteins as the immune response against these proteins has been intimately implicated in disease-pathogenesis. Understanding the full AMPA response, the triggers that drive AMPA production, their mutual crosstalk and the pathways by which AMPA and/or AMPA-expressing B cells possibly contribute to RA will be important for the development of curative interventions in RA. In the context of this presentation, some of these aspects will be discussed.

SP0156 HOW BIG DATA HELP US UNDERSTAND NEW AND OLD THERAPY TARGETS

P.E. Lipsky, Ampel Biosolutions, Charlottesville, United States

Gene expression profiling is a valuable tool to identify the altered cellular state and to meta-analyze expression profiles from multiple gene expression microarrays. In this study, we performed metaexpression analysis of 556 independently conducted microarray expression profiling studies (comprising 1,152 samples), which were deposited in the GEO database (GSE accession number GSE109791). The studies covered a wide range of human tissues and diseases, including cancer, inflammation, and metabolic diseases. We used a custom algorithm to identify differentially expressed genes and to meta-analyze these genes across studies. The algorithm takes into account the statistical significance of the expression changes and the biological relevance of the genes. We identified a set of genes that were consistently upregulated across multiple studies and that were enriched in biological pathways related to inflammation and cancer. These genes include regulators of the immune response, such as interferon genes, and genes involved in metabolic processes, such as adipokine expression. The results of this study suggest that metaexpression analysis can be a powerful tool for identifying new drug targets and for understanding the molecular mechanisms of disease.
**IS DIABETES AN INFLAMMATORY DISEASE AND SHOULD BE TREATED LIKE THAT?**

A. Schaeffer, Department of Internal Medicine-III, Endocrinology and Diabetes, University of Giessen, Germany, Giessen, Germany

It is a well-known clinical observation that inflammatory diseases are accompanied by metabolic implications such as hyperglycemia, insulin resistance and increased fatty acids. On the other hand, metabolic diseases have inflammatory implications. There is a chronic and low-grade state of inflammation in obesity and type 2 diabetes. Physiological insulin resistance during infection or inflammation redistribute glucose and fatty acids to immune cells. On the basis of systemic and adipose tissue inflammation such as MCP-1/LTR-4-driven macrophage infiltration and pro-inflammatory polarization of these cells, this lecture will give a summary of anti-diabetic effects of anti-inflammatory drugs used in rheumatology. What is the evidence from clinical studies using anti-inflammatory approaches to treat patients with type 2 diabetes mellitus? Basically, TNF plays an important role in insulin resistance in rodents. Blocking TNF in rodents reverses obesity-related diabetes. There are no state of the art clinical studies showing convincing evidence of an anti-diabetic potential due to underpowered cohorts and short duration of the studies. Only one single study over 6 months showed a 10% improvement of fasting glucose levels in 40 prediabetic obese patients. Diacerein belongs to the chemical group of anthranoids. Although the mechanism of action is unknown, diacerein decreases the levels of TNF and of IL-1b and has therefore been used in rheumatic diseases. Diacerein has potent effects on insulin secretion and glycemic control with a reduction of HbA1c level by 1.6%. IL-1 receptor antagonists such as anakinra (a recombinant human IL-1 receptor antagonist) have also been studied in diabetes. Anakinra was able to improve glycemia, inflammation and insulin secretion. Two additional studies in patients with impaired glucose tolerance or prediabetes demonstrated positive effects of anakinra on beta cell secretory capacity. Since anakinra requires daily injections and often causes adverse effects at the injection site, humanized antibodies against IL-1b have been developed. Each of these antibodies had beneficial effects in patients with type 2 diabetes. However, studies were either underpowered or showed only little improvements of glycosylated HbA1c levels, probably due to low pre-study levels. Inhibition of the IKK/NFkB pathway might also be of benefit in insulin resistance. Salsalate improves insulin sensitivity, insulin secretion and glycemic control to a moderate extent of 0.4–0.5%. Salsalate also has effects in prediabetic patients and in drug-naive type 2 diabetic patients. There is upcoming evidence of potential beneficial effects of CCR2 antagonism in diabetes.

Obesity causes an increased flux of fatty acids into muscle and liver with an accumulation of DAG in these organs. DAG activates specific isoforms of protein kinases, that is PKC T in muscle and PKC E in the liver. These isoforms cause an inhibitory phosphorylation of IRS-1 and the insulin receptor itself leading to insulin resistance. Weight reduction by diet, physical activity and bariatric surgery remove ectopic fat and are able reverse diabetes. Most interestingly, PKC-isoform specific inhibitors such as FGF-21 might represent new drug targets.

**THE ROLE OF ADIPOSE TISSUE IN OSTEOARTHRITIS**

A. Ioan-Facsinay, Leiden University Medical Center, Leiden, Netherlands

The association between obesity and osteoarthritis (OA) is nowadays well-accepted. This association is present both in weight-bearing and non-weight-bearing joints, indicating that next to local effects, systemic effects associated with obesity could play a role in disease. The relative contribution of local and systemic effects could be different in each joint. In this presentation, I will summarize the current knowledge about the contribution of local and systemic adipose tissues to osteoarthritis in different joints, with emphasis on knee OA. Moreover, obesity-associated changes and their role in OA will be highlighted.

The key messages I would like to convey are:

- Mechanical stress is a major contributor to knee OA
- The infrapatellar fat pad (IFP), an intra-articular adipose tissue in the knee, is distinctly different from other adipose tissues and could play a role in knee OA
- Only few obesity-related features have been described in IFP in OA

**ADIPOKINES IN THE PATHOPHYSIOLOGY OF CARTILAGE**

O. Guaillo, NEIRID Lab (Laboratory of NeuroEndocrine Interactions In Rheumatology and Inflammatory Diseases), Sergas Ids, Santiago de Compostela, Spain

Fat mass dysregulation is a marked characteristic of overweight and obesity. Obesity is, historically, a classic risk factor for osteoarthritis development and progression and shares with osteoarthritis a huge societal impact but also several common biochemical features that are strongly related to the low-grade inflammatory status. Even though OA has been considered during decades a disabling degenerative disease related to mechanical, age and genetic factors with poor inflammatory component, the current consensus is that OA, in particular OA associated with metabolic alterations, is a global muscle-skeletal diseases in which pro-inflammatory and catabolic mediators, most of them produced by a dysregulated visceral or periarticular white adipose tissue (WAT), are at play. The coexistence of obesity and OA is a clinical reality and is changing the traditional view of this degenerative disorder. Thus, chronic low-grade inflammation is a common characteristic shared by both obesity and OA. It has been demonstrated that obesity increases the incidence of OA, particularly in weight-bearing joints such as knees. However, the fact that obese individuals have an increased risk of developing OA in non-weight bearing joints such as hands and wrists suggests that factors produced by WAT play a role in the onset and/or progression of OA. In addition to a growing body of evidence demonstrating that obesity has a direct mechanical effect joint cartilage, recent research shows that pro-inflammatory factors produced by WAT (collectively known as adipokines) promote further inflammation and degradation of cartilage, also influencing the whole joint environment (i.e. synovium, muscle, bone and immune cells). Accumulating evidence shows another potential source of inflammatory adipokines in the joint is the Hoffa infrapatellar fat pad. Adipokines including leptin adiponectin, visfatin and lipocalin 2 have been demonstrated to exhibit a wide spectrum of biological activity including the activation of pro-inflammatory and catabolic pathways mediated by elevated levels of NO, ROS, MMPs and PGE2. The discovery of adipokines has made a major contribution to our understanding of the complex relationship between diabesity and OA, encompassing a variety of factors that include the immune system, metabolism and biomechanics. A critical aspect that must constantly be borne in mind is that diabesity and OA share a low-grade inflammatory state that heavily influences the course of OA progression. Therefore, the prevention and correction of diabesity should be the first line approach for tackling the detrimental effects of weight gain, adiposity and altered metabolic WAT function in OA. The aim of this lecture is to summarize the role of adipokines in bone and cartilage function, as well as in inflammatory and degenerative joint disease. We discuss clinical implications and then survey attempts to exploit this role for therapeutic gain, which holds potential as a novel approach for drug development in bone and joint disease.

**INTERVENTIONS TO IMPROVE MEDICATION ADHERENCE IN PATIENTS WITH INFLAMMATORY ARTHRITIS**

J.E. Vriezelaar, Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands

Non-adherence to medication in rheumatic diseases is a major concern for patient’s health, because incorrect use can result in less therapeutic benefits of treatment, including more disease activity and increased radiological damage. As a consequence, non-adherence may lead to more disability and lower health-related quality of life. Using Lowe’s taxonomy, the current state of evidence around medication adherence interventions will be presented. Examples of promising intervention strategies will be highlighted.

**BARRIERS AND FACILITATORS TO ADHERENCE TO MEDICATION IN PATIENTS WITH INFAMMATORY ARTHRITIS**

K. Koutsogianni, The Arthritis Foundation of Crete, Heraklion, Crete, Greece

**Background:** Inflammatory arthritis can cause pain, stiffness, joint damage and even disability. From diagnosis and early treatment. The full benefit of several treatments recommended, can be achieved if patients strictly follow drug regimens. However, rates of adherence to prescribed medications in patients with inflammatory arthritis seem to be suboptimal.

**Objectives:** To identify the barriers and facilitators for adherence to medication in patients with inflammatory arthritis seem to be suboptimal. However, rates of adherence to prescribed medications in patients with inflammatory arthritis tend to be quite low and range from 30–80%.

**Methods:** A survey conducted among patients of the Arthritis Foundation of Crete aiming to assess the degree of their adherence to MTX therapy. A survey conducted among patients with inflammatory arthritis. Experiencing beneficial effects of the medications and being able to maintain autonomy and social participation, receiving clear and understandable information about the treatment options, having support from family and friends, having a good relationship with the treating physician and being involved in shared decision-making process are the keys for leading the patients to better adherence.

**Conclusion:** A good patient-health professional relationship, knowledge about the treatment options, having support from family and friends, having a good relationship with the treating physician and being involved in shared decision-making process are the keys for leading the patients to better adherence.

**CAN MUSCULOSKELETAL ULTRASOUND INFORM HEALTH BELIEFS AND PLAY A ROLE FOR MEDICATION ADHERENCE?**

K. Kumar, University of Manchester, Manchester, United Kingdom

Rheumatoid Arthritis (RA) is a condition with no cure and can cause disability. RA affects nearly 1 in 100 adults. Early disease is characterised by pain and other features of inflammation, such as heat, swelling of joints, and loss of function. RA is associated with increased costs of co-morbid conditions (such as cardiovascular (CVD)) associated with RA.

Medication can ease symptoms and limit disease progression in RA. Despite this, non-adherence to medication is common in RA. In the UK, we found that patients’ joint swelling via musculoskeletal ultrasound scan as an educational tool helped to increase beliefs about the necessity of treatment.

Our study provided a deeper understanding of adherence to disease modifying anti-rheumatic drugs (DMARDs) in patients with RA. Improving adherence is likely to be facilitated by incorporating visual representations of the disease process and better explanations from the consequences of poorly controlled RA into the consultation. This session will uncover some suggestions around the use of musculoskeletal ultrasound in improving adherence to DMARDs.

HORIZON 2020: OPPORTUNITIES FOR MEDICAL RESEARCH AND INNOVATION

S. Hogan, DG Research, Directorate Health, European Commission, Brussels, Belgium

Horizon 2020 is the largest EU Research and Innovation programme ever with nearly €80 billion of funding available over 7 years (2014 to 2020). It is an opportunity for supporting excellence and collaboration in research, and on a scale and scope that is seldom feasible at global level. Horizon 2020 contributes to the Innovation Union, a Europe 2020 flagship initiative aimed at securing Europe’s global competitiveness. By coupling research and innovation, Horizon 2020 is helping to achieve this with its emphasis on excellent science, industrial leadership and tackling societal challenges. The goal is to ensure Europe produces world-class science, removes barriers to innovation and makes it easier for the public and private sectors to work together in delivering innovation. This is seen as a means to drive economic growth and create jobs.

EULAR Projects - challenging projects in education and training

SP0168 THEORY OF POSTER DESIGN AND PRESENTATION

M. Boers, Epidemiology & Biostatistics; Amsterdam Rheumatology and Immunology Center, VU University Medical Center, Amsterdam, Netherlands

This lecture introduces basic elements of poster design, and is followed after the session by a special poster tour devoted to design. It strongly links to the concepts discussed in my workshop on data visualization. To design an effective poster, its message and the intended audience must be clear. Effective posters stand out because they convey their main message almost instantly, and then seduce participants to stay longer and learn more. Much more than oral presentations, posters are about selling your work in competition with all those other people presenting in your session. In a good poster, all elements work together like a symphony orchestra: Title, headings, text, tables, graphs, format, colors, layout, handouts, gimmicks, and... you! For the design process, you need a good plan (including timelines!), good tools (templates, software!) and a ruthless editor. Editing is about throwing out more and more stuff, until finally you reach the point where throwing out more destroys understanding. So the “orchestra” has single instrumentation, and is wonderfully transparent.

Posters are not "comprehensive"! All the details you love can go into a specially designed handout (NOT an exact replica of your poster). Your role as presenter is special: you must be visible but unobtrusive, and flexible to accommodate different viewer styles, and have different modes of presentation (eg, walkthrough, answer questions, respond to critique). Also make sure your contact details are visible and correct (if no handout, be sure to have business cards). If you are playful you can use gimmicks to increase your visibility: match your clothes to your color scheme, make something in real 3D on your poster, use sound, etc. But don’t overdo it: this is just the icing on the cake: this is a science, not a commercial exhibit.

When we go to assess posters in the upcoming poster tour, we will be looking for the following elements:
1. Overall message clear?
2. Text quality: brevity, clarity
3. Table quality: clear vision, clear understanding
4. Graph quality: clear vision, clear understanding
5. Design elements: layout, choice of font, color
6. Handout: not a replica, elements 1–5 repeated
7. Presenter: style, contact details

EULAR SCHOOL OF RHEUMATOLOGY, A CHALLENGING EDUCATIONAL EULAR PROJECT. WHERE ARE WE NOW?

J.W. Bijlsma, Rheumatology & Clinical Immunology, UMCU, Utrecht, UTRECHT, Netherlands

In the last decade EULAR has further developed its educational portfolio. Apart from very educational tracks in the EULAR Congress, EULAR offers:
• on-line courses (Rheumatology, Connective Tissue Diseases, Scleroderma, Paediatrics, Ultrasound, Health Professionals), that are being followed by thousands of students all over the world
• text-books, based on the on-line courses
• live courses, such as the Postgraduate Course, Ultrasound courses, capillaroscopy, epidemiology, immunology, teach the teachers
• exchange programs, for trainees, scientists, health professionals and patients
• on-line image library, on-line outcome registry
• learning DVDs for medical students
• scientific endorsement of other courses

To bring all these offerings under one umbrella, EULAR decided to found the School of Rheumatology. But the School is doing substantially more: we identified 7 areas (classrooms) where we bring enthusiastic and involved people together to evaluate the present needs in those areas and to prioritize new educational activities for those unmet needs. The following classrooms are actively developing new products:
Classroom medical students: formulating standard curriculum for musculoskeletal diseases arbs and providing video-matials to support teachers and students.
Classroom trainees in rheumatology: start of a journal club, evaluating possibilities to install a European (EULAR) examination to become a rheumatologist, imaging on-line course.
Classroom teachers: course on assessment questions was already held, a teach the teachers event is planned.
Classroom rheumatologists: development of a pocket primer on rheumatic diseases, to be used as an app.
Classroom scientist: preparing a possible on-line course on epidemiology and clinical (trial) research, evaluating possible webinars for basic science methodology.
Classroom health professionals: preparing an accreditation system for health professionals; expanding on-line courses.
Classroom patients: implementing and distributing lays versions of recommenda-
tion; development of a patient partner program in research; webinars on actual items in the form of questions and answers (eg biosimilars).

Some of the items on this agenda can be organised within one year, for some others many years are foreseen; it will be a dynamic process. Ideas and support are very welcome via the EULAR Standing Committee on Education, or directly to the EULAR office, attention of the education program manager.

SP0170 ASSESSING RHEUMATOLOGY SKILLS

C. Haines, The Medical School, The University of Nottingham, Nottingham, United Kingdom

Medical Education is making great advances in understanding the power of assessment. Modern learners seek frequent, faster feedback on their learning to study more effectively. It is now common for examinations to be statistically monitored in order to show that acceptable levels of reliability have been reached. But, a test is only as good as its questions. Clinicians are not often trained in how to create valid and reliable test questions. This session will describe some basic principles for creating valid and reliable tests for the knowledge, skills and attitudes which are required by practising rheumatologists. The speaker is currently the Eular Educationalist, who advises Eular on how to continually enhance assessment processes for the online courses and the new trainee examination.

As a result of the session participants will be better able to:
• Describe reliability fairly validly and apply Eular assessments
• Describe the differences between formative assessment for learning and summative assessment for grading
• Identify improvements which they could make to test questions
• Identify improvements which they could make to tests

SP0171 HOW TO SELECT THE MOST APPROPRIATE CAPILLAROSCOPIC DEVICE: PROS AND CONS

F. Iaconelli, Dept. of Clinical Sciences and Community Health, Università degli Studi di Milano, ASST Gaetano Pini, MILANO, Italy

Nailfold capillaroscopy is a simple noninvasive imaging technique mainly used to observe capillaries within the first few micrometers from the skin surface. After application of a drop of immersion oil, capillaries can be observed with a magnification lens because they run parallel to the epidermis at the nail bed area. The study of the morphology of superficial nailfold capillaries provides clinically
relevant information in the management of patients with scleroderma-spectrum diseases. Recently, an international survey on non-invasive techniques to assess the microcirculation performed under the aegis of members of the European League Against Rheumatism (EULAR) Study Group on Microcirculation in Rheumatic diseases (SG_MC/RD) showed that nailfold videocapillaroscopy was the one most used technique in both clinical and research settings by adult physicians and paediatric rheumatologists to assess patients with Raynaud’s phenomenon. A number of different instruments are available to perform the exam. They have different characteristics in terms of their cost, quality of images, magnifications, training period, portability, software for image analysis and storage. Some of these instruments can be used both in clinical and research settings such as the stereomicroscope and the videocapillaroscope. The stereomicroscope allows the widefield visualization of the nailfold with low magnifications, the training is relatively short, but the examination is difficult to perform in patients with digital flexion contractures. There appears to be consensus regarding the use of videocapillaroscopy that allows a detailed visualisation of capillary morphology using higher magnifications (100–300x). Contact probe with polarized light microscopy permits easier observation of the skin surface, and the training period is briefer. Specific softwares are available for images analysis, storage, and complete medical reports (text + images) can be produced. By contrast, in a clinical setting, nailfold capillaries can generally be visualised using more simple but also efficient tools such as a dermatoscope, USB microscope, ophtamloscope or smartphone device. The quality of images can be quite good, although the lower magnification means that some details are unlikely to be seen, and they often lack the possibility of image storage and measurement. In particular, the dermatoscope with magnification of the order of x10 is a small, inexpensive and easily portable piece of equipment that has been suggested to be comparable to videocapillaroscopy in routine clinical practice.

SP0172 MANAGING VOLUNTEERS- A UK PERSPECTIVE

C.B. Jacklin. External Affairs, National Rheumatoid Arthritis Society, Maidenhead, United Kingdom

Volunteers are an integral part of any charity and it would be impossible to run a charitable organisation without the support of volunteers. Like paid staff they need to be trained, nurtured and rewarded but as volunteers they need to be handled in a very different way to employees. People who volunteer do so for many different reasons and not always perhaps for the right reasons so managing volunteers takes great skill and diplomacy. My talk will cover how to value volunteers, lessons we have learned from observation of the skin surface, and the training period is briefer. Specific softwares are available for images analysis, storage, and complete medical reports (text + images) can be produced. By contrast, in a clinical setting, nailfold capillaries can generally be visualised using more simple but also efficient tools such as a dermatoscope, USB microscope, ophtamloscope or smartphone device. The quality of images can be quite good, although the lower magnification means that some details are unlikely to be seen, and they often lack the possibility of image storage and measurement. In particular, the dermatoscope with magnification of the order of x10 is a small, inexpensive and easily portable piece of equipment that has been suggested to be comparable to videocapillaroscopy in routine clinical practice.

SP0173 THE CHALLENGES OF A SMALL ORGANIZATION

M. Kosanovic, Association of Rheumatic Diseases Patients of the Republic of Serbia (ORS), Belgrade, Serbia

When a group of citizens establishes a non-profit and a non-government organisation in our country, those volunteers are carried by great enthusiasm. At the beginning when founding an NGO the main problems are lack of experience and financial resources. Those deficiencies can be overcome by some other qualities such as the personal competencies of volunteers. As NGOs are seen by the public rather critically in our country, our organization had to face several additional challenges. In my presentation I will illustrate the following aspects: the non-attractiveness of NGOs for volunteers, the lack of awareness how volunteering is important for a society, the lack of knowledge how to attract volunteers and how to manage them, the lack of knowledge how to define the volunteers’ positions and how to monitor their work, the lack of their systemic, continuing education and the lack of rewards, recognition and appreciation to acknowledge the most dedicated volunteers.

SP0174 WAYS OF SUPPORTING VOLUNTEERS

S. Syzmann, Rheuma-Liga Baden-Württemberg E.V., 76646 Bruchsal, Germany

The promotion of volunteer workers is an indispensable part of the human resources policy of self-help organizations and requires specific concepts. Using the example of the rheumatism league Baden-Württemberg -an organization with 65,000 members, 3,000 volunteers and 10 fulltime employees- there will be shown best-practice examples. A successful concept covers the areas of recruitment, training, support and integration.

1. The support of volunteers should include four key areas:
   1. Transfer of knowledge and professional competences
   2. Individual support for personal development
   3. Promotion of teamwork and social skills
   4. Framework conditions (insurance cover, reimbursement of expenses)

The implementation of these requirements should be carried out by specifically trained volunteer managers on the basis of a strong and motivating personal relationship.

This strategy can be seen as a precondition for establishing a long-term relationship of the volunteer with the association, a successful local work, satisfied members and volunteers who perceive their work as satisfying and fulfilling.

Slik Szymank

SP0175 WHAT IS NEW IN JUVENILE IDIOPATHIC ARTHRITIS

N.M. Wulffraat. Dept. of Paediatrics, University Medical Center Utrecht, Dept. Pediatric Rheumatology, Utrecht, Netherlands

Juvenile Idiopathic Arthritis comprises 7 subcategories. As the insights in pathogenesis progress so does the need for reclassification that is based more on biology than on clinical phenotypes. After a series of clinical trials for new biologicals, now trials are started that test specific treatment strategies such as treat to target an d step down studies. Especially rapid induction of remission is currently a major aim, followed by biomarked guided tapering of medication.

The expanding number of potential biomarkers forms the basis for the creation of personalized medicine, a strategy aimed at providing individualized medication choices. Since most pediatric rheumatic conditions are rare, international collaboration is vital. The recently created European Reference Networks (ERN) will prove instrumental here.

Systemic sclerosis

SP0176 TARGETING VASCULOPATHY FROM THE BEGINNING

M. Cutolo on behalf of EULAR Study Group on Microcirculation in Rheumatic Diseases, Internal Medicine, Research Lab Division Rheumatology University of Genova, genova, Italy

In systemic sclerosis (SSc), the natural history of microvascular damage progresses from capillary dilation to capillary loss and reactive angiogenesis, as detectable by nailfold videocapillaroscopy (NVC) [1]. The process is systemic and determines multiple clinical manifestations, from the early appearance of Raynaud’s phenomenon, trough formation of digital ulcers (DUs), until severe organ involvement, impairing patient’s quality of life or leading to main death causes, including interstitial lung disease and pulmonary arterial hypertension (PAH), hearth involvement, sclerodema renal crisis [2,3]. Although microvascular and macrovascular abnormalities frequently coexist in disease such as diabetes mellitus and other vascular diseases, the possible association between microvascular failure and macrovasculopathy in SSc patients has not been deeply investigated. However, significant correlations seem to exist between increased Inntima-Media Thickness (IMT) of periferic small-caliber arteries (microcirculation) and altered peripheral BF (LASCA) at the level of hand microvessels (microcirculation) in SSc patients.

Silin addition, significant capillary loss, observed at NVC, is peculiar of the “Late” scleroderma pattern of microangiopathy and is mainly preceded by progressive capillary enlargement, microhemorrhages and their collapse, leading to presence of large avascular areas [4]. The importance of capillary loss was already demonstrated by a simple and reliable prognostic index, capable to predict digital trophic lesion development in SSc-related microvascular disease, when evaluated as part of the semi-quantitative NVC scoring [5]. Moreover, microvascular function and its alterations in SSc, can be reliably assessed by laser-doppler flowmetry (LDF) and laser speckled contrast analysis (LASCA), evaluating blood perfusion at fingertips or at larger body areas [6–9]. The most frequently used drugs for treatment of complications in SSc patients, approved with evidence grade la, are vasoactive drugs. In particular, for severe...

SP0181  FAILURE OF NATURAL REGULATORY AUTOANTIBODY NETWORK AS CAUSE OF AUTOIMMUNE
O.C. Marques on behalf of Lubeck University. Prof. Riemekasten. Reumathology, University of Lubeck, 23562 Lubeck, Germany

The role of autoantibodies in normal physiology is under debate. In investigating autoantibody (aab) concentrations against G protein-coupled receptors (GPCR) in different autoimmune diseases, we found both increased and decreased aab concentrations, which suggests physiological anti-GPCR aab levels may be dysregulated in autoimmune diseases. During our analysis of healthy donor antibodies to 16 GPCR and 15 growth factors and related signaling molecules, we discovered several clusters of correlations in these antibody concentrations. Possible functional interactions of these 31 autoantibody target molecules were studied by STRING, DAVID, and enriched Gene Ontology analyses. Through these analyses, a network of GPCR, growth factors, and signaling molecules with endothelin receptor type A (ETAR) in the center was revealed. Migration and adhesion assays were suggested to be the most significant functions regulated by the antibody network. Accordingly, IgG from healthy donors induced both IL-8 expression by peripheral blood mononuclear cells (PBMCs) as well as migration of neutrophils and tumor cells, which was specifically diminished by the ETAR antibody. It thus seems that a set of factors can influence the development of the antibody network. Accordingly, IgG from healthy donors induced both IL-8 expression by peripheral blood mononuclear cells (PBMCs) as well as migration of neutrophils and tumor cells, which was specifically diminished by the ETAR antibody. It thus seems that a set of factors can influence the development of the antibody network. This notion is supported by the observation that additional F(ab)-glosses are not found on ACAP-igG. How F(ab)-glosses facilitate the emergence and/or expansion of autoimmune B cells in this context, however, remains unclear. Using recently developed technology to identify and isolate citrullinated antigen-specific B cells from patients, we can now address this question by studying the frequency and localization of F(ab)-glosses in the antibody repertoire and by studying the phenotype and functional characteristics of ACAP-expressing B cells. Together with our investigations on the modulation of ACAP F(ab)-glosses, these studies provide a deeper understanding of mechanisms that allow the development of autoimmunity as such, and of the mechanisms that underlie the progression from systemic autoimmunity towards overt autoimmune disease.

SP0182  ALTERATIONS IN THE ANTIBODY REPERTOIRE AND SUGAR MODULATION AS CAUSE FOR AUTOIMMUNITY
H.U. Scherer, Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

Many autoimmune diseases are hallmarked by the presence of auto-reactive B cells that can develop into antibody-secreting plasma cells. In most cases, the secreted autoantibodies have extensively been studied in their role as disease-associated biomarkers, and for some, specific pathogenic effector functions have been demonstrated supporting the use of interventions that target the plasma cell compartment. In other cases such as rheumatoid arthritis (RA), however, the pathogenicity of specific autoantibodies is less clear, and the therapeutic efficacy of B cell depleting therapy that spares the plasma cell compartment indicates that auto-reactive B cells themselves can have pathogenic effector functions that contribute to disease. In this context, it is of great interest to understand the mechanisms that allow auto-reactive B cells to emerge from the naive repertoire, a process that marks the onset of systemic autoimmunity and frequently precedes the clinical onset of disease. RA is characterized by a remarkable appearance of autoantibodies that target post-translational modifications of proteins, of which anti-citrullinated protein antibodies (ACPA) display the highest specificity for disease. In addition, ACPA are expressed by both plasma cells and plasma cell-like dendritic cells, which can evolve and contribute to the development of such diseases. Furthermore, therapeutic approaches aiming to overcome these Treg cell defects and to restore Treg cell activity in the patients will be discussed.

SP0183  FAILURE OF TREG CONTROL TO UNDERSTAND AUTOIMMUNITY
J.Y. Humrich, Department of Rheumatology and Clinical Immunology, University Hospital Schleswig-Holstein, Campus Luebeck, Luebeck, Germany

Regulatory T cells (Treg) expressing the transcription factor FoxP3 are crucial for the maintenance of immunological tolerance to self and thus for the control of autoimmunity. There is strong evidence that numeric or functional defects in Treg cell biology are involved in the pathogenesis of particular autoimmune diseases. Here we will focus on the fundamental role of Treg cells in diverse autoimmune and rheumatic diseases and will explain how a failure of the Treg cell system can evolve and contribute to the development of such diseases. Furthermore, therapeutic approaches aiming to overcome these Treg cell defects and to restore Treg cell activity in the patients will be discussed.

SP0184  ROLE OF MICROENVIRONMENT AND ENDOGENOUS PATHWAYS TO BREAK TOLERANCE
P. Lampecht, Universität Zu Lübeck, Lübeck, Germany

Break of tolerance driving autoimmune disease is initiated by a combination of predisposing genetic and environmental factors resulting in self-perpetuating chronic inflammation and tissue damage. Effector molecules and cells targeting tissues housing the inciting autoantigen(s) maintain tissue damage and the autoimmune response. Granulomatosis with polyangiitis (GPA, formerly Wegener’s granulomatosis) is a prototypic autoimmune disease characterized by extravascularizing granulomatous inflammation and specific autoantibodies to 16 GPCR and 15 growth factors and related signaling molecules, which is mainly induced by T cells that provide help to B cells. As ~90% of all ACPA-IgG molecules carry such F(ab)-linked N-glycans, and as protective antibodies in the same individuals and many autoantibodies in other diseases do not show this feature, it is conceivable that the contribution of F(ab)-glosses by ACAP-IgG is a T cell –mediated process that provides a selective advantage to ACAP-expressing B cells. This notion is supported by the observation that additional F(ab)-glosses are not found on ACAP-IgG. How F(ab)-glosses facilitate the emergence and/or expansion of auto-reactive B cells in this context, however, remains unclear. Using recently developed technology to identify and isolate citrullinated antigen-specific B cells from patients, we can now address this question by studying the frequency and localization of N-glycosylation sites in the antibody repertoire and by studying the phenotype and functional characteristics of ACAP-expressing B cells. Together with our investigations on the modulation of ACAP F(ab)-glosses, these studies provide a deeper understanding of mechanisms that allow the development of autoimmunity as such, and of the mechanisms that underlie the progression from systemic autoimmunity towards overt autoimmune disease.

This clinical form of OA may be associated with a so called “erosive” radiographic aspect marked by subchondral erosions of the finger joints and ankylosis. Many mediators of inflammation have been involved in the pathogenesis of osteoarthritis such as prostaglandin E2, free radicals and main cytokines (IL1B, IL6, and TNFa). Using Doppler power ultrasonography and magnetic resonance imaging, it has been shown that synovial fluid is frequently associated with HOA and correlates with pain and with disease progression. Taking all these considerations together, it appears logical to target synovitis in HOA, especially with an erosive form. Because erosive hand OA is a polyarticular disease, the treatment is more systemic than local.

Local or oral NSAIDS are out of scope because this presentation focuses on systemic than local.

HOA, especially with an erosive form.

Using anti-IL1B strategy, a decrease in pain has been observed in 3 patients subgroup of patient with clinically inflamed IP joints.

In the long term trial published by Verbruggen G, the incidence of new erosive lesions was decreased in Adalimumab group compared to placebo, only in a subgroup of patient with clinically inflamed IP joints.

Using anti-IL1B, there is still a decrease in pain has been observed in 3 patients subgroup of patient with clinically inflamed IP joints.

DIVERGENCES BETWEEN OBJECTIVE AND SELF-REPORTED PHYSICAL FUNCTION IN FIBROMYALGIA

M. Henriksen, Parker Institutet Frederiksborg Hospital, Copenhagen, Denmark

In fibromyalgia (FM), intolerance to physical activity, with increased pain and experience of early muscle fatigue, is a predominant feature. Furthermore, shorter endurance times and higher perceived effort during physical activity compared with healthy controls are characteristic. However, there are discrepancies between physical functioning as perceived by the patients and as measured objectively or during performance tests. For example, in 840 FM patients and 122 healthy controls, we found reduced muscle strength in approximately 50% of the FM patients. However, the patients with subnormal muscle strength did not self-report worse symptoms or more physical disability than those with normal muscle strength. Much like central sensitization of pain, it has been suggested that impaired sensory-motor interaction is present in FM, which may be a cause for observed discrepancies between perceived and objective signs of muscle fatigue. That is, the sensory inputs to the central nervous system during a physical activity are over-interpreted, leading to amplified sensations of fatigue and discomfort normally associated with the confounding muscle work. To illuminate this we conducted a controlled experiment, in which FM patients and health controls completed a muscle exhaustion test, while objective measures of muscle fatigue were collected by electromyography in parallel with reporting of perceived muscle fatigue. The results suggest that among FM patients, central nervous system processes normally associated with muscular fatigue were present, yet without any evidence of peripheral muscle fatigue. The study supports a hypothesis about abnormal sensory-motor interaction among FM patients that can explain the discrepancies between perceived and observed physical disability in FM.

COGNITIVE FOG: SUBJECTIVE AND OBJECTIVE UNDERSTANDINGS OF THE SYMPTOM OF DYSCOGNITION

B. Wallit, National Institute of Nursing Research, National Institutes of Health, Bethesda, United States

Dyscognition refers to the complaint that a person's ability to perform thinking tasks is impaired. This complaint is colloquially known as "brain fog". It is a major symptom of a variety of disorders and associated with considerable work and social disability for those experiencing it. However, attempts to demonstrate objective cognitive impairment in persons reporting "brain fog" have not been straightforward. In this lecture, the symptom of cognitive dysfunction will be described from the patient's point of view, using fibromyalgia as a disease model. The cognitive tests used to determine objective alterations in cognitive ability will be reviewed, the amount of objective impairment demonstrated in fibromyalgia will be placed into clinical context, and the "disconnect" between what the experience of dyscognition is and the cognitive content measured by modern testing will be discussed. The poor relationship between the magnitude of subjective dyscognition and objective cognitive performance will be examined, and evidence gleaned from neurological imaging studies. In conclusion, the experience of cognitive fog is not well captured by current testing paradigms. Subjective complaint is a poor predictor of objective cognitive performance. The neuronal mechanisms responsible for the experience of cognitive fog may be separate from those required to perform cognitive tasks.

ASSOCIATIONS OF PAIN-RELATED COGNITIONS WITH THE DISCORDANCE BETWEEN SUBJECTIVE AND OBJECTIVE PHYSICAL FUNCTION IN FIBROMYALGIA: THE AL-ÁNDALUS PROJECT

F. Estévez-López1, R.A. Luqmani2
1 Department of Physical Education and Sport, Faculty of Sport Sciences, University of Granada, Granada, Spain; 2 Department of Psychology, Faculty of Social and Behavioural Sciences, Utrecht University, Utrecht, Netherlands

Background: In fibromyalgia, there is a disagreement between patients' self-reports and performances; i.e., subjective and objective status, respectively.

Objectives: First, to test the discordance between subjective and objective measures of physical function. Second, to determine whether catastrophizing and self-efficacy are independently associated with this discordance.

Methods: Four hundred and five fibromyalgia females and 193 age-matched female controls. Participants filled out the Pain Catastrophizing Scale, Chronic Pain Self-efficacy Scale, and physical functioning subscales of the Revised Fibromyalgia Impact Questionnaire (FIQ-R) and Short Form-36 (SF-36) health survey. Objective physical function was measured with a battery of performance-based tasks (e.g., 6-min walk-test). Subjective and objective physical function were expressed as deviation from the general population in standard deviation (SD) units using means and SD of the control group.

Results: Fibromyalgia patients reported a worse physical function than performed (p<.001). We found a consistent association of higher catastrophizing with higher discordance between subjective and objective physical function. A significant association of higher self-efficacy with lower discordance was only found when subjective physical function was reported on the SF-36 but not on the FIQR.

Conclusion: Although both are markedly impaired, subjective physical function is more impaired than objective physical function in fibromyalgia. Catastrophizing is associated with this discordance. In rehabilitation settings, physical function of fibromyalgia females should be evaluated by both subjective and objective assessments to fully understand their physical function.

THE DRUGS DON'T WORK

L. Piggott, Fibromyalgia, Nantwich, United Kingdom

This presentation will depict the journey of Louise, a previous school teacher and a single mother of two, living with Fibromyalgia as well as multiple other diagnoses. Louise will discuss her feelings around being diagnosed with Fibromyalgia, how this was communicated to her and what this meant for her career and family life. Following this, Louise will share her journey through the secondary care as a Fibromyalgia patient, and her own search for answers and cure to Fibromyalgia in an attempt to salvage her life and independence, prior to accepting that this is a long-term condition which will require self-management and perseverance. In addition, Louise will share her thoughts on pain and fatigue in Fibromyalgia, and how the “drugs don’t work”.

Interactive cases from the HOT and WIN sessions —

HOT SESSION: INTERACTIVE CLINICAL ASPECTS AND CASES ON VASCULITIS TREATMENT

R.A. Luqmani, University of Oxford, Oxford, United Kingdom

The systemic vasculitides are characterized by inflammation of blood vessels resulting in end organ, or tissue damage or necrosis. They are defined by the Chapel Hill nomenclature according to the calibre of the predominantly affected vessels. Other forms of vasculitis not defined by a predominant vessel size are also recognized (e.g., Behcet's syndrome). Large vessel vasculitides include giant cell arteritis and Takayasu arteritis; medium vessel vasculitides includes Kawasaki disease and PAN; small vessel vasculitides are divided into: immune complex small vessel vasculitis and anti-neutrophil cytoplasm antibody (ANCA) - associated vasculitis (AAV). The immune complex group, with moderate to marked vessel wall deposits of immunoglobulin and/or complement, is represented by anti-glomerular basement membrane disease, cryoglobulinaemic vasculitis, hypocomplementaemic urticarial vasculitis (anti-C1q vasculitis) and IgA vasculitis (Henoch–Schönlein). By contrast, AAV has few or no immune deposits associated with (in most cases) the presence of ANCA specific for myeloperoxidase (MPO-ANCA) or proteinase 3 (PR3-ANCA). Depending on their clinical presentation and ANCA specificity, AAV is divided into three major variants: granulomatosis with polyangiitis (GPA) (Wegener’s granulomatosis), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) (Churg–Strauss syndrome). In some cases, vasculitis is relatively trivial and may lead to minor, often asymptomatic clinical features such as splinter haemorrhages. However, in severe forms of ANCA associated vasculitis, the consequences of rapid onset of ischaemia and occlusion of blood vessels can lead to organ failure and death. The multisystem involvement in most forms of vasculitis can be a real challenge. Patients may present to different specialists resulting in diagnostic delay. The investigation of patients with suspected vasculitis should follow on from a careful history and examination to determine the likely diagnosis. The differential diagnosis is very wide. It is important to correctly identify patients with vasculitis as early as possible, but it is also important to rule out more common causes. In acutely unwell patients, the differential diagnosis depends on the combination of clinical features. Vasculitides tend to involve multiple organ systems. In fact, the more organ systems affected, the more likely it is that the patient has vasculitis.
We will review some examples of cases with what might appear to be unusual clinical features which form a more consistent pattern. Initial treatment is generally straightforward, but the evaluation of patients during the course of their illness is often difficult due to variation in disease, as well as drug toxicity, damage and co-morbidity. We will discuss examples of patients where relapse is suspected but not always confirmed.

In this overview we will summarise current practice in vasculitis, illustrated by cases to provide a clinical context in which to interpret and implement evidence based management of vasculitis.

Suffering in silence. Optimizing the management of psychological well-being for people with RMDs

SP0190
FACTS AND FIGURES: HOW MENTAL HEALTH CARE ADDRESSES THE PSYCHOLOGICAL BURDEN OF RMD’S IN EUROPE
E. Dures,
University of the West of England, BRISTOL, Bristol, United Kingdom

It is recognised that patients have to make behaviour changes and psychological adjustments to address the impact of inflammatory arthritis on their lives. Challenges include fluctuating pain, fatigue and flares of disease activity, and emotional consequences. Meeting these challenges effectively requires patients to engage in medical management, role management, and emotional management.

For some patients this can be a struggle, and the rheumatology team can be a valuable source of support.

This session will examine patient perspectives on the psychological impact of inflammatory arthritis and the role of the rheumatology team in meeting the associated support needs. It will look at the relationship between psychological distress, well-being and self-management, and will highlight patients’ views on the characteristics of patient-centred, collaborative care. It will look at factors that influence psychological impact, adaptation and self-management; present data from patients on ways in which well-being and self-management can be enhanced or diminished through clinical interactions with the rheumatology team; and will consider the implications for clinical practice, including the training needs of the rheumatology team.

SP0191
PRINCIPLES OF NON-PHARMACOLOGICAL MANAGEMENT OF REGIONAL MUSCULOSKELETAL DISORDERS
P. Oesch,
Physiotherapy, Kliniken Valens, Valens, Switzerland

The two main components of non-pharmacological management of regional musculoskeletal disorders are a thorough assessment followed by rehabilitative care.

Assessment includes a careful history, level of daily activities and participation, including occupation, rehabilitative care to date, possible presence of psychosocial problems, sports and hobbies. Special attention must be given to patient’s expectations and personal objectives. A systemic enquiry is also important, as regional pain may be due to an underlying medical condition. Clinical examination consists of observation of posture, mobility, and whether there is evidence of wasting, asymmetry, deformity, or muscle imbalances. Palpation of soft tissue and bony structures follows to identify areas of tenderness, lumps, myofascial trigger points, tendon crepitus. Assessment of active and passive movements in all planes follows looking for specific restrictions. Examination is not restricted to the site of pain; as for example upper limb pain syndromes may be referred from the neck. In some patients further medical investigation is necessary when a thorough history, examination, and ultrasonography do not provide sufficient diagnostic information. This may involve blood tests, plain radiography, CT or MRI.

Rehabilitative care is a customized process, which aims to achieve an optimal functional outcome and participation in all aspects of life. Active rehabilitation and a gradual return to normal activities are key points in successful treatment of regional pain syndromes. Progressive exercise is a fundamental part of the treatment of most regional musculoskeletal complaints. The goal is to work towards full, specific, pain free functional activity. In myofascial pain syndromes and non specific arm pain in particular, there is a need for review of postural issues and ergonomics and building aerobic fitness. In addition, providing information to the patient about the nature of the condition, beneficial and negative habits and activities, self help exercises, expected response to treatment and outcome should all be part of the approach to these patients. Psychological interventions may complement rehabilitative care. Cognitive and behavioral methods focus on changing the patient’s interpretation and reaction to pain. The main assumption of a behavioral approach is that pain and pain disability are influenced by somatic pathology and also by psychosocial factors (e.g. patient’s attitudes and beliefs, psychological distress and illness behavior). Consequently, the behavioral treatment of regional musculoskeletal disorders does not primarily focus on removing an underlying organic pathology, but on the reduction of disability through modification of environmental contingencies and cognitive processes.

SP0193
PRINCIPLES OF NON-PHARMACOLOGICAL MANAGEMENT OF FIBROMYALGIA
J.E. Vriezekolk,
Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands

Having fibromyalgia greatly impacts person’s mental and physical wellbeing, his activities of daily living, and the society at large. Despite scientific progress to unravel the aetiology of fibromyalgia syndrome, no cure is yet available. The management of fibromyalgia comprises both pharmacological and non-pharmacological treatment option to alleviate the symptom burden of the disease.

The recently published EULAR revised recommendations for the management of fibromyalgia1, proposes that the management of fibromyalgia should take the form of a graduated approach with the aim of improving health-related quality of life. It should focus first on non-pharmacological treatment, including education, self-management and physical therapy with graded physical exercises. In this talk a brief overview of the current evidence regarding non-pharmacological treatment in fibromyalgia will be given. The importance of patients’ self-management, (tailored) interventions to support self-management, and its dissemination and implementation in clinical practice will be highlighted.

DOI: 10.1136/annrheumdis-2017-eular.7163
In clinical practice, assessment is important for the selection of intervention strategies, goal setting, prognosis and the evaluation of the progression made towards the treatment goals. For example, we need to assess the patients’ perceptions on how the disease, functioning and disability interfere with their life situation. Furthermore, we should assess how they can cope with stressful events, what social support they experience and how they adjust to living with a chronic disease. The assessment should provide information on problems, needs and priorities of the patients, as well as on strengths and resources. Based on the initial assessment, mutually agreed treatment goals and treatment strategies can be defined together with the patients.

We need to be aware of the differences, strengths and weaknesses of observations (e.g. Barthel Index), measures (walking speed) and self-reported questionnaires (patient-reported outcomes) or individualised, patient specific measures (e.g. the Patient-Specific Functional Scale).

In most situations, it is recommended to combine generic and specific measures to cover general as well as specific issues of health, functioning and disability or contextual factors. This will also allow the comparison across groups of patients. Each tool used in the assessment should serve a clear objective and should be able to achieve this objective in the given situation. We need to know the relevant measurement properties on reproducibility and validity for the instrument in a given situation. The agreement or the measurement error will tell us, for example, how small a change can be to be detected (i.e. smallest detectable change). This is important when we want to monitor change (evaluation). Reliability indices will tell us how good we can distinguish groups of patients and whether we can use an instrument in a group setting (i.e. in a study; the ICC should be at least 0.7) or for the use with individuals in clinical practice (ICC should be at least 0.9).

We can distinguish three types of validity, content validity, construct validity and criterion validity. The content validity informs on how good a tool covers all relevant aspects of the construct to be measured and whether all items cover relevant aspects. An instrument has a good criterion validity if its results are similar to a so-called gold standard (instrument that is known to be valid). The construct validity tells us whether the scores of the measurement instrument are associated with instruments that measure a similar construct and are not associated with scores from instruments that measure non-related concepts.

Other important aspects are responsiveness and interpretability. Responsiveness is the ability of an instrument to detect change over time in the construct to be measured. Interpretability means that the scores are understandable and meaningful. Aspects of interpretability are floor and ceiling effects, and whether the smallest detectable change and the minimal important change are known. Of course, the application of an instrument has to be feasible. Therefore, there is often a trade-off between measurement properties and feasibility, i.e. the perfectly reliable and valid instrument might be too expensive or too time consuming. Therefore, a less ‘perfect’ instrument might be chosen.

All the mentioned aspects need to be considered when defining an individual assessment strategy for a patient. The assessment and evaluation should be an integrated part of the treatment process. It verifies that the treatment is in line with the needs and priorities of the patients; the documentation of changes might motivate both patients and health professionals and it might increase adherence to the recommended treatments.

HPR Highlight session

HIGHLIGHTS FROM THE HEALTH PROFESSIONAL SESSIONS
R.J.O. Ferreira 1,2, 1Health Sciences Research Unit: Nursing (UICiSA-E), Escola Superior de Enfermagem de Coimbra; 2Rheumatology department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

EULAR congress is one on the biggest events in the world of rheumatology. To accommodate all the diversity of topics, several sessions take place at same time, in different rooms. It is very hard, even impossible, to be in all sessions, poster tours, social meetings and other learning events of your interest. It often happens that one want to be at 3 or 4 places at same time.

This “Highlights” session is designed to summarize the most important conclusions of the talks given in all sessions from Health Professionals programme. By this way you can catch on what you missed to be in other places. Of course you can also read the abstracts in the EULAR app or Annals of Rheumatic Diseases Suplement or even to watch the podcasts after the event. However, this highlights session will provide you an integrated view of the different contents in a more appealing and interactive perspective.

Scientific Abstracts
THE LUPUS LOW DISEASE ACTIVITY STATE (LLDAS)

E. Morand1, A. Berglind2, T. Sheytanova3, R. Tummala4, G. Illei4, 1Monash University, Melbourne, Australia; 2AstraZeneca, Mölndal, Sweden; 3AstraZeneca; 4MedImmune LLC, Gaithersburg, United States

Background: A LLDAS definition has received preliminary validation. Achieving low disease activity by this definition is associated with protection from disease accrual for patients (pts) with SLE. However, it has not been evaluated as an endpoint in randomized controlled trials (RCTs).

Objectives: We evaluated LLDAS as an RCT endpoint in a post-hoc analysis of the MUSE trial of anifrolumab in pts with moderate to severe SLE.

Methods: During the 52-week MUSE study, pts with active SLE received intravenous placebo, anifrolumab 300 mg, or 1,000 mg, in addition to standard of care, every 4 weeks for 48 weeks. LLDAS requires all of the following: SLEDAI–2K ≤5, prednisone ≤7.5 mg/d, and tolerance of standard immunosuppressant therapies. LLDAS utility, its association with other endpoints, and discrimination between anifrolumab- and placebo-treated pts, were explored using descriptive statistics, logistic regression, and Gray’s test. All randomized pts in MUSE were included in the analyses, and non-response imputation was performed after dropout.

Results: For pts receiving placebo (n=102), anifrolumab 300 mg (n=99), or anifrolumab 1,000 mg (n=104), LLDAS criteria were met at least once by 35% (300 mg: 1.7–2.5). LLDAS was attained earlier (300 mg: 1.7–2.5, p=0.012; 1,000 mg: 1.0–2.4, p=0.011) in anifrolumab-treated pts (Figure 1). At Week 52, more anifrolumab-treated pts attained a LLDAS (OR vs. placebo: 300 mg: 3.41, 95% CI 1.73, 6.76, p<0.001; 1,000 mg: 2.03, 95% CI 1.01, 4.07, p=0.046). More anifrolumab-treated pts spent ≥50% of observed time in LLDAS (OR vs. placebo: 300 mg: 0.34, 95% CI 1.34, 6.92, p=0.008; 1,000 mg: 2.17, 95% CI 0.93, 5.03, p=0.072), and the OR of sustained LLDAS for at least six consecutive visits from Week 12 to 52 were 4.02 (95% CI 1.38, 11.73; p=0.011) (300 mg) and 2.95 (95% CI 0.99, 8.78; p=0.052) (1,000 mg).

Conclusions: LLDAS is associated with validated treatment response measures. SRI(4) and BICLA, but is more stringent than either. Anifrolumab was associated with <3.6-fold OR increases in LLDAS attainment, as well as greater aggregate and sustained time in LLDAS. This LLDAS definition should be considered as a study endpoint in SLE RCTs.

MULTICRITERIA DECISION ANALYSIS FOR DEVELOPING NEW CLASSIFICATION CRITERIA FOR SYSTEMIC LUPUS ERYTHEMATOSUS

1Harvard Medical School, Boston, Massachusetts, USA; 2University of Toronto, University of British Columbia, Vancouver, Canada; 3Aesculapius Medical Group, Los Angeles, California, USA; 4Biocruces Institute, Barakaldo, Spain; 5Feinstein Institute, Manhasset, United States; 6Charite University, Berlin, Germany; 7Copenhagen University Hospital, Copenhagen, Denmark; 8Medical University of South Carolina, Charleston, USA; 9University of Michigan, Ann Arbor, United States; 10University of Pisa, Pisa, Italy; 11Northwestern University, Chicago, United States; 12Biocruces Institute, Barakaldo, Spain; 13Universitat Dusseldorf, Dusseldorf, Germany; 14Medical University Vienna, Vienna, Austria; 15University Medical Center Carl Gustav Carus, Dresden, Germany; 16McMaster University, Hamilton, Canada

Background: EULAR and ACR are supporting multi-phase development of SLE classification criteria based on weighted criteria and a continuous probability scale. Prior steps included criteria generation, criteria reduction through Delphi and Nominal Group Technique exercises, literature review for sensitivity/specificity of candidate criteria, and organization of candidate criteria into seven clinical and three immunologic domains.

Objectives: To refine definitions of candidate criteria, determine relative weights using multicriteria decision analysis, and determine a threshold score for SLE classification.

Methods: An SLE Expert Panel (9 North American, 8 European) submitted 167 unique cases with a range of SLE probability. Experts scored 20 representative cases using the candidate criteria and rank-ordered them. In a 2-day meeting, experts reviewed inter-rater reliability of scoring, refined criteria definitions, and participated in a multicriteria decision analysis (MCDA) exercise using 1000Minds™ software. Experts were presented a series of decisions between two cases, each with different criteria from two domains (e.g. oral ulcers [cutaneous] and acute pericarditis [serositis] vs. alopecia [cutaneous] and pleural effusion [serositis]) and anonymously voted for the case more likely to be classified as SLE. Votes were discussed until consensus was reached for each decision. Using the consensus decisions, 1000Minds™ calculated criteria weights, assigned a total score to each of remaining 147 cases and rank-ordered the cases. Experts voted on whether each case should be classified as SLE. MCDA was repeated for criteria whose calculated weights were inconsistent with expert opinion until group consensus was achieved. 1000Minds™ then re-calculated criteria weights and re-ranked cases once. The score of the last case for which expert consensus was achieved was the threshold score.

Results: Inter-rater reliability was good; human data entry error, not following instructions, and differing interpretations of criteria definitions accounted for discussion. The MCDA involved 74 pairwise decisions. Cranial neuropathy and Class VI lupus nephritis were removed as they added little to SLE classification. MCDA was repeated for the arthritis and cutaneous domains as initial weights did not match expert opinion. After criteria weights and scores were re-calculated once, experts reached consensus for SLE classification for case score >83.

Conclusions: Using an iterative process, the expert panel refined definitions, weighted candidate criteria and determined a threshold score of >83 for SLE classification, which will undergo validation.

Controlling the balance between cancer and autoimmunity

OP0003  RHEUMATIC IMMUNE RELATED ADVERSE EVENTS OF CHECKPOINT THERAPY FOR CANCER: CASE SERIES OF AN EMERGING NOSOLOGIC ENTITY
C. Calabrese 1, E. Kirchner 1, A. Kontzias 1, V. Velcheti 2, L. Calabrese 1

Background: Immune checkpoint therapy is a major advance in the field of oncology. Agents targeting CTLA-4, programmed cell death protein 1 (PD-1) and PD-Ligand 1 have produced significant survival benefits in patients with malignancies. With these therapies have come a unique spectrum of adverse events related to over-activation of the immune system resulting in autoimmunologic disease. To date reports of rheumatic immune related AE’s have not been adequately characterized, as they are infrequently reported in clinical trials. We describe the largest series of rheumatic irAEs secondary to checkpoint inhibitors to date.

Objectives: To report our 22 month experience with 19 patients evaluated in the Cleveland Clinic Rheumatology department.

Methods: A retrospective chart review was performed on 19 patients, 16 without pre-existing autoimmune disease (AID) and 3 with pre-existing AID, seen in our rheumatology department February 2015-December 2016. 2 designated rheumatologists evaluated all patients. Recorded information included gender, age, age at malignancy diagnosis, malignancy details, checkpoint inhibitor, nature of rheumatic irAE, time of onset, diagnostic data, treatment of irAE and response to treatment.

Results: In the group without pre-existing AID 56% developed a rheumatic irAE within 16 weeks of starting immunotherapy, with median time to onset of 14.5 weeks (table 1). Of the 3 patients with pre-existing AID, 1 experienced a disease flare after starting immunotherapy.

Conclusions: Rheumatic irAEs is a new field that will continue to grow. At this stage we have more questions than answers regarding their epidemiology, natural history and pathophysiology. Our findings reinforce that rheumatic irAEs are complex, at times require aggressive immunosuppression and can impact checkpoint inhibitor therapy for the underlying malignancy.

OP0004  RHEUMATOID ARTHRITIS OCCURRING AFTER IMMUNE CHECKPOINT INHIBITORS
R. Belkhir 1, Pagebreak, S. Le Burel 1, O. Lambotte 1, G. Mouton 1, E. Pertuiset 1, L. Dumegant 1, A. Marabelle 1, A. Leary 1, A.-L. Voisin 1, X. Martielle 1, 1Hôpitaux Universitaires Paris-Sud, Université Paris-Sud, AP-HP, le Kremlin Bicêtre; 2Lapeyronie Hospital, Montpellier; 3CH René Dubos, Pontoise; 4Centre Hospitalier du Pays d’Aix, Aix-en-Provence; 5Drug Development; 6Université Paris-Saclay; 7Université Fonctionnelle de Pharmacovigilance, Université Paris Saclay, Gustave Roussy Cancer Center, Villejuif, France

Background: Immune checkpoints inhibitors (ICIs) targeting cytotoxic T lymphocyte-associated protein 4 (CTLA-4) and Programmed cell death protein 1 (PD-1) have demonstrated survival improvement in multiple cancers. Immune Related Adverse Events (IrAE) have been described with ipilimumab and anti PD1. Relapse or flare of preexisting auto-immune diseases has been reported but occurrence of new auto-immune diseases seems to be less frequent. A series of 13 patients with non-classified rheumatic irAE has been published: 9 patients developed non-specific inflammatory arthritis but no seropositive rheumatoid arthritis (RA) and 4 presented with sicca symptoms but did not fulfill criteria for Sjogren syndrome [1].

Objectives: We did a retrospective study for collecting patients who developed seropositive rheumatoid arthritis (RA) after exposition to ICIs.

Methods: We used the “Club Rhumatismes et Inflammation (CRI)” network, a section of the French Society of Rheumatology and the Gustave Roussy Cancer Therapeutics. All rheumatologists evaluated all patients. Recorded information included gender, age, age at malignancy diagnosis, malignancy details, date of first ICI, date of irAE, type of irAE, treatment of irAE and response to treatment, autoantibody results.

Results: In the group of 13 patients, we found seropositive rheumatoid arthritis (RA) in 3 patients, seronegative RA in 2 patients, and 4 patients with nephritis (table 1). 1 patient developed spondyloarthritis, and 2 patients had ANCA associated vasculitis. This series confirms that the occurrence of irAE is a frequent complication of ICI therapy.

Conclusions: The irAEs are complex; at times require aggressive immunosuppression and can impact checkpoint inhibitor therapy for the underlying malignancy.

Fibromyalgia: a disease of the peripheral or central nervous system

Background: Approximately 10% of patients with rheumatoid arthritis (RA) have coexisting fibromyalgia (FM). Little is known of the cross-sectional and longitudinal relationship between FM and RA disease activity.

Objectives: To examine the cross-sectional and longitudinal relationship between FM and RA disease activity.

Methods: Oslo RA register (ORAR) was established in 1994 as a prospective, observational, longitudinal nested cohort study. The inclusion criteria were RA according to the 1987-ACR classification criteria and a residential address in Oslo. 636 patients in ORAR were asked to participate in a clinical examination in 1999. A trained study-nurse systematically assessed the 18-tender point count and performed 28-tender and 28-swollen joint counts (TJC/SJC). Patients self-reported disease activity and pain related to RA, and completed the Stanford Health Assessment Questionnaire (HAQ). RA disease activity was calculated as DAS28. Fibromyalgia was diagnosed if ≥11 tender points were reported. FM associated variables; fatigue, muscular tenderness, headache, abdominal pain and difficulties concentrating were also scored (0–10 VAS).

At the 10-year follow-up patients completed a questionnaire that included RA Disease Activity Index (RADAI) and Routine Assessment of Patient Index Data (RAPID-3).

In cross-sectional and longitudinal analyses RA disease activity, FM associated variables and health status were compared between patients with ≥11 and <11 tender points. Level of significance was calculated using ANCOVA models corrected for age, gender, BMI and level of education. The FM associated variables at baseline were also corrected for baseline SJC 28 and C-reactive protein (CRP). The variables in the longitudinal study were corrected for the same variables as the cross-sectional analyses, but additionally for baseline values of the dependent variable when available.

Results: 488 patients agreed to participate in the baseline data-collection and 192 participated at the 10-year follow-up. The mean (SD) age was 59.5 (12.5) years, and 87% were female. There were no significant differences in age, disease duration or participation at follow-up between patients with and without FM, but only women had FM.

Patients with FM in addition to RA had higher DAS28, SJC, TJC, pain and patient globalVAS, but also higher levels of fatigue, abdominal pain and concentration difficulties (Table 1).

The Effect of an 8-Week Water Exercise Program on Anaerobic Exercise Capacity in Children With Juvenile Idiopathic Arthritis

D. Bayraktar 1, S. Savci2, O. Altug-Gucenmez 3, E. Manci 4, B. Makay3, N. Ilic2, S.E. Uzal1, 3.1 Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir Katip Celebi University; 2School of Physical Therapy and Rehabilitation; 3Faculty of Medicine, Division of Pediatric Rheumatology; 4Institute of Health Sciences, Dokuz Eylul University, Izmir, Turkey

**Background:** Anaerobic exercise capacity was reported to be lower in children with juvenile idiopathic arthritis (JIA) than healthy children. However, to our knowledge, there is no study focusing on improving anaerobic exercise capacity in JIA.

**Objectives:** To investigate the effect of an 8-week water exercise program, which was performed at the weekends, on anaerobic exercise capacity in children with JIA.

**Methods:** Forty-two children with JIA were divided into two groups as exercise and control. Prior to the study, anaerobic exercise capacity was measured performing a 30-second Wingate test. Deep water running was employed as the progressive water exercise program for the exercise group. Control group did not receive any additional treatment other than their usual care. Weekends were chosen for the exercise sessions considering the educational program of the children. Exercise intensity was set as moderate. Exercise intensity was determined with a wearable heart rate tracking system during the exercises. All children were reassessed regarding anaerobic exercise capacity two months after the first assessment.

**Results:** All children completed the study without any adverse effects. Twenty-one children were in the exercise group, others were assessed as controls. No significant differences were determined between groups prior the study regarding to age, disease duration, height, weight, body-mass index, and anaerobic exercise capacity related parameters (p>0.05). While all anaerobic exercise capacity parameters improved in the exercise group, no improvement were seen in the control group. The in-group comparisons were shown as Table 1. The comparison of the changes between groups after 8 weeks were demonstrated at Table 2.

The main outcomes that were analysed for the meta-analysis were RA occurrence at 52 weeks and beyond and the absence of radiographic progression at week 52. The meta-analysis was performed using RevMan with Mantel-Haenszel method. **Results:** The search identified 595 abstracts, of which 9 RCTs were finally selected (including 2 congress abstracts). Eight were related to undifferentiated arthritis. One (16%) was published in the antibody to RAP1B. The studies included 1156 patients, weighted mean age 45.8±15.2 years, mean symptom duration 16.2±12.6 weeks; 66.0±17.7% were female. The occurrence of RA at week 52 or more was available in 7 studies (assessing 800 patients). Early therapeutic intervention – either methotrexate (80 to 120mg IM), methotrexate, TNF-blocker, abatacept or rituximab – reduced the risk of occurrence of RA with a pooled odds ratio (OR) of 0.72 (95% CI [0.54; 0.96]), p 0.02 (Figure). There was a statistically significant difference between the treatments or placebo, for the absence of radiographic progression (pooled OR 1.36 [0.80; 2.32]). The outcome was assessed at Week 52 for all studies, except for Van Dongen 2007 (PROMPT), where it was assessed at Week 120. MethyLPDN, methotrexolone; MTX, methotrextate.

**Conclusions:** This meta-analysis demonstrates that early therapeutic intervention significantly reduces the risk of RA onset in pre-RA patients. The benefit risk balance and feasibility in clinical practice remain to be further assessed. **Disclosure of Interest:** None declared

**EULAR Campaign: Don’t Delay, Connect Today**

**RHEUMATOSPHERE: REACH NEW HEIGHTS IN DIAGNOSIS AND TREATMENT OF ARTHRITIS BY ENGAGING, EMPOWERING AND INSPIRING**

L.A. Bennett, J.S. Nijjar, G. Fragouli, S. Siebert, I.B. McInnes, Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom

**Background:** We aim to reach new heights in diagnosis and treatment of arthritis through research and we believe that part of this encompasses public engagement. Engaging the public is an essential part of scientific life, as the majority of work carried about by researchers is publically funded. Therefore the public are entitled to and should be encouraged to see the conclusions of this work in an easily accessible manner.

**Objectives:** 1) Engage the public about rheumatic disease, what it is, what it does to the body and how we, as scientists and clinicians, address unmet needs in this field. 2) Empower patients in order to help them understand their disease and treatments thereby improving patient satisfaction and compliance to therapy. 3) Inspire the next generation of scientist by encouraging children to study science at school and raise the profile of these subjects with education authorities and the government.

**Methods:** Rheumatosphere was established to address public engagement needs in the arthritis research field. We have used a variety of techniques to capture the attention of small and large audiences of all ages. Techniques include: Ultrasound scanning of coffee with patients at our (less than 70% of predicted, p 0.01) and FEV1 (12 patients and 2 controls, p 0.01) and FEV1 (% of predicted) 88 (14) 109 (11) p 0.01. HRCT showed ILD in 15 patients (29%). More patients than controls had abnormal FVC (11 patients and 0 controls, p<0.01) and FEV1 (12 patients and 2 controls, p<0.01). Diffusing capacity for carbon monoxide adjusted for alveolar volume was abnormal in 12 patients and 8 controls (p=0.34). One patient and 3 controls had a pathological FEV1/FVC less than 0.67 (p 0.02). HRCT showed ILD in 15 patients (29%). The extent of lung parenchyma involved was median 2% (range 1–75) in the patients with ILD. Two patients had more than 20% of lung parenchyma involved (graph 1). The most common abnormalities were reticular patterns, being present in 13 patients (25%). 2 patients (4%) had ground glass attenuation. We could not find correlations between the extent of ILD and PFT or 6MWT. There were no significant differences in PFT values or other disease related variables between the patients with and without ILD.

**Conclusions:** Patients with JMCTD had significantly reduced pulmonary function as compared to matched controls. However, overall lung function was only moderately reduced. The occurrence of ILD assessed with HRCT was 29%, but the majority of patients with ILD had mild disease. To our knowledge, this is the first systematic case-control study of pulmonary manifestations in JMCTD.

**PULMONARY MANIFESTATIONS IN JUVENILE ONSET MIXED CONNECTIVE TISSUE DISEASE AFTER LONG-TERM DISEASE DURATION – A NORWEGIAN CASE-CONTROL STUDY**

S.O. Hetlevik 1, T.M. Aaløkken2, B.L. Lund3, B. Flata4, E.B. Nordsletten5, M. Rygg5, T. Leslie5, 6 Rheumatology; 7 Respiratory medicine, Oslo University Hospital, Oslo; 9 Pediatrics, University hospital of North Norway, Tromsø; Pediatrics, St. Olavs University Hospital, Trondheim, Norway

**Background:** Pulmonary manifestations in mixed connective tissue disease (MCTD) are common and a major cause of morbidity and mortality [1]. Data on lung involvement in patients with juvenile onset MCTD (JMCTD) are scarce.

**Objectives:** The aim of this study was 1) to compare pulmonary function abnormalities in a nationwide representative Norwegian JMCTD cohort with that of matched controls, 2) investigate occurrence of interstitial lung disease (ILD) in JMCTD and 3) to evaluate possible associations between pulmonary findings and disease related variables.

**Methods:** Inclusion criteria were fulfillment of the Kasukawa or Alarcon-Segovia criteria and symptom-onset before 18 years. The control group was randomly drawn from the national population register, after matching for age and gender. Fifty-two patients with JMCTD were examined after mean disease duration 16.2 years, 44 (85%) were female. Patients and controls performed pulmonary function tests (PFT) and a 6 min walk test (6MW). The patients had a high-resolution CT (HRCT) of the lungs.

**Results:** Abnormal PFT were found in 24 patients (46%) and in 12 controls (23%) (p=0.01) (table 1).

**Table 1.** PFT at 52 weeks and beyond and the absence of radiographic progression at week 52.

OBJECTIVE: To provide pragmatic guidelines concerning conventional radiography (CR) in each subtype of JIA (exclusion of systemic JIA).

METHODS: A multidisciplinary task force of 15 French experts (rheumatologists, pediatricians, radiologists) plus one patient's representative, was convened. Following the GRADE method, they formulated a series of research questions concerning CR assessment, at diagnosis and follow-up of each subtype of JIA. Systemic JIA was ruled out. A systematic literature review was conducted, following evidence-based data, and expert opinion. It underwent an evaluation from an independent committee (including patient's representative), and a final round of Delphi-voting process from the whole expert group.

RESULTS: Of 646 publications identified, 73 original articles were included. The round of Delphi-voting process from the whole expert group.

CONCLUSIONS: These are the first pragmatic recommendations upon CR in JIA. They mostly rely on experts’ opinion, due to lack of evidence-based data. CR is still relevant in many situations in JIA, but should not be overlooked, while non-irradiating imagine techniques are developing.

Background: Treatment with TNF inhibitors is part of the management of patients with severe rheumatoid arthritis (RA). There is limited data on the comparative effectiveness of different TNF inhibitors from clinical trials and observational studies of patients treated in clinical practice.

Objectives: To compare effectiveness of different TNF inhibitors in a large, population representative, sample of bionaire patients with RA.

Methods: The study was based on the Swedish Rheumatology Quality register, in which clinical data are prospectively recorded at treatment initiation and at subsequent visits. Patients with RA initiating a TNF inhibitor as their first ever biologic DMARD in 2010–2014 were included and followed through 2015. The proportion remaining on drug at 1 year (+80 days) after starting therapy was compared. Furthermore, effectiveness at 1 year was assessed as the proportions with EULAR good response, remission (DAS28 <2.6), HAQ improvement (<0.2) and swollen and tender joint counts of 0, all corrected for drug survival (1). The relative response was estimated with log-binomial regression adjusting for potential confounders and using the largest group (etanercept) as reference.

Results: A total of 5568 patients were included. There was a significant difference in the adjusted chance of drug survival across TNF inhibitors (Table). Patients treated with certolizumab or infliximab were less likely to remain on treatment compared to those started on etanercept. The chance of achieving each of the clinical response measures was significantly lower for those initiating infliximab compared to patients treated with etanercept. There were no significant differences in these outcomes compared to etanercept for any of the other TNF inhibitors.

Conclusions: Patients with RA starting infliximab as their first biologic DMARD were less likely to remain on treatment with significant improvement at 1 year compared to those initiating etanercept. There was a similar trend for certolizumab vs. etanercept, but there were no consistent differences in clinical effectiveness between etanercept and adalimumab or golimumab. Treatment context may affect these patterns.

Disclosure of Interest:
tool and threshold in predicting a successful assessment of 3-month changes in bone DMARD withdrawal in RA patients achieving remission with TNFi tapering. We have developed a composite index able to predict remission with TNFi, baseline HAQ and CRP are independent predictor factors.

Composite criteria:

Conclusions:

Results:

Background: Tapering trials confirmed the feasibility of TNF inhibitors (TNFi) as an alternative treatment of RA, especially in the first few months of RA onset. With its resolution of up to 81 % after 6 months of treatment, TNFi are used in combination with non-biologic disease-modifying drugs (nbDMARDs) to achieve sustained remission. Determination of TNFi tapering.

Methods: Population: The64 patients of the Spacing arm were those who achieved a discontinuation due to improvements in pain and physical function. The strategy applied progressive spacing of ADA or ETN subcutaneous injections starting from every 2 weeks to every 4 weeks.

Results:

Discussion: This study was funded by UCB Pharma. We are indebted to the mothers and their infants for their altruistic participation. Editorial services were provided by Costello Medical Consulting.

Disclosure of Interest: X. Mariette Grant/research support from: Biogen, Pfizer, UCB Pharma. M. Foy Grant/research support from: UCB Pharma, A. Flynn Grant/research support from: UCB Pharma, F. Förger Grant/research support from: UCB Pharma, Speakers bureau: Mepha, Roche, UCB Pharma, A. Motto Grant/research support from: MSD, AbbVie, Pfizer, UCB Pharma, Consultant for: MSD, AbbVie, Pfizer, UCB Pharma, A. Van Tubergen Grant/research support from: AbbVie, Pfizer, UCB Pharma, J. Simpson Employee of: UCB Pharma, M. Tei Employee of: UCB Pharma, E. Helmer Employee of: UCB Pharma, M. Wibe.

Background: Tapering trials confirmed the feasibility of TNF inhibitors (TNFi) tapering for a relevant proportion of patients in remission and its low disease activity. However, there are no consensus indicators of a good response to therapeutic spacing among patients with rheumatoid arthritis (RA) in remission.

Objectives: To determine the most predictive tool and threshold of a successful TNFi tapering.

Methods: Population: The Banking of TNF-blocker injections in Rheumatoid Arthritis Study (STRASS) trial included 137 RA patients fulfilling the ACR 1987 criteria with sustained (at least 6 months) DAS28 ≤ 2.6. Patients were randomly assigned to one of the two following strategies: in the Maintain arm, patients continued to receive TNFi at the standard full regimen and in the Spacing arm, the strategy applied progressive spacing of ADA or ETN subcutaneous injections up to discontinuation at the forth step in the spacing arm. We used the data of the Spacing arm.

Analysis: The performances of several variables (DAS28, SDAI, CDAI, CRP, ACPA status, HAQ, patient/physician global assessment, and boolean remission criteria) were assessed for the prediction of successful TNFi tapering, defined as reaching at least 25% tapering of the full regimen during at least 6 months, using sensitivity and specificity for dichotomous variables, or the area under the ROC curve (AUC) and its 95% confidence interval for continuous variables. A predictive score of successful tapering was constructed using LASSO regression modeling technique to avoid overfitting (R software version 3.2.1).

Results: The main characteristic of the 64 patients of the Spacing arm were the following (mean ± SD): age 54.3±10.7 years, disease duration 8.3±5.4 years, and DAS28 1.9±0.6.

The baseline variables were similar between patients who failed or succeeded at TNFi tapering, except for the HAQ score (0.30 in the group success and 0.89 in the failure group, p<0.01) and the CRP (2.35 mg/l versus 3.48 mg/l, respectively, p<0.01). The CRP score of successful tapering was constructed using LASSO regression modeling technique to avoid overfitting (R software version 3.2.1).

Baseline variables performance in predicting successful TNFi tapering: None of the tested variables was able to predict successful TNFi tapering except the HAQ score and the CRP. A HAQ threshold ≥1.125 had a specificity (Spe) of 93% and an AUC 0.713 (95% CI: 0.540–0.886). A CRP threshold ≥6.8 mg/l had a Spe of 0.97 and an AUC 0.689 (95% CI: 0.542–0.831). Composite criteria: A composite criteria able to predict successful TNFi tapering has been elaborated, including ACPA status, Boolean criteria, SDAI, CRP and HAQ. A composite score lower than 0.502 was able to predict a successful TNFi tapering with a sensitivity of 85% (95% CI: 0.671–0.954), a specificity of 94%, and an AUC of 0.89 (95% CI: 0.807–0.973).

Conclusions: The remission maintenance in rheumatoid arthritis after TNFi tapering is possible. Our results showed that in a population of RA patients in remission with TNFi, baseline HAQ and CRP are independent predictor factors of successful tapering. We have developed a composite index able to predict successful TNFi tapering with an AUC of 0.89 (95% CI: 0.671–0.954), a sensitivity and specificity of 94%, and an AUC of 0.89 (95% CI: 0.807–0.973). A validation study will be needed to confirm its ability to select patients for treatment decrease.

increases in erosion volume at MCH2 and wrist despite low disease activity (Fig. B). In the anti-TNFα group, joint space width and volume of the MCP joints decreased significantly from BL to 3M and were positively correlated with erosion volume changes. Although microstructural parameters at the wrist and MCP remained largely unchanged, erosion volume changes were significantly negatively correlated with changes of trabecular BMD in the anti-TNFα group (Fig. C). No significant correlations were observed between HR-pQCT parameters and RAMRIS and DAS scores.

Figure. (A) Comparisons of changes of DAS 28 ESR and CRP from baseline (BL) to 3-months (3M). (B) Comparisons of changes of bone microarchitecture parameters from BL to 3M. *p<0.05; paired T test. (C) Spearman correlations between changes of erosion volume and each bone parameter in MCP in the anti-TNFα group.

Conclusions: We found that anti-TNFα treatment can prevent erosion progression and deterioration of bone microarchitecture within the first 3 months of treatment. HR-pQCT can serve as a sensitive and powerful tool to quantify bone changes and monitor RA treatment even over short time periods.

Background: TNF inhibitors (TNFi) can be used as monotherapy (mono) or in combination (combo) with conventional DMARDs (cDMARDs). Data from randomized clinical trials and European registries suggest there is evidence of better effectiveness of TNFi combo therapy than mono. Effectiveness of TNFi mono vs combo in US clinical practice, in particular among biologic naïve and experienced patients, has not been assessed. There have also been no assessments of tofacitinib (tola) mono vs tola combo nor tola mono vs TNFi combo in US clinical practice. Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA.

Objectives: This study quantifies the prevalence and effectiveness of TNFi monotherapy use compared to TNFi combination therapy by line of therapy in US clinical practice. Secondary objectives were to compare tola monotherapy use and effectiveness separately to tola combo and to TNFi combo therapies.

Methods: RA patients initiating a TNFi (adalimumab, etanercept, infliximab, golimumab, certolizumab pegol) or tola with a six month follow-up in Corrona were identified. A subcohort of TNFi initiators after 11/6/2012 (market approval of tola) were used for comparisons with tola initiators. We defined combo therapy as TNFi or tola used with MTX only and mono as no use of any cDMARD. The primary outcome was achieving LDA (low disease activity) or remission at 6 months. Patients switching to another biologic prior to 6 months were defined as non-responders. Secondary outcomes included modified ACR20/50/70 and mean change in CDAI. Combo and mono initiators were matched within line of therapy using a propensity score. Covariates for the model were selected if the standardized mean difference between the groups > 0.1.

Results: From 10/2001 to 8/2016 there were 7976 eligible TNFi initiations in Corrona, with 2511 (31%) mono initiations. Mono by line of therapy was 21%, 36% and 42% for 2nd, 3rd and 4th line therapy, respectively. There were 555 tola initiations with 338 (61%) mono and mono rates of 47%, 58% and 63% for 2nd, 3rd and 4th line therapy, respectively. In the matched populations, across outcome measures (Table 1), TNFi combo was more effective than TNFi mono in 2nd line therapy (55.6% LDA vs 47.1% LDA) and differences diminished with 3rd line (43.2% vs 36.6%) and 4th line (32.0% vs 34.0%). Tofa combo therapy was similar to mono in the matched 3rd and 4th line populations (35.1% LDA vs 31.1% LDA). Tola mono was similar to TNFi combo therapy in the matched 3rd and 4th line populations combined (33.6% LDA vs 37.5% LDA).

Conclusions: TNFi monotherapy is common in U.S. clinical practice. TNFi monotherapy is less effective than combination therapy especially in biologic naïve patients or with one prior biologic. There is no evidence that tofacitinib monotherapy is less effective than combination therapy or TNFi combination therapy in the outcome measures reported.

Background: RAPID-axSpA (NCT01087782) was a long-term study in patients (pts) with axial spondyloarthritis (axSpA) treated with certolizumab pegol (CZP). This is the first report of 4-year imaging results in CZP-treated axSpA pts, including ankylosing spondylitis (AS) and non-radiographic (nr)-axSpA.

Objectives: To report 4-year X-ray and MRI data in CZP-treated axSpA pts.

Methods: RAPID-axSpA was double-blind and placebo (PBO)-controlled to Week 24, dose-blind to Week 48, and open-label to Week 204. Pts fulfilling ASAS axSpA criteria were stratified using a local read according to presence/absence of radiographic sacroiliitis (AS/nr-axSpA) at randomization and had active disease. Week 204 CZP-randomized pts (200mg CZP/400mg C4W) continued assigned dose; PBO pts received CZP after Week 16/24. Centrally-read lateral X-rays of cervical/lumbar spine at baseline (BL), Week 96, and Week 204 were assessed using the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS); Sacroiliac (SI) joint X-rays were scored for sacroiliitis at BL and Week 204. MRI scans performed at Week 12, 48, 96, and 204 were assessed using Spondyloarthritis Research Consortium of Canada (SPARCC) score for SI joints and Berlin score for spine.

Results: Of 315 CZP-treated pts, 196 had available spinal X-rays and were included in MMRM analyses (BL mean mSASSS: 9.47). 158 pts had MRI assessments (BL mean SPARCC: 8.17 [n=151]; Berlin score: 6.10 [n=153]; 137 pts had SI joint X-rays at BL and Week 204 (67.9% radiographic sacroiliitis). In AS pts, mean mSASSS change between BL and Week 204 was 0.98; 0.67 from BL to Week 96, and 0.31 from Week 96 to Week 204 (0.06, -0.01, and 0.07 respectively for nr-axSpA) (Table A). MMRM estimates were similar to observed values (0.62 and 0.70, respectively [axSpA Week 204 mean change]). Limited changes in SI joint X-ray grading were observed to Week 204: only 4.5% of pts progressed to AS, whilst 4.3% moved from an AS classification to nr-axSpA. MRI assessments showed sustained improvement (Table B).

Table A: Mixed model for repeated measures (MMRM) estimates of mSASSS to Week 204 of the RAPID-axSpA study for all patients treated with CZP

Table B: MRI outcomes to Week 204 of the RAPID-axSpA study for all patients treated with CZP (observed values)

Conclusions: This is the first trial to report imaging data in both AS and nr-axSpA pts over 4 years. Limited spinal radiographic progression was observed in CZP-treated pts with lower progression between Wks96 and 204 compared with the first 96 wks. Limited change in radiographic sacroiliitis was observed. Early reductions in MRI inflammation were maintained to Wk204.

Background: Immuno sorbent assay for anti-drug antibodies is a reliable and sensitive test to detect anti-drug antibodies. However, it is not widely available and the test needs to be performed in a research laboratory. Moreover, anti-drug antibodies can be detected in samples without the corresponding clinical picture of adverse events. Therefore, we aimed to evaluate the association between anti-drug antibodies and adverse events.

Objectives: The objective of this study was to evaluate the association between anti-drug antibodies and adverse events in patients treated with adalimumab.

Methods: Adalimumab was administered in patients with moderate to severe rheumatoid arthritis and an inadequate response to nonsteroidal anti-inflammatory drugs. Anti-drug antibodies were determined by a commercial ELISA (Meso Scale Discovery, Gaithersburg, MD). The presence of antibodies was confirmed by using a second ELISA and retesting was performed in case of positive results. Adverse events were collected on a standardized form. The results were analyzed by comparing the group of patients with anti-drug antibodies with the group of patients without anti-drug antibodies.

Results: 313 patients with anti-drug antibodies were included in the study and 339 patients were included in the control group. The prevalence of anti-drug antibodies was 50.1% in the group of patients with adverse events and 41.8% in the group of patients without adverse events. The prevalence of adverse events was 60.1% in the group of patients with anti-drug antibodies and 44.7% in the group of patients without anti-drug antibodies. The difference in prevalence of adverse events between the two groups was statistically significant (p = 0.025) using the chi-square test.

Conclusion: Anti-drug antibodies are associated with an increased risk of adverse events in patients treated with adalimumab.

Disclosure of Interest: The authors declare that they have no conflict of interest.

Acknowledgements: The study was supported by the University of Athens, Greece.
(0.9–4.3) and 9.5 (5.3–13.3), p=0.000. When patients tested positive in the ARIA, ABT and the 2-sided ELISA almost all patients had undetectable drug levels.

Conclusions: The fast majority of the AS patients develop ADA. The ARIA detects more ADA compared to the assays susceptible for drug interference, the ABT and the more frequently used 2-sided ELISA. Immunogenicity data should be interpreted with the knowledge of the assay and in context of drug levels.

OP0026 HIGH DRUG-FREE REMISSION IN EARLY PERIPHERAL SPONDYLOARTHRITIS AFTER INDUCTION THERAPY WITH GOLIMUMAB

P. Carron 1,2, G. Varkas 1,2, H. Cypers 1,2, L. Van Praet 1, D. Elewaut 1,2, F. Van den Bosch 1,2, 1Rheumatology, University of Ghent; 2VIB Inflammation Research Center, Ghent University, Gent, Belgium

Background: In rheumatoid arthritis there is accumulating evidence for a so-called “window of opportunity” remission induction treatment at an early stage of the disease. Whether a similar concept also applies to Spondyloarthritis is currently unknown. Given the higher chance of obtaining remission or low disease activity with early aggressive (biologic) treatment in early axial SpA, one could speculate that there is at least also a possibility of a “window of opportunity” for drug-free remission in peripheral SpA (pSpA).

Objectives: To evaluate sustained drug-free clinical remission after induction therapy with golimumab in patients with active peripheral Spondyloarthritis in a very early stage of the disease.

Methods: CRESPA (Clinical REmission in peripheral SPondyloArthritis) is an ongoing monocentric study of golimumab treatment in pSpA patients. Eligible patients were ≥18 years and fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for pSpA. All patients had a symptom duration <12 weeks. Patients were randomized 2:1 to receive golimumab 50 mg every 4 weeks or matching placebo for 24 weeks. The primary endpoint was the percentage of patients achieving clinical remission at week 24, defined as the absence of arthritis, enthesitis and dactylitis on clinical examination. If patients were in clinical remission at two consecutive visits (major evaluations at week 12, 24, 36 and 48) treatment was stopped. These patients were prospectively followed to assess the percentage of patients in sustained drug-free clinical remission, compared to those experiencing a clinical relapse of arthritis, dactylitis or enthesitis. In case of clinical relapse patients were retreated with open-label golimumab in the extension part of this trial.

Results: In total 60 patients were randomized of whom 20 received placebo and 40 golimumab. Baseline demographics and disease characteristics were generally similar between the 2 groups. At week 24 a significantly higher percentage of patients receiving golimumab achieved clinical remission compared to patients receiving placebo (75% (30/40) versus 20% (4/20); P<0.001). At week 12 similar results were observed (70% (28/40) versus 15% (3/20); P<0.001). In 49 out of the 60 patients treatment could be stopped because they fulfilled sustained clinical remission at 2 major consecutive visits. All patients had at least a follow up of 12 months after discontinuation of treatment with a maximum of follow-up of 58 months. 53% (26/49) of these patients are still in drug-free sustained clinical remission and 47% (23/49) had a clinical relapse after withdrawal. The majority of relapsed patients experienced their flare within 6 months after discontinuation.

Conclusions: In patients with active, very early peripheral spondyloarthritis, treatment with golimumab led to high percentages of clinical remission at week 12 and 24. A remarkably high percentage of patients are still in sustained drug-free clinical remission after induction therapy with golimumab which indicates a window of opportunity for drug-free remission in this disease.

LOW DOSE IL-2 THERAPY CAN RECOVERY TH17/TREG CELL BALANCE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

D. Xu1, J. Fan1, Q. Chen1, K. Qiu1, X. Li1, C. Gao2. 1 The Department of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; 2 Department of Pathology, Joint Program in Transfusion Medicine, Brigham and Women’s Hospital/Children’s Hospital Boston, Harvard Medical School, Boston, United States

Background: Recent studies have shown that increased number of Th17 cells and decreased number of Treg cells in the peripheral blood contribute to ankylosing spondylitis (AS). However, current therapy for AS, including biological agents, immunosuppressant and glucocorticoid, can not correct the imbalance of Th17 and Regulatory T (Treg) cells in AS patients effectively. It has been reported that low dose IL-2 can selectively expand Treg cells and had a critical effect on homoeostatic balance between the Th17 and Treg cells.

Objectives: The study is to explore the effect of low dose IL-2 therapy on the balance of Treg and Th17 cells in patients with AS and observe the efficiency and side effects of the therapy.

Methods: Seventeen patients, who met the 1984 modified New York criteria and had evidence of active inflammatory spondylitis (defined as Bath AS Disease Activity Index (BASDAI) score >4) despite of receiving standard therapy including glucocorticoid, immune-suppressants, biological agents or combination of them, were enrolled. These patients were not only given traditional treatment, but also injected subcutaneously low-dose IL-2 (50 IU/day for 5 days). Clinical and laboratory indicators were compared before and after IL-2 treatment. The side effects were observed in the course of therapy.

Results: The number of Treg cells significantly increased after the treatment by 44.1% of patients had a global benefit of at least 50% at D15, 63.6% at M1, 25.6% at M3 and 33.3% at M6. There was no decrease of the BASDAI, BASFI, ESR, CRP, ASDAS ESR and ASDAS CRP. Moreover, no relationship was found between the efficiency of sacroiliac infiltrations in terms of global benefit as well as of decrease of the VAS at least of 50% and the presence of sacroiliac images on the MRI. Neither when looking at the different subtypes of sacroiliitis lesions (bone marrow oedema, synovitis, osteitis). Among the non active sacroiliac structural lesions (erosions, subchondral sclerosis, bone bridges…), only fatty involution was statistically more present in the group with a global improvement or a VAS of less than 50%.

Conclusions: Long acting corticosteroid infiltrations of the sacroiliac joints are useful in patients suffering from inflammatory sacroiliitis pain. However, the majority of sacroiliac joints images found on a concomitant MRI does not predict the treatment response except fatty involution that seems to be associated with a lower response. Likewise, composite indexes/scores as well as parameters of systemic inflammation are not relevant for the patients follow up in that indication.

INEQUITY IN BIOLOGIC DMARD PRESCRIPTION FOR SPA ACROSS THE GLOBE. RESULTS FROM THE ASAS COMOSPA STUDY

E. Nikhpron1, D. van der Heijide2, S. Norton1, R. Landewe3, A. Moltó4, M. Dougados5, F. van den Bosch6, S. Ramiro7, 1LUMC, Leiden; 2ARC, Amsterdam, Netherlands; 3Paris Descartes University, Paris, France; 4Ghent University Hospital, Ghent, Belgium

Background: The value of biologic DMARDs (bDMARDs) in SpA is well recognized but global access to these treatments can be limited due to high cost and other factors.

Objectives: This study explores variation in the use of bDMARDs in SpA across countries and to what extent socio-economic (SE) factors may explain variation.

Methods: Patients fulfilling the ASAS SpA criteria in the multi-national, cross-sectional ASAS COMOSPA study were studied. Multi-level logistic regression models with random intercept for country were constructed with current use of bDMARDs as the dependent variable. Contribution of socio-economic factors using country health expenditures and gross domestic product (GDP) (all low vs medium/high tertiles) as independent country-level factors, was explored in models adjusted for socio-demographic as well as clinical variables known to determine bDMARD-use in SpA.

Results: In total, 3370 patients from 22 countries were included (mean [SD] age 43 [14] years; 66% male; 88% axial disease). Across countries, 1275 (38%) were bDMARD users. Crude mean bDMARD-use varied between 5% (China) to 74% (Belgium). After adjustment for relevant socio-demographic and clinical variables, important variation in bDMARD-use across countries remained (Figure, p<0.001). Country-level socio-economic factors, specifically higher health...
expenditures were related to higher bDMARD uptake (Table), though not meeting statistical significance (OR 1.91; 95% CI 0.93,3.92). Similar findings were found with country GDP (OR 1.72;95% CI 0.83,3.57).

Conclusions: There remains important residual variation across countries in bDMARD uptake of patients with SpA followed in specialized SpA centers. This is in line with other similar studies report on variability in the use of other therapies for SpA, which may be related to different reimbursement strategies and differences in the disease burden in the countries.

Early diagnosis of systemic sclerosis and myositis: biomarkers and diagnostic tool

OP0031 DEVELOPMENT OF A NOVEL EPITOPE-BASED DIAGNOSTIC ASSAY FOR SYSTEMIC SCLEROSIS

G. Moroncini1, M. Mozzicafreddo2, M. Cucciolli2, A. Greico1, C. Paolini1, C. Tomini1, S. Salvucci1, E. Avvedimento3, A. Funaro4, A. Gabrielli1
1Department of Molecular and Clinical Sciences, Università Politecnica Marche, Ancona; 2School of Biosciences and Veterinary Medicine, University of Camerino, Camerino; 3Department of Molecular Medicine, Università Federico II, Napoli; 4Department of Medical Sciences, University of Torino, Torino, Italy

Background: We described the conformational PDGFRα biomarkers and diagnostic tool

Methods: i. The large PDGFRα peptide library used for epitope mapping of monoclonal anti-PDGFRα antibodies was screened with 25 SSC (12 limited, 13 diffuse) and 25 healthy control (HC) serum samples. ii. A smaller PDGFRα peptide library containing only the top 20 conformational binders plus 20 linear and 20 conformational controls was synthesized. 60 conformational and linear peptides of a cognate protein forming a molecular complex with PDGFRα were included in the array. 20 scrambled peptides were added as negative controls. This library was synthesized by Pepscan Presto, Netherlands. Statistical analysis was performed by Wilcoxon-Mann-Whitney test. Correlations between serological results and clinical status were made.

Results: i. An immunodominant peptide discriminating SSC from HC serum samples was identified in the first library. This was confirmed by the second library, which highlighted also one immunodominant epitope from the cognate protein. Statistical analysis identified two cohorts of SSC samples (reactive vs. nonreactive, the latter undistinguishable from HC) each composed by limited and diffuse SSC subtypes.iii. The third peptide library identified the chimeric peptide recognized exclusively by the reactive SSC serum samples, which were taken from patients with active, progressive disease regardless of limited vs diffuse classification, whereas the nonreactive SSC samples were taken from subjects with less active, non progressive disease.

Conclusions: We developed a conformational epitope-based assay detecting SSC-specific, agonistic, serum autoantibodies. The preliminary results suggest that this novel assay may identify SSC patients with active disease, regardless of the canonical classification criteria. We propose this assay for prospective screening of large cohorts of patients affected by, or suspected for, SSCs, to validate it as a tool for disease activity assessment and/or early diagnosis.

OP0032 IS IMMUNOHISTOCHEMISTRY USEFUL TO PREDICT RESPONSE TO TREATMENT IN NECROTIZING MYOPATHIES?

S. Fernandes1, B. Lopez2, P. Gordon2, S. Al-Sarraj3, 1Rheumatology, Instituto Português de Reumatologia, Lisboa, Portugal; 2Rheumatology; 3Clinical Neuphrology, King’s College Hospital, London, United Kingdom

Background: Muscle biopsy is the gold standard for the diagnosis of inflammatory myopathies, but the role of immunohistochemistry in Necrotizing Myopathies (NM) has not been fully characterized yet.

Objectives: To determine if MHC-I expression and pattern of Csβ-9 deposition in biopsies correlate with clinical phenotype and response to treatment in NM.

Methods: The Neuropathology Departmental database was searched to identify patients with a histological diagnosis of NM and follow up data for at least 6 months (30 patients). Electronic patient records were reviewed retrospectively to record demographics, autoimmune diseases, treatments, treatment, proximal muscle power at 3, 6 and 12 months by Manual Muscle Testing (MMT) (2), levels of CK and flares. Patients were classified as responders when there was improvement of MMT >20% and non-responders when MMT improvement was <20% (3). All biopsies were reviewed blindly by an experienced neuropathologist. MHC-I expression was classified as positive only if over expressed in all fibers. The patterns of Csβ-9 deposition in endomysial capillaries were classified as specific (solid), non-specific (granular) or negative.

Results: MHC-I positive group (n=16/30) had a higher proportion of responders (62.5% vs 7.7%, p<0.002), higher number of patients with total recovery of muscle power (n=4, 15.4%) when compared to the MHC-I negative group (n=4-14). 17 patients were positive for auto-antibodies of which 9 were myositis specific antibodies (SRP [n=6], HMGCaCoA reductase [n=1], Jo-1 [n=1], P15S140 [n=1]) and 4 were myositis associated antibodies [Ro-52 [n=2], KU [n=1], PrmScl [n=1]]. 13/30 patients had Csβ-9 deposition, with a specific pattern in 5 and non-specific in 8. The specific pattern group had a greater reduction of CK after 6 months compared to non-specific and negative respectively (98% vs. 77% vs. 56.8%, p=0.006), greater reduction in CK after 12 months (98.6% vs. 68.9% vs. 59.6%, p=0.015), and higher rate of responders (91.6% vs. 56% vs. 18.8%, p=0.001). Six patients were on immunosuppressants (azathioprine/hydroxychloroquine, n=2), steroids (n=3) or both (n=1) for a minimum of 4 weeks when the biopsy was performed. Differences in age, gender, clinical features or treatment were not found to be statistically significant.

Conclusions: Upregulation of MHC I and solid staining pattern of Csβ-9 in the capillaries of NM patients appears to be associated with a better outcome.

OP0033 SPECT- AND PET/CT IMAGING IN NEWLY ONSET IDIOPATHIC INFLAMMATORY MYOPATHY

J. Simonsen1, S. Hvidsten 1, P.F. Høilund-Carlsen1, K.F. Thøgersen1,2, J. Simonsen1, S. Hvidsten 1, P.F. Høilund-Carlsen1, K.F. Thøgersen1,2, J. Simonsen1, S. Hvidsten 1, P.F. Høilund-Carlsen1, K.F. Thøgersen1,2
1Nuclear Medicine, Odense University Hospital, Odense C; 2Aalborg University Hospital, Aalborg, Denmark

Background: Diagnosis of idiopathic inflammatory myopathies (IIMs) is challenging. Most patients harbor no pathognomonic features on imaging by imaging. Few radiologic imaging techniques have been tested for this purpose, mainly 99mTc-pyrophosphate planar imaging and 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG-PET/CT). However, 99mTc-PYP uptake has been assessed visually and at best graded semi-quantitatively.

Objectives: We aimed for quantitative 99mTc-PYP and 18F-FDG-PET/CT imaging in a group of newly onset IIM patients.

Methods: Thirty patients (mean age 62 years) with newly diagnosed, untreated IIM were included. 99mTc-PYP SPECT/CT and 18F-FDG-PET/CT imaging of the thorax, pelvis, and thighs. Seven of the patients also had a whole-body 99mTc-PYP PET scan. Forty-nine healthy controls (mean age 59 years) underwent 99mTc-PYP SPECT/CT and 26 healthy controls (mean age 57 years) had a 18F-FDG PET/CT scan done. Voltages of interest (VOIs) covering the right biceps, triceps, and quadriceps muscles were drawn manually on each series. Registered 99mTc-PYP and 18F-FDG uptake values (SU/mL) were analyzed.

Results: In the IIM group there was a greater uptake of 99mTc-PYP and 18F-FDG (75% vs. 35.7%, p=0.030) when compared to the IIM-group negative (n=14). The uptake was significantly higher (99mTc-PYP SUV [g/mL] 1.95 (0.25-4.26) vs. 0.42 (0.19-1.41), 18F-FDG SUV [g/mL] 2.93 (0.19-5.1) vs. 0.76 (0.09-2.08), p=0.001) in IIM patients compared to controls.

Conclusions: 99mTc-PYP and 18F-FDG-PET/CT imaging is useful for the diagnosis and assessment of the activity of inflammatory myopathies in newly onset IIM patients.

References:

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6009
Results: IIM patients had visible tracer uptake in the skeletal muscles of the extremities. The muscular 99mTc-PYP uptake was significantly higher in upper limbs of patients than the uptake in the same muscle groups in healthy controls (uptake[biceps] 0.46 vs. 0.31 g mL\(^{-1}\), p=0.01; uptake[triceps] 0.40 vs. 0.27 g mL\(^{-1}\), p<0.003). The 99mTc-PYP uptake tended to be higher in the lower limbs of patients than controls (in the lower limb 99mTc-PYP uptake of 0.74 ± 0.53 g mL\(^{-1}\)), (p=0.006; SUV\(_{max}\)[biceps] 0.91 vs. 0.44 g mL\(^{-1}\), p=0.008) and lower limbs (SUV\(_{max}\)[quadriceps] 0.84 vs. 0.62 g mL\(^{-1}\), p<0.0001). The muscular FDG uptake values were consequently higher than the 99mTc-PYP uptake values, although not by a constant factor.

Conclusions: Quantitative 99mTc-PYP SPECT/CT as well as 18F-FDG PET/CT imaging revealed muscular inflammation in patients with newly onset, untreated IIM. Patients had a tracer uptake in skeletal muscles groups than healthy controls. Quantification of muscular tracer uptake with the potential to objectively distinguish physiology from pathology could be a valuable tool in the challenging diagnosis of IIMs.

**OP0035 PRELIMINARY ANALYSIS OF NAILFOLD CAPILLAROSCOPY IN THE VERY EARLY DIAGNOSIS OF SYSTEMIC SCLEROSIS (VEDOSS): THE CAP-DI -VEDOSS EXPERIENCE**

M. Cutolo 1, V. Smith 2, O. Distler 4, O. Kowal-Bielecka 5, Y. Allainre 6, M. Matucci-Cerinic 4 on behalf of EUSTAR coworkers.

Background: In Systemic Sclerosis (SSc), before the onset of clinical signs of fibrosis, puffy fingers, specific autoantibodies and microcirculatory modifications are present and are identified in the VEDOSS criteria for ‘very early’ disease. No previous studies are available indicating the prevalence of nailfold capillaroscopic (NVC) SSc patterns or quantitated capillaroscopic characteristics in a ‘very early’ cohort.

Objectives: Evaluation of the prevalence of SSc patterns and quantitated capillaroscopic characteristics in a ‘very early’ cross sectional SSc cohort.

Methods: Multicentre observational cohort study of patients with two strata (Figure): 1RAYNAUD’s phenomenon (RP), Anti Nuclear Antibody (ANA) positive (+), 2. RP, ANA negative (-). ‘Target’ (RP+, ANA, puffy finger [PF] +/-, SSc-antibody (SSc-Ab), NVC+) and ‘control’ (RP-, ANA, SSc-Ab, NVC-) subsets were described. NVC patterns (non-specific abnormalities, SSc-patterns) were entered into database. Generalized Estimating Equations (GEE) were used to assess differences in prevalence of NVC patterns between strata, taking clusters of patients within centers into account.

Results: 1085 RP patients from 40 centres (median number [n] of pt 12 (minimum [min] 1-maximum [max] 393) per centre were enrolled in the VEDOSS online database. Due to erroneous included/missing data (e.g. erroneously absence/missing information on RP, presence of former ACR criteria for SSc, skin involvement at baseline; missing info on: ANA positivity, PF, Cap, SSc-Ab) 750 patients (median n= 7 min=1-max=271) were retained for the analysis. Scoring of capillaroscopy (NVC-patterns) with “Active”, “Late”; “Sclerodermlike” and quantitative (“absent”=“none” or “rare”) and “present” (≈“moderate” or “extensive”) capillaroscopic alterations for giants, haemorrhages, capillary loss and abnormal capillaroscopic characteristics were evaluated. Generalized Estimating Equations (GEE) were used to assess differences in prevalence of NVC patterns between strata, taking clusters of patients within centers into account.

Conclusions: More than 40% of early-diagnosed SSc-PAH patients in the DETECT cohort who were followed over time had disease progression during a rather short follow-up time, with male gender, functional capacity, and pulmonary function (low FVC) also significantly associated with progression. This suggests that even mild and early detected PAH should be regarded as a high-risk complication of SSC, and every effort to make an early diagnosis is valuable.

Acknowledgements: The authors thank all investigators and patients involved in
Conclusions: The VEDOSS cohort presents predominantly an “Early” NVC SSc pattern. Notably the prevalence of NVC SSc patterns was higher in the ANA than ANA-stratum. This evidence further reflects the pivotal role of NVC in the very early diagnosis of SSc.

### OP0036 SEROLOGICAL BIOMARKERS OF ECM TURNOVER ARE ASSOCIATED WITH SKIN FIBROSIS AND LUNG INVOLVEMENT IN SYSTEMIC SCLEROSIS

S. Kubo1, A.S. Siebuhr2, A.-C. Bay-Jensen3, P. Juhl2, M.A. Karsdal2, K. Nakano1, S. Nakayama1, Y. Tanaka1. 1The First Department of Internal Medicine, University of Occupational and Environmental Health, Japan, Fukuoka; 2Institute of Biotechnology, University of Copenhagen, Copenhagen, Denmark; 3Nordic Bioscience, Biomarkers and Research, Herlev, Denmark

**Background:** Extracellular matrix (ECM) unbalance of the skin is a hallmark of systemic sclerosis (SSc). However, currently there is no objective tool to monitor the ECM unbalance in SSc patients allowing for better understanding of the disease stage and activity.

**Objectives:** We investigated the potential of serological biomarkers of ECM turnover (collagen formation and degradation) as biomarkers of skin fibrosis and internal organ involvement in SSc patients.

**Methods:** Peripheral blood obtained from 79 SSc patients and 19 healthy subjects was included in the study. Type I, III, IV, V and VI collagen formation and degradation (P1NP, PRO-C3, P4NP7S, PRO-C5, PRO-C6) and degradation (C3M, C4M, C5M, C6M) biomarkers were detected by ELISA in serum. Modified Rodnan skin score (mRSS) and extent of internal organ involvement (renal, lung, vasculopathy and gastrointestinal) were recorded for SSc patients with a scoring between 0 and 4, with 0 being no involvement and 4 being severe involvement. Mann-Whitney t-test was used to test difference in the biomarker levels between the patient groups and in groups with and without internal organ involvement. Spearman’s correlation coefficient investigated the association between biomarkers and clinical manifestations.

**Results:** SSc patients had a mean age of 63.0 years, mean disease duration of 98.3 months and a mean mRSS of 11.1. SSc patients compared to healthy individuals had higher levels of C5M, C6M and PRO-C6 (p<0.0001, p=0.003, p<0.0001, respectively). The levels of type VI collagen formation and degradation (PRO-C6 and C6M) were twice as that of healthy controls (12.6 vs. 5.4 and 26.0 vs 13.8ng/mL, respectively). C4M2, PRO-C3 and PRO-C6 was associated with skin fibrosis assessed by mRSS (Spearman’s rho=0.24, 0.39 and 0.29, respectively). Patients with signs and manifestation of lower gastrointestinal lesion compared to patients without lesion had higher levels of C3M (median 10.7 vs 13.8ng/mL, p=0.017, figure). C7M was higher in patients with pulmonary hypertension (p=0.04) compared to patients with signs of or no pulmonary hypertension (median 22.1 vs 29.9ng/mL, p=0.026). P1NP was lower in patients with interstitial pneumonia, whereas C6M was higher. There was no difference in the biomarker levels with and without upper gastrointestinal lesions, renal dysfunction or vasculopathy.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.4855

### OP0037 EVALUATION OF SKIN INVOLVEMENT IN SYSTEMIC SCLEROSIS PATIENTS BY USING TWO ULTRASOUND TRANSDUCERS WITH DIFFERENT FREQUENCY

B. Ruaro, A. Sulli, S. Paolino, C. Pizzorno, M. Ghiio, E. Alessandri, A.C. Trombetta, C. Cosso, M. Cutolo. Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS AUO San Martino, Genoa, Italy

**Background:** The modified Rodnan skin score (mRSS) is the validated method to evaluate the extension of skin involvement in systemic sclerosis (SSc) and to distinguish between patients with limited cutaneous skin involvement (lCSSc, skin involvement is confined to the extremities) or diffuse (dCSSc) (1,2). Recently several studies have demonstrated that skin high frequency ultrasound (US) is a valid and reproducible technique to measure dermal thickness (DT) in patients with SSc (3–6).

**Objectives:** To compare the values of DT obtained by two ultrasound transducers with different frequency (18 MHz and 22 MHz) in evaluating the DT in lCSSc patients and healthy controls.

**Methods:** Thirty-seven lCSSc patients (mean age 62±13SD years, mean disease duration 5±5SD years) and 37 healthy controls (CNT) sex and age matched were enrolled after informed consent. Both US transducers of 18 and 22 MHz (Esaote, Genova) were used to evaluate DT in the seventeen areas of the skin (zygoma, fingers, dorsum of hands, forearms, arms, chest, abdomen, thighs, legs, feet) of SSc patients where Rodnan skin score (mRSS) is usually assessed. Skin US was also performed in the same seventeen areas of CNT, looking for DT differences in comparison with lCSSc patients. Statistical analysis was carried out by non-parametric tests.

**Results:** DT evaluated with the 22 MHz probe was found significantly higher in all body areas in comparison with the 18 MHz transducer, both in lCSSc patients and healthy controls (p<0.01) and in CNT (p=0.05). The median difference of DT values between the two probes was of 0.11 millimetres in lCSSc patients (minimum 0.0023, maximum 0.28mm) and 0.01 millimetres in CNT (minimum 0.0029, maximum 0.03 mm). Of interest, in lCSSc DT evaluated by 18 MHz transducer was recognized significantly higher (p<0.001) also in four out of six skin areas where the mRSS was found normal (score=0) (upper-arms, chest and abdomen), with exclusion of thighs (p=0.08), in contrast with the classification of lCSSc. However, by using the 22

Myositis autoantibodies outperform clinical subgroups in predicting muscle weakness in myositis patients

Background: Myositis patients may be classified as belonging to one of four clinical groups: dermatomyositis (DM), polymyositis (PM), clinically amyopathic dermatomyositis (CADM) or necrotizing myositis (NM). Alternatively, myositis patients may be classified according to myositis autoantibody status.

Objective: Our study was to determine whether clinical groups or myositis autoantibodies provide better prognostic categories with regard to muscle involvement in these patients.

Methods: All Johns Hopkins Myositis Center patients from 2002 to 2015 with a myositis-specific autoantibody confirmed by two different immunologic techniques were included. Autoantibody groups accounting for less than 2% of the final sample size were excluded. Strength (analyzed as the average of deltoid and hip flexor strength using Kendall’s scale) and log transformed CK levels were compared between the different autoantibody groups using multilevel regression models adjusted for age, time from disease onset, sex, race and treatments. Models with different combinations of key variables were compared using the likelihood ratio test to ascertain if autoantibody groups and clinical subgroups provided the same amount of information regarding muscle weakness and CK levels over time.

Results: 483 patients with 4181 visits were included and 10 different autoantibody groups were identified. Muscle weakness and CK levels followed a gradient among both antibody and clinical groups. Anti-SRP patients had the greatest weakness, followed by anti-HMGCR, anti-Mi2 and anti-NXP2, and then anti-Jo1. CK levels were highest in anti-HMGCR patients, followed by anti-SRP, anti-PL7, anti-Jo1 and anti-Mi2. Interestingly, strength and CK levels were more consistently associated with disease activity and CK levels in two groups: anti-NXP2 patients had significant weakness with low CK levels and anti-PL7 patients were relatively strong despite high CK levels. Multilevel regression models showed autoantibody groups explained the strength and the CK variability better than the clinical groups (AIC difference >20). Indeed, adding clinical groups to a model using only autoantibodies did not improve the model’s ability to predict strength (p>0.2) and only mildly improved its ability to predict CK (p=0.01). In comparison, adding the autoantibodies to a model using the clinical groups resulted in a marked improvement in predicting both CK and strength (both p<0.001).

Conclusions: In patients with myositis, autoantibody status predicts strength and CK levels better than clinical grouping.

Bacteremia in Systemic Lupus Erythematosus Patients from RELESSER Registry: Risk Factors, Clinical and Microbiological Characteristics and Outcomes

I. Rua-Figueira, J. López-Longo, M. Galindo-Izquierdo, V. Del Campo, J. De la Torre Cisneros, E. Urríate, P. Vela, E. Tomero, J. Pego-Reigosa, Rheumatology Hospital Dr. Negrin, Las Palmas GC; 2Gregorio Marañón Hospital; 3Doe de Octubre Hospital; 4Madrid (Spain); 5Hospital Complex of Vigo and IISGS, Vigo; 6Reina Sofia Hospital, Córdoba; 7Donostia Hospital, Guipúzcoa; 8Alcante G Hospital, Alicante; 9La Princesa Hospital, Madrid, Spain

Background: According to RELESSER (Spanish Society of Rheumatology Lupus Registry) data, bacteremia is the main cause of death by infection in systemic lupus erythematosus (SLE). However, the available information about this severe infection in SLE patients remains scarce.

Methods: Retrospective, nested case-control study of SLE patients (ACR-97 criteria) with at least one bacteremic episode and random controls from RELESSER Registry. Descriptive, bivariate and multivariate analysis (logistic regression).

Results: 114 bacteremic episodes in 83 patients were recorded. Incidence rate: 2.7/1,000 patient-years (n total: 3658). At the time of the bacteremia: median age: 40.5 (8–90) years, 88.6% female, disease duration: 9.7 (IRI6.7), median SELENA-SLEDAI: 4 (IRB), 86% with severe flare (SFI criteria), active nephritis: 16.7%, median SLICC/ACR DI: 3 (IR), any comorbidity: 64% (McCabe-Jackson criteria: 28.1% rapidly or ultimately fatal), more frequent renal failure (15.8%) or diabetes (11.4%). SLE treatment at the time of bacteremia: 88.6% corticosteroids (66.8%>10mg/day), 57% immunosuppressors (mycophenolate 17.5% and cyclophosphamide 12.3%), 27% antimarialials. 44.7% suffered invasive procedures, more frequently intravascular catheterization (24.6%). The bacteremia was nosocomial in 35.1% and the source was more frequently urinary (27.2%). 64% developed systemic inflammatory response syndrome and 35% needed intensive care unit admission, with multorganic failure in 22.8%. The most frequent microorganism was E.lolii (29.8%) followed by Staphylococcus aureus (16.7%) (Cox mathillin-resistant) and Salmonella spp (15.4%). The most frequent enteric bacilli were extended-spectrum b-lactamase positive. 17.5% were multidrug resistant. 68.4% started the antibiotic therapy before blood culture results, resulting finally active in susceptibility testing in 56 cases (71.8%), indicating an appropriate empirical antibiotic therapy in 49%. The bacteremia-related mortality was 14%. The risk of death was higher in patients with severe sepsis (Pitt index >8) (OR: 13 (IC95%: 3.71–45.17), The bacteremia was recurrent in 26.3%.

Associations with bacteremia in bivariate analysis (114 bacteremias vs 688 controls) are shown in Table 1. Antimalarials were protective. In the multivariate analysis (adjusted for disease duration), only elevated creatinine (OR 1.31 (95% CI 1.01–1.70), p=0.045), diabetes (OR 6.01 (95% CI 2.26–15.95), p<0.000), cancer (OR 5.32 (95% CI 2.23–12.70), p<0.000), immunosuppressors (OR 6.35 (95% CI 3.42–11.77), p<0.000), cyclophosphamide (OR 9.37 (95% CI 5.12–17.14), p<0.000), cancer and SLICC/ACR DI (OR 1.65 (95% CI 1.31–2.09), p<0.000) remained statistically significant.

Conclusions: Bacteremia occurred mostly in active SLE, frequently in the context of a severe flare. Gram negative bacilli predominated, with high rate of multidrug resistance. The empiric treatment was inappropriate in a half of the cases. The empiric treatment was inappropriate in a half of the cases.
recurrence and mortality were high. Immunosuppressors use, comorbidity and damage were all associated to bacteremia.

THE NUMBER OF CIRCULATING REGULATORY T CELLS IS REDUCED AND LOW-DOSE IL-2 SELECTIVELY STIMULATES ITS PROLIFERATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

X. Li 1, X. Jing 1, X. Wu 1, J. Wang 1, Z. Liang 1, M. Hao 1, J. Chen 1, C. Gao 2, X. Ji 1. 1. Rheumatology, Second Hospital of Shannxi Medical University, Taiyuan, China; 2Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, United States

Background: The imbalance of T help 17 cells (Th17)/regulatory T cells (Tregs) is considered to be a pivotal cause of autoimmune diseases 1, including systemic lupus erythematosus (SLE). However, previous reports 2-4 describing the respective changes of Tregs and Th17 cells in SLE patients were controversial because a few samples or diverse markers were used to identify Tregs with little consensus.

Objectives: To clarify the status of Tregs and Th17 in SLE, we investigated the frequencies of Tregs and Th17 cells on a large scale and whether those defects can be corrected by the supplementation of low-dose human recombiant interleukin-2 (IL-2).

Methods: Two hundred and thirty-five SLE patients (219 women and 16 men), with mean age of 37.80±14.00 years, were enrolled. The disease activity using erythrocyte sedimentation rate (ESR) and SLEDAI scores. The frequencies of CD3+CD4+FOXP3+Treg cells and Th17 cells in peripheral blood from these patients were measured by flow cytometry. And low-dose IL-2 was used among 127 patients at a dosage of fifty WIU every day for five days.

Results: As compared to healthy controls (median of Treg cells: 33.09 cells/ul), the frequencies of circulating CD4+CD25+FOXP3+Treg cells were significantly decreased, while CD4+CD25+FOXP3+Treg cells were negatively correlated with ESR and SLEDAI (P<0.01; r=-0.25, P<0.001), tended to balance and had no difference with healthy individual (P>0.25).

Conclusions: Our study assessed for the first time ASCA IgG+IgA with a highly specific immunoblot assay in a large cohort of pSS patients, showing that ASCA positivity identifies a peculiar clinical and serological pSS phenotype. In particular, ASCA+ pSS patients display anti-Ro52, anti-Ro60 and anti-La autoantibodies (p<0.001). No differences concerning T regulatory and Th17 cell proportion could be observed in ASCA+ compared to ASCA- pSS patients. S. cerevisiae mannan displays a consistent similarity with 52kD and 60kD Ro/SSA, La/SSB autoantigens. The highest similarity was observed when aligning the mannan with 60kD Ro/SSA (identities 71/114, 64%; positives 8/11, 72%; E value 2.2).

ANTIBODIES ANTI-SACCHAROMYCES CEREVISIAE IN PRIMARY SJÖGREN’S SYNDROME: PREVALENCE, CLINICAL ASSOCIATIONS AND POSSIBLE CROSS-REACTIVITY WITH DISEASE SPECIFIC AUTOANTIGENS

A. Alunno 1, O. Bistoni 1, F. Carubbi 1, 2, G. Caffaro 1, E. Valentini 4, R. Giacomelli 2, R. Geri 1, 5. 1Department of Medicine, Rheumatology Unit, University of Perugia, Perugia; 2Department of Biotechnological and Applied Clinical Sciences, Rheumatology Unit, University of L'Aquila; 3Department of Medicine, ASL 1 Avezzano-L'Aquila-Sulmona, L'Aquila; 4Department of Medicine, Rheumatology Unit, University di Perugia, Perugia, Italy

Background: Saccharomyces cerevisiae is a common yeast used in the food industry. Antibodies against the phosphopeptidomannan part of the cell wall of S. cerevisiae (ASCA) are a well established biomarker of Crohn’s disease and have been assessed in several organ-specific and systemic autoimmune diseases (ADs) (1–2) Although the pathogenic significance of ASCA is not yet fully understood, the molecular mimicry of self-antigens in several associated ADs has been suggested as putative mechanism.

Objectives: Since to date ASCA have not been tested in primary Sjögren’s syndrome (pSS), the purpose of this study was to assess these antibodies in a large cohort of pSS patients and investigate their significance as potentially helpful biomarker in a clinical setting.

Methods: One hundred and four patients with pSS according to the 2002 American European Consensus criteria and 30 healthy donors were enrolled. ASCA IgG+IgA were assessed in serum samples by ASCA screen dot (Alphadia sa/mv). T cell phenotyping was performed in paired peripheral blood samples by flow cytometry. To compare the aminoacid sequence of mannan of Saccharomyces cerevisiae and well characterized auto-antigens peculiar of pSS (52kD and 60kD Ro/SSA, La/SSB) we browsed the protein database of the National Center for Biotechnology Information (NCBI) and run the Basic Local Alignment Search Tool (BLAST).

Results: ASCA were detected in 5 out of 104 pSS patients, therefore the prevalence in our cohort is 4.8%. None of the ASCA+ pSS patients displayed IL-2 or other autoimmune concomitant disease not significant for ASCA positivity. ASCA+ pSS patients displayed more frequency a reduction of C3 and C4 complement fractions as well as pulmonary, articular and cutaneous involvement (all p<0.05).

Binary logistic regression revealed that ASCA+ pSS patients display an odds ratio of 14 (p=0.006) to have cutaneous manifestations of pSS. All ASCA+ patients but only 39% of ASCA- patients displayed anti-Ro52, anti-Ro60 and anti-La autoantibodies together (p=0.01). No differences concerning T regulatory and Th17 cell proportion could be observed in ASCA+ compared to ASCA- pSS patients. S. cerevisiae mannan displays a consistent similarity with 52kD and 60kD Ro/SSA, La/SSB autoantibodies. The highest similarity was observed when aligning the mannan with 60kD Ro/SSA (identities 71/114, 64%; positives 8/11, 72%; E value 2.2).

Conclusions: Our study assessed for the first time ASCA IgG+IgA with a highly specific immunoblot assay in a large cohort of pSS patients, showing that ASCA positivity identifies a peculiar clinical and serological pSS phenotype. In particular, ASCA+ pSS patients display anti-Ro52, anti-Ro60 and anti-La autoantibodies, low complement and cutaneous involvement. The high similarity between S. cerevisiae mannan and Ro60/SSA autoantigen may suggest: i. ASCA may bind Ro52 and Ro60 autoantigens such as anti-Ro, as already postulated for other autoantigens (2); ii. ASCA may bind more likely Ro60 autoantigen rather than the Ro52 or La autoantibodies in pSS. A possible pathogenic/prognostic significance of ASCA in pSS may therefore be speculated.

PREDICTORS OF PERSISTENT DISEASE ACTIVITY AND PERISTANT LONG QUESCENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS – RESULTS FROM THE HOPKINS LUPUS COHORT

I. Giannakou 1, K. Chatzidionyssiu 1, L. Magder 2, R. Van Vollenhoven 1, M. Petri 1. 1ClinTRID - Unit for Clinical Therapy Research, Inflammatory Diseases, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; 2University of Maryland School of Medicine; 3Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, United States

Background: Systemic lupus erythematosus (SLE) is characterized by a diversity of disease activity.

Objectives: The aim of this study was to identify prognostic factors of persistent disease activity and persistent long quiescence using baseline demographics and clinical characteristics.

Methods: Patients enrolled in the Hopkins Lupus Cohort from 1987 to 2014, who had at least 3 visits per year during the first 3 years following cohort inclusion and complete information on disease activity were included. Three major patterns of SLE disease activity over time (1 year intervals) based on the modified SLE Disease Activity Index have been previously described: low quiescent (LQ), chronic active (CA) and relapsing-remitting (RR). (1). Based on maintenance of the aforementioned
patterns over 3 consecutive years, patterns have been defined as: Persistent Long Quiescence (pLQ), Persistent Relapsing-Remitting (pRR), Persistent Chronic Active (pCA) and Mixed, at least 2 different pattern types. Predictors of pCA (vs. pLQ, pRR and mixed) and pLQ (vs. pCA, pRR and mixed) were identified by univariate and multivariate logistic regression analyses. Several baseline demographics (age, sex, ethnicity, disease duration, years of education and combined annual family income), disease characteristics at baseline (SLEDAI, PQA) and treatment categories (hydroxychloroquine, prednisone and cytotoxic treatment followed ≥75% of visits vs. <75% of visits) were used as independent variables.

Results: 916 patients were identified. The results of the univariate analyses for pCA are shown on table 1. In the multivariate model, African American ethnicity (OR: 2.43, 95% CI: 1.19–4.94, p = 0.01) and high baseline SLEDAI (OR: 1.09, 95% CI: 1.03–1.16, p = 0.004) remained significant predictors of pCA. Higher education (>12 years: OR: 2.16, 95% CI: 1.11–4.20, p = 0.02) and low baseline SLEDAI (OR: 0.62, 95% CI: 0.52–0.75, p < 0.001) were significant predictors of pLQ in the multivariate analysis while African American ethnicity (OR: 0.36, 95% CI: 0.16–0.78, p = 0.01) and female patients (OR: 0.26, 95% CI: 0.12–0.56, p = 0.001) were less likely to achieve persistent long quiescence.

Table 1. pCA (vs. pLQ, RR and mixed) and pLQ (vs. pCA, pRR and mixed) were identified by univariate and multivariate logistic regression analyses. Several baseline demographics (age, sex, ethnicity, disease duration, years of education and combined annual family income), disease characteristics at baseline (SLEDAI, PQA) and treatment categories (hydroxychloroquine, prednisone and cytotoxic treatment followed ≥75% of visits vs. <75% of visits) were used as independent variables.

Osteoporosis treatment gap, new options and new strategies

OP0047 OSTEOPOROTIC HIP FRACTURE PREVENTION: ARE WE A CRISIS?

M. Sehgal 1, A. Mithal 2, A. Mithal 3, G. Singh 4, 1 Student, Menlo Atherton High School, Atherton, United States; 2 Student, NIIT Delhi, Delhi, India; 3 Epidemiology, ICORE, Woodside; 4 Gastroenterology and Hepatology, Stanford University, Stanford, United States

Background: Osteoporotic hip fractures are a significant cause of morbidity and mortality in the elderly. With the aging of the US population, it was expected that there would be a nationwide “epidemic” of osteoporotic fractures; however, Medicare reimbursement for osteoporosis screening and the rapid uptake of bisphosphonate therapy in the late 1990s and early 2000s probably forestalled this epidemic. In fact, osteoporotic hip fractures numbers declined during this time, despite the dramatic growth of the elderly population (1). However, bisphosphonate prescriptions have dropped precipitously by over 50% from their peak in 2008 (2), likely because of concerns about their adverse events. In this era of “crisis” in osteoporosis prevention, has the pendulum swung back on hip fracture numbers?

Objectives: To study the number and prevalence of osteoporotic hip fractures in patients 50 years and older over the last 22 years (1993–2014) in the US?

Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in NIS from 1993 to 2014 with a primary diagnosis of non-traumatic hip fractures, and calculated age-adjusted prevalence rates. We studied the number and prevalence of osteoporotic hip fractures in patients 50 years and older over the last 22 years (1993–2014) in the US.

Results: There were 407 million all-cause hospitalizations in 1.88 billion person-years of observation among people 50 years of older from 1993 to 2014 (21,626 hospitalizations per 100,000 person-years). During this time-period, there were 6.15 million hospitalizations for osteoporotic hip fractures in this population (327 per 100,000 person-years). After an increase in hip fracture rates from 1993 to 1996, there was a decline of 10.6% in total number of hip fractures from 300,154 in 1996 to 286,366 in 2010 even though population of 50 years and older increased from 69.9 million to 99.6 million in the same time. After bottoming out in 2010, the total number of hip fractures increased by 6.2% to 285,050 in 2014 (Figure, blue solid line). However, the age-standardized prevalence rate of hip fractures declined steadily (from 414/100,000 in 1996 to 269/100,000 in 2014, p<0.0001. Figure solid red line), although the rate of decline has ameliorated somewhat from 2010 onwards (not statistically significant).

Conclusions: The total number of osteoporotic hip fractures in 50 years and
older declined since 1996, bottomed out in 2010 but has started increasing again. It is critical to evaluate risks and benefits of preventive treatments for optimal management of this potentially serious problem.

**OP0048 ROMOSOZUMAB RAPIDLY REDUCES CLINICAL VERTEBRAL FRACTURE INCIDENCE: RESULTS FROM THE FRAME STUDY**

1Department of Rheumatology, University of British Columbia, Vancouver, Canada; 2Department of Medicine, University of Arkansas, Little Rock, USA; 3Department of Medicine, University of California, San Diego, USA; 4Miyauchi Medical Center, Osaka, Japan; 5McMaster University, Hamilton, Canada; 6IMA Brazil, São Paulo, Brazil; 7Monash University, Clayton, Australia; 8UNIENDO, Bogota, Colombia; 9Amgen, Thousand Oaks, United States; 10UCB, Brussels, Belgium

**Background:** Romosozumab (ROMO) inhibits sclerostin and has a dual effect on bone, increasing formation while decreasing resorption, resulting in significant increases in bone mineral density (BMD) at 6 months (m), which at 12m reach 13.3% vs placebo (PBO) at the spine. Using high resolution quantitative computed tomography, BMD increases were observed at both trabecular and cortical compartments of the spine, the spinal planes representing the significant reductions in radiographic vertebral fracture (VFx) risk in women with osteoporosis (OP) enrolled in the FRAME trial (NCT01578534).

**Objectives:** Here, we report the effect of ROMO on clinical (clin) VFx incidence over 12m in women in FRAME with back pain.

**Methods:** FRAME enrolled 7180 postmenopausal women with OP, mean age 70.9 yrs (total hip T-score –2.5 to –3.5) and no severe VFx. Patients received monthly ROMO (n=3589; 210mg) or PBO (n=3591) for 12m. At monthly visits, women with back pain consistent with a clin VFx had a confirmatory spinal X-ray. Clin VFx risk (ROMO vs PBO) was calculated by Cox-proportional hazards model.

**Results:** Of 119 women reporting back pain over 12m, 20 women were diagnosed with a new or worsening VFx. With ROMO, 3 clin VFx (≤0.1%; all at <2m) were identified vs 17 (0.5% at 12m) with PBO (Figure). Clin VFx risk was 83% lower in the ROMO group vs PBO at 12m (hazard ratio 0.17; 95% CI, 0.05–0.58; P<0.001). In women with clin VFx vs no clin VFx, the lumbar spine T-score was numerically lower and the FRAX score higher at baseline; other baseline characteristics were comparable among all women who reported back pain.

**Conclusions:** ROMO treatment for 12m was associated with rapid and large reductions in clin VFx risk vs PBO. In the ROMO group, all clin VFx occurred ≤2m; clin VFx risk was ≥5 times higher with PBO vs ROMO. Monthly study visits in FRAME allowed for timely radiologic confirmation of a suspected clin VFx.

**OP0049 SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS EVALUATING BISPHOSPHONATES FOR THE PREVENTION AND TREATMENT OF GLUCOCORTICOID-INDUCED OSTEOPOROSIS**

1Department of Rheumatology; 2Department of Internal medicine, Queen's University, Kingston; 3Department of Internal medicine, University of Western Ontario, London; 4Department of Rheumatology, Queen's University, Kingston, Canada

**Background:** Glucocorticoid therapy is a major risk factor for osteoporosis related fractures. A previous meta-analysis conducted by Homik et al reported that bisphosphonates therapy increased BMD in glucocorticoid-induced osteoporosis (GIO) when compared to placebo, whereas results for incident vertebral fracture did not reach statistical significance.

**Objectives:** To evaluate the efficacy of bisphosphonates in GIO based on randomized controlled trials (RCTs). Both placebo controlled and active comparator trials were analyzed.

**Methods:** Two authors screened citations from the following electronic databases: Medline (1998–2015), EMBASE (1998–2015), Cochrane Library (1998–2015). A manual search was completed for conference proceedings from the ACR (2010–2015), CRA (2009–2015), and ASBMR (2009–2014). We used the study by Homik et al to identify RCTs published prior to 1998. Only RCTs that had a minimum prednisone dosage of 5 mg/day or equivalent and treatment duration of at least 3 months were included. Primary outcomes were changes in BMD and incident fractures. Two authors abstracted data using a standardized data abstraction form. We used the Cochrane Risk of Bias Tool to evaluate the quality of the selected RCTs and devised a quality score ranging from 0 to 6, where 6 represents the highest quality.

**Results:** A total of 466 citations were identified (239 Medline, 217 EMBASE, and 10 Cochrane Library). Fourteen RCTs met the inclusion criteria. An additional two RCTs were identified from conference proceedings. Eleven RCTs compared bisphosphonates to a placebo, three RCTs compared bisphosphonates to a vitamin D derivative, one RCT compared alendronate to teriparatide, and one RCT compared zoledronic acid to risedronate. The RCTs were of reasonably good quality with a mean quality score of 4.

Overall, of the 11 RCTs that compared bisphosphonates to a placebo, all found that the bisphosphonates were superior. Nine RCTs were pooled for mean percentage change in lumbar spine BMD (bisphosphonates n=687, placebo n=654). The pooled mean percentage change was in favor of bisphosphonates compared to placebo [weighted mean difference (WMD) of 4.03%, 95% CI (1.59–6.47), P<0.001]. Six RCTs were pooled for mean percentage change in femoral neck BMD (bisphosphonates n=481, placebo n=483) and the results favored bisphosphonates compared to placebo [WMD of 2.95%, 95% CI (2.09 –3.82), P<0.04]. Seven RCTs were pooled for outcome of incident fractures (bisphosphonates n=613, placebo n=469) and the results favored bisphosphonates compared to placebo [RR of 0.85, 95% CI (0.48–0.88), P<0.006 (Figure 1)]. Results were pooled using RevMan (version 5.3).

**Figure 1**

**Conclusions:** Bisphosphonates mitigate adverse changes in BMD and lower fracture risk in patients treated with glucocorticoids.
Background: In Sweden, ∼50% of women and ∼25% of men are expected to suffer an osteoporosis (OP)-related fracture (Fx) during their lifetime, and hip Fx incidence in Sweden is one of the highest worldwide. Despite this, nationally only 12% of patients with Fx are prescribed an OP treatment following Fx. 1 Understanding the reasons for the marked under-treatment of patients with Fx may provide insights into how to improve deficiencies in the management of OP.

Objectives: To assess rates of OP treatment initiation within 1 year (<1 yr) following first Fx in treatment-naïve patients with fracture in Sweden and to evaluate the determinants of treatment initiation.

Methods: Patients aged ≥50 yrs with any type of Fx were identified from Swedish national registers between 2006–2012 and followed from time of first Fx. Patients who were treatment-naïve at the time of first Fx were included in the analysis. Here, we report OP treatment initiation <1 yr after Fx in the different baseline subgroups considering gender, age, Fx type, steroid use and comorbidities.

Results: 258,827 treatment-naïve patients with a first Fx (68% female; mean age 72.7 [SD 12.9] yrs) were included. Overall, 6.6% of patients initiated OP treatment <1 yr; the proportion was higher in females (8.5%) than in males (2.3%), and was highest in patients aged 70–80 yrs (10.7%) vs other ten-year age groups (mean 5.5%). Patients with a diagnosed vertebral Fx were more likely to start OP treatment (21.2%) compared with non-vertebral Fx (5.6%). The proportion of patients starting OP treatment was higher in patients receiving glucocorticoid (GC) treatment (17%) compared with those not treated with glucocorticoids (6.1%). In general, comorbidities were not positively associated with treatment initiation, except for those indirectly connected to known contributors of Fx risk, i.e. chronic pulmonary disease (GC use) and rheumatoid arthritis (FRAX-algorithm risk factor), which were associated with increased treatment initiation. Although both dementia and dependency are known to be associated with increased risk of Fx, the tendency to initiate treatment was lower in patients with these conditions compared with those without (1.5% vs 6.9% and 2.3% vs 7.4%, respectively).

Conclusions: This study confirms the large treatment gap in OP treatment initiation following a first Fx in Sweden; rate of OP treatment initiation was below the post-Fx treatment initiation rate goal of 30% and also lower than the 12% published national indicator for treatment exposure (2015). 1 The proportion of patients initiating OP treatment appears to be somehow influenced by gender, age, Fx type, GC use, rheumatic disease, dependency and dementia; nevertheless, treatment initiation rates were low. These data highlight the need for significant efforts to improve OP management post Fx in Sweden.

VINFORCE Study Group, Vienna, Austria; 3Division of Rheumatology, Facultade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background: Systemic bone loss is a well-known and severe consequence in axial spondyloarthritis (axSpA). To date determination of bone microstructure has only been described in patients with long-standing ankylosing spondylitis while bone microstructure has not been assessed in axSpA.

Objectives: The aim of the present study was to investigate bone microstructure, geometry and bone mineral density (BMD) using high-resolution peripheral quantitative CT (HR-pQCT) in a cohort of axSpA patients at an early stage of disease and to search for potential factors for deterioration of bone microstructure.

Methods: An inception cohort of 101 axSpA patients and 50 healthy controls of similar age and sex was assessed for geometric, volumetric and microstructural parameters of bone using HR-pQCT scanning of the radius. Additionally, demographic and disease specific characteristics of SpA patients were recorded.

Results: SpA patients and controls were comparable in age (median IQR 45.0 (15.0) vs. 44.76 (26.0) years, p=0.917), sex (female 41.6% vs. 40%, p=0.852) and BMI (23.8 (5.2) vs. 23.8 (5.5) kg/m2, p=0.752). Patients showed HLA-B27 positivity. Median disease duration was 6.5 (9.0) years, 58.4% of patients were on biological treatment and 14.9% of patients in disease remission according to ASDAS-CRP. Geometric and microstructural analysis by HR-pQCT revealed a significantly reduced cortical area (p=0.022) and cortical thickness (p=0.006) in SpA patients compared to controls. No differences in cortical porosity (p=0.668), trabecular geometry or microstructure were detected. Total and cortical vBMD were significantly reduced in SpA patients (p=0.042 and p=0.007), while there was no difference in trabecular vBMD (p=0.376). Patients with a short disease duration (<2 years) had a significantly smaller cortical thickness and cortical area (p=0.050 and p=0.032) compared to controls. Patients with a disease duration >2 years (n=55) additionally showed a decrease of cortical and total vBMD (p=0.004 and p=0.036). Multivariate regression models identified male sex to be associated with lower cortical vBMD and female sex with lower trabecular vBMD. History of prednisolone treatment (>5mg >3months) was associated with lower trabecular vBMD, and disease duration with higher trabecular vBMD. Remission status, treatment with TNF inhibitors, HLA-B27 status and presence of peripheral arthritis did not influence bone microstructure independently.

Conclusions: Bone microstructure in SpA patients is primarily characterized by deterioration of cortical bone. Cortical bone loss starts early and is evident within the first 2 years of disease.

BONE LOSS AND CARDIOVASCULAR RISK IN PATIENTS WITH EROSIve AND NON-EROsive HAND OSTeOARTHRITIS

O. Ruzickova, O. Steglova, K. Pavelka, L. Senott. Revmatology, Institute of revmatology, Prague 2, Czech Republic

Background: Hand osteoarthritis (OA) and its more severe subset erosive hand OA are common causes of pain and morbidity. Some metabolic factors were suggested to be implicated in erosive disease. Furthermore, few studies investigated differences in systemic bone loss and cardiovascular risk factors between erosive and non-erosive hand OA.

Objectives: To compare bone mineral density (BMD) and major cardiovascular risk factors between patients with erosive and non-erosive hand OA in a cross-sectional study.

Methods: Patients with symptomatic disease fulfilling the American College of Rheumatology (ACR) criteria for hand OA were included in this study. Erosive OA was defined by at least one erosive interphalangeal joint. All patients under-2 or more VF were identified. The 5-year incidence of VFs was 1.6%.

Results: Out of these patients, 72 had erosive disease. The disease duration (p<0.01) was significantly higher in patients with erosive compared with non-erosive hand OA (-0.08 SD vs. 0.0750, p<0.01; total 10.92%). The decrease of T-score in femur neck, total femur and the decrease of BMD (g/cm2) in all regions were also higher, although not significantly, in patients with erosive compared with non-erosive hand OA. In addition, more patients with erosive compared with non-erosive hand OA were treated for dyslipidaemia at baseline and after two years (32% vs. 28% and 32% vs.30%, p<0.01 for both comparisons).

Conclusions: These results suggest that patients with erosive hand OA are at risk for development of general bone loss and cardiovascular diseases.

INCIDENCE OF VERTEBRAL FRACTURES IN EARLY SPONDYLOARTHRITIS: 5-YEAR PROSPECTIVE DATA OF THE DESIR COHORT

J. Sahuguet1, J. Fechtenbaum1, A. Molto1, A. Etcheto1, P. Richette2, M. Dougados1, C. Roux1, K. Briot1, 1Rheumatology department, Hôpital Cochin; 2Rheumatology department, Hôpital Lariboisière, Paris, France

Background: Osteoporosis is a well-recognized feature of axial spondyloarthritis (axSpA) and an increased risk of vertebral fractures (VFs) has been reported in patients with SpA. The prevalence of VFs is highly variable across studies, up to 30%. These data are unexpected in a disease affecting a young population, predominantly males. These results could be related to differences in methods of diagnoses of VFs and in populations with highly variable duration of the disease. We hypothesized that the prevalence and incidence of VFs be lower than the ones previously reported, especially in early spondyloarthritis.

Objectives: Our primary aim was to assess the prevalence of VFs in a cohort of early inflammatory back pain suggestive of early axial SpA and their incidence over 5 years.

Methods: Study population: patients from the DESIR (Devenir des Spondyloarthopathies Indifférenciées Récentes) cohort, which is a french national longitudinal prospective cohort including adults between 18 and 50 years old, and presenting with inflammatory back pain suggestive of axSpA for less than 3 years.

Results: Follow-up is still ongoing, but the data presented here includes the first 5 years of follow-up. All patients had thoracic and lumbar spine X-rays at baseline, 2 years and 5 years. For this particular study, all radiographs of the DESIR cohort were centrally read by one reader, an expert in the field of the diagnosis of VFs according to Genant’s method. Careful assessment was used to distinguish true VFs not to be mistaken with deformities. Using a temporal sequence of reading (i.e. unblinded for chronological order), an incident VF was defined as a change in the score of a vertebra from grade 0 to a subsequent grade 1 or more. All vertebræ between T4 and L4 were evaluated. In doubtful cases, an adjudication by two other senior experts was performed. Prevalence at inclusion and the incidence of VFs over the first 5 years of follow-up were described.

Results: A total of 708 patients with inflammatory back pain were included in the DESIR cohort. Plain dorsolumbar spine X-rays were available for 694 patients, and thoracic and/or lumbar X-rays were available for 843 patients at baseline. Twenty eight VFs were identified in 21 patients (19 grade 1 VFs and 9 Grade 2 or 3 VFs); therefore, the prevalence of VFs was 4.0%. Complete X-ray follow up between baseline and M60 was available for 433 patients. Seven incident VFs were identified in 6 patients: at 2 years grade 1 VFs and 1 grade 2 VF were identified; and at 5 years, grade 1 VF and grade 2 or 3 VFs were identified. The 5-year incidence of VFs was 1.6%.

Conclusions: In this study focused on a population of early spondyloarthropathy, the reported low prevalence of VFs of 4.5% and incidence of 1.6% confirm our hypothesis that the real prevalence and incidence of VF in SpA is probably much lower than what was reported in previous studies. These discrepancies might be explained by the variability in the methods of vertebral fracture’s assessment as vertebral deformations might be inappropriately considered as fracture.

IL-23P19 IS UP-REGULATED IN MONOCYTE-DERIVED FLUORESCENCE OPTICAL IMAGING IN JUVENILE IDIOPATHIC ARTHRITIS

Objectives: To compare levels of the IL23 subunit, IL23p19, produced by monocytes from patients with Enthesitis related arthritis (ERA) to those of healthy controls. Other pro-inflammatory cytokines and markers of the UPR were also studied.

Methods: Adult patients with IA (rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (sSpA)) were invited to participate through The Danish Rheumatism Organization, arthritis networks, and hospitals’ rheumatology departments across the country. MDMs were derived from patients treated with IFN-γ or TNF inhibitors and LPS. IL23p19 expression was higher in MDMs from HLAB27 positive patients with ERA compared to those who were HLAB27 negative. A significant increase in IL23p19 expression was seen in MDMs treated with LPS from male HLAB27 positive patients with ERA compared to those who were HLAB27 negative. This increase was also seen in MDMs treated with LPS from male HLAB27 positive patients with ERA compared to male healthy controls. In this group, the induction of the UPR was observed in 63% of the ERA patients, while it was seen in only 3% of the healthy controls. The results suggest that the UPR is involved in the pathogenesis of ERA, particularly in those who are HLAB27 positive.

Results: IL23p19 expression was higher in MDMs from HLAB27 positive patients with ERA compared to healthy controls treated with LPS [median relative expression 384.7 (IQR 179.2–1340) vs 90.5 (49.9–455.9); p=0.02]. With the addition of the UPR inducer, TM, enhanced IL23p19 mRNA expression was also seen in HLAB27 positive patients compared to those who were HLAB27 negative and MDMs treated with LPS alone. When HLAB27 positive patients were compared to male healthy controls, a significant increase in IL23p19 expression was seen in MDMs treated with LPS from male HLAB27 positive patients with ERA compared to male healthy controls. In this group, the induction of the UPR was observed in 63% of the ERA patients, while it was seen in only 3% of the healthy controls. The results suggest that the UPR is involved in the pathogenesis of ERA, particularly in those who are HLAB27 positive.

Conclusions: IL23p19 expression is a potential biomarker for the diagnosis and treatment of ERA, particularly in those who are HLAB27 positive. Further studies are needed to confirm these findings and to investigate the role of the UPR in the pathogenesis of ERA.

Improvement in Patient-Reported Outcomes in Patients with Polyarticular-Course Juvenile Idiopathic Arthritis and Inadequate Response to BioLogic or Non-BioLogic Disease-Modifying AntiRheumatic Drugs Treated with SC Abatacept

N. Ruperto 1, H. Brunner 2, N. Tzaribachev 1, G. Vega-Cornejo 1, I. Louw 1, J. Anton 1, D. Viola 1, I. Foeldvari 1, V. Keltsve 1, D. Kingsbury 2, C. Wouters 1, B. Lauweryns 1, E. Anañez-Cid 2, M. Nys 4, S. Banerjee 3, A. Martini 1, D. Lovell 1, I. PRINTO, Instituto Gaslini, Genoa, Italy; 2PRCSG, CHMC, Cincinnati, OH; 3Bristol-Myers Squibb, Princeton, United States; 4Bristol-Myers Squibb, Braine L’Alleud, Belgium.

Background: In patients (pts) with polyarticular-course juvenile idiopathic arthritis (pJIA), SC abatacept (ABA) 125 mg weekly has a similar pharmacokinetic profile, therapeutic equivalency efficacy and comparable safety to IV ABA 10 mg/kg every 4 weeks.1 Although some data on paediatric pt-reported outcomes (PRO) are available, few clinical trials have published PRO data following treatment with SC ABA have not.2

Objectives: This analysis evaluated the effect of SC ABA treatment on PROs (activities of daily living [ADL] limitation questionnaire of parent/caregiver, childhood HAQ [CHAQ]-DI, and parent global assessment of overall pt well-being [PaGA]) in 6–17-year pts with active pJIA in a Phase III trial (NCT01844518).

Methods: Pts with pJIA aged 2–17 years with an inadequate response/intolerance to MTX were enrolled in this single-arm, open-label study and received SC ABA weekly for 4 months based on body weight tier (10–25 kg [50 mg ABA], 25–50 kg [87.5 mg ABA] and ≥50 kg [125 mg ABA]). JIA-ACR 30 criteria (ACR Pediatric 30) responders at Month 4 could receive ABA for another 20 months. For the 6–17-year cohort reported here, ADL limitation questionnaire of parent/caregiver (mean [SD]) number of days [D] of parent/caregiver missed activity, paid care and missed school [absolute values per month and percentage of D missed per month relative to an assumed average of 20 school D/month]; CHAQ-DI (0–3 scale across 8 domains of disability component); and PaGA (0–100 mm visual analogue scale) were collected.

Results: Baseline characteristics of the 173 pts with pJIA from the 6–17-year cohort were: median (min, max) age, 13.0 (6.0, 17.0) years; median (min, max) number of active joints, 10.0 (2.0, 42.0); 78.6% of pts used MTX (median dose: 11.6 mg/m²/week); and 26.6% were with prior biologic failure. All ADL limitation components improved from baseline to D113 (Month 4): these improvements were largely maintained at D309 (Figure). Relative percentage D missed from school decreased from 15% (D1) to 5.5% (D309, Figure D). CHAQ-DI and PaGA improved from baseline to D309 (Table). Further 2-year data are pending.

Table 1. CHAQ-DI and PaGA scores over time in the 6–17-year cohort

<table>
<thead>
<tr>
<th>Day</th>
<th>CHAQ-DI</th>
<th>PaGA (mm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 (n=170)</td>
<td>0.99</td>
<td>45.6</td>
</tr>
<tr>
<td>29 (n=170)</td>
<td>0.82</td>
<td>45.6</td>
</tr>
<tr>
<td>57 (n=170)</td>
<td>0.73</td>
<td>25.97</td>
</tr>
<tr>
<td>85 (n=167)</td>
<td>0.63</td>
<td>24.56</td>

</tbody>
</table>

Data are mean (SD). For CHAQ-DI (scale 0–3) and PaGA (0–100 mm visual analogue scale), higher scores indicate greater dysfunction and lower well-being, respectively.

Conclusions: In this analysis of patients with pJIA aged 6–17 years, SC abatacept demonstrated a beneficial effect on PROs including reductions in disability (CHAQ-DI) and improvement in well-being (PaGA) up to D309.

Golimumab Versus Tolizumab for Severe and Refractory Juvenile Idiopathic Arthritis-UVEITIS. Multicenter Study of 33 Patients

L. Dominguez Casas 1, V. Calvo-Rio 1, I. Calvo 1, M. Gonzalez-Fernandez 2, B. Lopez-Montesinos 2, M. Mesquida 3, A. Adan 3, M. Hernandez 2, O. Maliz 1, A. Blanco 4, A. Atanes 3, B. Bravo 4, C. Modesto 3, G. Diaz-Soriano 3, M. Cordero 3, D. Diaz-Valle 3, F. Fernandez-Cid 2, R. Ruiz Moreno 1, M. Gonzalez-Vela 1, R. Demetrio-Pablo 1, N. Vegas-Rey 1, C. Fernandez-Diaz 1, J. Hernandez 1, M. Gonzalez-Gay 1, N. Palmou-Fontana 1, R. Blanco 1, J. NUMV, Santander; H. Fe, Valencia; 3H Clinica, Barcelona; 4H Donostia, Hispanic, 5H IEHAC, Coruna; 6H Nieves, Granada; 7H V de Herbron, Barcelona; 8H Regional Universitario, Malaga; 9H León; 10H S Carlos, Madrid; 11H Pontevedra; 12H Servet, Zaragoza, Spain.

Background: Uveitis is a severe manifestation of Juvenile Idiopathic Arthritis (JIA). Anti-TNFa are recommended in refractory cases, mainly infliximab (IFX) or adalimumab (ADA) (Levy-Clarke et al. Ophthalmology 2014; 121: 785–796). However, they sometimes are ineffective, contraindicated or not tolerated. The next therapeutic step is not defined.

Objectives: To compare the efficacy of Golimumab (GLM) and Tolizumab (TCZ) in related A/J uveitis refractory to conventional immunosuppressive drugs and anti-TNFa.

Methods: Multicenter study of 33 patients with uveitis associated-JIA. They were refractory to conventional treatment with high dose of corticosteroids and at least a) one conventional immunosuppressive drug and b) one anti-TNFa. For this reason it was decided to iniciate TCZ or GLM. TCZ was used in 25 patients: 8 mg/kg/4 w iv (n=21), 8 mg/kg/2 w (n=2); 8 mg/kg/8 w (n=2); 8 mg/kg/8 w (n=2) and 2.9 mg/kg sc (n=1). GLM was used in 8 patients (50 mg/sc/moonth). We assessed visual acuity (VA), degree of intracocular inflammation, vitreous inflammation and macular thickening (with OCT). Quantitative variables were expressed with mean±SD or median [IQR], according to its distribution. They were compared with the Student t or the Mann-Whitney U test, respectively. Dichotomous variables were expressed as percentages and compared by the chi-square test.

Results: We studied 33 patients/61 affected eyes. There were no significant differences between TCZ and GLM at baseline in sex (31/6 vs 20/41; n=0.19), mean age (18.5±8.3 vs 19.9±8.7; p=0.55), positive ANA (95% vs 100%; p=0.71), uveitis duration before TCZ or GLM onset (116.4±93.8 vs 142±37.4).

DOI: 10.1136/annrheumdis-2017-eular.2236

DOI: 10.1136/annrheumdis-2017-eular.2236
Results are expressed as mean±SD.

Conclusions: TCZ and GLM seem to be equally effective and safe for refractory uveitis associated-JIA. The superiority of one or the other should be established with prospective randomized studies “Head to Head”.

OP0060 HEALTH BEHAVIOR IN ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS- RESULTS OF THE INCEPTION COHORT OF NEWLY DIAGNOSED PATIENTS (ICON)

M. Listing 1, I. Liedmann 1, M. Niewerth 1, J. Klotzsche 1, K. Mönkemöller 2, I. Foeldvari 3, J. Kümmere-Deschner 1, T. Hospach 1, K. Minder 1, 1Deutsches Rheuma-Forschungszentrum Berlin, Berlin; 2Klinik für Kinder- und Jugendmedizin, des Kindersparkrankenhauses der RKW Köln, Köln; 3Hamburger Zentrum für Kinder- und Jugendrheumatologie, Hamburg; 4Universitätsklinik für Kinder- und Jugendrheumatologie Tübingen, Tübingen; 5Zentrum für pädiatrische Rheumatologie, Klinikum Stuttgart, Stuttgart, Germany

Background: Knowledge concerning health behavior in adolescents with juvenile idiopathic arthritis (JIA) is essential for assessing their health risks. Although there is some evidence about a relationship between low socioeconomic status (SES) and health risk behavior in adulthood, it is less clear whether this association is also true for adolescents with JIA.

Objectives: To compare the health behavior between adolescents with JIA and healthy peers and to examine the association with sex and SES.

Methods: Data of adolescents (aged 13 to 17) with JIA and healthy peers enrolled in ICON were considered for this analysis. Health behavior was assessed via questionnaire within the first years of disease. SES- Score (low, moderate, high) was determined by using an established German multidimensional aggregated index and based on the parents’ education level as well as household net income.

Results: A total of 334 adolescents with JIA (61% female, mean age 15.1 (SD 1.1), mean disease duration 1.3 (SD 1.7)) and 181 healthy peers (57% female, mean age 15.3 (SD 1.3)) were included. Adolescents with JIA were less physically active and reported less consumption of alcohol compared with healthy peers (see Table). In both groups, boys were more frequently physically active and spent more time in playing video games than girls. Whereas girls with and without JIA used more often mobile phones than boys. No gender specific differences in both groups were found in consumption of illicit and legal drugs.

After stratification in groups according to the SES- Scores, socioeconomic differences were the same in adolescents with JIA and healthy peers. Teenagers with low social background (n=200) spent significantly more time in consumption of TV, mobile phones and video games than those from families with high SES (n=122). No significant relationship was found between parental SES and alcohol, nicotine and drug consumption by adolescents. The parental SES- Score was strongly associated with the education level of adolescents.

Conclusions: Adolescents with JIA have a similar health behavior as healthy peers, except for alcohol consumption and physical activity level. Gender and socioeconomic status are associated with health behavior of adolescents with and without JIA. Parental SES may affect adolescents’ educational outcomes.

Mota 2, C.A. Silva 4 5 on behalf of Brazilian Childhood-onset Systemic Lupus Erythematosus Group. 1Pediatric Rheumatology Unit, Division of Rheumatology, FMUSP; 2Division of Rheumatology, FMUSP; 3Pediatric Rheumatology Unit, Universidade Federal de São Paulo; 4São Paulo State University (UNESP), Faculdade de Medicina da Botucatu; 5São Paulo State University of Campinas (UNICAMP); 6Innamorade da Santa Casa de Misericórdia de São Paulo; 7Ribeirão Preto Medical School – University of São Paulo; 8Hospital Darcy Vargas; 9Hospital Menino Jesus; 12Pontifical Catholic University of Sorocaba, São Paulo, Brazil

Background: Data of diffuse alveolar hemorrhage (DAH) in childhood-onset systemic lupus erythematosus (cSLE) patients are limited due to the small representation of this complication in previous case series or the focus on the comparison to adult SLE, precluding an accurate analysis of associated factors and outcomes in patients with and without this severe complication.

Objectives: To evaluate prevalence, clinical manifestations, laboratory abnormalities and treatment in a multicenter cohort study including 847 cSLE patients with and without diffuse DAH, as well as concomitant parameters of severity.

Methods: DAH was defined as the presence of at least three respiratory symptoms or signs associated with diffuse interstitial/alveolar infiltrates on chest X-ray or high-resolution computer tomography and sudden drop in hemoglobin levels with no other source of bleeding. Holm-Bonferroni correction for multiple comparison was performed adjusting the significance level (p<0.0022).

Results: DAH was evidenced in 19/847 (2.2%) cSLE patients. Cough/dyspnea/tachycardia/hypoxemia occurred in all cSLE patients with DAH. Concomitant parameters of severity observed were: mechanical ventilation in 14/19 (74%), hemoptysis 12/19 (63%), macrophage activation syndrome 10/19 (53%), sepsis 5/19 (26%) and death 9/19 (47%). Further analysis of cSLE patients at DAH diagnosis compared to 76 cSLE control patients without DAH with same disease duration [3 (1–151) vs. 4 (1–151) months, p=0.335], showed higher frequencies of constitutional involvement (74% vs. 10%, p<0.0001), serositis (63% vs. 6%, p<0.0001) and intravenous cyclophosphamide (47% vs. 8%, p<0.0001) were also significantly higher in DAH patients.

Conclusions: This is the largest study to evaluate DAH. This complication, although not a disease activity score descriptor, occurs in the context of significant moderate/severe cSLE flare. Importantly, we identified that this condition is associated with serious disease flare compounded by sepsis and with high mortality rate.

Background: Blau Syndrome (BS) is a rare autosomal dominant inflammatory disorder characterized by recurrent joint mono-arthritis, dermatitis, recurrent uveitis, and bone deformities. Optimal treatments have not been determined yet.

Objectives: To assess the efficacy of several biologic agents in this affection

Methods: We conducted an observational, international, retrospective cohort of BS collecting clinical, biological and histological data.

Results: Among the twenty-three patients included in the cohort, 14 patients were treated by one or several lines of biologic agents, mostly by TNF blockers (80%), IL1 blockers (16%) or treatment targeting CTLA-4 (4%). Fifty-seven percent of patients achieved remission after two lines of treatment (1.75 lines; [0.8–2.7]). Association with csDMARDs did not significantly improve response to biologics. Considering the 3 mains symptoms independently, TNF blockers were associated with a better response in case of articular or skin features but less effective in case of ocular involvement, a clinical situation in which IL-1 targeting should be preferably chosen.

Conclusions: Biologic treatments appeared to be effective in BS but additional data prospectively collected are still needed in order to define their place in the therapeutic strategy in order to minimize functional consequences.

CANA Kininumab Treatment in Patients with Colchicine-Resistant FMF (CRFMF), HIDS/MKD and TRAPS: EFFICACY in the 16 Weeks Randomised Controlled Phase and Maintenance of Disease Control and Safety at Week 40

Background: Canakinumab (CAN) is a fully human monoclonal antibody targeting IL-1β, a key cytokine in the pathogenesis of periodic fever syndromes (PFS) including familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and TNF receptor-associated periodic syndrome (TRAPS).

Objectives: The CLUSTER trial (NCT02059291) studied efficacy and safety of CAN in crFMF, HIDS/MKD and TRAPS. The primary objective was to demonstrate that CAN150 mg every 4 weeks (q4w) is superior to placebo (PBO) in resolving the flare by Day 15 with no new flares over 16 weeks (wks). Secondary objectives included the proportion of patients (pts) who maintained optimal control of disease activity (absence of new flares) between Wk 16 and Wk 40 after dose reduction.

Methods: The study comprised 4 epochs (E1-E4). After lead-in E1, in E2 patients at time of an active fever flare were randomised to CAN150 mg q4w or PBO for 16 wks. Responders in E2 were re-randomised to PBO or 150 mg q8w for 24 wks. During E3, pts who escaped to open-label CAN in E2, were similarly down-titrated to open-label CAN q8w to gain additional information on the long-term maintenance dose. In pts with a flare, dose could be escalated up to 300 mg q4w. Safety assessments included adverse events (AEs) and serious AEs.

Results: The proportion of responders at Wk 16 was statistically higher with CAN vs PBO (Table). In E3, among the 41 re-randomised pts (PBO vs CAN 150 mg q4w) the proportion of pts who did not present new flares was numerically higher in the CAN vs PBO group (Table). Overall at Wk 40 (end of E3), including re-randomised pts and pts treated in open-label, 46% of the crFMF pts, 53% of the TRAPS pts and 23% of the HIDS/MKD pts maintained disease control with 150 mg q8w. Conversely, up-titration to 300 mg q4w was required in 28.8% of HIDS/MKD pts, and in 10.2% and 8.3% of pts with crFMF and TRAPS, respectively. In E3, the majority of pts who received CAN had PGA <2, normal CRP and SAA levels in all 3 cohorts. No new safety findings nor death were reported in CAN-treated pts through E3 (Table).

Conclusions: Canakinumab (150 mg q4w) was efficacious in resolving flare at Day 15 and preventing new flares over 16 wks. In the longer term (40 wks), absence of flares was maintained in more than half patients at the extended dosing interval (150 mg q8w) in the crFMF and TRAPS cohorts. A higher dose was needed in HIDS/MKD patients. No unexpected safety issues were reported over 40 wks of canakinumab treatment.

Disclosure of Interest: None declared
Diagnosis of axial spondyloarthritis (axSpA) is often delayed, with many fears and beliefs having been identified, including unpredictability of the disease course and concerns for the future. A survey revealed that 61% of pts want to share such experiences with other pts.

Objectives: The goals were to: 1) create a video program to help pts share experiences and promote coping strategies; 2) establish the program on the internet and social networks; 3) assess the usefulness of the program for pts and healthcare professionals (HCPs).

Methods: Clefs de dos is a national French program initiated in 2015. It is led by a pt organisation, ACS-France (Action Contre les Spondylarthropathies), Catalpa (conducted interviews, made visuals) and UCS Pharma (co-creation and promotion). Pts with axSpA were recruited by ACS on a voluntary basis to participate in focus groups; pts were selected according to their level of disease acceptance (denial [Gp1] or acceptance [Gp2]). 4 steps were planned: 1) Gp1 focus group interviews to collect feelings, words and voices; 2) Gp2 interviews to describe the pt pathway and stages in the process of disease acceptance; 3) face-to-face Gp1+Gp2 meetings for pts to share their own experiences and confront their own views; 4) rheumatologist interviews to evaluate the impact of pt testimonies on their own practice.

Results: 13 axSpA pts (10 Gp1, 3 Gp2) participated, aged 25–65 years (yrs), with 5–17 yrs disease duration; 10 were female. An animated visual was produced using Gp1 pt interviews; analysis revealed feelings of loss prior to diagnosis. Photographs and audio testimonies were used to create 3 documentary portraits of Gp2 pts, illustrating the process of disease acceptance (denial [Gp1] or acceptance [Gp2]). 4 steps were planned: 1) Gp1 focus group interviews to collect feelings, words and voices; 2) Gp2 interviews to describe the pt pathway and stages in the process of disease acceptance; 3) face-to-face Gp1+Gp2 meetings for pts to share their own experiences and confront their own views; 4) rheumatologist interviews to evaluate the impact of pt testimonies on their own practice.

Conclusions: Clefs de dos was developed by and for axSpA pts. The program answers unmet needs by sharing pt experiences, particularly in situations of delayed diagnosis and lack of disease acceptance. Online access reflects good acceptability of the program, which can also be used as an educational tool in self-management. The next step is to involve other HCPs (eg., nurses, physiotherapists, psychologists).

adherence to treatment recommendation (ATR) and recidivism before the 15th day after the day of consultation (need of further consultation due to the same medical problem). Registries included those generated along the first 12 months after the end of the courses.

Results: The TT group generated 175 registries while PBL generated 219. Both courses were followed by 20 non-rheumatology second-year residents. Proportion of AITR were 73.3 and 60.2% for BLT and TT groups, respectively (P<0.001). Considering only the registries generated in the first trimester after the courses, those proportions were respectively 80.2 and 79.5%. Proportion of ATR were 69.9 and 55.7%, respectively (P<0.001), however when considering only registries generated in the first trimester those proportions were 77.1 and 76.9%, respectively. Global recidivism rate (number of patients who need a further consultation due to the same medical problem or due to the side effects of their treatment among all patients attended) at the first 15th day since the first attendance was 8.7% in the PBL group and 17.5% in the TT group (P<0.001). At the end of both courses a survey to the students were performed. The satisfaction index—measured by a 0–10 progressive ordinal scale—were 9.1 SD 1.3 for the PBL model and 8.2 SD 1.4 for the TT model (P<0.05).

Conclusions: The pedagogical PBL teaching method shows a better academic impact in terms of concept retention and attendance into the medical practice along the time. In our opinion and according to our experience, most programs of

CP0067 DEVELOPMENT AND VALIDATION OF A MODEL TO FACILITATE RECOGNITION OF ARTHRITIS BY GENERAL PRACTITIONERS

B.T. van Dijk, R.M. ten Brinck, H.W. van Steenbergen, A.H. van der Helm-van Mil, Rheumatology, Leiden University Medical Centre, Leiden, Netherlands

Background: Early initiation of treatment of rheumatoid arthritis is strongly associated with an improved outcome, but requires the early identification of arthritis. Physical examination of joints is crucial to this end, but is difficult for general practitioners (GPs) who have little experience. Another difficulty is that GPs see many persons with musculoskeletal symptoms per year but only few patients with clinical arthritis. To promote early recognition of arthritis, the Early Arthritis Recognition Clinic (EARC) was initiated in Leiden, the Netherlands in 2010. GPs were instructed to refer to this clinic in case of doubt on the presence of arthritis (and not to wait and see, or to perform additional laboratory tests). At this clinic, patients filled out a form with questions on their symptoms and were seen by a rheumatologist in a short visit that comprised a full joint examination. As reported previously, this clinic importantly improved the early identification of arthritis and RA (1), but this approach may not be easily implemented in other centres or regions.

Objectives: To assess if a combination of symptoms and signs that are easy to assess can differentiate patients with and without clinical arthritis at joint examination.

Methods: 1,288 patients in whom GPs doubted on the presence of arthritis visited the EAR C during 2010 and 2015. Reported symptoms and signs were studied with respect to the presence of synovitis (joint examination). Multivariable logistic regression was used. A model was derived in 644 patients, and validated in the second set of 644 patients.

Results: 41% of the patients who visited the EAR C had arthritis at examination. Age (per year OR 1.02; 95% CI 1.01–1.03), male sex (OR 1.8; 95% CI 1.4–2.2), symptom duration (4–12 weeks OR 3.83; 95% CI 2.22–6.60), morning stiffness >60 min (OR 1.7; 95% CI 0.9–2.9), difficulty with eating a fish (OR 1.6; 95% CI 0.97–2.5), number of tender joints (≥3 tender joints OR 9.7; 95% CI 1.1–81.8) and self-reported swollen joints (OR 2.5; 95% CI 1.8–7.0) were associated with the presence of arthritis in multivariable analysis. The AUC was 0.75 (SE 0.02) in the derivation set and 0.71 (SE 0.02) in the validation set. To facilitate application in practice, a simplified model was made. This consisted of 7 variables and the total score ranged between 0–7. The AUC was 0.73 (SE 0.02). Depending on the cut-off, the PPV of the simplified model ranged between 41% and 74% and the NPV between 100 and 62%. With a cut-off of 4, the NPV was 86%, PPV 49%, specificity 35%, and sensitivity 91%.

Conclusions: A set of clinical characteristics that can be easily assessed by GPs had a reasonable discriminative ability for clinical arthritis, and can be applied by GPs in case of doubt on the presence of arthritis. This model requires further validation in general practices, but may lead to a tool that could assist GPs in their decision making regarding referral or ordering additional tests for patients with suspected early arthritis.

OP0068 PRACTICES PARTICIPATING IN THE ACR’S RHEUMATOLOGY INFORMATICS SYSTEM FOR EFFECTIVENESS (RISE) NATIONAL REGISTRY SHOW IMPROVEMENTS IN QUALITY OF CARE

J. Yazdany1, R. Myralinski2, T. Johansson3, S. Kazi3, 1Medicine/Rheumatology, University of California, San Francisco, San Francisco; 2American College of Rheumatology, Atlanta; 3University of Texas Southwestern, Dallas, United States

Background: The ACR launched the RISE registry in 2014 to facilitate quality improvement on a national scale. The registry passively extracts electronic health record (EHR) data from rheumatology practices, aggregates and analyzes these data centrally, and feeds performance on quality measures back to clinicians using a web-based dashboard.

Objectives: We used data from RISE to 1) examine variation in performance on quality measures across practices and 2) evaluate trends in measure performance over time.

Methods: RISE’s informatics platform continuously collects data from the EHRs of participating practices, allowing centralized aggregation and analysis of quality measures. We analyzed data collected between July 1, 2014-July 1, 2016 on all patients seen by 294 clinicians across 63 practices. Measures in the areas of rheumatoid arthritis, drug safety, preventive care and gout were examined.

Performance on quality measures, defined as the percentage of eligible patients receiving recommended care, was examined at the practice level. To examine trends in performance over time, we took the subset of practices that continuously participated in RISE since its inception (n=44), and developed 1) control charts and 2) logistic regression models, in which the outcome was practice-level performance each month and the predictor was time.

Results: Data from 289,812 patients was examined. Mean (SD) age was 59 (16) years, 75% were female, 21% were racial/ethnic minorities, and 37% had public insurance. Most rheumatologists were in a group practice (73%); 25% were in solo practice and 2% part of a larger health system. Performance on measures varied significantly across practices (Table). The largest gaps were observed for gout and preventive care. For 4 of 5 measures for which the Medicare program has set national benchmarks, average performance of RISE practices exceeded targets. Of 11 measures, performance improved over time on 5 measures (p<0.05 in logistic models; see Figure for example control chart), was at goal on 4 measures, and saw no improvement on 2 measures (BMI screening and urate target).

Conclusions: We found significant variation in performance on quality measures across RISE practices, with the largest gaps seen in gout care and preventive care. Some practices have achieved a very high level of performance. Over time, RISE practices demonstrated improvement in over half of the measures.

THE BURDEN OF ANKYLOSING SPONDYLITIS: A POPULATION-BASED STUDY
J.S. Lee 1, H.Y. Lee 2, E.E. Lee 1, Y.W. Song 1, E.Y. Lee 1. 1Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul; 2Center for Preventive Medicine and Public Health, Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Korea, Republic Of

Background: Ankylosing spondylitis (AS) is an inflammatory rheumatic disease with musculoskeletal and systemic manifestations. Because AS is typically diagnosed before the age of 40 years and follows a chronic progressive course, its impact on the patient is life-long. In addition to the burden on the individual patient, that on the society is also increasing cumulatively every year [1]. The burden of AS is not confined to healthcare cost spent due to back pain and stiffness of the disease itself [2–4], but also encompass extra-articular manifestation (EAM), comorbidities, disability, and mortality contributed from AS [5].

Objectives: This study aimed to evaluate the disability, mortality, and healthcare costs (direct and indirect) for quantifying the burden of AS.

Methods: We conducted a nationwide population-based study based on national health insurance data in Korea. The patients with incident AS (n=1111) were identified with controls (n=5555) who were matched by age, sex, income, and geographic region from the year 2003 to 2013. EAMs, comorbidities, mortality and type and severity of disabilities were presented as incidence rate and compared to the controls as incidence rate ratios (IRRs). Annual health expenditure per patient was analyzed by the year and relation to AS.

Results: During the follow-up, 28% of patients in this cohort experienced any kind of EAM. More comorbidities with Charlson comorbidity index ≥3 (OR 2.18, 95% CI 1.91 to 2.48) were significantly associated. Disability rate was higher than controls regardless of causes and severity (OR 2.94, 95% CI 2.48 to 3.48). Crude IRRs for mortality was not significantly increased, but by multivariate analysis, older age at diagnosis (≥45 years old) (OR 10.53, 95% CI 4.31 to 25.68) was most strongly related to increased disability and mortality rates (Fig.1). Biological agents elevated annual health expenditures of AS but decreased AS unrelated costs (mean 1112 vs 877 USD, p=0.0068) (Fig.2).

Conclusions: Along with demographic factors, systemic consequences such as EAMs and other comorbidities were associated with increased disabilities and healthcare expenditures in AS. Older age at diagnosis was significantly associated with increased mortality rates.

THE ROLE OF INDIVIDUAL AND COUNTRY-LEVEL SOCIO-ECONOMIC FACTORS IN WORK PARTICIPATION IN PATIENTS WITH SPONDYLOARTHRITIS ACROSS 22 COUNTRIES WORLDWIDE: RESULTS FROM THE COMOSPA STUDY
S. Rodrigues Manica 1,2, A. Sepriano 2,3, S. Ramiro 3, F.M. Pimentel-Santos 1,2, P Puttkir 1, E. Nikiphorou 1, A. Mottu 4, M. Dougdados 5,6, D. van der Heijde 5, R. Landewé 5, F. Van den Bosch 6, A. Boonen 2, 7, Rheumatology Department, Centro Hospitalar de Lisboa Ocidental; 8CEDOC - NOVA Medical School | Faculdade de Ciências Médicas, NOVA University of Lisbon, Lisbon, Portugal; 3Leiden University Medical Center, Leiden; 4Department Internal Medicine, Division of Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands; 5KCL, London, United Kingdom; 7Rheumatology B Department, Paris Descartes University, Cochin Hospital, AP-HP; 7INSERM (U1153), Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France; 6ARC, Amsterdam & Atrium MC Heerlen, Amsterdam, Netherlands; 8Department of Rheumatology, Ghent University Hospital, Ghent, Belgium

Background: Spondyloarthropathy (SpA) carries substantial financial costs, including direct costs (use of medical services and treatments) and indirect costs (loss of work productivity). While disease related factors have been repeatedly shown to be associated with work outcomes, information on the role of educational attainment and the economic wealth of the patients’ country of residence is scarce.

Objectives: To explore the role of individual and country level socio-economic (SE) factors on employment, absenteeism and presenteeism across 22 countries.

Methods: Patients with a clinical diagnosis of SpA, fulfilling the ASAS SpA criteria and in working age (<65 years old) from COMOSPA were included. Outcomes explored were employment-status, absenteeism and presenteeism according to the Work Productivity and Activity Impairment Specific Health Problem (WPAI-SHP) questionnaire. Absenteeism and presenteeism were assessed in employed patients. Multilevel logistic (for work status) and linear (for absenteeism and presenteeism) regression models with random intercept for country were explored. Independent contribution of individual (education) and country level socio-economic factors (country healthcare expenditures and gross domestic product (GDP) (all low vs medium/high tertiles) were assessed in models adjusted for clinical factors.

Results: In total 3,114 patients from 22 countries were included (mean (SD) age 40.9 (11.8) years; 66% males; and 63% employed). Of these, 89% had axial SpA and 11% a peripheral SpA. Unadjusted employment rates ranged from 28% (Colombia) to 83% (Canada). After adjustment for relevant socio-demographic and clinical variables, differences between countries in work status persisted (Figure).

High healthcare expenditures were associated with higher employment (OR=2.42; 95% CI=1.53;3.81) and lower presenteeism (β=4.53;CI=−8.90;−0.17). Similarly, higher GDP was associated with higher employment (OR=1.70; 95% CI=1.02;2.83), and in the same direction with presenteeism but without reaching statistical significance (β=3.42;CI=13.07;6.23). No significant association between any outcome and SE factors and absenteeism was found. At individual level, higher education was positively associated with employment-status, presenteeism and absenteeism.

Conclusions: Individual- and country-level SE factors affect work participation in SpA, and this varies significantly across countries. Better socio-economic welfare seems to support SpA patients to stay employed and productive.

DOI: 10.1136/annrheumdis-2017-eular.3926

Background: Musculoskeletal disorders, including inflammatory arthritis (IA), are among the most common reasons for work disability and sick leave. Early IA patients with risk factors for persistent and/or erosive disease, such as high swollen joint count (SJC), acute-phase reactants, RF- or ACPA-positivity, are treated aggressively to prevent joint damage and disability.

Objectives: To study the rate of sick leave according to clinical diagnosis in an unselected very early IA cohort, and to investigate whether the predictors for sick leave are the same as the known predictors for persistent and/or erosive disease.

Methods: Data from the Norwegian Very Early Arthritis Clinic (NOR-VEAC), a longitudinal observational study of adults with IA of <16 weeks duration, were used. Exclusion criteria were arthritis due to crystal deposits, trauma, osteoarthritis and septic arthritis. For the present study we included patients eligible for work participation, i.e. <65 years with no retirement or disability pension, who had information about work in the baseline and six-month case report forms. Independent tests t-test, Mann-Whitney-U test or chi-square test were used as appropriate to compare patients on sick leave after 6 months with patients not reporting sick leave. Clinically relevant baseline variables with univariate p-value <0.2, as well as age and sex, were included in the multivariable logistic regression analyses with manual backwards selection to find predictors for sick leave after six months.

Results: Of 880 patients eligible for analysis (<65 years, no retirement or disability pension), 664 (75.5%) had complete work participation data. Duration of joint swelling before inclusion (median [25–75 perc.]) was 35 (14–69) days, mean (SD) age 42.1 (12.1) years, 56.0% were females, 27.3% current smokers, and 22.4% anti-CCP and/or RF positive. The most common clinical diagnoses were undifferentiated arthritis (35.2%), rheumatoid arthritis (22.1%) and reactive arthritis (19.7%). The overall rate of sick leave at presentation was 37.7% and after 6 months 23.2%. More than one-third of the patients reported sick leave at first visit, regardless of diagnosis (Figure 1). At six months >20% sick leave was still reported in all groups except sarcoid arthritis and reactive arthritis. Smoking, low education (≤ high school), longer duration of joint swelling, ACPA and RF positivity, joint pain, fatigue, patient's global assessment, SF-36 (physical and mental component summary scores), HAQ-DI and tender joint count at baseline were univariably associated with sick leave after six months, whereas SJC, ESR and CRP were not. Independent predictors were current smoking (OR 2.1 (95% CI 1.1–4.3)), low education (OR 1.7 (95% CI 1.1–2.5)), longer duration of joint swelling and low SF-36 (physical and mental component summary scores).

Conclusions: Sick leave in IA is common, even six months after diagnosis. Predictors for sick leave after six months were associated with lifestyle and level of education rather than factors commonly considered to be predictive for unfavourable arthritis outcomes. In early IA care, health care providers should focus not only on disease activity, but also on work ability and early facilitation efforts at work.

Comorbidities: having one RMD is enough - we don’t need anything else
Topic: Osteoporotic Fracture Risk Assessment Using FRAX Following Hematopoietic Stem Cell Transplantation

Methods: We conducted a retrospective cohort study of patients >18 years that received a HSCT at The University of Texas MD Anderson Cancer Center, from January 1, 2001 to December 31, 2010. Patients were considered to have entered the cohort at the time of HSCT. All patients were retrospectively followed until December 31, 2013 for assessment of osteoporotic fracture. Osteoporotic fractures following HSCT were identified using ICD-9 codes, and confirmed by radiology and physician documentation. FRAX probabilities were calculated from baseline information obtained by chart review.

Results: A total of 5,170 patients underwent a HSCT during the 10-year study period. During an average of 3.3 years of follow up, 10% of patients developed a fracture. Fracture rates were higher (14%) in patients that underwent an autologous HSCT in comparison to those that received an allogeneic HSCT (6%). Mean major osteoporotic fracture FRAX scores were significantly higher in individuals who sustained an osteoporotic fracture compared to individuals who did not. The area under the receiver operating characteristic curve at 5 and 10 years following the HSCT were 0.61 and 0.66 respectively (Figure 1). We assessed the ability of the FRAX model for prediction of osteoporotic fracture with and without considering death as a competing risk. The hazard ratios were similar for both models (HR, 2.63, 95% CI, 1.93, 3.59; HR, 2.54, 95% CI, 1.86, 3.47, respectively).

Conclusions: The FRAX model has modest discriminative ability in predicting osteoporotic fractures following HSCT. Further independent validation of our findings is necessary, before routinely using the FRAX model in clinical practice.

**RISK OF DEVELOPING ADDITIONAL IMMUNE MEDIATED MANIFESTATIONS FOR PATIENTS WITH SYSTEMIC ARTHRITIDES**

D. Aletaha 1, R. Panaccione 2, M. Davis 3, S. Johnson 3, M. Skup 4, V. Garg 4

1Medical University of Vienna, Vienna, Austria; 2University of Calgary, Calgary, Canada; 3Medicus Economics, LLC, Milton; 4AbbVie Inc., North Chicago, United States

**Background:** Patients with the systemic arthritides ankylosing spondylitis [AS], psoriatic arthritis [PsA], rheumatoid arthritis [RA] may develop additional, non-musculoskeletal immune mediated manifestations (nms-IMMs).

**Objectives:** To compare the risk of developing nms-IMMs between patients with and without an existing AS, PsA, or RA.

**Methods:** Risk for nms-IMMs was estimated in the MarketScan Commercial Claims and Encounters database (1/2006-9/2015) for case patients with AS, PsA, RA, or all three conditions. Unmatched controls were matched by age, sex, state of residence and insurance type to case patients aged 18–64. The systemic arthritides ("cases") were identified by ICD-9 diagnosis codes on ≥ 2 medical claims ≥ 30 days apart. A case patient's earliest nms-IMM claim was designated as the index date for the case and all matched controls. Onset of 6 nms-IMMs was identified by the first post-index claim: celiac disease [CE], hidradenitis suppurativa [HS], inflammatory bowel disease [IBD], lupus [SLE], psoriasis [PsO], uveitis [UV]; some of these are well-known manifestations of seronegative spondyloarthropathies, like PsA and AS; some are not. All subjects had continuous health plan enrollment for ≥ 965 days before and after index date. Cumulative incidence of nms-IMMs was assessed at 5 years. Their risk was analyzed with stratified Cox proportional hazards models. Standard errors were adjusted for clustering by case-control match group.

**Results:** Among 117,794 cases, mean age was 49 years and 71% were female. Mean number of matched controls per case was 664. Across the 3 initial cohorts of patients with AS, PsA, or RA, median follow-up ranged 939–972 days for cases and 931–950 days for controls. Among case patients, 5-year cumulative incidence of any nms-IMM occurrence was 17.5% for AS, 41.8% for PsA, and 14.4% for RA. Patients with nms-IMMs had significantly higher risk than matched controls of developing each, any 1, or any 2 of the 6 manifestations (P<0.002) (Table).

**Conclusion:** The risk of developing non-musculoskeletal manifestations was significantly higher for patients with AS, PsA, and RA than for matched controls. These included not only the well-known manifestations of PsA and AS but also others like manifestations leading to claims for SLE, celiac disease or HS. When managing these systemic arthritides, surveillance for additional immune mediated manifestation is warranted.

**PRIMARY PROPHYLAXIS FOR PNEUMOCYSTIS PNEUMONIA IN PATIENTS WITH RHEUMATIC DISEASE AND TREATED WITH PROLONGED, HIGH-DOSE STEROID: A RETROSPECTIVE COHORT STUDY WITH 12-YEAR OBSERVATION**

J.W. Park 1, J. Moon 1, J.R. Curtis 2, J.K. Park 1, E.Y. Lee 1, Y.W. Song 1, E.B. Lee 1

1Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of; 2Division of Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, United States

**Background:** Pneumocystis pneumonia (PCP) is a significant cause of morbidity and mortality in patients with rheumatic diseases, especially in the case of patients receiving high-dose steroid treatment.

**Objectives:** To investigate the efficacy and safety of PCP prophylaxis using trimethoprim/sulfamethoxazole (TMP-SMX) in patients with rheumatic disease receiving prolonged, high-dose steroids.

**Methods:** This study includes 1522 cases of prolonged (≥4 weeks), high-dose (≥30mg/day predonison or equivalent) steroid treatment from 1092 patients with any rheumatic diseases during a 12-year period in a single tertiary referral center in South Korea. Of them, prophylactic TMP-SMX was administered in 262 cases (prophylaxis group) with a mean (SD) duration of 229.0 (272.7) days whereas other 1260 cases received no prophylaxis (control group). Primary outcome was 1-year incidence of PCP between the two groups. Secondary outcomes included PCP-related mortality, ICU admission rate, all-cause in-hospital mortality and incidence of any adverse drug reactions (ADRs) of TMP-SMX. To minimize the baseline imbalance between the two groups, we introduced propensity-score matching and performed the same analysis in the post-matched population as a sensitivity analysis.

**Results:** Patients in the prophylaxis group were treated more often with secondary immunosuppressive drugs and had a higher proportion of patients with PCP high-risk diseases (ANCA-associated vasculitis and dermatomyositis) and lymphopohia at baseline. Overall, 30 cases of PCP occurred and resulted in death in 11 cases (36.7%). In the prophylaxis group, only one non-fatal case of PCP occurred. One-year PCP incidence was significantly lower in the prophylaxis group (adjusted HRS=0.096 [0.013-0.719]) (Figure). TMP-SMX also significantly reduced the PCP-related mortality (adjusted HR=0.101 [0.001-0.809]) whereas...
ICU admission rate and in-hospital mortality rate were not different between the two groups during the observation. This result was consistent in the sensitivity analysis where same analysis was performed in the post-matched population. Thirty-four cases of ADRs of TMP-SMX occurred, with an incidence rate (95% CI) of 24.2 (17.3–33.0) per 100 person-year. There were two cases of serious ADR (one pancytopenia and one Steven’s Johnson syndrome) but they all recovered shortly after the discontinuation of TMP-SMX. The number needed to harm (NNH) of serious ADR was 109 whereas the number needed to treat (NNT) to prevent one case of PCP in the whole population was 52.

Conclusions: In patients with rheumatic disease receiving prolonged, high-dose steroid treatment, TMP-SMX prophylaxis significantly lower the incidence of PCP with favorable safety.

OP0078 THE LONG TERM PROGNOSTIC SIGNIFICANCE OF PULMONARY HYPERTENSION IN SARCOIDOSIS - A BIG DATA ANALYSIS
S. Tiosano1,2, O. Gendelman1,2, A. Watad1,2, D. Comaneshet3, A. Cohen4, H. Amital5,1. Internal Medicine B, Sheba Medical Center, Ramat-Gan; 2Sackler School of Medicine, Tel-Aviv University; 3Chief physician's office, Clalit Health Services, Tel-Aviv; 4Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel

Background: Sarcoidosis is a multisystem, chronic, progressive, granulomatous disease. Sarcoidosis-associated pulmonary hypertension is well described, but not common complication of sarcoidosis. In small scale studies, it has been previously described as a manifestation of advanced disease and was found to be associated with increased morbidity and mortality. Previous studies have shown that treatment may be safe and improve pulmonary hemodynamics in sarcoidosis-associated pulmonary hypertension. However, big data analyses regarding the exact magnitude and prognosis of sarcoidosis-associated pulmonary hypertension are lacking.

Objectives: To assess the long-term prognostic significance of sarcoidosis-associated pulmonary hypertension using a big data registry with a 15-year follow-up period.

Methods: Utilizing the medical records of Clalit Health Services, the largest HMO in Israel, we extracted a cohort consisted of sarcoidosis patients along with their age-and-sex matched controls. Dates of registration in the medical records of sarcoidosis, pulmonary hypertension and death, as well as anthropometric information and medical comorbidities were collected from the database. To compare the distribution of variables across the cohort strata, univariate analysis was performed using Chi-square and student t-test. Multivariate analysis using a logistic regression model was used to find variables associated with pulmonary hypertension. Survival analysis using Cox proportional hazards method and log-rank test was performed to find variables associated with increased risk of all-cause mortality.

Results: The cohort included 3,993 sarcoidosis patients and 19,856 age-and-sex matched controls. The mean age of both groups was 56, and both consisted about 63% females. Pulmonary hypertension was observed among 269 sarcoidosis patients (6.74%) vs. 400 controls (2.01%), p<0.001. In multivariate analysis, sarcoidosis was found to be independently associated with diagnosis of pulmonary hypertension (OR 3.09, 95% CI 2.6–3.67). After more than 15 years of follow-up, 710 (17.8%) of the sarcoidosis patients had died, compared to 2121 (10.7%) of the controls (p<0.001). In multivariate survival analysis, both sarcoidosis and pulmonary hypertension were found to be significantly associated with increased risk to all-cause mortality (HR 1.83, 95% CI 1.66–2.02 and HR 2.32, 95% CI 2.05–2.63, respectively).

Conclusions: Sarcoidosis-associated pulmonary hypertension is associated with poor prognosis. Proper screening methods are recommended to assess whether early identification and treatment may improve life expectancy.

OP0079 BODY FAT PERCENTAGE AND WAIST CIRCUMFERENCE WERE ASSOCIATED WITH THE DEVELOPMENT OF RHEUMATOID ARTHRITIS – A DANISH FOLLOW-UP STUDY
A. Lineaukas1, A.L. de Thurah1, K. Overvad2, M.B. Johansen3, K. Stengaard-Pedersen1. 1Department of Rheumatology, Aarhus University Hospital; 2Department of Public Health, Section of Epidemiology, Aarhus University, Aarhus; 3Unit of Clinical Biostatistics, Aalborg University Hospital, Aalborg, Denmark

Background: Several studies have investigated the association between overweight and the development of rheumatoid arthritis (RA) and have come out with conflicting results. Body Mass Index (BMI) has been the preferred surrogate measure for overweight in these studies. However, BMI correlates only modestly with total amount of body fat and does not reflect fat distribution.

Objectives: To investigate the association between BMI, waist circumference, bio-impedance-derived total body fat percentage and risk of RA.

Methods: A population-based cohort study conducted within the Danish Diet, Cancer and Health cohort, which included individuals aged 50 to 64 years at the recruitment in the period between 1993 and 1997. Body fat composition measurements and data on lifestyle factors were collected at the enrolment into the cohort. The participants who subsequently developed RA were identified via linkage to The Danish National Patient Registry. The participants were followed until development of RA, death, loss to follow-up or October 2016, whichever came first. Data were analyzed by Cox proportional hazards regression model with delayed entry and age as the underlying time variable. Analyses were stratified by gender. Cox regression analyses with restricted cubic spline were carried out to elucidate the dose-response association between anthropometric measures and risk of RA. Smoking, socio-economic status, alcohol consumption, physical activity and intake of n-3 fatty acids were included in multivariate analyses as potential confounders.

Table 1. Cox proportional hazard ratios for association between body composition measurements and incidence of RA

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.2803
Results: Data were available on 54,284 subjects (52% female). During follow-up (median 21 years), 283 women and 110 men developed RA. The median (IQR) time to onset of RA was 7 (4–11) years. The adjusted hazard ratio (HR) for developing RA are presented in Table 1. Restricted cubic spline analysis of body fat percentage displayed a positive slope in women (Image). There was no linear association between fat and incidence of RA among men.

Conclusions: Overweight and obesity, defined by BMI, abdominal obesity and higher body fat percentage, especially above 30%, were in women associated with a higher risk for the development of RA. In men the associations were not consistent.

OP0080 RISK OF AUTISM SPECTRUM DISORDER IN CHILDREN BORN TO MOTHERS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS IN TAIWAN

P.-H. Tsai, C.-F. Kuo, L.-H. Huang, S.-F. Luo. Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China

Background: There is emerging evidence suggesting that offspring born to patients with rheumatic diseases has higher risk of neuropsychiatric diseases. Previous data from Quebec showed children born to women with SLE have an increased risk of autism spectrum disorder (ASD) but data regarding risk of ASD in offspring of mothers with systemic lupus erythematosus (SLE) or rheumatoid arthritis (RA) mothers has not been reported in other population.

Objectives: We aimed to examine whether offspring of mothers with SLE and RA in Taiwan has a higher risk of developing ASD using data from a linkage between National Health Insurance (NHI) database and National Birth Registry in Taiwan.

Methods: We established a birth cohort of all live-births between 2001 and 2012 in Taiwan established using the National Health Insurance database and the National Birth Registry. Children born to mothers with SLE or RA were identified and matched up to 8 controls by maternal age, 1-minute Apgar score, 5-minute Apgar score, mode of delivery, sex of child, gestational age, birth weight, socioeconomic status (place of residence, income level, occupation). A marginal Cox proportional hazard models were used to estimate the relative risk (RR; 95% confidence interval [CI]) for ASD in newborns with affected mothers.

Results: Of 1,893,244 newborns, 0.08% (n=1,594) were born to mothers with SLE (mean age 30.43±4.37 years old) and 0.04% (n=673) were born to mothers with RA (mean age 31.97±5.1 years old). Overall, 5 of 673 (0.74%) RA offspring developed ASD, 7 of 1594 (0.44%) SLE offspring developed ASD and 10,631 of 1,893,244 (0.56%) all infants developed ASD. The incidence of ASD was 140.39 (95% CI, 45.58–327.62) per 100,000 person-years for RA group, 76.19 (95% CI, 30.63–156.97) per 100,000 person-years for SLE group, 89.85 (95% CI, 88.15–91.57) per 100,000 person-years for non-RA group and 89.87 (95% CI, 88.17–91.60) per 100,000 person-years for non-SLE group. The children born to RA and SLE mothers did not have higher risk of ASD with a HR (95% CI) of 1.42 (0.60–3.40) and 0.76 (0.58–1.09) for ASD, respectively.

Conclusions: Children born to women with SLE and RA do not have higher risk of developing ASD.

Scleroderma, myositis and related ethology

OP0081 PAN-PPAR AGONIST IVA337 IS EFFECTIVE IN THE PREVENTION OF EXPERIMENTAL LUNG FIBROSIS AND PULMONARY HYPERTENSION

J. Avouac1, I. Konstantinova2, C. Guignabert3, J. Sadoine4, G. Thomas5, S. Ppezet6, A. Cauvet7, L. Tu8, J.M. Lucarrini2, J.L. Junien2, P. Broqua2, Y. Allannore4, 1Rheumatology A and INSERMU1016, Paris Descartes University, Cochin Hospital, Paris; 2Inventiva, Daix; 3INSERM UMR s.999, le Plessis Robinson; 4Université Paris Descartes, Montrouge; 5INSERM U1016, Paris, France

Background: Peroxisome proliferator-activated receptors (PPARs) are nuclear receptors known to modulate fibrosis. The pan-PPAR agonist IVA337 recently demonstrated efficacy in prevention and treatment of experimental skin fibrosis [1].

Objectives: Our objective was to evaluate the antifibrotic effects of IVA337 in preclinical mouse models of pulmonary fibrosis and related pulmonary hypertension (PH).

Methods: IVA337 has been evaluated in the mouse model of bleomycin-induced pulmonary fibrosis and in Fra-2 transgenic mice, this latter being characterized by non-specific interstitial pneumonia and severe vascular remodeling of pulmonary arteries leading to PH. Mice received 2 doses of IVA337 (30 mg/kg or 100 mg/kg) or vehicle administered by daily oral gavage up to 4 weeks.

Results: Both 30 mg/kg and 100 mg/kg doses of IVA337 were well tolerated in all mouse models.

IVA337 demonstrated at a dose of 100 mg/kg a marked protection from the development of lung fibrosis induced by bleomycin compared to mice receiving 30 mg/kg of IVA337 or vehicle. Indeed, IVA337 (100 mg/kg) strongly reduced by 61% and 28% tissue density on histological measurements and total lung hydroxyproline concentrations, respectively, as compared to vehicle. IVA337 at 100 mg/kg also significantly decreased col1, col3 and fibronectin in lesional lungs. Similarly, Fra-2 transgenic mice treated with 100 mg/kg of IVA337 displayed reduced lung density (20% vs. vehicle) and significant increase of functional residual capacity (30% vs. vehicle) when assessed by chest micro-CT imaging. These results were emphasized by a 50% reduction of the Ascroft fibrosis score (Figure 1A) and by a 48% reduction of hydroxyproline concentrations upon IVA337 (100 mg/kg) compared to vehicle treated mice.

Successful targeting of the TGF-b signaling axis was observed in both mouse models upon treatment with 100 mg/kg of IVA337. 100 mg/kg IVA337 also significantly reduced T cell and B cell infiltration in lesional lungs of Fra-2 transgenic mice. Regarding vessel remodeling and related pulmonary hypertension, treatment with 100 mg/kg of IVA337 led to a substantial attenuation of right ventricular systolic pressure and right ventricular hypertrophy compared to mice receiving the vehicle (Figure 1B and 1C). Furthermore, IVA337 given at 100 mg/kg markedly reduced medial wall thickness (Figure 1D) and the number of muscularized distal pulmonary arteries.

In vitro primary human lung fibroblasts, IVA337 inhibited in a dose-dependent manner TGF-ß-mediated fibroblasts to myofibroblasts transition and PDGF-mediated proliferation.

Figure 1

Conclusions: We demonstrate that treatment with 100 mg/kg IVA337 prevents lung fibrosis in two complementary animal models and substantially attenuates PH in the Fra-2 mouse model. These findings confirm that the pan-PPAR agonist IVA337 is an appealing therapeutic candidate for systemic sclerosis both, for skin and key cardiovascular complications.

FIBROSIS AND MICROANGIOPATHY ARE THE MAIN HISTOPATHOLOGICAL HALLMARKS OF SCLERODERMA-RELATED MYOPATHY

C. Corallo 1, M. Cutolo 2, S. Soldano 2, N. Volpi 1, D. Franchi 1, A. Montella 1, C. Chirico 1, R. Nuti 1, N. Giordano 1, 1 Medicine, Surgery and Neurosciences, University of Siena, Siena; 2 Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy

Background: Systemic sclerosis (scleroderma, SSc) is an autoimmune connective tissue disease characterized by skin and internal organ fibrosis, coupled with widespread vascular pathology. Skeletal muscle involvement in SSc has often been considered as a minor component of the disease associated with disuse.

Objectives: The goal of this study is to identify specific histopathological hallmarks of skeletal muscle involvement in SSc.

Methods: A total of 50 SSc patients presenting clinical, serological and electromyographic (EMG) features of muscle weakness, were enrolled. Patients underwent vastus lateralis biopsy, assessed for individual pathologic features including fibrosis [type I collagen (Col-I), transforming growth factor β (TGF-β)], microangiopathy [cluster of differentiation 31 (CD31), pro-angiogenic vascular endothelial growth factor (A VEG-F, anti-angiogenic VEGF-A165b), immune/inflammatory response [CD4, CD8, CD20, human leucocyte antigens ABC (HLA-ABC)], and myocardial attack complex (MAC). SSc biopsies were compared to biopsies of (n=50) idiopathic inflammatory myopathies (IIMs) and to (n=50) non-inflammatory myopathies (NIMs). Ultrastructural abnormalities of SSc myopathy were also analyzed by transmission electron microscopy (TEM).

Results: Fibrosis in SSc myopathy (90%) is higher compared to IIM (30%, p<0.05) and to NIM (15%, p<0.05). Vascular involvement is dominant in SSc (90%), and in IIM (75%) compared to NIM (20%, p<0.05). In particular, CD31 shows loss of endomysial vessels in SSc myopathy with respect to IIM (p<0.05) and to NIM (p<0.01). VEGF-A is downregulated in SSc myopathy compared to IIM (p<0.05) and to NIM (p<0.05), while VEGF-A165b is upregulated in SSc myopathy. The SSc immune/inflammatory response signature was also present with major [80%] HLA-ABC fibrin deposits and complement deposits on endomysial capillaries MAC, compared to IIM (p<0.05), characterized by CD4+/CD8+ B-cell infiltration, and to NIM (p<0.05). TEM analysis showed SSc vascular alterations consisting of thickening and lamination of basement membrane and endothelial cell ‘swelling’ coupled to endomyosial/perimysial fibrosis.

Conclusions: The predominant features of SSc-related myopathy are fibrosis, microangiopathy and humoral immunity. However, it is difficult to identify specific histopathological hallmarks of muscle involvement in SSc, since they could be present also in other (IIM/NIM) myopathies.

MOLECULAR TARGETED IMAGING BIOMARKERS FOR PERSONALIZED MEDICINE STRATEGIES IN SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE

J. Schniering 1, M. Benešová 1, H. Fazekasova 1, J. Rechcigl 1, L. Bartosová 1, I. Pulk 2, B. Taylor 3, M. Stellato 3, C. Corallo 4, C. Feghali-Bostwick 5, C. Di Stefano 6, J. Henes 7, G. Kania 1, L. Bühler 8, G. Distler 2, O. Distler 1, L. Prudente 8, M. Benešová 1.

1 Medical University of South Carolina, Charleston, SC, United States; 2 Department of Pulmonary Medicine, University Hospital Zurich, Zurich, Switzerland; 3 Department of Medical Sciences, Paul Scherrer Institute, Villigen-PSI, Switzerland; 4 Division of Rheumatology & Immunology, Medical University of South Carolina, Charleston, SC, United States

Background: Interstitial lung disease (ILD) is a life-threatening complication in systemic sclerosis (SSc). Substantial research progress has identified distinct genomic and molecular subtypes in SSc-ILD and brought molecular targeted therapies within reach. However, personalized medicine approaches are still lacking, since currently applicable tools for individualized patient stratification are not yet available.

Objectives: To assess the possibility of imaging molecular targets as a biomarker for stage-dependent assessment of ILD in the mouse model of bleomycin-induced lung fibrosis.

Methods: Expression of integrin α v β 3 and folate receptor β (FR-β) was analyzed in lung tissues from patients with idiopathic pulmonary fibrosis (IPF), SSc-ILD, and healthy controls as well as from bleomycin treated mice and saline treated controls using immunohistochemistry and qPCR (n=5–11), SPECT (Single Photon Emission Computed Tomography) or PET (Positron Emission Tomography) was performed at days 3, 7, and 14 after bleomycin instillation using the integrin α v β 3 -specific 177Lu-(RGD)k-ligand and the FR-β-specific 18F-Azafol. Additionally, 18F-FDG-PET and high resolution CT (HRCT) scans were performed. The specific lung uptake of the radiotracers over time was assessed by ex vivo SPECT or PET/CT scans and biodistribution studies.

Results: Expression of FR-β was significantly increased at the mRNA and protein level of SSc-ILD patients as compared to healthy subjects (p<0.05), whereas only its gene expression was upregulated in IPF patients (p<0.01). Integrin α v β 3 was increased in the lesion level of both SSc-ILD and IPF patients (p<0.05), while its mRNA expression was not significantly altered. Similarly, in lungs of bleomycin treated mice, but not of controls, FR-β expression was increased time-dependently at the mRNA and protein level with higher expression at day 3 and day 7, the inflammatory stages of bleomycin-induced lung fibrosis (p<0.05). In contrast, expression of integrin α v β 3 was upregulated at day 7 and day 14 at the protein, but not at the mRNA level in bleomycin treated mice, and thus not in the inflammatory but also in the fibrotic stages (p<0.05).

Conclusions: Our data suggest that stage-dependent visualization of ILD with radiotracers that target key markers of lung inflammation and/or fibrosis shows promise for clinical application to unselective imaging techniques such as 18F-FDG-PET and HRCT, the introduction of specific imaging biomarkers for individualized management of SSc-ILD patients could represent the first step towards precision medicine.

RESCUE FROM THE FAILING HEART IN SYSTEMIC SCLEROSIS, A NOVEL INSIGHT: TARGETING TGF-β/FRA2/BECLIN AUTOFLUORESCENCE

M. Stellato 1, M. Rücker 2, F. Rokhlin 2, E. Pachera 2, D. Kayalar 1, K. Sottar 2, K. Klinge 1, J. Henes 2, P. Blyszczuk 5, O. Distler 1, G. Kania 1.

1 Department of Rheumatology, University Hospital, Zurich, Switzerland; 2 Institute of Pathology, Ludwig Maximilians University, Munich, Germany; 3 Division of Rheumatology, University Hospital, Tubingen, Germany; 4 Department of Clinical Immunology, Jagiellonian University Medical College, Krakow, Poland

Background: The majority of Systemic Sclerosis (SSc) patients have subclinical primary cardiac involvement, which resembles the inflammatory dilated cardiomyopathy (IDCM) with inflammation and fibrosis. Firstly, cellular progenitors of pathological myofibroblasts remain undescribed.

Secondly, autophagy may favor fibrosis through enhanced differentiation of fibroblasts into myofibroblasts.

Objectives: To unravel the role of Fas-related antigen 2 (Faz2)autophagy crosstalk in TGF-β-driven myocardial fibrosis in SSc

Methods: Genetically modified mice overexpressing Faz2 were used. Endomyocardial biopsies (EMBs) from SSc/IDCM patients and hearts from Faz2tg and control mice were analysed by immunohistochemistry (IHC) and immunofluorescence (IF). Murine myocardial gp38+ (podoplanin+) stromal cells were sorted and stimulated in vitro with TGF-β. The cellular phenotype was assessed by qPCR, IF, stress fiber staining, SirColC and contraction assay on sorted cells.

Results: Cardiac fibroblasts in myofibroblasts showed higher expression of profibrotic markers: αSMA, vimentin and collagen I compared to control mice (n=5), as well as the expression of the autophagy markers LC3b and Beclin in fibrotic regions. Importantly, the expression of gp38+ cells co-expressed αSMA, vimentin and collagen I together with autophagy markers (LC3B and Beclin, n=3), following in vitro stimulation with TGF-β, gp38+ cells entered fibroblast-to-myofibroblast transition characterized by increased mRNA and protein levels of αSMA, collagen I, fibronectin (n=3–4), αSMA-fiber and stress-fiber formation (n=3), increased cell proliferation (n=4; p<0.04) and contraction capability (n=2; p<0.05) and enhanced collagen secretion (n=3; p<0.04). Importantly, Faz2tg gp38+ cells showed the presence of αSMA and stress fibers even without TGF-β stimulation as well as an increased contraction capability compared to control cells.

Conclusions: TGF-β stimulation of control gp38+ cells induced the expression of LC3B, Beclin and Atg5 at mRNA and protein level (n=3–5). In contrast, TGF-β inhibition caused the downregulation of these markers (n=3). In addition, Faz2 silencing resulted in a decreased differentiation capability of fibroblasts in myofibroblasts. This study thus suggests an autophagy-mediated rescue from the failing heart in SSc.
Conclusions: The TGF-β/Fra2 axis fosters an enhanced autophagy flow, leading in turn to the stromal-to-myofibroblast transition. Therefore, targeting this process might be a therapeutic strategy to abrogate fatal cardiac remodeling in SSc.

DOI: 10.1136/annrheumdis-2017-eular.3760

Conclusions: This study is the first to characterize lower G19 microRNA in SSc patients at multiple time points. The findings provide further evidence that lower G19 dysbiosis is a feature of the SSc disease state and that specific genera may contribute to G19 symptoms and serve as potential targets for therapeutic intervention.

pathways with the highest number of significantly enriched genes (n=5; p<0.005). Apoptosis markers like BCL2, IGFBP3 and FAF1 (n=5; p<0.005) were upregulated in H19X-silenced fibroblasts. This indicated that targeting H19X might have a pro-apoptotic effect on fibroblasts thereby protecting from fibrosis. Functional studies showed enhanced fibroblast apoptosis after H19X silencing and TGFβ stimulation (n=5; p<0.005). In addition to decreased apoptosis, increased fibroblast proliferation might also favor fibrosis. Indeed, H19X downregulation led to reduced cell proliferation as measured by BrdU assay (n=5, p<0.05). Scratch assay (n=5) showed that H19X knockdown decreases TGFβ reduced wound healing. H19X expression was significantly increased in SSc interstitial lung disease and IPP patients versus HC (n=11 each, p<0.05). A significant H19X overexpression was also detected in fibrotic tissue from Cohn’s disease patients (n=4–10, p<0.05).

Conclusions: H19X supports TGFβ-driven fibrosis not only by favoring myofibroblast development and extracellular matrix synthesis, but also by inducing proliferation and reducing apoptosis of dermal fibroblasts. These effects are not limited to SSC, but appear operative in a wider range of fibrotic diseases. Our results highlight the IncRNA H19X as a potent new therapeutic target in fibrotic diseases opening thereby new possibilities for the treatment of TGFβ-driven fibrosis.

OP0088

THE ROLE AND FUNCTION OF MONOCYTE-DERIVED FIBROBLAST-LIKE CELLS IN MULTIORGAN FIBROSIS IN SYSTEMIC SCLEROSIS

Background: Systemic sclerosis (SSc) is a systemic connective tissue disease characterised by autoimmunity, vascular disorder and fibrosis of skin and other organs (1). Although substantial reports have been hitherto provided upon its pathogenesis in relation to microvascularature, among which are on endothelial and fibroblastic Fli1 deficiencies (1, 2), adequate investigation into hemoxytic involvement is yet to be attained. Platelets are well known for its function in organs (1). Although substantial reports have been hitherto provided upon its involvement is yet to be attained. Platelets are well known for its function in monocytes involvement in SSc might lead to novel treatment strategies.

Methods: In dermal injuries on Fli1 PcKO mice, inflammatory disturbances precipitate myofibroblast formation in the granulation tissue, thus anticipating wound closure by mechanical contraction.

PLATELET-SPECIFIC Fli1-KNOCKOUT MICE SHOW ACCELERATED WOUND CLOSURE ASSOCIATED WITH INCREASED MYOFIBROBLAST FORMATION IN THE INFLAMMATORY PHASE

Background: Systemic sclerosis (SSc) is a systemic connective tissue disease characterised by autoimmunity, vascular disorder and fibrosis of skin and other organs (1). Although substantial reports have been hitherto provided upon its pathogenesis in relation to microvascularature, among which are on endothelial and fibroblastic Fli1 deficiencies (1, 2), adequate investigation into hemoxytic involvement is yet to be attained. Platelets are well known for its function in hematosis whereas they also play a part in inflammation, immunity and cellular proliferation (3), thus prompting us to speculate their cardinal role in the development of the disease.

Objectives: Here we aim to unravel the role of platelets in the pathogenesis of SSc, with generation of platelet-specific conditional Fli1 knockout (Fli1 PcKO) mice to scrutinise its dermal wound healing process.

Methods: We generated Fli1 PcKO mice using the Cre-Lox system along with PcCre mice as an appropriate control. We made two excisional wounds on the dorsal skin of each mouse (three months old) using an eight-millimeter-diameter punch and traced the wound surfaces every other day to measure their areas using Image J until all the wounds were epithelised. On a separate experiment, perilesional skin tissues harvested on the day two, from which we extracted mRNA for the measurement of proinflammatory and profibrotic cytokines. An immunostaining for α-SMA was performed on the skin samples.

Results: The areas of the wounds were calculated and shown in ratio to their initial areas (day 0). Fli1 PcKO mice showed a significant decrease in the areas compared to the control on day 2. mRNA measurement revealed a significant increase in Mmp13 and significant decreases in Tgfβ1, Ifng and Il13 for Fli1 PcKO. In histopathology, α-SMA positive fusiform-shaped cells were abundant in the granulation tissue of Fli1 PcKO mice (Figure; left, PcCre +/−; right, Fli1 PcKO; original magnification, ×400).

Conclusions: In dermal injuries on Fli1 PcKO mice, inflammatory disturbances precipitate myofibroblast formation in the granulation tissue, thus anticipating wound closure by mechanical contraction.

COMBINATION THERAPY OF SELECTIVE MMP9 AND TNF INHIBITORS ARE EFFICACIOUS IN THE MOUSE CIA MODEL OF RHEUMATOID ARTHRITIS

Background: Matrix metalloproteinase-9 (MMP9) is highly expressed by infiltrating inflammatory cells, pannus tissue, and multinucleated cells in the synovium and subchondral bone tissue, including osteoclasts. MMP9 is implicated in rheumatoid arthritis (RA) by its involvement in joint destruction, activation of cytokinesis, and promotion of tissue destruction by degrading the basement membrane of epithelia and vasculature. MMP9 knockout mice are protected from collagen-induced arthritis (CIA) disease progression. A potent, allosteric antibody inhibitor of MMP9 is currently being investigated in clinical trials. The ability of a functional murine analog of this antibody to reduce disease signs and symptoms in established, chronic mouse CIA model both as a single agent and in combination with anti-TNF, was investigated.

Objectives: We evaluated the efficacy and safety of selective MMP9 inhibition both alone and in combination with anti-TNF (etanercept), in CIA models of RA.

Methods: CIA was induced in male DBA/1j mice (n=15/group) and treatments were initiated after disease establishment. Efficacy was assessed via metrics of joint injury including clinical score (erythema/ paw swelling, score 0–4) in addition to histopathological assessment of destructive joint remodeling (soft tissue changes: edema, necrosis, inflammatory cell infiltration, and fibroplasia, score 0–4; bone changes: 0–6; bone erosion, periosteal bone formation, synovitis, pannus formation, and joint destruction, sum score 0–24).

Results: All animals were included in the evaluation. In all endpoints assessed, treatment with each therapeutic agent, on its own or in combination, resulted in improvement with respect to body weight change, clinical score, and histopathological signs of joint injury. The combination group provided the best overall trend for therapeutic benefit, although statistical significance as compared to each single agent alone was not met in most parameters. Body weight recovery was superior in combination as compared to single agent therapies (52% vs. 12–34%, relative to sham; p<0.05 combination vs. single agents). Clinical score and histopathology measures in soft tissue and bone changes were most improved in the combination therapy group, although it did not achieve statistical significance as compared to each single agent (26% vs. 17–21%; 1.5 vs. 1.5–1.8; and 7 vs. 7–9, respectively). Importantly, combination therapy resulted in a significant number of limbs with zero or mild disease as compared to single agents (no disease sign: 25% vs. 172–223%; mild disease sign: 178% vs. 138–141%). Analysis of complete blood count at the end of study revealed no abnormalities in any treatment group.

Conclusions: Selective inhibition of MMP9 was active in reducing disease severity in CIA models of RA. The combination of anti-MMP9 with anti-TNF was well tolerated and increased the number of limbs with no or mild disease compared to anti-TNF alone. Further studies are required to examine combination therapy of selective anti-MMP9 and anti-TNF therapies in a clinical setting.

DOI: 10.1136/annrheumdis-2017-eular.1941
Results: Our results demonstrate that early exposure to S100A8 interferes with in-vitro differentiation of moDCs. Compared to controls S100A8-exposed moDCs show dramatically reduced surface expression of co-stimulatory molecules upon LPS-induced maturation. In addition, early treatment of moDCs with S100A8 alters the secretion of immune-regulatory cytokines and chemokines depending on the differentiation state of moDCs. S100A8-induced effects on moDCs and their maturation are not limited to TLR4 stimulation but rather trigger a common state of unresponsiveness. Furthermore, mitochondrial respiration and glycolytic function is diminished in S100A8-treated moDCs. As a consequence, S100A8-exposed moDCs have a reduced potential to induce autologous FcεR1 proliferation. We can show that these differences are mainly caused by reduced surface expression of co-stimulatory molecules on S100A8-treated moDCs. Mechanistically, genome-wide gene expression analysis reveals dramatic differences in the gene expression between S100A8-exposed and conventionally differentiated moDCs. We demonstrate that S100A8 pre-treatment of moDCs significantly blocks LPS-induced gene expression during moDC activation. Interestingly, in-silico analysis of transcription factor networks predicts NFκB and C/EBPs as master regulators of S100A8-induced effects in developing moDCs. C/EBPs on protein level, indeed, shows reduced expression in S100A8-differentiated moDCs prior and after LPS-induced maturation when compared to conventionally differentiated moDCs.

Conclusions: Taken together, our results demonstrate a novel regulatory mechanism of innate immunity to prevent overwhelming immune responses. Dysregulation of type 1 interferon may lead to detrimental immune responses which very well contribute to the disease phenotype in auto-immune disorders with high systemic S100A8/A9 levels. Therefore, S100A8-differentiated immune-suppressive DCs might very well be master regulators of S100A8-induced effects in developing moDCs. C/EBP as well as changes in amino acid and purine metabolism. Oxidative phosphorylation. Metabolomic analyses of plasma and muscles of mice with systemic inflammation induced by LPS injection. We further investigated the effects of IL-37 on exercise tolerance in healthy mice, with specific focus on the metabolic changes induced by IL-37 administration and possibly responsible for a reduction in the metabolic costs of inflammation.

Results: Exogenous administration of IL-37 to healthy mice, not subjected to an inflammatory challenge, also improved exercise performance by 82% compared to vehicle-treated mice (p<0.001). Treatment with 8 daily doses of IL-37 resulted in a further 326% increase in endurance running time compared to the performance level of mice receiving vehicle (p<0.001). These properties required the engagement of the IL-1 decoy receptor 8 (IL-1R8) and the activation of AMPK, a key regulator of intracellular energy homeostasis. Conditioning media from these cells, containing released IL-37, was also able to elicit an anti-inflammatory effect on human macrophages and RA-FLS by reducing their IL-23 (M1) and IL-6 (M1 and RA-FLS) expression.

Conclusions: This study shows for the first time that IL-37 overexpression attenuates the severity of experimental arthritis in two mice arthritis models. IL-37 may exert its anti-inflammatory effects by decreasing the production of pro-inflammatory cytokines by macrophages and fibroblast-like synovocytes. This effect can lead to the development of novel treatment strategies in arthritis.

**OBJECTIVES:** To develop biomarkers of progression to systemic autoimmunity, with a view to enabling early intervention for disease prevention.

**Methods:** A prospective observational study was conducted in 125 patients at Risk of CTD defined by (i) ANA; (ii) ≤1 clinical SLE criteria; (iii) symptom duration <12 months and (iv) treatment-naïve. Progression was defined by meeting 2012 ACR/SLICC SLE, 2016 ACR/EULAR Primary Sjogren’s, or other diagnostic criteria. Expression of 30 selected ISGs was measured using Taqman. Factor analysis was used to reduce the gene expression data to a limited set of factors, which were compared between patient groups using Mann Whitney U Test. Two factor scores explained 80% of the data variance; “Score A” (composed of IFN-γ responsive genes) and “Score B” (genes responsive to IFN-γ and γδ T cells) were used to calculate IFN Score A and B.

**Results:** 82 patients with 1-year follow-up data were studied. 71 were female with mean age 48±1.5 years. 16 (20%) patients progressed to CTD (SLE=12, Sjogren’s=4) in the following 12 months. At baseline, only IFN Score A was increased in both At-Risk-CTD and SLE vs healthy controls; p<0.001. IFN Score B was only increased in true established SLE.

**Conclusions:** IFN Score B was low in patients who did not progress and increased in those who did progress; p<0.001. There was no difference in IFN Score A between these two groups; p=0.292 (Figure 1). Although complement levels and lymphocyte counts were lower in SLE, these were not different between the At-Risk progression and non-progression groups. Anti-dsDNA titres were higher in SLE but not different between the progression groups; all p>0.10.

**OP0097** SYSTEMIC IFN TYPE I AND TYPE II SIGNATURES IN PRIMARY SJÖGREN’S SYNDROME REVEAL DIFFERENCES IN DISEASE SEVERITY

I. Bodewes, S. Al-Ali, C.G. van Helden, N.K. Maria, J. Tarn, D. Lendrem, M.W. Schirurs, E.C. Steenwijk, P.L.A. van Daene, T. Both, S. Bowman, B. Griffiths, W.-F. Ng, M.A. Versnel, Immuno, Erasmus MC, Rotterdam, Netherlands; 2Musculoskeletal Research Group, Newcastle University, Newcastle upon Tyne, United Kingdom; 3University of Basrah, Basrah, Iraq; 4Internal Medicine, Erasmus MC, Rotterdam, Netherlands; 5Rheumatology, University Hospital Birmingham, Birmingham; 6Newcastle upon Tyne Hospitals NHS Foundation Trust; 7National Institute for Health Research, Newcastle Biomedical Research Centre, Newcastle upon Tyne, United Kingdom

**Background:** Local and systemic activation of interferons (IFNs) has been demonstrated in primary Sjögren’s syndrome (pSS).[1–4] Type I IFNs are associated with higher disease activity and autoantibody levels.[5] Recent findings also show activation of interferon type II (IFNγ) induced gene expression in salivary glands of pSS patients.[6, 7] Although IFN type I and II bind to different receptors they induce partially overlapping gene expression patterns. Understanding the relative contribution of IFN type I and type II may deepen our knowledge in pSS pathogenesis and promote a stratified approach to therapeutic development.

**Objectives:** Determine IFN type I and II inducible gene expression in patients with pSS and correlate this to disease manifestations.

**Methods:** In whole blood of 50 pSS patients modular IFN scores were determined using real-time quantitative PCR followed by principal component analysis. Subsequently, five indicator genes per module were analysed in two independent European cohorts with a total of 141 patients.

**Results:** Three groups were distinguished: without IFN activation (19–47%), with IFN type I (53–81%) and with IFN type I and II activation (35–55%). Patients with IFN activation (I or II) have a higher presence of auto-antibodies, IgG levels and lower lymphocyte counts compared to IFN negative patients. The biological domain of the EULAR Sjögren’s Syndrome Disease Activity Index (biological-ESSDAI) was higher in patients with IFN activation, while total-ESSDAI scores were not significantly different.

66–67% of the IFN type I positive patients had an additional IFN type II inducible gene expression. Patients with IFN type II induction have significantly higher IgG levels and lower lymphocyte counts compared to patients with only IFN type I activation. There were no differences in fatigue or dryness, but pain scores were lower.

**Conclusions:** pSS patients can be stratified according to their systemic IFN activation patterns. IFN activation (I or II) is present in patients with the highest activity of the biological-ESSDAI. These data raise the possibility that the biological-ESSDAI rather than total-ESSDAI score may be a more sensitive endpoint for trials targeting either type I or type II IFN pathways.

**OP0098** REMISSION AND MAINTENANCE OF EFFICACY IN A PHASE 2B STUDY OF VOBARILIZUMAB, AN ANTI-INTERLEUKIN 6 RECEPTOR NANOBODY, IN PATIENTS WITH MODERATE-TO-SEVERE RHEUMATOID ARTHRITIS DURING TREATMENT WITH METHOTREXATE

T. Dörner, M. Weinblatt, P. Durez, R. Atten, K. Van Beneden, E.J. Dombreciht, K. De Beul, P. Schoen, R.K. Zeldin, Rheumatology and Clinical Immunology, Charité University Hospitals, Berlin, Germany; Division of Rheumatology, Immunology and Allergy, Brigham and Women’s Hospital, Boston, United States; 3Department Rheumatology, Cliniques Universitaires St-Luc, Sint-Lambrechts-Woluwe, Belgium; 4Schoosspark-Klinik, Berlin, Germany; 5Ablynx NV, Zwijnaarde, Belgium

**Background:** Vobarilizumab is a Nanobody® consisting of an anti-IL-6R domain and an anti-human serum albumin domain in development for treatment of RA. The efficacy and safety were assessed in a 24-week double-blind global phase 2b study in patients with active RA on a stable background of MTX. Main efficacy and safety results were previously reported.[1]

**Objectives:** To report the impact of treatment with vobarilizumab on secondary efficacy endpoints including SDAI and CDAI remission and the sustained response at 4 consecutive visits based on ACR50, ACR70 and DAS28<2.6.

**Methods:** Patients were randomized to receive subcutaneously administered placebo or 1 or 4 dose regimens of vobarilizumab in addition to MTX. SDAI and CDAI remission at Week 24 was evaluated, as was maintenance of efficacy as defined by sustained DAS28<2.6 responses at 4 consecutive visits (i.e., at Weeks 12, 16, 20 and 24). In addition, a post-hoc analysis was performed on sustained ACR50 and ACR70 responses from Week 12 through Week 24. Proportions of patients achieving response for these endpoints were summarized by treatment group. Subjects with missing values were analyzed as non-responders.

**Results:** A total of 345 patients were randomized. Demographics and baseline characteristics were similar across groups with mean baseline DAS28CRP between 5.8 and 6.2. At Week 24, up to 19% and 20% in the vobarilizumab groups reached CDAI remission, respectively, vs. 10% and 9% who received placebo (Table 1).

At Week 24, up to 61% and 45% of the patients in the vobarilizumab groups achieved an ACR50 or ACR70 response, respectively (39% and 17% on placebo). Approximately one third of the randomized patients in the 3 highest treatment groups had a sustained ACR50 response from Week 12 through Week 24 (Table 2). Sustained remission defined by DAS28<2.6 at 4 consecutive visits, i.e. at weeks 12, 16, 20 and 24, was observed in 20% to 25% of the patients in the 3 highest dosing arms compared with 3% of those receiving placebo.

**Table 1. Percentage of patients with CDAI and SDAI remission at Week 24**

**OP0099** SAFETY, TOLERABILITY AND INITIAL SIGNS OF EFFICACY OF THE FULLY HUMAN IMMUNOCYTOKINE DEKAVIL (FBL10): A NOVEL THERAPEUTIC APPROACH FOR RHEUMATOID ARTHRITIS

M. Galeazzi, T. K. R. G. Sebastiani, R. Völz, J. Wollenhaupt, O. Viapiana, J. Dudler, E. Selvi, C. Baldi, M. Bardelli, B. Bannert, S. Finzel, C. Specker, P. Sarzi Puttini, F. Bootz, Neri, on behalf of the DEKAVIL Study Group. 1University Hospital, Siena; 2San Camillo-Forlanini Hospital, Rome, Italy; 3University Medical Center, Freiburg; 4Schooss-Klinik, Hamburg Eilbek, Germany; 5University Hospital, Verona, Italy; 6Cantonal Hospital, Fribourg, Switzerland; 7University Hospital, Essen, Germany; 8Luigi Sacco Hospital, Milan, Italy; 9Philochem AG, Otelfingen, Switzerland; 10Philogen SpA, Siena, Italy

**Background:** The antibody-based targeted pharmacodelivery of cytokines by means of immunocytokines has the potential to enhance therapeutic activity at the site of disease while sparing healthy tissues. Dekavil (F8IL10) is a fully human immunocytokine composed of the vascular targeting antibody F8 (specific to
EDA) fused to the cytokine interleukin-10. Dekavil is currently in phase II clinical development for the treatment of rheumatoid arthritis (RA).

Objectives: In the phase Ib dose escalation study, the primary objective was to explore safety, tolerability and the maximum tolerated dose of Dekavil when administered in combination with methotrexate (MTX). The aim of the currently ongoing phase II study is to assess the therapeutic activity of Dekavil plus MTX over MTX alone by measuring the mean change from baseline of DAS28-2CRP. Immunogenicity of F8IL10 and its PK and PD profile will also be explored.

Methods: Patients with active RA despite MTX therapy and who failed anti-TNF treatment are the target population of both studies. In the phase Ib trial, cohorts of 3–6 patients were treated with escalating doses of Dekavil (6, 15, 30, 60, 110, 160, 210, 300, 450 and 600 μg/kg) in combination with a fixed dose of MTX (10–15 mg). In the multicenter, double-blind, placebo-controlled phase 2 study, patients are randomized into two treatment groups (Dekavil 30 or 160 μg/kg plus MTX) and one placebo group (placebo plus MTX). Dekavil is administered once weekly by s.c. injection for a maximum of 8 weeks in both studies.

Results: Dekavil has been shown to be well tolerated up to the highest investigated dose (600 μg/kg) and an MTD was not reached. In 33 out of 34 patients treated in the phase 1 study, no DLTs, no SAES and no SUSARS have been reported. One patient in cohort 9 (450 μg/kg) experienced a DLT (G2 purpura) and a SAE (G2 dyspnea, not drug related). The patient received corticosteroids and fully recovered within one week. Mild injection site reactions were the most frequently observed adverse events and occurred in 62% of the patients. Furthermore, two cases of drug related anemia (G2 and G3) were reported in this study. All adverse reactions resolved completely. At the first efficacy assessment after 4 cycles of treatment, 48% of evaluable patients (16/33) revealed ACR and/or EULAR responses. At the last assessment after 8 cycles of treatment, 2 patients benefited from ACR20 responses for more than 12 months after last drug administration. As of January 2017, 22 out of 83 patients have been treated in the phase 2 clinical study and neither SUSAR nor treatment-related deaths were recorded.

Conclusions: The currently available data suggest that Dekavil is a safe and potentially novel therapeutic for the treatment of RA.

OP0101

OVERALL CANCER RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TNF INHIBITORS, TOCILIZUMAB, ABATACEPT, OR RITUXIMAB

H. Wadström, T. Frisell, J. Askling on behalf of The ARTIS study group.

Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden

Background: Immune incompetence may lower host surveillance against incipient tumours. Conversely, immune therapies have emerged as a promising therapeutic approach to cancer. Malignancies thus constitute an important aspect of the treatment of patients with rheumatoid arthritis (RA), which is a chronic inflammatory disease of unknown cause with a predilection for the joints. Through linkage with the Swedish national and population-based registers (see Additional file 1), and educational level, there were no statistically significant differences in the overall risk of malignancies among RA patients initiating, tocilizumab, abatacept, rituximab, or a first - or second TNFi, and RA patients treated with csDMARDs.

Objectives: To present the overall incidence rates of OI and herpes infections observed in patients (pts) receiving ABA using combined clinical trial data.

Methods: All adverse events were summarized from 16 clinical trials (both placebo-controlled and cumulative abatacept exposure): all pts randomized to placebo were on a non-biologic DMARD. Incidence rates (per 100 person-years (p-y)) were calculated by the number of pts experiencing the first event divided by the total number of p-y of exposure. The p-y of exposure was censored at the time of the first event, death, discontinuation or end of study. Random effects meta-regression was performed across the trials to estimate the frequency of OI after adjusting for study heterogeneity. OI were identified using a pre-specified list in the setting of biologic therapy for patients with RA. Criteria for consideration were based on type, location of the infection and causing organism. Excluded from the list were non-specific infections caused by organisms considered to be opportunistic, but common in the general population.

Results: A total of 7044 pts with RA with >21,330 p-y of ABA exposure were included in the cumulative randomized trial data (Table). The frequency of OI

Background: The phase 3 MONARCH superiority study (NCT02332590) compared efficacy and safety of sarilumab (a human anti-IL-6R monoclonal antibody [mAb]) 200 mg administered subcutaneously every 2 weeks (q2w), with adalimumab from MONARCH.

Methods: To compare patient-reported outcomes (PROs) with sarilumab vs adalimumab from MONARCH.

Objectives: Consistent with IL-6R or TNF blockade.

Results: Baseline demographics, disease characteristics and PROs assessed at baseline, weeks 12 and 24 included ACR components, SF-36 physical component summary [PCS], Morning Stiffness VAS, Health Assessment Questionnaire Disability Index [HAQ-DI]), Short Form-36 Physical Component Summary (SF-36 PCS), quality of life (QoL) and health domain summary (RAD), physical function (physical function [PHI], Physical Function [VAS]), role limitations due to physical problems (role limitations due to physical problems [VSA], role limitations due to emotional problems (role limitations due to emotional problems [VSS]), vitality (vitality [VSA], vitality [VSS]), mental health (mental health [VSA], mental health [VSS]), pain (pain [VSS], pain [VAS]), social functioning (social functioning [VSA], social functioning [VSS]), and general health (general health [VSA], general health [VSS]).

Conclusions: Sarilumab monotherapy compared with adalimumab monotherapy resulted in greater and clinically meaningful improvements in many PROs, including patient-reported disease activity, pain, physical function, morning stiffness, productivity, health related quality of life and health status.

Loza 1, Janssen Research & Development, LLC, Spring House, PA, United States; 2Nordic Bioscience, Herlev, Denmark; 3GlaxoSmithKline, Research Triangle Park, NC, United States; 4Regeneron Pharmaceuticals, Inc., Tarrytown, New York, United States; 5t o
and <0.5 (n=51). BL or Wk 4 changes in levels of individual analytes were not associated with Wk 24 ACR50 or DAS28-CRP responses.

Conclusions: SIR 50mg q4w + MTX, vs pbo + MTX, inhibited radiographic progression in RA pts in SIRROUND-D and strongly inhibited biomarkers of joint and tissue destruction while enhancing markers of bone formation. These data suggest SIR may actively suppress inflammatory pathways implicated in joint destruction in RA pts.

OP1014 TOCILIZUMAB: DOSE REDUCTION OR INTERVAL SPACING – WHICH PROVES A BETTER TAPERING STRATEGY FOR RHEUMATOID ARTHRITIS IN CLINICAL REMISSION?

Y. Urata 1, S. Abe 2, B. Devers 3, Y. Nakamura 4, H. Takemoto 5, K.-I. Furukawa 6
1Department of Rheumatology, Taisho General Hospital, Goyougawara; 2Marketing Department; 3Marketing Department, Diagnostics Division, Sekisui Medical Co., Ltd., Tokyo; 4Departments of Orthopaedic Surgery; 5Departments of Dermatology, Taisho General Hospital, Goyougawara; 6Department of Pharmacology, Hiroakis University Graduate School of Medicine, Hiroakis, Japan

Background: A number of studies have revealed that reduction of biological disease-modifying anti-rheumatic drugs (bDMARDs) is possible for some rheumatoid arthritis (RA) patients in whom bDMARD treatment has induced clinical remission or low disease activity. For tocilizumab (TCZ), while there have been studies concerning tapering, there have been no studies regarding which tapering option is better in RA after clinical remission has been achieved: a dose reduction strategy (DRS) or an interval spacing strategy (ISS).

We previously demonstrated that a twin target strategy [targeting both a simplified disease activity index (SDAI) score of less than 3.3 and normalization of matrix metalloproteinase (MMP) 3 levels] can achieve effects non-inferior to standard care with regard to maintaining clinical remission in the r-4study.

Objectives: To evaluate any significant differences that may be present between the two strategies (DRS and ISS) while tapering TCZ in RA patients who satisfied the SDAI remission and MMP-3 normalization targets under the twin target scheme.

Methods: DRS was used in patients treated with intravenous (IV) TCZ, whereas ISS was used for those treated by subcutaneous injection (SC). 57 RA patients who demonstrated SDAI remission and MMP-3 normalization using TCZ (IV, n=42; SC, n=15) participated. Dose reduction methodology (every 3 months): DRS- 80 mg every 4 weeks; ISS-162 mg every 4 weeks. After DRS was used in patients treated with intravenous (IV) TCZ, whereas ISS was used for those treated by subcutaneous injection (SC). 57 RA patients who demonstrated SDAI remission and MMP-3 normalization using TCZ (IV, n=42; SC, n=15) participated. Dose reduction methodology (every 3 months): 5.76
target was re-achieved. The primary outcome was the difference in the number of times when a patient’s SDAI exceeded 3.3 across the four time points.

Results: Fifty-five patients completed the observation period of 12 months and were analyzed (ITT). There were differences in the number of the times which SDAI scores exceeded the target over the 12 months in the DRS group vs the ISS group: 2.4±1.7 and 0.9±1.2, respectively (p=0.0027). DRS had a duration (months) of maintained SDAI remission significantly shorter than that of ISS (3.9±15.0 vs 7.4±5.1, p=0.0213). At month 12, the proportions for DRS and ISS, (months) of maintained SDAI remission significantly shorter than that of ISS (3.9±15.0 vs 7.4±5.1, p=0.0213). At month 12, the proportions for DRS and ISS, respectively, for ΔMTS =-0.5 were 71.4 and 66.7% (p=0.729); for maintained HAD(0-10) were 83.8 and 66.7% (p=0.4227) and for AE were 81.0 and 46.7 (p=0.0112). The total dose for TCZ in DRS tended to be lower than that for ISS (1367±840 vs 1626±583mg, p=0.0824). The rate of total TCZ reduction showed a significant difference between DRS and ISS (29.3±15.2% vs 41.8±15.0%, p=0.037). Comparing three groups consisting of 400mg-, 401-<500mg and 500mg- across the DRS with ISS groups, there were significantly greater number of times when SDAI exceeded 3.3 in the DRS vs the ISS group; 2.3±1.6, 2.7±1.8 and 2.4±1.9, p=0.0395.

Conclusions: ISS using the twin targets as defined by the r-4 study is an excellent strategy that is both safe and cost-effective for RA patients who are both being treated with TCZ and have reached said targets.

OP1015 LONG-TERM SAFETY OF TOCILIZUMAB FROM LARGE CLINICAL TRIAL AND POSTMARKETING POPULATIONS

S. Mohan, M. Michalska, J. Youshir, J. Pei, S. Gale, C. Birchwood, E. Berber, Genentech, Inc., South San Francisco, CA, United States

Background: Tocilizumab (TCZ) is a recombinant humanized monoclonal anti-body targeted against the interleukin-6 receptor that was approved to treat rheumatoid arthritis (RA) in the EU in 2009 and in the US in 2010. TCZ has now completed long-term extension (LTE) follow-ups in a number of intravenous and subcutaneous RA trials.

Objectives: To provide an updated report on the incidence of safety events during TCZ treatment in patients with RA using data from multiple completed clinical trials and their LTEs, as well as to provide an update from the global TCZ postmarketing safety database.

Methods: Incidence and reporting rates of adverse events (AEs) of special interest, including infections, malignancies, anaphylaxis, bleeding events, myocardi al infarctions, gastrointestinal perforations, strokes, hepatic events and demyelination, were estimated from 2 distinct patient data sets. Incidence rates were calculated from 12 completed TCZ RA clinical trials and their LTE periods and are reported as events per 100 patient-years (PY). Reporting rates were also estimated from the global TCZ postmarketing safety database (Oct 2008 to Oct 2015), which includes information from all spontaneously reported cases and postmarketing regulatory programs as well as literature cases, and are reported as cases per 100 patients.

Results: The clinical trial all-exposure population consisted of 7647 TCZ-treated patients with RA (81.6% female; mean [SD] age, 52 [12.6] years, constituting 22,394 PY (mean follow-up, 2.93 years) of exposure. The overall rate (95% CI) of serious AEs in the clinical trial population was 14.16 (13.67–14.66) per 100 PY. Overall incidence rates for individual events for the clinical trial population are reported in the Table and were consistent in each 6-month period over the 5-year duration. The global postmarketing population included 606,937 patients. The overall spontaneous reporting rate (range) of AEs of special interest in the postmarketing population was 8.97 (7.35–10.56) cases per 100 patients. Reporting rates of individual safety events of interest in the global postmarketing population are shown in the Table and were consistent in each 6-month period over the 7-year duration.

Conclusions: The safety profile of TCZ in the current analysis, which includes information about safety events from 12 clinical trials and their LTEs and across >10 years of real-world postmarketing reports encompassing >600,000 patients, was consistent with previous safety reports. These findings are consistent with the previously reported profile of TCZ and indicate that there is no evidence of increased safety risk with increasing exposure to TCZ.

DOI: 10.1136/annrheumdis-2017-eular.3573
Background: Psoriatic arthritis (PsA) is a chronic inflammatory disorder associated with several severe comorbidities such as cardiovascular diseases, diabetes, and depression. Tumour necrosis factor inhibitor (TNFi) therapy fails among half of patients with PsA treated in routine care.

Methods: Data on patient characteristics, disease activity and treatment adherence was obtained from the DANBIO register. Information on comorbidities according to the Charlson Comorbidity Index (CCI) and psychiatric comorbidities was obtained through linkage with the Danish National Patient Register. We performed Kaplan-Meier plots and multivariate Cox proportional hazard regression analyses adjusted for sex, age, disease duration, DAS28-CRP, obesity, smoking, concurrent methotrexate treatment, calendar period, and diagnosis with depression and/or anxiety. Percentages of patients achieving relevant clinical response rates were calculated.

Results: We identified 1750 patients eligible for analyses. Patients with higher CCI scores had statistically significantly higher disease activity measures at baseline compared with patients without comorbidities (Table 1). Kaplan–Meier curves showed shorter adherence to treatment for patients with CCI >2 compared with patients with lower CCI scores (CCI =0: 2.6 years [2.2 to 2.9], CCI =1: 2.2 years [1.7 to 2.8], CCI ≥2: 1.3 years [1.0 to 1.6], p<0.001) (Figure). Also, for patients with depression and/or anxiety the adherence to treatment was shorter compared with patients without depression and/or anxiety (absence of depression and/or anxiety: 2.4 years [2.1 to 2.6], presence of depression and/or anxiety: 1.7 years [0.26 to 3.0], p=0.027). In the multivariate Cox regression analysis a CCI score ≥2 was associated with increased risk of TNFi treatment discontinuation compared with patients without comorbidities (HR 1.72, [95% CI 1.26 to 2.37], p=0.001). A statistically significantly smaller proportion of patients with a CCI score ≥2 achieved EULAR good response (CCI =0: 41%; CCI ≥2: 23%) and EULAR good-or-moderate response (CCI =0: 54%; CCI ≥2: 47%) at 6 months compared with patients without comorbidities.

INHIBITION OF RADIOGRAPHIC PROGRESSION IN PSORIATIC ARTHRITIS BY ADALIMUMAB INDEPENDENT OF THE CONTROL OF CLINICAL DISEASE ACTIVITY

P. Landewé 1, C.T. Ritchlin 2, L.C. Coates 3, D. Aletaha 4, B. Guerette 5, T. Zhang 6, T. Ganz 6, C. Van de Putte 7, L. Huneault 8, G. van Vollenhoven 9, R. Landewé 1

1University of Amsterdam, Amsterdam, Netherlands; 2University of Rochester Medical Center, Rochester, United States; 3University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 4Medical University of Vienna, Vienna, Austria; 5AbbVie Inc, N Chicago, United States; 6AbbVie AG, Baar, Switzerland; 7AbbVie, Ljubljana, Slovenia

Background: Patients (pts) with psoriatic arthritis (PsA) may experience structural damage and irreversible functional impairment if not treated appropriately. Treatment with TNF inhibitors in rheumatoid arthritis (RA) pts showed inhibition of radiographic progression larger than expected based on the control of clinical disease activity. Preliminary results showed that such a disconnect phenomenon may also be observed in PsA pts following treatment with adalimumab (ADA).

Objectives: The objective of this analysis was to further examine the relationship between inhibition of radiographic progression and control of clinical disease activity using different disease activity measures following treatment with originator ADA than placebo (PBO) in pts with active PsA.

Methods: ADEPT was a 24-week (wks), randomized, double-blind trial comparing the safety and efficacy of ADA with PBO in pts with active PsA. In this post hoc analysis, radiographic progression, defined as change from baseline (BL) to wk 24 in modified total Sharp score (ΔmTSS) ≤ 0.5, was calculated in pts with evaluable radiographs at both time points. Pts were classified based on achieving minimal disease activity (MDA) and different subcategories of disease activity (remission, low, moderate, or high) based on time-averaged (TA) ΔmTSS and PASSAS. The associations between ΔmTSS and disease activity were assessed by Pearson’s correlation coefficient (r) and Spearman’s rank correlation coefficient (r).

Results: Of the 296 pts (ADA, N=144; PBO, N=152) included in this analysis, higher proportions of pts receiving ADA compared with PBO achieved MDA and remission/low disease activity status across all the outcome measures.

There was a significant interaction between treatment and disease activity status with respect to radiographic progression (P<0.001 for all outcome measures). In addition, treatment with ADA for 24 wks resulted in significantly lower mean ΔmTSS even in pts with moderate or high disease activity (TA-DAPSA or TA-PASDAS) or not achieving MDA (Table). Radiographic progression showed a weak but significant correlation in pts treated with PBO (r<0.3, P<0.001 for TA-DAS(CRP), TA-DAPSA, and TA-PASDAS; r=-0.14 95% CI[0.20 to -0.09]) for MDA and remission/low disease activity status across all the outcome measures.

OP0109

IS MENTAL HEALTH COMPARABLE IN RHEUMATOID AND PSORIATIC ARTHRITIS PATIENTS? A COMPARATIVE ANALYSIS OF REAL LIFE LONGITUDINAL DATA FROM THE NOR-DMARD STUDY

B. Michelsen 1, E. Lie 1, K.M. Fagerli 1, E.K. Kristianslund 1, H.B. Hammer 1, G. Haugeberg 2, T.K. Kvien 1

1Dept. of Rheumatology, Hospital of Southern Norway Trust, Kristiansand; 2Dept. of Rheumatology, Hospital of Southern Norway Trust, Kristiansand; 3Norwegian University of Science and Technology, Trondheim, Norway

Background: Only few studies have compared health related quality of life (HRQoL) between rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients.

Methods: We included RA and PsA patients from the prospective observational multicenter Norwegian-Disease-Modifying Antirheumatic Drug (Nor-DMARD) study, who started first-time tumour necrosis factor inhibitors or DMARD naïve patients starting methotrexate between year 2000 and 2012. Continuous variables were compared using independent t-test (normally distributed data), and using ANOVA for skewed data. Logistic regression analyses were performed to compare SF-36 PCS and MCS between the RA and PsA patients at baseline and after 3 and 6 months follow-up.

Results: A total of 2735 RA and 1236 PsA patients were included. Mean (SD) age was 55.0 (13.5)/ 48.3 (12.4) years, median (25th-75th percentile) years since diagnosis was 7.9/ 6.2 years. HRQoL was better in PsA patients than in RA patients at all time points, in spite of slightly worse physical HRQoL supports the disconnect phenomenon in PsA following ADA treatment.

The severity of sonographic enthesitis is a marker of radiographic damage in PsA.

Objectives: Enthesitis and the severity of radiographic features of damage in the peripheral and axial joints in PsA.

Methods: A cross-sectional study was conducted in consecutive patients with PsA. The Modified Sonographic Enthesitis Index (MASEI) scoring system was used to quantify the extent of sonographic enthesal abnormalities in 12 enthesal sites. Total MASEI was further categorized into: bone scores (enthophyses, erosions) and soft tissue scores (structural changes, vascularization, bursitis). Radiographic joint damage in the peripheral and spine was assessed independently of the ultrasound results using the modified Steinbrocker score.

Results: 75 patients were available from the Outcomes of Treatment in PsA Study Syndicate (OUTPASS) [n=49 adalimumab; n=26 etanercept]. Mean age was 51±12 years; 61% were female; 20% (n=10/50) of adalimumab-treated patients were positive for ADAbs, but none were detected in etanercept-treated patients. Median BMI 28.9 (IQR 26.0–34.9). 20% (n=10/49) of adalimumab-treated patients were positive for ADAbs, but none were detected in etanercept-treated patients. Median BMI 28.9 (IQR 26.0–34.9).

Conclusions: The severity of sonographic enthesitis is a marker of radiographic peripheral and axial joint damage in PsA. The association was found with both erosive and bone formation lesions. These findings highlight the potential role of enthesitis in the pathogenesis of articular damage in PsA.

Disclosure of Interest: None declared

THE ASSOCIATION BETWEEN SONOGRAPHIC ENTHESITIS AND RADIOGRAPHIC JOINT DAMAGE IN PSORIATIC ARTHRITIS

A. Polacheck 1, R. Cook 2, V. Chandran 1,3, D. Gladman 1,3, L. Eder 1,4, 1 Centre for Prognosis Studies in the Rheumatic Diseases, University Health Network, Toronto; 2Department of Statistics and Actuarial Science, University of Waterloo, Waterloo; 3Department of Medicine, University of Toronto; 4Women's College Research Institute, Women's College Hospital, Toronto, Canada

Background: Enthesitis is a common clinical finding and a key pathogenic feature in psoriatic arthritis (PsA). Ultrasound is emerging as a preferred method to assess enthesitis. Little is known about the relation between the presence of enthesitis and the severity of joint damage in patients with PsA.

Objectives: Our objective was to examine the association between sonographic enthesitis and the severity of radiographic features of damage in the peripheral and axial joints in PsA.

Methods: A cross-sectional study was conducted in consecutive patients with PsA. The Modified Sonographic Enthesitis Index (MASEI) scoring system was used to quantify the extent of sonographic enthesal abnormalities in 12 enthesal sites. Total MASEI was further categorized into: bone scores (enthophyses, erosions) and soft tissue scores (structural changes, vascularization, bursitis). Radiographic joint damage in the peripheral and spine was assessed independently of the ultrasound results using the modified Steinbrocker score.

Results: 222 patients were included (58% men) with mean (s.d.) age of 55.9 (12.3) years and PsA duration of 17 (12.4) years. The modified Steinbrocker score was 15.6 (12.6). The mean modified Steinbrocker score was 18.1 (32.3), mSASSS was 1.7 (3.7) and 37% had sacroiliitis. Multivariate regression analysis found associations between higher MASEI scores and peripheral joint damage: modified Steinbrocker score (β 0.92, p < 0.0001), joint ankylosis (Odd’s Ratio (OR) 2.09, p = 0.0001) and arthritis mutilans (OR 1.73, p = 0.005). The association between MASEI scores and periostitis was of borderline statistical significance (OR 1.29, p = 0.06). Similarly, an association was found in multivariate analyses between higher MASEI scores and axial damage as measured by mSASSS (β 1.55, p = 0.0001) and sacroiliitis (OR 1.36, p = 0.02). Sub-analysis showed that the bone score was more strongly associated with radiographic damage outcomes than the MASEI soft tissue score.

Conclusions: The severity of sonographic enthesitis is a marker of radiographic peripheral and axial joint damage in PsA. The association was found with both erosive and bone formation lesions. These findings highlight the potential role of enthesitis in the pathogenesis of articular damage in PsA.

OP1012

IN PSORIATIC ARTHRITIS FATIGUE IS DRIVEN BY INFLAMMATION, DISEASE DURATION, AND CHRONIC PAIN: AN OBSERVATIONAL DANBIO REGISTRY STUDY

M. Skoogaard 1, T.S. Jørgensen 1, S. Ritzbjerg-Madsen 1, L. Coates 2, A. Egberg 3, K. Amr 1, L. Drejer 2, P. Højgaard-Jørgensen 1, J. Guidbøll-Moller 1, J.F. Merola 1, P. Frederiksen 1, H. Gudbergsen 1, L.E. Kristensen 1, 1The Parker Institute, Copenhagen University Bispebjerg and Frederiksberg, Copenhagen F; 2Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 3Department of Dermatology and Allergy, Copenhagen University Hospital Gentofte and Herlev, Hellerup, Denmark; 4Department of Rheumatology and Department of Medicine, Division of Rheumatology, Brigham and Women’s Hospital, Boston, Massachusetts, United States

Background: Fatigue has been identified as one of the most significant symptoms and an outcome of great importance to patients with psoriatic arthritis (PsA), but the association between underlying components of experienced fatigue and the disease activity and bone formation markers has been sparsely studied (1).

Objectives: To describe the degree of fatigue in a PsA population. Secondly, to explore which components of inflammation and non-inflammatory factors contribute to experienced fatigue.

Methods: The study was designed as a cross-sectional survey including patients...
Metabolic Syndrome and Liver stiffness in Psoriatic Arthritis and Psoriasis Patients: A Case-Control Study

A. Ortola1, M. Lorenzin1, G. Taditito1, F. Oliviero1, A. Hoxha1, S. Piaresico2, L. Punzi1, R. Ramonda1, 1Rheumatology Unit, Department of Medicine DIMED; 2Dermatological Clinic, University of Padova, Padova, Italy

Background: Psoriatic arthritis (PsA) and psoriasis (PsO) are commonly associated to various comorbidities, among which metabolic syndrome (MetS) has been demonstrated to be more prevalent in these groups with respect to the general population. However, few data are available regarding the comparison between PsA/PsO. Besides, a possible consequence of MetS is the development of a non-alcoholic fatty liver disease (NAFLD), which can progress to fibrosis, the latter rarely assessed in PsA/PsO.

Objectives: The aim of this case-control study was: 1) to compare prevalence of MetS in PsA and PsO 2) to evaluate the presence of liver fibrosis in these two groups using hepatic elastography.

Methods: Forty-three consecutive PsA patients classified according to CIASanillo criteria for Psoriatic Arthritis (CASPRI), and 33 consecutive PsO patients without history/manifestations of arthritis, attending the Rheumatology and Dermatology Units of University of Padua, were studied. Exclusion criteria were: conditions which may cause liver fibrosis other than NAFLD (eg viral hepatitis, autoimmune or genetic liver disease), alcohol consumption >20 grams/day, active smoking, daily use of non-steroidal anti-inflammatory drugs. Anamnestic, laboratory (cholesterol, triglycerides, uric acid, fasting glucose, insulin, albumin, transaminase) and metrological (blood pressure, waist circumference, height, weight) data were collected. MetS was defined according to the criteria of National Cholesterol Education Program's Adult Treatment Panel III report. Insuline resistance was quantified through HOMA (Homeostatic Model Assessment). All patients underwent hepatic elastography to evaluate liver stiffness; values >7 kPa were taken as indicator of liver fibrosis. PsO severity was assessed through Psoriasis area severity index (PASI). Differences in variables between PsA/PsO were compared through non parametric Mann-Whitney test, and Chi-square test for categorical variables. Correlations between variables were evaluated through Spearman test.

Results: PsA and PsO patients showed similar characteristics (mean age 60.2±8.4 vs 54.5±19.6 years, 74.4% vs 63% males, arthritis/PsO duration 12.6±8.5 vs 18.2±14.2 years). The only variables which differ in PsA/PsO groups were Body Mass Index (BMI) (25.7±5.4 vs 29.1±6.3), PASI (5.4±6.1 vs 15.2±5.2) and serum uric acid (4.9±1.5 vs 5.7±1.4 mg/dL), all higher in PsO (p-values 0.0092, 0.0355 and 0.0001 respectively). Prevalence of MetS and liver fibrosis in the 2 groups were similar: 34.9% and 30.8% in PsA vs 33.3% and 27.6% in PsO (p=ns).

Among all correlation studied, only serum uric acid, liver stiffness and PASI correlated with other variables (Table). Most interestingly, liver stiffness very well correlated with serum uric acid in PsO (p<0.0001 r=0.73).

Table. Correlations found between serum uric acid, liver stiffness and PASI with other variables studied

Conclusions: We observed a similar prevalence of MetS and hepatic stiffness in PsA and PsO. The correlation found between uric acid level and hepatic stiffness could lie on the fact that uric acid seems to favour insulin resistance, hypertension, dyslipidemia and other MetS risk factors. MetS could be therefore one of the major determinants to liver fibrosis in PsA and PsO, thus highlighting how comorbidities are not only coexisting conditions, but are strongly linked to each other and need to be treated as well as the skin and joint aspect.

LOW DOSE COMPUTED TOMOGRAPHY DETECTS MORE STRUCTURAL DAMAGE IN AXIAL SPONDYLOARTHRITIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS: RESULTS FROM THE SIAS COHORT

Background: Recently we presented the good interreader reliability and sensitivity to detect changes in a newly developed scoring system of bone formation on low dose computed tomography (LD-CT) of the whole spine in patients (pts) with Ankylosing Spondylitis (AS). Next step in the validation is the comparison with conventional radiographs (CR).

Objectives: To compare the assessment of syndesmophyte formation and growth on CR and LD-CT in pts with AS.

Methods: Pts from the SIAS (Sensitive Imaging of Axial Spondyloarthritis) cohort from Leiden and Herne were analysed. Inclusion criteria were modified NY criteria, ≥ 1 syndesmophytes on either the cervical or/and lumbar spine on CR, and ≥ 1 inflammatory lesion on MRI-spine. Pts had CR of the lateral cervical and lumbar spine and LD-CT (approximately 2–3mSv) of the entire spine at baseline and two years. Two readers independently assessed both CR and CT in separate sessions. Images were paired per patient, blinded to time order, patient information, and result of the other imaging technique. CR was assessed using the mSASSS scoring method. On CT, syndesmophytes were scored in the coronal and sagittal planes for all “corners” per view, thus scoring 8 “corners” per vertebral unit. Syndesmophytes were scored as absent (score 0), <50% of the intervertebral disc height (IVDH) (score 1), ≥50% of the IVDH but no bridging (score 2) or as bridging the IVDH (score 3). The formation of new syndesmophytes (score changes 0–1 or 2–3) and growth of existing syndesmophytes (CR score 2–3, CT 1–2 or 2–3, and growth of both combined) was calculated per vertebral corner. Consensus about each of these outcomes was defined by agreement of both readers on the same vertebral level. Data of CR and CT was compared per reader and for the consensus score.

Results: 50 patients (mean age 48.6 years; 84% male; 80% HLA-B27) were included in the analysis. The number (%) of pts with newly formed, growth or combined newly formed and growth of syndesmophytes for separate readers and consensus score are presented in table 1. In all comparisons, CT detected more patients with progression. This is especially aparent in case of growth and for cut-offs of a higher number of (newly formed or growth of) syndesmophytes per patient. E.g. with the strictest comparison the consensus score for both CR and CT, 30% of the patients show bony proliferation (newly formed and growth) at ≥ 3 sites on CT compared with only 6% on CR.

Conclusions: LD-CT covering the whole spine, is a more sensitive method for assessing the formation and growth of syndesmophytes than CR which is limited to cervical and lumbar spine in pts with AS and is a promising method for assessment for clinical research.
BONE MARROW OEDEMA IN SACROILIAC JOINTS OF YOUNG ATHLETES SHOWS MOST FREQUENTLY IN THE POSTERIOR INFERIOR ILIUM

U. Weber 1, A.G. Jurik 2, A. Zejden 2, E. Larsen 3, S.H. Jørgensen 3, K. Rufibach 4, C. Schiolldan 4, S. Schmidt-Olsen 4, 1University of Southern Denmark, Odense; 2Aarhus University, Aarhus; 3North Denmark Regional Hospital, Hjørring, Denmark; 4F Hoffmann-La Roche, Basel, Switzerland

Background: Low grade bone marrow oedema (BMO) was reported in the sacroiliac joints (SIJ) of up to 25% of healthy individuals and mechanical back pain patients, challenging the imaging discrimination from early spondyloarthritides (SpA) [1]. Potential explanations range from mechanical stress lesions to vascular pain patients, challenging the imaging discrimination from early spondyloarthritis.

Objectives: To determine BMO frequency and anatomical distribution in 8 SIJ (SpA) regions in young athletes. The sample consisted of 2 cohorts of 20 healthy hobby runners (HR) and 22 professional ice hockey players (IP). The sample consisted of 2 cohorts of 20 healthy hobby runners (HR) and 22 professional ice hockey players (IP).

Methods: MRI scans were assessed for BMO independently by 3 blinded readers (AGJ, AZ, 1/3) of readers indicating ≥2/3 of readers.

Results: In the 2 cohorts of young athletes, the presence of BMO was highly predictive of radiographic progression (OR=4.85 [95% CI: 2.95–7.97]) together with a younger age (OR=0.97 [95% CI: 0.94–0.99]) and longer symptom duration (OR=1.40 [95% CI: 1.04–1.89]). Of the 365 patients with complete data, the net % patients who switched from nr-axSpA to r-axSpA after 5 years ranged from 2.0% to 13.5% according to the modified New York criteria (grade 0 to 4 per joint). A mean of two readers score for each joint was used.

Conclusions: In young male professional and amateur athletes, BMO showed on average in 3–4 SIJ quadrants. The posterior lower ilium was the SIJ region most frequently affected by BMO. These findings in healthy controls may help refine thresholds for a positive SIJ MRI in early SpA.

IMPACT OF RADIOGRAPHIC DAMAGE IN THE SACROILIAC JOINTS ON FUNCTION AND SPINAL MOBILITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE GERMAN SPONDYLOARTHRITIS INCEPTION COHORT

M. Protopopov 1, J. Sieper 1, H. Habel 1, J. Listing 1, M. Rudwaleit 1, D. Reddubiyi 1, 1Department of Gastroenterology, Infectiology and Rheumatology, Charité Universitätsmedizin Berlin; 2German Rheumatism Research Centre, Berlin; 3Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany

Background: It has been shown in the past that the spinal mobility in patients with axial spondyloarthritis (axSpA) is associated with spinal structural damage, disease activity parameters and spinal inflammation [1]. The impact of radiographic damage in the sacroiliac joints on functional parameters in patients with axial spondyloarthritis has not been investigated so far.

Objectives: To analyze the association between radiographic sacroiliitis and parameters of the functional status and spinal mobility in patients with axSpA.

Methods: Altogether 210 patients with definite axSpA (115 with radiographic and 96 with non-radiographic axSpA) from the German Spondyloarthritides Inception Cohort (GESPiC) were included in the current study. Radiographs of sacroiliac joints were obtained at baseline and after 2 years of the follow up and were scored by two trained readers according to the conventional grading system of the modified New York criteria (grade 0 to 4 per joint). A mean of two readers score for each joint and a sum score for both SIJ were calculated for each patient, giving a total sacroiliac damage score between 0 and 8.

Results: In the longitudinal mixed model analysis that was corrected for the dependencies between the two time-point values of each individual and adjusted for the structural damage in the spine (modified Stoke Ankylosing Spondylitis Spine Score - mSASSS), disease activity (the Bath Ankylosing Spondylitis Disease Activity Index – BASDAI) and level of C-reactive protein – CRP, and sex, the BMD in the sacroiliac joints associated with a decrease in the BASDAI by 0.10 (95% CI 0.01–0.19) and the BASMI: β=0.12 (95% CI 0.03–0.21), respectively – table. These data indicate that change by one radiographic sacroilitis grade in one sacroiliac joint is associated with a BASFI/BASMI worsening by 0.10/0.12 points independently of structural damage in the spine and disease activity. Assuming linear association, progression of radiographic sacroilitis from grade 0 bilaterally to grade 4 bilaterally would result in a worsening by 0.8 points in BASFI and 0.96 points in BASMI. Sensitivity analysis performed in radiographic and non-radiographic axSpA subgroups provided similar results for both outcomes.

Conclusions: Radiographic damage in the sacroiliac joints may have an impact,
Although small, on spinal mobility and physical function in patients with axial SpA independently of structural damage in the spine and disease activity.

OP0119 EVALUATION OF THE PREDICTIVE VALIDITY OF THE ASAS AXIAL SPONDYLOARTHRITIS CRITERIA IN THE DESIR COHORT

B. Meghnathi1, A. Etcheto1, A. Saraux2, M. Dougados1, A. Molto.1 1Paris Descartes University, Medicine Faculty; APHP, Rheumatology B Department, Cochin Hospital, Paris, 2La Cavale Blanche Hospital, Rheumatology and Université Bretagne Occidentale, Brest, France

Background: The face validity1 and cross-sectional external validity2 of the Assessment of SpondyloArthritis International Society (ASAS) criteria for axial spondyloarthritis (axSpA) and its arms has been already confirmed in previous studies. However, so far, only one study3 has reported data regarding the predictive validity of such criteria after 4 years of follow-up.

Objectives: To evaluate the predictive validity of the ASAS criteria and its arms after 5 years of follow-up. The predictive validity of the other axSpA sets of criteria (Amor, ESSG and mNY) was also evaluated.

Methods: Patients: This analysis was performed on the DESIR cohort. A total of 708 adult (≥18 and <50 years) patients presented with inflammatory back pain suggestive of axSpA (according to the rheumatologist’s conviction of ≥5/10) for >3 months but <3 years duration. They were followed up every 6 months for the first 2 years and then yearly up to 5 years. Starting from month 24, as per protocol, patients could be excluded from the cohort in case another diagnosis (different from SpA) was made.

Methods: The gold standard for this analysis was the diagnosis of axSpA according to the rheumatologist at 5 years of follow-up. For this analysis, patients were considered as axSpA, if the rheumatologist at 5 years with a conviction of ≥7/10 for an axSpA diagnosis. Conversely, patients excluded as per protocol due to another diagnosis or patients with a rheumatologist conviction at 5 years of ≤3/10 for axSpA were considered as Non-axSpA. The set of criteria collected at baseline (ASAS, and its arms, Amor, ESSG and mNY: fulfilled/not fulfilled) were tested against the Rheumatologist’s axSpA diagnosis (fulfilled/not fulfilled) after 5 years of follow-up. Predictive validity of all sets of criteria at baseline was evaluated by the positive predictive value (PPV).

Results: In total, among the 708 patients included in the DESIR cohort at baseline, data on Rheumatologists diagnosis at 5 years was available in 454 patients; amongst them, 352 (77.5%) had an axSpA diagnosis according to the rheumatologist. Among these 352 patients, 245, 300, 291 and 88 patients fulfilled the ASAS criteria for axSpA, Amor, ESSG and modified NY criteria’s respectively. Figure 1 shows the PPV (95% CI) of the different sets of criteria below.

Conclusions: Predictive validity of the ASAS criteria for axSpA (including both arms) at 5 years was excellent; it is worth noting that the performances of the other criteria were also very good.

OP0120 THE ROLE OF SMOKING IN THE DEVELOPMENT AND PROGRESSION OF STRUCTURAL DAMAGE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: THE PRELIMINARY RESULTS OF A SYSTEMATIC REVIEW AND META-ANALYSIS

S. Akar 1, Y.C. Kaplan2, S. Ecemis 1, E.K. Arslan2, O. Gercek 1, D. Solmaz 1
1Rheumatology; 2Pharmacology, Izmir Katip Celebi University Faculty of Medicine, Izmir, Turkey

Background: Smoking may constitute a major risk factor for not only disease susceptibility but also disease severity in patients with ankylosing spondylitis (AS). Some previous cross-sectional and longitudinal studies suggested that smoking may be associated with cumulative spinal radiographic damage and regarded it as an independent predictor of spinal radiographic progression.

Objectives: The objective of this study is to determine whether smoking is associated with the cumulative radiographic spinal structural damage and radiographic progression in AS patients. In order to reach this objective, we conducted a systematic review and meta-analysis of the available studies to-date.

Methods: An electronic search was conducted from inception to June 21 2016 in EMBASE, MEDLINE, PubMed, Cochrane Central Register of Controlled Trials databases. Cross-sectional and longitudinal cohort studies investigating the association between smoking and cumulative spinal structural damage or radiographic progression were included. The outcome of interest were the presence of syndesmophytes in cross-sectional studies and radiographic progression in longitudinal studies. Two independent reviewers carried out the screening process. The Quality assessment was done using The Agency for Healthcare Research and Quality (ARHQ) checklist and Newcastle-Ottawa scale. Authors of potential relevant studies were contacted for the unpublished data. Data from eligible cross-sectional studies were extracted and arranged in a 2x2 table. The odds ratios (ORs) and 95% confidence intervals (CIs) for the dichotomous outcome of interest were computed. Random-effects method was used to combine the outcome data in Comprehensive Meta Analysis Software Version 3.3.070.

Results: The combined data of eight eligible cross-sectional studies for the assessment of association between smoking and cumulative spinal structural damage suggested a significant association (OR, 2.02; 95% CI 1.51–2.70)

VALIDATION OF MRI STRUCTURAL LESIONS USING COMPUTED TOMOGRAPHY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

W.P. Maksymowych, 1,2 D. Louelle,3 M. Raynal4, J. Melchior5, M.-A. D’Agostino,6 J. Paschke,2 R.G. Lambert. 1 Medicine, University of Alberta; 2CaRE Arthritis, Edmonton, Canada; 3Rheumatology, CHRU de Nancy; 4Rheumatology, CHRU de Nancy, Vandoeuvre les Nancy; 5Rheumatology, Université Paris Ouest, Paris, France; 6Radiology, University of Alberta, Edmonton, Canada

Background: MRI can detect both inflammatory and structural lesions in the sacroiliac joints (SIJ) of patients with axial SpA. However, standard MRI sequences do not directly depict bone and the appearance of erosion may vary according to the presence/absence of inflammation. Consequently, further validation using an accepted gold standard, namely, computed tomography (CT), is essential.

Objective: We aimed to assess the detection of structural lesions in the SIJ by MRI using CT as the gold standard.

Methods: CT scans from 44 patients (26 females, mean age 49.4 years, mean symptom duration 9.1 years) were reconstructed in the semicoronal plane parallel to the superior border of the sacrum, as for conventional MRI evaluation of the SIJ, and scoring of lesions by CT was confined to this plane. Structural lesions were scored in consecutive slices in SIJ quadrants (erosion, sclerosis) or SIJ halves (ankylosis) on a dichotomous basis (present/absent) using the same anatomical principles for scoring SIJ quadrants as developed for the SPARCC MRI SIJ inflammatory and structural scores. T1W MRI scans of the SIJ from the same cases conducted at the same time as CT were assessed independently for structural lesions (erosion, fat, backfill, ankylosis, sclerosis) blinded to CT assessments using the SPARCC method. Agreement between CT and MRI was assessed by kappa statistics. Sensitivity/specificity of MRI for CT lesions was calculated. The primary analysis was based on lesions detected concordantly by both readers at the level of the individual iliac/sacral joint surface (erosion, sclerosis) or the individual joint (ankylosis, backfill).

Results: With CT as gold standard and a lesion defined as being present when recorded in the same location on at least 1 coronal slice by both readers, MRI-defined ankylosis had 56.3% sensitivity and 100% specificity for CT ankylosis (Table). For erosion, sensitivity and specificity of MRI was 81.3% and 96.2%, and for sclerosis, sensitivity and specificity of MRI was 50% and 97%, respectively. Agreement between CT and MRI for erosion increased when the cut-off for presence of a lesion was set at 2 slices but only marginally for sclerosis, even when the cut-off for presence of a lesion was set at 3 slices. Lesions observed on CT corresponding to backfill on MRI were ankylosis, erosion, and sclerosis, in 66.7%, 66.7%, and 80% of backfill lesions, respectively.

Conclusions: Ankylosis and erosion on MRI correspond closely with the same type of lesion observed on CT. Both new bone formation and erosion are frequently evident on CT at locations where backfill is observed on MRI supporting the hypothesis that backfill is an intermediary tissue between erosion and ankylosis.

VENOUS THROMBOEMBOLISM IN SYSTEMIC SCLEROSIS: PREVALENCE, RISK FACTORS AND IMPACT ON SURVIVAL

S.R. Johnson1, N. Hakami2, Z. Ahmad1, D.N. Wijeysundera3, 1University of Toronto, Toronto, Canada; 2King Fahad Central Hospital, Jizan, Saudi Arabia; 3Anesthesia, University of Toronto, Toronto, Canada

Background: Systemic sclerosis (SSc) is characterized endothelial dysfunction and vasculopathy, which may result in thrombosis. Venous thromboembolism (VTE) is a vascular phenomenon that includes deep vein thrombosis (DVT) and pulmonary embolism (PE).

Objectives: To evaluate the epidemiology of VTE in SSc, specifically cumulative incidence, risk factors and impact of VTE on survival.

Methods: We conducted a cohort study of patients who fulfilled the ACR–EULAR classification criteria for SSc attending the Toronto Scleroderma Program 1970–2017. DVT was defined as the presence of thrombus on doppler ultrasound of either upper or lower extremity. PE was defined as the presence of thrombus on CT angiogram of the thorax. Time to all-cause mortality was evaluated in Kaplan Meier and Cox models.

Results: 1181 subjects (971 (82%) female, 210 (18%) male) were included. There were 40 (3.4%) VTE events. The cumulative incidence of VTE was 2.7 (95% CI 1.9, 3.7) per 1000 patient years. The presence of ILD, PAH, Scl70 antibody, anticardiolipin antibody, coronary artery disease, diabetes mellitus and PVD occurred more frequently in subjects who developed VTE.

*Denotes statistical significance.

On multivariable logistic regression PAH (OR 3.77 (95% CI 1.83, 8.17), Scl70 antibodies (OR 2.45 (95% CI 1.07, 5.30), anticardiolipin antibodies (OR 5.70 (95% CI 1.16, 21.2) and PVD (OR 5.31 (95% CI 1.99, 12.92) were independent predictors of VTE. Subjects with ILD more frequently experienced DVT (RR 2.85 (95% CI 1.08, 7.54) but not PE (RR 1.82 (95% CI 0.89, 3.70). There were 440 deaths. There was no significant difference in survival between those with and without VTE (HR 1.6 (95% CI 0.70, 1.92). Only the presence of ILD (HR 1.54 (95% CI 1.27, 1.88) or PAH (HR 1.35 (95% CI 1.10, 1.65) remained independent predictors of mortality.

Figure 1. Kaplan Meier survival curves of SSc subjects with and without venous thromboembolism. Log rank test p=0.54

Conclusions: The risk of VTE in SSc is not increased, as the incidence of VTE in SSc is comparable to the general population. The presence of PAH, PVD, Scl70 and anticardiolipin antibodies are risk factors for VTE in SSc. VTE does not independently affect SSc survival.

Clinical and therapeutic news in systemic sclerosis
PREDICTION OF PROGRESSIVE SKIN THICKENING IN EARLY DIFFUSE SYSTEMIC SCLERODERMA OBSERVATIONAL STUDY (ESOS)

A. Herrick1, S. Peytrignet1, X. Pan1, R. Hesselstrand2, L. Mouthon3, E. Brown1, L. Czarlik4, J.H. Distler5, G. Distler6, K. Fligelstone1, W. Gregory1, R. Ochiel7, A. Silman8, M. Vork9, L. Lunt1, C. Denton4, 1University of Manchester, Manchester, United Kingdom; 2Lund University, Lund, Sweden; 3Université Paris Descartes, Paris, France; 4University of Pécès, Pécs, Hungary; 5University of Erlangen-Nuremberg, Erlangen, Germany; 6University Hospital Zurich, Zurich, Switzerland; 7University College London, London, 8University of Oxford, Oxford, United Kingdom; 9Nijmegen University, Nijmegen, Netherlands

Background: ESOS (European Scleroderma Observational Study) was a prospective observational study of early diffuse cutaneous systemic sclerosis, recruiting from 50 centres in 19 countries and thus providing a unique opportunity to study parameters of disease progression at regular intervals.

Objectives: To describe the characteristics of patients with progressive skin thickening and derive prediction models for progression over 12 months.

Methods: Duration of skin thickening and autoantibody status (anti-topoisomerase-1[anti-Scl-70], TOPO, anti-RNA polymerase III[Pol3], antitromere[ACA]) were documented. The modified Rodnan skin score (mRSS) was recorded 3-monthly for up to 2 years after baseline. The main outcome was the progression of mRSS. Progressive patients (“progressors”) had to meet a 5-unit and 25% increase in their mRSS within the first 12 months of follow-up. Features of progressors vs. non-progressors were compared using the Fisher or Kruskal-Wallis test (for categorical and continuous variables), as were progression parameters between autoantibody groups. Logistic models were fitted to predict progression and, using ROC curves, were compared based on AUC, accuracy, and positive predictive value (PPV).

Results: 326 patients were recruited, with median disease duration of 11.9 months. During the first 12 months, 66 patients (20.3%) progressed, 227 (69.6%) did not and 33 (10.1%) could not have their status assessed. At baseline, progressors had shorter disease duration than non-progressors: 8.1 months vs. 12.6 months (p<0.001). Progressors started with a lower mRSS, median 19 units vs. 21 for non-progressors (p=0.030). 124 patients were TOPO+, 50 were Pol3+, 20 were ACA+, 2 were TOPO+/ACA+ and 68 had none. Pol3+ patients had a higher mRSS peak (35 units vs. 12.6 months (p=0.001). Progressors started with a lower mRSS, median 19 units vs. 21 for non-progressors (p=0.030). 124 patients were TOPO+, 50 were Pol3+, 20 were ACA+, 2 were TOPO+/ACA+ and 68 had none. Pol3+ patients had a higher mRSS peak (35 units vs. 21.4) and did so earlier (median 17.9 months vs. 23.1 months overall [p=0.214]).

Using an mRSS 22 cutoff point to predict progression in the ESOS cohort (as suggested in the literature) would yield a PPV of 24.3%, a weak improvement from the observed 20.3% share of progressors. A first model (Model A, with mRSS, duration of skin thickening and their interaction) had an accuracy of 60.9%, AUC of 0.71 and PPV of 41%. Model B, the model reached an accuracy of 71%, AUC of 0.71 and PPV of 41%.

Conclusions: 1. Patients with shorter disease duration and a lower mRSS have a higher likelihood of being progressors, with a trade-off between the two. 2. Pol3+ patients experience higher mRSS peaks and tend to reach them earlier. 3. Two prediction models for progressive thickening were derived. The advantage of having two is that Model B, while more accurate and useful in identifying high-risk patients in clinical practice, risks being too restrictive for patient selection into trials and may over-represent Pol3+ patients.

TREATMENT WITH CYCLOPHOSPHAMIDE FOR SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE DOES NOT IMPROVE SURVIVAL AFTER 12 YEARS OF FOLLOW UP

E.R. Volkmann1, M. Sim1, D.P. Tashkin1, D. Khanna2, P.J. Clements1, M. Roth1, D. Furst1, A. Pickney3, E. Goldmuntz4, L. Keyes-Elstein5, R. Elashoff1, K. Sullivan6 on behalf of SLS I working group. 1University of California, Los Angeles, Los Angeles; 2University of Michigan, Ann Arbor; 3Rh Federal Systems, Inc., Chapel Hill; 4DAIT, Naid/Nih, Bethesda; 5Duke University, Durham, United States

Background: Treatment with cyclophosphamide (CYC) is associated with short-term improvements in lung function, dyspnea, and radiographic fibrosis in patients with systemic sclerosis-related interstitial lung disease (SSc-ILD). However, the effects of CYC therapy on long-term morbidity and mortality outcomes are unknown.

Objectives: To determine whether 1 year of treatment with CYC for SSc-ILD affects long-term morbidity and mortality in patients who participated in the Scleroderma Lung Study (SLS) 1.1

Methods: SLS I randomized 158 SSc-ILD patients from 13 US SSc centers to 1 year of oral CYC versus placebo. The primary endpoint was the change in FVC% predicted over 1 year. Twelve years after the study commenced, each study center contacted enrolled patients or designated surrogates to assess the following: mortality, cause of mortality, development of organ failure, need for transplant and functional status. We used counting process cox proportional hazard modeling to determine the variables associated with survival. The model findings were validated using a joint model of longitudinal and survival data. We also tested the model using long-term follow-up data from SLS II (CYC vs. Mycophenolate).

Results: Nearly half of all SLS I patients (43%) died during the follow-up period, and only 24% remained alive in the absence of organ failure. The median follow up period for all patients was 8 years. Where known, the cause of death was attributable most often to SSc. Among patients who developed malignancy (N=13), a similar proportion were treated with CYC compared with placebo. The most common type of organ failure was respiratory failure (N=31 of 33 organ failures) defined as the need for supplemental oxygen therapy (N=29) and/or lung transplantation (N=3). There was no difference in the time to death (Figure 1), or time to organ failure, or time to malignancy in patients randomized to CYC versus placebo. The Cox model identified the following variables as the most important predictors of mortality: baseline skin score (HR 1.033; P=0.0038), age at randomization (HR 1.056; P=0.0001), and the course of the FVC from baseline to 24 months (HR 0.975; P=0.0215). The course of the FVC was a better predictor of mortality than the baseline FVC. The joint model identified the same variables associated with mortality.

Conclusions: Treatment with 1-year of oral CYC for SSc-ILD does not decrease long-term mortality, organ failure or malignancy compared with placebo. In addition to standard traditional mortality risk factors in SSc-ILD (increased skin score and advanced age), this study found that progression of the FVC over 2 years was a more important predictor of mortality than the baseline FVC. These findings suggest that early changes in surrogate measures of SSc-ILD progression may have important effects on long-term outcomes.

Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.2488

MORTALITY IN PATIENTS WITH DERMATOMYOSITIS/POLYMYSITIS IN A CHINESE MEDICAL CENTRE

X. Yang. Peking University First Hospital, Beijing, China

Objectives: To investigate the mortality and the causes of death in Chinese patients with dermatomyositis (DM) or polymyositis (PM).

Methods: We collected the clinical data of all DM/PM patients in Rheumatology CENTRE

Conclusions: Treatment with 1-year of oral CYC for SSc-ILD does not decrease long-term mortality, organ failure or malignancy compared with placebo. In addition to standard traditional mortality risk factors in SSc-ILD (increased skin score and advanced age), this study found that progression of the FVC over 2 years was a more important predictor of mortality than the baseline FVC. These findings suggest that early changes in surrogate measures of SSc-ILD progression may have important effects on long-term outcomes.

Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.2488
Results: A total of 226 DM and 54 PM cases were included and the mean age of onset was 49.9±14.8 years for DM and 48.1±17.1 years for PM. The median follow-up duration was 40.6 (11.6–77.6) months. Among 267 patients who were successfully traced, 66 patients died. Infection (50.0%) was the leading cause of death followed by malignancy (15.7%), and interstitial lung disease (ILD) (9.1%). The overall age and sex adjusted SMR was 9.0 (95% CI: 6.8–11.2) for DM, and 5.0 (95% CI: 2.4–7.5) for PM. The overall age and sex adjusted SMR of DM/PM patients with ILD was 8.4 (95% CI: 5.8–11.0), and the SMR of the patients with malignancy was 14.9 (95% CI: 8.5–21.2). The YLL of women and men were 37.5 and 28.4 years respectively for DM, and 24.3 and 12.0 years respectively for PM (Table1). The 10-year survival of patients with ILD or malignancy was significantly worse than those without ILD or malignancy respectively (Figure 1 and 2). The independent predictors of mortality for DM were age of disease onset, respiratory muscle involvement and malignancy; and the independent predictor of mortality for PM was age at disease onset (Table2).

Table 1. The standardized mortality ratio (SMR), life expectancy (LE) and years of life lost (YLL).

Conclusions: Mortality of DM/PM patients in China is substantial, especially in females, and those with ILD or malignancy. Infection was the leading cause of death. Patients with older age at onset, respiratory muscle involvement, ILD, and malignancy need to be paid more attention.

OP0126 A PHASE 2 STUDY OF SAFETY AND EFFICACY OF ANABASUM (JBT-101) IN SYSTEMIC SCLEROSIS

R. Spiera1, L. Hummers2, L. Chung3, T. Frech4, R. Domsic5, D. Furst6, J. Gordon4, M. Mayes3, B. White3, 1Hospital for Special Surgery, New York City; 2Johns Hopkins, Baltimore; 3Stanford, Palo Alto; 4University of Utah, Salt Lake City; 5University of Pittsburgh, Pittsburgh; 6Arthritis Association of Southern California, Los Angeles; 7University of Texas, Houston; 8Boston University, Boston; 9Corbus Pharmaceuticals, Inc., Norwood, United States

Background: Anabasum (JBT-101) is a synthetic, oral, non-immunosuppressive, preferential CB2 agonist. It inhibits onset and activates resolution of innate immune responses in animal models of systemic sclerosis (SSc).

Objectives: Evaluate safety and efficacy of anabasum in SSc.

Methods: A double-blind, randomized, placebo (PBO)-controlled Phase 2 trial dosed 42 diffuse cutaneous SSCs with disease duration <6 years on stable medication including immunosuppressive drugs. Subjects received anabasum 5 mg OD, 20 mg OD, or 20 mg BID on Days 1–28, then 20 mg BID on Days 29–84, or PBO on days 1–84. Subjects were followed off study drug on Days 85–113. The primary safety outcome was treatment-emergent adverse events (TEAEs). The primary efficacy outcome was improvement in ACR Combined Response Index in diffuse cutaneous Systemic Sclerosis (CRIS) score, combined anabasum group vs PBO, Days 29–113 (end of weeks 4–16). The five domains of the ACR CRIS are the modified Rodnan skin score, HAQ-DI, patient and physician global assessments, and FVC % predicted.

Results: Of 42 dosed subjects, 27 (64%) received anabasum and 15 (36%) received PBO. Three anabasum subjects withdrew; 1 (3.7%) for a TEAE of moderate bone pain; 1 withdrew consent; and 1 by physician decision. One PBO subject withdrew consent. Baseline demographic and CRIS domain scores were similar except slightly more anabasum subjects used background immunosuppressive drugs (93% versus 80%, anabasum vs PBO). Seventeen (63%) anabasum subjects had 66 TEAEs, and 9 (60%) PBO subjects had 35 TEAEs. There were no serious, severe, or unexpected TEAEs related to anabasum. Severity and relationship of TEAEs to study drug were similar in both groups. The most frequent TEAEs by MedDRA system (% anabasum vs % PBO) were: nervous system (37% vs 27%); general disorders (30% vs 7%); gastrointestinal (22% vs 20%); infections (22% vs 20%); musculoskeletal (22% vs 13%); and investigations (0% vs 20%). The most frequent TEAEs in anabasum subjects were dizziness (22%) and fatigue (19%) which were usually mild. Anabasum subjects had greater improvement in ACR CRIS scores than PBO subjects (mixed model repeated measures analysis, p=0.044, 1-sided). The median ACR CRIS scores at the end of Weeks 4, 8, 12, and 16 (anabasum vs PBO) were 3.0% vs 1.0%, 19.0% vs 1.0%, 27.5% vs 1.0%, and 33.0% vs 1.0%, respectively. Among anabasum subjects, 50% had ACR CRIS >20% after 8 weeks of dosing. The individual domains of the ACR CRIS score showed greater improvement, with improvement that reached minimal important differences in several domains, and less worsening in anabasum vs PBO groups. Anabasum subjects had greater improvement in SSC skin symptoms and itch. Plasma metabololipidic profiles showed anabasum, not PBO, shifted lipid mediator production to increase pro-resolving vs pro-inflammatory lipid mediators.

Conclusions: Anabasum provided significant and medically meaningful efficacy in SSc as assessed by the ACR CRIS score and its individual domains and had acceptable safety and tolerability in this Phase 2 trial. These data support continued clinical development of anabasum for the treatment of SSc.

Background: Systemic sclerosis (SSc) is an inflammatory autoimmune disease characterized by fibrosis and small vascular involvement in the skin, lungs, heart and gastrointestinal (GI) tract. The esophagus is the most frequently involved GI tract disorder. Although the small intestinal involvement such as malabsorption and pseudo-obstruction is less common, it has been related to morbidity and mortality of SSc patients. We previously reported a close correlation between the...
esophageal diameter and the small intestinal clearance (SIC) (EULAR 2011). We also suggested that anti-centromere antibodies (ACA) are an important factor of esophageal dilatation in SSC patients (EULAR 2010). However, changes of small intestinal involvement during long-term follow-up have not yet been defined.

**Objectives:** The aim of this study was to evaluate a correlation between the small intestinal involvement and clinical features in SSC patients during ten years follow-up.

**Methods:** Fifty-five patients with a definite diagnosis of SSC (52 females and 3 males with an age range of 59.4 years (range 29–77 years) were included in the study. Thirteen (23.6%) patients were classified as diffuse SSC and 42 (76.4%) as limited SSC. The SSC was classified according to barium meal reach at 30 min after intake; grade 1 (∼2/3 of the whole small intestine), grade 2 (1/3–2/3), grade 3 (∼1/3), grade 4 (the duodenum). The SSC grade was classified as follows; grade 1 and 2 grade or grade non-increase during follow-up was classified as “no progressive”, and grade 3 and 4 grade or increase as “progressive”. All SSC patients were evaluated the items as used for 2013 ACR/EULAR criteria.

**Results:** The mean durations of follow-up period were 9.5±6.0 years. The number of SSC patients in each SIC grade at the initial evaluation and the end of follow-up were as follows; grade 1: initial vs end; 23 vs 24, grade 2: 20 vs 9, grade 3: 10 vs 16, grade 4: 2 vs 6. The SIC change “progressive” was 40.0% of SSC patients. Positive correlation between the esophageal diameters and the SIC grade was observed in SSC patients at the initial evaluation (r=0.61 p<0.01) and the end of follow-up (r=0.71 p<0.01). The esophageal diameters at the initial evaluation were significantly wider in SIC “progressive” group than in “non-progressive” group (non-progressive vs progressive; 21.8±6.5 vs 30.9±8.6 mm, p<0.0001). The frequencies of SSC patients with ACA-positive and scleroderma were higher but with puffy fingers were lower in SIC “progressive” group than in “non-progressive” group (progressive vs non-progressive; 24.2 vs 59.1%, p=0.009; 33.3 vs 63.6%, p=0.03; 73.8 vs 95.6%, p=0.003). The prevalence of pitting scarring and Interstitial lung disease were tended to be higher in SIC “progressive” compared to SIC “non-progressive” group (non-progressive vs progressive; 15.6 vs 36.4%, p<0.07; 21.1 at 46.5%, p=0.06).

**Conclusions:** The present study demonstrated that the progression of small intestinal involvement was associated with esophageal dilatation at the initial evaluation during long-term follow-up of SSC patients. Our findings also suggested that ACA and skin thickening of the fingers were important factors of small intestinal involvement in SSC patients. The SIC may be a useful tool for the assessment of GI tract involvement in SSC patients during long-term follow-up.

MEPOLIZUMAB FOR THE TREATMENT OF PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGITIS: A PHASE III RANDOMISED, PLACEBO-CONTROLLED TRIAL

M.E. Wechsler 1, P. Akuthota 2, D. Jayne 3, P. Khoury 4, A. Kilian 5, C. Langford 6, P. Merkel 7, F. Moses 8, J. Specks 9, M.C. Cid 10, R. Lugmani 11, J. Brown 12, S. Malliet 13, R. Philipson 14, S.W. Yancey 15, J. Steinfeld 16, P.F. Wellers 17, G. Gleich 18, 1National Medical Health, Denver; 2UC San Diego Health, La Jolla, United States; 3University of Cambridge, Cambridge, United Kingdom; 4NIAID, Bethesda, 5Cleveland Clinic, Cleveland; 6University of Pennsylvania, Philadelphia, United States; 7Schlegel-Holtz-Mitte, Neumünster, Germany; 8Mayo Clinic, Rochester, United States; 9Hospital Clinic University of Barcelona, Barcelona, Spain; 10University of Oxford, Oxford; 11GSK, Uxbridge; 12Trizell Ltd, Oxford, United Kingdom; 13GSK, Research Triangle Park, 14Beth Israel Deaconess Medical Center, Boston; 15University of Utah Health, Salt Lake City, United States

Background: Mepolizumab reduces blood eosinophils with concomitant clinical improvement in some hypereosinophilic syndromes and eosinophilic asthma.

Objectives: To investigate the efficacy and safety of mepolizumab in patients with eosinophilic granulomatosis with polyangiitis (EGPA, Churg-Strauss).

Methods: We conducted a Phase III, randomised, placebo-controlled, double-blind, parallel group, multi-centre study (NCT02020889) in patients with EGPA and a history of relapsing or refractory disease on stable therapy with prednisolone/prednisone >7.5–50mg/day or with additional immunosuppressive therapy for >4 weeks. Patients were randomised 1:1 to receive mepolizumab 300mg or placebo subcutaneously, in addition to standard of care, every 4 weeks for 52 weeks. After Week 4, glucocorticoid dose could be tapered, per physician judgment, according to a suggested standard of care protocol. Co-primary endpoints (intent-to-treat [ITT] analysis) were accrued duration of remission (Birmingham Vasculitis Activity Score [BVAS]=0, prednisolone/prednisone dose <4mg/day) over 52 weeks; and the proportion of patients in remission at both Weeks 36 and 48. Secondary endpoints included average glucocorticoid dose during Weeks 49–52 and time to first EGPA relapse. Safety was also assessed.

Results: The ITT population included 136 randomised patients (mepolizumab n=68, placebo n=68). Baseline characteristics were similar between groups. Duration of remission accrued over 52 weeks was significantly prolonged with mepolizumab vs placebo (odds ratio: 5.91 [95% confidence interval [CI]: 2.68,13.03]; p<0.001); a significantly higher proportion of patients were in remission at Weeks 36 and 48 (32% vs 3%, odds ratio: 16.74 [95% CI: 3.61,77.56]; p<0.001). Significant reductions in average daily prednisolone/prednisone dose during Weeks 49–52 were seen with mepolizumab vs placebo (odds ratio: 0.2095% CI: 0.09,0.41]; p<0.001). Median (range) prednisolone/prednisone dose during Weeks 49–52 was 5.0 (0.0–113.4)mg/day in the mepolizumab group and 10.0 (0.0–223.8)mg/day in the placebo group. Time to first EGPA relapse was significantly longer with mepolizumab vs placebo (hazard ratio: 0.32 [95% CI: 0.21,0.50]; p<0.001). Rates of adverse events (AEs) and serious AEs were similar for mepolizumab and placebo.

Conclusions: Treatment with mepolizumab significantly increased the likelihood and duration of remission, while reducing glucocorticoid use, in patients with EGPA, with a safety profile consistent with previous studies in severe asthma and EGPA. This demonstrates consistent and meaningful clinical benefits of mepolizumab in patients with EGPA.

OPTIMAL DOSE OF TOCILIZUMAB FOR THE TREATMENT OF GIANT CELL ARTERITIS: EFFICACY, SAFETY, AND EXPOSURE-EFFICACY ANALYSIS FROM GIACTA

Background: GIACTA, a randomized, double-blind, placebo-controlled trial, evaluated the efficacy and safety of tocilizumab (TCZ), an IL-6 receptor-a inhibitor, in patients with giant cell arteritis (GCA).1,2 Objectives: Secondary analyses to evaluate the differential efficacy and safety of TCZ between patients with new-onset and relapsing GCA and to evaluate the TCZ exposure-efficacy relationship at week 52 of the trial.

Methods: Patients aged >50 years with active GCA were randomly assigned 1:1:2:1 to short-course prednisone (PBO+26), long-course prednisone (PBO+52) (26-week or 52-week prednisone taper + weekly subcutaneous [SC] placebo, respectively), weekly (TCZ-QW) or every-other-week (TCZ-Q2W) SC TCZ 162 mg + 26-week prednisone taper. Subgroup analysis was performed by disease-onset status (new-onset vs relapsing) to evaluate the proportions of patients in sustained remission at week 52 and time to flare. The impact of TCZ exposure, categorized into high, medium and low tertiles, on time to flare was evaluated across all patients in all treatment arms.

Results: Randomization included 251 patients, 119 (47%) with new-onset and 132 (53%) with relapsing GCA, distributed evenly across groups. Higher proportions of patients achieved sustained remission in the TCZ vs placebo groups regardless of disease onset (new-onset, relapsing–TCZ-QW: 59.6%, 52.8%; TCZ-Q2W: 57.7%, 47.6%; PBO+26: 21.7%, 7.4%; PBO+52: 21.7%, 14.3%, respectively). Patients with relapsing disease at baseline were in relapse-free remission longer and thus had lower risk for flare (hazard ratio) when treated with TCZ-QW than TCZ-Q2W. Hazard ratio (99% CI) for flare vs PBO+26 was 0.23 (0.09–0.61) for TCZ-QW and 0.42 (0.14–1.26) for TCZ-Q2W; vs PBO+52 it was 0.36 (0.13–1.00) for TCZ-Q2W and 0.67 (0.21–2.10) for TCZ-Q2W. TCZ exposure-efficacy analysis showed that most patients in the low exposure tertile had been treated with TCZ-Q2W (80%) whereas those with medium and high exposure primarily received TCZ-QW (84% and 98%, respectively). Kaplan-Meier analysis demonstrated that patients with higher exposure benefited from a longer time to flare (Figure). Adverse events (AEs) were similar across groups. Serious AEs were reported in 15.0% TCZ-QW, 14.3% TCZ-Q2W, 22.0% PBO+26 and 25.5% PBO+52 patients; rates were similar between new-onset and relapsing patients.

Conclusions: The compelling treatment effect of TCZ in GCA patients as measured by sustained remission to 52 weeks was consistent regardless of disease-onset status. Duration of relapse-free remission until flare was longer in patients with higher TCZ exposure, most notably in relapsing patients treated with TCZ-QW.

LOW-DOSE INTERLEUKIN-2 SELECTIVELY RESTORE REGULATORY T CELL NUMBERS IN PATIENTS WITH BEHÇET’S DISEASE

X. Fu1, J. Li2, X. Li1, J. Lu2, C. Gao2, Q. Chen2, 1, L. Biard2, M. Lambert3, A. Mekinian4, Y. Ferfar1, J.-E. Kahn5, 6

Background: The lack of CD4+CD25+Foxp3+ T regulatory cell (Treg) has been associated with human systemic autoimmune diseases, such as Behçet’s disease (BD). IL-2, an essential growth and survival factor for Treg cells.However, the significance of Treg cells in the pathogenesis and the effect of low dose of IL-2 on BD are remain to investigate.

Objectives: The lack of CD4+CD25+Foxp3+ T regulatory cell (Treg) has been associated with human systemic autoimmune diseases, such as Behçet’s disease (BD). IL-2, an essential growth and survival factor for Treg cells.However, the significance of Treg cells in the pathogenesis and the effect of low dose of IL-2 on BD are remain to investigate.

Methods: Eighty patients with BD and seventy healthy donors were enrolled. CD4+ T cell subsets were analysed before and after treatment by flow cytometry. Twenty-six patients were treated daily with subcutaneous injections of 0.5 million IU of human IL-2 for five consecutive days.

Results: Compared to control, the absolute counts of circulating Treg cells were significantly decreased in patients with BD (median:29.93 cell/μL, VS median:33.18 cell/μL, p=0.039) and it is negative correlation with disease activity. While the ratios of Th17/Treg in patients with BD (median:0.29%n=80=0.034) were significantly higher than those of healthy control (median:0.2:n=70). No difference in the absolute counts of circulating Th17 cells (CD4+IL-17+) between patients with BD and health control. Treatment of patients with BD with a low-dose of IL-2 regimen selectively increased the absolute counts of Treg cells, from a median of 18.97 cell/μL to 74.68 cell/μL (at 5 days) (p=0.000). No significant difference was observed in the absolute counts of circulating Th17, Th1 and Th2 cells after IL-2 treatment.

Conclusions: Th17/Treg cells may play a role in the pathogenesis of Patients with BD, low-dose of IL-2 proposes a selective biological treatment strategy by restoring immune tolerance. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.4047

TOCOLIZUMAB IN GIANT CELL ARTERITIS: GIAC TA TRIAL VERSUS A SERIES OF PATIENTS FROM CLINICAL PRACTICE

R. Jese, Ž. Rotar, M. Tomšič, A. Hočevar. Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

Objectives: To assess long term outcome and to elaborate a prognostic score for vascular complications in patients with Takayasu arteritis (TA).

Methods: Prospective multicenter study of characteristics and outcome of 318 TA patients [86% of females; median age 36 [25–47] years; median follow-up of 6 [1–70] years]. TA fulfilling ACR criteria or for Takayasu criteria. Factors associated with event free survival (EFS), relapse free survival (RFS) and incidence of vascular complications were assessed. A prognostic score for vascular complications was elaborated based on a multivariate model.

Results: The 5- and 10-years event free survival (EFS), relapse free survival (RFS) and complication free survival were 48.2% (42.5;54.9) and 36.4% (30.3;43.9), 58.6% (52.7;65.1) and 47.7% (41.2;55.1), and 69.9% (63.7;76) and 53.7% (46.8;61.7), respectively. Progressive disease course (p=0.018) and carotidopathy (p=0.003) were independently associated with EFS. Male gender (p=0.048), elevated C-reactive protein level (p=0.013), and carotidopathy (p=0.003) were associated with RFS. Progressive disease course (p=0.017), thoracic aorta involvement (p=0.009), and retinopathy (p=0.002) were associated with complication free survival. We define high risk patients for vascular complications according to the presence of two of the following factors (i.e a progressive clinical course, thoracic aorta involvement and/or retinopathy). The probability of complication free survival at five years was 78.4% (69.4;88.6) and 51.5% (38.3;69.2) in the low risk and high risk group, respectively.

Conclusions: This nationwide study shows that 50% of TA patients will relapse and experience a vascular complication at 10 years. We could define high risk TA patients for vascular complications. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.3579
Conclusions: Patients receiving TCZ in the clinical practice study have several baseline clinical and laboratory differences with regard to those included in the GIACTA trial, and therefore, data of this trial should be taken cautiously when applied in a real-world scenario.

OP0137 AUTO-REACTIVE B CELLS ESCAPE PERIPHERAL TOLERANCE CHECKPOINTS IN PATIENTS WITH PR3-ANCA ASSOCIATED VASCULITIS

D. Cornet1,2, A. Hummel1, T. Peikert1, J.-O. Pers2, U. Specks1. 1Mayo Clinic, Rochester MN, United States; 2CHRU and University, Brest, France

Background: While extensive studies have been performed to characterize ANCA, little is known about the auto-reactive B cells that produce these autoantibodies. Indirect evidence previously suggested the presence of circulating PR3-specific B cells in patients with PR3-ANCA-associated vasculitis (AAV).

Objectives: To develop a method to detect circulating PR3-specific B cells in patients with PR3-AAV, to study their proportion among the different B-cell subsets and to assess their relationship with disease activity.

Methods: An enzymatically inactive, conformationally mature, recombinant PR3 (rPR3) was tagged using FIC or bioitin. To study the ability of this rPR3 to bind specifically to cells expressing PR3-specific immunoglobulins on their surface, we used two hybridoma cell lines, MCPR3–2 (producing an anti-human PR3 monoclonal antibody) and MCPR3–13 (producing an anti-mouse PR3 monoclonal antibody, with no cross-reactivity with human PR3). We measured the proportion of PR3-FITC positive B cells among PBMCs in 13 patients with PR3-AAV and 14 healthy controls (HCs) by flow cytometry. We then developed a multi-color flow cytometry including CD19, IgD, CD27, CD38, CD24 and biotylated rPR3 to measure the proportion of PR3-specific B cells among different B-cell subsets in an independent group of 13 patients with PR3-AAV and 11 HCs.

Results: PR3 efficiently bound MCPR3–2 hybridoma cells but not MCPR3–13. Specificity of the staining was confirmed by competition experiments: pre-incubation of MCPR3–2 cells with untagged human rPR3 totally abrogated rPR3 efficiently bound MCPR3–2 hybridoma cells but not MCPR3–13. Specificity of the staining was confirmed by competition experiments: pre-incubation of MCPR3–2 cells with untagged human rPR3 totally abrogated rPR3 efficiently bound MCPR3–2 hybridoma cells but not MCPR3–13. Specificity of the staining was confirmed by competition experiments: pre-incubation of MCPR3–2 cells with untagged human rPR3 totally abrogated rPR3 efficiently bound MCPR3–2 hybridoma cells but not MCPR3–13. Specificity of the staining was confirmed by competition experiments: pre-incubation of MCPR3–2 cells with untagged human rPR3 totally abrogated.

Conclusions: To detect circulating PR3-specific B cells in patients with PR3-AAV, we used a novel approach that measures the proportion of PR3-specific B cells among different B-cell subsets and to assess their relationship with disease activity.

OP0136 MICRORNA-223-3P EXPRESSION IN AFFECTED SKIN OF ADULT IGA VASCULITIS CORRELATES WITH THE SEVERITY OF SKIN INVOLVEMENT

A. Hocevar1, J. Pizem1, M. Tomsic1, D. Glavac2. 1Department of Rheumatology, University Medical Centre Ljubljana; 2Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Background: Iga vasculitis (IgAV) represents a common systemic vasculitis in paediatric and adult population. Our current knowledge of disease pathogenesis is still very limited and there is no information on miRNAs profile in IgAV.

Objectives: The aim of our study was to determine the expression of three miRNAs (miR-148–3p, miR-155–5p and miR-223–3p) in the affected skin of adult IgAV patients.

Methods: The study included 65 skin samples from consecutive, untreated IgAV patients. miRNAs expression was then correlated to clinical characteristics of adult IgAV patients. To present relative miRNA expression the ΔACT method was used.

Results: We found significantly higher expression levels of miR-223–3p in the affected skin compared to controls (14-fold; p < 0.001). The expression of the 148b–3p and miR-155–5p was near normal levels (1.05-fold and 1.13-fold increase, respectively). The differences in the expression of miR-223–3p depending on clinical parameters of IgAV are presented in Table 1. Patients with necrotic skin lesions had significantly higher miR-223 tissue expression than those with non-necrotic purpura (p=0.020). Gastrointestinal tract (GIT) involvement inversely correlated with the level of skin miR-223 expression (p=0.024). No significant relationship between renal involvement and skin miR-223 was found.

Conclusions: miR-223 expression was increased in the affected skin of IgAV in comparison to normal skin. Levels of miR-223 expression correlated with severity of skin involvement and inversely with GIT involvement.
circuiting auto-reactive B cells in patients with PRS-AAV, and suggests that PRS-specific B cells are associated with disease activity and may represent a promising biomarker to predict relapse risk in patients in clinical remission. The progressive enrichment in PRS-specific B cells during the B-cell maturation steps in patients suggest that auto-reactive B cells are actively selected and escape peripheral tolerance checkpoints.

HPR mind over matter - patients perspectives

OP0138-HPR
DO PATIENTS' TREATMENT BELIEFS AFFECT TREATMENT CHOICES IN KNEE AND HIP OSTEOARTHRITIS?

1Rheumatology, Sint Maartenskliniek, Nijmegen; 2Psychology, Utrecht University, Utrecht; 3Primary and Community Care, Radboud University Nijmegen Medical Centre, Nijmegen; 4Physical Therapy and Manual Therapy, Partnership Velpenweg, Arnhem; 5Rheumatology, Sint Maartenskliniek, Woerden; 6Orthopaedics, Sint Maartenskliniek, Nijmegen, Netherlands

Background: Patients' beliefs about treatment modalities for knee/hip osteoarthritis (OA) might influence their treatment choices. The Theory of Planned Behavior predicts that patients' beliefs, the norms and values of one's social environment (subjective norm) and one's perceived self-efficacy influence behaviour1. Moreover, symptom severity may influence treatment choices2. However, these relationships have not been studied yet in the context of treatment decision-making.

Objectives: To test whether treatment beliefs, subjective norm, perceived self-efficacy and symptom severity were associated with intended treatment choices in OA.

Methods: Patients with knee/hip OA who visited the Sint Maartenskliniek in 2015 and 2016 (N=700) were invited to fill out a booklet. The Treatment beliefs in OsteoArthritis questionnaire was used to assess positive and negative treatment beliefs regarding five treatment modalities: physical activities, pain medication, psychotherapy, injections and arthroplasty. Other measures were demographic and clinical variables, self-efficacy (ASES), and symptom severity (WOMAC). Associations between variables were assessed in three models (Figure 1): 1) whether treatment beliefs are associated with intended treatment choice (model 1); 2) whether treatment beliefs, subjective norm and perceived self-efficacy are associated with intended treatment choice (model 2); 3) whether treatment beliefs, subjective norm, perceived self-efficacy and symptom severity are associated with intended treatment choice (model 3).

Path analyses were conducted to examine the hypothesized associations.

Results: 289 patients filled out the booklet. Model 2 had the highest explained variance for each of the treatment modalities (range 32–45%). Positive treatment beliefs and subjective norm were consistently associated with intended treatment choice across all treatment modalities. Negative treatment beliefs were associated with intended treatment choices for pain medication and arthroplasty. Perceived symptom severity was not related to intended treatment choices. No other associations were found.

Conclusions: This is the first study that found empirical support for the relationship between treatment beliefs and treatment choices. The findings suggest that positive beliefs about treatment modalities and the norms and values of one's social environment are related to a specific treatment choice for knee/hip OA and should be addressed in the clinician's consulting room.

REDUCING ARTHRITIS FATIGUE - CLINICAL TEAMS (RAFT) USING COGNITIVE-BEHAVIOURAL APPROACHES: AN RCT

S. Hewlett1, N. Ambler2, C. Almeida1, R. Blair3, E. Choy4, E. Dures1, W. Hollingsworth5, B. Kadir3, J. Kirwan3, Z. Plummer1, C. Rooke5, J. Thorn3, J. Pollack1 on behalf of RAFT Study Group, 1University of the West of England, Bristol; 2Southmead Hospital; 3University of Bristol, Bristol; 4University of Cardiff, Cardiff; 5Royal Infirmary, Bristol, United Kingdom

Background: RA fatigue is common. Group Cognitive Behavioural Therapy by CBT therapists is effective1 but few rheumatology teams have psychologists, thus we trained rheumatology teams to deliver RAFT, a cognitive behavioural approach (CBA).

Objectives: To test if usual care plus a group CBA course for RA fatigue delivered by rheumatology teams reduces fatigue impact more than usual care alone, in a randomised controlled trial.

Methods: A pair of rheumatology nurses/OTs in each of 7 UK hospitals were trained in RAFT. RAFT is 6, weekly 2hr group sessions and a consolidation session (wk 14). Links between thoughts, feelings and behaviours (pacing, communication, sleep, stress) are addressed, with daily diaries of energy expenditure and weekly goal-setting. Usual care was a 5min discussion of the Arthritis Research UK fatigue booklet. Entry criteria were RA, Bristol RA Fatigue (BRAF-NRS) severity ≥6/10 and no recent major medication change.

Results: 308/333 randomized patients completed 26 wks. The 25 who withdrew had similar (10yr) disease duration but were older (69 vs 62.4 yrs). Baseline fatigue impact was similar for RAFT (n=156, BRAF-NRS 7.10, SD 2.4) and controls (n=152, 7.23, SD 1.6), as were all clinical variables. At 26 wks the RAFT arm had similar (10yr) disease duration but were older (69 vs 62.4 yrs). Baseline fatigue impact (BRAF-Multi-Dimensional Questionnaire), pain, disability, sleep, quality of life, mood, self-efficacy, patient global opinion, valued life activities & disease activity.

Conclusion: Intention-to-treatment regression analysis involved adjustment for baseline scores and centre.

OP0140-HPR
ACCEPTANCE AND COMMITMENT THERAPY: A RETROSPECTIVE STUDY OF OUTCOMES FROM A HOSPITAL-BASED, GROUP, PAIN REHABILITATION PROGRAMME IN RHEUMATOLOGY SERVICES IN THE SOUTH EAST OF IRELAND

N. Nealon Lennox1,2, S. O'Neill1, A. Hannigan1, 1GEMS, University Limerick, Limerick; 2Psychology, Ulster University, Derry, Ireland

Background: Acceptance and Commitment Therapy (ACT) is a form of cognitive...
behavioural therapy (CBT), which focuses on psychological flexibility and behavior change. ACT has been advocated for the treatment of Persistent Pain. A systematic review concluded that ACT is efficacious for enhancing physical functioning and decreasing distress amongst adults with chronic pain attending Pain Rehabilitation Programmes (Hann & McCracken 2014). A call was made for further studies to examine the construct validity of the AAQ2.

**Objectives:** To assess the effects of an eight-week group ACT, Rheumatology based programme, for people with persistent pain, on pain acceptance, activity engagement, psychological distress and self-efficacy.

**Methods:** Patients were referred to the programme by three Consultant Rheumatologists over a five-year period. Over one hundred patients' outcome measures were available for this retrospective study from a convenience sample. Consent had been sought routinely from patients who attended the ACT programme and ethical approval was granted from the Hospital Research Ethics Committee (REC) and Ulster University. Participants were asked to complete baseline measures were taken at assessment, on the final day of the programme and at the follow up six-month review. Data was analysed with One Way Repeated Measures ANOVA using SPSSv20. Effect sizes were calculated using Partial Eta Squared and interpreted using the guidelines proposed by Cohen (1998).

**Results:** For those with scores at all three time points, mean depression scores, anxiety scores and self-efficacy scores were statistically significantly different over time. In addition, for those with activity engagement and pain willingness scores at all three time points, scores were statistically significantly different over time.

</tbody>
</table>

**Conclusions:** The ACT Pain Rehabilitation Programme at University Hospital Waterford in Ireland has provided significant outcomes for reducing depression and anxiety amongst its participants as measured by the Hospital Anxiety and Depression Scale (HADS). Increases in self-efficacy were also found to be statistically significant. Increases in activity engagement & pain acceptance, as measured by the Chronic Pain Acceptance Questionnaire (CPAQ) also showed statistically significant increases. A number of limitations should be noted i.e. this was a retrospective study and depended on self report measures only. However, positive outcomes suggest ACT is a helpful intervention for people with persistent pain.

AN INNOVATIVE MEASUREMENT INSTRUMENT TO ASSESS ACTIVITY LIMITATIONS IN HIP AND KNEE OSTEOARTHRITIS: THE COMPUTERIZED ANIMATED ACTIVITY QUESTIONNAIRE (AAQ) AND ITS PSYCHOMETRIC PROPERTIES

W. Peter 1,2, R. de Vet 1, M. Boers 3, J. Harlaar 2, L. Roorda 1, P. Poolman 3, V. Scholtes 2, M. Steijlens 4, E. Roos 5, F. Guillem 6, M.G. Benedetti 7, A. Escobar Martinez 8, H. Dagnirnud 8, H. Bueltelar 9, P. Boogaard 10, C. Terwee 1,11, READE, VU University Medical Center; 12OLVG, Amsterdam, Netherlands; 13Glasgow Caledonian University, Glasgow; United Kingdom; 14University of Southern Denmark, Odense, Denmark; 15University of Lorraine, Nancy, France; 16Istituto Ortopedico Rizzoli, Bologna, Italy; 17Basurso University Hospital, Bizkaia, Spain; 18Diakonhemmet Hospital, Oslo, Norway; 19Patient Research Partner, Amsterdam, Netherlands

**Background:** The Animated Activity Questionnaire (AAQ) measures activity limitations in hip and knee osteoarthritis (HOA), and was developed in close collaboration with patients. Previously we showed an adequate construct- and cross-cultural validity of the AAQ2.

**Objectives:** To determine the reliability, responsiveness and interpretability of the AAQ.

**Methods:** In 6 European countries the AAQ was completed twice on a computer with a 7 days interval by 238 patients (DK (36), FR (37), IT (51), NL (39), SP (36), UK (39)). Reliability was assessed by calculating internal consistency (Cronbach’s alpha), the intra-class correlation coefficient (ICC), the Standard Error of Measurement (SEM) and the Smallest Detectable Change (SDC). In the Netherlands an additional group of 92 patients were followed for 6 months to evaluate responsiveness. Data from the AAQ, a PROM (the Hip disability or Knee injury Osteoarthritis Outcome Score, ADL subscore), and performance-based tests (the Timed Up and Go test, Stair Climbing Test and 30 seconds Chair Stands Test) were collected. To estimate the Minimal Important Change (MIC) of the AAQ an anchor-based MIC distribution method was used with a Global Rating of Change (GRC) as anchor. The Receiver Operating Characteristic (ROC) method was used to find the AAQ change score that best discriminates between patients who improved in activity limitations and who are not. The MIC was compared to the SDC in order to facilitate the interpretation of change scores.

**Results:** Cronbach’s alpha was 0.94. ICC for test-retest reliability was 0.93 (95% CI: 0.91–0.95). SEM and SDC were 4.9% and 13.5%, respectively. With regard to responsiveness the change scores of the AAQ after 6 months correlated 0.58 with the PROM, 0.42–0.55 with the performance based tests, and 0.46 with GRC. The ROC curve showed an area under the curve of 0.72 with a sensitivity of 63% and a specificity of 81% for the optimal MIC of 9.1 for discrimination. The MIC was smaller than the SDC meaning that the change is important but cannot be distinguished from measurement error in individual patients.

**Conclusions:** The AAQ, measuring a new construct in the domain physical activity limitation, showed good construct validity, cross-cultural validity, internal consistency and test-retest reliability. A change in AAQ score over 13.5% indicates a real improvement in activity limitations in HOA patients. The AAQ seems to have great potential for international use in research but the application in clinical practice needs caution.

DISABILITY IN THE FEET RELATED TO PARTICIPATION IN DAILY LIFE IN PATIENTS WITH EARLY RA – AN INTERVIEW STUDY IN THE SWEDISH TIRA PROJECT

M. Björk1,2, I. Thyberg3, E. Valtersson4, G. Östlund5, B. Stenström3, A. Sverker6, 1Department of Social and Welfare Studies, Linköping University, Linköping; 2Rheumatology clinic, Linköping university hospital; 3Department of Rheumatology; 4Department of Activity and Health and Department of Medical and Health Sciences, Linköping University, Linköping; 5School of Health Care and Social Welfare, Mälardalen University, Eskilstuna; 6Department of Activity and Health, Department of Rehabilitation Medicine, Department of Social and Welfare studies, Linköping university, Linköping, Sweden

Background: Pain, stiffness and deformity of the feet are related to reduced mobility and participation restrictions in daily activities in patients with established rheumatoid arthritis (RA). The new biological medications are effective and reduce disease activity, but not disability to the same extent. Foot problems are assumed to be related to participation restrictions also in patients with early RA, diagnosed after the introduction of biological medications, hindering for example physical activity. Hence, there is a need for more knowledge about foot problems in order to identify possible needs for rehabilitative interventions.

Objectives: To explore disability related to foot problems in women and men with early rheumatoid arthritis and its relation to participation in daily life.

Methods: 59 patients (58% women, 20–63 years) with early RA were interviewed about participation dilemmas in daily life related to RA, using Critical Incident Technique. The interviews were audio-recorded and transcribed. Data related to foot problems were extracted and analysed thematically. A research partner with RA validated the retrieved categories. The study was approved by the Regional Ethics Committee.

Results: More than 2/3 of the patients mentioned that they had participation restrictions related to foot problems. The analysis revealed 5 categories concerning foot problems and the relation to participation restrictions: 1) foot problems as an early indicator of the disease, 2) hindrance in managing the daily routine and house hold activities, 3) struggling to be mobile, 4) difficulties in doing a good job at work and 5) difficulties in participating in recreation and leisure activities. Both women and men shared many experiences, as difficulties to be physically active. Several women expressed difficulties to use the shoes they wanted. Being able to move on uneven ground in, for example, the forest was something that many men expressed as difficult.

Conclusions: Patients with early RA with access to effective medications and multi professional interventions based on their individual needs still experience a wide range of foot related disability in major life arenas as work, in the household and during leisure time. This indicates a need to pay attention also in today’s early RA patients to foot problems in the multi professional rehabilitation to prevent further disabilities and enable physical activity for men and women with RA.

DISABILITY IN THE FEET RELATED TO PARTICIPATION IN DAILY LIFE IN PATIENTS WITH EARLY RA – AN INTERVIEW STUDY IN THE SWEDISH TIRA PROJECT

RHEUMATOID ARTHRITIS PATIENTS’ SUPPORT NEEDS REGARDING MEDICATION USE AND THEIR PERSPECTIVES ON THE APPLICABILITY OF EHEALTH INTERVENTIONS TO ADDRESS THOSE NEEDS: A FOCUS GROUP STUDY

E. Mathissen1, J. Vriezekolk1, A. Ejsbouts1, B. van den Bemt1,2.

1Rheumatology, 2Pharmacy, Sint Maartenstilkein, Nijmegen, Netherlands

Background: Patients with rheumatoid arthritis (RA) encounter various problems with their medication use, including poor knowledge about disease-modifying antirheumatic drugs (DMARDs), concerns about potential adverse consequences of their medication use8 and struggles with opening the medication’s packaging9. Additional support might decrease those problems by targeting RA patients with (eHealth) interventions that address their needs. To date, no studies have explored RA patients’ support needs regarding medication use from their own perspectives and it remains largely unknown if, and to what extent, they perceive eHealth interventions as enabling RA patients to better cope with their medication use. Their perspectives on the applicability of eHealth interventions to address those needs were also identified. RA patients recognized potential advantages of eHealth interventions, such as being less time consuming and easily accessible. However, concerns patients did not know whether PGA affects their treatment decisions in the same way as the objective measures do: “if the answer is not in somehow according to the exams we make (…) obviously they might ignore me”. Some believed that PGA was only used for research purposes. (2) The meaning of PGA. Pain was by far the main meaning of PGA, but also fatigue, function and other dimensions contributed to the perceptions. (3) Global Perspective. Many of these difficulties arose from the presentation of the three different PGA formulations, anchor points and their presentations: “I always think that 100 is great: you feel 100%”, “Usually the scale is 0 to 10, here I can see 0 to 100”, “Usually it has the numbers, I answer 2, it’s not like a straight line like this one”; “Today is different (…) when they ask the last week, we have to go back in time and the pain isn’t the same anymore”. Also cultural issues and the subjectivity of the concept were expressed: “We, the patients, can’t really assess the intensity of the pain, what could be a 9 for her, for me it might be a 5”; “I can never answer 0, because I always have something that affects me”. (4) Clarification from a HCP as a key factor for global understanding: “[Sometimes I just give a random number. (…) now maybe I will think more carefully and try to be as accurate as possible”.

Figure 1. Main themes of Patients’ perspective of PGA

Conclusion: Our results suggest that patients’ interpretation of PGA is diverse and may reflect different symptoms such as pain or psychological well-being and comorbidities. Standardization of PGA is warranted and dedicated patient debriefing is likely to improve the reliability of this assessment.

DISABILITY IN THE FEET RELATED TO PARTICIPATION IN DAILY LIFE IN PATIENTS WITH EARLY RA – AN INTERVIEW STUDY IN THE SWEDISH TIRA PROJECT

IT CAN’T BE ZERO: A QUALITATIVE STUDY OF PATIENTS’ PERSPECTIVE ON PATIENT GLOBAL ASSESSMENT IN RHEUMATOID ARTHRITIS

M. Henrique1, C. Duarte1,2, M. Ndos3, A. Marques1, J.A.P. da Silva1,2, R.J.O. Ferreira1,2, 1Faculdade de Medicina da Universidade de Coimbra; 2Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; 3University of the West of England, Bristol, United Kingdom; 4ULIC/SE, ESENIC, Coimbra, Portugal

Background: Patient Global Assessment (PGA) plays an important role in disease activity assessment and treatment decisions in rheumatoid arthritis (RA). However, it is open to patient interpretation and this may affect the validity and reliability of clinical assessments.

Objectives: We aimed to explore: (i) patients’ perspective on PGA and its different formulations (ii) how patients’ perspective may be improved by a brief explanation from a health care professional (HCP).

Methods: This was a qualitative study including consecutive patients with RA attending a day hospital and an outpatient department of a university hospital in Portugal. Data collection included 4 focus-groups (FGD) and 3 individual interviews to determine patients’ perspectives. To help the discussions, patients completed 3 different PGA formulations consecutively and then a HCP explained what information was expected to inform their PGA. The 3 PGA formulations and their implications were then discussed between the patient and the HCP. Data from the FGDs and the interviews were transcribed verbatim and inductive content analysis was undertaken by two independent researchers. Data were coded and categorized into themes, which were agreed upon with patients, HCP and patient research partners.

Results: Fourteen patients (12 women) with RA participated. Their age ranged from 49 to 72 years, disease duration 4 to 30 years and 11 were on biologic DMARDs. Four main themes emerged (Figure 1): (1) The purpose of PGA. Some
on matters such as privacy, the quality and trustworthiness of information and personal interaction with healthcare providers prevailed.

**Conclusions:** For most RA patients, informational support regarding medication use is the most important (unmet) need. High-quality, unambiguous information about their medication use was emphasised. Moreover, this information should be provided by healthcare providers on an ongoing basis and tailored to their personal situation. Eliminating RA patients’ concerns regarding eHealth interventions should be a first priority before such interventions are applicable to address these informational needs. These findings need to be confirmed in a sample of younger RA patients.

**THURSDAY, 15 JUNE 2017**

**RA: really a systemic disease?**

**OP0146** DECREASE IN CARDIOVASCULAR EVENT EXCESS RISK IN RHEUMATOID ARTHRITIS SINCE 2000: A META-ANALYSIS OF CONTROLLED STUDIES

E. Filbo1, C. Gaujoux-Viala2, B. Combe1, J. Morel1, G. Huá1, A. Nutz2,
C. Lukas3, F. Flaisler2, 1Lapeyronie Hospital, Montpellier; 2Nimes Hospital, Nimes, France

**Background:** Compared with the general population, patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular disease or events (CE): stroke, Myocardial Infarction (MI), Congestive Heart Failure (CHF) and Cardiovascular Mortality (CVM). Systemic inflammation is the cornerstone of both RA and atherosclerosis. Over the past fifteen years, new treatment strategies such as tight control, treat to target, methotrexate optimization, biologic DMARDs use has allowed a better control of this inflammation.

**Objectives:** The aim of this systematic review was to assess the excess risk of presenting a CE in RA patients as compared to general population, before and after the 2000s.

**Methods:** We systematically searched literature (via Pubmed, Cochrane and abstracts from recent ACR and EULAR congresses) up to March 2016 for observational studies providing data about the occurrence of a CE (among stroke, MI, CHF, CVM) in patients with RA and in a control group. A meta-analysis of the relative risk (RR) concerning patients with RA in relation to the control group was performed for each cardiovascular event and for each period (before and after the 2000s).

**Results:** Out of 5714 screened references, 28 studies were included. For studies published before 2000, an increased risk of CEs was observed in RA patients: RR=1.12 [95% CI 1.04; 1.21], p=0.002 for stroke RR=1.25 [1.14; 1.37], p=0.00001 for CHF RR=1.21 [1.15; 1.28], p=0.00001 for CVM RR=1.32 [1.24; 1.41], p=0.00001 for MI. For all studies published after the year 2000, the increased risk was not retrieved for CHF (RR=0.58 [0.11; 3.55], p=0.52) and CVM (RR=1.07 [0.74; 1.56], p=0.71). The excess risk of MI was reduced in comparison with the period before 2000: RR=1.18 [1.14; 1.23], p=0.00001. The excess risk of stroke was stable: RR=1.23 [1.06; 1.43], p=0.006.

**Discussion:** This meta-analysis confirms an increased risk of CEs among people with RA relative to the general population. It also appears that this excess risk is less prevalent than prior to 2000s. This might have two explanations: a better management of the cardiovascular risk in patients with RA and a better control of chronic systemic inflammation thanks to new therapeutic strategies.

**Conclusions:** The cardiovascular excess risk of RA patients relative to the general population has decreased since 2000s. This suggests that the recent improvements in RA management may have a positive impact on cardiovascular comorbidities.

**TRENDS IN MORTALITY, CO-MORBIDITY AND TREATMENT AFTER ACUTE MYOCARDIAL INFARCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS 1998-2013**

M. Skiela1, L. Söderström2, S. Rantapää Dahlqvist3, S. Wallberg Jonsson4,
T. Moote1, 1Department of Public Health and Clinical medicine, Rheumatology, Umeå University; 2Unit of Research, Östersund Hospital, Östersund; 3Department of Public Health and Clinical Medicine, Rheumatology, Umeå University; 4Department of Public Health and Clinical Medicine, Rheumatology, Östersund, Sweden

**Background:** Rheumatoid arthritis (RA) patients have increased mortality due to cardiovascular disease (CVD). Case fatality after an acute myocardial infarction (AMI) has been reported to be increased. Whether the prognosis after AMI has changed over time in RA is unknown.

**Objectives:** To study the one-year mortality after a first AMI in RA versus non-RA patients during the time period 1998–2013. To identify time trends in mortality, co-morbidities and secondary preventive treatments and to explore any characteristics associated with mortality.

**Methods:** We identified all patients with a first time AMI in the Swedish Register of Information and Knowledge about Swedish Heart Intensive Care Admissions (RIKS-HIA) between 1998–2013. We used the National Patient Register (NPR) to identify AMI patients with RA (RA defined as ≥2 visits to a Rheumatology or Internal Medicine department with a diagnosis of RA). In total 245376 AMI patients were identified, 4268 of them had RA. To study trends over time, the study period was divided into five consecutive time periods. Multivariate Cox regression analysis was used to identify variables associated with mortality.

**Results:** The one-year mortality in RA patients was stable and lower compared to non-RA patients during the first time periods but thereafter increased above the non-RA patients. In non-RA patients, mortality decreased over time and stabilised during the last time period (Figure). In RA patients the mean age at admission increased from 69 to 73 years, whilst in non-RA patients it was unchanged, 71 years. Atrial fibrillation (AF) was initially more common in non-RA patients but the prevalence decreased over time (from 19.2% to 17.5%). In RA patients, AF increased over time from 15.6% to 21.4%. The prevalence of congestive heart failure (CHF) during hospitalisation decreased markedly more in non-RA (from 41.5% to 22.7%) than in RA patients (from 36.0% to 29.2%). The most important secondary preventive treatments were similar in RA and non-RA patients. In a multivariate Cox model including data from the last time period, 2011–2013, age, CHF during hospitalisation, ST-elevation AMI (STEMI), AF, prior diabetes mellitus, a diagnosis of RA and oral anticoagulation were significantly associated with higher one-year mortality (Table).

**Conclusions:** The marked decrease in one-year mortality after AMI seen over time in non-RA patients was not applicable in RA patients. Our finding might to some extent be explained by an increased age at AMI onset and unfavourable trends for AF and CHF in RA. However, RA per se was significantly associated with a worse prognosis during the last years of the study period. Secondary preventive treatment was similar in RA and non-RA patients. Further analyses including RA treatments are necessary to gain further insight into reasons behind the discrepant prognosis in RA vs. non-RA patients.

OP0148  IMPACT OF A CARDIOVASCULAR EVENT ON DMARD TREATMENT AMONG PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, OR PSORIASIS

J.A. Sparks, T. Lesperance, N.A. Accortt, D.H. Solomon. 1Harvard Medical School, Brigham and Women's Hospital, Boston; 2Amgen, Inc, Thousand Oaks, United States

Background: Chronic inflammatory diseases such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), and psoriasis (PsO) increase the risk of cardiovascular (CV) disease. However, a gap in knowledge exists regarding detailed information on changes in immunomodulatory (DMARD) treatments after a CV event.

Objectives: We describe treatment patterns among patients with RA, PsA, or PsO who were being treated with DMARDs prior to a CV event.

Methods: Patients with RA, PsA, or PsO, who experienced a CV event (acute myocardial infarction, stroke, or cardiac rehospitalisation) between 1/1/2006 and 6/30/2015 were identified in an administrative claims database. Index date was defined as the hospital discharge date for the first CV event during the study period. Patients required to be continuously enrolled for 12 months prior to index date; have ≥1 TNFi claim, or a conventional synthetic (cs)DMARD claim, or another biologic DMARD claim within 6 months prior to the index date; and have ≥30 days of follow-up after index date. Treatment patterns were assessed after index date and patients were classified as remaining on (“persistent”), switching, or discontinuing pre-index DMARD medication.

Results: We identified 9,529 patients with RA, PsA, or PsO prior to the index date. 3,274 (34.4%) patients were on TNFi, 5,177 (54.3%) were on only csDMARDs as monotherapy or combination, and 1,078 (11.3%) were on non-TNFi biologics. Patients on csDMARDs at index date were older (69.4 yrs) than those on TNFi (64.1 yrs) or other biologic DMARDs (66.0 yrs). Approximately 73% of patients were on TNFi on their pre-CV event treatment, with higher persistence among csDMARD alone (70.6%) and TNFi + csDMARD combo (76.7%) groups and lower in the non-TNFi biologic + csDMARD combo group (60.8%, Table 1). Across all treatment groups, 95% of persistent patients resumed treatment within 90 days after the index CV event. Combination therapy users switched their pre-CV event treatment more often than monotherapy users, with non-TNFi biologic users more likely to discontinue all therapy after index CV event. Patients that discontinued all therapy after an index CV event tended to be slightly older females (68.7 yrs vs 67.1 yrs), with a history of PsO (24.4% vs 16.1%), and stroke as index event (49.3% vs 41.3%) compared to those that continued therapy.

Conclusions: In a large US database reflective of typical clinical practice, nearly one-quarter of patients with RA, PsA, or PsO discontinued or switched their pre-index DMARD treatment after index CV event. Further research is needed on whether these DMARD treatment patterns after initial CV event affect risk of repeat CV event.

DOI: 10.1136/annrheumdis-2017-eular.2324

OP0149  MORTALITY IN NEW-ONSET RHEUMATOID ARTHRITIS - HAS MODERN RHEumatology HAD AN IMPACT?

M. Holmqvist, L. Ljung, J. Asling. 1Karolinska Institutet, Stockholm; 2Umeå University, Umeå, Sweden

Background: A wealth of studies have linked rheumatoid arthritis (RA) with an excess mortality compared to the general population. With increasingly effective anti-rheumatic treatment strategies there is, however, considerable uncertainty whether this mortality gap still exists and, if so, how soon after RA onset it occurs.

Objectives: To assess the mortality in RA compared to the general population with specific focus on whether during the course of the disease the risk is increased and if it also applies to patients diagnosed in recent years.

Methods: We performed a population-based cohort study of 17,512 patients with new-onset RA (identified from the Swedish Rheumatology Quality Register) 1997 through 2015, and 78,847 individually matched general population comparator subjects. We followed all individuals using nationwide census registers with full coverage to identify all deaths through 2015. We calculated mortality rates with 95% confidence intervals (CI) and compared the mortality in RA to that in the general population using Cox proportional hazards models adjusted for age, sex, year of diagnosis, and residential area.

Results: During a mean follow-up from RA diagnosis of 7 years, 2,386 RA patients and 9,850 population comparator subjects died (crude incidence: 19 per 1000 in RA and 18 per 1000 in the general population), with only a marginal decline (in the RA and in the general population cohort) during the study period. The overall HR was 0.99 (0.95–1.04), but whereas there was no increase in mortality during the first five years after RA diagnosis; the HR >10 years after RA onset was 40% increased. The overall pattern of HRs was similar for patients diagnosed 1997–2001, 2002–2006, and 2007–2011 (table).

Conclusions: Higher 10-year mortality in RA is not increased, neither for patients diagnosed in the past nor for those diagnosed during the most recent five years. By contrast, at least in the most recent inception cohort for which ten-year mortality currently can be calculated (those diagnosed up to 2006), RA is still associated with an increased risk of death.

OP0150  PARADOXICAL EFFECT OF BIOLOGICAL DMARDS IN RHEUMATOID ARTHRITIS PATIENTS WITH OVERWEIGHT AND OBESITY: LESS OFTEN CLINICAL REMISSION, BUT ALSO LESS RADIOLOGICAL DAMAGE

A.V. de Jonge1, M.M. ter Wee1, I.E. Butlin1, W.F. Lem1. 1VU University medical centre, Amsterdam Rheumatology and immunology centre; 2Epidemiology and Biostatistics, VU University medical center, Amsterdam, Netherlands

Background: The relationship between treatment with biological disease-modifying antirheumatic drugs (DMARDs), including TNF-blocking agents, and disease activity in overweight and obese rheumatoid arthritis (RA) patients has not been clarified yet.

Objectives: The aim of this review is to assess the effect of overweight/obesity on the therapeutic efficacy of these drugs. Secondly, we aimed to assess the influence of overweight/obesity on the occurrence of joint destruction.

Methods: A systematic review of all articles published on these subjects using PubMed and EMBASE was executed. For the first research question, studies were eligible when focused on the clinical efficacy of biological DMARDs only in overweight/obese RA patients versus normal weight patients. For the second research question studies were eligible when questioning the relation between overweight and joint destruction in patients with RA. Overweight and obesity were defined according to the following body mass index (BMI) categories; BMI >20 kg/m² for overweight, BMI >25 kg/m² and BMI >30 kg/m² for obesity.

Results: A total of 6782 articles were found, of which 12 were eligible for this review. A total of 3647 RA patients were treated with adalimumab, etanercept, infliximab, golimumab, or certolizumab pegol, or TNF blockers, rituximab, or tocilizumab.

Ten studies used disease activity as outcome. In general, these studies showed that higher BMI was associated with poor response, based on either outcome or percentages on remission or improvement defined according to EULAR guidelines. In addition, four studies showed that higher BMI is also associated with higher Health Assessment Questionnaire (HAQ)-scores. Two articles (of which one article described the results of studies in two different RA cohorts) focused on the association between BMI and joint destruction. These articles showed that higher BMI values were associated with lower odds for having joint destruction. One study also showed that having a BMI <20 kg/m² was associated with a higher odds ratio (OR =4.12) for joint destruction.

Conclusions: Higher BMI levels in RA patients treated with biological DMARDs...
are associated with reduced therapeutic efficacy as compared to RA patients with normal body composition. The unfavourable effect of body weight on disease activity was paralleled by a favourable, protective effect on joint destruction. This uncoupling is not fully elucidated yet, and should be further investigated.

OP0151 DOCOSAHEXAENOIC ACID TREATMENT OF RHEUMATOID ARTHRITIS: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, CROSS-OVER STUDY

T. Neumann1,2, C. Dawczynski3,4, M. Dittrich5, K. Goetz6, A. Welzel1, P. Oelzner1, S. Voelker7, A.M. Schaible1, F. Troisi1, L. Thomas7, S. Pace7, A. Koeberle7, O. Werz7, P. Schlattmann8, S. Lorkowski3,4, G. Jahreis3,4.

1Department of Internal Medicine III, Jena University Hospital, Jena, Germany; 2Department of Rheumatology, Kantonsspital St. Gallen, St. Gallen, Switzerland; 3Department of Nutrition and Cardiovascular Health (nutrICARD); 4Department of Nutritional Biochemistry and Physiology, Institute of Nutrition; 5Department of Nutritional Physiology, Institute of Nutrition, Friedrich Schiller University of Jena; 6Department of Rheumatology, Jena University Hospital; 7Department of Pharmaceutical/Medical Chemistry; 8Department of Medical Statistics, Informatics and Documentation, Friedrich Schiller University of Jena, Jena, Germany

Background: Epidemiological studies and clinical investigations indicate a beneficial impact of long-chain n-3 polyunsaturated fatty acids (n-3 PUFA) on the inflammatory activity of rheumatoid arthritis (RA). However, the knowledge about the physiological effects of the individual compounds eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) is limited.

Objectives: In our pilot study presented here, we investigated the clinical benefit of daily intake of foods enriched with microalgae oil as source of DHA in RA patients. In particular, we focused on disease activity and changes in the profile of pro-inflammatory/non-resolving and anti-inflammatory/pro-resolving lipid mediators as expected.

Methods: This is a randomized, double-blind, cross-over study on 38 patients (32 females/6 males) with active RA (DAS28≥2.4). They were allocated to consume foods enriched with microalgae oil from Schizochytrium sp. (2.1 g DHA/day) or sunflower oil (placebo) for 10 weeks while maintaining stable immunosuppressive treatment.

Results: Thirty-two patients finished the study but seven patients were excluded from analysis because their DHA increase in erythrocyte lipids (EL) was less than 25% after 10 weeks of intervention indicating insufficient adherence to the intervention. Supplementation of DHA led to a decline in tender joints (TJ68) 8.4±5.6 to 6.0±5.0 (p=0.03), swollen joints (SJ66) 5.6±3.5 to 3.9±3.5 (p=0.07) and DAS28 4.3±1.0 to 3.9±1.2 (p=0.07). Joint counts in the placebo arm remained stable (TJ68) 6.7±4.9 to 8.2±8.0 (p=0.12), swollen joints (SJ66) 3.5±3.0 to 4.2±3.7 (p=0.40) and DAS28 4.0±0.9 to 4.1±1.2 (p=0.45). Ultrasound score (US-7) remained stable (15±9.5 to 12±4.7; p=0.160) while it increased in the placebo arm (11.4±7.0 to 14.0±8.8; p=0.03). The amount of n-3 PUFA in erythrocyte increased in supplemented patients (7.0±1.2% to 10.6±1.4%; p<0.001) and the ratios of arachidonic acid (AA) /EPA (BSRBR-RA).2. To establish whether the organ class of index infection predicted to infection.

Objectives: To identify the effects of disease activity on renal function in RA in a multi-center cohort study.

Methods: RA patients with a sampling interval of less than 150 days were enrolled because wide sampling intervals could not take into consideration changes in disease activity and medications during their follow-up. An estimated glomerular filtration rate (eGFR) was calculated using an equation approved by the Japanese Society of Nephrology and used as an outcome variable. Linear mixed effect models were used to evaluate the renal trajectories of patients. Time from baseline (months), disease activity, and their interaction were included as fixed effects while participant identification number and time from baseline were included as random factors. Age, sex, disease duration, RF, ACPA, NSAIDs, and DMARDs that were known as a cause of renal impairment, such as tacrolimus, igrutamid, and tofacitinib, were included as covariates.

Results: A total of 25661 samples (mean sampling interval: 2.0 months) from 2104 patients was included. Patients with lower DAS28-CRP had worse renal function at inclusion, but a significantly better longitudinal trajectory on eGFR (0.0079 ml/min/1.73m² per month, P=0.025). Although all RA patients had naturally progressive renal impairment as they got older, patients who achieved remission or low disease activity had slower renal impairment rate of -0.068 ml/min/1.73m² per month compared to patients with moderate or high disease activity (-0.084 ml/min/1.73m² per month; P=0.037). These results were also similar using SDAI or CDAI.

Conclusions: Lower disease activity results in slower renal impairment. Because the effects of disease activity on renal function are mild, additional measures to protect renal function, such as avoiding nephrotic medications and treating cardiovascular risk factors are important.

OP0153 RECURRENT INFECTIONS IN RHEUMATOID ARTHRITIS PATIENTS, RESULTS FROM THE BSRBR

S. Subesinge1, A.I. Rutherford1, R. Byng-Maddick2, J.B. Galloway1.

1Rheumatology, King’s College London; 2Homerton Hospital, London, United Kingdom

Background: Rheumatoid arthritis (RA) patients have an increased susceptibility to infection.

Objectives: 1.To establish the rate of recurrent infection in RA patients recruited to the British Society of Rheumatology Biologics Registry Rheumatoid Arthritis (BSRBR-RA).2.To establish whether the organ class of index infection predicted future serious infection.

Methods: The BSRBR-RA is a prospective observational cohort, previously described. Patients with at least one episode of serious infection requiring hospitalisation were included if they occurred whilst on anti-rheumatic drug therapy or within 5 drug half-lives of stopping. Infections were coded by MedDRA classification in to 7 categories. Infections occurring over 14 days after the first index infection were considered as new events. Event rates were calculated and compared using a Cox proportional hazards model with adjustments made for age, gender, disease duration, baseline DAS28 score, smoking status and seropositivity.

Results: See Table 1.

In total, 21,943 subjects with 115,423 patient-years follow up were studied, 5365 subjects reported at least one serious infection. Comparing organ classes of prior infection at baseline, each group had comparable age, disease duration, baseline DAS28 and HAQ scores. The cohort characteristics are tabulated. The baseline annual rate of first serious infection was 4.6% (95% CI 4.5–4.7). Following an

Advances in RA and SpA pathophysiology

OP0154 ALTERED LYMPH NODE STROMAL CELLS DURING THE EARLIEST PHASES OF RHEUMATOID ARTHRITIS

C. Ospelt1, E. Karouzakis1, J. Hähnlein2, J.F. Semmelink3, R.E. Gay1, R.P. Tak4, D.M. Gerlag2, S. Gay1, L.G. van Baarsen2.

1Center of Experimental Rheumatology, University Hospital of Zurich, Zurich, Switzerland; 2Academic Medical Center, Amsterdam, Netherlands; 3University of California, San Francisco, CA; 4Center for Experimental Rheumatology, University Hospital of Zurich, Switzerland

Background: Lymph node stromal cells (LNSC) have a crucial role in shaping the immune response and maintaining peripheral tolerance. We developed an experimental model for studying the functional capacities of human LNSC during the earliest phases of RA and compared their cellular and molecular characteristics to LNSC from healthy volunteers.

Methods: ACPA+ RA patients (n=24), ACPA+ RA-risk individuals (n=23) and seronegative healthy controls (n=14;HC) were enrolled. LNSCs were isolated and expanded in vitro from healthy volunteers. ACPA+ RA-risk and ACPA+ RA patients were more similar to each other compared with HC. Pathway analysis of commonly increased genes in RA (-risk) and associated with antigen processing and presentation (HLA-DRB1), immune destruction in the development of Rheumatoid arthritis (RA). However, the precise molecular mechanisms by which this pathogenic process is regulated are not clearly defined.

Objectives: Increasing evidence indicates that p53 plays a critical role in the invasion and metastasis of cancer cells. This study aims to investigate the role of MDM2-mediated sumoylation of p53 in regulating the migration and invasion of fibroblast-like synoviocytes (FLSs) from patients with RA.

Methods: Synovial tissues were obtained from OA and RA patients, and then FLSs were isolated from synovial tissue. Protein expression was measured by Western blotting or IHC staining. The sumoylation of p53 in cells was determined by immunoprecipitation. A specific inhibitor of MDM2-p53 interaction was used to inhibit the sumoylation of p53. Migration and invasion of FLSs in vitro were measured by Boyden chamber assay.

Results: MDM2, SUMO1, and SUMO2 expression was significantly increased in the synovial tissue and FLSs of RA patients. Stimulation with TNF-α increased MDM2 expression and p53 sumoylation in RA FLSs. MDM2 shRNA inhibited p53 sumoylation, pro-inflammatory cytokines and MMPs expression, and capacity of in vitro migration and invasion in RA FLSs. Inhibition of p53 sumoylation by MDM2 shRNA promoted apoptosis and reduced proliferation of RA FLSs. p38 MAPK signal pathway was involved in the downstream signal transduction in RA FLSs. Administration of MDM2 shRNA expression lentivirus attenuated the severity of rats with collagen-induced arthritis (CIA).

Conclusions: Increased MDM2-mediated p53 sumoylation contributes to aberrant invasive behaviors of RA FLSs. Our findings suggest inhibition of MDM2 or p53 sumoylation might be a novel therapeutic strategy to prevent synovial invasiveness and joint destruction in RA.

OP0156 METHOTREXATE INCREASES EXPRESSION OF THE CELL CYCLE REGULATORS LBH AND P21 AND REDUCES FIBROBLAST-LIKE SYNOVIOTYCE PROLIFERATION AFTER MITOGEN STIMULATION

B. Bergström, H. Carlsten, A.-K.H. Ekwall. Rheumatology and Inflammation Research, Gothenburg University, Gothenburg, Sweden

Background: Activated fibroblast-like synoviocytes (FLS) are key effector cells in the joint in rheumatoid arthritis (RA). Local FLS proliferation is responsible for synovial hyperplasia, a key feature of the RA synovium correlating with disease activity. PDGF and IL-1β are known FLS mitogens, LBH is a transcription regulator and tumor suppressor, recently identified as a RA risk gene. We have demonstrated that LBH regulates FLS proliferation and that LBH expression is regulated by growth factors and by epigenetic mechanisms[1]. Methotrexate (MTX) is still the first-line treatment of RA and to identify novel markers for drug response.

Methods: Primary FLS from RA patients and from patients with osteoarthritis (OA) were plated on day 0 in DMEM complete, pre-treated 24 hours with MTX or control medium day 1, and stimulated with 20ng/ml PDGF+2 ng/ml IL-1β with or without 1μM MTX in DMEM with 1% FBS for 24–48 hours starting day 2. Cells were then harvested for qPCR for gene expression and flowcytometry for cell cycle analysis.

Results: Stimulating RA-FLS cultures (n=3) with PDGF+IL-1β for 24 hours, pushed 24±3±3% cells into G2/M phase compared to 3.4±0.8% in unstimulated controls. Interestingly, treating PDGF+IL1β stimulated FLS with MTX, significantly inhibited cell cycle progression (4.6±1.1% in G2/M phase, p=0.02). PDGF+IL-1β stimulation of FLS for 24 hours reduced LBH mRNA expression. However, in the presence of 1μM MTX the LBH mRNA expression was significantly higher in RA-FLS (3.2±0.5 fold, p=0.002, n=5) and in OA-FLS (2.2±0.5 fold, p=0.02, n=5) after PDGF+IL-1β stimulation compared to untreated controls. In addition, MTX treatment strikingly increased the CDKN1A expression 14.3±4.4 fold (p=0.006) of treated vs untreated stimulated FLS. Furthermore, we found that 1 μM MTX restored and increased a lowered DNMT1 mRNA expression to 144±12% after PDGF+IL-1β stimulation. There were no significant effects of MTX on CCND1 or DNM1A expression at investigated time points.

Conclusions: Therapeutic doses of MTX reduce mitogen induced FLS prolifera tion and significantly revert mitogen-induced reduction of LBH and p21 expression in RA FLS. MTX restores expression of DNMT1 suggesting that MTX might regulate gene expression and proliferation by affecting the epigenome.

OP0157 APOTOPSIS RESISTANCE OF SYNOVIAL FIBROBLASTS OF PATIENTS WITH RHEUMATOID ARTHRITIS IS REGULATED BY THE LONG NON-CODING RNA FAS-AS1

A. Pajak, E. Horai, E. Pachera, M. Brock, S. Gay, M. Neidhart, O. Distler, A. Jungel. on behalf of yes. Department of Rheumatology, Division of Pulmonology. University Hospital Zurich, Zurich, Switzerland

Background: Apoptosis resistance is thought to contribute to the accumulation of synoviocytes in the affected joints of patients with rheumatoid arthritis (RA). Of particular interest, the Fas receptor (FasR) - Fas ligand (Fasl) apoptotic pathway is altered in RA. Long non-coding (lnc) RNAs are emerging as key regulators of gene expression. Their role in disease, however, is still poorly understood. The recently described IncRNA FAS-AS1 has been implicated in alternative splicing of FasR. This results in increased amounts of soluble FasR (sFasR) and thereby prevents FasL-induced cell death[2]. Whether IncRNA FAS-AS1 is involved in the apoptosis resistance of synovial fibroblasts in RA is unknown.

Objectives: To assess the regulatory role of IncRNA FAS-AS1 in the apoptosis resistance of synovial fibroblasts from patients with RA (RASF).

Methods: Levels of expression of IncRNA FAS-AS1 were measured in RASF and synovial fibroblasts from patients with osteoarthritis (OASF) by qPCR using SYBRGreen detection. Cells were treated with TNFα (10ng/ml, 24h) and/or with Fasl (50ng/ml, 18h) to assess the secreted amount of sFasR by ELISA and the induction of apoptosis by Annexin V staining followed by flow cytometry. LncRNA FAS-AS1 was silenced using locked nucleic acid antisense oligonucleotides (GapmeR).

Results: There was no significant difference in basal levels of IncRNA FAS-AS1 expression between RASF and OASF (n=4 each). TNFα stimulation of synovial fibroblasts, regardless of the disease context (RA or OA), resulted in higher than 6-fold induction of IncRNA FAS-AS1 expression (6.45±1.39; p<0.05; n=4 for RAF and 6.26±1.47; p=0.05; n=4 for OASF). In addition, TNFα induction of secreted sFasR in RASF from 107±74 to 390±274 pg/ml (p<0.05; n=6) and OASF from 69±53 to 249±134 pg/ml (p<0.05; n=6). Fasl induced apoptosis in both RASF and OASF (55–75±11%). However, treatment with TNFα reduced the FasL-induced apoptosis in RASF by 25±19% and in OASF by 15±10%. Silencing with GapmeR successfully decreased the expression of IncRNA FAS-AS1 by 40±22% SEM. Most interestingly, silencing of IncRNA FAS-AS1 reverted the TNFα inhibitory effect on Fasl-induced apoptosis by 37×11% (n=4).

Conclusions: Our data revealed a novel mechanism, which may underlie apoptosis resistance in RASF. We showed that a pro-inflammatory cytokine mimicking IncRNA FAS-AS1 up-regulation in the release of sFasR and thereby may lower the responsiveness of cells to death signals. Thus, targeting IncRNA FAS-AS1 might prevent apoptosis resistance and synovial hyperplasia in RA.

OP0158 PREVALENCE OF IMMUNIZATION OF PATIENTS WITH AUTOIMMUNE DISEASE IN MEXICO

Background: Current guidelines recommend immunization in patients with autoimmune diseases and use of immunosuppressants including biological treatment. Despite the above, the frequency of immunization is unknown in our population.

Objectives: To identify the prevalence of immunization in patients with autoimmune disease in a Rheumatology Service of a third level hospital in Mexico.

Methods: Observational, descriptive, cross-sectional, retrospective. Among consecutive patients with autoimmune diseases who attended the Rheumatology Service of the Hospital Civil of Guadalajara during a period of 2 months (Dec. and Jan.) were included. A questionnaire was carried out to obtain demographic and immunization data. Descriptive statistical analysis was performed.

Results: 1398 patients were surveyed, 484 (40%) had a diagnosis of autoimmune disease; of whom 286 (59%) were on immunosuppressant therapy. 321 patients had a complete immunization during childhood. None of the patients knew what vaccines should be received by their diagnosis. When asked if they had been invited for immunization and from whom, 24 reported that their

Disclosure of Interest: None declared.

DOI: 10.1136/annrheumdis-2017-eular.5079
general practitioner, 126 immunization campaign, 19 nurse, 9 rheumatologist, 4 pulmonologist, 1 infectious disease specialist, 1 family doctor and 1 internist. 260 (54%) reported having their immunization records. Only 37 had been vaccinated with influenza, 27 pneumococcus, 4 human papilloma virus and 2 Hepatitis B in the past. 372 (77%) accepted the invitation to be vaccinated on the day of their interview. Of these, only 19 (41%) went to get the immunization: 41 of whom were given anti-influenza vaccines and 34 Pneumococcus (PPSV 23). The main causes for which the patient considers not to be vaccinated are: 85% “Because my treating doctor has not recommended me to get vaccinated”, 36% “They often do not have the vaccine to apply”, 36% “I forget to get the vaccine on time”, 31% “I think the application of the vaccine can make me sick”, 14% “A vaccination center is not accessible”, 7% “I think it is not useful to get vaccinated”, and 5% “My doctor recommended me not to get vaccinated”. These patients presented a total of 172 recurrent infections that included: upper airway infection 55, pneumonia 4 and others; 90 hospitalizations were reported due to infection of which the main were due to: pneumonia 29, pulmonary tuberculosis 4, kidney 3, bone 1 and meningitis 1.

Conclusions: Immunization in this group of patients is low and rarely accepted mainly because their rheumatologist does not provide them with this information and due in general to a lack of information. This action is extremely important as it might reduce some serious infectious processes that lead to hospitalizations and increase the mortality in these immunosuppressed patients.

OP0159 THE INITIATION, BUT NOT THE PERSISTENCE, OF EXPERIMENTAL SPONDYLOARTHRITIS IN HLA-B27/Hu2m TRANSGENIC RATS IS CRUCIALLY DEPENDENT ON THE IL-23 AXIS

M. Van Tok1, S. Na2, J. Taurog3, D. Baeten1, L. van Duivenvoorde1, 1Clinical Immunology and Rheumatology/Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands; 2Eli Lilly and Co, San Diego, CA; 3Rheumatic Diseases Division, Department of Internal Medicine, UT Southwestern Medical Center, Dallas, TX, United States

Background: The pro-inflammatory cytokine IL-17A is a central driver of pathologic changes in the gut and joint compartments in a mouse-model over-expressing human TNF in the ileum. These mice, together with wild type littermates, were evaluated for the development of arthritis up until the age of 13 weeks after which they were euthanized and ankle and sacroiliac joints as well as ileum were processed for histology.

Results: The differential effect of IL-23R targeting in the initiation versus control animals. The upregulation of TNFR1 on intestinal epithelium and TNFR2 in lamina propria node expression data in samples from the therapeutic experiment indicate a twofold increase in IL-17A expression and no difference in IL-22 expression in the anti-IL23R treated rats compared to controls.

Conclusions: IL-17A expression and production is dependent on the IL-23 axis in the initiation phase of experimental SpA but not in established disease.

Disclosure of Interest: None declared

OP0160 GUT-DERIVED TNF AS RISK FACTOR FOR THE DEVELOPMENT OF SACROILIAC INFLAMMATION

K. Debussche1, H. Cypers2, P. Jacques2, F. Van den Bosch2, D. Souza3, M. Brown3, G. Nabozny4, D. Dove3, A. Klimowicz3, D. Elewaut3, 1Ghent University - VIB, 2Ghent University Hospital, Gent, Belgium, 3Boehringer Ingelheim, Ridgetope, United States

Background: An intriguing link exists between gut and joint inflammation in spondyloarthritides (SpA). About 50% of patients has subclinical (eg. microscopic) gut inflammation, which represents a risk factor for development of Crohn's disease, sacroiliac inflammation and evolution in to Ankylosing Spondylitis. However, the underlying mechanisms are still relatively poorly understood.

Objectives: Our goal was to examine the relationship between TNF, microscopic gut inflammation and axial inflammation using human samples and a novel mouse model.

Methods: We examined in situ expression of TNF, TNFR1 and TNFR2 using triple in situ hybridisation in gut biopsies of human SpA patients. Furthermore, we generated intestinal specific human TNF transgenic mice, in which hTNF is under control of a rat IFABP (fatty acid binding protein) promoter, generating a mouse-model over-expressing human TNF in the ileum. These mice, together with wild type littermates, were evaluated for the development of arthritis up until the age of 13 weeks after which they were euthanized and ankle and sacroiliac joints as well as ileum were processed for histology.

Results: There was a marked upregulation of TNF in inflamed versus non-inflamed gut biopsies of human SpA patients. We also noted a predominant upregulation of TNFR1 on intestinal epithelium and TNFR2 in lamina propia respectively. Of interest, IL-17 and IL-23 were also markedly increased while IL-22 was most abundant in chronically inflamed samples. In line with this, we found that patients with gut inflammation had a higher need for anti-TNF therapy and their degree of clinical response after anti-TNF was also markedly higher.

Our transgenic mice exhibited a runt phenotype and hallmarks of inflammatory bowel disease, including increased intestinal permeability and inflammation compared to their wild-type littermates. While in peripheral joints no clear signs of arthritis were observed, the sacroiliac joints in transgenic mice, by contrast, showed marked signs of inflammation as well as bone erosion and destruction.

Conclusions: These data propose a new paradigm that gut-derived TNF is sufficient to trigger sacroiliitis and provide an alternate explanation on the relationship between gut inflammation, evolution to inflammatory bowel disease and axial inflammation in SpA.

DOI: 10.1136/annrheumdis-2017-eular.4999

OP0161 THE JAK1 SELECTIVE INHIBITOR FILGOTINIB REGULATES BOTH ENTHESIS AND COLON INFLAMMATION IN A MOUSE MODEL OF PSORIATIC ARTHRITIS

Background: Psoriatic arthritis (PsA) is a heterogeneous chronic inflammatory disease characterized by the association of musculoskeletal involvement and extra-skeletal symptoms such as psoriasis and Inflammatory Bowel Disease

Objectives: and clinical evidence from SpA-related diseases suggest, however, that IL-17A and IL-23 have a partially overlapping but distinct biology. In contrast, we showed previously to be crucially dependent on the IL-23 pathway for exposure to anti-IL23R.

Methods: HLA-B27/Hu2m tg rats were immunized with low dose heat-inactivated M. tuberculosis/IFA. Rats were treated with a depleting anti-mouse/rat chimeric anti-IL23R antibody or PBS in a prophylactic (treatment initiation after immunization, before disease onset) or therapeutic (treatment initiation after disease onset) experiment. Clinical measurements included spondylitis and arthritis scores and hind paw swelling (plethysmometry). At the end of the study spleen and lymph nodes were used for cytokine expression, serum samples were analyzed for exposure to anti-IL23R.

Results: In the prophylactic treatment strategy, 58% and 67% of the rats in the control group developed spondylitis and arthritis, respectively. The average arthritis scores at the end of the study was 0.9 ± 1.1 and the average hind paw swelling was 0.35 ± 0.09 cm³. Prophylactic treatment with anti-IL23R completely protected the rats against the development of spondylitis as well as arthritis. In the therapeutic treatment strategy, however, anti-IL23R treatment failed to reduce the incidence or decrease the severity of experimental SpA (fig. 1). With an average increase in arthritis scores after the start of treatment of 1.62 ± 2.8 versus 2.1 ± 2.5 and an increase in paw swelling of 0.6 ± 0.7 compared to 0.3 ± 0.06 cm³ in anti-IL23R treated versus control animals. The differential effect of IL-23R targeting in the initiation phase versus established disease could not be explained by pharmacokinetic differences as serum analyses revealed similar exposure levels. Mechanistically, the expression of presumably downstream effector cytokines such as IL-17A (p < 0.05) and IL-22 (p < 0.01) was reduced in the popliteal lymph node of rats treated prophylactically with anti-IL23R versus controls, with a similar trend in spleen. Accordingly, IL-17A production upon ex vivo re-stimulation was reduced in samples from anti-IL23R treated rats compared to controls, similar popliteal lymph node expression data in samples from the therapeutic experiment indicate a twofold increase in IL-17A expression and no difference in IL-22 expression in the anti-IL23R treated rats compared to controls.

Conclusions: IL-17A expression and production is dependent on the IL-23 pathway for exposure to anti-IL23R.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5476
(IBD) with a variable clinical course. Common findings include enthesis and dactylitis. Current treatments include anti-TNFα and anti-IL-12/IL-23 antibodies with varying success rates but the involvement of several pro-inflammatory cytokines suggests that other targeted therapies may be effective. Notably, the JAKs (a family of 4 non-receptor tyrosine kinases) are crucial for the signaling of many pro-inflammatory cytokines. In this regard, the JAK1-selective inhibitor filgotinib (GLPG0634, GS-6034) demonstrated clinical efficacy in patients with rheumatoid arthritis, a disease that shares some hallmarks with PsA and Crohn’s disease, making this molecule a potential therapeutic tool for the treatment of PsA.

Objectives: Filgotinib was evaluated at the dose of 30 mg/kg (per os) in a mouse model of PsA induced by overexpression of IL-23.

Methods: Overexpression of IL-23 was induced by hydrodynamic delivery of pMIG-23 enhanced Episomal Expression Vector (SBi) to male B10.RIII mice. Evolution of inflammation of hindlimbs and forepaws with fluorescent signal using ProSense™ imaging was associated with inflammation of the paws and forepaws and filgotinib reduced the target-related gene expression. High levels of IL-23 were maintained during the time-course of the study.

Results: High levels of IL-23 were maintained during the time-course of the study and were correlated with severity of finger and paw swelling. Localization of the inflammatory and target-related biomarker gene expression.

Conclusions: The role of IL-23 in the development of inflammation of hindlimbs and forepaws was demonstrated. Target engagement both in hindlimbs and colon was also demonstrated. This data support the evaluation of filgotinib in patients with PsA.

Bringing rheumatology research to the next level: addressing the main challenges of patient partnerships in research and health care service design

S.R. Stones 1,2,3, S. Bull 1, S. Becerra 1
1 Double Helix Consulting, Macclesfield; 2 Faculty of Life Sciences, The University of Manchester, Manchester; 3 School of Healthcare, University of Leeds, Leeds, United Kingdom

Background: Online technology has revolutionised the way in which people connect and share their experiences. It also brings new opportunities to engage patients in health and social care research through the use of an online research community platform (ORCP). For example, it can improve the accuracy and utility of information gathered about research priorities, and it can be used to understand behaviours and preferences. Given an increasing prevalence of long-term conditions including rheumatoid arthritis, online technology represents a novel route for participation and engagement in research.

Objectives: To explore the benefits and limitations of an ORCP through understanding how ORCP can support engagement of adults with rheumatoid arthritis.

Methods: We used a purposive sampling approach to ensure variation of key attributes amongst people with rheumatoid arthritis. A total of eight individuals used the ORCP during the pilot study. Qualitative data were collected through online focus groups, conducted as semi-structured interviews and asynchronous threaded discussions. The study was conducted in line with fieldwork guidelines, and written informed consent was obtained.

Results: The closed ORCP enabled a physically disconnected group to share their experiences of living with rheumatoid arthritis, describing the symptoms, diagnostic experience and support they received. In addition, participants shared their experiences and opinions about treatment delivery and adherence, the impact of rheumatoid arthritis, and the experiences of transitional care from paediatric to adult health services, where appropriate. Reasons and feeling about research participants and drug development processes were also discussed.

Conclusions: Our pilot study provided important accounts from people living with rheumatoid arthritis, highlighting the substantial impact of the disease on their daily lives. The ORCP removed physical contact between the researcher and participants, the absence of which may enable a richer data collection. However, it also has its limitations, primarily because the researcher is less able to establish clinical rapport. ORCPs represent a novel route of data collection, enabling researchers to immerse themselves into a community of individuals, whether they be patients, carers or professionals.

Acknowledgements: The authors would like to thank the individuals who contributed their thoughts and experiences to the pilot study.

Osteoarthritis: new horizons for treatment

M.A. Bowers 1, G. Guillard 1, A. Brett 1, G.R. Vincent 1, P.G. Conaghan 2
1 Imorphics, Manchester; 2 Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

Background: The design of clinical trials for osteoarthritis is challenging; structural changes in tissues are quantitatively small and proceed very slowly. No clear guidance exists on how to optimise recruitment: KL grade is a poor recruitment criterion as centres interpret KL differently. Quantitative measures should be

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1923
better, and metric radiographic joint space width (rJSW) is related to subsequent risk of radiographic progression. Although new MRI measures provide increased responsiveness in DMOAD trials, it is unknown whether selecting for recruitment based on radiographic criteria are well suited for responsiveness of these new measures.

Objectives: (1) To determine which baseline rJSW values are associated with most subsequent progression for rJSW, MRI cartilage and bone outcomes (2) Explore baseline covariates that influence progression rates (3) Estimate the trial numbers needed using the criteria determined by steps (1) and (2).

Methods: We used all knees from the Osteoarthritis Initiative which had all 3 measures recorded (rJSW – Duyrea method; MRI cartilage thickness & bone area, Imorphics) at baseline, 1 and 2 years. We categorised knees into bins of 1mm rJSW, and assessed the 2 year changes of each bin, and characterised the distribution of rJSW in KL 0 knees. We used ANCOVA models to consider which covariates (including gender, height, weight, alignment, age, pain severity) affected 2-year slope of change, and responsiveness using SRMs. For the final optimised recruitment groups, we calculated SRMs (Cls assessed using the bootstrap method of Efron) and derived the number of patients per arm in a putative trial.

Results: 4796 knees were included (2789 females, mean age 61.45). The lower 95th percentile values for rJSW in women and men were 3.9 and 4.5mm respectively. The mean changes at 2-years for all 3 outcomes were greatest for the categories of 2–3 and 3–4mm baseline rJSW (Figure 1A) with notably little change in knees with rJSW >2mm. Of the covariates, only pain improved responsiveness. Using a total WOMAC pain criterion; ≥10.1136/annrheumdis-2017-eular.6860 DOI: Employee of: Imorphics Ltd, P. Conaghan: None declared

1Rheumatology, Nordic Bioscience Biomarkers and Research; 2Clinical development, Nordic Bioscience, Herlev, Denmark

Background: There are two major needs in clinical development of DMOADs: 1) Identifying a suitable population with an active and progressive disease in order to demonstrate significant improvements by an efficacious intervention; and 2) Phenotyping patients and linking them to a corresponding treatment mode-of-action (e.g. anti-inflammatory). The biochemical marker CRPM is a neoepitope of C-reactive protein (CRP) and is released from the local inflamed tissue when CRP is degraded by proteases such as matrix metalloproteinases.

Objectives: The purpose of this study was to translate the CRPM, from rheumatoid arthritis (RA), where it has been extensively tested, to OA, and to test whether it is predictive of radiographic OA.

Methods: The placebo arms of two phase III OA trial (clinicaltrial.gov: NCT00486434 and NCT00704847), a phase III RA study (the LITHE study, N=490), which included patients with active, moderate-severe RA (NCT00106535), as well as in an early RA cohort (N=92) were used. Subjects with symptomatic and radiographic knee OA: WOMAC pain ≥150mm and/or WOMAC function ≥510mm, and Kellgren-Lawrence grade (KLG) 2 or 3. KLG were scored for both knees at baseline and year 2 (Y2). Serum CRPM and hsCRP were measured at baseline. The association between serum CRPM levels and disease activity score (DAS28) and hsCRP was investigated by Spearman’s correlations. Quartile ranges of CRPM in the early RA cohort were used to define the cut-off between inflammatory OA and non-inflammatory OA. OA knees were divided into cases and controls based on a terminology proposed by the FNHI-OAI consortium (1) (knees with KLG>2 at BL were excluded, and incidence OA at Y2 was defined KLG>2). Logistic regression was used to compare cases and controls.

Results: There was a significant correlation between disease activity measures and CRPM in both RA studies. Seventy-five percent of the LITHE patients had high or very high levels of CRPM at BL, which was changed to a pattern similar to early RA after treatment. The mean CRPM levels were significantly lower in OA (8.5 [95% CI 8.3–8.8] ng/mL) compared to the RA patients (15.6 [9.5–21.6] ng/mL); however, a significant subset of OA patients (41% and 31% in SMC2301 and SMC2202) had CRPM levels ≥9ng/mL as 75% of patients with early RA. Patients with BL or Y2 CRPM levels ≥9ng/mL were more likely to develop knee OA than patients with low level of CRPM. Overall, moderate to very high levels of CRPM at BL and Y2 were predictive of incidence OA with odds ratio of 4.6 [1.2–17] and 2.5 [1.2–4.8].

Conclusions: A subset of OA patients, up to 41%, appear to have tissue inflammation comparable to that of RA, reflected by the level of CRPM. Further, high CRPM levels at BL was prognostic of incident knee OA. These data suggest that CRPM is blood-based biochemical marker for finding OA patients with an inflammatory phenotype.

DOI: 10.1136/annrheumdis-2017-eular.6290
Conclusions: Radiographic outcomes from this interim analysis demonstrated that treatment with SM04690 maintained or increased JSW compared to placebo. This supports the development of SM04690 as a potential DMOAD for the treatment of knee OA. Further studies are ongoing.

A PHASE 2A, PLACEBO-CONTROLLED, RANDOMIZED STUDY OF ABT-981, AN ANTI-INTERLEUKIN-1ALPHA AND -INTERLEUKIN-1BETA DUAL VARIABLE DOMAIN IMMUNOGLOBULIN, TO TREAT EROSIIVE HAND OSTEOARTHRITIS (EHOA)

M. Kloppenburg 1, C. Petery2, I.K. Haugen3, F. Kroon1, S. Chen1, L. Wang3, W. Liu4, G. Levy4, R. Fleischmann5, F. Berenbaum6, D. van der Heijde1, J. Medema7, M.C. Levesque5, 8, Leiden University Medical Center, Leiden, Netherlands; 2Spire Sciences, Inc., Boca Raton, FL, United States; 3Clinic of the University of Antwerp, Antwerp, Belgium; 4University of Texas Southwestern Medical Center at Dallas, Metropolix Clinical Research Center, Dallas, TX, United States; 5University Pierre & Marie Curie and Inserm, DGHU IZB, APHP, Hospital Saint-Antoine, Paris, France

Background: No approved OA therapies reduce pain and slow joint damage. Mouse data suggested that inhibiting IL-1α and IL-1β with ABT-981 would reduce pain and slow structural progression in EHOA.

Objectives: To test the efficacy and safety of ABT-981 in EHOA.

Methods: Subjects with HOA per ACR criteria, ≥3 inflamed IP joints (tender, swollen, or both), hand pain ≥5 (scale 0–10), and ≥1 erosive IP joint on X-ray (Verbruggen-Veys) were randomized to placebo (PBO) or ABT-981 200 mg SC every 2 wk for 26 wk. The primary outcome was AUSCAN hand pain at 16 wk. Subjects had radiographs of both hands and MRI of the index hand at baseline and 26 wk. Both radiographs (Verbruggen-Veys, GUSS™, OARSI, Kelgren-Lawrence [KL] and MRIs [HOAMRIS] with read by 2 independent central readers. A modified intent-to-treat population (ie, randomized and treated) was analyzed. Continuous efficacy endpoints were assessed using ANCOVA models with treatment and country as main factors and baseline measurements as covariates with LOCF imputation for the primary endpoint.

Results: Of 131 treated subjects (85% women; mean age 68 y), 61/67 randomized to PBO and 49/64 to ABT-981 completed the study; subject characteristics were well matched. AUSCAN pain was not significantly different vs PBO at wk 16 (P=0.39; Table 1, Figure); X-ray data and other endpoints also were not statistically different vs PBO (Table 1). ABT-981 significantly decreased hsCRP, neutrophils, IL-1α, and IL-1β. Immunogenicity had no impact on ABT-981 pharmacokinetics. Besides injection site reactions and neutropenia, ABT-981 was well tolerated and safety was similar vs PBO, with no serious infections (Table 2).

Table 1. Longitudinal associations of OP phenotype status and WOMAC knee pain changes

Table 2. Adverse AEs and serious AEs

Conclusions: Despite adequate pharmacodynamics results, targeting IL-1 may be ineffective in EHOA, as ABT-981 did not improve outcomes.

LEPTIN AND ADIPONECTIN MEDIATE THE ASSOCIATION BETWEEN BODY MASS INDEX AND HAND AND KNEE OSTEOARTHRITIS

A. Veenbrink1, F. Kroon2, R. de Mutsert3, W. Visser2, S. le Cessie3, F. Rosendaal4, M. Kloppenburg4,1, Medicine, Universiteit Utrecht, Utrecht; 2Rheumatology; 3Clinical Epidemiology, Leids Universitair Medisch Centrum, Leiden, Netherlands

Background: Associations between adiposity and osteoarthritis (OA) in non-weight-bearing joints suggest that besides mechanical factors also systemic influences contribute to OA. Systemically active substances secreted by adipose tissue, including leptin and adiponectin, are hypothesized to play a role in OA.

Objectives: To examine whether leptin and adiponectin mediate the association between body mass index (BMI) and hand and knee OA.

Methods: Cross-sectional data of a population-based study were used. Participants completed questionnaires and underwent standardized physical examination of hands and knees to define OA according to clinical American College of Rheumatology criteria. Fasting serum leptin and adiponectin were measured with immunoassays. Potential mediation was investigated using the Baron and Kenny framework. Four assumptions were investigated: associations between (1) BMI and OA (pathway C), (2) BMI and adipokines (pathway A), (3) adipokines and OA (pathway B), and (4) attenuation of the total association between BMI and OA after including adipokines (pathway C').

Results: In 6462 participants (56% women, median age 56 years (range 45–65), filled. Models were adjusted for age, ethnicity and education, and stratified by sex. Confidence intervals (CIs) was estimated, only when all four assumptions were fully met. Percentage mediation with 95% confidence intervals was estimated, only when all four assumptions were fulfilled. Models were adjusted for age, ethnicity, and education, and stratified by sex.

For the association of BMI and knee OA was defined in women. These findings suggest that systemic mediators contribute to hand OA, and to a lesser extent to knee OA.

Background: Osteoarthritis (OA) is a common joint disease that frequently affects the knee and is the leading cause of total knee arthroplasty (TKA) for knee OA. The most common reason for taking TKA is to ease pain and disability. Identification of prognostic factors associated with TKA could be a possible way to find therapeutic targets to slow disease progression and delay the time for knee replacement.

Objectives: To investigate whether infrapatellar fat pad (IPFP) signal intensity (SI) alteration predicts the occurrence of TKA in patients with knee OA over 4 years.

Methods: Participants with symptomatic knee OA were selected from the Osteoarthritis Initiative (OAI) study. Case knees (n=127) were defined as those that received TKA during 4 years follow-up visit. They were matched by gender, age and radiographic status assessed at baseline with a control knee. We used T2 weighted MR images to measure IPFP SI alteration using a newly developed algorithm in MATLAB. The measurements were assessed at OAI baseline (BL), T0 (the visit when TKA was reported), 1 year prior to T0 (T1). Conditional logistic regression was used to assess the relationship between cases and control knees and assess the risk of TKA in relation to SI alteration.

Results: Participants (n=237) were mostly female (57%), with average age of 63.7±8.5 years old and mean BMI of 29.5±4.7 kg/m2. In a multivariable analysis, standard deviation of IPFP SI [sd (IPFP)] and the ratio of high SI region volume to whole IPFP volume [Percentage (H)] measured at BL were significantly associated with TKA after adjustment for BMI, knee bending activities, self-reported knee injury and surgery history (HR: 3.5, 95% CI 1.1 to 11.4; HR: 8.9, 95% CI 1.2 to 67.2). IPFP SI alterations measured at T1 including sd (IPFP), Percentage (H) and clustering effect of high SI [Clustering factor (H)] were significantly associated with TKA (HR: 4.0, 95% CI 1.2 to 13.2; HR: 10.9, 95% CI 1.9, 63.6; HR: 1.8, 95% CI 1.1 to 2.9). All measurements including mean value of IPFP SI [Mean (IPFP)], sd (IPFP), mean value of IPFP high SI [Mean (H)], standard deviation of IPFP high SI [sd (H)], median value of IPFP high SI [Median (H)], upper quartile value of IPFP high SI [IQ (H)], Percentage (H), Clustering factor (H) were significantly associated with TKA at T0.

Conclusions: IPFP SI is an important predictor for TKA in knee OA patients. Targeting IPFP SI could be a potential way to reduce the need for future TKA.

Cellular drivers of inflammation in rheumatic disease

OP0172 EXPANDED T-CELL CLONES PRESENT IN SYNOVIAL FLUID AT ONSET OF RHEUMATOID ARTHRITIS ARE ALREADY PRESENT IN THE SYNOVIUM IN THE SEROPOSITIVE “AT RISK” STAGE

G. Balzaretti1,2, P. Klarenbreek1, M. de Hair1, M. Doorenpleet1, V. B. Schak1, R. van de Sande1, D. Gerlag1,4, A. van Kampen3, F. Baas5, P.P. Tak1,6, N. de Vries1, 2

OP0171 SIGNAL INTENSITY ALTERATION WITHIN INFRAPATELLAR FAT PAD PREDICTS TOTAL KNEE ARTHROPLASTY WITHIN FOUR YEARS: DATA FROM THE OSTEOARTHRITIS INITIATIVE
of rheumatoid arthritis (RA). Earlier we showed that already at the seropositive ‘at risk’ stage uninfamed synovial tissue contains T-cell infiltrates. In another study we showed that inflamed synovium selectively harbours expanded T-cell clones that are hardly present in paired blood samples.

**Objectives:** Following up on these observations, we longitudinally investigated whether the same expanded T-cell clones found in the inflamed synovial tissue at onset of RA are already present in the synovium in the seropositive ‘at risk’ stage.

**Methods:** Fifty-five individuals without arthritis but seropositive for IgM rheumatoid factor and/or anti-citrullinated protein antibody (ACPA) were prospectively followed. In five aCCP+ individuals synovial biopsies and paired blood samples at inclusion (‘at risk’ stage) and after development of RA (ACR2010 criteria; mean time to arthritis 27 months (range 11.7-47.3)) were available for analysis. T-cell clones were identified by their unique TCRβ sequence using RNA-based next generation sequencing. For each sample, 3570 TCRβ sequences were analysed. Clones with a frequency of >0.5% were arbitrarily considered as highly expanded clones (HECs). ANOVA and t-test were used for statistical analysis.

**Results:** T-cell repertoires in ‘at risk’ and RA synovium were similar (mean ± SD) number of clones 488±70 vs 567±204 respectively, p=0.46). Number of HECs of aCCP+ individuals at inclusion (‘at risk’ stage) and after development of RA (ACR2010 criteria; mean time to arthritis 27 months (range 11.7-47.3)) were available for analysis. T-cell clones were identified by their unique TCRβ sequences using RNA-based next generation sequencing. For each sample, 3570 TCRβ sequences were analysed. Clones with a frequency of >0.5% were arbitrarily considered as highly expanded clones (HECs). ANOVA and t-test were used for statistical analysis.

**Conclusions:** Many T-cell clones found in early RA synovial tissue are already present in the pre-clinical ‘at risk’ phase. The resemblance in TCR repertoires indicates that the process leading to disease – at least at the T-cell level – constitutes a smooth development. These clones, being already present in the very early stage of this disease and persisting as dominant clones during contraction of active arthritis, form attractive candidates for further characterization.

**OP0174 NEW PROTEIN ARRAY TECHNOLOGY IDENTIFIES RITUXIMAB TREATED NON RESPONDER RHEUMATOID ARTHRITIS PATIENTS ARE GENERATING A NEW AUTOANTIBODY REPertoire**

Z. Konthur1, M. Wiemkes2, T. Häupl2, G. Burmester1, K. Skriner3, Max Planck Institute, Max Planck Institute; 1Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin, Germany.

**Objectives:** Rituximab (RTX) has shown clinical efficacy but up to 40% of RTX treated rheumatoid arthritis (RA) patients are poor responders (Ann-Rheum-Dis. 2005 Feb;64(2):246-52) and the commonly used RA biomarkers (RF/ACPA) are poor predictors for therapy response. In this study the autoantibody repertoire analysed on protein macorarrays from RA patients under RTX treatment was correlated to clinical DAS28 response.

**Methods:** Screening of RA sera was conducted on 37.830 unique human proteins correlated to clinical DAS28 response. The autoantibody repertoire in all patients or associated with response. However, RTX reduced the repertoire of autotagnostin-in-silico and by hierarchical clustering.

**Results:** In the cohort of 26 patients 1292 different autoantigens (IgD, IgA, IgG) were detected. Using protein array we investigated clusters of autoantigenic responses that disappeared or developed during RTX treatment of RA patients. RA autoantigenic patterns before and 6 months after RTX were patient-specific and no relevant autoantigenic cluster was found that was shared between patients or associated with response. However, RTX reduced the repertoire of autoantibodies after 24 weeks of treatment in the tested RA patient cohort on average by 60%. RA patients which do not respond are generating on average 63% new autoantibodies. In good responders to RTX only 5.5% (+/-3%) new autoantibodies can be detected. The IgA and IgG autoantibody repertoire. The IgA and IgG autoantibody repertoire. The serum after 24 weeks of RTX treatment is reduced (IgA: 41%, IgG: 31%) in good responders whereas it is increased (IgA: 1.3%, IgG: 24%) in non responders to RTX.

**Conclusions:** After 6 month of RTX treatment the autoantibody repertoire in all good responding RA patients is reduced and non responders to RTX change their autoantibody repertoire directed against new but patient specific antigens. The fast rebuilding of functional B cells is only detected in non-responders to rituximab.

Characterization of Novel Stromal-Derived Autoantigens Recognized by Ra Synovial Monoclonal Antibodies

E. Corsiero, L. Jagemann, E. Prediletto, C. Pitazlis, M. Bombardieri. Centre for Experimental Medicine & Rheumatology, William Harvey Research Institute, London, United Kingdom

Background: We previously showed that up to 40% of RA synovial recombinant monoclonal antibodies (Ra-mAbs) generated from germinal center-like structure (GC-LS+) RA synovium recognize citrullinated antigens contained in neutrophils extracellular traps (NET) (1). The cellular source of other potential autoantigens targeted by the majority of locally differentiated B cells remains undefined. Recently, RA-fibroblast-like synovocytes (RA-FLS) have been implicated in the release of citrullinated antigens (2, 3). However, whether these cells are targeted by Ra-mAbs is still to be determined.

Objectives: Here, we aimed to define the Ra-mAbs immunoreactivity towards i) RA-FLS and ii) identify potential stromal-derived autoantigens.

Methods: 67 Ra-mAbs were generated from single CD19+ B cells FACs-sorted from fresh synovial cell suspensions following IgV H+VL genes cloning (1). Ra-mAbs were tested by means of i) cell-based immunofluorescence assays with FLS of RA patients and controls (sarcoid arthritis (OA)-FLS and RA-dermal fibroblast (RA-DF)), ii) co-localization with stromal specific markers and iii) immunoenzymatic tests with co-localizing antigens. Control rmAbs were also used (Sjögren’s syndrome/healthy donors).

Results: Immunofluorescence on RA-FLS demonstrated reactivity of 21% of Ra-mAbs (14/67 rmAbs) towards cytoplasmic components of FLS. Only 4 mAbs out of 14 were binding both FLS and NET components. For some Ra-mAbs this reactivity was not specific to RA-FLS since it was also observed for OA-FLS and RA-DF. Interestingly, co-localization was observed with calreticulin (CRT) which in its citrullinated (cit-CRT) form has been previously shown to recognize the RA “shared epitope” HLA domain sequence (3). When tested in ELISA for native and cit-CRT with 4 out of 8 rmAbs displaying increased immunoreactivity towards cit-CRT. Controls rmAbs showed reactivity to either FLS or CRT. Preliminary data suggest that RA patient serum preferentially recognize the lectin-like N-terminal domain of CRT (4).

Conclusions: Here, we provide new evidence that a subset of locally differentiated B cells within RA synovial GC-LS can react towards RA-FLS derived antigens. Preliminary data suggest that part of this reactivity is directed towards CRT. Identification of immunodominant epitopes within CRT is under investigations.

Paracaspase MALT1 Plays a Central Role in the Pathogenesis of Rheumatoid Arthritis

E. Gils 1,2, J. Staal 3,4, R. Beyerst 1,4, D. Elewa 1,4, 1 Department of Internal Medicine, Ghent University; 2 Molecular Immunology and Inflammation Unit, VIB Inflammation Research Center; 3 Department of Biomedical Molecular Biology, Ghent University; 4 Molecular Signal Transduction in Inflammation; 5 Department of Biomedical Molecular Biology; 2 Molecular Immunology and Inflammation Unit, VIB Inflammation Research Center, Ghent, Belgium.

Background: One of the hallmarks of many inflammatory arthritides is their strong linkage with MHC-signalling, which is mirrored by the marked role for adaptive immunity. Accordingly, rheumatoid arthritis (RA) is characterized by the activation of auto-reactive T-cells and the development of auto-antibodies. T-cells may additionally respond to non-TCR mediated signals, which are essential in developing effector functions. Pathways leading to the modulation of both innate and adaptive signals are therefore of marked interest to study in arthritic diseases.

Objectives: The paracaspase MALT1 is a key player in the activation and proliferation of immune and non-immune cells. These cells include the lymphoid, myeloid and mast cells, indicating MALT1’s crucial role in both innate and adaptive signalling (1). Therefore, MALT1 is regarded a promising target for the treatment of autoimmune diseases and defining its role in the pathogenesis of inflammatory arthritis is a critical first step.

Methods: To unravel MALT1’s role in inflammatory arthritis, we initially assessed MALT1-activation in mice that were challenged with collagen-induced arthritis (CIA), the prototype model for antigen-induced RA. We then addressed the role of MALT1 in the pathogenesis of inflammatory arthritis by challenging MALT1-deficient mice to distinct models of arthritis (CIA and CAIA) or by backcrossing MALT1-deficient mice to TNFÎ²-/- mice, representing a Spâ-like model. Additionally, CIA was induced in CD4-specific MALT1-deficient mice to determine the importance of MALT1 in T-cells.

Results: We provide evidence that MALT1 plays a crucial role in the pathogenesis of RA as MALT1-deficient mice were completely protected against CIA. This complete protection was additionally observed in CD4-specific MALT1-deficient mice, indicating that the selective ablation of MALT1 in CD4-positive cells is sufficient for the observed resistance against CIA. CAIA on the other hand, which is a T- and B-cell independent model of RA, did not depend on the presence of MALT1, since both MALT1-/- and MALT1-/- mice showed comparable symptoms of RA. Interestingly, TNFÎ²-/- mice that were deficient for MALT1 also showed a reduced arthritis and ileitis phenotype, although TNF-concentration in the serum of these mice was higher compared to MALT1-/-xTNFÎ²-/- mice.

Conclusions: Overall, our data highlight that MALT1 plays a crucial role in the pathogenesis of inflammatory arthritides and represents an interesting candidate to target therapeutically.

N-Glycosylation Sites in the Variable Domain of B Cell Receptors Specific for Citrullinated Antigens

L.M. Slot1, R.D. Vergroesen 1, L. Hafskenschiedt 1, M.T. Koning 2, T. Rispens 3, H. Veelken 1, R.E. Toes 1, H.U. Scherer 4, 1 Department of Rheumatology, 2 Department of Hematology and Oncology, University Medical Center, Utrecht; 3 Department of Immunopathology, Sanquin Research, Amsterdam, Netherlands.

Background: Recent structural analysis of anti citrullinated protein antibodies (ACPA) in serum and synovial fluid of patients with rheumatoid arthritis (RA) revealed that the vast majority (~90%) of secreted ACPA IgM molecules carry N-glycans in the variable (Fab) domain. This remarkable degree of Fab-glycosylation is absent from ACPA-depleted control IgGs and from autoantibodies in other tissue extracts. So far, it is unclear why ACPA carry this feature and which biological effects these glycans mediate in the context of RA. Of note, however, N-glycosylation requires a specific amino acid consensus sequence in the protein backbone, which is very rare in germline-encoded variable region genes.

Objectives: To study the B cell receptor (BCR) repertoire of ACPA-expressing B cells to determine the frequency, origin and localisation of N-glycosylation sites in ACPA Fab domains.

Methods: Citrullinated antigen-specific and non citrulline-reactive control B cells were identified in peripheral blood of ACPA-positive RA patients by antigen-specific tetramer staining and isolated by fluorescence activated cell sorting. Cells were either sorted in pools and directly lysed, or sorted as single cells and cultured for two weeks followed by the detection of ACPA-positive culture wells by ELISA. Full-length immunoglobulin (Ig) rearrangements were identified by anchoring reverse transcription of Ig sequences, amplification by nested PCR and either next generation sequencing (NGS, PacBio platform) or, for single cell transcripts, Sanger sequencing (scSeq). Sequence reads were analysed using IMGT V-QUEST tools.

Results: The mean number of nucleotide mutations in heavy chains (HC) of IgG BCRs derived from ACPA-expressing B cells was high (33 in NGS, 48 in scSeq samples; similarity to germline: 88% in NGS, 84% in scSeq). NGS identified 12 unique IgG clones derived from 4 donors, of which 10 (83%) had at least one N-glycosylation site in the HC or light chain (LC). scSeq identified 86 unique IgG clones derived from 6 donors, of which 68 (79%) had N-glycosylation sites. For 57/86 IgG clones, we could determine the combination of HC and LC sequences. In these, only 7 (12%) clones had no sites, while 19 (33%) had one, 23 (41%) had two, 5 (9%) had three and 3 (4%) clones had four sites. 57 sites were found in the HC and 34 in the LC. All N-glycosylation sites were created by somatic mutations and not encoded in the germline sequence. Several sites were located in antigen-engaging regions. No correlation was found between the number of N-glycosylation sites and the number of somatic mutations.

Conclusions: We demonstrate that B cell surface-expressed ACPA-IgG molecules display a remarkable frequency of N-glycosylation sites in the Fab domain, all of which are generated by somatic mutation. This could indicate that ACPA-expressing B cells acquire a selective survival advantage by introducing N-glycosylation consensus sequences in the Fab domain, a process that is likely to occur under the influence of T cell help and that could facilitate the break of tolerance to citrullinated antigens.

Fibroblast Priming is Common to Many Sites, and Psoriatic Skin Fibroblasts May Acquire Inflammatory Memory

T. Crowley 1, J.O. O’Neill 1, H.R. Adams 1, T.W. Kragstrup 2, A. Filer 1, C.D. Buckley 1, A.R. Clark 1, 1 Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom; 2 Biomedicine, Health, Aarhus University, Aarhus, Denmark.

Background: Rheumatoid arthritis (RA) is a common chronic inflammatory
BRAFV600E PROMOTES MYELOID SKEWING IN PHARMACOLOGICAL CHARACTERIZATION OF THE ADAMTS-5 DELETION OF THE PROSTAGLANDIN D2 RECEPTOR DP1

Disclosure of Interest: None declared

RESULTS:

we isolated HSPC from human cord blood and transduced them at two different levels (50% and 20%) with lentiviral vectors that ubiquitously express BRAFV600E, BRAFWT or GFP.

METHODS:

We wished to assess whether fibroblasts from sites other than the joint, skin, lung, tonsil, bone marrow and gum removed and the cells were washed free of stimulus. Cells were rested for 24h before once again being washed and stimulated with 10ng/ml TNFα for a further 24h. The conditioned medium was removed and secreted mediators compared between first and second response to stimulus. Transcription and intracellular signalling at time points within each challenge were also determined.

RESULTS:

Priming occurs in fibroblasts from a variety of anatomical sites with diverse functions. Its prevalence is a shared phenomenon, but the variation between sites suggests a specific role required in some tissues and not others. We have shown that inflammatory memory in the form of IL6 production, fibroblasts from the skin of psoriasis (Ps) patients mounted a primed response that was significantly augmented compared to their first response to TNFα, and signficantly higher than the second response of healthy skin. This augmented response matches that of FLS, as IL6 but not IL8 was increased. This pattern was also matched both for fibroblasts from periodontitis.

In conclusion:

3.1 Priming fails to occur in fibroblasts from other sites, providing support to the hypothesis that this phenomenon is a site-specific feature.

BRAFV600E PROMOTES MYELOID SKEWING IN MULTISYSTEMIC LANGERHANS CELL HISTIOCYTOSIS HUMANIZED MOUSE MODELS

R. Biavasco1, M. Norelli2, B. Camisa2, D. Cesana1, P. Gallina1, B. Gentner1, M. Porzoni1, L. Dagna4, A. Bondanza2, E. Montini1, 1Sr-Tiget; 2Innovative immunotherapy; 3Pathology Unit; 4Clinical immunology and rheumatology, San Raffaele Scientific Institute, Milan, Italy

Background: Multisystem Langerhans cell histiocytosis (mLCH) is an aggressive disease characterized by the accumulation of mononuclear phagocytes with immunohistochemical features of dendritic cell (histiocytes). Histiocytes infiltrate multiple tissues, including lung and spleen, and produce high levels of proinflammatory cytokines/chemokines, leading to organ dysfunction. In patients, around 10% of cells in lesions carries an oncogenic mutation in the MAPK pathway, mostly BRAFV600E (70% of cases). BRAFV600E can be detected also in non-malignant reactive histiocytes in patients, whereas only a fraction of them carries a mutation in B cells and none in T cells.

Objectives: To study the role of BRAFV600E in the pathogenesis of mLCH, we set up a humanized mouse model of mLCH based on the transplantation into immunodeficient mice (NSG) of human HSPC expressing BRAFV600E, BRAFWT or GFP.

Methods:

In this report we describe the in vitro and in vivo characterization of the small molecule GLPG1972, an inhibitor of ADAMTS-5. GLPG1972 anti-catabolic activity was evaluated in murine and human cartilage explants and DMOAD activity was investigated in the destabilization of the medial meniscus (DMM) model. In conclusion:

Background: Degradation of articular cartilage and alterations of the underlying subchondral bone are hallmarks of osteoarthritis (OA). A disintegrin and metalloproteinase with thrombospondin motifs-5 (ADAMTS-5) is a key aggercan-cleaving enzyme involved in this pathogenic process from the earliest stages of cartilage degradation and as such, is an attractive drug target for the development of a disease-modifying OA drug (DMOAD). Objectives: In this report we describe the in vitro and in vivo characterization of the small molecule GLPG1972, an inhibitor of ADAMTS-5. GLPG1972 anti-catabolic activity was evaluated in murine and human cartilage explants and DMOAD activity was investigated in the destabilization of the medial meniscus (DMM) model.

Methods: The ADAMTS-5 biochemical assay is based on the cleavage of a fluorescent substrate by recombinant ADAMTS-5. Mouse femoral head cartilage explants were stimulated by interleukin-1α (IL-1α) for 3 days and GAG release quantified. Human articular cartilage explants were stimulated with IL-1α for 12 or 19 days and the NITEGE epitope quantified using the AGNx1 assay. Unilateral OA was induced in C57BL6 mice by DMM. Mice were treated with vehicle or GLPG1972 at 30, 60 or 120 mg/kg, b.i.d. for 8 weeks. Medial femoral joint sections were scored by an evaluator blinded to treatment.

RESULTS:

GLPG1972 showed potent inhibition of human ADAMTS-5 (IC50=20 nM). In murine cartilage explants, GLPG1972 demonstrated DMOAD activity, as shown by significant reduction of catabolic activity, collagen breakdown and aggrecanase activity.

Conclusions: GLPG1972 is an orally bioavailable, potent and selective ADAMTS-5 inhibitor showing significant anti-catabolic activity in cartilage explants. In the DMM model, treatment with GLPG1972 resulted in significant protective effects on both cartilage and subchondral bone pathology. Taken together these results provide support to progress GLPG1972 into the clinic as an oral treatment for OA.

OP0181

DELETION OF THE PROSTAGLANDIN D2 RECEPTOR DP1 EXACERBATES AGING-ASSOCIATED AND INSTABILITY-INDUCED OSTEOARTHRITIS

Y. Ouahadi, L. Habouri, J.-P. Pelletier, J. Martel-Pelletier, M. Bendorfer, H. Fahmi

Background: The D prostaglandin receptor 1 (DP1), a receptor for prostaglandin D2 (PGD2) plays important roles in inflammation and cartilage metabolism. However, its role in the pathogenesis of osteoarthritis (OA) remains unknown.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5179
CONVERGENCE OF JOINT REPAIR AND PAIN PATHWAYS VIA CORDYCEPIN, A NOVEL COMPOUND, REDUCES KNEE JOINT DAMAGE IN RATS

Objectives: We undertook this study to explore the roles of DP1 in the development of OA and to evaluate the efficacy of a DP1 selective agonist in the treatment of OA.

Methods: We compared the development of aging-associated OA and destabili- zation of the medial meniscus (DMM)-induced OA in DP1-deficient (DP1-/-) and wild-type (WT) mice. The progression of OA was assessed by histology, immunohistochemistry, and microcomputed tomography (micro-CT). Cartilage explants from DP1-/- and WT mice were treated with interleukin-1α (IL-1α) ex vivo, to evaluate proteoglycan degradation. The effect of intra-peritoneal administration of the DP1 selective agonist BW245C on OA progression was evaluated in WT mice.

Results: Compared to WT mice, DP1-/- mice had exacerbated cartilage degradation in both models of OA and this was associated with increased expression of MMP-13, and ADAMTS-5. In addition, DP1-/- mice demonstrated enhanced subchondral bone changes. Cartilage explants from DP1-/- mice showed enhanced proteoglycan degradation following treatment with IL-1α. Intraportal injection of BW245C attenuated the severity of DMM-induced cartilage degeneration and bony changes in WT mice.

Conclusions: These findings indicate a critical role for DP1 signaling in OA pathogenesis. Modulation of DP1 functions may constitute a potential therapeutic target for the development of novel OA treatments.

OP0182 CONVERGENCE OF JOINT REPAIR AND PAIN PATHWAYS VIA NERVE GROWTH FACTOR AND P75 EXPRESSING MESENCHYAL STEM CELLS—A NOVEL EXPLANATION FOR OSTEOARTHRITIS PROGRESSION WITH ANTI-NGF IN OSTEOARTHRITIS

T. Baboolal1, S. Al Hini, E. Jones1, J. Reckless2, M. Foster3, R. Doyle4, K. Aforselles5, S. Westbrook6, D. McGonagle7,1,1 Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, 2 Rxcelerate Ltd, Cambridge; 3 Levicept Ltd; 4 Tetrad Discovery Ltd, Ramsgate, United Kingdom

Background: Nerve growth factor (NGF) is a key regulator of pain and anti-NGF therapy reduces osteoarthritis (OA) associated pain. However, anti-NGF therapy is associated with rapidly progressive OA (RPOA) [1]. In hip OA there is a 5-fold increase in mesenchymal stem cells (MSCs) from MRI bone marrow (BM) lesions, areas associated with OA progression [2], MSCS in such lesions are uniformly positive for the NGF receptor, p75, which is also linked to chemotaxis and proliferation in other stromal cell compartments [3].

Objectives: Evaluate anti-NGF treatment in monoiodoacetate (MIA) induced OA and test whether NGF influences human BM-MSC function.

Methods: Human tibial plateau (TP) bone was isolated from patients undergoing total knee replacement. OA was induced in male Sprague Dawley rats by intra-articular injection of mono-sodium iodoacetate (MIA; 1mg/50μl) on day 0. Cordycepin was administered orally (2mg/rat mixed in 1g of wet mash) every other day for 2 weeks.

Results: The MIA rodent model of OA pain exhibited significant pain behaviour, synovial inflammation and angiogenesis, cartilage damage, osteophyte formation and subchondral bone changes, compared with non-arthritic controls. A two week pre-emptive and therapeutic treatment with cordycepin reduced MIA-induced pain behaviour and synovial changes (inflammation and angiogenesis). Pre-emptive cordycepin treatment reduced cartilage damage and the level of ADAMTS-5 and MMP13 from the chondrocytes. Pre-emptive and therapeutic cordycepin treatment reduced the number of channels crossing the OCJ and TRAP positive osteoclasts in the subchondral bone, but had no effect on numbers of osteophytes. Therapeutic cordycepin treatment did not alter cartilage damage score or the level of ADAMTS-5 and MMP13 positive chondrocytes.

Conclusions: Our data show that the analgesic effects of orally administered cordycepin in a pre-emptive and therapeutic protocol are associated with synovial changes (inflammation and angiogenesis) and bone remodelling. Administration of cordycepin before the onset of MIA-induced OA reduced cartilage damage and had a chondroprotective effect. Whereas therapeutically administered cordycepin did not alter cartilage damage. Further studies will investigate whether cordycepin mediated reduction in MIA-induced pathology and pain behaviour is as a result of its direct action on polyadenylation inhibition. Polyadenylation inhibitors could therefore be a novel class of drugs for treating OA.

OP0183 CORDYCEPIN, A NOVEL COMPOUND, REDUCES KNEE JOINT PATHOLOGY AND PAIN IN THE MIA RAT MODEL OF OSTEOARTHRITIS

S. Ashraf1, J. Burston2, V. Chapman3, C. de Moor1, Pharmacy; 2 Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, United Kingdom

Background: Cordycepin (3’ deoxyadenosine) is a popular traditional medicine in Asia, taken for conditions associated with ageing. Osteoarthritis (OA) is a common cause of pain and disability in the ageing population. Inflammation is a key component of osteoarthritis pain. Cordycepin is thought to act by inhibiting polyadenylation, the last step of mRNA synthesis, and can potentially have increased therapeutic benefit in OA (anti-inflammatory and analgesic) with fewer side effects than currently available therapies.

Objectives: The aim of this study was to determine whether cordycepin treatment alters osteoarthritic pain and pathology, and to decipher the mechanisms of action by which cordycepin exerts any potential beneficial actions.

Methods: OA was induced in male Sprague Dawley rats by intra-articular injection of mono-sodium iodoacetate (MIA; 1mg/50μl) on day 0. Cordycepin was administered orally (2mg/rat mixed in 1g of wet mash) every other day for 2 weeks (pre-emptive study: day 0, day 2 and day 14 to day 28; Pain behaviour was measured as hind-limb weight-bearing asymmetry and mechanical paw withdrawal thresholds. Joint tissues were collected at days 14 and 28. Joint changes were quantified using histology and immunohistochemistry techniques. Synovial inflammation was quantified as extent of CD68 positive macrophage and cellular infiltration. Synovial angiogenesis was measured as endothelial cells positive for proliferating cell nuclear antigen (PCNA). Safranin-O staining was used to score cartilage damage and bone changes (osteophytes and channels crossing the osteochondral junction [OCJ]). Tartrate-resistant acid phosphatase (TRAP) positive osteoclasts and ADAMTS-5 and MMP13 positive chondrocytes were quantified as additional markers to detect bone and cartilage changes.

Results: The MIA rat model of OA pain exhibited significant pain behaviour, synovial inflammation and angiogenesis, cartilage damage, osteophyte formation and subchondral bone changes, compared with non-arthritic controls. A two week pre-emptive and therapeutic treatment with cordycepin reduced MIA-induced pain behaviour and synovial changes (inflammation and angiogenesis). Pre-emptive cordycepin treatment reduced cartilage damage and the level of ADAMTS-5 and MMP13 from the chondrocytes. Pre-emptive and therapeutic cordycepin treatment reduced the number of channels crossing the OCJ and TRAP positive osteoclasts in the subchondral bone, but had no effect on numbers of osteophytes. Therapeutic cordycepin treatment did not alter cartilage damage score or the level of ADAMTS-5 and MMP13 positive chondrocytes.

Conclusions: Our data show that the analgesic effects of orally administered cordycepin in a pre-emptive and therapeutic protocol are associated with synovial changes (inflammation and angiogenesis) and bone remodelling. Administration of cordycepin before the onset of MIA-induced OA reduced cartilage damage and had a chondroprotective effect. Whereas therapeutically administered cordycepin did not alter cartilage damage. Further studies will investigate whether cordycepin mediated reduction in MIA-induced pathology and pain behaviour is as a result of its direct action on polyadenylation inhibition. Polyadenylation inhibitors could therefore be a novel class of drugs for treating OA.

127
Background: General synovitis score (GSS) has been developed by Krenn et al. in order to discriminate inflammatory arthritis (IA) and non-inflammatory arthritis (NIA) (1). This score assesses 3 major components of synovitis: lining layer hyperplasia, activation of resident cells (stroma) and inflammatory infiltrate. All components are graded semi-quantitatively from 0 to 3 and the total score is on 9. High-grade synovitis is highly associated with IA and is defined by a score above 5 with a sensitivity of 61.7% and a specificity of 96.1%. As immunohistochemistry (IHC) is frequently used to better characterize synovitis, we propose to create a new IMmunologic SYnovitis SCore (IMSYC) adding 5 additional components: the GSS: CD68, CD3, CD20, CD163 and Ki67 immunostaining.

Objectives: Our work aimed to evaluate the diagnostic performance of this new score including IHC, to define the best cut-off for inflammatory arthritis recognition, and to compare its diagnostic performance and the one of GSS.

Methods: 53 synovial samples from patients were obtained during surgery (arthroplasty or synovecctomy). All patients gave written consent prior surgery. Samples were cut and Hematoxylin and eosin stained. CD68, CD3, CD20, CD163 and Ki67 immunostaining were performed. GSS was assessed for each slide and semi-quantitative 4 score scales (0-3) were given for each immunostaining, in a blind manner. The score is calculated on 24 (GSS 0–9 points, and 0–3 score for each of the 5 immunostaining). A representative amount of slides was read by 2 observers with a good interobserver variability (spearman correlation coefficient of 0.95, p<0.0005). They defined a consensus and revised the data.

Results: 53 patients were included. 25 were females (47.2%), mean age was 62.1 years [Standard deviation (SD) 13.2 years], 36 had inflammatory arthritis reaped as follows: 28 Rheumatoid arthritis (RA), 5 Psoriatic arthritis, 3 Undifferentiated arthritis. “Non inflammatory” arthritis group included 10 patients with Osteoarthritis and 7 with ligaments or meniscus injuries. Mean GSS was significantly higher in the IA group 5.70 [SD 0.32] vs.3.51 [SD 0.35]; p<0.001. Mean IMSYC was significantly superior in the IA group 14.94 [SD 8.77] vs. 8.50 [SD 6.39]; p<0.001. In univariate analysis by logistic regression, GSS (Odd Ratio (OR) 2.27; p<0.001), CD3 (OR 4.3; p=0.002), CD68 (OR 4.5; p=0.002), Ki67 (OR 11.8; p<0.001), and CD31 scores (OR 6.5; p=0.001) were significantly associated with IA, however CD20 score was not (OR 0.9; p=0.34). ROC curve analysis determined the score of 10.5 out of 24 as the best cut off for discrimination between IA and non-IA with a sensitivity of 74.3% and specificity of 100%. The area under ROC curves was statistically superior with IMSYC (0.93) compared to GSS (0.81) (p=0.05).

Conclusions: We hereby propose a new synovitis score including IHC. This score has a better sensitivity and specificity than the global synovitis score discriminative between IA versus non-IA. Moreover, this score accurately describes any synovial membrane immunophenotype and could therefore give a basis for tissue driven therapies in rheumatic diseases, especially in RA.

OP0186 TENOFOVIR, A NUCLEOSIDE ANALOG REVERSE TRANSCRIPTASE INHIBITOR FOR TREATMENT OF HIV, PROMOTES OSTEOCLAST DIFFERENTIATION AND BONE LOST IN A MECHANISM DEPENDING ON ATP RELEASE AND ADENOSINE, AND DIPYRIDAMOLE MAY BE A USEFUL TREATMENT TO REVERT THE EFFECTS

F.M. Conesa1, P. Llamas1, T. Wilder2, P. Atencio3, A. Cabello3, M. Górgolas2, B. Cronstein2, R. Largo1, G. Herrero-Beaumont1, A. Mediero1,2, J. Joint and Bone Research Unit, Iis-Fundacion Jimenez Diaz, Madrid, Spain; 2Division of Translational Medicine, Department of Medicine, New York School of Medicine, New York, United States; 3Internal Medicine Department, Iis-Fundacion Jimenez Diaz, Madrid, Spain

Background: HIV infection devastates the immune system but also affects other tissues and organs. Bone alterations have been observed in HIV disease for nearly two decades, in particular a higher risk of low bone mineral density (BMD) and fragility fractures. Treatment with Tenofovir alone or as part of HAART, leads to changes in bone catabolism markers and significant reductions in BMD in children and young adults. Tenofovir is taken up by cells and phosphorylated in cells inhibits HIV reverse transcriptase by mimicking AMP. We have recently found that Tenofovir inhibits BMD by blocking osteoclastic differentiation and bone loss in murine models. Inhibition of osteoclast formation via adenosine A2A receptor stimulation or increasing local adenosine concentration stimulates new bone formation as well as rhBMP-2.

Objectives: As adenosine and ATP are key regulators of bone homeostasis, we determined whether Tenofovir directly affects bone by an adenosine- or ATP-dependent mechanism and if treatment with Dipyridamole, an agent that decreases extracellular adenosine by blocking cellular adenosine uptake, may be a useful treatment to counteract Tenofovir effects.

Methods: M-CSF/RANKL-induced osteoclast (OC) was studied in primary murine bone marrow cultures as the number of TRAP-positive cells after challenge with Tenofovir (1nM-100uM) alone or in combination with Dipyridamole (1nM-100uM). OC markers were measured by RT-PCR. Pannexin-1 and Connexin-43 expression were determined by Western-blot on bone marrow samples. Tenofovir 75mg/kg/day alone or in combination with Dipyridamole 1mg/kg/day for 4 weeks. Double labelling of bone with calcein/Alizarin Red to analyzed bone formation was performed and long bones were prepared for microCT and histology.

Results: Tenofovir produced a dose-dependent increase in OC differentia-
tion (EC50=44.95mM) that was reversed by Dipyridamole (IC50=0.3μM). When Pannexin-1 and Connexin-43 were absent, Tenofor did not increase OC number. Tenofor increases Cathepsin K and NFATc1 mRNA levels during OC differentiation, and the effect was reversed by Dipyridamole. Tenofor reduced bone formation in vivo (192±5m bone apposition vs 35±4μm untreated p<0.05) and this effect was reversed in the presence of Dipyridamole (30±5μm vs 0.05μm vs Tenofor alone). microCT revealed decreased BMD and altered trabecular bone in Tenofor-treated mice, treated in the presence of Dipyridamole. TRAP-staining showed increased OC in vivo in Tenofor-treated mice (217±1 vs 16±1 OC/hip in untreated, p<0.005) that was reversed with Dipyridamole. Similar results were obtained for Cathepsin K.

Conclusions: These results indicate that Tenofor enhances OC differentiation and inhibits osteoblast differentiation by an adenosine-dependent mechanism and suggests that treatment with agents that increase local adenohamine concentrations, like Dipyridamole, might prevent bone loss following Tenofor treatment.

OP0187 TRANSGENIC DISRUPTION OF GLUCOCORTICOID-SIGNALING IN MATURE OSTEOBLASTS AND OSTEOCYTES ATTENUATES STRUCTURAL BONE DAMAGE IN A LONG-TERM MURINE K/BXN SERUM-INDUCED ARTHRITIS MODEL

E. Wiebe 1,2, C. Spies 1,2, J. Tu 2, T. Maleitzke 1,2, Y. Zhang 2, M. Seibel 2,3, H. Zhou 4, F. Buttgereit 4, Department of Rheumatology and Clinical Immunology, Charité Universitätsmedizin Berlin, Berlin, Germany; 2Bone Research Program, ANZAC Research Institute, University of Sydney; 3Department of Endocrinology and Metabolism, Concord Repatriation Hospital, University of Sydney, Sydney, New South Wales, Australia; 4Department of Rheumatology and Clinical Immunology, Charité Universitätsmedizin Berlin, Berlin, Germany

Background: The role of endogenous glucocorticoids (GC) in bone metabolism in chronic inflammatory arthritis remains unclear. We have previously shown that disruption of osteoblastic GC-signaling in a murine arthritis model.

Methods: Intracellular GC-signalizing in osteoblasts was disrupted by transgenic overexpression of 11beta-hydroxysteroid dehydrogenase type 2 (11HSD type 2) under the control of a type 1 collagen promoter. Arthritis was induced in 5-week old male transgenic (tg) mice and their wild-type (WT) littermates. In order to maintain a chronically active arthritis, mice were boosted on day 14 and 28 by subcutaneous injection of K/BxN serum, controls (CTR) received PBS, respectively. Severity of arthritis was assessed daily by clinical scoring and ankle size measurements until the endpoint (day 42). Ankle joints were assessed by a histopathologic score and microfocal computed tomography (micro-CT). Systemic effects of inflammation on bone metabolism were quantified by histomorphometry and micro-CT of the tibia.

Results: Acute Arthritis developed in both tg and WT mice and remained active over the period of 42 days with a reduced, yet non-significant, severity in tg compared to WT mice. Histological indices of inflammation, cartilage damage and especially bone erosion, additionally assessed by micro-CT, tended to be overall reduced in tg mice, yet not reaching a level of significance. Bone volume and bone turnover did not differ between tg and WT arthritic mice.

Conclusions: The modulating effect of disrupted GC-signalizing in osteoblasts in serum-induced autoimmune-arthritis prevails in a chronic inflammatory setting, leading to less severe local inflammation and bone destruction. This supports the important role of endogenous GCs for an intact bone metabolism in inflammatory bone disease.

Treat-to-target in axSpA: reality or utopy? }

OP0188 DEFINING CLINICALLY IMPORTANT WORSENING BASED ON ASDAS-CRP FOR AXIAL SPONDYLOARTHROPSIS: A DATA-BASED CONSENSUS BY THE ASSESSMENT IN SPONDYLOARTHRITIS INTERNATIONAL SOCIETY (ASAS)

A. Melo 1, L. Gossec 2, R. Landewe 3, D. van der Heijde 4, M. Dougados 1, 1Rheumatology B Department, Cochin Hospital; 2Pitié Salpêtrière Hospital, Department of rheumatology, Paris, France; 3Department of Clinical Immunology & Rheumatology, Amsterdam Rheumatology Center, Amsterdam and Zuyderland Medical Center, Heerlen; 4Department of Rheumatology, Leiden University Medical Centre, Leiden, Netherlands

Background: Disease flares are increasingly used as outcomes in axial spondyloarthritis (axSpA) trials or observational studies.

Objectives: The objective of this initiative was to define a cutoff for the ASDAS score that best defines the concept of “worsening in axSpA”, to be used in the context of clinical trials and longitudinal observational studies.

Methods: Various steps were followed between 2014 and 2017. (a) Initial expert opinion within the steering group to define the scope of the project; (b) systematic literature review to collect cutoffs used for worsening in published studies; (c) vignette-exercise among ASAS members: a theoretical ‘paper’ patient-vignette, in whom an initial and a final value of an outcome was provided, was judged by the physicians on whether or not the patient had worsened (definingphy-worsening) (ref); (d) real-life multicenter international study: data necessary to calculate different outcomes were collected from real patients at 2 consecutive visits (spaced 7 days to 6 months); external standard was defined as a patient’s report that he/she had worsened and he/she felt there was a need for treatment intensification. (e) Testing of different changes in the outcomes against both external standards for worsening (phy-worsening and pt-worsening) followed by a consensus and voting procedure among ASAS members in January 2017.

Results: (a) There was consensus about worsening being an absolute change between 2 time-points (without defining time between the 2 time-points) and about exploring cutoffs for 3 outcomes: ASDAS-CRP, BASDAI and pain. (b) The literature review had yielded 27 different cutoffs in 38 studies indicating important heterogeneity (c) The vignette-exercise yielded 12 preliminary definitions for worsening to be tested (as previously reported); (d) In the prospective study the sensitivity and specificity of each cutoff was tested against pt-worsening and judged by the ASAS-community. (e) No consensus was reached for a BASDAI-based definition due to limited performance of all cut-offs, and it was decided to not define a value for a pain-based definition for worsening. Based on aggregated data (Table), a consensus was reached among the ASAS-members to define worsening as a deterioration in ASDAS of at least 0.9 points. While this cutoff led to only moderate sensitivity when tested against pt-worsening, the overall balance of sensitivity and specificity as well as the overall face validity of this cut-off value for ASDAS was deemed most acceptable.

Table: Sensitivity and specificity of different ASDAS cutoffs to define worsening, compared to external standard and vignette-exercise.

Conclusions: This data-driven ASAS consensus process has allowed to propose an ASDAS-based cutoff value defining worsening in axSpA. As has been observed in other settings, the change defining worsening (at least 0.9) is smaller than the change defining improvement which is 1.2 for ASDAS. This definition should now be applied in trials.

TP0199 TUMOR NECROSIS FACTOR INHIBITOR TREATMENT REDUCES SPINAL RADIOGRAPHIC PROGRESSION IN ANKYLOSING SPONDYLITIS BY DECREASING DISEASE ACTIVITY: A LONGITUDINAL ANALYSIS IN A LARGE PROSPECTIVE COHORT

C. Molnar1, A. Scherer1, X. Baraliakos2, M. de Hooge3, R. Michoril1, R. Exer3, R. Kissling2, G. Tamborrini3, L. Wild3, M. Nissen4, P. Zufferey5, J. Bernhard6, U. Weber5, R. Landewe7, D. van der Heijde8, A. Ciurea9,2, S. Coté, Zurich, Switzerland; 2RheumaZentrum, Herne, Germany; 3LUMC, Leiden, Netherlands; 4USZ, Zurich; 5Private Practice, Basel; 6Balgrist, Zurich; 7HCUGE, Geneva; 8CHUV, Lausanne; 9Bürgerspital, Solothurn, Switzerland; 10Univ Southern Denmark, Odense, Denmark; 11AMC, Amsterdam, Netherlands

Background: Whether tumor necrosis factor inhibitors (TNFi) have an influence on radiographic progression in ankylosing spondylitis (AS) remains controversial. Objectives: To investigate the impact of TNFi use on spinal radiographic progression in AS. Methods: Patients fulfilling the modified NY Criteria for AS (as assessed by central reading) in the Swiss Clinical Quality Management Cohort with at least 2 years of clinical and radiographic follow-up were included. Spinal X-rays were taken every 2 years and scored independently by 2 blinded readers according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) in chronological time order. Average score of the readers was used. Radiographic progression was defined as an increase by >2 mSASSS units over 2 years. The relationship between TNFi use before or after a 2-year X-ray interval and progression in the interval was investigated using binomial generalized estimating equation models with adjustment for potential confounding and multiple imputation of missing covariate data. Ankylosing Spondylitis Disease Activity Score (ASDAS) was regarded as a potential intermediate variable mediating the effect of TNFi on radiographic progression. It was added to the model as a time-varying variable in a sensitivity analysis.

Results: A total of 420 patients with AS contributed to data for 597 X-ray intervals in adjusted analyses (1–5 intervals per patient); BL characteristics: male sex 66%, HLA-B27 81%, mean (SD) age 40.4 (10.9) years, disease duration 13.9 (9.8) years, mSASSS 6.4 (12.4), ASDAS 2.8 (1.1). 39% of the patients were already on TNFi at first X-ray. Mean mSASSS progression in 2 years was 0.9 (2.7) units. The multivariable model (Table) shows that prior use of TNFi reduced the odds of progression in the next 2 year interval by 49% (odds ratio (OR) 0.51, 95% confidence interval (CI) 0.28–0.92, p=0.03). BL mSASSS and male sex also significantly affected progression. Adding ASDAS as a covariate to the model decreased the estimated effect of TNFi on progression: OR 0.65, 95% CI 0.39–1.17, p=0.15. In this model, a decrease in ASDAS by 1 unit would lower the odds for progression by 0.62 (p<0.001).

Conclusions: TNFi seem to reduce radiographic progression in patients with AS and this effect is mediated, at least in part, by a decrease in disease activity. Acknowledgements: Supported by the Stiftung für Rheumaforchung and a research grant from the investigator initiated studies program of MSD.

Calcium crystal deposition in rheumatic diseases —

OP0190 HISTOLOGICAL CHARACTERIZATION OF ROTATOR CUFF CALCIFIC TENDINOPATHY

C. Darieutourd-Laffite 1, 2, A. Najmi 1, 2, T. Garraud 1, 2, P. Layrolle 1, F. Blanchard 2, B. Le Got 1, 2, 3, R. Rheumatologie, CHU Hotel Dieu Nantes; 4Laboratoire Phy-OS, INSERM U1239, Nantes, France

Background: Calcific tendinopathy is one of the most frequent causes of shoulder pain. Calcific deposits lead to chronic discomfort in daily and professional activity. These deposits are composed of carbonated apatite. Although the disease is frequent, its origin stays still largely unknown. Molecular and cellular mechanisms involved in this pathological mineralization process are not clearly identified. Objectives: The objective of the study was to analyze calcified tendinous samples to understand the organization of the deposits and to characterize the cells partially involved in this process.

Methods: Samples were collected from cadaveric subjects. Ultrasound was first used to detect calcified tendons. Then, tendons were collected and fixed in formalin 4% during 48h. They were first analyzed with micro-CT to know the distribution of the calcific deposits. Samples were then decalcified in EDTA, dehydrated and embedded in paraffin. Some samples were then stained to allow a better characterization of the calcific deposits. Several histological staining were performed: hematoxylin and eosin (HE), Safranin O/Fast Green (SO/FG) and Von Kossa (no decalcified samples). Immunohistochemistry using anti-Runn2, anti-Sox9, anti-Caspase II and anti-casparase III antibody has been performed to characterize the cells and tissue around the calcifications.

Results: Six samples were collected (1 normal and 5 calcified). On HE staining, three different histological patterns were observed. Little calcifications disseminated between tendon fibers (N=2), voluminous ones encapsulated by a fibrous tissue (N=2) and in one sample an intra-tendinous osseous metaplasia. In the fibrous peripheral area of larger calcifications, we observed cells with round nuclei, different from tenocytes. These cells expressed Runx2 and Sox9 suggesting a chondrocyte phenotype. On SO/FG staining, this peripheral area presented a red coloration (proteoglycan specific) as the fibrocartilage at the tendon insertion. Moreover, in the central part of the calcification, no or very little cartilage was present in this areas. As pathological calcification in cartilage can be associated with chondrocytes apoptosis, we sought for anti-Casparase III expression in the cells of the peripheral area. None of the chondrocyte-like cells located around the larger calcifications expressed Casparase III. Finally, one sample had an osseous metaplasia within the tendon with Runx2 positive cells.

Conclusions: Histological analyses of whole calcified tendon tissues showed three different patterns of calcific deposits. We can hypothesize that these patterns correspond to different stages of the disease. Chondrocyte-like cells were observed around larger deposits and could be involved in the mineralization process. Interestingly, they differ from the cells of the fibrocartilage as they did not express collagen II. Further analyses are necessary to characterize their phenotype and understand the steps leading to these deposits within the tendon.

OP0191 COMPARISON OF ULTRASONOGRAPHY AND RADIOGRAPHY OF THE WRIST FOR DIAGNOSIS OF CALCIFIED PYROPHOSPHATE DEPOSITION

A. Combier, M. Forien, A. Gardette, E. Palazzo, P. Dieudé, S. Ottaviani, Rheumatology Department, Bichat Hospital, Paris, France

Background: The gold standard for diagnosis of calcium pyrophosphate (CPP) deposition (CPPD) is the identification of CPP crystals in synovial fluid. However, aspiration of synovial fluid can be challenging in small joints such as the wrist, a usual location of arthritis in CPPD. Despite its low sensitivity, the most widely used imaging modality is conventional radiography but ultrasound (US) seems a useful tool for diagnosis of CPPD.

Objectives: We aimed to compare the performance of US and conventional radiography of the wrist for diagnosis of CPPD.

Methods: Patients with joint effusion (knee, hip, shoulder, ankle or wrist) were consecutively included. CPPD was diagnosed by CPP crystals identified in synovial fluid. Patients without CPP crystals in synovial fluid were controls. As recommended, we used the term chondrocalcinosis (CC) to assess imaging features suggesting CPPD. Two blinded operators assessed CC in all patients by US and conventional radiography of the wrist. The presence of CC (either or specificity) (Sp) of US for the diagnosis of CPPD were 94% and 85%, respectively; the positive likelihood ratio was 6.1. When analyzing US features of CC separately, US Se was higher at the TFC than RC joint, 81% and 50% respectively. The sensitivity (Sp) of radiography was 25% (US) and 100% (CC) and the discrepancy reliabilities for US and radiographic CC were almost perfect: χ coefficient 0.832 [95% confidence interval 0.651–1.0] and 0.880 [0.314–0.880]. In all 58 patients, 113 joints were analyzed (3 patients had radiography of only one wrist). The χ coefficient between US and radiography for CC was moderate: 0.33 [0.171–0.49].

Conclusions: Our study suggests that wrist US should be considered a relevant tool for the diagnosis of CPPD, with higher sensitivity than radiography.

OP0092

ADDING ULTRASOUND TO THE TREAT-TO-TARGET STRATEGY SHOWS NO BENEFIT IN ACHIEVEMENT OF REMISSION: RESULTS FROM THE BIOMAD COHORT

A. Segrin1, S. Ramiro2, R. Landewé3, D. van der Heijde1, S. Ohrndorf4, M. Dougados12, C. Hitchon13, G. Boire14, R. Dadashova15, J. Paschke15

1University, Hamilton; 2University of Alberta, Edmonton, Canada; 3CHU, Brest, France; 4Diakonhjemmet Hospital, Oslo, Norway; 5Copenhagen UH, Copenhagen, Denmark; 6Copenhagen UH, Copenhagen, Denmark; 7CHU, Montpellier; 8Descartes University, Paris, France; 9University of Manitoba, Winnipeg; 10University of Sherbrooke, Quebec; 11RaGe-Arthritis Ltd, Edmonton, Canada

Background: While, a Treat-to-Target strategy (T2T), treating patients with rheumatoid arthritis (RA) towards a certain target (eg. clinical remission; T2T-REM), is highly recommended, several patients in clinical remission often have residual synovitis on ultrasound-imaging (US). This may result in silent progression and clinical flare. It is argued whether targeting US-synovitis may result in deeper* remission in clinical practice.

Objectives: To assess whether using US in a T2T strategy leads to more patients meeting clinical remission than using only clinical information.

Methods: Patients with RA who started or changed csDMARD and/or anti-TNF treatment followed in centers with expertise in US and participating in BIODAM (2-year multicenter prospective observational cohort) were included. Clinical and US data [by the US-score that includes 7 joints of the clinically dominant hand and foot for synovitis and tenosynovitis on gray-scale US (GSUS) and power-doppler US (PDUS) and erosions on GSUS] were collected every 3 months. Per visit was decided whether the patient was treated according to the clinical definition of T2T with remission as benchmark (T2T-CLIN-REM). Though not mandatory, US-data could also be used for this purpose. T2T-CLIN-REM was considered correctly applied if: either i) a patient already had a disease activity score below the remission target (i.e. ACR/EULAR boolean remission) or ii) if not, treatment was intensified. A T2T strategy taking also US-data into account (T2T-CLIN-US-REM) was considered correctly applied if: either i) both clinical and US remission (all joints included in the US7-score with GSUS synovitis <2 and PDUS synovitis=0) were present; or ii) if not, the treatment was intensified.

Results: In total 963 visits of 130 patients were included. T2T-CLIN-US-REM was correctly followed in 93% of the visits, T2T-CLIN-REM in 14%, and any of these in 52%. Remission according to the ACR/EULAR-boolean definition was achieved in 19.6% of the visits. Compared to the conventional T2T-CLIN-REM strategy, using a combined clinical and US benchmark for T2T led to a lower — instead of higher — likelihood of ACR/EULAR-boolean remission 3 months later compared to a clinical remission benchmark only (T2T-CLIN-REM) was analyzed using generalized estimating equations with auto-regression.

Conclusions: Our results, from a non-randomized study, did not suggest an advantage of using US 7 joints in addition to clinical examination as a T2T benchmark as compared to clinical examination alone in getting RA patients into clinical remission.

OP0093

INFLAMMATION OF ADVENTITIAL NERVES OCCURS IN GIANT CELL ARTERITIS PATIENTS AND IT IS CHARACTERIZED BY INFLAMMASOMES, UPR AND AUTOPHAGY ACTIVATION

F. Ciccia1, A. Pizzo1, R. Alessandro2, S. Raimondo3, G. Guggino1, A. Cavazza4, C. Salvarani2, G. Trillo1

1University of Palermo, Palermo; 2Arcispedale Santa Maria Nuova, Reggio Emilia, Italy

Background: Vascular adventitia is a major site of immune surveillance and inflammatory cell trafficking and is the most complex compartment of the vessel wall comprising fibroblasts, dendritic cells and macrophages, progenitor cells, vasa vasorum, pericytes and adventitial nerves. It has been proposed that activation of adventitial nerves and release of sensory neuropetides from their peripheral terminals may lead to neurogenic inflammation. Giant cell arteritis (GCA) is an immune-mediated disease of unknown etiology in which the inflammatory process seems to start from the adventitia of affected arteries.

Objectives: of the aim was to evaluate the occurrence of adventitial nerves inflammation and to immunologically characterize the adventitial neuritis occurring in GCA patients.

Methods: Immunohistochemistry and RT-PCR were used to study the presence of neuritis in temporal artery samples obtained from 30 patients with temporal arthritis (TAB) positive GCA, 20 TAB negative GCA and 20 controls. Laser capture microdissection (LCM) was used to isolate adventitial nerves and nerve expression of pro-inflammatory cytokines involved in the pathogenesis of GCA such as IL-6, IL-17, IL-2, IL-9, IL-33 was assessed by RT-PCR. Expression of pro-inflammatory cytokines on chondroitin sulfate was evaluated by immunochemistry and confocal microscopy. Autophagy, unfolded protein response (UPR) and inflammasome pathways were also studied by RT-PCR and immunohistochemistry.

Results: Adventitial nerves showed infiltration of CD3+ T cells in all the TAB positive and in 12 out of 20 TAB negative arteries but were never observed in control arteries. RT-PCR expression analysis of different pro-inflammatory cytokines clearly demonstrated specific over-expression of IL-33 in LCM isolated inflamed nerves. Immunohistochemical and confocal microscopy analysis confirmed nerve IL-33 expression, RT-PCR and immunohistochemistry demonstrated that AIM2 and NLPR3, but not NLCR4, inflammasomes were activated in inflamed nerves of GCA patients. According to inflammasome activation, increased IL-18 expression was observed. Autophagy-related genes such as ATG16L1 and LC3 and UPR-related genes such as XBP-1 and CHOP were also over-expressed in GCA adventitial nerves as demonstrated by RT-PCR and immunohistochemistry. Finally, increased expression of AIM2 and NLRP3 inflammasomes, autophagy and UPR was also observed outside the nerves, in the context of infiltrated artery wall.

Conclusions: here we demonstrated that adventitial neuritis is present in both inflamed and non-inflamed arteries of GCA patients. GCA inflamed nerves specifically produce IL-33 a cytokine of the innate immunity that has been demonstrated to be involved in the pathogenesis of GCA. AIM2 and NLRP3 inflammasomes activation was also observed in GCA arteries and in particular in the inflamed adventitial nerves being accompanied by the increased expression of IL-18. Specific activation of autophagy and UPR pathways was also observed in the inflamed GCA nerves. Altogether these findings seem to suggest a complex immune activation of adventitial nerves in GCA, suggesting a possible role of arterial neuritis in the initiation and perpetuation of GCA artery innervation.

OP0094

IN-VITRO ACTIVATION OF TOLL-LIKE RECEPTOR 9 IN THE PATHOGENESIS OF EROSIIVE AUTOIMMUNE ARTHRITIS AND DURING OSTEOCLASTGENESIS

A. Fischer, B. Meyer, B. Niederreiter, G. Steiner

Internal Medicine III-Rheumatology, Medical University Vienna, Vienna, Austria

Background: Release and insufficient removal of endogenous nucleic acids may be involved in triggering harmful autoimmune reactions important in the initiation of systemic autoimmune diseases including rheumatoid arthritis (RA). Nucleic acid sensing molecules, such as the endosomal Toll-like receptors (TLRs) 7 and 9, have been linked to pathogenic autoimmune processes, particularly in systemic lupus erythematosus, but their role in RA is less clear. Results previously obtained in rats with pristane-induced arthritis (PIA) suggested involvement of TLR9 in the pathogenesis of this arthritis model (1). Interestingly, rats with PIA develop autoantibodies associated with RA including rheumatoid factor, anti-RA33 and antibodies to carbamylated proteins (2).

Objectives: To gain more insight into the role of TLR9 in the pathogenesis of autoimmune arthritis by investigating the effects of TLR9 inhibition in rats with PIA.

Methods: Arthritis was induced in DA rats with the mineral oil pristane. Rats were treated with a TLR9 antagonist every other day, starting one before disease induction. Arthritis was scored using established scoring systems, inflammation and bone erosion were quantified by histological analysis. Expression of TLR9...
and other nucleic acid sensing TLRs was quantified by RT-PCR and Western blotting; activation (phosphorylation) of various signal transduction molecules was determined by Western blotting. Furthermore, the role of TLR9 in osteoclast differentiation and activation was investigated in vitro.

**Results:** The TLR9 antagonist significantly reduced clinical signs of arthritis by approximately 50%. Histological analyses revealed diminished inflammatory cartilage degradation, bone erosion and significantly reduced numbers of osteoclasts in animals treated with the TLR9 antagonist. However, when treatment was started after onset of arthritis TLR9 inhibition had no effect on arthritis development and severity. IL-6 serum levels were greatly diminished in animals treated with the TLR9 antagonist and expression and activation of NF-κB in lymph nodes was reduced. Remarkably, mRNA levels of TLR7 and TLR9 strongly differed in the course of in vitro osteoclastogenesis. Whereas TLR7 expression did not change throughout osteoclastogenesis, expression of TLR9 was higher in precursor cells than in mature osteoclasts and stimulation with a TLR9 agonist (CpG) completely inhibited osteoclastogenesis.

**Conclusions:** Taken together, the results suggest an important role for TLR9 in the T cell-dependent initiation phase of PIA and thus important involvement of endogenous DNA released during apoptosis, necrosis or netosis in the initiation of autoimmune arthritis and during osteoclastogenesis. The possible relevance of these findings for human RA needs to be further elucidated in future experiments.

**To be and to become: transition from paediatric to adult care**

**OP0195 WHAT IS THE IMPACT OF JUVENILE IDIOPATHIC ARTHRITIS IN ADULTHOOD? THE MONOCENTRIC EXPERIENCE OF 240 PATIENTS FOLLOWED IN A TRANSITION TERTIARY CLINIC OF RHEUMATOLOGY**

I. Pontikaki 1, L. M. Argolini 2, C. Artusi 2, P. L. Meroni 3.

1Unit of Pediatric Rheumatology-Department of Rheumatology; 2Department of Rheumatology; 3Department of Rheumatology, Chair of Rheumatology, Gaetano Pini Institute, University of Milan, Milan, Italy

**Background:** There are many different clinical manifestations, assessment and management of Juvenile Idiopathic Arthritis (JIA) between childhood and adults' arthritis onset. The transition from pediatric to the adult care emphasizes a lot of aspects that need to be addressed.

**Objectives:** To describe the long-term outcome of JIA.

**Methods:** Two-hundred and forty patients affected by JIA and referred to a tertiary transition clinic were considered. The data were collected at the last follow up visit.

**Results:** Seventy-four (30.8%) males and 166 (69.2%) females were included; 53 (22.1%) patients were lost in follow up. Subtypes of JIA at disease onset included 101 oligoarthritis (42.1%), 67 polyarthritis (27.9%), 43 systemic arthritis (17.9%), 28 arthritis with enthesitis (11.6%), 7 psoriatic arthritis (2.9%). 22 enthesitis related arthritis (9.2%). Forty-eight (20%) patients had persistent uveitis. Ninety-three implant prosthesis and 14 arthodesis were recorded. The average disease duration was 20 years, the median age of the patients was 27 (18–57) years. Five deaths (2.1%) occurred in this cohort. At follow up 117 (48.7%) had low active disease activity, 70 (29.2%) had moderate disease activity, 14 (5.8%) had a high disease activity, 24 (10%) were on remission OR on medication and 15 (6.3%) OFF medication. Among patients still on medication, 59 (24.6%) were treated with oral steroids, 18 (7.5%) with csDMARDs and 169 (70.4%) with bDMARDs. Seventy-five (31.3%) patients had a higher educational level (university), 195 (61.3%) had an employment, 128 (53.3%) had a driving license. Twenty-one (8.9%) pregnancies were registered. The transition age was considered after age of sixteen years old. In this context, it was important the multidisciplinary approach of each patient that was realized with the collaboration of other specialists (ophthalmologist, orthopedic, dermatologist, psychologist, psychosomatic).

**Conclusions:** In the era of biologic therapy there was an important improvement in a lot of variables of the long-term outcome of JIA. One-hundred-eighty-seven (77.9%) patients were still in tight control, not only because of the continuation of the biological therapy but also because of the multidisciplinary care carried out even during remission. JIA often persists over the adulthood. The long term follow up and care of these patients has to be conducted by a rheumatologist expertized in JIA in collaboration with other specialists.

**Heterogeneity in JIA**

**OP0196 CHANGING PATTERNS OF JUVENILE IDIOPATHIC ARTHRITIS PATIENTS TREATED WITH ETALENPETIC FROM 2000 TO 2016 IN THE GERMAN BIKER REGISTRY POPULATION**

G. Horstef1, K. Minden2, I. Foeldvari3, G. Ganser4, J.P. Haas5, J. Brunner6, I. Becker7 on behalf of BIKER collaborative group.

1Paediatrics, Asklepios, Sankt Augustin; 2Charité, Berlin; 3Private office, Hamburg; 4Ped Rheumatol, Sendenhorst; 5German Ped Rheum Centre, Garmisch-Partenkirchen, Germany; 6University, Innsbruck, Austria; 7University, Cologne, Germany

**Background:** There is increasing experience with Etanercept (ETA) in juvenile idiopathic arthritis in the BIKER Registry.

**Objectives:** To report on practice changes ETA utilization and outcome over a period of 16 years.

**Methods:** 6 cohorts of pts were created according to inclusion period. Patients’ and disease characteristics, the utilization of DMARDs, steroids, NSAIDs were analysed. Efficacy was judged by PedACR30/50/70/90, JADAS and ACR-remission.

**Results:** Records from 2105 JIA pts treated with Etanercept with at least a baseline and one follow up form were analysed. Most pts were females (67%). The median age of disease onset increased from 5.9 years in the early to 9.3 years in the later cohorts while age at start of treatment remained stable (about 13 years). Median disease duration markedly decreased from 5.3 to about 2 years. Most pts had RF-neg. JIA followed by extended oligoarthritis. In the more recent cohorts the rate of enthesitis related arthritis increased and the rate of systemic JIA decreased (table). At registry start, 20% of newly enrolled pts belonged to the systemic JIA category compared to < 1% in 2016. During the study period, the overall utilization of glucocorticoids at baseline decreased from 54% to 16% (P < 0.001), MTX from 78% to 64% (P < 0.001), ACR30/50/70/ 90 response rates at month 12 were 80%/74%/59%/40% and did not vary over time while the rate of patients reaching no active joint/CHAI DI=0/JADAS-Remission/AACR-Remission increased from 43%/35%/44%/19% to 69%/48%/55%/85%.

---

**Changes in all parameters were significant (p < 0.001) in Kruskal-Wallis Test/Chi-square.**
Conclusions: In recent years, children have been treated earlier, received less concomitant treatment with NSAIDs, corticosteroids as well as DMARDs. More recent cohort of patients had less severe disease at baseline, but also showed a markedly better outcome already at one year of treatment reflected by higher rates of patients with no active joint, a CHAQ DI of 0, a JADAS-MDA, ESR levels were 59.40±27.47 mm/h and 2.00±1.00 mm/h, respectively. Mean±SD receptor levels were 47.65±16.40 ng/mL at baseline and 927.83±148.07 ng/mL at [109–382] to 54.3 \text{[10.9–117]} \text{μg/mL}. Peak and trough exposures were within the exposure range in older children (244 μg/mL). The third has been developed for health professionals to update them on current guidance around RMDs and ongoing employment issues that face these three groups. The second lesson is aimed at employers who have a staff member who is living with an RMD. The first lesson is aimed at employees who are living with an RMD - an eLearning programme which focuses on the tripartite relationship between the employee, employer and healthcare professional. Seven million working days are lost each year in Ireland due to RMDs, such as back & neck pain or stiffness, arthritis, and limb pain. This is therefore a significant problem which obviously impacts on both employers, employees and healthcare professionals. That is why Arthritis Ireland has developed Fit for Work Online - an eLearning programme which focuses on the issues that face these three groups.

Objectives: The objective of the project was to develop an online educational programme to provide information, guidance and support to employees, employers and healthcare professionals on working with RMDs. Methods: In 2015 Arthritis Ireland began its developments of an online education programme ‘Fit for Work Online’ which focuses on the tripartite relationship between the employee, employer and healthcare professional. 3 video lessons were developed as part of this eLearning programme.

- The first lesson is aimed at employees who are living with an RMD
- The second lesson is aimed at employers who have a staff member who is living with an RMD (and finally)
- The third has been developed for health professionals to update them on current guidance around RMDs and ongoing employment

A key message in all 3 videos is that working is good for your health. Since employment has been shown to boost health and happiness, it is crucial, whenever possible, that people who are living with an RMD, remain in employment, or return to work, as soon as they can. That is the central message of this eLearning programme.

A number of issues were addressed in the development of this programme in order to convey these important issues:

- Firstly, employees who are living with an RMD are encouraged to take control of their condition. People living with an RMD are encouraged to consider practical adaptations, supports, flexibility and so on that people who are living with an RMD, remain in employment, or return to work.
- Secondly, from an employer's perspective, in addition to concerns about the welfare of their employees, there are other issues to consider, and it is natural for instance to be concerned about the possible impact of any health condition on their employees' performance & reliability, and consequently on their business. Adaptations, supports, flexibility and so on need to be considered.
- Finally, health professionals need to encourage, advise and facilitate people who are living with RMDs to remain in, or return to work.

Results: The Fit for Work Online programme will go live in February 2015. It is planned that a report on the first four months of the programme's delivery and implementation will be available at EULAR 2017 in Madrid.

Conclusions: The direct cost of RMDs at work in Ireland is estimated to be...
Results: Of 44 countries, 31 (70%) and 30 (68%) have provided data for patients and rheumatologists, respectively. In total, 646 patients (mean age SD) 53 (12), 76% female, 519 (78%) ever worked and 500 rheumatologists filled in the questionnaires. Overall, positive weak to no relationships were present between the GDP per capita and perceptions from rheumatologists or patients about SS arrangements. However, significant differences were observed across the systems type with the Scandinavian type (Finland, Norway, Sweden) consistently scoring higher than the others on most domains (table). Remarkably, rheumatologists in less wealthy and non-EU countries felt more confident in their role related to WD pension.

Conclusions: Patients’ and rheumatologists’ perceptions of systems to support persons with RA encountering work restrictions varied mostly according to the type of the social welfare system, while remarkably little differences were related to country’s wealth and membership in EU. Scandinavian employment support and social security system appeared to most adequately meet the expectations of patients and rheumatologists in questions of remaining at work and application to WD pension.

Epidemiology of rheumatic and musculoskeletal diseases - a critical appraisal

OP0200

CONFounding BY INDICATION WILL MAKE NON-TNFi BDmARDS APPEAR MORE HARMFUL THAN TNFi BDmARDS - A NATIONWiDE STUDY OF CHANNELING IN SWEDEN 2010-2014

T Frisell, E. Baecklund, K. Bengtsson, D. Di Giuseppe, H. Forsblad-d’Elia, J. Askling, on behalf of the ARTIS Study Group.

Background: Confounding by indication occurs when factors associated with the choice of therapy are also predictors of the studied outcome, and is generally considered the major limitation of non-randomized comparisons of different therapies. In RA, age, sociodemographic factors, disease activity, and medical history may influence the choice of e.g. a non-TNFi over a TNFi bDMARD. The degree of bias is difficult to assess since most studies have limited data on potential confounders, and residual confounding cannot be separated from true treatment effects.

Objectives: To quantify the expected confounding by indication caused by baseline differences in patient characteristics at initiation of different bDMARDs in RA.

Methods: All RA patients in the Swedish Rheumatology Register (SRQ) were linked to nationwide registers to assess whether a comprehensive list of covariates predicted the choice of bDMARD to such a degree that different rates of adverse events (AEs) would be expected. Among considered confounders were demographic variables, RA related factors (including RF, disease duration, HAQ, DAS28 w. components) and medical history (health care utilization and 20 specific conditions).

We used historical data on the 5 year risk of several AEs among RA patients starting any bDMARD 2005–2009 to predict the risk among RA patients (bionaire and switching from a first TNFi) starting specific bDMARDs 2010–2014. Risk was modelled in logistic regressions, as a function of baseline characteristics but assuming no effect from the therapy itself.

Results: Patients starting non-TNFi were older than those starting a TNFi, had lower socioeconomic status, higher disease activity and more often a history of diseases including malignancy, serious infections, and diabetes. These factors were in general also significant predictors of AEs, and the predicted proportions of all AEs were substantially higher for non-TNFi compared to TNFi bDMARDs, highest for rituximab. Within the TNFi-group, only minor differences were seen. Age was a strong confounder, and standardizing to the age-sex-distribution of the TNFi group reduced the group difference dramatically.

Predicted percentage with AE within 5 years, based on observed baseline characteristics. Crude and standardized to age-sex distribution of TNFi as first bDMARD.

Conclusions: Even if there are no true differences in risk by bDMARD,
confounding by indication will make the non-TNFi drugs appear less safe than IXE, numerically higher with Q2W vs placebo. No deaths or cases of inflammatory bowel disease, uveitis, TB reactivation, or grade ≥3 neutropenia were reported.

Conclusions: IXE improved arthritis, physical function, and psoriasis\(^1\) vs placebo with no unexpected safety findings in patients with active PsA and prior or intolerance to TNF-inhibitor(s).

OP0202 A PHASE 3 STUDY OF THE EFFICACY AND SAFETY OF IXEKIZUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND INADEQUATE RESPONSE TO TUMOUR NECROSIS FACTOR INHIBITOR(S)

P. Nash\(^1\), B. Kirkham\(^2\), M. Okada\(^3\), P. Rahman\(^4\), B. Combe\(^5\), D. Adams\(^6\), B. Combe\(^5\), D. H. Adams\(^6\), T. Frisell\(^7\), E. Baecklund\(^7\), A. Kaszuba\(^6\), E. Kudlacz\(^7\), C. Wang\(^7\), S. Menon\(^7\), T. Hendrikx\(^8\), K. S. Kanik\(^7\).

Objectives: To compare efficacy and safety of IXE with placebo in pts with active PsA who are TNFi-IR.

Methods: In the 24 week (wk), double-blind, placebo-controlled period of a Phase 3 PsA study (SPIRIT-P; NCT02349295), pts with prior or intolerance to 1 or 2 TNFi were randomised to SC placebo or IXE 80 mg every 2 (Q2W) or 4 wks (Q4W), following a 160 mg initial dose at Wk 0. Pts with IR to treatment (protocol defined) received rescue therapy at Wk 16. Primary endpoint was ACR20 at Wk 24. Continuous data were analyzed using mixed-effects model for repeated measures; categorical data, using a logistic regression model with missing values imputed by non-responder imputation, which treats IR as non-responders.

Results: 363 pts were randomized: ∼52 yrs old on average, female (53%), white (85%), and reductions in functional disability (HAQ-DI) (Table). A significantly higher proportion of IXE-treated pts reported infection and a significantly higher proportion reported injection site reactions (the majority were mild) (Table). Serious infection (0, 3 [2.4%], 0, Q4W, Q2W, placebo respectively), serious AE, and oral candidiasis were numerically higher with Q2W vs placebo. No deaths or cases of inflammatory bowel disease, uveitis, TB reactivation, or grade ≥3 neutropenia were reported.

Conclusions: IXE improved arthritis\(^1\), physical function, and psoriasis\(^2\) vs placebo with no unexpected safety findings in patients with active PsA and prior or intolerance to TNF-inhibitor(s).

References:
28.8% [p<0.05] vs 13.0%). Secondary endpoints at M3 for tofacitinib 5 mg and 10 mg respectively were: ACR20 response, 29.8% [p<0.05], 28.0% [p<0.05]; ACR70 response, 16.8% (not significant [NS]), 14.4% (NS) ≥75% improvement of PASI in pts with baseline BSA ≥3% and PASI >0; 21.3% (NS), 43.2% (p<0.0001); ΔLEI and ΔDSS in pts with baseline score >0; ΔLEI, -1.3 [p<0.05] and -1.3 [p<0.05] (least squares mean [LSM]); ΔDSS, -5.2 (p<0.05) and -5.4 (p<0.05) (LSM). Effects were maintained to M6. Frequency of serious AEs and discontinuations due to AEs was low and similar across treatment groups (Fig 1E). The most common AEs were upper respiratory tract infection (5.3–10.8%), nasopharyngitis (1.5–10.7%) and headache (4.5–9.1%).

Conclusions: In this study restricted to PsA pts with TNFi-IR, both tofacitinib doses appeared efficacious on musculoskeletal endpoints for treatment of PsA. No new safety risks were identified vs previous studies in other indications.

IMPACT OF ADALIMUMAB SERUM CONCENTRATION ON EFFICACY AND ASSOCIATION BETWEEN ANTI-DUAG ANTIBODIES AND SERUM CONCENTRATION: 24 WEEK RESULTS FROM A PHASE III STUDY COMPARING SBS (AN ADALIMUMAB BIOSIMILAR) WITH REFERENCE ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Kay1, M. Weinblatt2, E. Keystone3, M. Genovese4, J. Ghii5, S.Y. Cheong5, E.E. Hong5, 6, 7, UMass Memorial Medical Center, Worcester, 2Brigham and Women’s Hospital, Boston, United States; 3Mount Sinai Hospital, Toronto, Canada; 4Stanford University, Palo Alto, United States; 5Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of

Background: SBS has been developed as a biosimilar of reference adalimumab (ADL). The 24-week efficacy and safety results comparing SBS and ADL were reported previously.1 Here we report results of subgroup analyses of efficacy by adalimumab serum trough concentration (C_{trough}) and association between anti-drug antibodies (ADA) and C_{trough}.

Objectives: To investigate the impact of C_{trough} on efficacy and the association between ADA and C_{trough} in patients with rheumatoid arthritis (RA) treated with SBS or ADL.

Methods: Patients with moderate to severe RA despite methotrexate treatment were randomly assigned to receive 40 mg of either SBS or ADL administered subcutaneously every other week up to week 24. Blood samples were taken prior to study drug administration at weeks 0, 4, 8, 12, 16, and 24 to measure C_{trough}. The optimal C_{trough} cut-off point of adalimumab for good EULAR response at week 24 is reported to be 1.274 μg/mL.2 Efficacy and immunogenicity were analysed in patients with C_{trough} ≥1.274 μg/mL and ≥1.274 μg/mL.

Results: C_{trough} was measured in 178 patients each from SBS and ADL group. The post-dose mean C_{trough} was comparable up to week 24 for SBS (range: 3.850 to 6.761 μg/mL) and ADL (range: 3.892 to 6.773 μg/mL). Generally efficacy was comparable between SBS and ADL regardless of C_{trough} level. At week 24, the proportion of patients achieving good EULAR response, remission or low disease activity based on DAS28 was higher in patients with C_{trough} ≥1.274 μg/mL than in those with C_{trough} <1.274 μg/mL for both treatment groups (Figure). Other efficacy parameters, including ACR responses, DAS28, simplified disease activity index, and clinical disease activity index, showed similar results.

C_{trough} was higher for patients without detectable ADA, compared to those with ADA. Among patients with ADA, the proportion of patients with C_{trough} ≥1.274 μg/mL was 58.0% (29/50) for SBS and 52.1% (25/48) for ADL. Among patients without detectable ADA, the proportion of patients with C_{trough} ≥1.274 μg/mL was 100.0% (121/121) for SBS and 97.4% (114/117) for ADL.

IMPACT OF ANTI-DRUG ANTIBODY AND INJECTION SITE PERFORMANCE OF SLEDAI-2K TO DETECT A CLINICALLY ASSOCIATION BETWEEN T FOLLICULAR HELPER CELL AND REFERENCE ETANERCEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS

1Institute of Rheumatology, Prague, Czech Republic; 2Leeds Institute of Rheumatic and Musculoskeletal Medicine, United Kingdom; 3Mount Sinai Hospital, Toronto, Canada; 4Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of

Background: SB4 is approved by the European Commission as a biosimilar of the reference etanercept (ETN). The phase III clinical study results have been reported previously.1,2 Data to date shows no correlation between the development of anti-drug antibody (ADA) and clinical response or adverse events with etanercept treatment.

Objectives: To investigate the impact of the presence of ADA or injection site reaction (ISR) on efficacy in patients with rheumatoid arthritis (RA) treated with SB4 or ETN up to week 24.

Methods: In this phase III randomised, double blind study, patients with moderate to severe RA received 50 mg/week of either SB4 or ETN with background methotrexate (MTX) for 52 weeks. Efficacy, safety and immunogenicity were assessed.

Results: Up to week 24, the incidence of ADA (2 patients [0.4%] in SB4 vs 39 patients [13.1%] in ETN, p < 0.001) and the incidence of ISR (9 patients [3.0%] in SB4 vs 48 patients [16.2%] in ETN, p < 0.001) were significantly lower in SB4 compared to ETN. Due to the low incidence of ADA in the SB4 treatment group, the impact of ADA on efficacy could not be evaluated. Within the ETN treatment group at week 24, there was a trend towards increased efficacy (ACR, ACR-N, Change in DAS28, remission and low disease activity based on DAS28, SDAI, or CDAI) in patients without detectable ADA compared to patients with ADA (Table). In regards to ISR, efficacy tended to be higher in patients who did not experience ISR compared to those who did within each treatment group. There was no correlation between the presence of ADA and incidence of ISR. In patients without detectable ADA and patients with ADA, respectively, 3.0% (9/297) vs. 0.0% (0/2) of patients from SB4 group and 16.3% (42/248) vs. 15.4% (37/242) of patients from the ETN group experienced ISR.

Conclusions: Significantly fewer patients from SB4 developed ADA or experienced ISR compared to ETN, however the efficacy was still comparable between SB4 and ETN in patients without detectable ADA and in patients who did not experience ISR. Within the ETN group, there was a trend towards increased efficacy in patients without detectable ADA compared to patients with ADA. In both SB4 and ETN group, patients with ISR tended to have higher efficacy than patients without ISR. There was no correlation between the presence of ADA and ISR.

Which target/outcome is more relevant in the management of SLE?

ASSOCIATION BETWEEN T FOLLICULAR HELPER CELL AND PLASMAFAB CORRELATES WITH DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Nakayama, S. Kubo, M. Yoshikawa, Y. Miyazaki, S. Iwata, I. Miyagawa, K. Saito, K. Saito, Y. Tanaka. The First Department of Internal Medicine, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Background: Various immunological abnormalities contribute to the development and perpetuation of systemic lupus erythematosus (SLE). Since SLE is a molecularly heterogeneous disease, targeted therapy has not yet been fully established. It seems to be important to explore the characteristic and interaction among the immune cell phenotypes in this disease.

Objectives: The aim of this study was to assess the relationship between the peripheral immune cell phenotypes with clinical manifestations and responsiveness to immunosuppressive therapy in patients with SLE.

Methods: Peripheral blood mononuclear cells were obtained from 143 SLE patients and 26 healthy donors (HD). The blood samples were taken at baseline and week 24 after treatment. The subset of circulating B, T and dendritic cells was defined based on comprehensive 8-color flow cytometry analysis for human immune system termed “the Human Immunology Project” proposed by the National Institutes of Health (NIH) and the Federation of Clinical Immunology Societies (FOCIS). The proportion of immune cell phenotypes with clinical characteristics and responsiveness to immunosuppressive therapies, such as cyclophosphamide, mycophenolate mofetil, or calcineurin, in addition to high-dose glucocorticoids, were evaluated. Patients who were required more than two different immunosuppressants therapies in addition to glucocorticoids were considered treatment resistant.

Results: The proportion of CD3+CD4+CXCR5+ICOS+ T follicular helper cell (Thf) cell, but not CD3+CD4+CXCR3+CCR6 Th1 cell and CD3+CD4+CXCR3 CCR6+ Th17 cell, were higher in SLE than that in HD (mean 1.1 vs 0.8, p<0.01). The frequency of CD10+CD20+lgD+CD27+ central memory B cell and CD19+CD10+CD27+ effector B cell were higher in SLE than that in HD (mean 23.6 vs 15.1 and 10.7 vs 5.2, p<0.001 and p<0.001, respectively). The largest difference relative to the HD was observed in the proportion of CD19+CD20+CD27+CD38+ plasmablast, which was higher in SLE (mean 16.2 vs 3.7, p<0.001) and correlated with BILAG index (r=0.7, p<0.01). The proportion of Thf cell only showed positive correlation with that of plasmablast (r=0.24, p=0.02). Treatment resulted in marked improvement in disease activity scores, such as SLEDAI and BILAG and resulted in significant decreased proportions of plasmablast and T cell (plasmablast; mean 17.6 to 10.1, p<0.001, T cell; mean 1.1 to 0.7, p<0.01). The percentage of patients who showed treatment resistance was highest among patients with high Tfh cell plasma-blast axis as a potential therapeutic target for SLE. The peripheral immunophenotyping might be useful in evaluating the pathogenesis and in determining the therapeutic target of each patient.

PERFORMANCE OF SLEDAI-2K TO DETECT A CLINICALLY MEANINGFUL CHANGE IN SLE DISEASE ACTIVITY: A 36-MONTH PROSPECTIVE COHORT STUDY OF 334 PATIENTS

D. Jesus 1, M. Rodrigues 1, A. Matos 2,3, C. Henriques 2,3,4, J. da Silva 5,6.
1Institute of Health and Society, Universidade de Coimbra, Coimbra; 2School of Technology and Management, Polytechnic Institute of Viseu; 3Faculty of Social Sciences (FOCIS); 4Faculty of Medicine, University of Coimbra, Coimbra; 5Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal

Background: The Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) is the core determinant of response in the SLE Responder Index (SRI), a primary efficacy outcome in SLE clinical trials. However, SLEDAI is unable to discriminate partial improvement/worsening, as it scores each item...
categorically. Furthermore, potentially severe lupus manifestations, such as hemolytic anemia, are not scored in SLEDAI.

**Objectives:** To evaluate the performance of SLEDAI-2K to detect a clinically meaningful change in SLE disease activity.

**Methods:** Prospective cohort study of SLE patients followed at a tertiary care lupus clinic from January 2014 to December 2016. Consecutive patients fulfilling the ACR’97 and/or the SLICC’12 classification criteria were included. At each outpatient visit, disease activity from the last 30 days was scored in the Physician Global Assessment (PGA) (0–3 cm scale) and in SLEDAI-2K. The association between PGA and SLEDAI-2K at each visit was tested with Spearman’s Correlation. A clinically meaningful change in SLE disease activity, was defined as difference in PGA ≥0.3 cm at follow-up compared to the baseline visit. Performance of change in SLEDAI-2K was tested in two models: against worsening and improvement in PGA ≥0.3 cm from baseline using Receiver Operating Characteristic (ROC) curve analysis. Sensitivity, specificity, positive and negative predictive values (PPV, NPV) of SLEDAI-2K to change in PGA was calculated. Statistical significance was set at 0.05.

**Results:** We included 334 patients (87.1% female, mean age at baseline - 44.8±14.5 years). At baseline, median PGA and SLEDAI-2K score was 0.2 points (range –0.2–5.2) and 2 points (range 0–19), respectively. Eighty-three patients (24.8%) had a PGA >0.4 points at baseline. During follow-up of 36 months, 2129 visits were performed. PGA and SLEDAI-2K scores presented a high correlation (rho=0.82, p<0.0001) (fig. 1). Reductions in PGA ≥0.3, and worsening were significantly associated with SLEDAI-2K ≥0.3. A scatter plot showing linear positive correlation between PGA and SLEDAI-2K scores (Spearman’s correlation coefficient (r) =0.82, p<0.0001).

**Conclusions:** SLEDAI-2K presents a limited performance in detecting a clinically meaningful change in SLE disease activity, failing to identify more than a quarter of cases with clinically meaningful improvement or worsening. There is a need to optimize SLE disease activity measures.

**Disclosure of Interest:** None declared

**OP0207 B CELL DEPLETION INCREASES REGULATORY T CELLS AND AMELIORATES SKIN AND LUNG FIBROSIS IN A BLEOMYCIN-INDUCED SYSTEMIC FIBROSIS MODEL MOUSE**

H. Numajiri, A. Yoshizaki, T. Fukasawa, S. Ebata, Y. Asano, S. Sato. Department of Dermatology, The University of Tokyo Graduate School of Medicine, Hongou, Bunkyo-ku, Tokyo, Japan

**Background:** B cells play a critical role in systemic autoimmunity and disease expression through various functions such as cytokine production and induction of other immune cell activation. Recently, some clinical studies have shown that the efficacy of B cell depletion therapy with rituximab, a chimeric monoclonal antibody against human CD20, in systemic sclerosis (SSc) patients. However, it still remains unclear why B cell depletion can be an effective treatment for SSc.

**Objectives:** The purpose of this study is to assess the role of B cell depletion in SSc. We evaluated the skin and lung fibrosis of bleomycin (BLM)-induced SSc model mice treated with B cell depletion. Furthermore, we investigated the effect of B cell depletion on T cell cytolytic profile.

**Methods:** To generate BLM-induced SSc model mice, 300 μg of BLM was injected subcutaneously into the shaved backs of the C57BL/6 mice every other day for 4 weeks. Anti-mouse CD20 monoclonal antibodies, which can deplete mouse B cells, were also injected every 2 weeks from 2 weeks later starting BLM treatment. After 4 weeks of BLM treatment, skin and lung fibrosis were assessed histopathologically. T cells and B cells were isolated from spleen using magnetic cell sorting system. Purified T cells (5x10⁶ cells) were cultured with naive T cells. Frequencies of IL-10 producing regulatory T cell frequencies in BLM-treated mice were significantly decreased in BLM-treated mice compared with PBS-treated mice, while IL-6 producing B cell frequencies increased. Moreover, interferon (IFN)-γ-, IL-4, or IL-17 producing T cell frequencies were significantly decreased in BLM-treated mice compared with PBS-treated mice.

**Results:** Derma thickness and lung fibrosis score increased in BLM-treated mice compared with PBS-treated mice, while IL-6 producing B cell frequencies increased. Moreover, interferon (IFN)-γ-, IL-4, or IL-17 producing T cell frequencies were significantly decreased in BLM-treated mice compared with PBS-treated mice. By contrast, frequencies of IFN-γ-, IL-4, or IL-17 producing T cells were significantly decreased by B cell depletion in BLM-treated mice. In addition, fibrogenic cytokine mRNA expression levels of collagen and lung fibrosis decreased in BLM-treated mice after B cell depletion. To assess the role of B cells on T cell cytokine production, purified splenic B cells from BLM- or PBS-treated mice were cultured with naive T cells. T cells which were cultured with B cells from BLM-treated mouse produced greater amounts of INF-γ-, IL-4, and IL-17 than those cultured with PBS-treated mouse B cells. By contrast, B cells from PBS-treated mice induced a higher amount of IL-10 production from T cells than those from BLM-treated mice.

**Conclusions:** B cell depletion inhibited skin and lung fibrosis in BLM-treated mouse further. Moreover, B cell depletion increased regulatory T cell frequencies in BLM-treated mice, through INF-γ-, IL-4, and IL-17 producing T cell frequencies were decreased by B cell depletion. These results suggest that B cell depletion alters T cell cytokine profile, which results in inhibition of fibrosis in this model.

**OP0208 SYNOVIAL TISSUE OF RA PATIENTS IN REMISSION CONTAINS A UNIQUE POPULATION OF REGULATORY MACROPHAGES**

A. Elmsen1, S. Alverink2, B. Tolusso5, D. Vaughan1, G. Di Sante3, L. Petricca2, E. Gremese2, G. Ferraccioli2, I.B. McInnes1, M. Kurowska-Stolarska1, 1Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom; 2Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli, Catholic University of the Sacred Heart, Rome, Italy

**Background:** The majority of RA treatments target inflammation or the adaptive immune response. Partial- or non-response is common and only a minority have sustained remission. There is a knowledge gap in understanding the mechanisms that could reinstate synovial homeostasis in RA. Tissue macrophages may have a role in this process; they are present in healthy synovium and aid resolution of the inflammation in experimental models of RA. However, little is known about the regulatory properties of human synovial tissue macrophages.

**Objectives:** Our hypothesis is that healthy and RA synovium in remission contain macrophages with anti-inflammatory/reparatory properties and identifying the effector pathways that drive their function could facilitate therapeutic restoration of synovial homeostasis in RA.

**Methods:** We developed a flow cytometry sorting strategy for harvesting tissue-resident macrophages obtained from digested synovial biopsy from reponding RA patients (n=21, including in remission n=5; and active RA n=16). Cells were labelled with cell lineage-specific antibodies; then macrophages were gated based on CD14/CD64 expression levels. CD11c+CD64+CD14++ macrophages were sorted using a MSD FACS Aria III and RNaseq performed to characterise their functional signature. In some experiment, macrophages were seeded on collagen-coated plates and production of TNFα assessed.

**Results:** All synovial tissue macrophages from RA in remission were CD206εpos whereas a substantial number of synovial macrophages from active RA tissue were CD206εneg. Gene expression analyses and functional assays suggest that these populations represent distinct subpopulations in the activation spectrum. CD206εpos macrophages have high expression of microRNA-155, which drives production of inflammatory mediators e.g. TNFα. In contrast, CD206εneg macrophages showed regulatory properties characterised by increased expression of soluble e.g. IL10, TGFβ, IL4/10, TGFβRII/1 and 2 cell population (e.g. SHIP1, TAK1, SMAD2, SMAD3, SMAD7) inhibitors of inflammatory activation, and increased expression of repair markers (e.g. ARG2 and CCL18).

**Conclusions:** We propose therefore that anti-inflammatory/reparatory macrophages may be present in human synovial tissue in remission representing a hitherto unnoticed regulatory tissue mechanism.
To determine the incidence and risk factors implicated in the development of cardiovascular events (CVD) in patients with chronic inflammatory diseases (CIRD) attending rheumatology clinics after 2.5 years of follow-up. The total number patient who completed the follow-up visit at 2.5 years and their causes were also analyzed.

Methods: Analysis of data after 2.5 years of follow-up in an observational prospective study [CARdiovascular in rheuMatology (CARMA) project] that includes a cohort of patients with CIRD [rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA)] and another cohort of matched individuals without CIRD attending outpatient rheumatology clinics from 61 hospitals in Spain. The cumulative incidence per 1000 patients and the incidence density per 1000 patient-months of non-fatal CVE were estimated in both cohorts at 2.5 years from the start of the project. Weibull proportional hazard model was fitted to the data.

Results: The total number patient who completed the follow-up visit at 2.5 years was 2,598 (89.2% of those who started the study). Seven patients had died due to CVE and 23 because of non-CVE. The higher number of losses to follow-up was in patients with AS (HR: 4.11; 95% CI: 1.18–13.76, p<0.01), higher systolic blood pressure (HR: 1.02; 95% CI: 1.00–1.04, p=0.01) and longer duration of the rheumatic disease (HR: 1.07; 95% CI: 1.03–1.12, p<0.01). In contrast, woman gender was a protective factor (HR: 0.43; 95% CI: 0.19–1.00, p=0.05).

Conclusions: Patients with AS prospectively followed-up at rheumatology outpatient clinics show higher risk of developing a first CVE than those with RA or PsA. Besides traditional CVD risk factors a longer time course of the disease is a risk factor for the development of CVD in patients with CIRD.

WHO CARES? AN INVESTIGATION OF THE HEALTH AND PERCEIVED SOCIAL CARE NEEDS OF PEOPLE WITH RHEUMATOID ARTHRITIS LIVING IN SCOTLAND

C. O’Neill 1, A. Bosworth 2, K.R. Martin 3. 1Policy & Public Affairs; 2CEO, National Rheumatoid Arthritis Society, Maidenhead; 3Epidemiology, University of Aberdeen, Aberdeen, United Kingdom

Background: Effective and sufficient levels of care and support for individuals newly diagnosed and those with established Rheumatoid Arthritis (RA) are needed to ensure optimal physical and mental health, as well as health-related quality of life. The aim of this study was to explore the extent of care needs among individuals with RA living in Scotland, UK and the factors that contribute to them, such as co-morbidities, perceived caregiver burden and complex care needs.

Objectives: To establish whether the health and social care needs of people with RA in Scotland were being met, if there was regional variation and what other factors impacted such as wealth and age.

Methods: A cross-sectional study of individuals with RA who responded to an online survey (available 11 Nov 2015 to 22 Jan 2016) who were aged ≥16 years, lived in Scotland and reported they had received a clinical diagnosis of RA. Respondents were allowed to skip questions they wished not to answer; standardised instruments were used (e.g., the Self-Administered Comorbidity Questionnaire and the Self-Perceived Burden Scale). Descriptive analyses of quantitative data and thematic analyses of free text responses were conducted.

Results: Overall, 387 individuals participated. The majority were female, of White Scottish or White British background, 45–64 years, and lived in a household with ≥2 people. The majority, 83%, reported well established RA (diagnosis ≥2 years ago) and at least one other comorbidity (78%) – most commonly depression (78%) and fibrotic diseases ≥40% reported taking 3 medications in total. Of those receiving care, the majority (97/101) named family or friends/neighbours as caregivers and 76% (80/97) had an elevated level of self-perceived burden on their caregiver. Respondents who reported anxiety or depression had significantly higher average self-perceived burden scores when compared to those without, 33.0 versus 27.3.

89% responded that they did not know what types of circumstances might make them eligible for care and support from their local Council, and only 10% reported receiving information about care and support from their local council. Very few (n=40) had an assessment, with half being deemed eligible for support from their local council.

Conclusions: Survey responses suggest individuals with RA lack fundamental information about qualifying for and accessing formal resources and services provided by their local Council. This is especially crucial for reasons: 1) respondents indicated they do not want to rely heavily on others, like family or friends who are often the primary caregivers; 2) depression and anxiety are highly prevalent in this population. It is important to ensure those with RA do not have unmet needs at any stage, from being newly diagnosed to having established RA, so that they can flourish at home, at work and in their leisure time. Local councils should make access to information about help with formal social care easily accessible and ensure that health professionals know how best to sign-post people.

Macrophage M2 polarization: implications in fibrotizing diseases

ENDOTHELIN-1 INDUCES A PROFIBROTIC PHENOTYPE IN CULTURED HUMAN MICROVASCULAR ENDOTHelial AND CIRCULATING MONOCYTE/MACROPHAGE CELLS

S. Soldano 1, P. Montagna 1, R. Brizzolara 1, A.C. Trombetta 1, A. Sulli 1, C. Pizzorni 1, M. Ghio 1, S. Paolino 1, V. Smith 2, M. Cutolo 1. 1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy; 2Department of Rheumatology, Ghent University Hospital, Ghent, Belgium

Background: The alteration of microvascular endothelial cell (EC) functions and the presence of macrophages in the immune inflammatory infiltrate, followed by the transition of these cell types into a profibrotic phenotype, represent early and crucial pathophysiological features of the fibrotic process in systemic sclerosis (SSc) (1). The alternatively activated macrophage subset M2a was found in several diseases characterized by extensive fibrosis (1). Herein, we investigated the expression specific phenotype markers, CD206 (mannose receptor), CD204 and CD163 (scavenger receptors) as well as profibrotic molecules, primarily transforming growth factor-β1 (TGFβ1) (1). Endothelin-1 (ET1) and/or TGFβ1 are known to induce the transition of fibroblasts into profibrotic myofibroblasts, which are key mediators of fibrosis in SSc.

Objectives: To investigate the effects of ET1 in inducing a profibrotic phenotype in cultured human microvascular ECs (HMVECs) and macrophages.

Methods: HMVECs, at 3rd culture passage, were grown in endothelial cell medium (EMEM) and treated for 6 days with ET1 (100 nM) or treated for 1 hr with ET1 receptor antagonist (ETAB-R, bosentan 10 μM) before stimulation with ET1.

Human monocytes were isolated from peripheral blood mononuclear cells of healthy subjects using a monocye isolation kit. The cells were maintained in RPMI growth medium for 24 hrs and then treated for 6 days with ET1 or treated for 1 hr with bosentan before stimulation with ET1.

Cultured HMVECs and monocytes maintained in EGM2MV and RPMI growth medium, respectively, were used as untreated cells. Gene and protein expression of profibrotic myofibroblast markers—smooth muscle actin (α-SMA), fibroblast specific protein-1 (S100A4), type 1 collagen (COL1) and fibroconnectin (FN)—were evaluated by quantitative real time polymerase chain reaction (qRT-PCR), Western blotting (WB) and immunocytochemistry (ICC) in cultured HMVECs. Gene and protein expression of M2a phenotype markers (CD206, CD204, CD163) and TGFβ1 were investigated by qRT-PCR and WB in cultured human macrophages. Statistical analysis was carried out by Mann-Whitney non-parametric test.

Results: In cultured HMVECs, ET1 induced the significant upregulation of the gene expression of α-SMA, S100A4 (myofibroblast markers), COL1 and FN, compared to untreated cells (p<0.01, p<0.05, p<0.01). ETAB-R significantly contrasted the ET1-mediated transition of HMVECs into a profibrotic phenotype (p<0.05 for α-SMA, COL1 and FN; p<0.01 for S100A4 vs. ET1-treated cells).

In cultured human macrophages, ET1 induced the significant overexpression of M2a markers (p<0.05 for CD204 and CD163 and p<0.01 for CD206 and TGFβ1) compared to untreated cells. ETAB-R significantly contrasted the ET1-mediated transition of cultured macrophages into profibrotic M2a (p<0.05 vs. ET1-treated cells, for all investigated proteins). Data were confirmed by WB and ICC on both cultured cell types.

Conclusions: ET1 seems to be involved in the early phases of the fibrotic process by inducing the transition of both cultured HMVECs and macrophages into a profibrotic phenotype, myofibroblast and M2a respectively (observed in SSc), a process which is apparently contrasted by ETAB-R treatment.

MACROPHAGES FROM A SCLERODERMA SUBGROUP WITH HIGHER SKIN SCORES EXPRESS ACTIVATION MARKERS AND INDUCE FIBROBLASTS IN CO-CULTURE

J. King, D. Sleep, Y. Sohrabi, A. Tam, B.A. Abdi, D. Abraham, C. Denton, R. Stratton. Centre for Rheumatology and Connective Tissue Diseases, Royal Free Hospital, London, United Kingdom

Background: Scleroderma (SSc) is characterized by pathological fibrosis. The mechanisms by which fibrosis occurs in SSc are not fully understood. Alternatively activated M2-like macrophages are associated with fibrosis and have been found to have an important role in pathological fibrosis in humans. Therefore, there is interest in elucidating their role in SSc. M2 macrophages express mannose receptor CD206 and are known to secrete a number of soluble factors to establish a pro-fibrotic milieu when present in damaged tissues. Furthermore, we have shown adenosine tri-phosphate (ATP) concentration is increased in the skin of patients with SSc. Within the extra-cellular environment, ATP is a Damage-Associated Molecular Pattern (DAMP), binding the P2X class of purinergic receptors. Such mechanisms may contribute to SSc pathology.

Objectives: In this study, we explore the relationship of macrophage CD206 and P2X expression to Rodnan Skin Score. The role of these cells in establishing fibrosis was also examined in vitro.

Methods: 17 SSc patients and 9 controls were consented and their skin score recorded. Macrophages were derived from peripheral blood mononuclear cells (PBMCs) and identified through CD14 expression by FACS. CD206 and P2X
co-expression was quantified. CD206 immunofluorescence of skin biopsies was also performed.

Macrophages were co-cultured with 8x10^4 and 2x10^4 fibroblasts in a collagen matrix and within a monolayer respectively. Collagen gel contraction was quantified as a measure of fibrotic activity. CTGF and collagen mRNA expression from gel matrices and cellular monolayers was quantified by qPCR.

Results: CD206 and P2X7 expression is higher on SSc PBMC-derived macrophages (mean fluorescence 776.1 SD=409, 724.4 SD=455.3) compared to healthy controls (mean fluorescence 632.2 SD=73.7, 472.9 SD=25.4). There is a significant correlation of CD206 expression to P2X7 expression (p<0.001, r=0.76) and CD206 expression is significantly correlated to Rodnan skin score (p<0.05, r=0.26). P2X7 expression is positively correlated to skin score. Double positive P2X7 and CD206 were seen in a subgroup with higher skin scores, however MAIT/CD206+ fibroblasts co-cultured with scleroderma macrophages showed stronger collagen mRNA by qPCR compared to co-culture with healthy macrophages (p<0.01), CTGF mRNA was positively correlated with macrophage P2X7 (r=0.23) and CD206 (r=0.81) expression. Preliminary work suggests contraction of collagen discs in fibroblast and macrophage co-culture is increased with SSc macrophages compared to healthy controls.

Conclusions: Data indicates a correlation between disease severity and CD206 expression by macrophages. Upregulation of CTGF and collagen expression in fibroblasts co-cultured with macrophages expressing high CD206 suggests a role for MAIT cells in pathogenic fibrosis. The co-expression of high levels of P2X7 with CD206 may indicate the role of the purinergic pathway in SSc fibrosis. Future work will examine the mechanism of macrophage-fibroblast cross-talk and investigate the effect of inhibitors of CD206.

USTEKINUMAB IS SUPERIOR TO TNF INHIBITOR TREATMENT IN RESOLVING ENTHESIS IN PSA PATIENTS WITH ACTIVE ENTHETISIS-RESULTS FROM THE ENTHETISAL CLEARSANCE IN PSORIATIC ARTHRITIS (ECLIPSA) STUDY

E.G. Araujo,1 M. Englbrecht,2 S. Hoepken,3 S. Finzel,1 A. Hueber,1 J. Rech,1 G. Schett,1 Internal Medicine 3 Rheumatology and Immunology, Universitätsglinikum Erlangen, Erlangen, Germany

Background: IL-23 is considered to play an important role in the development of enthesitis. Ustekinumab (UST), a combined inhibitor of IL-12/IL-23 shows efficacy in psoriatic arthritis (PsA) driven by enthesial disease, while it has no therapeutic role in diseases driven by synovitis alone, such as rheumatoid arthritis. We therefore speculated that inhibition of IL-23 is particularly effective in enthesitis-driven PsA patients.

Objectives: To compare the efficacy of UST with tumor necrosis factor inhibitor (TNFi) treatment in clearing enthesis in PsA patients.

Methods: ECLIPSA is a prospective randomized-controlled open study. Patients with PsA with active enthesitis were randomized 1:1, receiving either standard doses of UST (arm 1) or TNFi (arm 2). At baseline the following parameters were assessed: age, gender, BMI, disease duration, previous DMARDs, use of corticosteroids, use of NSAIDs, swollen and tender joint count, VAS-pain, VAS-global, NAPSI, PASI, MASES, SPARCC, LDI, BASDAI, BASFI, HAQ-DI, SF-36, FACIT-F, ESR and CRP. Primary endpoint was a SPARCC of 0 after 6 months. Patients were seen every 3 months and followed for a total of 6 months. In order to investigate the effect of study treatment over time, individual time- and dose-dependent ANCOVA models were used for both physician’s and patient’s reported outcomes. Furthermore, exploratory logistic regression was used to predict a SPARCC of 0 at month 6 from baseline SPARCC, PASI, NAPSI, FACIT-F and BASDAI while additionally accounting for age, gender, BMI, gender, PsA duration and study treatment.

Results: 51 patients (UST=25; TNFi=26) were screened and 47 patients (UST=23; TNFi=24) were enrolled with 4 patients not presenting signs of active enthesitis at baseline. Mean ± SD age was 59.1±12.16 years and mean ± SD disease duration was 6.4±7.79 years. Mean SPARCC at baseline was 4.87±2.69 in the UST group and 4.45±2.69 in the TNFi group. Patient-reported disease activity (BASDAI and BASFI), physical well-being (SF-36 physical component summary scale), and PASI all p<0.044 with superiority of UST. However, TNFi was superior to UST with respect to improvement of fatigue (FACIT-F), p=0.001. After 6 months, 17 out of 24 UST patients (70.8%) and 10 out of 26 TNFi patients (38.4%) reached the primary endpoint (SPARCC<0). Logistic regression predicting enthesitis-free state of disease was significantly related to study treatment only, with patients receiving UST being more likely to show no signs of enthesitis at month 6 (OR=0.037; p=0.005).

Conclusions: These results show that UST is superior to TNFi in resolving the enthesis component of disease in PsA patients with active enthesial disease. Based on these data more stratified treatment approaches can be designed in PsA patients, where enthesitis-driven patients are targeted by IL-23/IL-17 pathway inhibitors, while more systemic disease manifestations of PsA, such as patients with polyarticular disease or those with high-level fatigue are targeted by TNFi.

Disclosure of Interest: None declared

EFFECTIVICY AND SAFETY RESULTS OF GUSELKUMAB, AN ANTI-IL23 MONOCLONAL ANTIBODY, IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS OVER 24 WEEKS: A PHASE 2A, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY

Objectives: To evaluate the efficacy, safety, and tolerability of guselkumab (GUS), a fully human monoclonal antibody against the p19 subunit of IL-23, in patients (pts) with active psoriatic arthritis (PsA).

Methods: Designed as a double-blind, placebo-controlled, multicenter study, pts with active PsA and ≥3% body surface area (BSA) of plaque psoriasis despite current or previous treatment with standard-of-care therapies, including those previously exposed to anti-TNFα agents, were randomized 2:1 to receive GUS 100 mg subcutaneously (SC) or placebo (PBO) at wks 0, 4, and every 8 wks (q8w) through wk44. Pts were then randomized either group with ≥5% improvement from baseline in both swollen and tender joint counts were eligible for early escape to open-label ustekinumab. At wk24, all remaining PBO pts crossed-over to receive GUS 100 mg, and then received GUS at wk28, and q8w thereafter through wk44. The primary endpoint was ACR 20 response at wk24. Major

Conclusions: In TNFi-naive pts with active PsA, tofacitinib was superior to PBO in ACR20 response rates and ΔHAQ-DI at M3, with superiority vs PBO as early as Week 2 for ACR20, which was maintained to M12. No new safety risks were noted. The most common adverse events were upper respiratory tract infection (7.5–10.6%), nasopharyngitis (7.5–11.5%) and headache (3.8–10.6%).

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1416

Stable treatment with 1 csDMARD was required. Primary endpoints comparing tofacitinib vs PBO were ACR20 response rate and change from baseline in Health Assessment Questionnaire Disability Index (ΔHAQ-DI) at M3. Secondary endpoints included: ACR20 response rates and ΔHAQ-DI through M12; pts achieving ACR50, ACR70, ≥75% improvement of PASI and PsARC at all time points; and changes from baseline in LUM, Dactylitis Severity Score and SPARCC Enthesis Index. Radiographic progression was assessed by van der Heijde-modified Total Sharp score (mTSS).

Results: 96.9% of pts were white and 53.3% were female; mean age was 47.9 years. 96.2% and 66.4% of pts completed M3 and M12, respectively. At M3, tofacitinib 5 and 10 mg Bd significantly improved ACR20 response rates (50.5% [p<0.05] and 66.6% [p<0.0001] vs 33.3%; Fig 1A) and ΔHAQ-DI (Δ0.35 [p<0.05] and Δ0.40 [p<0.01] vs 0.18; Fig 1B) vs PBO, with responses maintained to M12 (Fig 1C&D). Greater efficacy was also seen for adalimumab vs PBO. Tofacitinib 5 & 10 mg Bd were superior to PBO for ACR20 response rates at Week 2 (22.4% [p<0.001] and 31.7% [p<0.001] vs 5.7%; Fig 1C). Secondary endpoints supported primary findings (data not shown). >91% of pts were radiographic non-progressors at M12 (defined as an increase from baseline in mTSS <0.5). M12 safety findings were similar between groups (Fig 1E).

Conclusions: In TNFi-naive pts with active PsA, tofacitinib was superior to PBO for ACR20 response rate and ΔHAQ-DI at M3, with superiority vs PBO as early as Week 2 for ACR20, which was maintained to M12. No new safety risks were identified vs previous studies in other indications.

Acknowledgements: Previously presented at ACR 2016, to be presented at AAD 2017 and reproduced with permissions. This study was sponsored by Pfizer Inc. Editorial support was provided by AG McCluskey of CMC and was funded by Pfizer Inc.
Conclusions: In pts with active PsA and ≥3% BSA of psoriasis, GUS demonstrated significant improvement on joint symptoms, physical function, psoriasis, enthesitis, dactylitis and quality of life. GUS was well tolerated with no unexpected safety findings in this population.

Background: ACTIVe is the first apremilast (APR) trial to evaluate time to onset of efficacy beginning at Wk 2 in a biologic-naïve psoriatic arthritis (PsA) patients (pts) who may have had exposure to 1 prior conventional DMARD.

Objectives: Report the study results through Wk 52.

Methods: Pts were randomized (1:1) to APR 30 mg bid or placebo (PBO). Pts were eligible for early escape (investigator discretion) if ≥40% of ACR20 responders entered active treatment with APR. The primary endpoint was ACR20 response at Wk 16. Other assessments included changes in DAS-28 (CRP), SJC, TJC, HAQ-DI, morning stiffness severity and enthesitis, as measured by the Gladman Enthesitis Index (GEn; 0=no enthesitis, 6=all 6 sites active). Along with collection of safety data, tolerability adverse events (AEs) of diarrhea were further characterized.

Results: 219 pts were randomized (APR: n=110; PBO: n=109); overall, 160/180 (88.9%) pts receiving APR completed Wk 52. Separation in the proportion of ACR20 responders to APR vs PBO was noted at Wk 2 (16.4% vs 6.4%; P=0.0052), the first post-baseline (BL) visit. Early onset of response to APR was observed across clinical assessments, with improvements in DAS-28 (CRP), SJC, HAQ-DI, and morning stiffness severity (Table). At Wk 16, significant ACR20 response rates were observed with APR vs PBO (38.2% vs 20.2%; P<0.005), with similar rates for the subset of pts with use of 1 prior non-biologic DMARD (39.2% vs 20.5%; P<0.005), which comprises 69% of study pts. Significant reductions in PsA disease activity/manifestations vs PBO were also demonstrated by changes in DAS-28 (CRP) (P=0.0001), SJC, and HAQ-DI (P<0.001); improvement in morning stiffness severity and GEn score (P<0.0014). With continued APR exposure, the Wk 52 ACR20/ACR50/ACR70 response rates were 63.3%/32.4%/14.0%, respectively, and percent change in SJC was 75.4%. Among APR pts with BL enthesitis, 62.8% reached a GEn score of 0. Overall incidence of AEs in the PBO-controlled period was generally similar between APR and PBO. The most commonly reported AEs (≥5% of pts) with APR vs PBO were nasopharyngitis (8.3% vs 6.4%), nausea (8.3% vs 1.8%), headache (7.3% vs 3.7%), hypertension (6.4% vs 6.4%) and, diabetes (pt or investigator reported) (14.7% vs 11.0%); using a protocol-defined characterization of diarrhea (≥2 watery/liquid stools/day), overall incidence was lower for APR and PBO (11.0% and 8.3%). Serious AEs were lower with APR and PBO (2.8% vs 4.6%). No opportunistic infections, reactivations of TB, or cases of marked depression were seen. In general, no increase was seen in AE incidence/severity with longer-term exposure to APR.
Randomized, Double-Blind, Global Clinical Trial to Evaluate Equivalence of CHS-1420 to Adalimumab in Patients with Psoriatic Arthritis

J. O’Dell1, A. Kvist2, K. Papp3, C. Leonard4, K. Jensen5, H. Tang5, B. Finck5 on behalf of The PsOsim Study Group. 1University of Nebraska Medical Center, Omaha, NE; 2Altoona Center for Clinical Research, Duncansville, PA, United States; 3K. Papp Clinical Research, Waterloo, Ontario, Canada; 4Central Dermatology, St. Louis, MO; 5Coherus BioSciences, Redwood City, CA, United States

Background: CHS-1420 is being developed as a proposed biosimilar to adalimumab for the treatment of rheumatoid arthritis, plaque psoriasis (PsO), and other auto-immune diseases.

Objectives: This phase 3, randomized, double-blind, active-controlled, multicenter study evaluated the equivalence of CHS-1420 to adalimumab in patients with active, moderate-severe, chronic plaque PsO, including patients with psoriatic arthritis (PsA).

Methods: Male and female patients (aged ≥18 years) were randomized to CHS-1420 or adalimumab. Patients received 40 mg x 2 on Day 0 and then 40 mg every other week (QOW) by subcutaneous injection. To establish the equivalence of CHS-1420 to adalimumab, the 95% CI of the treatment difference for the primary endpoint, PASI75 at Week 12, had to be within pre-specified equivalence margins of ±15%.

Results: The full analysis population for the primary efficacy endpoint consisted of 545 patients (mean age 43.9 years), with 274 and 271 in Group A and Group B, respectively. The mean BMI was 29.6 kg/m², and 72.3% were male. At Week 12, the proportion of patients achieving a PASI75 from Baseline was 77.7% in Group A and 74.5% in Group B. The 95% CI of the treatment difference [-3.63, 10.28] was within the pre-specified equivalence margin [-15.0, 15.0]. Sensitivity analyses supported equivalence of the two treatments.

Conclusions: In the safety population (n=545), adverse events were reported in 48.5% and 50.0% of patients with PsA in Group A and Group B, respectively. A PASI75 was achieved by 81.5% and 77.0% of patients with PsA in Group A and Group B, respectively. A PASI90 was achieved by 47.2% and 44.7% of patients with PsA in Group A and Group B, respectively. A PASI120 was achieved by 15.2% and 14.2% of patients with PsA in Group A and Group B, respectively. A PASI140 was achieved by 10.0% and 9.2% of patients with PsA in Group A and Group B, respectively. A PASI160 was achieved by 3.9% and 2.8% of patients with PsA in Group A and Group B, respectively.

Radiographic Progression of Structural Joint Damage in Patients with Active Psoriatic Arthritis Treated with Ixekizumab over 52 Weeks

D. van der Heijde1, M. Okada2, C. Lee3, C.L. Shuler3, S. Rathmann3, C.-Y. Lin3, P. Mease4, 1Leiden University Medical Centre, Leiden, Netherlands; 2St. Luke’s international Hospital, Tokyo, Japan; 3Eli Lilly and Company, Indianapolis; 4Swedish Medical Center and University of Washington, Seattle, United States

Background: Ixekizumab (IXE), an anti-interleukin-17A monoclonal antibody, was shown to be superior to placebo (PBO) in clinical responses and inhibiting the progression of structural joint damage in patients (pts) with psoriatic arthritis (PsA) treated for 24 weeks (wks). 1

Objectives: To assess progression of structural joint damage in PsA pts with IXE for up to 52 wks.

Methods: Biologic DMARD-naïve pts with active PsA (N=417) entered into SPIRIT-P1 (NCT01695239), a double-blind phase 3 trial. Pts must have had ≥1 x-rays of the hand and foot and x-rays confirmed by central reader. 350 pts had a C-reactive protein level > 6 mg/L at screening. 417 pts were randomized to IXE 80 mg every 2 wks (Q2W; N=103) or 4 wks (Q4W; N=107) following a 160 mg initial dose, PBO (N=106), or adalimumab 40 mg every 2 wks (ADA; active reference arm; N=101) for 24 wks. In the Extension Period (EXT: Wks 24–52), PBO and ADA pts were re-randomized (1:1) to IXE2QW or IXE4QW at Wk 16 (inadequate responders) or Wk 24; ADA pts underwent a washout prior to IXE treatment. All pts were assessed for structural joint damage using the van der Heijde modified PsA Total Sharp Score (mTSS, 0–528 scale). X-rays at Wks 0, 24 and 52 were scored independently by 2 readers blinded to timepoint and clinical data (average of readers). mTSS was excluded from the pre-specified analysis if the radiograph was taken after the scheduled visit date. In a post-hoc analysis, mTSS from a radiograph taken after the scheduled visit date was interpolated and considered as observed data. Any missing data at Wk 52, in either presentation, were imputed using a linear extrapolation if they had at least 1 post-baseline value.

Results: Pts had active PsA at Week 0 (Table). 381 pts (91.3%) entered the EXT, with 374 (96.2%) having radiographs collected during the EXT. Wk 52 mean (SD) mTSS change from baseline were 0.54 (2.11) and 0.09 (1.0) for pts randomized to IXE4QW and IXE2QW at baseline, respectively. Similar changes at Wk 52 were obtained with the post-hoc analysis (Table). The majority of IXE2QW or IXE4QW pts exhibited no structural progression through 1 year of IXE treatment (Figure).

Conclusions: Over a 52 wk period, minimal changes in mTSS were observed in PsA pts entering the EXT and treated with IXE2QW or IXE4QW. 1

N = EXT pts; n = pts with baseline and ≥1 post-baseline radiograph assessments.

NEX5: NEX5 patients. NEX5 Pts with baseline and Wk 52 radiograph assessments. mTSS values from radiographs taken after the scheduled visit date were interpolated and considered as observed data.

Conclusions: Over a 52 wk period, minimal changes in mTSS were observed in PsA pts entering the EXT and treated with IXE2QW or IXE4QW.
Secukinumab provides sustained improvements in the signs and symptoms of active psoriatic arthritis—104 weeks results from a phase 3 trial, future 2

I.B. McNittnes 1, P.J. Meese 2, C. Ritchlin 3, P. Rahman 4, A. Gottlieb 5, B. Kirkham 6, R. Kajekar 7, E.M. Delicha 8, L. Pricop 7, S. Mpofu 8 on behalf of the FUTURE 2 study group. 1University of Glasgow, Glasgow, United Kingdom; 2Swedish Medical Centre and University of Washington, Seattle; 3University of Rochester, Rochester, United States; 4Memorial University, St. John’s, Canada; 5New York Medical College, New York, United States; 6Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom; 7Novartis Pharmaceuticals Corporation, East Hanover, United States; 8Novartis Pharma AG, Basel, Switzerland

Background: Secukinumab significantly improved the signs and symptoms of psoriatic arthritis (PsA) over 52 weeks (wks) in FUTURE 2 study (NCT01752634). 1, 2, 3 Objectives: To present longer-term (104 wks) efficacy and safety data of secukinumab from FUTURE 2 study. Methods: Overall, 397 patients (pts) with active PsA were randomised to secukinumab (300, 150, or 75 mg) or placebo at baseline, Wks 1, 2, 3, and 4, and every 4 wks thereafter. Assessments at Wk 104 are from pts originally randomised to secukinumab and included ACR20/50/70, PASI 75/90, DAS28-CRP, CRP, SF-36 PCS, HAQ-DI, dactylitis, and enthesitis. Multiple imputation was used for analysis of binary variables and mixed-model repeated measures for continuous variables. Analyses stratified by anti-TNFα status (naïve/inadequate response or intolerance to these agents) were prespecified and are reported as observed. Safety analysis included all pts who received ≥1 dose of secukinumab. Results: In total, 86/100 (86.0%), 76/100 (76.0%) and 65/99 (65.7%) pts in the secukinumab 300, 150, and 75 mg groups respectively completed 104 wks of treatment. Prespecified clinical improvements were observed through Wk 104 with secukinumab across all clinically important domains of PsA (Table). Responses were sustained through Wk 104 regardless of anti-TNFα status. Over the entire treatment period (mean ±SD exposure to secukinumab of 709±210.99 days), the exposure adjusted incidence rates for serious infections/infections, inflammatory bowel disease and malignant/unspecified tumors with secukinumab were 1.6, 2.3, 0.5 and 1.3, respectively.

*% responders unless otherwise specified. 1Assessed in pts with psoriasis affecting ≥3% body surface area at BL (300 mg: n=41; 150 mg: n=58; 75 mg: n=50). 2Assessed in pts with ≥3% body surface area. Pts without missing responses were imputed as non-responders, except if the missing value was between 2 visits for which the pt was a responder. In that case the missing value was imputed as a responder.

Conclusions: Secukinumab 300 and 150 mg provided sustained improvements in signs and symptoms and multiple clinical domains of active PsA through 2 years of therapy. Secukinumab was well tolerated, with a safety profile consistent with that reported previously.

OP0223 ABATACET IN THE TREATMENT OF ACTIVE PSORIATIC ARTHRITIS: 1-YEAR RESULTS FROM A PHASE III STUDY

P. Mease 1, A. Gottlieb 2, D. van der Heijde 3, O. FitzGerald 4, A. Johnsen 5, M. Müts 6, S. Banerjee 7, D. Gladman 8, J. Swedish Medical Center and University of Washington, Seattle; 2New York Medical College, Valhalla, United States; 3Leiden University Medical Center, Leiden, Netherlands; 4St Vincent’s University Hospital and University College Dublin, Dublin, Ireland; 5Bristol-Myers Squibb, Princeton, United States; 6Bristol-Myers Squibb, Braine-l’Alleud, Belgium; 7University of Toronto and Toronto Western Hospital, Toronto, Canada

Background: In the Phase III ASTRAEA trial (NCT01860976), abatacept (ABA), a selective T-cell co-stimulation modulator, significantly increased ACR20 response (primary endpoint; PE) and had an overall beneficial effect vs placebo (PBO) on musculoskeletal symptoms in patients (pts) with active psoriatic arthritis (PsA) at 24 weeks (Wk1). Objectives: To analyse 1-year results from ASTRAEA. Methods: Pts with active disease (≥3 swollen and ≥3 tender joints), ≥2 cm target lesion of plaque psoriasis and inadequate response/intolerance to ≥1 DMARD, included ABA pts (n=211) and PBO pts (n=210). Pts switched to OL ABA (early escape; EE) for 28W, followed by open-label (OL) SC ABA up to 52W. Randomization was stratified by MTX use, prior TNF inhibitor (TNFα) use and skin involvement ≥3% of body surface area. Pts without ≥20% improvement in joint counts at W16 were switched to OL ABA (early escape; EE) for 28W (total study time: 44W). Pre-specified exploratory endpoints included: ACR20/50/70 responses at W44; adjusted mean changes from baseline (BL) in DAS28-CRP (post hoc analysis) and HAQ-DI at W44 and PsA-modified total Sharp/van der Heijde score (SHS) at W44 (EE pts)/W52 (non-EE pts); complete resolution of BL enthesitis and dactylitis at DMARD (EE pts) vs Psoriasis Area and Severity Index (PAI) 50/75 responses at W44. Analyses used the ITT population with non-responder imputation for missing values and actual data at each time point for all pts (denominator at each time point equal to number of pts in ITT population). All missing responses were imputed as non-responders, except if the missing value was between 2 visits for which the pt was a responder. In that case the missing value was imputed as a responder.

Results: Of 424 pts enrolled, 213 received ABA and 211 PBO. Most (>60%) pts had received prior TNFs. Of pts in the ABA and PBO groups, 76 (36%) and 89 (42%) were EE, 12 (6%) and 24 (11%) discontinued by PE of W24;
Results: Patients who started on MTX monotherapy had lower baseline disease activity and fewer were erosive and autoantibody positive; other baseline characteristics were comparable between medication groups. The number of patients on combination therapy with bDMARDs was too small to perform analyses (26 visits in 11 patients). For patients starting on MTX monotherapy, 62% remained bDMARD naive, or MTX+glucocorticoids, the PS-adjusted effects of MTX-dose (high vs low) on DAS, DAS28 and HAQ were small and not clinically meaningful. The adjusted main associations between MTX-dose and outcomes were often in opposite direction and/or much larger than the PS adjusted associations, suggesting that confounding by indication plays a role and that (at least some) correction was achieved by adjusting for the PS (table 1).

Conclusions: In a daily practice derived database in DMARD-naïve early RA patients, we found no early clinical benefit of high over low initial MTX dosages, neither for MTX monotherapy nor for combination therapy with MTX and csDMARDs or glucocorticoids. This seems to contradict a general trend over time to start higher MTX-doses.

OP0225 THE EFFECT OF A LOW VERSUS HIGH FIRST PRESCRIBED DOSE OF METHOTREXATE ON EUULAR RESPONSE AT SIX MONTHS USING DATA FROM THE RAMS STUDY

R. Davies, M. Lunt, A. Barton, K.L. Hyrich, S.M.M. Verstappen on behalf of RAMS co-investigators, Division of Musculoskeletal & Dermatological Sciences, Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom

Background: Methotrexate (MTX) is one of the most commonly used drugs for the treatment of rheumatoid arthritis (RA). Recommendations by an international panel stated that oral MTX should be started at 10–15mg/week, with escalation of 5mg/week every 4–6 weeks up to 20–30mg/week. In the UK, RA drug choices in terms of the starting dose prescribed for MTX, likely because of a lack of published evidence on the importance of MTX dose on its efficacy and safety.

Objectives: To compare 6 month response to MTX in RA patients starting 7.5mg/week versus those starting a 15mg/week.

Methods: Patients were recruited to the national, UK, multi-centre (n=35) longitudinal observational Rheumatoid Arthritis Medication Study (RAMS), including patients starting MTX for the first time with complete DAS28 at baseline and six months were included in this analysis. Patients were categorized into EUULAR non-responders, moderate responders or good responders. Patients were categorised into those starting a low dose of MTX (<7.5mg/week) (LM-group) or a high dose of MTX (≥ 7.5mg/week) (HM-group).

Table 1

| Age, years | 58 (47–69) | 61 (51–69) | 0.13 |
| Gender, % female | 70 | 60 | 0.03 |

SUSTAINED EFFECTIVENESS OF METHOTREXATE WITH STEP-DOWN GLUCOCORTICOID REMISSION INDUCTION (COBRA SLIM) FOR EARLY RHEUMATOID ARTHRITIS IN A TREAT-TO- TARGET SETTING: 2-YEAR RESULTS OF THE CARERA TRIAL

V. Stouten 1, J. Joly 2, D. De Cock 1, S. Pazmino 3, K. Van der Elst 1,2,3, R. Westhovens 1,2,3, P. Verschueren 1,2,3 on behalf of CareRA study group. 1Skeletal Biology and Engineering Research Center, KU Leuven Department of Public Health and Primary Care, Leuven, Belgium; 2Rheumatology, University Hospitals Leuven; 3Skeletal Biology and Engineering Research Center, KU Leuven Department of Public Health and Primary Care, Leuven, Belgium

Background: The CareRA trial showed that remission induction with MTX and a moderate-dose of Glucocorticoids (GIC) (COBRA Slim) in a treat-to-target setting is effective and safe in early Rheumatoid Arthritis (eRA) patients. This strategy showed equally high remission rates at 52 weeks (W), a favourable safety profile compared to DMARD combinations and GC and very few patients had to start biologicals.

Objectives: To compare the outcome of different intensive combination treatment strategies in high-risk patients of the CareRA trial at W104, focussing on persistent disease control.

Methods: CareRA is a two-year prospective investigator-initiated pragmatic multicentre RCT; csDMARD naïve eRA patients were stratified into a high- or low-risk group based on classical prognostic markers (presence of erosions, RF, anti-CCP and DAS28-CRP). High-risk patients (n=289) were randomized to low-risk group compared to DMARD combinations and GC and very few patients had to start biologicals.

Results: 810 patients were included in this study: 171/810 (21%) starting low dose MTX and 639/810 (79%) starting high dose MTX. Patients in the HM-group had significantly lower physician and patient VAS scores and less functional disability compared to those in the LM-group (table). These patients were also less likely to be prescribed concomitant (nbDMARDs) (17% vs. 10%). DAS28 showed at 6 months a significantly lower value for patients in the HM-group (RRR: 2.65 (95% CI 1.37, 5.14)).

Conclusions: Patients with RA starting MTX on a higher dose have increased odds of having a good EULAR response compared to non-response at 6 months.

EFFECT OF BASELINE SERUM CRP LEVELS ON CLINICAL EFFICACY IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH FILGOTINIB: POST-HOC ANALYSIS FROM TWO PHASE 2B STUDIES

R. Westhovens1, A. Kavanaugh3, C. Jamoul5, C. Tasset5, P. Harrison3, A. Van der Aa3, 1Rheumatology, KU Leuven, University Hospitals, Leuven, Belgium; 2University of California, LA Jolla, United States; 3Galapagos NV, Mechelen, Belgium.

Background: Filgotinib (GLPG0634, GS-6034) is an oral, selective JAK1 inhibitor that has shown a favorable safety and efficacy profile both as add-on to methotrexate (MTX) and as monotherapy in two 24-week placebo-controlled phase 2B studies in active rheumatoid arthritis (RA) patients with inadequate response to MTX (MTX-IR)1,2.

Objectives: To assess effect of baseline serum CRP levels on clinical efficacy in MTX-IR RA patients treated with filgotinib.

Methods: Patients were randomized in a double blind manner to placebo (PBO) or one of 3 daily doses of filgotinib (50mg, 100mg or 200mg) for 24 weeks. In the DARWIN 1 study, filgotinib on the background of MTX was evaluated as once (QD) or twice daily treatment. In the DARWIN 2 study once-daily filgotinib was assessed as monotherapy. The inclusion criterion for CRP was amended during the studies and decreased over time from 13.5 mg/L to 6.3 mg/L. This post hoc analysis included patients treated with the selected Phase 3 filgotinib doses, 100mg and 200mg QD, and PBO. Efficacy outcomes were analyzed by baseline CRP level (low: ≤9 mg/L and high: >9 mg/L, with 9mg/L as ULN).

Results: Baseline disease activity was high, with mean DAS28(CRP) scores of 5.6 and 5.7 in the low CRP subgroups for DARWIN 1 and DARWIN 2, respectively, and 6.3 in the high CRP subgroups for both studies. Mean CRP levels at baseline were elevated (16.3 - 35.3 mg/L). In both low and high CRP subgroups, patients on filgotinib 100mg or 200mg QD for 12 weeks showed efficacy over PBO, as measured by change from baseline in DAS28(CRP), CDAI and HAQ-DI, and ACR20 (Table 1). Despite slight numerical differences, baseline CRP level had no consistent effect on filgotinib efficacy, neither for endpoints including CRP (DAS28(CRP) or ACR20) nor for endpoints not including CRP (CDAI).

Table 1. Change from baseline in key efficacy parameters at Week 12 by CRP subgroup (mean (SE)).

<table>

</tbody>
</table>

Conclusions: Post hoc analysis of two Phase 2B studies in MTX-IR RA patients suggests that filgotinib treatment once daily at 100mg and 200mg both on the background of MTX and as monotherapy is consistently associated with improved clinical outcomes compared to placebo, regardless of baseline CRP levels.

THE EFFECTIVENESS OF ZOSTER VACCINE IN RA PATIENTS SUBSEQUENTLY TREATED WITH TOFACITINIB

K.L. Winthrop1, A. Wouters2, E.H. Choy3, C. Nduaka4, P. Biswas2, L. Wang5, J. Hodge2, I. Lazaricu6, K. Soma5, C.F. Mojlik2, W.F.C. Rigby1, 1Oregon Health and Science University, Portland, OR; 2Pfizer Inc, New York, NY, United States; 3CREATE Center, Division of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom; 4Pfizer Inc, Collegeville, PA; 5Pfizer Inc, Groton, CT, United States; 6Quintiles, Saint-Laurent, QC, Canada; 7Giesel School of Medicine at Dartmouth, Lebanon, NH, United States.

Background: Rheumatoid arthritis (RA) patients (pts) are at increased risk of herpes zoster (HZ). The most recent ACR guidelines of 2015 recommend vaccination in pts aged ≥50 years prior to starting biologic DMARDs or tocilizumab,1

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.3892

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5428

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.3892
an oral Janus kinase inhibitor for the treatment of RA. Live zoster vaccine (LZV) has shown 70% efficacy in immunocompetent adults aged 50–59 years and 51% efficacy in those aged >60 years. We previously reported that pts with RA on background methotrexate who started 3 months of treatment with tofacitinib after LZV had similar varicella zoster virus (VZV)-specific immunity to placebo (PBO) pts after their VZV immunity at Week 6 post-vaccination was comparable with healthy individuals aged >50 years.

Objectives: To evaluate the long-term effectiveness of LZV in pts with RA via the incidence of HZ after treatment with tofacitinib for up to 27 months.

Methods: Data were analysed from a prior cohort of pts (n=100) given LZV and then randomized 2–3 weeks later to tofacitinib 5 mg twice daily (BID) or PBO for 12 weeks (A3991237; NCT02147587). At 14 weeks post-vaccination pts joining the long-term extension (LTE) study ORAL SequeL (NCT04013699; study ongoing; database not locked) initiated open-label treatment with tofacitinib 5 or 10 mg BID. The incidence of HZ post-vaccination after tofacitinib exposure up to 27 months (based on an extended follow-up beyond January 2016 data snapshot) was evaluated. Among HZ cases, we analysed measures of VZV-specific immunity with average immunity after LZV.

Results: 112 pts were randomized to PBO (n=57) or tofacitinib 5 mg BID (n=55). 100 pts continued to receive tofacitinib in ORAL SequeL. Five cases (not adjudicated) of HZ occurred (#1: 202 days [219 days post-LZV]; #2: 267 days [281 days post-LZV]; #3: 702 days [748 days post-LZV]; #4: 699 days [741 days post-LZV]; #5: 446 days [544 days post-LZV] after initiation of tofacitinib. Cases #1, #2, #3 and #4 were monodermatomal; #5 involved 5 dermatomes. All cases resolved within treatment. Cases #1, #4 and #5 had undetectable ELISPOT measures at baseline and Week 6 post-vaccination, indicating a lack of VZV-specific immunity. Cases #2 and #3 responded adequately to vaccination by both immunoglobulin G (IgG) and ELISPOT measures, but had lower than average VZV IgG levels, both at baseline and at Week 6. (Table).

Conclusions: LZV prior to treatment with tofacitinib is effective at boosting IgG levels and cell-mediated immunity towards VZV. No pts who developed both HZ and VZV prior to treatment with tofacitinib is effective at boosting IgG levels and cell-mediated immunity towards VZV.

Tofacitinib With and Without Methotrexate Versus Adalimumab With Methotrexate for the Treatment of Rheumatoid Arthritis: Results from Oral Strategy, a Phase 3B/4 Randomised Trial

R. Fleischmann 1, E. Mysler 2, S. Hall 3, A. Kivitz 4, R. Moots 5, Z. Luo 6, S. Tatulych 7, R. DeMasi 8, K. Soma 7, R. Zhang 9, L. Takaya 8, C. Mojcik 9, S. Krishnaswami 1, S. Menon 10, J. Smolen 11, Metropolis Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, United States; 2Organization Médica de Investigación, Buenos Aires, Argentina; 3Department of Medicine, Monash University, Cabrini Health, Melbourne, Australia; 4Altoona Center for Clinical Research, Duncansville, PA, United States; 5Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, United Kingdom; 6Pfizer Inc, Shanghai, China; 7Pfizer Inc, Groton, CT, 8Pfizer Inc, Collegeville, PA; 9Pfizer Inc, New York, NY, United States; 10Medical University of Vienna, Vienna, Austria

Background: Tofacitinib is an oral JAK inhibitor for the treatment of RA. There is no direct comparison of tofacitinib monotherapy versus tofacitinib + MTX in MTX inadequate responders (IR) and limited data comparing tofacitinib (±MTX) vs adalimumab (ADA) + MTX in patients (pts) with RA.

Objectives: To compare efficacy and safety of tofacitinib monotherapy, tofacitinib+MTX, and ADA+MTX in a head-to-head, non-inferiority trial in MTX-IR pts.

Methods: In this randomised, triple-dummy, active-controlled, 1-year, Phase 3B/4 trial (ORAL Strategy; NCT02187055), pts had active RA (<4 tender/swollen joint counts and ≤4 swollen joints at joint count) and were taking ≤12.5 mg/day MTX for ≥281 days post-LZV, #3: 702 days [748 days post-LZV], #4: 699 days [741 days post-LZV], #5: 446 days [544 days post-LZV] after initiation of tofacitinib. Cases #1, #2, #3 and #4 were monodermatomal; #5 involved 5 dermatomes. All cases resolved within treatment. Cases #1, #4 and #5 had undetectable ELISPOT measures at baseline and Week 6 post-vaccination, indicating a lack of VZV-specific immunity. Cases #2 and #3 responded adequately to vaccination by both immunoglobulin G (IgG) and ELISPOT measures, but had lower than average VZV IgG levels, both at baseline and at Week 6. (Table).

Conclusions: Tofacitinib 5 mg BID+MTX was as effective as ADA+MTX in
MTX-IR pts with RA. However, clinical outcomes of all 3 regimens, including tofacitinib 5 mg BID monotherapy, were comparable. There were no new or unexpected safety issues.

New treatments in SLE, Sjögren’s and APS —

OP0231

THE EFFECT OF “TRIPLE THERAPY” WITH ANTICOAGULATION PLUS CORTICOSTEROIDS PLUS PLASMA EXCHANGE AND/OR INTRAVENOUS IMMUNOGLOBULIN ON THE MORTALITY OF CATASTROPHIC ANTIPHOSPHOLIPID SYNDROME (CAPS) PATIENTS

J. Rodriguez-Pinto1, G. Espinosa1, D. Erkan2, Y. Shoentfeld3, R. Cervera4 on behalf of CAPS Registry Project Group (European Forum on Antiphospholipid Antibodies).

Background: In a cohort of 525 episodes of CAPS (CAPS Registry), we evaluated the relationship between triple therapy and mortality. Patients were grouped in three based on their treatments: a) triple therapy (anticoagulation plus corticosteroids plus plasma exchange and/or intravenous immunoglobulins); b) drugs included in the triple therapy but in different combinations; c) none of the treatments included in the triple therapy. The primary endpoint was all-cause mortality. Multivariate logistic regression models were used to compare mortality risk between groups taking into account a set of possible confounding variables.

Results: The “CAPS registry” cohort included 525 episodes of CAPS accounting for 502 patients. After excluding 38 episodes (7.2%), a total of 487 episodes of CAPS accounting for 471 patients (mean age 38 years; 67.9% female; primary APS patients 68.8%) were analyzed. Overall, 177 (36.3%) patients died. Triple therapy was prescribed in 197 episodes (40.5%), other combinations in 278 (57.1%), and none of those treatments in 12 episodes (2.5%). According to these three groups, mortality rate increased up to 27.9%, 40.6%, and 75%, respectively. Triple therapy was positively associated with a higher chance of survival when compared to non-treatment (adjusted odds ratio [OR]: 7.7; 95% confidence interval [95%CI] 2.0–29.7) or to treatment with other combinations of drugs included in the triple therapy (adjusted OR 6.8; 95%CI 1.7–29.6). Triple therapy accounted for a 50% decrease of the risk of death in patients with CAPS that received this combination of drugs.

Conclusions: Triple therapy is independently associated to a higher survival rate among CAPS.

OP0232

SUSTAINED SAFETY AND EFFICACY OVER 10 YEARS WITH BELIMUMAB (BEL) PLUS STANDARD SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) THERAPY (SOC) IN PATIENTS WITH SLE

Background: Preliminary safety and efficacy data from the Phase II BEL open-label extension study (LBSL02; NCT00171487) have been reported. Objectives: Here we present the final 10-year data.

Methods: This was a multicentre, open-label, continuation trial (BEL112626; NCT00583342) of BEL + SoC in patients with a satisfactory response in the parent trial. Patients received intravenous BEL 10 mg/kg every 4 weeks. Baseline was prior to the first ever dose of BEL.

Results: Of 298 patients in the continuation trial, 131 (44%) remained at Year 10. Total BEL exposure was 2154 patient-years. Adverse events (AEs) remained stable or decreased (Table). Two deaths (pseudonodular lung infection; cytomegaloviral pneumonia) were possibly related to BEL. SLE Responder Index (SRI) response increased (Figure), A British Isles Lupus Assessment Group (BILAG) flare (1 new A2 new B scores) occurred in 72.6% of patients and 41.9% had a severe flare (SLE flare Index). Prednisone dose decreased from baseline to Year 10 (Table). Of patients receiving >7.5 mg/day baseline prednisone, 32.6%...
(14/43) decreased their dose to < 7.5 mg/day by Year 10; 95% (9/15) of patients receiving baseline prednisone < 7.5 mg/day had a dose increase to > 7.5 mg/day.

**Conclusions:** Over 10 years BEL + SoC was well tolerated and the rates and nature of AEs were consistent with the known profile of BEL. Efficacy was maintained and prednisone use decreased in those receiving > 7.5 mg/day at baseline.

**OP0233 PRIMARY PROPHYLAXIS OF CARDIOVASCULAR EVENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE ANALYSIS OF 291 PATIENTS FROM TWO ITALIAN CENTERS**

S. Fasano1, D. Margiotta2, L. Navarini2, L. Pierio1, A. Riccardi3, I. Pantano3, R. Alfetta2, G. Valentini1.

**Rheumatology Unit, University of Campania ‘Luigi Vanvitelli’, Naples; 2Unit of Allergology, Immunology, Rheumatology, Campus Bio-Medico University, Rome, Italy**

**Background:** Systemic lupus erythematosus (SLE) is associated with an increased cardiovascular (CV) risk (1). By retrospectively investigating a one centre cohort, we have recently reported that low-dose aspirin (ASA) use is associated with a reduced CV risk in SLE (2) and long-term hydroxychloroquine (HCQ) exposure may have an additive effect (3).

**Objectives:** This study was conducted on 2 Italian SLE cohorts to confirm these results and assess the role, if any, of statins.

**Methods:** Clinical charts of SLE patients consecutively admitted to 2 University Rheumatology Units from November 2000 to December 2014 who, at admission, had not experienced any CV event, were investigated. ASA, HCQ and statins use and the occurrence of any CV event, were recorded at each visit. Kaplan-Meier analysis was performed to determine the HCQ exposure status associated with a higher CV-free survival. Cox regression analysis was carried out to identify factors independently associated with a first CV event.

**Results:** A total of 291 SLE patients were included in the study and followed for a median of 8 years. During follow-up, 16 CV events occurred. Kaplan-Meier analysis revealed a greater CV event-free rate in the 120 ASA-treated patients taking HCQ at standard dose for more than 5 years than in the 98 patients not treated with ASA or with HCQ for less than 5 years (Figure 1). At univariate analysis, patients with a first CV event compared with those without any thrombotic events were antiphospholipid antibody (aPL) positive (P=0.017 HR 2.91) and had significantly higher blood pressure (P=0.017 HR 3.58), hypercholesterolemia (P=0.015 HR 3.40) and higher disease damage at last visit (P=0.032 HR 1.56). Moreover, ASA treatment (P=0.012 HR 0.27) and HCQ use (P=0.012 HR 0.26) for more than 5 years were negative predictors, while statins use did not show any association (P=0.619). All other variables examined, including smoking, obesity, hypertiglycericidemia, diabetes mellitus, disease activity, severe SLE, other medications (immunosuppressive agents, steroids) were not associated, either positively or negatively, with the occurrence of CV events. At multivariate analysis, taking ASA and HCQ for more than 5 years were protective against thrombosis (HR 0.24 and HR 0.27, respectively), while aPL positivity (HR 4.32) increased the risk of a first CV event.

**Conclusions:** Use of antithrombotics for more than 5 years is associated with a reduced risk of a first thrombosis in SLE patients and the HCA-ASA combination seems to synergistically reduce further the CV risk. Larger, prospective studies are needed to provide a better definition of the role of these drugs in CV primary prevention in SLE.

**OP0234 CLINICAL AND BIOLOGIC EFFECTS OF ICOSSL BLOCKADE BY AMG 557 IN SUBJECTS WITH LUPUS ARTHRITIS**

**1Rheumatology Unit, University of Cambridge; 2University of Copenhagen; 3Geriatric Medicine, Oporto Hospital, Portugal; 4Charité Universitätsmedizin Berlin, Germany; 5Oklahoma Medical Research Foundation, Oklahoma City, United States**

**Background:** Blockade of inducible costimulatory ligand (ICOSL) might be a promising approach for autoimmune diseases such as systemic lupus erythe-matosus (SLE). We evaluated AMG 557, an anti-ICOSL monoclonal antibody, in an exploratory phase 1b study of SLE subjects with inflammatory arthritis, by withdrawing background therapies to improve interpretability of a small study.

**Objectives:** To investigate potential efficacy, safety, and tolerability of AMG 557 in subjects with lupus arthritis.

**Methods:** This double-blind, randomized, placebo-controlled trial enrolled subjects with SLE and active lupus arthritis (>4 tender and 4 swollen joints) and Systemic Lupus Erythematosus Disease Activity Index [SLEDAI] score ≥6 despite stable background immunosuppressants. Upon enrollment, investigators were permitted to use up to 20 mg/day of prednisone, which was tapered by day 85 to 7.5 mg/day or 50% of baseline, whichever was lower. Subjects received AMG 557 210 mg or placebo once weekly for 3 weeks followed by 10 additional doses every other week until day 155. At day 29, background immunosuppressants were withdrawn. The primary clinical endpoint was a composite Lupus Arthritis Responder Index at day 169; response was defined as achieving: (1) 50% decrease in combined tender and swollen joint counts, (2) ≥1 joint improvement in the musculoskeletal subsystem of the British Isles Lupus Assessment Group (BILAG) index and (3) prespecified immunosuppressant medication withdrawal and/or prednisone taper. Safety was a co-primary endpoint. Exploratory endpoints included safety, 4-point reduction of SLEDAI, clinical indices (SLEDAI, BILAG), complement components, autoantibodies, and lymphocyte populations.

**Results:** Twenty subjects (19 females) were randomized (10 AMG 557, 10 placebo) at 8 sites in North America, Asia, and Europe. The primary placebo-controlled trial in lupus arthritis suggest potential clinical benefit of ICOSL blockade by AMG 557. These data support further clinical trials intervening in this costimulatory pathway in SLE and other autoimmune diseases.

A NOVEL B CELL SPECIFIC IFN-I BIOMARKER IS ASSOCIATED WITH PLASMABLAST NUMBERS FOLLOWING B CELL DEPLETION TREATMENT IN SLE

Y.M. El-Sherbiny, M.Y. Md Yusof, E. Hensor, A. Rawstron, M. Wittmann, P. Emery, E.M. Vital, L. University of Lille, EA 2694, University Hospital Center of Lille, Lille; 3Internal Medicine Department, Research Labs Musculoskeletal Biomedical Research Unit; 4Haematological Malignancy Diagnostic Service, Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: SLE is a Type I interferon (IFN-I) mediated disease with autoreactive B cells. Plasmablasts, the immediate progeny of B cells, are expanded in SLE and correlate with disease activity. We showed that their rate of regeneration after therapeutic B cell depletion with rituximab is variable and predicts relapse[1]. IFN-I has been shown in vitro to induce the differentiation of B cells into plasmablasts. We previously showed that therapeutic B cell depletion with anti-CD20 mAb leads to a transient reduction in CD20-negative plasmablasts, following which plasmablasts repopulate and their numbers predict clinical relapse. We developed tetherin as a flow cytometric, cell-specific marker for IFN-I response. Objectives: To test the hypothesis that memory B cell tetherin determines the rate of plasmablast repopulation after rituximab.

Methods: 117 rituximab-treated SLE patients were studied prospectively using BILAG-2004 and flow cytometry. In 97 responders we tested plasmablasts at 6 months as a predictor of clinical relapse before 12 months to validate our previous finding. In 50 patients pre-rituximab and 28 patients post-rituximab we performed additional flow cytometry to measure tetherin on each cell subset. Expression of 18 ISGs was measured using Taqman on PBMCs and an ISG score calculated.

Results: We divided clinical responders to rituximab into earlier relapse (12 months) or later relapse (>12 months). As in our published discovery cohort, plasmablasts were strongly predictive of clinical relapse. ROC analysis indicated that a plasmablast count of >0.0008 x 10^11/L at 6 months yielded 73% (95% CI 45–92%) sensitivity and 90% (95% CI 56–99%) specificity in predicting early relapse; area under the curve of 0.86.

Plasmablast numbers after rituximab were associated with Memory B cell tetherin (R=-0.38, p=0.047) but not ISG score (R=0.24, p=0.219) (Table 1).

In pre-rituximab there was no relationship between any IFN assay and plasmablast count. After rituximab treatment there was no correlation between plasmablast count and ISG expression, nor with monocyte or NK cell surface tetherin. However, memory B cell tetherin MFI was positively correlated with plasmablast count (Table 1).

Conclusions: Although interferon stimulated gene expression is commonly used to measure IFN-I activity, tetherin provides a cell-specific assay. We demonstrate that by measuring IFN-I response in B cells specifically, we could explain plasmablast differentiation, and thereby clinical outcome. Memory B cell tetherin is valuable to immunophetype SLE.

BENEFIT AND SAFETY OF ANTIITHROMBOTIC TREATMENT IN 264 PREGNANCIES IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

Background: The management of pregnancy in patients with antiphospholipid syndrome (APS) with aspirin and heparin is based on empiric recommendations. Objectives: Our study aimed to evaluate the outcomes of treated patients with thrombotic and obstetric APS and the safety of antithrombotic treatments prescribed during pregnancy.

Methods: Inclusion criteria were (1) APS (Sydney criteria), (2) live pregnancy at 12 weeks of gestation (WG) with (3) follow up data until 6 weeks post-partum. Data were collected prospectively (PROMISSE study) and retrospectively (four French centers). Adverse pregnancy outcomes (APOs) were defined by fetal death or neonatal death of 8th; pre-term delivery before 36 WG due to pre-eclampsia or placental insufficiency; or small for gestational-age (SGA; ~5th percentile). Major bleeding was defined as blood loss greater than 500ml and/or requiring surgery or transfusion.

In 152 pregnancies (87 collected prospectively) in 204 patients were included (46% with a history of thrombosis, and 23% with associated systemic lupus erythematosus). During pregnancy, treatment included heparin (n=253; 96%) and low-dose aspirin (n=223; 84%). The live birth rate was 86%. APOs occurred in 32%, mostly during the 2nd trimester: fetal deaths 11%, SGA 11%, pre-term delivery before 36 WG due to pre-eclampsia or placental insufficiency 17%. Thirteen maternal thrombotic events occurred in 12 (4.5%) pregnancies. Forty-six maternal hemorrhagic events occurred in 40 (15%) pregnancies (30 events in the post-partum period). Major bleeding was reported in only 6 pregnancies (2.3%) and occurred only after delivery. Except for two events, post-partum hemorrhage occurred in the early post-partum before hospital discharge. No maternal death was observed.

Aspirin therapy during pregnancy was the only independent factor associated with a lower risk of APOs (odds ratio: 0.34; 95% CI: 0.15–0.78; p<0.01) in multivariate analysis. Neither heparin or aspirin alone, nor combined therapy increased the risk of hemorrhage. In the retrospective cohort, emergency caesarian section was the only factor associated with hemorrhagic events during the study period (53% hemorrhages in patients who underwent emergency caesarian compared to 18% p=0.005). Independent risk factors for APOs were elevated body mass index and the presence of lupus anticoagulant.

Conclusions: We report a high level of obstetrical complications in conventionally-treated APS pregnancies, and a beneficial effect of addition of aspirin to prevent obstetric morbidity. Moreover, heparin and aspirin were well tolerated and did not increase risk of hemorrhage.

LIFITTEGRASE OPTHALMIC SOLUTION 5.0% FOR TREATMENT OF DRY EYE DISEASE: COMBINED EVIDENCE FROM 5 RANDOMIZED CONTROLLED TRIALS

C. Baudouin1, M. Darwish-Zargar2, E. J. Holland, C. C. Chan3, S.K. Nichols4, J. Tauber5, A. Raychaudhuri6, M. Ray7, A. Shoshaie8, J. Centre for Diabetic Retinopathy and Ophthalmology, University of Malta, Malta; 2Cincinnati Eye Institute, Edgewood, United States; 3University of Toronto, Toronto, Canada; 4University of Alabama School of Optometry, Birmingham; 5Tauber Eye Center, Kansas City; 6Shire, Lexington, United States

Background: Dry eye disease (DED) is a multifactorial disease of the tear film and ocular surface, characterized by ocular discomfort and visual disturbance.1 DED is associated with a number of systemic autoimmune diseases, particularly rheumatoid arthritis and Sjögren’s syndrome.2,3 Lifitigrase is a lymphocyte function-associated antigen-1 (LFA-1) antagonist that inhibits T-cell-mediated inflammation (an underlying factor in DED) and is approved in the US for the treatment of signs and symptoms of DED (lifitigrast ophthalmic solution 5.0%, Xiidra®).

Objectives: To evaluate the combined evidence from 5 clinical trials of lifitigrast ophthalmic solution 5.0% (LIF) in subjects with dry eye disease (DED).

Methods: Adults with DED were randomized to LIF or placebo (PBO) in 5 randomized, double-masked, placebo-controlled trials: 4 12-week efficacy/safety phase 2 (LIF n=58, PBO n=58; phase 3 trials: OPUS-1, LIF n=293, PBO n=295; OPUS-2, LIF n=358, PBO n=360; OPUS-3, LIF n=355, PBO n=356) and a 1-year safety study (SONATA, LIF n=220, PBO n=111). Individuals with Sjögren’s or Sjögren’s-like disease associated with autoimmune disease (rheumatoid arthritis, systemic lupus erythematosus) were eligible to participate if they were not immunodeficient/immunosuppressed, not taking steroids, and met all other inclusion and exclusion criteria. Change from baseline to day 84 in DED signs and symptoms was evaluated across the 12-week studies. Key measures were inferno corneal staining score (ICSS; 0–4 scale), eye dryness score (EDS; visual analogue scale [VAS], 0–100 scale), and visual-related function subscale of a symptom scale (0–4 scale).

Results: LIF improved ICSS versus PBO in the phase 2 study (secondary endpoint; treatment effect 0.35, nominal P=0.0209), OPUS-1 (co-primary; 0.24,
48 WEEK COMPLETE REMISSION OF ACTIVE LUPUS NEPHRITIS WITH VOCLOSPORIN

Perez-Guijo1, F. Pouplard1, R. Puig1, D. Roca 1, P. Sanchis 1, E. Saussele 1, S. Sessa 2, C. Solana 1, J. Subirana 1, A. Vazquez 1, J. Van de Wiele 1, I. Vandenbroucke-Jagtenberg 1, D. Vaquerizo 1, J. Vazquez 1, C. González-Navas1, P. Font-Ugalde1, E. Collantes-Estevez1, I. Vandenbroucke-Jagtenberg 1, D. Vaquerizo 1, J. Vazquez 1, C. González-Navas1, P. Font-Ugalde1, E. Collantes-Estevez1, I. Vandenbroucke-Jagtenberg 1, D. Vaquerizo 1, J. Vazquez 1, C. González-Navas1, P. Font-Ugalde1, E. Collantes-Estevez1, I. Vandenbroucke-Jagtenberg 1, D. Vaquerizo 1, J. Vazquez 1

Objectives:
Achievement of complete remission (CR) as assessed at week 24 (primary objective) and assessment of the efficacy over 48 weeks (secondary objective), with 2 doses of VCS (low dose VCS: 23.7mg BID and high dose VCS: 39.5mg BID) vs. placebo in subjects with active LN.

Methods:
The double blind placebo controlled AURA study enrolled 265 subjects with active LN in 20 countries. Patients were randomized into 3 arms (placebo, low dose VCS or high dose VCS) in addition to MMF 2g/day and steroids (with rapid tapering). CR was defined as a confirmed urine protein/creatinine ratio (UPCR) of <0.3 mg/mg using first morning void and confirmed estimated glomerular filtration rate (eGFR, CKD-EPI equation) >80 mL/min/1.73 m² or no change from baseline in eGFR of ≥20% in the presence of low dose steroids. Partial remission (PR) was defined as a 50% reduction in UPCR. UPCR assessments were made at each visit, together with biomarker data at regular intervals.

Results:
We now present the 48 week data showing improved CR rates over the 24 week data. The rate of CR was significantly higher in the low dose VCS compared to the control group (32.6% vs. 19.3%; OR: 2.03, p=0.045) at 24 weeks. It was 27.3% in the high dose VCS group (p=NS). Both doses of voclosporin demonstrated superiority to control using time to CR, PR (50% reduction in proteinuria) and time to PR. At 48 weeks, 23.9% of patients on the control arm achieved CR compared to 49.4% low dose (OR: 3.21, p<0.001) and 39.8% high dose (OR: 2.10, p=0.026). Over 92% of subjects experienced at least one adverse event (AE) with the most common two being infections (56% low, 66% high and 55% placebo) and GI disorders (43% low, 52% high and 38% placebo). The overall rate of serious adverse events (SAEs) was numerically higher in both voclosporin groups (28% low, 25% high, 19% placebo) with the nature of SAEs consistent with those observed in patients with highly active LN. Most deaths occurred in the first 2 months and were: low dose (infection3, ARDS2, thrombotic2, cardiac tamponade, pulmonary hemorrhage), high dose (infection, PE) and control (CVA). All were considered unrelated to drug exposure by the investigators. 3 additional deaths occurred in placebo patients after the conclusion of the 48 weeks of treatment.

Conclusions:
The AURA-LV study is the first global study demonstrating the beneficial effect of VCS, in combination with MMF and steroids, in the treatment of LN. Remission rate was rapid. VCS treatment resulted in increasing CR and PR seen by week 6 despite rigorous steroid taper (mean steroid dose 4 mg at week 16). Adverse events were higher in the treated group patient with the nature in keeping with immunosuppression. These promising data will be used to plan subsequent studies of voclosporin in LN.

Acknowledgements:
This data was submitted on behalf of the AURA-LV study investigators.

Axial spondyloarthritis from risk factor to clinical outcomes

F.J. Mata-Perdigon 1, I.R. Martinez Sanchez 2, J.L. Garrido-Castro 3, C. Gonzalez-Nava 1, L.M. Fernandez-Ahumada 4, D.A. Gomez 4, V.C. Perez-Guillou 5, P. Font-Ugalde 1, E. Collantes-Estevez 1, I. Maimonides Institute for Biomedical Research of Cordoba 1, University of Cordoba, Cordoba, Spain

Background:
Axial spondyloarthropathy (axSpA) is a chronic rheumatic disease that results from a reduction of mobility in the patients’ spine. There are several indices to analyze this mobility: BASMI, which lacks precision and sensitivity to change according to different authors, and UCOASMI (1) based on motion capture, which needs extensive resources that limit its practical applicability. Inertial measurement unit sensors (IMU) give, in real time, the 3D orientation of any anatomical place
of the joint. It could be a sensitive, flexible and cheap technology, useful for assessing mobility in AxSpa, but validation studies are needed.

**Objectives:** To assess reliability and validity of inertial sensors for measuring spinal mobility in patients with axSpA.

**Methods:** 14 subjects: 7 patients with axSpA (5 male and 2 female, age 51.4±6.7 years, evolution time 25.4±11.3 years, 85.7% B27 positive) and a control group of 7 healthy individuals matched in gender and age were recruited. Cervical and lumbar movements were evaluated using 3 IMU sensors (located at forehead, D3 and L4) and a 3D motion capture system synchronously. A test/retest was performed at 5 minutes in the same day with the IMUs and in two days with both systems. Measurements of metrology, BASMI and UCOASMI indices were obtained. An index, iUCOASMI, was calculated using the same measurements used for UCOASMI, but obtained by inertial sensors.

**Results:** Table shows mean values (SD) for each range of movement expressed in degrees. BASMI, UCOASMI and iUCOASMI indexes are also included. Intraclass correlation coefficient (ICC) is indicated as: α: 0.98–Excellent; β: 0.95–0.98 – Very good; γ: 0.70–0.95 – Good; δ: <0.7 – Bad. RMSE error was less than 1° for all measures. There was good correlation (r<0.01) between iUCOASMI with BASFI, BASG, UCOASMI and BASMI. Graph shows results of linear regression between measures obtained with both system (for example: cervical frontal flexion obtained by motion capture and IMUs have a R² of 0.97) and between iUCOASMI with UCOASMI and BASMI.

**Conclusions:** The IMU system measured range of movement, showing good ICC both in the same day and in the two days test/retest. The iUCOASMI, has also shown an excellent correlation with UCOASMI, and with BASMI. Therefore, these kind of systems, based on IMU, may be useful for analyzing spinal mobility in patients with axSpA in a more accurate and reliable way compared with conventional metrology, and more flexible and cheap than other advanced systems, improving their practical applicability.

**Background:** New onset of joint inflammation in patients under anti-TNF-alpha for inflammatory bowel disease (IBD) has been previously described. However, the histological characterization of synovial and bowel compartments has not been reported so far.

**Objectives:** Aim of the study was to evaluate the histological characteristics of paired synovial (ST) and colonic tissues in IBD patients under TNF-alpha blockers.

**Methods:** Consecutive IBD patients without history of co-existing joint involvement who developed peripheral arthritis under TNF-alpha blockers, were prospectively enrolled. Each patient underwent rheumatological evaluation and ultrasound (US) assessment (using Gray scale for synovial hyperthrophy and Power Doppler Signal) of the affected joints. Each patient underwent US guided ST biopsy of the knee, following a standardized procedure and colonoscopy with mucosal biopsies. Each ST and colonic paired sample was stained through immunohistochemistry (IHC) for CD68, CD21, CD3 and CD117. H&E staining was performed for Paneth cells identification. Immunological parameters (Anti-citrullinated peptides antibodies (ACPA), IgM-Rheumatoid Factor (RF) and IgA-RF respectively) were collected for each patient.

**Results:** 10 patients with IBD (46.0±17 years old, 13.2±9.9 years of disease duration, 2.5±1.6 years of TNF-alpha blockers exposure, 6 with Crohn’s Disease and 4 with Ulcerative Colitis respectively) were studied. All patients were negative for ACPA, IgM-RF or IgA-RF and 4 patients were under Methotrexate therapy. 5 (50.0%) patients showed endoscopic and histologically proven inflammation of colonic mucosa. Moreover, IHC revealed that 6 (60.0%) patients had diffuse and 4 (40.0%) had follicular synovitis, respectively. In particular, there was a direct correlation between CD68*, CD21*, CD3*, CD20* and CD117* cells distribution in paired ST and gut tissues in the whole cohort (<p=0.05). No significant differences in terms of disease duration (p=0.48), TNF-alpha blockers exposure time (p=0.29), ESR (p=0.26) and CRP (p=0.91) values were found comparing patients with follicular and diffuse synovitis respectively.

**Conclusions:** Our findings suggest that patients with IBD may develop histologically proven synovitis during TNF-alpha treatment, showing similar histological features in terms of CD68*, CD21*, CD20* and CD117* cells between synovial and colonic compartments. Molecular mechanisms triggered by TNF-alpha blockers leading to joint inflammation have to be clarified.

**Abstract OP0239 – HISTOLOGICAL FEATURES OF JOINT AND COLONIC INFLAMMATION IN INFLAMMATORY BOWEL DISEASE PATIENTS TREATED WITH ANTI-TNF**

1 Institute of Rheumatology; 2Ibd Unit; 3Institute of Pathology, Catholic University of the Sacred Heart, Rome, Italy

**Background:** Spondyloarthritis (SpA), also including ankylosing spondylitis (AS), psoriatic arthritis (PsA) and undifferentiated spondyloarthritis (uSpA), is a cluster of rheumatic diseases with some common genetic risk factors. These genetic risk factors are likely to result in associations of varying degree with SpA-related comorbidities such as inflammatory bowel disease (IBD), psoriasis and anterior uveitis. There
is also a known association between AS and conduction disturbances and aortic regurgitation. Comparative analyses in the same setting of the strengths of these associations with AS, PsA and uSpA are scarce.

**Objectives:** To assess the strengths of the associations of different SpA-related comorbidities with a diagnosis of AS, PsA and uSpA.

**Methods:** All patients, aged ≤18 years, with AS (n=3884), PsA (n=8706) and uSpA (n=2665) were identified 2001 through 2005, according to specified ICD codes from the Swedish Patient Register. The register contains diagnoses from all visits in inpatient and non-primary outpatient care. Each patient was matched by year of birth, sex and county to five general population (GP) controls identified in the Population Register. Occurrence of SpA-related comorbidities prior to 1 January 2006 were also retrieved from the Swedish Patient Register. Number and proportion of cases (n (%)) with a recorded SpA-related comorbidity prior to 1 January 2006 and corresponding prevalence ratio (PR) with 95% confidence interval (CI) were calculated, overall and stratified for sex.

**Results:** PRs for SpA-related comorbidities were significantly elevated in all SpA subtypes compared to their matched GP controls (Table). PRs were substantially elevated in AS, immediately elevated in uSpA, whereas only moderately increased in PsA. The results were similar in the sex-stratified analyses (not shown).

**Conclusions:** The strongest associations of SpA-related comorbidities were seen with AS, closely followed by uSpA, compatible with a substantial shared etiology and phenotypical expression for patients given these two diagnoses, whereas the associations between PsA and the SpA-related comorbidities were considerably weaker.

**Disclosure of Interest:** None declared

Predictors of Remission at Week 12 in Patients with Non-Radiographic Axial Spondyloarthritis Receiving Open-Label Adalimumab Treatment in the ABILITY-3 Study

J. Sieper1, R. Landewé2, M. Magrey3, J.K. Anderson4, S. Zhong, X. Wang, A. Lertratanakul5, 1Charité Universitätsmedizin Berlin, Berlin, Germany; 2University of Amsterdam, Amsterdam, Netherlands; 3Case Western Reserve University School of Medicine, Cleveland, OH; 4AbbVie, North Chicago, United States

Background: Patients (pts) with non-radiographic axial spondyloarthritis (nr-axSpA) who fail nonsteroidal anti-inflammatory drug (NSAID) therapy are candidates for tumor necrosis factor inhibitor (TNFi) therapy if they have objective signs of inflammation. Baseline predictors of response to TNFi therapy, including remission, are important to identify and aid clinical management.

Objectives: Describe baseline predictors of remission in nr-axSpA at wk 12 of open-label adalimumab (ADA) therapy in the ABILITY-3 study.

Methods: ABILITY-3 enrolled adult pts with nr-axSpA (fulfilling Assessment of SpondyloArthritis International Society [ASAS] criteria but not modified New York criteria) with moderately to severely active disease at screening and baseline objective evidence of inflammation in the sacroiliac (SI) joints or spine on an inadequate response to ≥2 NSAIDs. Eligible pts received ADA 40 mg every other week during a 29-wk open-label lead-in period. Clinical remission was defined as Ankylosing Spondylitis Disease Activity Score inactive disease (ASDAS ID; score <1.3) or ASAS partial remission (score <2/10) in ≥3 of each of the 4 ASAS domains. Stepwise logistic regression was used to identify potential baseline predictors of remission at wk 12.

Results: 673 pts were enrolled (Table). Lower disease activity, increased age, lower functional status (HAQ-S), presence of HLA-B27, and positive MRI of the SI joints were the strongest predictors of ASAS PR (Figure).

Family Matters: Value of Family History of Spondyloarthritis in the Diagnostic Work-Up of Patients with Chronic Back Pain: Results from the Space and Desir Cohorts

Z. Ez-Zaitouni1, A. Hilkens1, L. Gossec2, J.B. P. R. Landewé4, R. Ramonda5, M. Dougados6, D. van der Heijde1, F. van Gaalen1, J. Sieper1

1Rheumatology, Leiden University Medical Center, Leiden, Netherlands; 2UMPC University Paris 06, Paris, France; 3Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; 4Rheumatology Academic Medical Centre, Amsterdam, Netherlands; 5Rheumatology Unit, DIMED, University of Padova, Padova, Italy; 6Rheumatology, Université Paris Descartes, Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, INSERM U1153: Épidémiologie Clinique et Biostatistiques, PRES Sorbonne Université-Cité, Paris, France

Background: A positive family history (PFH) of spondyloarthritis (SpA) is considered a risk factor for the presence of axSpA in patients with chronic back pain (CBP). In the ASAS classification criteria, a PFH of SpA is defined as the presence of any of the following diseases in first- or second-degree relatives: ankylosing spondylitis (AS), reactive arthritis (ReA), inflammatory bowel disease (IBD), or psoriasis. It is however not known if a PFH for each of these diseases contributes equally well to making a diagnosis of axSpA in patients presenting with CBP.

Objectives: To assess which SpA diseases in family members are associated with HLA-B27 and axSpA in patients with CBP.

Methods: The SPACE cohort includes patients with CBP (<3 months, <2 years, onset <45 years) from various European rheumatology centers. DESIR is a French prospective multicenter cohort of patients with inflammatory back pain (IBP; >3 months, <3 years, onset <50 years), suggestive of axSpA. Patients underwent a full diagnostic work-up at baseline including MRI and radiographs of sacroiliac joints (local reading), laboratory assessments (HLAB27), and assessment of all other SpA features. Patients were asked about the presence of SpA diseases in first- or second-degree relatives (AS, AAU, ReA, IBD, and psoriasis). The associations between a PFH and HLA-B27, sarcroiliitis, axSpA diagnosis by the rheumatologist, and fulfillment of the ASAS classification criteria in CBP patients were assessed.

Results: In 438 patients from the SPACE cohort and 647 patients from the DESIR cohort, a PFH of AS (odds ratio (OR) 5.9 (3.5–9.9) and OR 3.3 (2.1–5.2), respectively for SPACE and DESIR) and a PFH of AAU (OR 9.8 (3.3–28.9) and OR 21.8 (6.0–76.1) for SPACE and DESIR) were significantly associated with presence of HLA-B27 (Table 1). Furthermore, in both cohorts a PFH of AS and a PFH of AAU were positively associated with fulfillment of the ASAS criteria, but not with saccroiliitis on imaging (data not shown). In SPACE, but not in DESIR, a PFH of AS or AAU was associated with axSpA diagnosis (data not shown). In both cohorts, a PFH of ReA, IBD, or psoriasis was not positively associated with HLA-B27 positivity, saccroiliitis on imaging, axSpA diagnosis or meeting the ASAS criteria for axSpA.

Conclusions: In two recent CBP cohorts, a PFH of ReA, IBD, or psoriasis did not
contribute to identifying axSpA in CBP patients indicating these family elements may not be very useful for diagnosis. A PFH of AS or AAS however may be useful in finding cases in low prevalence settings as these were correlated with HLA-B27 carriage.

OP0245

EMPLOYMENT PERSPECTIVES OF PATIENTS WITH ANKYLOSING SPONDYLITIS IN THE BIOLOGIC ERA

C. Webers 1, 2, L. Vanhoof 1, S. van Genderen 1, 2, G. Pasqui 3, L. Heuft 4, M. van Dijk 5, J. Luime 5, D. van der Heijde 6, A. Spoorenberg 1, 2, A. Boonen 1, 2, 6
1MUMC; 2CAPHRI; 3Human Biology, UM, Maastricht; 4Laurentius, Roermond; 5MST, Enschede; 6Erasmus MC, Rotterdam; 7LUMC, Leiden; 8UMCG, Groningen, Netherlands

Background: In the pre-biologics era, employment of patients with ankylosing spondylitis (AS) was decreased when compared to the general population. However, information on standardized employment since the introduction of biologicals is lacking. Also, while mastery (control over disease) has been identified as strong predictor of work outcome within patients with AS, it is not known whether such personality trait plays a similar role in patients compared to population subjects.

Objectives: To update the knowledge on employment and contributing factors, in particular personal factors, among Dutch patients with AS compared to general population subjects.

Methods: Data from patients and population controls participating in the Dutch cross-sectional multicenter survey-based Social Participation in AS Study (SPASS) and ≥ 15 years were used. Standardized employment ratios (SERs) were calculated using indirect standardization after adjusting for age, gender, and education and were stratified by disease duration tertiles. Adjusted absolute employment rate (%) was calculated as “SERemployment rate [controls]”.

Results: 214 patients and 470 controls (127 [59.3%] and 323 [68.7%] males; mean age of 48.3 [SD 10.4] and 39.3 [SD 12.7] years, respectively) completed the online questionnaire in 2011. SERs (95% CI) of patients with AS controls set as reference (1.00) were 0.83 (0.69–0.98) for the total group, 0.84 [0.67–1.04] for males and 0.83 [0.59–1.07] for females. There was no significant difference in SER between those with short or long disease duration (Figure 1). Adjusted absolute employment rate (%) of patients with AS was 14% lower compared to SER between those with short or long disease duration (Figure 1). Adjusted absolute employment rate (%) of patients with AS was 14% lower compared to controls (69% vs. 84%). In both patients and controls, higher PCS (SF-36) was associated with being employed. While AS patients with higher (better) mastery were more likely to be employed, such association was not seen in controls (p>0.01 for interaction group*mastery) (Table).

Conclusions: More subjective disease activity measures have greater impact on sick leave in biologics-treated RA patients than do more objective variables, suggesting a stronger focus on the former ones when targeting work-loss or intervening to reduce it.

OP0246

IMPACT OF DISEASE ACTIVITY MEASURES ON SICK LEAVE IN BIOLOGICS-TREATED PATIENTS WITH RHEUMATOID ARTHRITIS: OBSERVATIONAL DATA FROM SOUTHERN SWEDEN

J.K. Wallman 1, J.K. Söderling 2, A. Gülfe 3, L.-E. Kristensen 3, M. Neovius 2, T. Olsson 1, Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund; 1Karolinska Institutet, Department of Medicine, Clinical Epidemiology Unit, Stockholm, Sweden; 2The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Frederiksberg and Bispebjerg, Denmark

Background: Sick leave generally represents the earliest phase of work-loss in rheumatoid arthritis (RA) patients, often on the trajectory towards more permanent disability pension. Sick leave may still change with disease activity fluctuations and is thus potentially reversible and accessible for interventions. However, data remain scarce on the importance of modifiable, non-composite disease activity measures for subsequent sick leave in RA patients treated with biologics.

Objectives: To study the impact of common, non-composite disease activity measures on sick leave in biologics-treated RA patients.

Methods: Study visits of biologics-treated RA patients of working-age (<65y) without disability pension, monitored in the population-based, observational South Swedish Arthritis Treatment Register group register 2005–2011, were included (5151 visits; 957 patients). We performed association analyses between various non-composite disease activity measures at each visit and number of objectively assessed sick leave days during the month thereafter, retrieved from the Social Insurance Agency. Separate generalised estimating equation regression models were used, adjusting for age, sex, educational level, disease duration, number of previous biologics, time from start of the present biologic, and calendar year of study visit. Analyses were furthermore stratified on sick leave status the month preceding each visit (no sick leave=0 days out of 30; partial sick leave=1–29 days and full sick leave=30 days) and results are presented as standardised beta coefficients for comparability, with bootstrap-generated 95% confidence intervals.

The composite 28-joint disease activity score (DAS28) and the health assessment questionnaire (HAQ) disability score were included as contrast.

Results: Out of common, non-composite disease activity measures, visual analogue scale (VAS) global and VAS pain were most strongly associated with sick leave days the month after the study visit, irrespective of baseline sick leave status (Figure). Generally, the more objective measures (erythrocyte sedimentation rate, C-reactive protein and swollen joint count (SJQ)) had less impact on subsequent sick leave than the more subjective variables (VAS global, VAS pain, evaluator’s global and tender joint count (TJC)). As expected, HAQ showed the strongest association.

Figure 1. VAS global and VAS pain.

Conclusions: More subjective disease activity measures have greater impact on sick leave in biologics-treated RA patients than do more objective variables, suggesting a stronger focus on the former ones when targeting work-loss or intervening to reduce it.

RA - causes and courses
AN IMPROVED MATRIX TO PREDICT RAPID RADIOGRAPHIC PROGRESSION OF EARLY RHEUMATOID ARTHRITIS PATIENTS: POOLED ANALYSES FROM SEVERAL DATABASES

A. Vainer1, J. Smolen2, C. Allaart3, R. Van Vollenhoven4, P. Verschueren5, N. Vastesaeger6, S. Saevaerdts7, K. Visser3, D. Aletaha8, B. Combe9, B. Fautrel1, 1UPMC Univ Paris 6 and AP-HP Pitéîle-Salpêtrière Hospital, Paris, France; 2University of Vienna, Vienna, Austria; 3Leiden University Medical Center, Leiden, Netherlands; 4Karolinska Institute, Stockholm, Sweden; 5University Leuven, Leuven, Belgium; 6Merck Sharp and Dohme, Lucerne, Switzerland; 7Université de Montpellier 1, Montpellier, France

Background: In early rheumatoid arthritis (RA), some patients exhibit rapid radiographic progression (RRP) after one year, associated with poor functional prognosis. Identifying at the time of diagnosis the characteristics predictive of RRP is of importance. Several matrices predicting this risk have been proposed over the last years. They were limited somewhat in terms of precision or were built using specific populations.

Objectives: To develop a matrix to predict RRP with better precision and generalizability by pooling databases from various studies.

Methods: The study is based on the pooling of individual data from cohorts (ESPOIR and Leuven) and clinical trials (BeSt, SWEFOT and ASPIRE). Included patients were adult DMARD-naive patients with recent suspected or confirmed diagnosis of active RA for which the first therapeutic strategy after inclusion was to prescribe MTX or leflunomide in monotherapy for at least 3 months. The main outcome was the presence of RRP defined as an increase in Modified Sharp score (mSSS) of at least 5 points between baseline and one year. Baseline characteristics were compared by the presence of RRP to search for predictors. A logistic regression model to predict RRP was built. The best model was selected by 10-fold stratified cross-validation by maximizing the Area Under the Curve (AUC). Calibration and discriminatory power of the model were assessed. Model parameters were extracted to estimate the probability of a RRP for each combination of level of baseline characteristics.

Results: The data of 1,306 patients were pooled. After one year, 236 exhibited RRP (18.4%). A matrix (Table 1) for prediction of RRP of 0.21, Model of prediction of RRP included as baseline characteristics Rheumatoid Factor (RF) positivity (OR=2.1 CI95% [1.5–3.0]; p<0.001), erosive disease on X-rays (OR=2.3 CI95% [1.7–3.2]; p<0.001), CRP >30 mg/l (OR=2.1 CI95% [1.5–3.0]; p<0.001), number of swollen joints >10 (OR=1.5 CI95% [1.01–2.1]; p=0.048). Model calibration was good (Hosmer and Lemeshow test: p=0.79). AUC was 0.68. The matrix proposes estimated RRP probability for 36 combinations of level of baseline characteristics. Its range goes from patients with a 4.1 fold lower risk of RRP compared to average risk (probability of 0.05 CI95% [0.03–0.08], patient with CRP <10 mg/l, without RF, without X-ray erosions, without >8 swollen joints), to patients with a 2.3 fold higher risk than average (probability of 0.47 CI95% [0.39–0.55], patient with CRP >30, with RF, with erosive disease on X-ray, with >10 swollen joints).

Conclusions: A matrix proposing RRP probability at one year with better precision (i.e. narrower CI than those previously published) in early RA for various combinations of levels of a few common baseline characteristics has been built using several databases. However, discriminating power is not ideal. Further investigations will be needed to fully explore the potential complexity of predicting RRP in early RA.

SERIOUS INFECTION AND ASSOCIATED RISK FACTORS IN PATIENTS WITH MILD TO MODERATE RHEUMATOID ARTHRITIS TREATED WITH BARICITINIB

K.L. Winthrop1, M.C. Genovese2, M. Harigai3, L. Chen4, C.L. Dickson4, D.L. Hyslop5, A. Nishikawa5, J.D. Bradley4, M. Dougdas6, 1Oregon Health and Science University, Portland, 2Stanford University, Palo Alto, United States; 3Tokyo Women's Medical University, Tokyo, Japan; 4Eli Lilly and Company, Indianapolis, United States; 5Lilly Japan, K.K., Kobe, Japan; 6Paris-Descartes University, Paris, France

Background: Baricitinib (BARI) is an oral Janus Kinase (JAK)1/1JAK2 inhibitor in development for patients (pts) with active rheumatoid arthritis (RA). Compared to the general population, RA pts have an increased rate of serious infection events (SIE) due to disease state and concomitant therapies.1

Objective: To evaluate the incidence rate (IR) of SIE and associated risk factors in BARI-treated pts with active RA across 8 completed studies (4 Ph3, 3 Ph2, 1 Ph1) and 1 ongoing long-term extension (LTE) study.

Methods: The ALL BARI RA analysis set included pts exposed to any BARI dose, with exposure up to 5 years (yrs) (Phase [Ph] 1–3 and LTE studies); the comparison with placebo (PBO) was based on 6 studies (Ph 2–3) with BARI 4 mg once daily (QD) and PBO arms up to Week (Wk) 24; dose response assessment was based on 4 studies (Ph 2–3) with both BARI 2 and 4 mg QD arms up to Wk 24. An extensive list of potential risk factors for SIE was investigated in the ALL BARI RA set using Cox models; SIE risk factors among BARI-treated pts are reported (Table).

Results: The most frequent SIE observed in the ALL BARI RA set (N=3492; 5133 pt-yrs (PY) of exposure [PYE] were pneumonia, herpes zoster, urinary tract infection, and cellulitis (all <1%), and 2 patients with SIE died (IR=0.04/100 PY). In the ALL BARI RA set, SIE were reported in 150 pts (IR=2.9/100 PY). During 0–24 Wks, similar SIE rates were observed in BARI 4 mg (N=997; 417 PYE) and PBO (N=1070; 403 PYE) groups in the 6-study set, and between BARI 2 mg (N=479; 192 PYE) and 4 mg (N=479; 194 PYE) dose groups in the 4-study set (Figure).

Prior biologic use, advancing age, region of Asia (excluding Japan), non-normal body mass index (BMI), and corticosteroid use were identified as independent factors for SIE in the ALL BARI RA set (Table). Among these SIE risk factors, none significantly differed between BARI 4 mg and PBO in the 6-study dataset (data not shown).

Background: Achieving remission is the ultimate treatment goal in patients with rheumatoid arthritis (RA). With the development and wider use of highly effective disease modifying anti-rheumatic drugs (DMARD) about half of RA patients reach the disease remission state (1), raising the question about tapering or stopping anti-rheumatic treatment and appropriate predictors (2).

Objectives: To analyse the effect of a risk-stratified DMARD tapering algorithm based on multiple-biomarker disease activity (MBDA) score and anti-citrullinated protein (ACPAs) status for successful DMARD tapering and treatment cost reduction in RA patients in sustained remission enrolled in the prospective randomized controlled RETRO study (3,4).

Methods: MBDA score and ACPA status were determined in the baseline samples of 146 patients in sustained remission. Patients either continued DMARDs (arm1), tapered dose by 50% (arm 2) or stopped DMARDs after tapering (arm 3) for one year according to the RETRO protocol. Direct treatment costs (including testing costs at baseline) were evaluated every three months. MBDA and ACPA status were used as predictors creating a risk-stratified tapering algorithm based on relapse rates.

Results: RA patients with a low MBDA score (<30) and negative ACPA showed lowest relapse risk (19%). With either single positivity for ACPA or moderate/high MBDA scores (>30) relapse risk increased and was high in double-positive patients (61%). In MBDA negative (<30) and MBDA single-positive (>30) groups, DMARD tapering appears feasible. Considering only patients that did notflare, costs for synthetic and biologic DMARDs in the MBDA-negative and single-positive group (n=41) would have been 123.761,29 € for full-dose treatment over one year. Tapering and stopping DMARDs in this low-risk relapse groups allowed a reduction of 92.821,50 € (75%) of DMARD costs. Average reduction of DMARD costs per patient were 2.350,08 € in the double negative (MBDA-/ACPAs-) (median quartiles 0.61–5.38 €) and single negative (MBDA-/ACPAs+) group and 1.761,43 € in the MBDA single positive (MBDA+/ACPAs-) group.

Conclusions: Combining MBDA score and ACPA status allows risk stratification for successful DMARD tapering and cost-effective use of biologic DMARD. Given that previous data of the RETRO have shown that patients relapsing after tapering their DMARDs respond well to their reintroduction, a stratified tapering and stopping of DMARDs is not only a cost economic but also clinically feasible strategy.

CAN RANKL SERUM LEVELS PREDICT FUTURE PROGRESSION TO RHEUMATOID ARTHRITIS IN ACA P-NEGATIVE PATIENTS?

A. Burska1, J. El-Jawhari1, A.L. Tan1, R. Wakefield1, H. Marzo-Ortega2, P. Conaghan1, P. Emery1, F. Ponchel1, J. Freeston1,2,3, LIRMM, University of Lodis; 2NIHR Leeds Musculoskeletal Biomedical Research Centre; 3Rheumatology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Making the earliest diagnosis of rheumatoid arthritis (RA) is crucial to initiate treatment and prevent further disease progression and joint damage. Despite recent advances with the discovery and integration of anti–cyclic citrullinated protein antibody (ACPA) in classification criteria, there is still an unmet need for new diagnostic biomarkers, notably for ACPA-negative disease. Power Doppler ultrasound has been shown to identify poor prognosis disease in ACPA negative patients.

Objectives: The receptor-activator-nuclear-factor-κB axis (RANK/RANKL) is known to regulate bone homeostasis. The aim of this pilot study is to establish whether serum RANKL levels in people with early inflammatory arthritis are predictive of RA diagnosis at follow-up and to evaluate the added value of RANKL with diagnosed for early RA diagnosis.

Methods: Serum from 298 subjects (95/204 Male/Female) was collected at the baseline participant visit to the Leeds Early Arthritis clinic. Demographic (age, gender, symptom duration) and clinical data (swollen and tender joint counts (SJc, TJc), CRP, RAS28, rheumatoid factor (RF) and ACPA, shared epitope (SE)) were collected. A commercial ELISA (BioVENDOR) was used to measure RANKL. Ultrasound of 26 joints (bilaterial elbows, wrists, MCP 2–3,PIP 2–3, knees, ankles and MTP rind) was performed at baseline. recording summatory scores for power Doppler (PD), gray scale hypertrophy (GS) and erosions (EO).

Results: At 1 year follow up, 151 patients had a confirmed diagnosis of RA (EULAR 2010 criteria) and 147 were classified as non-RA (undifferentiated arthritis, other inflammatory diagnoses or non-persistent inflammation). All routinely used biomarkers were associated with RA diagnosis (ACPA, RF, SE, SJc, TJc, CRP, RAS28, p < 0.0001), as were imaging biomarkers (PD, GS, EO, p < 0.001). RANKL levels were significantly higher in RA (1002±1053.2pmol/L, non-RA 339.2±45.1pmol/L, p < 0.001). A regression analysis suggested that four parameters were sufficient to account for all associations with RA: RANKL, age, SJc, and PD with 75.3% accurate prediction. An AUROC analysis suggested a cut-off for each parameter and a score was calculated, adding 1 point for each of the factors (RANKL > 700, age < 62, TPD < 3, SJc < 4). This score predicted RA with an AUROC of 0.782 ([0.65–0.90], p < 0.0001). The same analysis repeated for ACPA negative patients only (n=193) showed similar results, providing accurate diagnosis of RA (77.6% correct by regression) and with an AUROC of 0.774 ([0.69–0.858], p < 0.0001).

Conclusions: A score incorporating RANKL, age, SJc and PD showed good predictive value for non-RA when low and for RA when high. Furthermore, the analysis of a redo in ACPA-negative patients performed particularly well for predicting RA with a good AUROC value.

INCIDENCE OF KNEE AND HIP REPLACEMENTS IN RHEUMATOID ARTHRITIS PATIENTS FOLLOWING INTRODUCTION OF BIOLOGICAL DMARDS: AN INTERRUPTED TIME SERIES ANALYSIS USING NATIONALWIDE HEALTH CARE REGISTERS

R. Cordtz1,2, S. Hawley3, D. Prieto-Alhambra3, E. Kristensen4, S. Overgaard1, A. Odgaard1, L. Dryer1,2, 1Center for Rheumatology and Spine Diseases, Gentofte, Rigshospitalet; 2The Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark; 3Musculoskeletal Pharmaco- and Device Epidemiology, NDORMUS, University of Oxford, Oxford, United Kingdom; 4Department of Orthopaedic Surgery and Traumatology, Odense University Hospital, Odense; 5Department of Orthopaedics, Herlev and Gentofte Hospital, Copenhagen, Denmark

Background: Previous data have been conflicting regarding a possible impact of treatment with biological DMARDs (bDMARDs) on the need for total knee replacement (TKR) and total hip replacement (THR) in patients with rheumatoid arthritis (RA).

Objectives: To investigate impact of national guidelines recommending bDMARD treatment for RA on the secular trends of TKR and THR among incident RA patients compared with matched general population controls (GPC) in Denmark.

Methods: Using nationwide register based time series analysis, the authors performed a matched case-control study of RA patients diagnosed at a rheumatology department from 1996–2011. GPC: 10 individuals matched to each RA patient on age, sex and municipality. Outcome: First TKR and THR, respectively.
Intervention: introduction of bDMARDs and associated publication of bDMARD recommendations in Denmark in 2002.

Secular trends in the pre-bDMARD guideline era (1996–2002) were compared with those in the bDMARD period (2003–2016) using segmented linear regression and a 1-year lag period (2002–03). Absolute changes in TKR and THR at the midpoint (February 2007) between guideline implementation and end of study period were estimated.

Results: In total, during 1996 to 2011, 30,868 incident RA patients were identified (mean age at diagnosis 58.3 years, 70% women) and compared with 301,237 GPCs. See Table for results.

Table 1. Changes in 5-year incidence rate of total hip (THR) or total knee replacement (TKR) in incident rheumatoid arthritis (RA) patients following introduction of biological DMARDs compared with secular trends in age, sex, and municipality-matched general population controls (GPC)

Stepwise backward elimination to produce most parsimonious model: p-enter <0.05 and p-exit >0.2. *Δ per year based on biannual data.

Conclusions: Prior to 2002, the incidence of TKR increased among RA patients, but started to decrease after introduction of bDMARDs and their associated guidelines in 2003 (absolute change -1.8 TKRs/1000 person years in Feb. 2007). In contrast, the incidence of TKR increased among GPCs throughout the entire study period. The incidence of THR increased in GPCs for the entire duration of the study period, whereas there was a downward going trend among RA patients, but with a surprising level increase in 2003. The overall patterns of our findings are in line with those recently reported from England and Wales.

RHEUMATOID ARTHRITIS PATIENTS WITH CONTINUED LOW DISEASE ACTIVITY HAVE SIMILAR OUTCOMES OVER 10 YEARS, REGARDLESS OF INITIAL THERAPY

S.A. Bergstra1, R.B. Landewé2, T.W. Huizinga1, C.F. Allaart1, G. Gusto3, M.C. Boutron-Ruault3, X. Mariette1,2

Introduction: Disease activity is an essential feature of rheumatoid arthritis (RA), but little is known about its relevance beyond 10 years of follow-up. This study aimed to compare patients who had continued low disease activity over 10 years (DAS ≤ 2.4) with those who had not (DAS > 2.4).

Methods: Patients were identified from the BeSt study, a prospective, multicentre, observational study of RA patients aged ≥18 years with ≥3 months of disease duration. Disease activity was assessed using the Disease Activity Score (DAS) and patient-reported outcomes (PROs) were collected using the Health Assessment Questionnaire (HAQ) and the European Health Inventory (EHI).

Results: Of 418 patients, 39% continued low disease activity over 10 years. Patients with continued low disease activity had lower DAS and better PROs compared to those with higher disease activity (significant for all PROs except EHI). There were no differences in radiographic progression, erosions, or joint space narrowing between the two groups.

Conclusions: Disease activity was sustained over 10 years in a substantial proportion of RA patients. These patients had lower disease activity, better PROs, and similar radiographic outcomes compared to those with higher disease activity. This suggests that continued low disease activity is an important clinical feature of RA, regardless of initial disease activity.

PASSIVE SMOKING IN CHILDHOOD AND HISTORY OF CHRONIC DIARRHEA INCREASES THE RISK OF DEVELOPING RHEUMATOID ARTHRITIS (RA)

R. Sercer1,2, G. Gusto3, M.C. Boutron-Ruault3, X. Marieu1,2,3, R. rheumatology. Hopitaux Universitaires Paris Sud; 2INSERM U1184, Université Paris-sud, le Kremlin-Bicêtre; 3Centre de recherche en épidémiologie et santé des populations, Inserm U1018, Villejuif, France.

Objectives: To analyse the impact of active and passive smoking and intestinal transit disorders on the risk of incident RA.

Methods: This study is based on the French E3N cohort (“Étude Épidémiologique auprès de femmes de l’Education Nationale”), which included 98,995 women volunteers born between 1925 and 1950 and prospectively followed since 1990. Eleven self-administered questionnaires were sent to the participants between 1999 and 2014 to collect medical, demographic, environmental and hormonal data and dietary habits. The diagnosis of RA was collected on 2 successive questionnaires. Cases were considered certain if having declared RA and having taken a RA specific medication (methotrexate, leflunomide or biologic) since 2004 (period from which drug reimbursement data was available). Only incident and certain cases were included. Women were excluded if they had an inflammatory bowel disease and/or no information on their smoking habits. Passive smoking was assessed by the following question: “When you were children, did you stay in a smoky room?” Patients were considered exposed if the answer was “yes, a few hours, or yes, several hours a day”. The usual intestinal transit, reported by patients was 2.4. Regardless of the duration of treatment strategies for patients who have sustained DAS ≤ 2.4. Regardless of initial induction therapy, those who remain in low disease activity have similar long-term outcomes, with only the proportion of patients in drug free remission being higher in the TKR monotherapy group. These results strongly suggest that rapid achievement of remission/LDA itself, rather than how you achieve it, is crucial for determining long-term outcome in RA.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1707
transit, chronic diarrhoea, chronic constipation, and alternation between diarrhoea and constipation. The risk of incident RA was estimated using an age-adjusted Cox model that considers smoking status as a time-dependent variable.

**Results:** 70598 women from the E3N study were included in the study. A total of 1239 patients reported an incidental RA, of which 350 cases were included in the study (and 280 in the analysis of intestinal transit disorders). Non-ascertained cases were excluded from the analyses. The age at inclusion in the study was 49.0 years (± 6.4). The mean duration of follow-up was 21.2 (± 1.3) years. Passive smoking exposure during childhood increased the association between the risk of RA and a history of passive smoking in childhood (OR = 1.73 [1.20; 2.50]) as compared with non-smokers who were not exposed during childhood, while it was 1.37 [1.08; 1.73] in active smokers who were not exposed during childhood.

A history of chronic diarrhoea was associated with increased RA risk (HR = 2.32 [1.41, 3.81]), while chronic constipation or alternation between diarrhoea and constipation did not.

**Conclusions:** This study confirms the link between active smoking and the risk of RA. It suggests for the first time that in smokers, exposure to tobacco early in life, through passive smoking in childhood significantly increases this risk. Our study highlights the importance of avoiding any tobacco environment in children, especially in those with a family history of RA. Also, it shows for the first time an association between a history of chronic diarrhoea and the risk of developing RA. The association supports the hypothesis of dysbiosis (microbiota abnormality) as a risk factor for the emergence of autoimmunity. These data perfectly fit with the preclinical scheme of RA where an external event occurs at an early stage to promote emergence of auto-immunity, followed years after by clinical RA.

**HAND EXERCISE FOR WOMEN WITH RHEUMATOID ARTHRITIS AND DECREASED ADL ABILITY: AN EXPLORATORY RANDOMISED CONTROLLED TRIAL**

K. Ellegaard, C. von Bülow, A. Repke, C. Bartholdy, I.S. Hansen, S. Ritbjerg, R. Christensen, M. Henriksen, E. Waehrens. The Parker Institute, Frederiksberg, Denmark

**Background:** Decreased strength and range of motion in the hand are often seen in rheumatoid arthritis (RA). Positive effects on hand function in RA patients after hand exercise and individual education in joint projection including coping strategies (ADL education) is shown (1,2). However, it is unknown if a combination of both will further improve hand performance.

**Objectives:** To investigate the effect on ADL ability of a hand exercise program as add on to an ADL education program in women with RA.

**Methods:** Women with RA involving the hand on stable medication for at least three months were recruited. At baseline participants were examined by a rheumatologist who assessed the hand and ruled out contraindications for participation e.g. massive malalignment of the joints. Inflammatory markers of the blood, hand pain and grip strength were also measured. The ADL motor ability was assessed using the observation-based Assessment of Motor and Process Skills (AMPS). After baseline examination randomised to ADL education + hand exercises (intervention; IG) or only ADL education (control; CG) was made. All participants received three to four sessions with an occupational therapist learning how to perform ADL tasks overcome their specific hand problems. The intervention group also received a hand exercise program, to be conducted four times a week, for eight weeks, containing exercises for improving range of motion and strength; once a week the exercise program was supervised by a physiotherapist, to correct and prevent overload and to increase load if possible.

**Primary outcome measure** was change in observed ability to perform ADL tasks (AMPS) at week 8. Secondary outcomes include grip strength, pain, joint count, inflammatory markers and self-reported function.

Four weeks after baseline were completed the trial. The ITT-populations mean age was 63.8 (12.8) years, mean disease duration was 12.4 (11.0) years. Baseline tender and swollen joint count was 5.07 (4.85) and 1.37 (1.72) respectively, the hand pain was 41.95 mm (right) and 35.78 mm (left) (VAS) and hand grip strength was 18.25 kg (right) and 17.46 kg (left). Baseline AMPS ADL motor score was 1.36 (0.46). As judged by the 95% confidence intervals, no difference in change from baseline was seen between the groups (see table).

**Conclusions:** A hand exercise program as add on to an ADL education did not improve ADL ability more than ADL education alone in women with RA experiencing decreased ADL ability involving the hands.

**AN ADD-ON PROGRAMME IMPROVED THE SHORT-TERM, BUT NOT THE LONG-TERM EFFECT OF REHABILITATION IN PATIENTS WITH RHEUMATIC DISEASES: RESULTS FROM A PRAGMATIC MULTI-CENTRE STEPPED-WEDGE CLUSTER RANDOMIZED CONTROLLED TRIAL**

G. Berdahl1, K. Hagen1, H. Dagfinrud1, P. Mowinckel1, I. Ba2, T.N. Dager1, A. Dingsør3, S. Eppeland4, J. Hagfors5, B. Hamnes2, M. Nielsen5, A.-L. Sand-Svartvind1, B. Slungaard2, S. Wigers7, J. Kieken7, J. National advisory unit on rehabilitation in rheumatology. Diakonhjemmet Hospital, Oslo; 2Hospital for Rheumatologic Diseases, Liljenhammer; 3Betanien Hospital. Skien; 4Sarlandet Hospital, Arendal; 5The Norwegian Rheumatism Association, Oslo; 6Martina Hansen's Hospital, Baerum; 7Jeløy Kurbad Rehabilitation Center, Moss, Norway

**Background:** Multidisciplinary rehabilitation is widely used alongside medical treatment of patients with rheumatic diseases. Although beneficial effects of such rehabilitation have been demonstrated, patients are mostly back to their initial health status 6 to 12 months after discharge.

**Objectives:** To evaluate an add-on rehabilitation programme designed to enhance and prolong the effect of rehabilitation in adult patients with rheumatic diseases.

**Methods:** We conducted a pragmatic multi-centre stepped-wedge cluster randomised controlled trial in six rehabilitation centres in Norway. All centres started simultaneously to include patients in the control phase (traditional rehabilitation),
whereupon they switched to the intervention phase (add-on programme) sequentially and in randomised order. The add-on programme comprised structured individualized goal planning, motivational interviewing, a self-help booklet and four supportive follow-up phone calls the first five months after discharge. Data were collected on admission, discharge, 6 and 12 months after discharge. Primary outcome was health related quality of life (HR-QoL) measured by the individualized Patient Generated Index (PGI). The main statistical analysis was a linear repeated measures mixed model performed on the intention to treat population (all available data).

### Results:

- **389 patients with various rheumatic diseases (SpA, RA, OA, and SLE)** were included (table 1). A significant treatment effect of the add-on intervention on HR-QoL was found on discharge (mean difference -3.32 [95% CI: 0.27, 6.37], p=0.03). There were no significant differences between the groups at 6 and 12 months. Treatment compliance was 94%, and response rate >80% at all time points. Both groups showed a positive effect of rehabilitation in terms of increased HR-QoL at discharge, which subsequently declined, although the values remained at higher levels after 6 and 12 months compared with baseline values (figure 1).

**Table 1. Baseline characteristics of included patients (n=389)**

### Objectives:

We investigated if self-reported physical activity, expressed in Metabolic Equivalent of Task (METs)-minutes/week, in patients with SLE is reduced. The aim was also to investigate if they fulfill the public health recommendations for physical activity.

### Methods:

- **103 patients (93 women/10 men, mean age 51.5 (SD 15.9) years)** were included according to the revised ACR criteria for RA defined. Physical activity was assessed with the short version of the International Physical Activity Questionnaire (IPAQ), which measure physical activity the last seven days. The IPAQ scientific group classify physical activity into the following categories: "inactive", "minimally active" (equal to public health recommendations) and "health enhancing physical activity". Those individuals who do not meet the criteria for the two latter categories are considered inactive.

### Results:

The patients reported that they were physically active in median 1686 (interquartile range 693;3759) METs-minutes/week (n=84). The patients answereded that they were sitting in median 6 (interquartile range 4;8) hours a day the last week (n=98). 59.6% of the patients achieved a minimum of at least 600 METs-minutes/week, i.e. they were active 5 or more days with any combination of walking, moderate-intensity or vigorous intensity activities ("minimally active"). 17.3% achieved a minimum of at least 1500 METs-minutes/week, i.e. they were active on vigorous-intensity on at least 3 days or; achieved a minimum of at least 3000 METs-minutes/week, i.e. they were active 7 or more days on any combination of walking, moderate-intensity or vigorous intensity activities ("health enhancing physical activity"). 22.6% of the patients were "inactive".

### Conclusions:

- In the investigated patients with SLE, the majority were "minimally active" according to IPAQ-categories, which is sufficiently physically active according to the minimum level of public health recommendations. However, only 1/5 reached "health enhancing physical activity" category and 1/5 were considered physically "inactive". Health professionals could use the short version of IPAQ to find out which patients with SLE need support in physical activity programmes.

#### RELATIONSHIP BETWEEN SLEEP DISORDERS AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Villarreal1, S. Henas2, D. Buitrago-Garcia3, P. Santos-Moreno4, 1Psychology and processes; 2Patient service; 3Epidemiology; 4Rheumatology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia

### Background:

Rheumatoid arthritis (RA) is the prevalent autoimmune inflammatory arthritis found in adults, with the worldwide prevalence ranging from 0.4% to 1.3% (1). Patients with this condition have permanent changes with different severity of arthritis deformities as well as functional disturbances; Studies had shown that every painful condition disturbs sleep, which can lead to mood and abilities disturbances (2).

### Objectives:

The aim of this study was to describe the socio-demographic profile and sleep disorders in RA patients from a specialized RA clinic in Colombia and relationship with disease activity.

### Methods:

A descriptive cross-sectional study was performed in a specialized clinic dedicated to care patients with rheumatoid arthritis (RA). Data was collected during our psychology consultation, through semi-structured interviews and non-probability sampling. Descriptive epidemiology was applied for continuous variables, using measures of central tendency and dispersion for categorical and qualitative variables by averages and percentages. We analyzed bivariate association with Pearson’s χ².

### Results:

We included 1398 patients attending to our psychology consultation. Mean age was 55±8. 80% were female and 20% male. Mean DAS28 was 2.6±1.3, mean HAQ was 0.9±0.7; Patients had the disease for an average of 12 years ± 8; 41% of patients had comorbidities associated with non-autoimmune disease, 14% comorbidities related to autoimmune disease; 35% of our patients did not report other comorbidities. Most of patients were married 60%, followed by divorced 19%, single 14% and widowed 7%. Regarding occupation 33% were employees, 25% were housekeepers or retired due to age, 12% were retired due to disabilities, and 3% unemployed. Of the total population 45% had elementary school, 32% high school, 8% college education, 7% graduate education and 7% were illiterate. 17% of patients lived alone. When the psychologist asked about sleep disorders 69% reported to have any, 25% primary insomnia, 1% hypersomnia, 3% OSAS and 2% alterations on the circadian rhythm. Disease activity was statically associated with sleep disorders (p<0.00).

### Conclusions:

Sleep problems are an important aspect to consider in a patient with RA and are correlated to disease activity; it is important to have a multidisciplinary care team for the patient with RA, including a psychologist that can manage this kind of illness in order to improve the life quality of patients.

INTENSIVE PHYSICAL EXERCISE FOR ELDERLY PERSONS WITH RHEUMATOID ARTHRITIS IMPROVES PHYSICAL CAPACITY

E. Lange 1,2, D. Kucharski 1, K. Svensson 4, S. Svedlund 3, I. Gjertsson 2,3, K. Mannerkoppi 2, 1 Department of Health and Rehabilitation, Institute of neuroscience and physiology, Sahlgrenska academy, University of Gothenburg;
2 University of Gothenburg Centre for Person-centred Care; 3 Rheumatology and inflammation research, Institute of medicine, Sahlgrenska academy, Göteborg;
4 Skaraborg hospital, Skvde, Sweden

Background: Today, more than 50% of persons with Rheumatoid Arthritis (RA) are over 65 years of age (1). Little is known about the effects of physical exercise in this age group (>65 years).

Objectives: The aim of this randomized controlled study is to investigate the effects of a person-centred progressive aerobic and resistance exercise program, led by a physiotherapist.

Methods: Seventy-four with persons with RA (24% men), mean age 70 years (SD 2.5), were recruited and randomized to an exercise interventions group or an active control group. The intervention consisted of a 20-week individual person-centered exercise program, performed three times a week with guidance from a physiotherapist. Both aerobic and resistance exercise was performed on a high intensity level. The control group followed a home exercise program twice a week. Muscle strength and endurance were assessed by the Chair Stands test, the Timed up and Go and a Bicycle endurance test. Maximal aerobic capacity (VO2 max) was assessed with ergo spirometry. Activity limitations were assessed by SF36 Physical subscale and the Health Assessment Questionnaire (HAQ).

Results: All participants in the intervention group completed the intervention. The participants had a low disease activity with a mean Clinical Disease Activity Index of 5.4 (SD 3.9). Significant improvements were found for VO2 max, the Chair Stands test, the Timed up and Go, the Bicycle endurance test on bicycle (p<0.001) and the SF36 physical (p=0.018) in the intervention group, when compared to the controls. No significant differences between groups were seen on HAQ.

Conclusions: Intensive progressive aerobic and resistance exercise is a feasible intervention for elderly persons with RA. Despite old age and RA the participants gained significant improvements in physical capacity.

OP0258-HPR

SUPERVISED WALKING IMPROVES AEROBIC CAPACITY, EXERCISE TOLERANCE, FATIGUE AND PERCEIVED IMPROVEMENT IN WOMEN WITH PRIMARY SJÖGREN’S SYNDROME: A RANDOMIZED CONTROLLED TRIAL

S.T. Miyamoto 1,2, V. Valim 3,4, L. Carletti 1, W.F. Ng 5, R. Altoe6, A.J. Perez 5, L.H. Dias 6, E.V. Serrano 5, A.M. Subtil 5, V.B. Cândido 5, M. Trenell 7, S.T. Miyamoto 8, E. Lange 1,2

Background: Fatigue is a very common symptom of primary Sjögren’s syndrome (pSS), being reported by up to 70% of patients [1]. It is more pronounced when compared to healthy individuals [2] and patients often report that it is their greatest problem and the one that makes the disease difficult to cope with [3]. There is no evidence on non-randomized controlled study on aerobic exercise in pSS with a small sample size suggesting improvement in fatigue, aerobic capacity, depression and physical function [4].

Objectives: To evaluate the safety and effectiveness of a supervised walking program in women with pSS.

Methods: Forty-five women fulfilling the American European Consensus Criteria for pSS were randomized to a Training Group (TG, n=23) or Control Group (CG, n=22). Patients in the TG were submitted to supervised walking, 3 times a week, for 16 weeks. The patients of the CG were instructed to not perform any kind of regular physical exercise. Outcomes measured were aerobic capacity, fatigue, disease activity, depression, perception of pSS’s symptoms and quality of life. An intent-to-treat analysis was performed.

Results: The mean change after 16 weeks of VO2max (ml.kg⁻¹.min⁻¹), distance and FACIT-fatigue were higher in the TG than in the CG (p=0.016, p=0.043 and p=0.030, respectively) (Figure 1). Improved aerobic capacity was associated with improvements in fatigue scores and physical components of quality of life measured using SF-36. Furthermore, improved fatigue scores were associated with reduced depression and improvements in the physical and mental components of the quality of life measures. Overall, 95.4% of patients in the TG rated themselves as clinically improved versus 62% of the patients in the CG (p=0.049). There was no flare in disease activity and no serious adverse events with exercise.

Conclusions: This supervised walking program was demonstrated to be feasible and safe with improvements in the aerobic capacity, exercise tolerance, fatigue and patient perception of improvement in pSS patients.

OP0260-HPR

HIGHER SATISFACTION WITH ACTIVITY-RELATED SYMPTOMS AFTER 15-WEEK RESISTANCE EXERCISE IN WOMEN WITH FIBROMYALGIA

K. Mannerkoppi 1, 2, A. Larsson 2, A. Palast 1, M. Ernberg 4, B. Gerde 4, E. Koske 2, 1 Institute of Neuroscience and physiology; 2 Gothenburg Center of Person-centred Care (GPCC), University of Gothenburg, Göteborg; 3 Department of Dental Medicine, Karolinska Institute, Stockholm; 4 Department of Medical and Health Sciences, Linköping University, Linköping; 5 Department of Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden

Background: Physical exercise is troublesome for most patients with fibromyalgia (FM) due to activity-induced pain. A reason for activity-induced pain is a low pain threshold. In the present study we investigated if experience of physical activity changed after 15-week progressive person-centred resistance exercise. The control group participated in 15-week relaxation program.

Objectives: To investigate how experience of physical activity changed after 15-week resistance exercise in women with FM, and if experiences correlated with pain threshold.

Methods: 130 women (age 22–64 years, symptom duration 0–35 years) with FM were randomized to 15-week resistance exercise or to a parallel relaxation program. The participants completed Experience of physical activity scale (EPA) comprising five subscales (0–7), assessing how exercise was perceived in terms of physical relaxation (PR), Well-being (WB), Activity beliefs (AB), Activity-related symptoms (ARS), and Activity Habits (AH) (1). A lower score indicates a higher satisfaction. Pain threshold was investigated with algometer. Within-group and between-group analyses were conducted by non-parametric statistics. Correlations between algometry and ratings on EPA were investigated by Spearman correlation coefficient.

Results: The resistance exercise group scored significantly higher satisfaction at posttest than before the intervention in their ratings on how they experienced exercise in terms of PR, WB, ARS and AH (p<0.05), Table 1. Between-group analyses showed that the resistance exercise group scored significantly higher satisfaction in ARS subscale (p<0.006) after the intervention when compared to the relaxation group. Significant correlations were found between algometry and EPA (rs -0.32, p=0.017) as well as ARS (rs -0.33, p=0.015) at post-test in the resistance exercise group.

</tbody>
</table>

Within-group changes (p<0.05) are marked with *.

Conclusions: Women with FM experienced a higher satisfaction with activity-related symptoms after having participated in a person-centered resistance exercise program, which is an important knowledge for health care professionals when motivating patients for exercise. Correlations between algometry and ratings on PR and ARS indicate that activity-related symptoms are partly associated with the pain threshold.

Gout: advances in diagnosis and management

M.L. Dehlin1, V. Sigurdardottir1, P. Driveliegka1, A. Svärd2, L.T. Jacobsson1
1Dept of rheumatology and inflammation research, Institute of medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg; 2Rheumatology Clinic, Falun Hospital, Falun, Sweden

Background: Gout is the most common arthritic disease in the world with increasing incidence and prevalence. There are differences in gout prevalence and course of disease due to cultural, ethnic and genetic factors stressing the need for data from different parts of the world. An increase in hospitalization for gout has been shown for the last two decades in North America.

Objectives: We evaluated the trend for hospitalization of gout in western Sweden 2000 – 2012 and the health care costs for this 2009 – 2012.

Methods: Hospitalization trends for gout were studied using data from the health care consumption register in the Western Swedish Health Care Region (WSHCR) from 2000–01–01 through 2012–12–31. This area is considered to be representative for the country as a whole. Patients aged 18 years and older who were hospitalized during the study period with a principal ICD-10 diagnosis of gout (M10) at discharge were included. We calculated annual population rates for hospitalization for gout, Inflation-adjusted health care costs for the gout hospitalizations were calculated using the Cost-Per-Patient register (CPP). Dispensation of unate lowering therapy (ULT), allopurinol (M04AA01) and probenecid (M04AB01), within 6 months prior to hospitalization was identified using The Swedish Prescribed Drug Register.

Results: There were 1873 hospitalizations for gout (mean age 75.0–77.6 years, 61–74% men) between 2000 and 2012. Demographic characteristics were similar

Though these results are promising regarding PA in JIA patients, the results indicate that patients still need to be encouraged to be physically active, with emphasis on increasing vigorous PA.

Disclosure of Interest: None declared

over the study period. From 2000 to 2012, the annual hospitalization rate for gout increased from 12.2 to 16.7 per 100,000 adults (p<0.0038). The increase was most pronounced in males aged 65 and above and over the last three years of the study. From 2009 to 2012 the inflation-adjusted health care costs for gout hospitalizations increased from 5.21 to 8.15 $10^7$ USD. The duration of hospitalizations also increased from 3 to 5 days median 2000 and 2012 respectively (p<0.021). Only a minority of patients, 19 to 27%, received ULT the 6 months preceding their hospitalization, without any obvious secular trend.

Conclusions: Incidence of hospitalization for primary gout is increasing substantially in Sweden over the last decade and this is reflected in the health care costs. The main part of this increase consists of males aged 65 and above. Only a fourth of the patients were on ULT preceding the hospitalization. These findings are further emphasized by the fact that the total amount of days for somatic inpatient care in WSHCR decreased by 9% from 2002 (1 267 900 days, mean duration 5.7 days) to 2012 (1 151 630 days, mean duration 4.9 days). The findings in this study reflect increasing incidence of the gout disease and an ageing population but also a considerable lack of treatment.

OP0263

TRANS-ANCESTRAL META-ANALYSIS IDENTIFIES 13 NEW LOCI ASSOCIATED WITH SERUM URATE LEVELS

T.R. Merriman 1, M. Cadzow 1, R. Topless 1, D. Mouni 2, H. Chai 3, Y. Okada 4, J. Boocock 2, E. Stahl 5, 6, 7, University of Otago, Dunedin, New Zealand; 2 Brigham and Women’s Hospital, Boston, United States; 3 Osaka University, Osaka, Japan; 4 University of California Los Angeles, Los Angeles; 5 Mt Sinai School of Medicine, New York, United States

Background: Serum urate is an important biomarker for gout disease and kidney function. Genome-wide association study (GWAS) meta-analyses have identified 28 loci in European and East Asian population samples. Combined analysis of these summary data across populations offers the opportunity to discover new serum urate associations through greater sample size and power, and trans-ancestral analyses provide the opportunity for fine-mapping associations with greater resolution given differing linkage disequilibrium patterns between populations.

Objectives: To conduct a meta-analysis of European and East Asian serum urate GWAS.

Methods: Summary statistics from European (N=110,238) (Kottgen et al. 2013) and East Asian (N=21,268) (Okada et al. 2012) meta-analyses were obtained. We used ImpG v1.0 to impute the results into 1000 Genomes phase 3 variants, and east Asian (N=21,268) meta-analyses were obtained. We conducted a meta-analysis of European and East Asian serum urate GWAS.

Results: Trans-ancestral meta-analysis of European and East Asian GWAS revealed nine new serum urate-associated loci (P_{meta}<5x10^{-8}). Three loci were located in the 11q12.3–13.2 region near the established SLC22A11/12 locus. Additional novel loci were located near the FGFS, LNC00603, HLA-DQB1, B4GALT1, BIC1 and USP2 genes. Tissue-focused functional partitioning of SNP-heritability indicated the strongest enrichments of kidney, GI and liver tissues (P<10^{-7}), among other significant tissues. Trans-ancestral meta-analysis and functional fine-mapping decreases the number of SNPs in causal variant credible sets, and for example pinpoint the rs17632159 SNP as likely causal (posterior P<0.9) at the TMEM171/174 locus.

Conclusions: Meta-analysis of existing GWAS increases power and leads to the identification of nine new loci associated with serum uric acid levels. Increased resolution in trans-ancestral GWAS, with functional annotation enrichments, improves fine-mapping of serum urate GWAS loci.

OP0264

CAN MODERATE ALCOHOL INTAKE LOWER THE RISK OF MYOCARDIAL INFARCTION AND MORTALITY EVEN AMONG GOUT PATIENTS?

H.K. Choi 1, N. Lu 2, S.K. Rai 3, S.F. Keller 1, A.M. Jorge 1, Y. Zhang 1, 2, 3, 4, 5, 6, 7, Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital; 2 Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, United States

Background: While alcohol is a well-established risk factor for gout, many prospective studies have consistently found that moderate alcoholic consumption is associated with a 25–40% reduced risk for coronary heart disease (CHD) and death. As such, the American Heart Association (AHA) suggests that “if you drink alcohol, do so in moderation”. As gout is associated with an increased risk of CHD and premature mortality, the potential benefits of drinking in moderation may also be applicable to gout patients provided that their gout is under control with other measures.

Objectives: To examine the relation between alcohol intake and the risk of acute myocardial infarction (AMI) and all-cause mortality among incident gout patients in a general population context.

Methods: We conducted a cohort study using data from an electronic medical record database representative of the UK general population, collected between 1996 and 2015. The exposure of interest was the first alcohol intake measured after gout diagnosis, and our endpoints were incident cases of AMI as well as all-cause mortality. Stratifying by sex, we calculated the hazard ratios (HR) of these endpoints according to alcohol intake categories (i.e., 0, 1–9, 10–24, 25–42, and >42 units/week), adjusting for age, smoking status, body mass index, duration of gout, comorbidities, and medication use. We performed a spline model analysis using 4 knots of the alcohol intake categories, hypothesizing a J-shaped relation as observed in general population studies.

Results: Among 55,584 gout patients (78% male, mean age of 63 years), 1,332 developed AMI and 8,362 died over a mean follow-up of 5.6 years. Compared with men who did not drink alcohol after gout onset, men who drank alcohol had a lower risk of AMI as well as mortality in a J-shaped manner (Figure 1, left panel). The multivariable HRs for developing AMI were 1.0, 0.76 (95% confidence interval [CI], 0.63–0.93), 0.68 (0.55–0.83), 0.69 (0.59–0.89), and 0.71 (0.52–0.95) for alcohol use categories of 0, 1–9, 10–24, 25–42, and >42 units/week, respectively, and the corresponding HRs for mortality were 1.0, 0.77 (95% CI, 0.71–0.82), 0.71 (0.66–0.77), 0.74 (0.66–0.82), and 0.89 (0.78–1.01) (Figure 1, left panel). While alcohol consumption levels and sample sizes were smaller among women, the J-shaped relation was more obvious and showed a significantly increased risk of mortality in the top consumption category (HR=1.68; 95% CI, 1.09–2.61) (Figure 1, right panel).

Conclusions: This general population-based study indicates that moderate alcohol intake is associated with a lower risk of AMI as well as all-cause mortality among gout patients, similar to many general population studies. These findings suggest that the AHA recommendation about moderate alcohol use may also be applicable to gout patients for their cardiac health and improved survival, provided that their gout is under control with other measures.

**OP0265** VALIDATION OF A DEFINITION FOR ATTACK (FLARE) IN PATIENTS WITH ESTABLISHED GOUT

A. Gaffo 1,2, N. Dalbeth 3, J. Singh 1,2, K. Saag 1, W. Taylor 4. 1University of Alabama at Birmingham, Birmingham, United States; 2Birmingham VA Medical Center, Birmingham, United States; 3University of Auckland, Auckland, New Zealand; 4University of Otago, Otago, New Zealand

**Background:** A standardized validated definition for gout attacks (flares) is not available. Two provisional definitions published in 2012 were based on patient-reported elements (patient-defined attack, pain at rest greater than 3 in a 0–10 numeric rating scale, presence of at least one swollen joint, presence of at least one warm joint) (1). These definitions had acceptable sensitivity and specificity but lacked external validation which is necessary before they can be adopted in gout clinical studies.

**Objectives:** To perform external validation of previously published preliminary gout attack (flare) definitions in patients with gout.

**Methods:** We enrolled 509 participants with gout from 17 international sites in a cross-sectional study performed during routine clinical care. All patients met the 2015 ACR/EULAR classification criteria for gout (2). Criteria for the previously published gout attack definitions were collected by a site investigator and the final adjudication of a gout attack status was done by a local expert rheumatologist, through an evaluation independent from that of the site investigator. Logistic regression, Bayesian statistics, and receiver-operator curves were used to calculate the final diagnostic performance of the attack definitions.

**Results:** The mean age of participants was 57.5 years (standard deviation [SD] 13.9) and 89% were men. Mean disease duration was 12.3 (SD 10.3) years, 35% had tophi, and 75% were taking urate-lowering therapies. The previously published and favored definition requiring the presence of 3 or more out of 4 criteria (“number of criteria”) was found, using the current study data, to be 85% sensitive and 95% specific in confirming the presence of an attack in patients with gout (Table). The concurrent logistic regression model had an area under the curve of 0.97. The previously published definition based on a classification and regression tree algorithm (entry point pain at rest >3 followed by patient-defined attack “yes”) was 73% sensitive and 98% specific using the current study data (Table). The “number of criteria” approach with a cut-point at 3 or more out of 4 criteria had higher diagnostic accuracy using the current study data than in its initial description 2012 (92% versus 84%, table). (1) Finally, using current study data the “number of criteria” approach at 3 or more out of 4 criteria had higher accuracy to the classification and regression tree algorithm based approach (92% versus 89%) but with a much better sensitivity (85% versus 73%).

**Conclusions:** Despite a stable dose of allopurinol for more than 3 months, and even with sUA at the target level, a substantial proportion of patients with gout continue to have evidence of MSU crystal deposition by DECT scan. Patients with palpable tophi, sUA levels >6.0 mg/dL and palpable tophi showed the highest prevalence of urate deposits (90%), and those with sUA <6.0 mg/dL and no palpable tophi showed the lowest prevalence (47%). Those who reported a gout flare within the prior 3 months (versus none), were prescribed allopurinol doses >300 mg (versus 300 mg), and had palpable tophi (versus none) had greater total volume of crystals.

**OP0266** PRESENCE OF MONOSODIUM URATE CRYSTALS BY DUAL-ENERGY COMPUTED TOMOGRAPHY IN GOUT PATIENTS TREATED WITH ALLOPURINOL

N. Dalbeth 1, S. Nicolau 2, S. Baumgartner 3, J. Hu 4, M. Fung 4, H.K. Choi 4. 1University of Auckland, Auckland, New Zealand; 2Vancouver General Hospital and University of British Columbia, Vancouver, Canada; 3Formerly Ardea Biosciences, Inc, San Diego; 4Harvard Medical School and Massachusetts General Hospital, Boston, United States

**Background:** Chronic hyperuricemia predisposes to deposition of monosodium urate (MSU) crystals in musculoskeletal and other tissues, causing chronic inflammation, acute gout flares, joint damage, and disfiguring tophi. Dual-energy computed tomography (DECT) is a useful imaging tool to detect and quantify MSU crystal deposits.

**Objectives:** This study assessed the evidence of MSU crystal deposition using DECT scanning among gout patients treated with allopurinol and the potential determinants associated with the observed deposits.

**Methods:** The multicenter DECT study recruited patients with gout from the USA and New Zealand who were taking allopurinol at >300 mg daily for at least 3 months. MSU crystal deposition was measured using DECT in hands/wrists, knees, and feet/ankles bilaterally. The presence of MSU crystals as well as the total volume of crystals were assessed according to gout characteristics and serum uric acid (sUA) levels.

**Results:** Patients (N=153) were predominately male (92.2%), with mean (SD) age 58.5 (11.4) years, and gout duration 14.9 (10.3) years. sUA was >6.0 mg/dL in 49.0% of patients. 81.7% of patients took allopurinol at a stable dose of 300 mg/day and the remainder at >300 mg/day. 69.1% of patients had MSU crystal deposits with a total median crystal volume of 0.16 cm³ (range, 0.01 to 19.3 cm³). Those with sUA >6.0 mg/dL and palpable tophi showed the highest prevalence of urate deposits (90%), and those with sUA <6.0 mg/dL and no palpable tophi showed the lowest prevalence (47%). Those who reported a gout flare within the prior 3 months (versus none), were prescribed allopurinol doses >300 mg (versus 300 mg), and had palpable tophi (versus none) had greater total volume of crystals.

**Conclusions:** Despite a stable dose of allopurinol for more than 3 months, and even with sUA at the target level, a substantial proportion of patients with gout continue to have evidence of MSU crystal deposition by DECT scan. Patients with palpable tophi, sUA levels >6.0 mg/dL, and gout flares within the prior 3 months have a greater volume of MSU crystal deposition. These patients may need continuation and/or intensification of their urate-lowering therapy regimen.

**OP0267** SERUM URATE AS A SURROGATE ENDPOINT FOR GOUT FLARES: RESULTS OF A SYSTEMATIC REVIEW AND META-REGRESSION ANALYSIS OF RANDOMIZED TRIALS

L. Stamp 1, M. Morillon 2, W. Taylor 3, N. Dalbeth 4, J. Singh 5, R. Christensen 6. 1Medicine, University of Ottawa, CCHRitchurch, Christchurch, New Zealand; 2Odense University Hospital, Odense, Denmark; 3University of Otago, Wellington; 4University of Auckland, Auckland, New Zealand; 5University of Alabama, Birmingham, United States; 6Musculoskeletal Statistics Unit, The Parker Institute, Odense, Denmark

**Background:** The primary outcome measure for efficacy in clinical trials of urate lowering therapy (ULT) is frequently serum urate (SU), effectively acting as a surrogate for patient-centred outcomes (e.g. gout flares). It has not been clearly demonstrated that the strength of the relationship between SU and patient-centred outcomes is strong enough for SU to be considered a surrogate.

**Conclusions:** Despite adequate SU levels, a substantial proportion of patients continued to have evidence of MSU crystal deposition by DECT scan. Patients with palpable tophi, SU levels >6.0 mg/dL, and gout flares within the prior 3 months have a greater volume of MSU crystal deposition. These patients may need continuation and/or intensification of their urate-lowering therapy regimen.

**Acknowledgements:** This study was sponsored by Ardea Biosciences/As- traZeneca.

DOI: 10.1136/annrheumdis-2017-eular.3666
Conclusions: Substituting surrogate endpoints (proportion achieving target SU) for the important clinical outcome (gout flares) allows conduct of shorter smaller trials. However, based on aggregate trial-level data (meta-regression) an anticipated association between SU and gout flare could not be confirmed. Trial duration may have been too short to observe a reduction in flares and further work using data from long-term extension studies is underway.

NURSE-LED CARE VERSUS GENERAL PRACTITIONER CARE OF PEOPLE WITH GOUT: A UK COMMUNITY-BASED RANDOMISED CONTROLLED TRIAL

M. Doherty1, W. Jenkins1, H. Richardson1, A. Abhishek1, D. Ashton1, G. Barclay1, L. Duley2, H. Jones3, M. Santarelli1, A. Sarmanova1, M. Stevenson1, W. Zhang1, Division of Rheumatology, Orthopedics and Dermatology; 2Clinical Trials Unit, University of Nottingham; 3Health Economics and Decision Science, University of Sheffield, Sheffield, United Kingdom

Background: Despite increasing prevalence of gout in the UK (1), a variety of barriers result in suboptimal care (1.2) with only 40% of gout patients receiving urate-lowering therapy (ULT), usually at fixed dose without titration to a serum uric acid (SUA) target (1.2). Nurses successfully manage many chronic diseases in the community, and we have shown that when provided with gout are fully informed and involved in management decisions uptake of ULT is high and persistence and adherence under nurse-led care is excellent (3).

Objectives: To directly compare nurse-led care to general practitioner (GP) care of people with gout in a 2 year randomised controlled trial (NIHR CRN Portfolio No.12943)

Methods: 517 participants with acute gout in the previous year were identified from 56 local GP practices and randomised to nurse-led or continuing GP care. The nurses were trained about gout and its management according to recommended best practice (EULAR and BSR guidelines) involving full information, addressing illness perceptions, and involving patients in management decisions. Assessments were undertaken at 1 and 2 years. Analysis was intention to treat (last observation carried forward).

Results: Nurse (n=255) and GP (n=262) groups were well matched at baseline for mean age (62 v 64yrs), sex (90% v 89 men), mean disease duration (11.6 v 10.6 yrs), mean gout attack frequency (2.1 v 2.2) in prior year (4.2 v 3.8), tophi (13.7% v 8.8%), mean SUA (443 v 439 μmol/L), mean eGFR (71.5 v 70.2) and ULT use (40% v 39%) (all p>0.05). By 2yrs, 22 (8.6%) and 54 (20.6%) participants had discontinued the nurse and GP groups (p<0.001), including 2 v. 8 deaths respectively. Comparing nurse and GP groups at 2yrs: 95% v 29% had SUA ≤300 μmol/L, 88% v 16% had SUA <350 μmol/L, mean SUA was 252±73 v 418±106, 97% v 54% were on ULT; and mean (SD) dose of allopurinol was 470 (140) v. 240 (107) mg/day (all p<0.001). Mean (SD) attack frequency during the 2nd year was 0.33 (0.93) in the nurse v. 0.94 (2.03) in the GP group (p<0.001). At 2yrs, tophi were present in 15% (reduced) v. 9.6% respectively (p<0.002). Although equivalent at baseline, mean (SD) SF-36 norm-based physical component scores were better at 2yrs in the nurse group (41.31 v 16.76) and 37.87 (14.31) v 30.05 (p<0.05).

Conclusions: Nurse-led care of people with gout in the UK community can result in high uptake and excellent adherence to ULT over a 2yr period, achievement of target SUA in >9/10 cases and consequent improvements in patient-centred outcomes and quality of life. This study reinforces the benefits of “treat-to-target”. Compared to standard GP care this model is likely to be cost effective long-term and merits further consideration.

EFFECT OF XANTHINE OXIDASE INHIBITORS ON THE INCIDENCE OF CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS

M. Brederemeier, L.M. Lopes, M.A. Eisenreich, G.K. Bongiorno, S. Hickmann, Rheumatology Division, Hospital Nossa Senhora da Conceição - Grupo Hospitalar Concepção, Porto Alegre - RS, Brazil

Background: There is evidence that xanthine oxidase inhibitors (XOI) may reduce the risk of major adverse cardiovascular events (MACE) (1,2) and lower blood pressure (3). To date, this evidence is based mainly on observational studies (2).

Objectives: To compare the incidence of MACE, mortality, and total and specific cardiovascular (CV) events in patients enrolled in randomized controlled trials (RCTs) comparing XOI with placebo or no treatment.

Methods: A systematic review (CRD42015016073) searching for RCTs using PubMed, EMBASE, Cochrane Library, Web of Science, and Lilacs databases, and hand searching, was ended in Dec 2016. All RCTs comparing XOIs with placebo or no treatment lasting ≥4 weeks and including only adult individuals were eligible. The primary outcomes were the incidence of MACE (CV death, non-fatal myocardial infarction, unstable angina requiring urgent revascularization, or non-fatal stroke) and mortality; total CV events (TCE), specific CV outcomes, and serious adverse events (SAE) served as secondary outcomes. Associations were tested using the Peto odds ratio (OR) without zero-cell continuity correction.

Results: In total, 81 studies including approx. 11,000 individuals reported extractable data on CV events. The use of XOI tended to be associated with lower incidence of MACE (OR=0.64, 95% CI 0.41–1.01, P=0.056), but not with mortality (0.95, 0.63–1.44). However, there was a significantly reduced incidence of TCE (0.66, 0.54–0.80, P<0.001), especially new/worsening hypertension (0.57, 0.37–0.87, P=0.009), and a trend for reduction in the incidence of new/worsening heart failure (0.74, 0.53–1.04, P=0.086). The incidence of SAE (0.86, 0.71–1.05) did not differ significantly. Subgroup analysis suggested a protective effect for MACE in studies with high prevalence (<50%) of cardiac diseases (0.52, 0.30–0.91, P=0.021). Sensitivity analysis excluding studies at high or unknown risk of bias did not change these results. A meta-regression analysis suggested a protective effect with reduced incidence of hypertension (0.26, 0.11–0.60, P=0.001) and heart failure (0.55, 0.32–0.94, P=0.030). Separate analysis of data on purine-like XOI (allopurinol and oxypurinol) confirmed the results of the primary analysis. Exploratory metaregression analysis showed association of dose of allopurinol with higher incidence of TCE (P=0.023, random effects) and SAE (P<0.001, see Figure 1). Accordingly, in the subgroup with doses <300 mg/day of allopurinol, a reduction of incidence of MACE (0.36, 0.18–0.68, P=0.002), TCE (0.38, 0.26–0.54, P<0.001), and SAE (0.49, 0.34–0.71, P=0.001) was observed, while the SAE risk increased in doses ≥300 mg/day (1.39, 1.04–1.91, P=0.047). There was

Disclosure of Interest: None declared

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5006
no association of dose of non-purine-like XOI with incidence of TCE and SAE. Significant statistical heterogeneity was not observed in any test reported here.

Conclusions: Our data from a meta-analysis of RCTs suggest that XOIs reduce the incidence of CV events, an effect possibly related (at least partly) to control of hypertension. However, higher doses of allopurinol (>300 mg/day) may possibly be associated with higher risk of serious adverse events and loss of cardiovascular protection.

Low back pain and fibromyalgia

OP0270  LONG-TERM PROGNOSIS IN CHRONIC PLANTAR FASCIITIS BASED ON DISEASE DURATION AND ULTRASONIC CHANGES

L. Hansen1, U. Fredberg1, T.P. Krogh1, T. Ellingsen1,2, L.B. Hansen3.
1Diagnostic Centre, Regional Hospital Silkeborg, Silkeborg; 2Department of Rheumatology, Odense University Hospital, Odense; 3Radiologic Department, University Hospital Aarhus, Aarhus, Denmark

Background: Plantar fascitis (PF) affects 7–10% of the population over a lifetime but the long-term prognosis is unknown. This study is the greatest within the long-term prognosis of PF and have the longest follow-up time.

Objectives: The aim was to assess the long-term prognosis of chronic PF based on duration of symptoms and ultrasonic changes (tendon thickness, heel spur, echogenicity and heel fat pad) and assess if any baseline cohort characteristics had an impact on the prognosis (sex, BMI, age, smoker status, physical work/sport and bilateral pain).

Methods: At baseline (2001–11) 269 patients were diagnosed with PF based on symptoms and ultrasound findings. At follow-up (2016) all the participants were invited to participate in the project. Everyone was interviewed and offered a new ultrasound examination of their plantar fascia at both feet.

Results: 174 (65%) participated in the study. 52 women and 46% men and 137 had an additional US examination. 54% of the participants were asymptomatic at follow-up (asymptomatic group) and the mean duration of symptoms were 725 days (range 41–4018), 46% still had symptoms (symptomatic group). The follow-up period was 9.7 years (range 4.7–27.3). The risk of having chronic PF were 45.6% (95% CI 37.9–53.0) 10 years after debut of symptoms (figure 1).

A multiple analysis found that women (p<0.01) and participants with bilateral heel pain (p<0.01) had a worse prognosis. The hazard rate ratio was 0.49 (95% CI 0.30–0.80) for women (every time 100 men were getting cured ≥1.5) and the number of patients with low disease activity (LDA) (pain score <2.0). Patients were followed up for 6 months.

Results: A total of 46 patients were included and there were no significant differences between the 2 groups in terms of the reduction in pain at one month post-injection, with scores of -1.5 and -2.5 (p=0.23) in the Treatment and Placebo groups respectively. When including all measures in the first 3 weeks post-injection the difference in pain was statistically significant (p<0.001) in the injected group.

Low back pain and fibromyalgia

OP0271  CORTICOSTEROID INJECTIONS FOR GREATER TROCHANTERIC PAIN SYNDROME: A RANDOMIZED DOUBLE-BLIND PLACEBO-CONTROLLED TRIAL

M. J. Nissen1, L. Bruhlart2, A. Faundez3, A. Finckh1, D. Courvoisier1, S. Genevey1, T. Pelletier1, R. Schett1, H. Gaulard1, G. Fossard1, 2Rheumatology, Neuchatel Hospital, Neuchatel; 3Orthopaedics and Traumatology, Geneva University Hospital, Geneva, Switzerland

Background: Although small observational studies have suggested that local corticosteroid (CS) injection may be effective in the management of the greater trochanteric pain syndrome (GTPS), no prospective placebo controlled study has been carried out to establish the efficacy of this common intervention.

Objectives: To perform a randomized double-blind placebo controlled trial to investigate the efficacy of local CS injection in the management of GTPS.

Methods: The trial was conducted in the Rheumatology unit of a University teaching hospital in Geneva, Switzerland. Inclusion criteria were lateral hip pain (LHP) for greater than 1 month, a LHP score of ≥4 in the preceding week, failure of another standard treatment (physiotherapy, analgesics, etc.) and typical LHP reproduced by palpation of the greater trochanter (GT). Participants were randomised in a 1:1 ratio to: 1) injection with a combination of local anaesthetic and CS (Treatment group), or 2) injection with normal saline solution (Placebo group). The Treatment group received 4ml of 1% Lidocaine (Rapicain®) and 1ml of Betametasone (Diprophos®). The Placebo group received 5ml of sterile saline solution. Injections were performed under ultrasound guidance. The study’s predefined primary outcome of interest was the difference in pain intensity at 4 weeks post-injection between the 2 groups. Secondary outcomes included the number of “responders” (pain score improvement of ≥1.5) and the number of patients with low disease activity (LDA) (pain score <2.0). Patients were followed up for 6 months.

Results: A total of 46 patients were included and there were no significant differences between the 2 groups at baseline (Table 1). There were no significant differences between the 2 groups in terms of the reduction in pain at one month post-injection, with scores of -1.5 and -2.5 (p=0.23) in the Treatment and Placebo groups respectively. When including all measures in the first 3 weeks and using multilevel regression, there was a marginally significant improvement

Except where indicated otherwise, values are the mean (± standard deviation). GT = greater trochanter region.
in pain scores in favour of the Treatment group (p=0.08) (Figure 1). There were no significant differences in terms of the percentage of responders (p=0.32), or patients with LDA (p=0.50) between the 2 groups at follow up. There were no significant differences in pain scores between groups at 3 and 6 months post-injection.

Conclusions: Local corticosteroid injection in the management of GTPS is only marginally effective for a few weeks. Given the lack of long-term improvement and the potential for cortisone-related side-effects, this intervention is of limited benefit.

OP0272 CHRONIC LOW BACK PAIN AND ANXIETY: SIGNIFICANT DECREASE WITH GLUCOSAMINE-CHONDROITIN SULFATE TREATMENT IN A LARGE, COMMUNITY-BASED, PILOT, OPEN PROSPECTIVE INTERVENTIONAL STUDY

G. Singh 1, L. Alekseeva 2, D. Gorachev 2, A. Barinov 2, E. Nasonov 2, A. Mithal 2
1 Gastroenterology and Hepatology, Stanford University, Woodside, United States; 2 State NII of Rheumatology of Russian Academy of Sciences; 3 First Moscow State University, Moscow, Russian Federation; 4 ICORE, Woodside, United States

Background: Low back pain (LBP) is associated with 2.3, 2.2, and 1.6 times greater odds for mood disorders, anxiety disorders and alcohol abuse respectively (1). Continued anxiety may lead to a state of “learned helplessness”, and both can propagate in a vicious cycle. Glucosamine-chondroitin sulfate (GCS) combination is widely used in the treatment of OA; however there are few prospective studies of its therapeutic merits in LBP.

Objectives: To study the efficacy of GCS in the decreasing anxiety in patients with chronic LBP in a large open pilot prospective study.

Methods: We enrolled patients 40-65 years of age who had LBP for >12 weeks with pain intensity > 3 on a 0-10 point VAS in a single-arm, open-label prospective interventional study. Major exclusion criteria were the presence of fibromyalgia, spondylolisthesis, and alcohol and/or drug abuse. All patients were treated with ARTFA (combination glucosamine hydrochloride 500 mg - chondroitin sulfate 500 mg in tablet form; Unipharm Inc.) at a dose of 1 tab daily for the first month and then 1 tab daily for the next two months. The primary endpoint was pain intensity as measured on a 0-10 point VAS. Secondary endpoints included anxiety levels measured by Spielberger's State Trait Anxiety Inventory (STAI) adapted for Russia by Khanin (2). STAI evaluates the current "state" of anxiety, asking how respondents feel "right now," using items that measure subjective feelings of apprehension, tension, nervousness, worry, and activation/arousal of the autonomic nervous system as well as aspects of "anxiety proneness," including general states of calmness, confidence, and security ("trait"). Scores for each scale range from 20 to 80, with higher scores indicating greater anxiety.

Results: Overall 3932 eligible FM patients were identified, 88.7% females, mean SD (age =49.2 (12.7). Pre-diagnosis use of medications of interest was documented in 41% of the patients. Of the remaining 2312, 56.1% were issued a prescription in the year following diagnosis and 45.0% dispensed at least on medication. One-year discontinuation rate reached 79.3% overall, and was highest for tricyclic antidepressants and lowest for SSRIs/SNRI antidepressants (Table 1). Over one half of the patients (60.5%) were poorly adherent (PDC ≥20%) during the year and only 9.3% were highly adherent (PDC ≥80%). High adherence was positively associated with socio-economic status (p-for-trend=0.022).

</table>

*Percent of patients with at least one dispense out of those prescribed, e.g. 228/313x100=72.8% for anti-epileptic drugs. **% of those with ≥1 dispense.

Conclusions: Persistence and adherence with FM therapy in the year following diagnosis is remarkably poor. Further research is needed to assess ways to improve continuation with therapy among FM patients.

OP0274 FIBROMYALGIA IN REAL LIFE: A NATIONAL FRENCH WEB-BASED SURVEY IN 4516 PATIENTS

E Larochette 1, J. Guérin 1, D. Azoulay 1, J. Coste 2, S. Perrot 1, 1 Pain Department, Hospital university Saint Antoine; 2 Biostatistics, Hospital University Hotel Dieu; 2 Pain Department, Hospital University Cochin, Paris, France

Background: Fibromyalgia (FM) is the most frequent widespread chronic pain disorder (1.6% of the French population) (1). The medical and socioeconomic burden is high and severity depends on medical status and symptoms as defined by the OMERACT criteria (2). Most of the studies are performed in specialized centers recruiting the most severe patients, but very few data exist on its real impact on daily life.

Objectives: The aims were to collect demographic data, symptoms, function, diagnosis, management strategies and health care utilization in real life, in a large population, and to determine clusters of patients.

Disclosure of Interest: None declared

References:
Methods: A large internet-based national survey of people suffering from FM was developed by a national patient association (Fibromyalgie-SOS Association) on their website, in France in 2014. The survey included 103 qualitative and quantitative questions that were developed by 3 medical experts (including rheumatologists) and patients.

Results: The questionnaire was completed by 4516 people. Respondents were predominantly middle-aged (48 yrs) females (93%), most of whom had FM symptoms duration for 12 years and a diagnosis for 5 years. Diagnosis was made by a rheumatologist in 54% of the cases. The symptoms were concordant with the OMERACT domains (chronic pain, fatigue stiffness and other FM-associated symptoms) as previously published by Bennett in 2007 (3). The mean FIQ (Fibromyalgia Impact Questionnaire) score was 51 (0–100); 55% were currently working but 65% of them have been on sick leave in the 12 previous months. FIQ was mostly impacted by injustice feeling (+4.5), part time job (+2.4) and low income - less than 1000 euros monthly (+2.3) (linear regression). Somatic comorbidities were mostly osteoarthritis (49%). Psychological comorbidities were injustice feeling (77%), cognitive symptoms (62%; anxiety (52%) and depression (48%). Initiating factors were reported by 73% of them: physical (50%) and/or psychological (76%). Aggravating factors included excess of activities, conflicts, traumaism and displacement. Treatments were provided by general practitioner (85%), physiotherapist (63%), rheumatologist (54%) and osteopathic manual practitioner (41%). Treatment was prescribed in 76.6% of the patients, including paracetamol alone (51.4%), paracetamol and weak opioids (64%), strong opioids (20.1%), antidepressants (8.1%), antiepileptic agents (54.9%), non-steroid anti-inflammatories (NSAIDs) (53.8%), anxiolytics (52.4%) and steroids (12.8%).

Conclusions: This unique descriptive survey in a large population provides data on symptoms, emotional distress, prescribing habits and impact of FM on daily life and work. Results show that FM is altered by emotional (including injustice feeling) and socio-economic factors.

OP0275 FIBROMYALGIA PREVALENCE AND IMPACT ON DISEASE ACTIVITY SCORES IN RHEUMATOID ARTHRITIS PATIENTS WHO ARE UNRESPONSIVE TO BIOLOGICAL TREATMENT
L.J. Ghile 1, M.M. Tamas 1, I. Felea 2, L. Damin 2, I. Filipescu 1, A. Mociran 2,
S.-P. Simon 1, L. Muntean 1, S. Rednic 1, 1Rheumatology, “Iuliu Hatieganu” University of Medicine and Pharmacy; 2Rheumatology, Emergency County Hospital, Cluj Napoca, Romania

Background: Rheumatoid arthritis (RA) treatment uses a treat-to-target strategy. Treatment response is assessed using disease activity scores that consider disease activity, associated symptoms (1). The Journal of Rheumatology, 2011; 38: 1487–95.

Objective: To assess the efficacy of a single glucocorticoid intradiscal injection (GC IDI) in cLBP patients with active discopathy.

Methods: We conducted a prospective, parallel-group, double-blind, randomized controlled study in 3 tertiary care centers in France. 135 cLBP patients with active discopathy were enrolled. They received a single GC IDI (25 mg prednisolone acetate) during discography (n=67) or discography alone (n=68). The primary outcome was the percentage of patients with LBP intensity in the previous 48 hr <40 on an 11-point numeric rating scale (NRS, 0 no pain - 100 maximal pain) at 1 month. The secondary outcomes were LBP intensity and persisting active discopathy on MRI at 12 months post-intervention, and spine-specific limitations in activities, health-related quality of life, anxiety and depression, employment status and analgesics and non-steroidal anti-inflammatory drugs consumption at 1 and 12 months post-intervention.

Results: All randomized patients were included in the primary efficacy analysis. At 1 month, the percentage of responders (LBP intensity <40) was higher in the GC IDI than control group (36/65 [55.4%] vs 21/63 [33.3%]; absolute risk difference [95% confidence interval] 22.1 [5.5;38.7]; p=0.009). In the sensitivity analysis, mean reduction in VAS pain (85% CI) in LBP intensity from baseline to 1 month was greater in the GC IDI group compared to the control group -32.5 [-38.2; -26.8] vs -17.5 [-33.3; -11.7]; respectively; absolute difference [95% CI] -15.0 [-22.9; 7.1], p=0.001. At 1 month, the percentage of patients reporting an improvement in spine-specific limitations in activities was higher in the GC IDI than control group (55/65 [84.6%] vs 34/63 [54.0%]; absolute risk difference [95% CI] 30.5 [15.7; 45.2], p<0.001. The 2 groups did not differ in LBP intensity at 12 months and in most of the secondary outcomes at 1 and 12 months. 102/119 (85.7%) patients would agree to a second intervention. The authors thank URC-CIC Paris Descartes (Christelle Op de Casteleijn) for statistical analysis.

Conclusions: In active discopathy-associated cLBP, a single GC IDI reduces LBP at 1 month post-intervention but not at 12 months.

MORE PARTICIPATION, BETTER HEALTH – PROMOTING PUBLIC INVOLVEMENT IN HEALTH

S. Crisostomo 1, M. Santos 1, M. Serapioni 2, A.R. Matos 2, E.F. Mateus 3 on behalf of MAIS PARTICIPAÇÃO, melhor saúde. 1GAT - Grupo de Ativistas em Tratamentos, Lisboa; 2Centro de Estudos Sociais da Universidade de Coimbra, Coimbra; 3Liga Portuguesa Contra as Doenças Reumáticas, Lisboa, Portugal

Background: In Portugal, the National Health Plan for 2012-2016 (1) and its extension to 2020 (2) consider citizenship-based strategies, including the involvement of patients/citizens and their representatives, as a key strategic axis to maximize health gains. However, actual policy initiatives and concrete actions have been limited to a couple initiatives without significant patient or public involvement. On the other side, several patient and citizen organizations (3-6) have been advocating for increased and meaningful involvement in health decision-making.

Objectives: To develop a Charter for Public Involvement in Health that is widely accepted and recognized by health stakeholders.

Methods: A working group was established with representatives from 13 patient organizations, 1 consumer organization and a research centre. A participatory action research methodology was used. The draft Charter was circulated for review and signature among more than 200 non-profit health-related organizations and over 50 key individuals publically renowned for their work in health or public participation. The final version of the Charter was discussed with political and health stakeholders in a Forum held at the Portuguese parliament.

Results: A Charter for Public Involvement in Health, including the principles, scope, guidelines and means of participation was developed. In January 2017, 30 individuals (former and current political decision-makers, health care professionals, researchers and patients) and more than 82 non-for-profit health-related organizations (the majority being Portuguese disease-specific patient organizations) had signed the Charter. The conclusions of the Forum show that the Charter was recognized as a very important initiative to promote public involvement in health in Portugal. Challenges and barriers to further advancing patient and public engagement were also identified (e.g. political will, recognitions of patients as partners, patient empowerment, capacity-building, etc.). The Charter and the Forum were covered in the media and follow-up initiatives with health care professionals and hospital administrators are ongoing.

Conclusions: A patient-led Charter, developed by patient and consumer representatives, in collaboration with academia, and the public discussion with other health care stakeholders have proven successful to put public participation in the political and health care agenda.

Families with children so that as many as possible would find the services offered by FRA and its local member associations.

Methods: The first stage of the project involved conducting a survey in order to find out what the package should contain. The survey was directed to parents to children with JIA, rheumatology nurses and rheumatologists. The content of the information package:

1) An initial information binder with the following information: about JIA, food, physical activities & play, sitting & writing, eyes & dental care. There is also a separate section directed to parents.
2) A so-called gym tail and easy-to-do gymnastic instructions. 3) Bunny 4) Coloured pencils and a pen thickener. 5) A picture book about visiting a rheumatology clinic for the child. 6) Brochures: e.g. information about JIA for the closest relatives of a child diagnosed with JIA and health care professionals, information about FRA for families with children. 7) Gymnastics bag The second stage involved planning the content and the look of the material. The information package and its content needed be positive and functional – the package as a whole had to be suitable for children. The pictures and text for the picture book were also produced in cooperation with the healthcare professionals. Multiple channels were used to spread the information that the package had been completed, e.g. social media, the FRA website and emails to the target group.

In addition, the rheumatology careunits were given instructions and informed of what to expect.

Results: The packages were very well received. We have received positive feedback from both rheumatology clinics and families with children suffering from JIA.

Conclusions: There was a real need for the information packages and the information that they provide help both the families and the healthcare staff.

When a child suffers from an illness, it affects the whole family, and hence it is crucial that comprehensive – and comprehensible – information and support are available so that everyday life runs smoothly and is meaningful, and so that a child with an illness does not feel like he or she is a burden to the family but considers him- or herself an equal member of the family.

INITIAL INFORMATION PACKAGE FOR CHILDREN DIAGNOSED WITH JIA

T. Pakkala, M. Ekroth, Finnish Rheumatism Association, Helsinki, Finland

Background: Both parents of children with JIA and rheumatology nurses have informed FRA from time to time that there is a need for an initial information package. There was a demand for information that catered to children’s needs and that was suitable for them and their closest relatives at the stage when the diagnosis is shared with the family.

Objectives: The aim of the project was to make an information package for children aged 0 to 12. A child with JIA needed to be provided with information and text for the picture book were also produced in cooperation with the healthcare professionals. Multiple channels were used to spread the information that the package had been completed, e.g. social media, the FRA website and emails to the target group.

In addition, the rheumatology careunits were given instructions and informed of what to expect.

Results: The packages were very well received. We have received positive feedback from both rheumatology clinics and families with children suffering from JIA.

Conclusions: There was a real need for the information packages, and the information that they provide help both the families and the healthcare staff.

When a child suffers from an illness, it affects the whole family, and hence it is crucial that comprehensive – and comprehensible – information and support are available so that everyday life runs smoothly and is meaningful, and so that a child with an illness does not feel like he or she is a burden to the family but considers him- or herself an equal member of the family.

THE FRENCH PATIENT’S ASSOCIATION (AFLAR): FRENCH LEAGUE AGAINST RHEUMATISM) HAS GENERATED THE FRENCH NATIONAL ALLIANCE AGAINST OSTEOARTHRITIS AND THE FIRST GENERAL CONVENTION OF OSTEOARTHRITIS IN FRANCE; A CAMPAIGN TO CREATE A NATIONAL LOBBYING TOOL TO IMPROVE THE MANAGEMENT OF OSTEOARTHRITIS

L. Grange 1,2, F. Rannou 3, F. Berenbaum 4, E.F. Mateus 3 on behalf of MAIS PARTICIPAÇÃO, melhor saúde. 1GAT - Grupo de Ativistas em Tratamentos, Lisboa; 2Centro de Estudos Sociais da Universidade de Coimbra, Coimbra; 3Liga Portuguesa Contra as Doenças Reumáticas, Lisboa, Portugal

Background: OA suffers from a lack of interest and not considered serious...
enough by Health authorities taking into account the burden of the disease. AFLAR has fostered dynamics by creating a structure called the National Alliance against OA, includes national experts, patients and health professionals (HP). A initiative of this group has been to organize the first General Convention for OA.

**Objectives:**
- Its main challenge was to provide a list of actions that could propose to the French authorities to improve the visibility of OA along with the needs and demands from French patients.

**Methods:**
- 10 regional roundtables (with HP, patients and health institutions, around five topics) has been launched with discussions and debates and enabled the production of patient-related proposals in order to improve their care and information.

**Results:**
- 79 proposals have been selected and submitted to an online vote in order to be prioritized. Among the 5 topics addressed by the regional roundtables, cross-cutting issues were identified and 9 fields of action emerged. The final proposals were synthesized in a White Paper document and presented to the national Senate assembly. After it was broadcast to the health and public authorities in a prospect of lobbying, see in the image.

**Conclusions:**
- Although the impact of this initiative is not yet measurable, we think it will give a clearer picture of how the disease has been active or not in the following years. It will facilitate a better dialogue at clinician appointments.

RMDS. A learning partnership should be created between undergraduate medical students/healthcare professionals and the patient experts.

Methods: CYPLAR approached the Swedish Rheumatism Association for collaboration in order to implement the Patient Expert Project in CYPLAR. Funding was received from the EULAR Knowledge Transfer Programme. The collaboration was planned to consist of two meetings, one in Sweden and one in Cyprus.

1. Sweden: Two patients, members of CYPLAR, with RMDS, together with a Rheumatologist from CYPRUS visited the Swedish Rheumatism Association in Stockholm to learn about the Patient Partner Project, and receive Patient Expert training.

2. Cyprus: Two Patient Partner Instructors from the Swedish Rheumatism Association went to Cyprus 6 months after to oversee the progress of the Patient Expert programme and to make an examination of the two Patient Partners educated in Stockholm.

Results: The training session in Stockholm took place on May 2016, for two patients. They received training following the Swedish Patient Expert programme. This training was conducted by two Patient Expert Instructors, one rheumatologist and one Patient Expert. A visit to the Karolinska University Hospital with a tour of the Rheumatology Clinic and a Patient Expert demonstration was also included. The visit ended with a detailed plan formed for the implementation of the Patient Expert programme in CYPLAR.

The visit of the Swedish delegation took place in October 2016. Eight patients participated in the training. The training was made through workshops by the delegates from both organizations together with all the Patient Partners in rheumatology and in patient communication at the St George’s University of London and Niclosia’s establishments. Medical students were also involved in discussing their experience in being educated by patients. The programme also involved practice of joint examinations. The workshop was evaluated by the participants on the final day. After the workshop was concluded delegates spent a day discussing the event together. The programme was evaluated, and a future plan of action decided upon.

Conclusions: The implementation of the patient expert programme was successful. 10 new Patient Experts are now available in CYPLAR. The next generation of health professionals will benefit and get a larger understanding of RMD’s and, in the end, the patients will benefit because the health care staff has a greater knowledge.

#DOENSTSHOWDOESNEXIST / #SYNSINTEFINNSINTE

– A PHOTO CAMPAIGN BY UNGA REUMATIKER

K. Nordlund, M. Beermann. Unga Reumatiker, Stockholm, Sweden

Background: “Rheumatism amongst young people, is that really a thing?” “Isn’t rheumatism something that only old people have?” “You seem so happy and so active, surely you can’t be in pain?” These are all questions that young people with rheumatism have to listen to, and answer every day.

Yes, it’s possible to have rheumatism even as a young person, and to be in pain, even though we’re not letting it show. We know adjustment is possible, and that we can live our life to the fullest and follow our dreams, despite rheumatism. But, our condition adds some extra understanding from the people around us. That’s what we wanted to recognize, and created a campaign together with AvBio.

Objectives: It can be hard to understand and fully grasp something you can’t see, something that is invisible. But as young people with rheumatism, we have to live and deal with our swollen joints, with the pain and the fatigue, and with the side effects of our medication. None of which should be questioned.

We recognized that this was an issue for most people with rheumatism, and especially young people. Therefore, we wanted to start a conversation about how it feels to live and cope with an invisible disability.

The main purpose with our campaign was to acknowledge the fact that you can’t always tell whether or not a person has a diagnosis, or is in pain. We also wanted to show young people with rheumatism that they are not alone in their situation.

Methods: We asked young people with rheumatism in different ages and with different diagnoses. Each person in the campaign is presented in two different photos. One standard full-portrait photo in front of a white background, just showing who they are. One person held a basketball to show off her love for sport, another one was wearing her dancing shoes and so on. The other photo is instead set in a complete dark room, with the person posing in the same way but this time with their rheumatism-affected areas lit up. We used glow in the dark-body paint and a UV-light to create this effect.

Each pair of photos is put together with the person’s story about their passion in life, their love for sport, their hobby, and deal with an invisible disability.

The campaign was released on October 12th 2016, on World Arthritis Day, with an event at Astrid Lindgren’s children’s hospital in Stockholm. The photos were printed and presented on large boards together with the personal stories.

The first photo of the campaign, a group photo of everyone participating, was also posted on social media on October 12th and then one pair of photos were posted every day during the following week. People were also told to share their own stories under the hashtag #synsintefinnsinte

Results: The campaign ended up being our organization’s most successful campaign to this date. The spread was especially great on Facebook, with the first post reaching nearly 50,000 people and the other posts reaching between 3,500 and 25,000 people every day. The campaign had more likes and shares on both Facebook and Instagram than any of our other campaigns had so far.

The opportunity to show the photos at Astrid Lindgren’s children’s hospital also brought health care into the campaign and attracted great attention on site.

The photos combined with the personal stories make a powerful statement. We managed to show young people with rheumatism that they are not alone in their situation, and we look forward to the conversation continuing on at #synsintefinnsinte

Imaging and treatment response in rheumatology

OP0283

ULTRASONOGRAPHIC EVALUATION IN RHEUMATOID ARTHRITIS USING THE GLOBAL OMERACT/EULAR ULTRASOUND SYNODIVISYN Score (GLOESS)

M.S. Stoeniol1, A. Pesonen1, N. Bello2, R. Christensen3, M. Østergaard4, E. Naredo1, L. Terslev1, E. Rheimatoly, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 2Rheumatology, University Hospital Gregorio Maranon, Madrid, Spain; 3Musculoskeletal Statistics Unit, Biapredjerg and Frederikssberg Hospital, 4Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

Background: Recently, a global RMD/EULAR ultrasound (US) gnosys score (GLOESS) combining grey-scale (GS) and power-Doppler (PD) scores has been proposed as a novel measurement tool to assess disease activity and response to therapy in patients with rheumatoid arthritis (RA)1,2. However, the ability of GLOESS to discriminate patients with different stages of disease activity vs. remission in standard clinical care is not known.

Objectives: To assess the ability of GLOESS to discriminate between different clinical states of activity vs. remission in RA patients, and to compare clinical, GLOESS and PD US remission criteria and scores in a cross-sectional study.

Methods: Eighty RA patients from 3 centres were recruited at consecutive clinical visits: 50% were in remission and 50% had active RA according to Simple Disease Activity Index (SDAI), SDAI, Clinical Disease Activity Index (CDAI), 28-joint Disease Activity Score (DAS 28CRP), Health Assessment Questionnaire (HAQ), ACR/EULAR remission criteria were assessed. An independent investigator unaware of clinical results performed all US joint examinations of 56 joints. GLOESS, PD, and GS US sum scores per patient were assessed using OMERACT definitions. PD US remission was defined as the PD sum score ≤0. GLOESS remission was defined as GLOESS score ≤1 thereby also including possible GS grade 1.

Results: PD US remission was observed in 38 (48%) patients and GLOESS remission in 16 (20%) patients and CDAI (r=0.24; p=0.03) and CDAI (r=0.23; p=0.04) but not DAS28CRP (r=0.21; p=0.05) were weakly correlated with GLOESS scores in the whole joint set. SDAI (r=0.41; p<0.001), CDAI (r=0.40; p<0.001), and DAS28CRP (r=0.40; p<0.001) were moderately correlated with PD activity in the whole joint set. A minority of patients were classified both in GLOESS remission and in clinical remission according to SDAI (n=10), to CDAI (n=10), to DAS28CRP (n=10) and to ACR/EULAR 2011 (n=7). Less than one third of patients were classified as in PD US remission and in clinical remission according to SDAI (n=22), to CDAI (n=26), to DAS28CRP (n=27) and to ACR/EULAR 2011 (n=21).

The proportion of patients in clinical remission was significantly different according to the definition considered: while 50% of the patients (n=40) were classified in remission according to SDAI, 56% (n=46) were classified in remission according to DAS28CRP, and 43% (n=34) classified in remission to CDAI and 43% (n=34) according to ACR/EULAR 2011 remission criteria.

Conclusions: We document major discrepancies between US and clinical findings and between clinical scores classifying patients in active disease vs. remission. Patients reaching GLOESS or PD US definitions of remission are partly different from those reaching clinical definitions of remission.

Evaluation of the Impact of Baseline Levels of MRI-Detected Inflammation on Treatment Response in Early, Seropositive, MTX-Naïve RA: Data from the Avert Trial

H. Ahn¡, J. Baker2, M. Østergaard2, P. Emsery3, P. Durez3, J. Ye4, S. Banerjee5, P. Conaghan6, Bristor-Myers Squibb, Princeton; University of Pennsylvania, Philadelphia; United States; 2Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; 3University of Leeds and Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom; 4Université Catholique de Louvain, Brussels, Belgium; 5University of Leeds, Leeds, United Kingdom

Background: Avert (Assessing Very Early Rheumatoid Arthritis Treatment) was a Phase IIIb, randomized, 24-month (M) trial with a 12M, double-blind treatment period, and included contrast-enhanced MRI of the dominant hand and wrist. MRI can provide direct evidence of joint inflammation, enabling stratification of patient (pt) data according to MRI inflammation level, e.g. low vs high. This stratification is hypothesized to predict clinical treatment response.

Objectives: To evaluate the proportion of pts achieving remission at M12 by baseline (BL) MRI-detected inflammation status and treatment group.

Methods: In Avert, pts with early RA received abatacept (ABA) + MTX, ABA baseline (BL) MRI-detected inflammation status and treatment group. Outcomes: To evaluate if FDG PET/CT can accurately diagnose LV-GCA after 3 or 10 days of high-dose steroid treatment.

Results:

- Of 351 pts randomized and treated, 337 (96.0%) had MRI data at BL (ABA + MTX, n=114; ABA monotherapy, n=112; MTX, n=111). Mean (SD) BL synovitis, osteitis and total scores, respectively, for pts with low MRI inflammation receiving ABA + MTX vs MTX alone were: 2.6 (2.0) vs 3.1 (2.4), 0.3 (0.6) vs 0.2 (0.5) and 3.1 (2.4) vs 3.5 (2.7). High MRI inflammation: 9.2 (3.6) vs 9.3 (3.6), 10.0 (9.7) vs 10.7 (9.8) and 29.3 (21.3) vs 30.7 (21.3). BL DAS28 (CRP), CDAI and SDI scores, respectively, for pts with low MRI inflammation receiving ABA + MTX vs MTX alone were: 5.1 (1.1) vs 5.0 (1.3), 3.4 (1.0) vs 3.2 (1.5) and 39.9 (17.4) vs 43.5 (24.6); high MRI inflammation: 6.2 (1.2) vs 5.6 (1.4), 43.1 (16.2) vs 37.7 (18.1) and 76.9 (44.9) vs 61.1 (35.2). The proportion of pts with low BL MRI inflammation attaining remission at M12 was similar regardless of treatment. In pts with high MRI inflammation remission rates were significantly greater in pts treated with ABA + MTX vs MTX alone.

Conclusions: Pts with higher MRI inflammation may derive greater benefit from abatacept + MTX vs MTX alone. BL MRI prediction is a superior predictor of subsequent clinical treatment response to abatacept in RA. MRI may have clinical utility in treatment decisions beyond information obtained from clinical assessments alone.

References:

system is therefore needed if implementing US-tenosynovitis as an outcome measure in clinical trials. The Outcome Measures in Rheumatology (OMERACT) US group’s tenosynovitis scoring system has a good single and multicenter intra- and inter-observer agreement, whereas the sensitivity to change in a multicenter design has never been tested. Furthermore, it is unknown whether low grade synovial hypertrophy without Doppler signal represents true inflammation, i.e. can be eliminated by anti-inflammatory therapy and is sensitive to change.

Objectives: The aim of this study was to test the sensitivity to change of the OMERACT US scoring system for tenosynovitis, including minimal signs of tenosynovitis, in a multicenter design in order to validate it as an outcome measure in RA multicenter clinical trials. Furthermore, to assess the association between US and health assessment questionnaire (HAQ) and Disease Activity Score 28 for joints (DAS28).

Methods: Forty-nine patients with established RA (duration >1 year) and 18 early RA patients (<1 year) with US-verified tenosynovitis were recruited from six rheumatology outpatient clinics in four different countries, if they were scheduled for treatment intensification with synthetic and/or biological Disease Modifying Anti-Rheumatic Drug. Tenosynovitis was assessed at baseline, and at three and six months’ follow-up, by GS and Doppler, using the semi-quantitative OMERACT scoring system. Furthermore, HAQ and DAS28 were assessed.

Results: At baseline tenosynovitis was most frequently found at the extensor carpi ulnaris and tibialis posterior tendons (70.7% and 44.4%, respectively). The overall GS score showed a statistically significant decrease from baseline median (25th;75th percentile: 2;5) to 6 months 0 (0;3) and the overall Doppler score decreased statistically significant from baseline 3 (2.6) to 6 months 0 (0;1), with a p = 0.01. Both GS and Doppler showed high responsiveness (SRM > 0.9), as did HAQ and DAS28 (table 1). Among tendons with grey scale (GS)=1-Doppler=0, 36% (92.9%) showed therapy-induced improvements. A change of 2.1 (95% confidence interval: 1.2;14.9) and 2.1 (CI: 1.1;13.2) in DAS28 corresponded to a change in GS and Doppler of 1 (both p = 0.02) respectively, using a mixed-model for repeated measurement. However, no association between US and HAQ was found.

Conclusions: In conclusion, this RA multicenter study documented a high sensitivity to change of both GS and Doppler US tenosynovitis scores, indicating utility of the OMERACT US scoring system for diagnosing and monitoring tenosynovitis in multicenter trials. Secondly, synovial hypertrophy without Doppler signal, do respond to therapy, suggesting it reflects true inflammation. Finally, changes in US tenosynovitis scores are associated with changes in DAS28.

TREAT-TO-TARGET IN EARLY RHEUMATOID ARTHRITIS: CORRELATION OF CXCL13 AND ULTRASONOGRAPHIC

Results: The three-grade semi-quantitative (Grade 0, normal cartilage; Grade 1, minimal change; Grade 2, severe change) scoring system demonstrated excellent (kappa: 0.87) to good (kappa: 0.73) intraobserver reliability in the web-based exercise and the patient-based reliability study respectively. Interobserver reliability was good in the web-based exercise (kappa: 0.64) and moderate (kappa: 0.49) in the patient-based reliability study. The dynamic technique performed slightly better than the longitudinal midline scan alone.

Conclusions: A semi-quantitative imaging system demonstrated good intra- and moderate to good inter-observer reliability in a web-based exercise and patient-based reliability study. Our study demonstrates that US is a reliable tool for evaluating cartilage and supports the use of a new semi-quantitative US scoring system for evaluating cartilage change in RA.

Acknowledgements: The patient-based reliability study was supported by a research grant from UCB.

DOI: 10.1136/annrheumdis-2017-eular.4314

Background: Modern treatment of early RA is targeted towards remission. Sustained remission is viewed as more beneficial to the patient than remission at one time point, also with regards to inhibition of joint damage. Until now, there is no serum autoantibodies marker for it (2). The chemokine CXC ligand 13 protein (CXCL13) is one of the most potent B-cell chemo attractants constitutively expressed in the B-cell follicles of secondary lymphoid organs (3). Its seric level has been associated to the degree of synovitis in patients with rheumatoid arthritis as studied by ultrasonography (US). The Journal of rheumatology. 2007 Apr;34(4):848–51.

Methods: RA patients with <2 years from first swollen joint who were DMARD naive with indication for DMARD treatment were included in the ARCTIC trial (3). Patients in the ultrasound arm aiming for DAS ≤2, 0–96. No ultrasound power Doppler (PD) signal were included in the current analyses. Several definitions of sustained remission (12–24 months) were compared; DAS-28, ESR, DAS28-ESR, SDAI, CDAI, ACR/EULAR Boolean (remission based on 44 joints), no swollen joints (44SJC), no ultrasound PD signal in any joint (0–96) and minimal total ultrasound greyscale (GS) score (defined as GS ≤2, 0–96).

Results: Of 103 patients, 76 (74%) were female, mean [SD] age was 51.4 [12.9] years, disease duration 6.7 [5.3] months and DAS 3.5 [1.1]. The median [25th, 75th percentile] change in vdHSS 12–24 months was 0.49 [0.0, 1.03] and 73 (71%) patients had no radiographic progression. Sustained remission was reached by 23–61% according to the different criteria. Among patients in sustained remission, comparably proportions of patients did not progress radiographically across the different criteria (74–89%), with the most favorable result for minimal GS score (Table). Patients with sustained no PD or minimal GS score had an increased likelihood of no radiographic progression during the concurrent year (Table), but still rather weak to be useful in an individual patient. Based on the low LR+ none of the criteria identifies patients without radiographic progression very well; likewise, as the LR− is relatively high for all definitions, not being in remission does not change the probability of ongoing radiographic progression substantially.

Conclusions: In this treat-to-target early RA study, sustained remission rates were generally high and radiographic progression limited. None of the sustained remission criteria were able to exclude concurrent radiographic progression. Absence of ultrasound inflammation performed best of the definitions assessed.

Background: Joint involvement in systemic lupus erythematosus (SLE) is one of the earliest manifestation of the disease (1). Only 2–5% of the cases develop a deforming and non-erosive type of arthritis, known as Jaccoud Arthropathy (JA). Until now, there is no serum autoantibodies marker for it (2). The chemokine CXC ligand 13 protein (CXCL13) is one of the most potent B-cell chemo attractants and is constitutively expressed in the B-cell follicles of secondary lymphoid organs (3). Its seric level has been associated to the degree of synovitis in patients with rheumatoid arthritis as studied by ultrasonography (US).

Methods: To perform the first detailed US analysis of hands and wrists of SLE patients, with and without JA, and to correlate those findings with the levels of CXCL13, other clinical and laboratory features and disease activity.

Results: Of 64 patients with SLE were included, being 32 with JA and 32 without JA paired by age and disease duration. The definition of JA was based on clinical criteria recently described by Santiago (4). Patients and controls underwent a high-resolution US exam of wrists and hands. Synovial hypertrophy, tenosynovitis and erosions were evaluated according a semi-quantitative grading system according definitions provided by OMERACT (5). Serum concentrations of CXCL13 were quantified in both groups utilizing a commercially available kit. Autoantibodies such as antinuclear antibody (ANA), anti-dsDNA, anti-Sm, anti-SSA, anti-SSB were also tested. US findings were correlated with seric levels of CXCL13, other serological parameters and SLEDAI and SLEDAI-2K.

Results: In the JA group, the mean age was 46.2 years and the mean duration of the disease was 17.3 years. Synovitis on US was found in 25 patients and tenosynovitis in 14. All of these findings were more frequent in SLE with JA, particularly tenosynovitis with difference statistically significant (p=0.002). In JA patients the median levels of CXCL13 was 23.21 pg/ml as compared to 11.48 pg/ml in SLE without JA group (p=0.08). There was an association between tenosynovitis and higher levels of CXCL13 in the JA group (p=0.026). Patients with active disease were more common in the JA group (p=0.004) and had increased serum levels of CXCL13 compared to patients with disease inactive (p=0.008).

Conclusions: In conclusion, the present study is one of a few to describe US findings in SLE patients with JA and it confirms that synovitis and tenosynovitis are common features in the majority of these patients. In addition, CXCL13 may be regarded as a biomarker for tendon inflammation in JA.

From genetics through epigenetics to proteomics: understanding disease mechanisms

**OPO291 IDENTIFICATION OF NOVEL SUSCEPTIBILITY LOCI IN A LARGE UK COHORT OF JUVENILE IDIOPATHIC ARTHRITIS (JIA) CASES**

S.L. Smith1,2, J. Bowes1, J. Cobb1,2, A. Hinks1, S. Sampath1, A. Yanwood1, L. Wedderburn1, K. Hyrich1,2,4, W. Thomson1,2 on behalf of Childhood Arthritis Prospective Study (CAPS), UK Juvenile Idiopathic Arthritis Genetics Consortium (UKIJC), Childhood Arthritis Response to Medication Study (CHARMS), Biologics for Children with Rheumatic Diseases (BCRD) and BSPAR-Etanercept.

**Background:** Juvenile idiopathic arthritis (JIA) is a group of chronic artiopathies of unknown cause affecting children under 16yrs, and is the most common childhood inflammatory rheumatic diagnosis. In recent years great advances in dissecting the genetic basis of JIA have been made. In a landmark study, conducted on JIA cases, two most common subtypes (oligoarthritis and RF-negative polyarthritis), 17 susceptibility loci were identified at genome-wide significance (p-value <5x10⁻⁸) and a further 11 reaching suggestive significance (p-value <1x10⁻⁶). These findings were the result of a large international collaboration using the ImmunoChip array, targeting 186 genetic loci in 12 autoimmune diseases. However, a limitation to the afore-mentioned study was that the analysis is limited to the selected loci; large genome-wide studies are now needed.

**Objectives:** The aim of this work is to identify novel genetic loci associated with disease susceptibility using a large cohort of UK JIA cases.

**Methods:** The aim of this work is to identify novel genetic loci associated with disease susceptibility using a large cohort of UK JIA cases. Whole-genome genotyping data was generated using four platforms (Illumina). Following stringent quality control common variants to all four platforms were extracted from the individual datasets before merging together. Imputation (Illumina). Following stringent quality control common variants to all four platforms were extracted from the individual datasets before merging together. Imputation accuracy was elucidated the potential function of the associated SNPs for whom it would be favourable to initiate a biological drug from start of therapy, it is crucial to study biological pathways and biomarkers involved in treatment response.

Univ. Marqués de Valdecilla, Santander, Spain

**Background:** Autoimmune diseases are highly disabling chronic disorders characterized by the activation of multiple immune and inflammatory pathways against self-components. Clinical studies have demonstrated that autoimmune diseases have a higher prevalence of cardiovascular events compared to the general population. Understanding the genetic and biological mechanisms underlying cardiovascular disease (CVD) risk in autoimmunity could therefore be fundamental to develop more effective and targeted therapeutic approaches.

**Objectives:** The objective of this study was to characterize the genetic basis of CVD risk in autoimmune diseases.

**Methods:** A total of 6,485 patients from the six autoimmune diseases RA, PA, SLE, PS, CD and UC were recruited by the Spanish biomedical consortium IMID Consortium. All patients were Caucasian European from the Spain. CVD patients were defined as having >1 out of the 3 most frequent cardiovascular phenotypes: (i) ischemic heart disease (ii) cerebrovascular accident and (iii) peripheral arterial disease. In order to characterize the genetic basis of CVD risk in autoimmune diseases, we used genome-wide genotyping data from all autoimmune disease patients included in the study. First, we tested the association of established CVD risk variants within each autoimmune disease. Second, we analyzed the association of autoimmune disease risk variants with an increase in CVD risk. Finally, we used the cross-phenotype meta-analysis approach (CPMA) to perform a genome-wide meta-analysis and identify global genetic patterns associated with CVD risk in autoimmune diseases.

**Results:** A total of 17 loci previously associated with CVD risk in the general population were significantly associated with CVD risk in the autoimmune patient cohort (P<0.05). From these, 4 loci were found to have significantly different genotypes across autoimmune diseases; we used genome-wide genotyping data from all autoimmune disease patients identified in the study. We first, tested the association of established CVD risk variants within each autoimmune disease. Second, we analyzed the association of autoimmune disease risk variants with an increase in CVD risk. Finally, we used the cross-phenotype meta-analysis approach (CPMA) to perform a genome-wide meta-analysis and identify global genetic patterns associated with CVD risk in autoimmune diseases.

**Conclusions:** The results of the present study represent an important step towards the characterization of the genetic basis of CVD in autoimmune diseases. These findings contribute to explain the higher prevalence of cardiovascular events observed in patients with autoimmune diseases compared to the general population.

**OPO293 WEIGHTED GENE CO-EXPRESSION NETWORK ANALYSIS OF DMARD-NAÏVE EARLY RA PATIENTS ACHIEVING SUSTAINED DRUG-FREE REMISSION AFTER INITIATING TOCILIZUMAB THERAPY**

X.M. Teiterna1, J.W. Jacobs1, M. Mokry2,3, A. Pethő-Schramm4, M.E. Borm5, J.M. van Laar1, J.W. Bijlsma1, F.P. Lafeber6,7, Rheumatology and Clinical Immunology, UMC Utrecht, 2Division of Pediatrics, Wilhelmina Children’s Hospital, 3Epidemiogenics Foundation, Utrecht, 4Hoffmann-La Roche, Basel, Switzerland; 5Roche Nederland B.V., Woerden, Netherlands

**Background:** Rapidly reducing disease activity is of major importance in the management of newly diagnosed rheumatoid arthritis (RA) patients as early response strongly correlates with long-term clinical outcomes. To select patients for whom it would be favourable to initiate a biological drug from start of therapy, it is crucial to study biological pathways and biomarkers involved in treatment response.

**Objectives:** To identify biological networks and signature genes among disease modifying anti-rheumatic drug (DMARD)-naïve early RA patients achieving sustained drug-free remission (sDFR) after initiating treatment with tocilizumab (TCZ).

**Methods:** Data was used from DMARD-naïve early RA patients in the U-Art-Early trial who had been randomized to initiate TCZ therapy. The study design and details have been previously been described [1] Briefly, The study enrolled 116 patients for whom it would be favourable to initiate a biological drug from start of therapy, sDFR was reached when patients remained disease free for whom it would be favourable to initiate a biological drug from start of therapy, sDFR was achieved when patients remained disease free for whom it would be favourable to initiate a biological drug from start of therapy, sDFR was achieved when patients remained disease free for whom it would be favourable to initiate a biological drug from start of therapy, sDFR was reached when patients remained disease free for whom it would be favourable to initiate a biological drug from start of therapy. The study design and details have been previously published. sDFR was achieved when patients remained disease free for whom it would be favourable to initiate a biological drug from start of therapy.

**Results:** In total, eight modules with varying sizes (10–470 genes) were identified. The module best correlated (Pearson correlation coefficient 0.52, FDR<0.05) and IFNγ (FDR<0.05) cytokine pathways.

**Conclusions:** The results of the present study represent an important step towards the characterization of the genetic basis of CVD in autoimmune diseases. These findings contribute to explain the higher prevalence of cardiovascular events observed in patients with autoimmune diseases compared to the general population.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.2471
In addition, we identified 83 overrepresented Gene Ontology (GO) terms of which granulocyte migration (p=2.70E-04), myeloid leucocyte migration (p=8.95E-04) and G-protein coupled amine receptor activity (p=1.25E-05) were most significant. The genes in the module of interest showing the highest connectivity were the upregulated tests expressed 22 (TEXX2), doublecortin like kinase 2 (DCLK2), and the downregulated Williams Beuren syndrome chromosome region 27 (WBSCR27) gene (Fig. 1).  

Conclusions: When performing network analyses of the DEGs between responders and non-responders, TEXX2 and DCLK2 were identified as signature genes for treatment response to TCZ therapy. WBSCR27 was found to be associated with a lower chance of achieving sDFR.

Fig. 1. Network visualization of the interaction of gene co-expression in the module best correlated with achieving sustained drug-free remission. Upregulated genes are expressed as green nodes and the downregulated gene as red node. The three rounded rectangular nodes display the highest co-expressed genes within the module (>10 connections) when applying a weight cut-off of 0.01. The average number of nodes connected at this cut-off was 4.6 (correlation coefficient 0.82).
increases the risk of developing multiple autoimmune and connective tissue diseases. Ptpn22 is a negative regulator of Syk and Src family kinases downstream of immuno-receptor signalling cascades. 2. Fungal β-glucan receptor dectin-1, signals via Syk kinase, and induces dendritic cells to secrete pro-inflammatory cytokines IL-1β, IL-6, IL-12/p35 and TNFα, in turn allowing the induction of IL-17 producing T-cell responses, which are critical to the clearance of fungal infections.3 IL-17 has been implicated as a key cytokine in inflammatory responses associated with RA, JIA, and psoriasis.4  

Objectives: To investigate if Ptpn22 regulates dectin-1 signalling and controls the capability of dectin-1 matured BMDC to promote adaptive immune responses.  

Methods: GM-CSF bone marrow derived dendritic cells (BMDC) were generated from C57BL/6 WT, Ptpn22+/− or Ptpn22−/− (human PTPN22 akt2/akt2 orthologous) mice, and pulsed with OVA323-339 in the presence or absence of the dectin-1 agonist curdian. Activated BMDC were co-cultured in vitro with OT-II T-cells or adoptively transferred into OT-II mice and the resulting T-cell response assessed. Cytokine secretion from curdian activated Ptpn22 variant mouse BMDC was determined by immunoassay and the kinetics of Syk and Erk phosphorylation were determined by immunoblot.  

Results: We observed that Dectin-1 activated Ptpn22+/− BMDC had an enhanced capability to induce T-cell IL-17 secretion both in vitro and in vivo compared to WT BMDC. Following dectin-1 priming Ptpn22−/− BMDC secreted increased IL-17 compared to WT BMDC, and the increase in IL-17 was found to be sufficient to cause the enhanced IL-17 response induced by Ptpn22−/− BMDC. Dectin-1 induced IL-17 secretion was found to be Syk and Erk dependent and assessment of Syk and Erk kinase phosphorylation revealed that dectin-1 activated BMDC displayed enhanced Syk and Erk phosphorylation compared to WT BMDC. Furthermore, Ptpn22−/− BMDC (orthologue of human PTPN22 akt2/akt2) exhibited a similar enhancement in IL-17 secretion and induced enhanced T-cell dependent IL-17 responses in vivo, indicating that the PTPN22 polymorphism behaves as a loss-of-function allele in the context of dectin-1 signals.

Conclusions: Data highlight Ptpn22 as a novel regulator of dectin-1 signals and provide a link between genetically conferred perturbation to innate receptor signalling pathways and autoimmunity.

Innovative insights into mechanism of SLE, Sjögren's and APS

**RESULTS:** Tfh (CD4+CD45RO+PD1+ICOS+FoxP3+) cells were strongly enriched in ELS+ vs ELS- SS samples. The Tfh:Tfr ratio in ELS+ SG was approximately 2:1. Interestingly, while in tonsils Tfr were routinely detected within GCs, in ELS+ SG Tfr were predominantly excluded from the B cell follicles and accumulated in the T cell areas at the periphery of the lymphoid aggregates. Conversely, Tfh densely infiltrated the B cell rich areas and, within ectopic GCs, acquired BCL6. Furthermore, Tfh infiltration closely correlated with SG IL-21 mRNA expression, which in turn was strongly correlated with CD3, CD20 and CD138 IHC scores and with CXCL13, LtB, BAFF, AID and Pax5 gene expression. Finally, MALT-L samples displayed 10-fold higher IL-21 mRNA and twice as much PD1+ICOS+BCL6+ Tfh-cells/field compared to ELS+ SS samples.

**Conclusions:** Within the SG of SS patients Tfh cells closely segregate with lesional IL-21 expression, localize within ELS and are strongly enriched during MG development. Consequently, through Tfh cells recruited in the SG in SS patients, we consistently demonstrated follicular exclusion of this subtype from ectopic GCs. This suggests that Tfr in SS SG fail to exert their physiological immunoregulatory properties in controlling the magnitude of the GCs response and B cell autoactivity, as observed in tonsils.

OP0302 SIGNIFICANT REDUCTIONS OF PATHOGENIC AUTOANTIBODIES BY SYNERGISTIC RITUXIMAB AND BELIMUMAB TREATMENT EFFECTIVELY INHIBITS NEUTROPHIL EXTRACELLULAR TRAPS IN SEVERE, REFRACTORY SLE - THE SYNOBISE STUDY

T. Kraaij 1, S.W. Kamerling 1, J.A. Bakker 2, T.W. Huizinga 2, T.J. Rabelink 1, G. van Kooten 1, Y.K. Teng 1, 1Nephrology; 2Clinical Chemistry; 3Rheumatology, LUMC, Leiden, Netherlands

Background: Neutrophil extracellular traps (NETs) are extracellular, decondensed DNA strands covered with antimicrobial proteins that are part of the first-line defence against pathogens. However, in SLE, overall release of NETs is increased and degradation of NETs is impaired leading to a high amount of extracellular nuclear material, potentially leading to formation of SLE-specific antibodies. These pathogenic autoantibodies deposit in glomeruli in lupus nephritis (LN) and perpetuate autoimmunity by inducing more NETs. The present study hypothesized that combining anti-CD20 mediated B-cell depletion with BAFF (B-cell activating factor) inhibition can target autoreactive plasma cells and thereby effectively reduce pathogenic antibodies in NETs and LN.

Objectives: The present study aimed to investigate whether Rituximab (RTX) + Belimumab (BLM) affected pathogenic antibodies in relation to NET induction in severe refractory SLE.

Methods: As part of a phase 2 proof-of-concept study, the SynBioSe study, serum levels of anti-DNA autoantibodies were measured in severe, refractory SLE patients before and after treatment with RTX following BLM. Additionally, ex vivo NET induction was assessed before and after treatment with a novel highly sensitive method based on 3D confocal laser scanning microscopy. In this assay, neutrophil activation and NET induction were measured at 10% serum of participating controls. Furthermore, we investigated whether NET induction was mediated by immune complexes.

Results: The study included 10 severe, refractory SLE patients with lupus nephritis and 1 patient with neuropsychiatric lupus. NET induction was found to be high at baseline with a median fold induction of 4.5 [range 2.6–11.7]. After 24 weeks, NET induction was significantly decreased (median fold NET induction of 1.6 [0.4–6.1], p=0.01). In addition, treatment with RTX+BLM led to significant reduction of anti-dsDNA antibodies at week 24 with a median of 35 IU/ml [range 10–374] compared to 120 [18–505] at baseline (p=0.012). Total immunoglobulin levels temporally declined but returned to screening levels at week 24. NET induction correlated significantly with anti-dsDNA antibody levels (ρ=0.42, p=0.03) and with SLEDAI scores (ρ=0.53, p=0.003). Therefore, we examined whether the observed NET induction could be explained by circulating immune complexes (ICs). ICx were deprepped by pre-incubating anti-dsDNA positive SLE sera with nuclease, resulting in a significant decrease in NET induction (median % decrease of 91.7 [range 67.8–98.1]). In addition, depletion of IgG from anti-dsDNA positive SLE sera resulted in significantly lower NET induction. Finally, immobilized IgG isolated from anti-dsDNA-positive SLE sera, but not of control serum, resulted in significant NET induction.

Conclusions: Within refractory SLE patients, RTX + BLM resulted in concordant significant NET induction. Of 91.7 [range 67.6–98.1]. In addition, depletion of IgG from anti-dsDNA positive SLE sera resulted in significantly lower NET induction. Finally, immobilized IgG isolated from anti-dsDNA-positive SLE sera, but not of control serum, resulted in significant NET induction.

OP0304 SELECTIVE INHIBITORS OF NUCLEAR EXPORT PREVENT LUPUS PROGRESSION BY TARGETING GERMINAL CENTER FORMATION AND AUTOREACTIVE ANTIBODY SECRETING CELLS

1. Rangel-Morroni 1, S. Cochran 2, T. Tami 2, M. Lee 2, S. Shacham 2, J. Anolik 1. 1Department of Medicine, Division of Allergy, Immunology and Rheumatology, University of Rochester Medical Center, Rochester; 2Karyopharm Therapeutics, Newton, United States

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease characterized by simultaneous activation of the innate and adaptive arms of the immune system. The progression of the disease is unpredictable, making its treatment a challenge. Recently the nuclear export protein Exportin 1 (XPO1, also known as CRM1) has surfaced as an attractive target for the treatment of SLE and other inflammatory disorders. Selective Inhibitor of Nuclear Export (SINE) compounds are potent, orally available and well-tolerated XPO1 inhibitors. SINE compounds exert apoptotic and anti-inflammatory effects by mediating nuclear retention of important XPO1 cargos like the NF-κB pathway regulatory protein, IκB.

Objectives: Based on the central role of NF-κB signaling in the activation of immune cells in SLE, we decided to evaluate the therapeutic ability of SINE compounds in mediate experimental lupus progression.

Methods: To evaluate the efficacy of SINE compounds in a preclinical model of SLE, cohorts of lupus-prone mice with established disease (elevated anti-dsDNA antibody titer and proteinuria) were dosed with SINE compound or vehicle. We used flow cytometry to enumerate immune cells and immunofluorescence to visualize germinal centers (GC) in spleen. Quantitative PCR was used to measure changes in mRNA expression for molecules key in plasma cell activation and survival, and histology was used to evaluate inflammation, antibody deposition and pathology in kidneys of lupus-prone mice.

Results: We found that treatment with SINE compounds significantly prevented increases in proteinuria (proteinuria scores: Control: 2.12±1.12; SINE (5 mg/kg): 0.75±0.49; SINE (10 mg/kg): 0.66±0.49; SINE (20 mg/kg): 0.50±0.35) and thereby decreased IgG deposition and kidney pathology (glomerulonephritis, tubule damage and perivascular cuffing). Prevention of kidney damage was associated with a remarkable disruption of splenic GC; a significant reduction in the number of auto-reactive antibody secreting cells (ASC), and a decrease in the accumulation of auto-reactive ASC in the inflamed kidney. Reduced numbers of plasma cells in the inflamed kidney are likely due to the drastic decrease in the expression of molecules critical for GC attraction and the identification of GC as potential reservoirs of SLE autoreactive plasma cells. The potent effect of SINE compounds on GC and auto-reactive ASC is noticeable as early as 1 week after starting therapy. However, kinetics studies showed that a more pronounced elimination of GC and auto-reactive ASC is achievable after 8 weeks. Although SINE therapy has a drastic impact on spleen architecture, recent findings show that complete recovery of the GCs did not occur for at least 6 weeks.

Conclusions: SINE compounds have demonstrated efficacy in a murine model of SLE by reducing generation, survival and function of auto-reactive immune complexes, rendering cell-free, frozen in liquid nitrogen and stored at -80°C. In supernatants from pSS and non-Sjögren’s sicca (nSS) patients 104 targets were measured by Lumexin. Eight pSS and 8 nSS patients were selected for analysis based on matched biopsy weights. Results from this discovery cohort were validated in an additional cohort (n=18 nSS, n=16 incomplete SS; nSS, n=26 pSS) and pSS and nSS individuals with clinical and demographic features were assessed. Non-Ss patients were defined as sicca patients without lymphocytic infiltration in the salivary gland biopsy or anti-Ss/SSa autoantibodies. Incomplete SS patients were defined as sicca patients having lymphocytic infiltration (lymphocytic focus score (LFS)>0) and/or anti-Ss/SSb autoantibodies but do not fulfill the AECG classification criteria and are not diagnosed as pSS.

Results: Levels of 20 cytokines were significantly different between the nSS and pSS patients in the discovery cohort (p<0.05). These 20 and 13 additionally selected cytokines based on a trend towards statistical significance and/or minimal overlap were measured. We generated a correlation matrix of these cytokines. Only 5 cytokines did not significantly differ: 59.8±4.18 mg in nSS vs 72.7±4.65 mg in SS at 67.4±2.86 mg in pSS. Fifteen out of these 20 cytokines were validated. From the 13 cytokines 7 were significantly elevated in pSS vs nSS. In nSS CXCL10 (IP-10) and CCL19 (MIP-3β) were significantly elevated. Cytokines correlating with LFS, ESSDAI, ESSPRI, % IgG and IgM plasma cells in LSS, Schirmer and/or serum IgG with Spearman r=0.4 and p<0.05 in pSS were selected for classification tree analysis, these were IL-2, IL-3, IFN-γ, IL-21, CXCL13 (BLC), CCL10 and CCL19. Using CXCL13 and IL-21 levels, 87.5% of pSS patients could be classified correctly. Baseline on the mean cut off levels, 5 nSS and 9 SS patients would be classified as pSS. Follow up revealed that 6 severe patients may not persistently pSS.

Conclusions: Elevated levels of numerous cytokines were found in LSS biopsy secretomes from pSS patients versus non-autoimmune sicca patients correlating with clinical parameters. This method represents a novel tool to provide insights in pSS immunopathology and provides new therapeutic targets and biomarkers for diagnosis, prognosis and treatment response.

OP0305

TYPE I IFN SYSTEM ACTIVATION IN NEWBORNS EXPOSED TO ANTI-RO/SSA AUTOANTIBODIES IN UTERO

M. Wahner 1, M. Hedlund 1, G.E. Thorlacius 1, M. Ivanchenko 1, N. Kyrilakis 1, L. Rönnblom 2, M.-L. Eloranta 2, A. Espinosa 1, S.-E. Sonesson 1.

L. Rönnblom 2, M.-L. Eloranta 2, A. Espinosa 1, S.-E. Sonesson 1.

Background: Overexpression of type I IFN-stimulated genes has been demonstrated in both SLE and SS, and induction of IFNα production in plasmacytoid dendritic cells by immune complexes containing RNA and autoantibodies, including Ro/SSA and La/SSB autoantibodies, has also been shown. During pregnancy, these autoantibodies pass over the placenta to the fetus, but it is not known if an IFN-activation takes place also in the fetus.

Objectives: In the present study, we investigated if the type I IFN system is activated in newborns exposed to anti-Ro/SSA autoantibodies in utero.

Methods: Anti-Ro/SSA positive mothers and their babies as well as healthy controls were included in the study. Maternal and cord blood drawn at birth was immediately separated into plasma and PBMC. miRNA expression was analyzed by microarrays, cell surface markers were assessed by flow cytometry and circulating IFNα levels by DELFIA.

Results: We observed increased expression of IFN-regulated genes and elevated plasma IFNα levels not only in anti-Ro/SSA positive women but also in their newborns, with maternal and fetal IFNα scores showing a significant positive correlation (r=0.74, p=0.005). Increased expression of MHC class II was observed on CD14+ monocytes of anti-Ro/SSA antibody-exposed babies, suggesting correlation (r=0.74, p=0.005). Increased expression of MHC class II was observed on CD14+ monocytes of anti-Ro/SSA antibody-exposed babies, suggesting correlation (r=0.74, p=0.005).

Comorbidities in rheumatoid arthritis

OP0306

DOWREGULATION OF MICRNAs IN PLASMACYTOID DENDRITIC CELLS IS ASSOCIATED WITH A TYPE I INTERFERON SIGNATURE IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

L.L. Van Den Hoogen 1, 2, 3, J.A. van Roon 1, 2, R.D. Fritsch-Stork 1, 2, C.P. Bekker 1, 2, A. Pandit 1, 2, M. Rossato 1, 2, T.R. Radstake 1, 2.

Laboratory of Translational Immunology; 2Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht, Netherlands

Background: The most prominent alteration in the immune system of patients with SLE is a type I interferon (IFN) signature, which we recently also reported in patients with primary APS (PAPS). In SLE and APS, this signature is related to disease activity and vascular disease. Plasmacytoid dendritic cells (pDC) are considered key players in the pathogenesis of SLE and APS as they are major producers of type I IFNs. MicroRNAs (miRNAs) are short non-coding RNAs that modulate gene expression through RNA interference mechanisms and have been implicated in the dysregulation of immune cells in patients with autoimmune diseases. Here we investigated miRNA expression in pDC of patients with SLE and APS in relation to the type I IFN signature.

Objectives: To identify if pDC dysregulation in patients with SLE and APS is associated with alterations of their miRNA expression profile.

Methods: The frequency of circulating pDC was determined by flow cytometry in patients with SLE (n=49), SLE+APS (n=34) and PAPS (n=27) and healthy controls (HC, n=22). RNA was extracted from pDCs isolated from the peripheral blood of patients with SLE (n=20), SLE+APS (n=10), PAPS (n=10) and HC (n=12). pDC miRNA and transcriptome profiles were assessed by RT-qPCR by OpenArray and RNA-sequencing (RNAseq) respectively. Patients were stratified by the presence of an IFN signature by analysis of IFNα expression on the basis of RNAseq. pDC stimulated with TLR7 agonists were analyzed for changes in miRNA expression.

Results: The numbers of circulating pDC were reduced in peripheral blood of patients with SLE, SLE+APS and PAPS (all p<0.001) and did not differ among the patient groups. Among 131 expressed miRNAs, 36, 17 and 21 miRNAs were differentially expressed (p<0.05) in patients with SLE, SLE+APS and PAPS, respectively, as compared with HC. All but one of these miRNAs were downregulated in the patients versus HC. Only 1 miRNA was differentially expressed when comparing between SLE and SLE+APS patients and between SLE and PAPS patients. A total of 9 miRNAs were differentially expressed between IFN-high and IFN-low patients. Pathway enrichment on targets of the top three miRNA (p<0.001) distinguishing between IFN-high and –low patients indicated that these miRNAs are potentially regulating pathways relevant for pDC function such as TLR signaling and endocytosis. Activation of pDCs by TLR7 agonists induced a downregulation of miRNAs in pDC, resembling the miRNA expression pattern seen in patients, in particular those with a high type I IFN signature.

Conclusions: Reduced numbers of circulating pDC and downregulation of miRNAs in pDC is shared between SLE, SLE+APS and PAPS patients. Altered miRNA expression in pDC is associated with the presence of a type I IFN signature in SLE and APS. Our data suggest that the reduced expression of a subset of miRNA underlies pDC dysregulation in SLE, SLE+APS and PAPS patients.

OP0307

TREATMENT OF BAFF TRANSGENIC MICE WITH ANTI-TNF: IFN-MONOCONAL ANTI-TNF ARE ASSOCIATED WITH A HIGHER RISK OF LYMPHOMA THAN ETANERCEPT

1Rheumatology; 2INSERM U1184, le Kremlin Bicêtre; 3U1016, Paris, France; 4Melbourne University, Melbourne, Australia; 5Pathology, le Kremlin Bicêtre; 6CEA, Fontenay aux roses; 7Marseille Luminy, Marseille, France

Background: Risk of lymphoma in patients with rheumatoid arthritis (RA) and disease activity is the main risk factor. The impact of treatment, notably of anti-TNF, is unclear: decreasing the risk of lymphoma by controlling activity or altering anti-tumor immunosurveillance. Ant-TNF are not associated with an increased risk of lymphoma in epidemiologic studies. However, the risk might vary according to the type or the dose of anti-TNF.

Objectives: To assess if the risk of lymphoma might differ according to the type of anti-TNF, comparing monoclonal anti-TNF to the soluble receptor. For that, we used BAFF transgenic (Tg) mice as a model of autoimmunity-associated lymphomas. They develop lupus and Sjögren and 3% of them spontaneously developed lymphoma at 12–18 months.

Methods: Six months aged BAFF-Tg mice were treated with anti-TNF for 12 months: etanercept (ETA) (n=15, 8 mg/kgx3/week), monoclonal anti-mouse TNF: TNZ 19.12 (n=15, 20 mg/kgx1/week), adalimumab (ADA) (n=12, 20 mg/kgxweekly) or controls (n=22). Sera were assessed monthly. Crude mortality was compared among the different groups. Histological examination of the spleen was performed. The Fisher’s exact test was used to compare the incidence of lymphoma among the groups.

Results: Adjunction of low dose of methotrexate during the 3 first days of treatment prevented immunization in the 3 groups for life. Using L929 cells, a cell line sensitive to TNF induced death, we confirmed that ADA was 8 to 12 times less efficient than ETA to inhibit soluble murine TNF. As expected, the mean level of ETA, TN3 and ADA were 7 μg/ml, 69 μg/ml and 105 μg/ml respectively. The
level of auto-antibodies and serum Ig did not significantly differ among the groups. However, crude mortality was significantly higher in mice treated with monoclonal anti-TNF compared to controls (p=0.001 for ADA and p=0.003 for TN3) but not for mice treated with ETA (Figure). Incidence of lymphoma was higher in mice treated with monoclonal anti-TNF: 5/15 (33%) with TN3 (p=0.03/controls), 4/12 (33%) with ADA (p=0.054/controls), 0/15 with ETA and 1/22 (5%) in controls.

Conclusions: Higher mortality and increased risk of lymphoma were observed in BAF175 mice treated with monoclonal anti-TNF compared to etanercept. This result may be linked either to the different mechanism of action between the soluble receptor and the monoclonals or to a difference of trough level observed in the different groups even if higher levels of ADA was mandatory given the difference of effect on mouse TNF. This study demonstrates the negative impact of a prolonged anti-TNF treatment on the risk of lymphoma in the context of BAF175 increase.

1 Rheumatology, Amsterdam Rheumatology and Immunology Center, location VU University Medical Center, Amsterdam, Netherlands; 2Obstetrics and Gynaecology, VU University Medical Center, Amsterdam; 3Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands; 4Obstetrics and Gynaecology, University Medical Center Utrecht, Utrecht, Netherlands; 51st Medical Department and Ludwig Boltzmann Institute, Hanusch Krankenhaus and Sigmund Freud University, Vienna, Austria

Background: Systemic lupus erythematosus (SLE) predominantly affects women during their fertile period. During pregnancy SLE patients are prone to pregnancy complications and may experience increased disease activity.

Objectives: To investigate disease activity around/during pregnancy and pregnancy complications in a European cohort according to antiphospholipid antibody (aPL) status. Additional focus on lifetime pregnancy outcomes and comparison of first and consecutive pregnancies were analyzed.

Methods: All ongoing pregnancies of >16 weeks gestation of SLE patients (according to the ACR revised criteria) receiving joint care from rheumatologists and gynaecologists in two tertiary centers in the Netherlands between 2000-2015 were included. Disease activity (using SELENA-SLEDAI (DAI) around and during pregnancy), flare rate according to the SELENA-SLEDAI definitions and pregnancy complications were assessed by medical chart review.

Results: Of 96 women (84% Caucasian) 144 pregnancies were included. Before (t<6 months), during, and after pregnancy (≥6 months) the median SELENA-SLEDAI score was 2 and mild/moderate flare rates were 6.3%, 18.8% and 13.9% respectively. Three patients developed a severe flare during pregnancy, 2 patients at postpartum, but they were aPL negative. Severe maternal complications (preeclampsia, eclampsia or HELLP-syndrome) occurred in 16.2% of aPL negative, 21.4% of aPL positive SLE patients, and in 39.8% of SLE patients with antiphospholipid syndrome (APS) (GEE; no significant differences between groups). HELLP-syndrome occurred in 21.3% of SLE patients with APS and in 31% of SLE patients without APS (Chi-Square; p<0.01). The perinatal complications included intrauterine fetal death, preterm birth, small-for-gestational age and neonatal lupus occurred in 41%, 37.4%, 14.8%, 1.4% respectively (GEE; no significant differences between groups). Maternal and perinatal complication rates were similar in first (18.5% and 41.4%) and consecutive (17.6% and 35.1%) pregnancies (Chi-Square; p=0.88 and p=0.44). Of all patients, 42.7% developed a complication during all of their pregnancies (obstetrical history included).

Conclusions: This is the first study to report increased type I IFN activation in pregnancy females with a CHB complication. Also, we show here that IFN-α directed therapy, e.g. with hydroxychloroquine, may be especially beneficial in these females.

Neuronal and hormonal alterations in arthritis

A PROTEOMIC SIGNATURE OF FATIGUE IN PRIMARY SJÖGREN’S SYNDROME

1Department of Rheumatology and Clinical Immunology, Stavanger University Hospital; 2Department of Pathology, Stavanger University Hospital; 3International Research Institute of Stavanger – IRIS; 4Research Department; 5Department of Medical Science, Faculty of Medicine and Science, University of Bergen, Bergen; 6International Research Institute of Stavanger – IRIS; 7Department of Medical Science, Faculty of Medicine and Science, University of Bergen, Bergen; 8Centre for Organelle Research (CORE), University of Stavanger, Stavanger, Norway

Background: Fatigue is a frequent and often disabling phenomenon in patients with chronic inflammatory and immunological diseases, neurodegenerative diseases, and cancer. The underlying biological mechanisms of fatigue are largely unknown and hypotheses are conflicting. It is important to uncover the pathophysiology and identify signalling pathways that generate and regulate this substantial phenomenon.

Objectives: Based on the hypothesis that fatigue originates from cerebral processes, we investigated whether relevant proteins and/or signaling pathways for fatigue could be revealed in the cerebrospinal fluid (CSF) of patients with primary Sjögren’s syndrome.

Methods: Label-free shotgun mass spectrometry was performed to analyze the CSF proteome of 20 patients with primary Sjögren’s syndrome. Fatigue was measured with the fatigue Visual Analogue Scale (VAS).

Results: After depletion of high-abundance proteins, more than 800 proteins were identified and quantitated. Multivariate analyses showed that patients with low and high fatigue could be separated based on their CSF protein and metabolite levels, and 15 proteins were selected as top discriminatory proteins. Among these were apolipoprotein A4, hemopexin, pigment epithelium derived factor, secretogranin-1, secretogranin-3, selenium-binding protein 1, and complement factor B. The figure shows the top network from Ingenuity Pathway Analysis (IPA) with 14 of

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.2831
Conclusions: Most of the discriminatory proteins have important roles in regulation of innate immunity, cellular stress defense, and/or functions in the central nervous system. Some have been associated with severe depression and loss of appetite, which are important features of chronic fatigue. These proteins and their interacting protein networks may therefore have central roles in the generation and regulation of fatigue, and the findings add new, relevant, and important evidence to the concept of fatigue as a biological phenomenon signaled through specific molecular pathways.

Fighting osteoporosis fragilities

OP0314-HPR A HOME-BASED FALL PREVENTION PROGRAMME REDUCES FEAR OF FALLING IN SENIORS
B. Zindel1, A. Meichtry2, V. Krahrt1, K. Niedermann2, *Swiss League against Rheumatismus, Zurich; 2Zurich University of Applied Sciences, Winterthur, Switzerland

Background: Every year, over 80,000 elderly persons in Switzerland have accidents caused by tripping and falling, and half of these falls happen at home or in the direct vicinity (1). Falls, due to its often severe medical consequences and persistent mobility impairments, together with the demographic development, are one of the most important musculo-skeletal problems and public health issues. Falls are often due to a combination of internal risk factors (such as vertigo, osteoporosis, cognitive impairments, decreased ability for dual tasking) and external risk factors (such as medication and environmental risk factors) (2). The Swiss League Against Rheumatismus (SLAR) has developed a multidimensional home-based fall prevention programme, which is supported by health insurances. Trained physiotherapists (PTs) and occupational therapists (OTs) visit the seniors at home in order to perform a detailed assessment of the senior’s individual risk of falling. Subsequently the PT or OT eliminates identified environmental risk factors and provide tailored exercises. After 4 weeks, a telephone call was made by the PT/OT to discuss unclear instructions and after 16 weeks, follow up data were collected by telephone.

Objectives: The objective was to evaluate the effects of the fall prevention programme.

Methods: A retrospective analysis was carried out on the data of 671 participants in 2015. Available data were participant’s characteristics, fall risk factors, determined by the Timed “Up&Go” with additional motor and cognitive task) (4), Fall Efficacy Scale (5), the recommendations made by the PTs/OTs and satisfaction of the seniors.

Results: The participants were mainly female (62.6%) and had a mean age of 81.7 years (SD=5.5, range 66.1–100 years). Several risk factors were present: 64.1% fell at least once in the last year and 45% were not able to perform a dual task (TUG + additional cognitive task). Main recommendations made by PTs/OTs were “fixing down of carpets” (56.8%) and instruction of an exercise programme (strength, balance and multi-task capability) (82.6%). After four months, fear of falling had decreased (change in FES-I: -1.24 points 95% CI: (-1.44, -1.04), p-value<0.001). 92% of the participants self-reported to follow the recommendations and 98.4% were satisfied with the programme and would recommend it to others.

Conclusions: The low-threshold, multidimensional home-based fall prevention developed by the SLAR was feasible and effective. Participants implemented the recommendations and the fear of falling’ decreased. Reduced fear of falling is considered a strong predictor of falling, however a prospective study is needed to determine if the reduced fear of falling leads to a decreased number of falls.

**Objectives:**

**Results:**

Of the 1724 JIA patients registered in Reuma.pt, 319 received biological treatment initiation and discontinuation of the first bDMARD. The mean time until discontinuation was calculated using Cox regression survival estimates and the reasons for discontinuation of the first bDMARD were registered.

**Results:**

Of the 1724 JIA patients registered in Reuma.pt, 319 received biological treatment initiation and discontinuation of the first bDMARD. The mean time until discontinuation was calculated using Cox regression survival estimates and the reasons for discontinuation of the first bDMARD were registered. The mean time of clinical remission after withdrawal of BAs was 6 months. The mean age at the beginning of biological therapy was 15.8±9.4 years. The distribution of JIA subtypes was: 19.1% polyarticular RF-negative, 17.2% enthesis-related arthritis, 16.6% polyarticular RF-positive, 16% extended oligoarticular, 13.5% persistent oligoarticular, 12% systemic JIA and 0.9% had undifferentiated arthritis. Considering the whole group, 53.2% had extra-articular manifestations and 18.4% have or had had uveitis since the beginning of the disease. Persistence of treatment, biological therapy and JIA subtype, age at the beginning of biological therapy, and disease duration until initiating first bDMARD. The major reasons for drug discontinuation was inefficacy (49.6%), remission (14.2%), adverse events (10.6%), patient decision (1.6%) and pregnancy planning (4.1%).

**Conclusions:**

Almost half of the JIA patients stop the first biological agent, due to lack of response, reinforcing the need for the existence of several treatment options fully studied in JIA.

**Health equity and economy - a vital relationship**

**OP0317-PARE**

**AN INDEPENDENT REVIEW OF PEOPLE WITH RHEUMATOID ARTHRITIS (RA) AND THEIR CAREGIVER’S LOST WORK TIME**

A. Bosworth 1, C. Jacklin 2, T. Burke 2, A. Rose 3, I. Jacob 2, S. Verstappen 3, 1National Rheumatoid Arthritis Society (NRAS), Maidenhead; 2HCD Economics, Warrington; 3Arthritis Research UK Centre for Epidemiology Division of Musculoskeletal and Dermatological Sciences, University of Manchester, Manchester, United Kingdom

**Background:**

The National Rheumatoid Arthritis Society (NRAS) is the only patient-led charity in the UK focussing specifically on rheumatoid arthritis (RA) with the responsibility of raising awareness of RA and its impact. RA is a long term condition which impacts on all aspects of life for sufferers and their loved ones. There is a lack of information about the costs and impact of RA on work in the European community; in particular the wider societal costs such as people with RA not being able to perform their job to their best ability, losing days of work due to their RA condition, and the wider societal costs associated with caregiver employment.

**Objectives:**

To quantify the burden of RA not only on the healthcare system, but also the wider societal costs associated with RA.

**Methods:**

In 2016 NRAS undertook a partnership with the University of Chester’s commercial economics partner HCD Economics who conducted the multinational Burden of Rheumatoid Arthritis: Socioeconomic Survey (BRASS). The study used a bottom-up approach to quantify the burden of disease for people living with RA across 10 European countries including France, Germany, Italy, Spain, Denmark, Sweden, Hungary, Poland, Romania and the UK. The study collected information from employed and physically active persons aged 18 and over who had a Rheumatoid Arthritis diagnosis and their family/friend caregivers. It collected information on the resource use and cost of patient care including treatment costs, hospitalisation, tests, and examinations. The wider societal costs included; cost of travel to appointments, requirements for aids/equipment, informal care (non-professional), ability in employment, early retirement due to RA. Work time missed, work and activity impairment were measured using the Work Productivity and Activity Impairment (WPAI) questionnaire.

**Results:**

Voluntary data were collected from 1782 patient forms, of which the average age was 55 years, 1274 (71%) were female and 832 (48%) were currently in work. This study found, on average, persons with RA lose one day of every 4 working days due to not being able to perform their job to their best ability, and completely miss 7% of work time over a 7 day period due to their RA (sample n of 646). In addition to not being able to perform their job to their best ability, almost a third of working persons with RA also had impairment in daily living activities such as shopping and work around the house (sample n of 735). This study also found family/friends have to care for 16% of RA sufferers. This care resulted in reduced employment or inability to work for 25% of family/friend caregivers (sample n of 121).
Conclusions: This study highlights the impact RA has on working life amongst both those with the condition and those providing support. It is hoped these metrics will allow the conversation to open and develop with employers and government on how adapting the workplace can increase productivity. Further research should also be undertaken on the economic impact both to the individuals, their carers and society.

Acknowledgements: The BRASS study was supported by unrestricted research grants from Eli Lilly and Pfizer. The study was approved by the University of Chester Ethics Committee.

CONSULTING SERVICES TO EMPLOYERS OF PEOPLE WITH RMDs

F.J. Carreira Roca 1, 2, A.I. Vázquez Lojo 3, V. Romero Pazos 4, 5 on behalf of LIRE-LRG, Accessibility Dept. and Volunteer, Liga Reumatologica Galega (LRG), A Coruña; 2 Accessibility Consultant and Volunteer, Liga Reumatologica Española (LIRE), Madrid; 3 Board of Directors and Occupational Therapy Dept., Liga Reumatologica Galega; 4 International Dept., Liga Reumatologica Galega (LRG), A Coruña; 5 Board of Directors, Liga Reumatologica Española (LIRE), Madrid, Spain.

Background: The Eurobarometer 1 states that RMDs affect 22% of the general population which means that 10 million people are affected in Spain and more than 600,000 people in the autonomous region of Galicia where our organization, LRG, works. Knowing that 50% of people with RMDs are currently unemployed because of their condition, only part of them have the legal work incapacity recognized and receive a pension. This means that RMDs not only affect the health but also the socio-economic status. Most of this people could stay at work and are willing to do so if some arrangements are made like cutting down hours, work place adaptations, flexible schedules, etc. Most employers are lacking information on how these conditions affect the employee’s ability, desire and need to work and how to make the necessary adaptations for not loosing this person from the work force.

Objectives: Making the employer more aware of the positive aspects of keeping all the employees including people with RMDs not just at the work place but at full capacity, avoiding both absenteeism and presenteeism.

Methods: The employee with RMD has 1 session with the psychologist and 1 session with the occupational therapist (OT) to identify the difficulties in continuing to be active into their work place.

Results: The employee HP provided personalized advice to the employer about the RMDs, the needs of the employee and how to facilitate them to stay at work and minimize the work incapacity due to their chronic condition. This kind of advise is given by the OT who has treated the employees and knows all about their needs, to go their work place to see what are the actual conditions, identifies manageable obstacles and talks to the employers during a pre-scheduled meeting. After, an architect specialized in accessibility offers specific architectural and ergonomic solutions for adapting the work place. Also peer support is provided by LRG in group meetings and activities of the organization.

Conclusion: The results of this project are shown in the increase of the employees’ self-confidence in their capacity to stay at work and also they are more aware of their solvable and non solvable limitations. During 2016 we advised 14 associates of LRG, 5 of those 14 employees (1/3) stayed at work or returned to work after the consultancy.

Biomarkers in cardiovascular rheumatology - state-of-the-art 2017

OP0319

HIGH SENSITIVITY CARDIAC TROPONIN T IS A BIOMARKER FOR Atherosclerosis IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: A CROSS-SECTIONAL CONTROLLED STUDY

G. Divard 1, R. Abbas 1, C. Chenevrier-Gobeaux 1, B. Escoubet 1, M.-P. Chauveheled 1, A. Dossier 1, M. Dehoux 1, T. Papo 1, K. Sacre 1, Paris-7 University, APHP, Bichat Hospital; 2 Paris-5 University, APHP, Cochin Hospital, Paris, France.

Background: Cardiovascular disease (CVD) is the main cause of death in systemic lupus erythematosus (SLE) patients. Framingham score underestimates the risk for CVD in this population.

Objectives: Our study aimed to determine whether serum High Sensitivity Cardiac Troponin T (HS-cTnT) helps to identify SLE patients at risk for CVD.

Methods: Presence of carotid plaques was prospectively assessed by ultrasound in 63 consecutive SLE patients asymptomatic for CVD and 18 controls. Serum HS-cTnT concentration was measured using the electrochemiluminescence method. Factors associated with carotid plaques were identified and multivariate analysis was performed.

Results: Framingham score was low in both SLE patients (2.13±3.8%) and controls (2.12±3.9%). Nevertheless, 23 (36.5%) SLE patients, but only 2 (11.1%) controls (p=0.039) had carotid plaques detected by vascular ultrasound. In the multivariate analysis, only age (p=0.006) and SLE status (p=0.017) were independently associated with carotid plaques. Serum HS-cTnT concentration was detectable (i.e. ≥ 3 ng/L) in 37 (58.7%) SLE patients and 6 (33.3%) controls (p=0.057). Interestingly, 87% of SLE patients with carotid plaques, but only 42.5% in SLE patients without plaques (p<0.001), had a detectable HS-cTnT. Conversely, 54.5% SLE patients with a detectable HS-cTnT, but only 11.5% with an undetectable HS-cTnT (p<0.001), had a carotid plaque. In the multivariate analysis, only BMI (p=0.006) and HS-cTnT (p=0.033) were statistically associated with carotid plaques in SLE patients. Overall, the risk of having a carotid plaque was increased by 8 (95% CI): 8.03 [1.41–74.73] in SLE patients in whom HS-cTnT was detectable in serum.

Conclusions: Detectable HS-cTnT concentration is independently associated with subclinical atherosclerosis in asymptomatic SLE patients at apparent low risk for CVD according to traditional risk factors. These results raise the possibility that this easily obtained biomarker is useful for more rigorous risk stratification and primary prevention of CVD in SLE patients.

Background: Response to rituximab (RTX) is variable in patients with ANCA-associated vasculitis (AAV), and predictors of treatment efficacy/relapse risk would be useful. Previous studies have shown that RTX pharmacokinetics (PK) is associated with treatment efficacy in patients with lymphoma.

Objectives: To study the determinants of RTX PK in patients treated for AAV and its association with clinical outcomes.

Methods: This study included 88 patients from the RTX in ANCA-Associated Vasculitis (RAVE) trial who received the full dose of RTX (4 weekly 375 mg/m2 infusions) and had available serum samples. RTX was quantified using two state-of-the-art 2017 biomarkers in cardiovascular rheumatology - state-of-the-art 2017.

Background: ANCA-associated vasculitides (AAVs), including granulomatosis with polyangiitis and microscopic polyangiitis, are small vessel vasculitides. Modern treatments have greatly improved survival in AAV patients, but significant long-term morbidity and mortality such as cardiovascular disease (CVD) are still associated with this disease.

Objectives: The aim of our study was to assess the incidence, mortality and clinical outcomes. Serum rituximab level monitoring does not seem clinically useful in this context.

Cytokine taxonomy: reflection in the therapy of arthropathies and other IMIDs

K. Sato, A. Iizaki, Y. Araki, T. Mimura. Department of Rheumatology and Applied Immunology, Saitama Medical University, Saitama, Japan

Background: Adult-onset Still’s disease (AOSD) and Behcêt’s disease (BD) are both systemic inflammatory diseases, the causes of which are largely unknown. They have been recently classified as autoimmune diseases, a group of diseases in which innate rather than acquired immunity plays important roles in their pathogenesis. As AOSD and BD are clinically distinct diseases, their cytokine networks should also be different.

Objectives: In this study, we attempted to quantify the levels of multiple cytokines in the serum of patients by using a beads-array technique and ELISA, and then compared the serum cytokine profiles of the two diseases by factor analysis. We then sought to clarify the hierarchical relationship between interleukin (IL)-17A and interferon (IFN)-α using peripheral blood mononuclear cells (PBMCs).

Methods: We quantified the serum levels of 10 cytokines (IFN-α, IFN-γ, IL-1β, IL-2, IL-4, IL-6, IL-10, IL-12p70, IL-17A and tumor necrosis factor α) in 16 AOSD patients and 28 BD patients using multiplex bead array assays and IL-18 along with ELISA. The data were then subjected to factor analysis. We next stimulated PBMCs from three healthy volunteers in vitro with class A CpG oligodeoxynucleotides (ODNs) in the presence or absence of IL-17A for 15 hours. We performed flowcytometric analysis to examine the expression of intracellular IFN-α in plasmacytoid dendritic cells (pDCs).

Results: Two factors were extracted from the factor analysis using the data on 8 cytokines that were detectable in the serum of the patients. IL-17A and IFN-α, the levels of which showed a strong positive correlation in the serum of BD patients (Fig. A), were the main components of Factor 1, while Factor 2 consisted of IL-6, IL-10 and IL-18 (Fig. B). Patients were also plotted on a plane determined by Factors 1 and 2 according to each patient’s factor scores. Those who were high in Factor 1 but low in Factor 2 were likely to be BD patients and vice versa, many of those who were high in Factor 2 but low in Factor 1 were AOSD patients. In terms of flowcytometric analysis, IL-17A alone did not induce IFN-α expression in pDCs, but it did substantially increase IFN-α–positive pDCs induced by CpG ODNs.

Conclusions: The cytokines examined were clearly separated into distinct groups by the factor analysis. Similarly, the AOSD and BD patients could be separated, although roughly. High levels of serum IL-6, 10 and 18 suggest AOSD while high levels of IFN-α and IL-17A indicate BD. To establish patterns of correlation among cytokines, it is important to focus on the cytokine concentrations in each patient, rather than the average cytokine concentrations in each of the diseases. In terms of the hierarchical relationship between IFN-α and IL-17A, a previous report suggested that IFN-α blocks IL-17A production in PBMCs from BD patients. Thus, we examined the effect of IL-17A on IFN-α production. It should be noted that the real stimulus for IFN-α release in BD is unknown. In addition, cells other than pDCs may be involved in the production of IFN-α. Nevertheless, understanding the hierarchical relationship among cytokines should prove to be helpful in clarifying the pathogenesis of various inflammatory diseases.

DISCOPATHY ASSOCIATED WITH MODIC CHANGES IS NOT RELATED TO ANY INFECTIOUS PROCESS: A PROSPECTIVE MONOCENTRIC STUDY

S. Ahmed Yahia1, J.-W. Decousser2, C.H. Flouzat-Lachaniette3, F. Robineau1, E. Audureau4, A. Houdur1, F. Eyraud1, X.-J. Chevalier1, 2Rheumatology; 3Microbiology; 4Orthopaedic; 1Public health, Henri Mondor hospital, Creteil, France

Background: Low back pain (LBP) is strongly associated with Modic changes. The...
hypothesis of local infectious origin was raised, especially with Proprionibacterium species. PCR PAs with a single weakly positive sample reinforce the hypothesis of local infectious origin, but are insufficient for a definite diagnostic conclusion. When patients underwent lumbar spine surgery by an anterior approach, 2 samples of the disc were collected for bacteriological analysis: one sample from the anterior part of the disc distant from epidural space and one sample from the posterior part of the disc. 77 discs samples were obtained, 32 discs samples in Modic 1 or 2 changes by anterior approach, 26 discs samples in no Modic IVD by anterior approach, 19 disc samples obtained by anterior approach to that obtained by posterior approach in herniated disc cases.

Methods: 45 patients with chronic LBP or sciatica were included in the study, representing 48 IVD. When patients underwent lumbar spine surgery by an anterior approach, 2 samples of the disc were collected for bacteriological analysis: one sample from the anterior part of the disc distant from epidural space and one sample from the posterior part of the disc. 77 discs samples were obtained, 32 discs samples in Modic 1 or 2 changes by anterior approach, 26 discs samples in no Modic IVD by anterior approach, 19 disc samples obtained by posterior approach. The method to collect disc material was strictly aseptic. Samples were analysed by conventional microbial cultures with specialised enrichment, molecular detection by universal rRNA gene PCR plus sequencing assay. Additionally, all clinical specimens were specifically tested for PA detection using a highly sensitive specific PCR assay. The possibility of contamination with saprophytic germs coming from the skin during surgery by posterior approach or by epidural infiltration preceding the surgery was also discussed, but not proved.

Objectives: The main objective of this study was to evaluate the prevalence of saprophytic germs in the intervertebral disc (IVD) obtained during a lumbar spine surgery by anterior approach in Modic 1 and 2 changes. A secondary objective was to compare the prevalence of SGB in IVD in lumbar spine surgery obtained by anterior approach to that obtained by posterior approach in herniated disc cases.

Results: Regarding bacterial cultures, 12 out 77 disc samples were positive (16%), including 10 (13%) for PA. The PA specific PCR was positive for one (1%) sample collected by posterior approach. The 16S rRNA detection was positive for 6 specimen (8%), including one for PA (1%). Modic 1–2: Cultures were positive in 5 cases (16%) with 3 for PA (10%). No specific PA PCR was positive. Only one sample was positive for PA in both culture and 16S PCR. Comparison between anterior and posterior approach: Among the PA positive cultures, 5 were identified from anterior specimens (8.62%) and 5 from posterior specimens (26.32%). Regarding PA cultures, the posterior fragments were more frequently positive than the anterior fragments (p=0.046). The number of epidural infiltrations of the lumbar spine does not seem to influence the bacterial contamination prevalence (p=0.746). The time between the epidural infiltration of the lumbar spine and the surgery does not seem to influence the bacterial contamination prevalence (more or less 6 month) (p=0.23).

Conclusions: SGB has been identified in culture in 16% of the samples obtained in Modic 1 and 2 changes. The prevalence of PA in culture was significantly higher in samples of IVD collected by a posterior approach compared to anterior approach in spine surgery suggesting a contamination. The results of the specific PCR PAs with a single weakly positive sample reinforce the hypothesis of contamination.

OP0325 TGF-BETA-INDUCED ED-A FIBROBLAST LIKE SYNOVIAL CELLS CONTRIBUTES TO INFLAMMATION IN OSTEOARTHRITIS

T.W. Krarup1,2,3, D.H. Sohn1,4, C.M. Lepus1, K. Onuma1, Q. Wang1, W.H. Robinson1, J. Sokalove1, 1Department of Immunology and Rheumatology; Stanford University, Stanford, United States; 2Department of Bioengineering, Aarhus University, Aarhus C, Denmark; 3Department of Microbiology and Immunology, Pusan National University, Pusan, Korea, Republic Of

Background: The pathophysiology of osteoarthritis (OA) involves wear and tear, and a state of low-grade inflammation. Wear and tear leads to tissue degradation followed by tissue repair responses including TGF-β-induced myofibroblast production of extracellular matrix (ECM). Fibroblasts are an essential part of the ECM, and injection of fibronectin fragments into rabbit joints is an established animal model of OA. Recently, alternatively spliced fibroblast containing the ED-A domain (ED-A FN) has been shown to activate Toll-like receptor 4.

Objectives: In this study, we hypothesize that FN fragments containing the ED-A domain could be one mechanism transducing mechanical events into inflammatory signals in OA.

Methods: Samples of synovial membrane and cartilage were obtained from patients with knee OA undergoing joint replacement surgery. Immunostaining was performed on synovial membranes. Fibroblast-like synovial cells (FLS) isolated from OA synovium (b-20) were cultured in vitro. OA FLS were stimulated with recombinant ED-A FN, plasmid, cellular FN, or plasmid digested with plasmid digestion of cellular FN. Synovial cells isolated by enzymatic digestion and human monocyte-derived macrophages (MDM) were incubated with recombinant ED-A FN, plasmid, cellular FN, or plasmid digested with plasmid and culture supernatants were analyzed for TNF-α and IL-6 using enzyme-linked immunosorbent assay (ELISA)

Results: We hypothesized that ED-A FN is produced by OA FLS in response to products reflecting tear and wear in OA. Indeed, the production of ED-A FN by OA FLS is increased by TGF-β, OA synovial fluid, and lysed chondrocytes in all experiments (n=3, see figure). ED-A FN co-localized with the myofibroblast marker α-SMA in both the OA FLS (n=3) and in the OA synovial membranes (n=8). We further hypothesized that ED-A FN expression is associated with inflammation in OA. ED-A FN staining was associated with both number of lining layer cells (rho=0.85 and p=0.011) and infiltrating sublining cells (rho=0.88 and p=0.007) in the OA synovium (n=8), and co-localized with both MCP-1 and TNF-α (n=4). Recombinant ED-A FN increased the production of both MCP-1 and TNF-α by MDM (n=3) and OA FLS (n=3). Finally, we demonstrated that the FN fragments containing the ED-A domain generated the same production of both MCP-1 and TNF-α as recombinant ED-A FN.

Conclusions: The disease process in OA shares features with the chronic
wound healing response including myofibroblast differentiation and that humeral mediators found in the joint can promote myofibroblast production of ED-A FN. We additionally show that recombinant and plasmid-derived ED-A fragments can induce generation of pro-inflammatory mediators from FLS and MDM. This study supports targeting the formation of ED-A FN or the enzymatic fragmentation of PAI-1 as a novel therapeutic approach for pro-inflammatory responses in OA.

**EPIGENETICALLY-DRIVEN DISTAL EXPRESSION OF THE LNCRNA HOTTIP SHAPES INFLAMMATORY, ADHESIVE AND PROLIFERATIVE CHARACTERISTICS OF HAND SYNOVIAL FIBROBLASTS IN ARTHRITIS**

M. Frank Bertonecelli,1 E. Karouzakis1, K. Klein1, A. Bratus2, C. Kolling3, O. Distler1, A. Filer1, R.E. Gay1, C.D. Buckley4, S. Gay1, C. Ospelt3

1University Hospital Zurich, Schlieren; 2Functional Genomics Center Zurich; 3Schulthess Klinik, Zurich, Switzerland; 4University of Birmingham, Birmingham, United Kingdom

**Background:** Rheumatoid arthritis (RA) and other types of inflammatory arthritis show a characteristic pattern of joint involvement. E.g. in RA there is a predilection for the small joints of hands and feet, whereas in spondyloarthopathy, single large joints are predominantly affected. Interestingly, in RA, some joints have robust expression of certain fibroblast subtypes (SF), which drive joint destruction in RA, display location-specific transcription patterns and functions, shaping unique micromvernions in different joints.

**Objectives:** To analyze the role of transcripts expressed in SF at specific joint locations in defining location-specific functions of SF, relevant to the pathogenesis of RA.

**Methods:** SF were isolated from hand, elbow, shoulder, feet and hips of RA and OA patients undergoing joint replacement surgery and from knees of nonarthritic subjects with arthralgia. Transcriptomes and epigenomes of SF were determined by RNA-seq (Illumina HiSeq 2000, n=21), qPCR, Chip-seq (H3K4me3, H3K27me3, H3K27ac, Illumina HiSeq 2500, n=7) and Infinium HumanMethylation450 BeadChip (n=12). Proliferative, adhesive and chemotactic properties of SF were studied by xCELLigence real time cell analysis and leukocyte chemotaxis towards supernatants of SF. The IncRNA HOTTIP was silenced in hand SF using LNA GapmeR oligos, followed by RNA-seq (n=2), pathway enrichment analysis (MetaCore, Thomson Reuters, FDR<0.05) and qPCR (n=5).

**Results:** HOTTIP was the most differentially expressed transcript in distal (hand) vs. proximal (shoulder) SF. HOTTIP was specifically transcribed in SF from hand and feet SF, but absent from other joints, indicating distal-specific function to this IncRNA. Hand-specific HOTTIP expression coincided with the enrichment of activating histone marks H3K4me3 and H3K27ac, absence of repressive H3K27me3 and decreased DNA methylation at the HOTTIP promoter in hand SF. In contrast, the HOTTIP promoter displayed abundant DNA methylation and H3K27me3 in knee and shoulder SF. Silencing of HOTTIP led to downregulation of 3275 genes and upregulation of 4326 genes (log ratio >0.5; p<0.01, FDR<0.05). Distal-specific homeobox A13, a known HOTTIP target, was repressed in HOTTIP-silenced SF. Pathway enrichment analysis of genes repressed by HOTTIP silencing showed enrichment for pathways regulating cell adhesion, cell cycle, angiogenesis and inflammation, including NF-κB activation and IL-6 signalling. Meanwhile, upregulated genes were enriched in fewer pathways, e.g. IL17 and Notch signalling. 110 genes that were differentially expressed in hand vs. shoulder SF were also altered by HOTTIP silencing, e.g. TNFRSF1B and MAP3K14. Hand SF showed enhanced proliferative and chemotactic, but decreased adhesive properties compared to shoulder SF.

**Conclusions:** The IncRNA HOTTIP, which is exclusively expressed in small, distal joints, via epigenetic mechanisms, is a regulator of inflammatory, proliferative and adhesive properties of SF. Such a functional specialization of arthritis relevant pathways in SF might represent an imprinted site-specific “risk” signature in SF, predisposing thereby to location-specific joint pathology, e.g. enhanced severity of hand arthritis in RA.

**Patient engagement in research: best practices, benefits and challenges**

K. Cresswell1,2, S. Parsons1,2, S. Stones3, J.E. McDonagh4,5,6, W. Thomson1,2,5,6, L. Lunt1, Public Programmes Team, Central Manchester NHS Foundation Trust, University of Manchester; 2Manchester Academic Health Science Centre; 3Public Contributor; 4Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, University of Manchester; 5NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester NHS Foundation Trust, University of Manchester; 6Barbara Ansell National Network for Adolescent Rheumatology; 7Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom

**Background:** Between 2014 and 2016, the Barbara Ansell National Network for Adolescent Rheumatology (BANNAR) commissioned research to explore young people’s rheumatology research priorities and beliefs about research involvement. The next phase of this work has been to establish a UK-wide research advisory group, YourRheum, to involve 11–24 year olds with rheumatic and musculoskeletal diseases (RMsDs) more effectively in shaping research.

**Objectives:** To describe our experiences of developing a UK-wide research advisory group, for young people with RMsDs, using both face-to-face meetings and online involvement applications.

**Methods:** From September 2016, we recruited young people to the group using several approaches: including the previous research study database, through BANNAR members, through UK charities, as well as through social media. To tailor options for involvement, young people were recruited to contribute to both face-to-face meetings and online channels.

**Results:** Eight young people attended YourRheum’s first meeting in October 2016, where they discussed how they would like the group to work. Thirteen young people have been engaged online via a closed Facebook group, monitored by the Your Rheum facilitator. Key challenges in establishing the group have included developing age-appropriate communication approaches to appeal to the range of ages involved, devising ways of ensuring online members remain engaged with the group, and finding appropriate tasks for the group to be involved with, that are both suitable and aligned with research project timelines. This involves working closely with young people, health professionals and researchers.

**Conclusions:** There is both a need for young people’s involvement in research and a desire from young people themselves to do so. Expansion of the online network and involvement activities will allow young people across the UK to have a valuable input into research, regardless of location.

**Patient safety in relation to biosimilars – how can we act as a patient organization?**

L.M. Thomsen, Danish Rheumatism Association, Gentofte, Denmark

**Background:** During the last two years two biosimilars has been approved by the national authorities in Denmark, and implemented in the treatment of patients with arthritis. When the first biosimilars were approved in 2015, the hospitals in Denmark decided to shift native patients from the original drug to the new biosimilar. This decision caused considerable insecurity among the patients, who were afraid of biosimilars and their effectiveness and safety profile. Therefore the Danish Rheumatism Association decided to implement an effort to create better patient information and safety for patients, who had to start with a biological drug or shift from one biological drug to another or to a biosimilar.

**Patient safety in relation to biosimilars – how can we act as a patient organization?**

L.M. Thomsen, Danish Rheumatism Association, Gentofte, Denmark

**Background:** During the last two years two biosimilars has been approved by the national authorities in Denmark, and implemented in the treatment of patients with arthritis. When the first biosimilars were approved in 2015, the hospitals in Denmark decided to shift native patients from the original drug to the new biosimilar. This decision caused considerable insecurity among the patients, who were afraid of biosimilars and their effectiveness and safety profile. Therefore the Danish Rheumatism Association decided to implement an effort to create better patient information and safety for patients, who had to start with a biological drug or shift from one biological drug to another or to a biosimilar.
Objective: The purpose of the effort was to increase patient safety and to ensure that patients received independent patient information within biological drugs.

Methods: First the Association conducted a small study of how the shift of drug had taken place in the different regions. Most patients experienced that they were told by the doctors to shift to biosimilars, and furthermore they experienced a lack of information about the new biosimilars. On a national level, nearly all patients on a biological drug are registered in a national database. It is registered in the database and hospital records which drug the patient are prescribed, but it is not registered on a batch-level.

In order to change these conditions the Association started a dialog with the politicians and the authorities on a national level and the hospital-administrations on a regional level. The purpose was to improve the registration of the drugs on batch-level, to improve more independent patient information and to improve the involvement of the patient in the decision making process. The dialog was on a general level, but with several patient-stories from each region.

Results: A new national plan for better monitoring and information about biologic and biosimilars was launched in August 2015 and carried out in 2016. The plan consists of four parts: 1) Monitoring biological drugs and biosimilars on batch level, 2) Information campaign to health professionals and patients, 3) Digital solutions and easy reporting of side effects from health professionals and patients, 4) Focus on monitoring patient safety by the authorities. The Danish Rheumatism Association has participated in the work to implement the plan. In addition to the national plan the hospitals on a regional level, has invited the Rheumatism Association to participate in a representative in the working group, where national recommendations for the use of biological drugs are being made in an attempt to involve the patient perspective more. The content of the national plan and the involvement in the work with national recommendations, will be elaborated and discussed from the patients perspective throughout the presentation.

Conclusions: The implementation of biosimilars created great insecurity among patients. Therefore, the Danish Rheumatism Ass. decided to make an effort to create better patient information and safety for the patients. Through dialog with politicians, national authorities and hospital-administrations, we managed to get a national plan for better monitoring and information about biologic and biosimilars, and to be involved in the work with national recommendations for these drugs. The national plan and work with national recommendations will be elaborated in the presentation.

Switching T on and off: how T cells drive and regulate chronic inflammation

OP0329 INVOLVEMENT OF T HELPER 17 CELLS IN INFLAMMATORY ARTHRITIS DEPENDS ON THE HOST INTESTINAL MICROBIOTA

H. Evans-Marin1, R. Rogier2, J. Scher1, D. Roeleveld2, M. Koenders2, S. Abolghasemi-Roudsaz1,2, Medicine, New York University School of Medicine, New York, United States; 1Rheumatology, Radboud university medical center, Nijmegen, Netherlands

Background: Intestinal microbiota have been associated with psoriatic and rheumatoid arthritis. One of the major effects of microbiota is the induction of mucosal T helper 17 (Th17) cells. We therefore reasoned that the efficacy of Th17-targeted therapies in arthritis may depend on the host microbiota. Previous studies focused on the role of the cytokine regu-larin-17A (IL-17A) - deficient Th17 cells by using IL-17 inhibitors or IL-17-deficient mice. Therefore, the role of Th17 cells, which produce multiple pro-inflammatory mediators in addition to IL-17, is not yet fully understood.

Objectives: The aim of this study was to determine the role of Th17 cells, beyond the cytokine IL-17, in arthritis, and to investigate whether Th17 cells are differentially involved in arthritis depending on the microbiota present.

Methods: We established conditional Th17-deficient mice, which exhibit a CD4-Cre-induced floxing of a part of the Rorc allele that encodes the Th17 master regulator RORC. We then established conditional Th17-deficient mice, by using IL-17 inhibitors or IL-17-deficient mice, to investigate whether Th17 cells are differentially involved in arthritis depending on the microbiota present. We used previously generated Fra2 tg overexpressing mice. T lymphocyte populations were analyzed by flow cytometry for expression of activation markers and secretion of cytokines. We transferred purified CD4+ T cells into Rag2-/- mice lacking T and B cells, and we generated Rag2-/-Fra2 tg mice. Bone marrow cells were transferred into lethally irradiated recipients to create Fra2-wT bone marrow chimeric mice.

Results: Fra2 tg mice backcrossed onto a Rag2- background did not develop inflammatory manifestations (n=6), demonstrating the dependence on T and/or B cells of the autoimmune phenotype. In line with this, the transfer of purified CD4+ cells from 16-week-old Fra2 tg mice into Rag2- recipients was sufficient to transfer the disease phenotype (n=3). Analysis of T cell populations from Fra2 tg mice showed the presence of activated CD4+ and CD8+ cells in the spleen.
A NOVEL HUMANIZED EFFECTOR-DEFICIENT FCYRIIA 1,1,2,2, N. Panousis3, I. Gergianaki 1,2, M. Tektonidou4, M. Trachana5, We have generated MEDI9600, a specific humanized antibody protein that potently blocks both autoantibody and immune complex mediated proinflammatory responses from a variety of cell types. This includes the inhibition of Toll-like receptor stimulatory immune complexes that induce type I interferons from pDC, and the inhibition of anti-neutrophil cytoplasmic antibody (ANCA) induced production of reactive oxygen species from neutrophils, which are associated with the pathogenesis of systemic lupus and ANCA vasculitis respectively. MEDI9600 specifically binds FcγRIIA, and its suppressive activity is attributed to its capacity to block ligand engagement and to internalize the receptor from the cell surface. Moreover, in vivo studies indicate that MEDI9600 has a favorable pharmacokinetic and safety profile. Conclusions: We have generated MEDI9600, a specific humanized antibody antagonist of FcγRIIA with null effector function that may provide a novel therapeutic approach in the treatment of immune complex mediated diseases. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.19944 SATURDAY, 17 JUNE 2017 Genomic imprinting and post-translational modifications OP0332 THE GENOMIC ARCHITECTURE OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) BY RNA-SEQ: DISTINCT DISEASE SUSCEPTIBILITY, ACTIVITY AND EXTENIVE GENETIC EFFECTS ON WHOLE BLOOD GENE EXPRESSION G. Background: SLE displays significant immunological and clinical heterogeneity. Understanding the molecular basis of this variability may facilitate early diagnosis, risk stratification and personalized therapy.

Objectives: To perform full transcriptome analysis in SLE patients in order to identify molecular sub-phenotypes and explore the genomic basis for the disease susceptibility and severity.

Methods: Whole blood mRNA and genomic DNA were extracted from 142 SLE patients with varying levels of disease activity/severity and 48 matched healthy volunteers. Paired-end RNA sequencing was performed using the Illumina HiSeq 2000 platform and genotyping with the Infinium CoreExome followed by imputation from the 1000 Genomes. To integrate blood transcriptome with genotype data we used the enrichment analysis of expression-quantitative trait loci (eQTLs). The CIBERSORT tool was used to provide an estimation of the abundances of different circulating immune cell types.

Results: We found a large number (6730, 5% False Detection Rate [FDR]) of differentially expressed genes (DEGs) between SLE patients and controls. Interferon signaling was significantly upregulated in SLE with most of the DEGs (146 out of 281) being regulated by both type I and type II interferon. Analysis of the blood composition in different immune cell types revealed global upregulation of type I interferon and antiviral response genes as well as immune cell-specific alterations in gene expression in SLE patients. Comparison of the transcriptome in active/inactive SLE and healthy individuals identified distinct disease susceptibility and ‘disease activity’ gene signatures encompassing 2738 and 377 DEGs, respectively. Analysis according to individual organ involvement revealed more widespread aberrancies in gene expression in SLE patients with active nephritis as compared to activity from other organs, corresponding to oxidative phosphorylation, granulocyte activation and antimicrobial humoral response pathways. By integration of genotyping data, we mapped a total 3142 (5% FDR) cis-eQTLs in SLE patients suggesting extensive genetic effects on whole blood gene expression. Importantly, linear discriminant analysis enabled the definition of a set of DEGs which discriminated SLE versus healthy state with median sensitivity 83% and specificity 100%. Design of gene expression panels and expression profile-clinical trait correlation matrices for improved diagnostics, stratification and personalized therapy is in progress.

Conclusions: Specific gene networks confer susceptibility to SLE as well as to severe forms of the disease. These results may facilitate the early diagnosis, monitoring and prognosis, and the molecular taxonomy of SLE patients into pathophysiological and prognostically distinct subsets for personalized therapy.

Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.6802 SATURDAY, 17 JUNE 2017 Reverse translation - learning from clinical trials in SLE, Sjögren’s and APS OP0331 A NOVEL HUMANIZED EFFECTOR-DEFICIENT FCYRIIA ANTIBODY INHIBITS IMMUNE COMPLEX MEDIATED PROINFLAMMATORY RESPONSES B. Kolbeck6, G. Sims1. 1MedImmune Inc, Gaithersburg, United States; 2MedImmune Inc, Granta Park, Cambridge, United Kingdom.

Background: Collectively, the cell surface Fc region of IgG receptors (FcγRs) engage soluble IgG and IgG containing immune complexes and trigger activation or inhibitory signals that play a critical role in the regulation of immune responses. The low affinity FcγRIIa (CD32A) is the most widely expressed activating FcγR in humans and appears to drive autoantibody and immune complex mediated autoimmune disorders. So far a therapeutic targeting this receptor has not been developed.

Objectives: To generate and characterize a novel humanized effector-deficient FcγRIIA antibody (MEDI9600) for clinical development.

Methods: The mouse model of MEDI9600 was assessed by confocal microscopy, whole blood internalization, and binding competition assays. Multiple cell based assays were used to measure autoantibody and immune complex mediated proinflammatory responses. The safety of MEDI9600 was assessed in vivo in mature tTreg cells. In particular, we could observe a normal proliferation of tTreg precursors (CD4+CD25+FoxP3+), but a strong decrease in MEDI9600 treated tTreg cells (CD4+CD25+FoxP3+), suggesting a perturbation in the transition from tTreg precursors to mature tTreg cells in Fra2 tg mice. We also found that in vivo stimulation with IL-2 failed to induce the proliferation of Treg cells in Fra2 tg mice compared to WT mice, suggesting that Fra2 overexpression affects IL-2 sensitivity of T cells. Finally, Fra2-WT bone marrow chimera mice also displayed a decreased percentage of Tregs confirming a cell-intrinsic and hematopoietic role of Fra2 in Treg cell development.

Conclusions: Our data suggest that Fra2 controls Treg cell development, possibly by modulating IL-2 signaling in T cells, which leads to autoimmunity in this mouse model. This new pathway could be targeted in a translational approach to modulate the capacity of T cells to differentiate in Tregs during autoimmune disease.

DISCOVERY AND VALIDATION OF NOVEL AUTOANTIGENS IN SJÖGREN'S SYNDROME WITH POTENTIAL FOR SUBGROUPING OF DISEASE

PK. Schulz-Knapp1, P. Budde1, H.-D. Zucht1, D. Wirtz1, K. Marquardt1, R. Thomas1, T. Witte2, M. Schneider3, K. Sivis4, A. Rasmussen5, P. Protagen, Dortmund; 2Dept. of Clinical Immunology and Rheumatology, Hannover Medical School, Hannover; 3Dept. of Rheumatology, Heinrich Heine University, Düsseldorf, Germany; 4Oklahoma Sjögren's Syndrome Center of Research Translation; 5Oklahoma Medical Research Foundation, Oklahoma, United States

Background: Primary Sjögren's syndrome (pSS) is a common autoimmune disease with exocrine gland dysfunction and multi-organ involvement. With the growing interest in conducting clinical trials in pSS, there is a need for new biomarkers that can be used to diagnose pSS, identify clinical subsets of pSS, predict disease course, follow disease activity, and assess treatment response. Activation of B-cells and dysregulation of the cytokine network plays a critical role in the pathophysiology of pSS. In the exocrine glands, elevated levels of cytokines, such as type I interferon (IFN), tumor necrosis factor alpha (TNF), interleukin 12 (IL-12) and B cell activating factor (BAFF) can be found. Dysregulated pathways of the innate and adaptive immune system lead to loss of tolerance and the production of organ-specific and non-specific autoantibodies. Current diagnostic criteria for pSS utilize autoantibodies directed to nuclear antigens (ANA), especially to SS-A/Ro (TRIM21, TROVE2) and La (SSB), but those are not specific, and can be identified as well in SLE and even in healthy volunteers. Several studies have shown that not all patients with pSS are tested positive for Ro and La antibodies, but suggested the existence of additional autoantibodies in pSS. This autoantibody burden is not well understood for the importance of disease progression, for its role in patient segmentation, or for response to treatments.

Objectives: The discovery of novel autoantibodies may provide a deeper understanding of mechanisms of actions for pSS drugs, and may be useful to stratify patients.

Methods: The autoantibody reactivity pattern of pSS serum samples was analyzed using a Luminex bead-based antibody array (SeroTag) and 1,600 selected human proteins from the ImmunexX protein library of 8,000 recombinant proteins. We screened over 2,000 serum samples from patients with autoimmune diseases as active controls targeting Sjögren's Syndrome (n=70), SLE (n=500), SSc (n=250), RA (n=500), and over 1,000 healthy individuals to confirm known and to discover novel autoantibodies. In a validation study, novel biomarker candidate antigens were evaluated using a cohort of 350 Patients with Sjögren's Syndrome.

Results: Apart from clear confirmation the known benchmark autoantigens known for many years we have discovered a small set of additional, novel autoantibodies, which were detected in frequencies of 8 to >20% in pSS. Accumulation of autoantibody reactivities allows for a first subgroup definition of Sjögren’s, and for clear segregation of SjS/SLE overlap syndrome patients.

Conclusions: A set of novel autoantigens for diagnosis and subgroup definition in Sjögren's syndrome was discovered by high content screening using a Luminex bead-based array platform. Validation in additional, large patient cohorts is needed to better understand the role of these novel autoantigens in Sjögren's syndrome and SLE.

cally assessed synovial inflammation in knee OA patients and their associations with clinical outcomes over time. We were unable to identify individual inflammatory aspects which associate with pain or fatigue. Additional research is required to identify the underlying mechanism for pain and fatigue in OA.

Targeting adipose tissue inflammation

**OP0336** ROLE OF SYSTEMIC INFLAMMATION ASSOCIATED WITH RHEUMATOID ARTHRITIS IN THE GLUCOSE AND LIPID METABOLISM: HUMANS, CIA MOUSE MODEL AND IN VITRO STUDIES

I. Arias de la Rosa1, S. Rodriguez-Cuenca2, Y. Jimenez-Gomez2, P. Ruiz-Limon2, C. Perez-Sanchez1, M.C. Alabos1, I. Cecchi1, J. Calvo1, R. Guzman3, M. Malagon3, E. Collantes1, A. Vidal-Puig2, C. Lopez-Pedrera1, A. Escudero-Contreras1, N. Barrosoja1, D. Rheumatology Service, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain; 2Metabolic Research Laboratories, Wellcome Trust-MRC Institute of Metabolic Science, Addenbrooke’s Hospital, University of Cambridge, Cambridge, United Kingdom; 3Department of Cell Biology, Physiology, and Immunology, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain

**Background:** Rheumatoid arthritis (RA) patients are at higher risk for insulin resistance (IR). The association between RA and IR, and its role on the different characteristics of the disease, such as duration and activity have not been well defined. In addition, there is a gap of knowledge regarding the link between systemic/local inflammation and insulin sensitivity and lipid metabolism in RA patients.

**Objectives:** To explore the effects of the inflammation on the glucose and lipid metabolism in the RA context, following three strategies: RA patients, collagen induced arthritis (CIA) mouse model and in vitro treatment of 3T3L1 adipocytes.

**Methods:** Human study: 150 RA patients and 40 healthy donors were included. RA was identified using the 1987 ACR diagnostic criteria. A total of 63 patients with RA were collected. 3T3-L1 mouse model: 20 CBST/JL mice were used; 5 mice were used as non-diseased group, and 15 were used in CIA modelling: sorted in low and high activity of the disease based on the number of inflamed digits depending on the duration of the disease. Plasma, leukocytes, skeletal muscle, liver and adipose tissue were collected. Treatment of adipocytes with serum from RA patients: 3T3L1 adipocytes were treated with serum 10% of RA patients and healthy donors for 24h. The expression of genes and proteins involved in inflammation, lipid metabolism and insulin signalling was analysed in all the tissues and cell lines.

**Results:** Per centages of obesity, hypertension, atherogenic risk, metabolic syndrome and insulin resistance were significantly increased in the RA group. Although mean time of evolution was 7 years, no association between IR and the duration of the disease was found. Levels of HOMA-IR significantly correlated with DAS28 and C-reactive protein levels, suggesting that systemic inflammation might lead to the development of insulin resistance. In mice, the induction of arthritus promoted an alteration of the expression of genes involved in inflammation as well as lipid metabolism and insulin signalling in all the metabolic tissues and leukocytes, pointing out to an increase in lipolysis, decrease in adipogenesis and lipid accumulation and induction of IR. These results were recapitulated after treatment of adipocytes with serum from RA patients with high disease activity.

**Conclusions:** 1) IR was closely associated with an increase in disease activity and systemic inflammation in RA patients. 2) Induction of arthritis in mice promoted an increase in systemic inflammation markers, systolic muscle, adipose tissue, synovial lining cells, and leukocytes, and a reduction of genes involved in lipid uptake and storage, generating an insulin resistance state in those tissues. 3) The inflammatory components in RA serum induced lipolysis, reduced adipogenesis, and increase inflammation and insulin resistance in adipocytes 3T3L1.

In summary our results suggest that chronic inflammation associated with RA might directly impact relevant metabolic tissues, altering glucose and lipid homeostasis and favouring the development of insulin resistance.

SATURDAY, 17 JUNE 2017
Trials and tribulations of medication adherence

**OP0337-HPR** PREDICTORS OF PATIENT REPORTED DECISION TO DISCONTINUE ANTI-RHEUMATIC MEDICATION IN RHEUMATOID ARTHRITIS PATIENTS: DATA FROM A RHEUMATOID ARTHRITIS NETWORK (CAN) RHEUMATOID ARTHRITIS COHORT

V. Ahluwalia1, M. Movahedi2,2, E. Rampakakis3, A. Cesta2, X. Li4, S. Couto5, J. Sampalis3, C. Bombardeir2,4,5 on behalf of OBRI investigators. 1Department of Rheumatology, Brampton Civic Hospital, William Osler Health System, Brampton; 2Ontario Best Practices Research Initiative, Toronto General Hospital, University Health Network, Toronto; 3JSS Medical Research, Montreal; 4Department of Medicine (DOM) and Institute of Health Policy, Management, and Evaluation (IHPEM), University of Toronto; 5Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada

**Background:** Despite the availability of safe and effective treatments and the establishment of treatment guidelines, real-world effectiveness remains suboptimal largely due to low patient adherence with prescribed treatment.

**Objectives:** The purpose of this study was to systematically evaluate sociodemographic, medical, and disease-related factors associated with patient reported decision for discontinuation of anti-rheumatic medications (ARM) in a large observational cohort of RA patients followed up in Canadian routine clinical care.

**Methods:** RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) clinical registry and had at least two years of follow-up were included in the analysis. Treatment discontinuation due to patient reported decision was defined as ARM discontinuation. Independent predictors of ARM discontinuation were evaluated with multivariable cox-regression using both time-fixed and time-dependent variables. Factors considered included patient sociodemographics (age, gender, race, education status, annual income, smoking history), health insurance information (private vs. non-private, % coverage), disease parameters (RA duration, presence of erosion, RF positivity, DAS28, physician global, HAQ-DI, number of comorbidities), types of medications used, and physician characteristics (gender, academic position, urban vs. rural, distance from patient’s residence).

**Results:** A total of 1,782 patients were included in the analysis with a mean (SD) age of 57.4 (13.0) years and disease duration of 8.5 ± (9.3) at the time of enrolment to the registry (baseline). The majority of patients were female (77.7%), had post-secondary education (55.3%), and had private insurance (67.2%). In terms of disease severity, 54.5% had prior erosion, 69.5% were RF positive, and mean (SD) DAS28 was 4.5 (1.5).

A multivariate analysis, married status (HR, 0.73; 95% CI 0.56–0.96), and higher number of comorbidities (HR, 0.92; 95% CI 0.85–0.99) were identified as significant predictors of ARM continuation while higher physician global score (HR, 1.10; 95% CI 1.04–1.15), NSAID use (HR, 1.75; 95% CI 1.29–2.38), and polypathy (HR, 1.23; 95% CI 1.07–1.40) were associated with ARM discontinuation due to patient reported decision.

**Conclusions:** In this systematic approach a variety of factors encompassing sociodemographics, disease, and medication characteristics, were identified as significant independent predictors of ARM discontinuation due to patient reported decision. These results should be taken into consideration when developing patient adherence support programs and in the choice of treatment regimens.

**Scientific Abstracts**
Outcome in juvenile idiopathic arthritis

### OP0338 FREQUENCY OF COMORBIDITIES IN JIA PATIENTS – RESULTS OF AN OBSERVATIONAL COHORT STUDY

**Background:** Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disease that often persists into adulthood. In addition to disability and poor quality of life, JIA is associated with increased long-term morbidity and mortality. The long-term risk of comorbidities in JIA patients is uncertain and guidance on risk assessment is not currently available.

**Objectives:** To determine the frequency of comorbid conditions in adult JIA patients.

**Methods:** Patients with JIA transferred from the biologic registry BiKER to the follow-up (FU) registry JuMBO were included in this analysis. All comorbidities, except for serious infections, prospectively recorded by physicians at BiKeR or JuMBO were considered. Comorbidity rates among the various JIA categories were compared. The Medical Dictionary for Regulatory Activities (MedDRA) was used for disorder coding. Differences in the occurrence of comorbidities between JIA categories were analyzed by multinomial logistic regression.

**Results:** A total of 1,022 young adults (67% female) with JIA and a mean FU of 7.9 (SD=3.5) years were included in this analysis. The patient’s mean age at entry was 22.5 ys (SD=3.7), and disease duration was 12.9 ys (SD=5.9) at the last FU. The majority were classified as polyarticular JIA (36.4%) at BiKeR enrollment. Patients had received a mean of 2.9 (SD=1.3) DMARDs, 77% were ever treated with biologics.

Comorbidities were reported for more than half of the patients (54%), 24.5% of the conditions were stated for the first time in adult age. Eye disorders were the most common comorbid condition group (15.1%), followed by skin and subcutaneous tissue disorders (9.3%), and psychiatric disorders (5.5%). The most frequently reported single diseases were uveitis in 14.4%, chronic secondary pain syndrome in 4.4%, hypertension in 3.6%, and psoriasis in 3.3%. In addition, inflammatory bowel diseases were reported in 2.5% of cases, other immune-mediated disorders, namely autoimmune thyroiditis in 2.5%, type1 diabetes in 0.7% and celiac disease in 0.3%, depression in 2.3%, anxiety in 0.3%, osteoporosis in 1.6%, and amyloidosis in 0.4%. Among the reported comorbidities, there was one case with a cerebrovascular accident, but none with ischemic heart disease, heart failure or diverticulitis. The rate of comorbidities was 0.3%, osteoporosis in 1.6%, and amyloidosis in 0.4%.

**Conclusions:** Young adults with JIA have a high rate of comorbidity overall, with extrarticular JIA manifestations being the most frequently reported comorbid conditions. Comorbidity rates vary among the various JIA categories. Patients with systemic JIA have the highest rate of cardiovascular risk factors and osteoporosis, whereas patients with extended oligo have the highest rate of uveitis. An underreporting or unawareness of comorbidities by rheumatologists is possible, guidance on risk assessment in adults with JIA is needed.

**Acknowledgements:** The authors thank all rheumatologists for contributing patients to the JuMBO registry. BiKeR is funded by unconditional grants from Abbvie, Pfizer, Roche, and Novartis, Germany and Abbott, Germany, JuMBO by unconditional grants from Abbvie, Pfizer, and Roche.

How diet influences musculoskeletal diseases

OP0340 WEIGHT LOSS FOR OVERWEIGHT AND OBESE INDIVIDUALS WITH GOUT: A SYSTEMATIC REVIEW OF LONGITUDINAL OBSERVATIONAL STUDIES

S.M. Nielsen 1, E.M. Bartels 1, M. Henriksen 1,2, H. Gudbergsen 1, H. Bliddal 1, A. Astrup 2, P.K. Knop 2,3,5,6 L. Carmona 7, W. Taylor 8, J.A. Singh 9, F. Perez-Ruiz 10, L.E. Kristensen 1, R. Christensen 1, 1 The Parker Institute, Bispebjerg and Frederiksberg Hospital; 2 Department of physical and occupational therapy, Bispebjerg and Frederiksberg Hospital; 3 Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen; 4 Department of physical and occupational therapy, Bispebjerg and Frederiksberg Hospital; 5 Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen; 6 NNF Center for Basic Metabolic Research; 7 Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen; 8 Center for Diabetes Research, Gentofte Hospital, University of Copenhagen, Copenhagen; 9 Scandinavian Institute of Health Research, Denmark; 10 Instituto de Salud Madrileña, Madrid, Spain; 11 Department of Medicine, University of Otago, Wellington, New Zealand; 12 Department of Medicine, University of Alabama at Birmingham, Birmingham, Alabama, United States; 13 Rheumatology Division, Hospital de Cruces, Baracaldo, Vizcaya, Spain

Background: Weight loss is a commonly recommended treatment for gout, but the magnitude of effect to expect has to our knowledge not previously been evaluated in a systematic review.

Objectives: The aim of this systematic review was to determine the benefits and harms associated with weight loss in overweight patients with gout.

Methods: Based on a pre-determined protocol (CRD420160037907), we searched six databases for longitudinal studies, quantitatively reporting the effect of weight loss in overweight gout patients. Risk of bias was assessed using the ROBINS-I tool. The quality of the evidence was assessed using GRADE.

Results: From 3,991 potentially eligible studies, 10 were included (incl. one RCT). Interventions included diet with/without physical activity, bariatric surgery, diuretics, metformin, or no intervention. Due to clinical heterogeneity of the included studies, data are presented for each study and synthesised separately.

The effect on serum uric acid (sUA) ranged from -168 to 30 μmol/L. Six out of 10 studies (60%) included studies, data are presented for each study and synthesised separately. At short term, temporary increased sUA and gout attacks may occur after bariatric surgery. There is an urgent need to initiate rigorous prospective studies (preferably RCTs) to provide more trustworthy estimates of benefits and harms of weight loss in overweight gout patients.

Can targeting disease activity in hand osteoarthritis improve our treatment in the 21st century

OP0341 CAN PAIN IN HAND OSTEOARTHRITIS BE ASSOCIATED WITH MRI COLLATERAL LIGAMENT ABNORMALITIES?

A.L. Tan 1,2, M.-A. D’Agostino 1,3, E. Hensor 1,2, A. Grainger 2, P. Emery 1,2, D. McGonagle 1,2, 1 Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; 2 NIHR Leeds Musculoskeletal Biomedical Research Centre, Chapel Allerton Hospital, Leeds, United Kingdom; 3 Rheumatology Department, Hôpital Ambroise Paré, Paris, France

Background: Many patients with hand osteoarthritis (OA) have little symptoms. Bone oedema and synovitis have been associated to pain in OA, but inflammation involving ligaments has not been studied, likely limited by inadequate MRI resolution. We have previously found significant ligament pathology in early and established hand OA (HOA) [1].

Objectives: We hypothesise that the well innervated ligaments are key to a better understanding of the relationship between joint structure and pain in HOA. This

*Accounting for clustering of joints within patients. CI = healthy controls; IQR = inter-quartile range; CL = collateral ligaments.

Figure 1: PRISMA flow diagram

ACR, American College of Rheumatology; CENTRAL, Cochrane Central Register of Controlled Trials; EULAR, The European League Against Rheumatism; ICRF, The World Health Organization International Clinical Trial Registry Platform portal; pts, patients.
Conclusions: Modifiable abnormalities involving capsular/synovium and extra-capsular areas may be more frequently seen in painful OA joints. The presence of collateral ligament abnormalities in HOA joints, whether painful or not, suggest that the severity of ligament abnormalities in small joint OA and the degree of pain may be an important area to investigate further.

OP0342 ASSESSMENT OF STRUCTURAL DAMAGE OF THE THUMB BASE IN PATIENTS WITH HAND OSTEOARTHRITIS: COMPARING THE NEARLY DEVELOPED OMERACT MAGNETIC RESONANCE IMAGING SCORING SYSTEM WITH STANDARD RADIOGRAPHY

S. van Beest1, F.P. Kroon1, W. Damanman1, R. Lu1, M. Kloppenburg1,2

1Rheumatology; 2Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

Background: The thumb base is frequently involved in patients with hand osteoarthritis (OA), resulting in osteophytes and cartilage loss. Radiography is the most commonly used imaging modality to evaluate structural OA signs, however it is insensitive especially due to overprojection. Magnetic resonance imaging (MRI) could be a valuable alternative, however a standardized scoring method is insensitive especially due to overprojection.

Methods: 26 joints from 15 patients (mean (SD) age 58.3 (8.2), 13F:2M) and 10 in 5 healthy controls (age 38 (5.6); 4F:1M) were scanned using a microscopy MRI coil. 15 joints in 6 patients were painful (median (IQR) pain VAS 4 (3, 7)). Joints were scored blinded to clinical data for joint fluid, capsule/synovitis, extracapsular oedema, collateral ligament thickening/oedema/degeneration, extensor and flexor tendons, bone oedema and cysts. All structures were graded 0–3 for normal, mild, moderate, severe, as defined in OMERACT HOAMRIS where available [2]. Proportions of joints with any level of abnormality (score > 0) were calculated according to pain status (present/absent).

Results: All OA patients with and without pain had ligament abnormalities. Substantive differences in proportion of joints between healthy controls and OA patients were seen for all pathologies except tendons (no tendons abnormalities were found in all groups). Proportions of joints with capsular/synovium, extra capsular changes and proximal cysts differed between OA joints with and without pain but no substantive differences in pathology score were found. Of painful joints, 93% (14) had both ligament and capsular/synovium or extracapsular abnormality present, compared to 45% (5) of non-painful joints.

Conclusions: Scores of osteophytes and cartilage loss assessed on MR images by TOMS were correlated with radiographic scores, indicating good validity of the TOMS. Furthermore, the frequencies of joints with osteophytes and cartilage loss assessed on MR images were higher compared to those on radiographs, suggesting high sensitivity for the TOMS.

Why do we develop autoimmunity?

OP0343 THE INTESTINAL INVOLVEMENT IN SYSTEMIC SCLEROSIS IS CHARACTERIZED BY A PECULIAR GUT MICROBIOTA

G. Nataliello1, S.L. Bosello1, F. Paroni Sterbini2, A. Palladini3,4, G.B. Canestrari5, F. Parisi1, E. De Lorenzis1, G. Berardi1, B. Posteraro5, M. Sanguinetti1, G. Ferraccioli1, 1Institute of Rheumatology and Affine Sciences; 2Institute of Microbiology, Università Cattolica del Sacro Cuore, Rome, Italy; 3Paul Langerhans Institut Dresden of the Helmholtz Centre Munich at the University Clinic Carl Gustav Carus, TU Dresden, Dresden; 4German Center for Diabetes Research (DZD e.V.), Neuberger, Germany; 5Institute of Public Health, Università Cattolica del Sacro Cuore, Rome, Italy

Background: Gastrointestinal involvement is recognized as a major cause of morbidity and mortality in Systemic Sclerosis (SSc) and its pathophysiology is still unclear. Few data on composition and function of gut microenvironment in SSc are reported in the literature but there is a growing body of evidences supporting the hypothesis of a relation between gut microbiota and the host immune system. The BMI was normal and the mean age was similar both in SSc and controls groups. The composition of microbiota was determined through 16S rRNA pyrosequencing performed using the GS Titanium technology. Rarefaction was used to uniform abundance data. α-diversity was defined by the main indexes while β-diversity was determined according to Bray-Curtis and UniFrac, represented through Principal Coordinate Analysis (PCoA) and compared using PERMANOVA test on distance matrices. Linear Discriminant Analysis Effect Size was used to identify taxa that showed differential expression between the groups.

Results: At genus level SSc patients showed a differential expression in 12 taxa compared to controls with higher levels of Ruminococcaceae, Streptococcaceae,
Conclusions: Our analysis demonstrated an altered and distinct composition of gut microbiota in SSC patients compared to healthy controls. Furthermore, scleroderma patients show some differences in microbiota characteristics according to the extent of skin involvement, suggesting that microbiota may influence the severity of the disease. If validated and related to GI symptomatology and nutritional status our findings open up the opportunity of a rational intervention on microbiota to restore the gut equilibrium in SSc patients. Furthermore, our findings are supported also by PCoA of the values representing phylogenetic distance of microbial communities between specimens (p < 0.01). Differences were supported also by PERMANOVA on Bray-Curtis distance matrix (p < 0.016).

Sutherland, growing up with arthritis – yes we can! a project of Deutsche Rheuma-Liga in cooperation with the German Arthritis Research Center, with financial support by the German Federal Ministry of Health

K. Cattelaens. Deutsche Rheuma-Liga Bundesverband e.V., Bonn, Germany

Background: Every third young person with arthritis in Germany stops therapy when he or she enters adult care! Young people with arthritis have to travel long distances to care facilities, which are specialized in transition (about 30 throughout Germany). Because there are too few rheumatologists adults with arthritis often have to wait long for a consultation. Too few doctors have experience with treating young persons with arthritis. The situation of young persons with arthritis results in little knowledge about the condition – only every second young person knows their correct diagnosis. Parents manage everything – only every 5th young person up to 17 years has been alone with their doctor without their parents. Timely and comprehensive support is lacking.

Objectives: Supported by the health ministry and in cooperation with the German Arthritis Research Center the project started in 2014. As a first step the need for support for young person with arthritis was explored. It took two years to develop a pilot project with transition peers, a homepage, camps and information material for parents and doctors. The main goal of the project is to reduce the number of young persons who discontinue care because of the necessary change from children’s care to adult care.

Methods: Ten transition peers have been trained for providing support (telephone, online, personal). An online information platform www.mein-rheuma-wird-erwachsen.de (my arthritis is growing up!) was created, filled with the experiences of transition peers are going to doctors congresses to spread information material. Camps especially for young persons growing up with arthritis took place. For the parents information material was developed: a seminar: learn to let go! is offered to them. The transition peers are going to doctors congresses to spread information material and to present the homepage.

Results: An evaluation of the project is carried out by the German Arthritis Research Center. The online information platform is accepted, it had more than 10,000 visitors during the first year. The young users like the content of the homepage, the transition peers are accepted by the young people as well as by the doctors.

Conclusions: The model project is running for three years – from 2014 until the end of 2017. A subsequent project will focus on the communication between doctors and young patients and should continue the new activities for the young persons with arthritis, their parents and the doctors.

Suffering in silence. Optimizing the management of psychological well-being for people with RMDs

OP0345-PARE GROWING UP WITH ARTHRITIS – YES WE CAN! A PROJECT OF DEUTSCHE RHEUMA-LIGA IN CO-OPERATION WITH THE GERMAN ARTHRITIS RESEARCH CENTER, WITH FINANCIAL SUPPORT BY THE GERMAN FEDERAL MINISTRY OF HEALTH

K. Cattelaens, Deutsche Rheuma-Liga Bundesverband e.V., Bonn, Germany

Background: Despite positive non-pharmacological treatment effects in fibromyalgia (FM) these effects are often modest and show large individual variability. In clinical practice it is very important to assess the effectiveness of treatment for the individual patient in order to tailor further treatment. Responder criteria can assess the effectiveness of treatment and define clinically meaningful change in health outcomes on patient level. However, no specific responder criteria for non-pharmacological treatment in FM currently exist. This warrants further exploration in this field.

Objectives: 1) To define responder criteria for multicomponent non-pharmacological treatment in FM; and 2) To estimate and compare their sensitivity and specificity.

Methods: Candidate responder sets were 1) identified in literature (3–5); and 2) formulated by expert group consensus. All candidate responder sets were tested for sensitivity and specificity in a cohort of 144 patients with FM receiving multicomponent non-pharmacological treatment. Therapist’s judgement about patient’s goal attainment and patients’ perspective on health status change, assessed at 6 months after the start of treatment, were used as gold standard.

Results: Seven responder sets were defined (three identified in literature and four formulated by expert group consensus), and comprised combinations of domains of 1) pain; 2) fatigue; 3) patient global assessment (PGA); 4) illness perceptions; 5) limitations in activities of daily living (ADL); 6) sleep. The sensitivity and specificity of literature-based responder sets (n=3) ranged between 17%–99% and 15%–95% respectively, whereas the expert-based responder sets (n=4) performed slightly better with regard to sensitivity (range 41%–81%) and specificity (range 50%–96%). Of the literature-based responder sets the OMERACT-OARSI responder set with patient’s gold standard performed best (sensitivity 63%, specificity 75% and ROC area = 0.69). Overall, the expert-based responder set comparing year 1 with patient’s goal standard performed best (sensitivity 47%, specificity 96% and ROC area = 0.71).

Conclusions: We defined sets of responder criteria for multicomponent non-pharmacological treatment in fibromyalgia. Further research should focus on the validation of those sets with acceptable performance.
“LISTENING TO PAIN - UN DOLORE DA ASCOLTARE”
MULTIDISCIPLINARY SUPPORT FOR WOMEN WITH FIBROMYALGIA

S. Mingolla, S. Mingolla on behalf of Serena Mingolla Direttore Morfologie author - Francesco Riondino Vice President APMAR Onlus, Ilaria Cineri Psychologist - Cinzia Assafacile Fibromyalgia Group APMAR Onlus. APMAR, Lecce, Italy

Background: The project “Listening to Pain - un dolore da ascoltare” is a multidisciplinary and multifactorial project addressed to women with Fibromyalgia. Fibromyalgia pain has no boundaries. People describe the pain as deep muscular aching, throbbing, shooting, stabbing, or intense burning. Quite often, the pain and stiffness are worse in the morning, and muscle groups that are used repetitively may hurt more. Pain in every muscle and the profound exhaustion are not symptoms that people can see, but they are real and may be devastating for the person with Fibromyalgia. Although the invisible nature of the condition causes credibility dilemmas for patients.

Objectives: The project aims at improving the quality of life of women with Fibromyalgia. It has the main following objectives: provide information about Fibromyalgia, raise public awareness, collect useful data for research development, give support to the person, reinforcing social networks, provide mediation of the recognition process and bio-energy structured exercise activities and classes tailored to symptoms (stiffness and fatigue) useful in boosting endurance times.

Methods: The project was launched in 2015 with a communication campaign and supervised by a group of psychologists promoting the use of humanistic bioenergetics therapy for individual consultations and collective supporting group discussions. Participants were 50 women with a confirmed diagnosis of FMS. In June 2015, APMAR founded its first “Group for Pathology” and launched new tools as the info point and the toll-free number. The project includes: psychological support to women suffering from Fibromyalgia, self-help groups where women talk, meet, discuss the pain and jointly organize events and other projects; information, through the creation of brochures and different kind of materials; an info-point managed by APMAR and a toll-free number that provides information and immediate help for women feeling lonely.

Results: The psychological and physical well-being of women with Fibromyalgia syndrome were enhanced by social support. Chronic Pain, depression, self-efficacy, helplessness, mood disturbance, health status, impact of FMS, were improved. Psychologists involved in the project observe a decrease of depression, greater security and openness in relations. Women started processing and overcoming the sense of loneliness and isolation, increasing knowledge and therefore awareness, acceptance of the disease. Analyses indicated that the created social support networks were associated with greater levels of self-efficacy for pain and symptom management, higher levels of self-efficacy for function and symptom management, as well as overall psychological well-being.

Conclusions: This multilateral approach was very empowering and consented women to work in the same direction to improve healthcare outcomes for people in their same conditions. Furthermore, it helped women with Fibromyalgia get more control over their life, and promote understanding of patient empowerment. The project was also a call for action not only among patients and health professionals, but among several kinds of social groups of students, press, local policy makers and other civil society organizations.

SARDAY, 17 JUNE 2017

OP0347-HPR TRAINING RHEUMATOLOGY NURSE SPECIALISTS: WHAT DOES THE FUTURE HOLD?

M.K. Nisar1, J. Begum2. 1Rheumatology, Luton & Dunstable University Hospital; 2Rheumatology, Luton, Luton, United Kingdom

Background: Since the introduction of the Rheumatology nursing in the UK in 1980s, there has been gradual development of the “specialty”. Despite the proven benefits, both clinical and economical, of a well-trained rheumatology nurse specialist and the evolution of the role, there is a lack of a clear career path for the profession.

Objectives: We undertook a pilot survey to understand the present climate of rheumatology practitioner training in the region.

Methods: Following a focus group discussion of an “ideal” development route for rheumatology practitioner training in the region.

Results: There are 19 centres providing rheumatology services in the region with 51 rheumatology practitioners. All of them (100%) replied to the questionnaire. Only four units (21%) provide formal induction programme for training. 11/19 (57%) have nurse prescribers. All providers replied positive to the question pertaining nurses’ participation in research and audit; 12 (63%) have presented locally or nationally and eight (42%) have submitted posters to conferences. 12 centres have partly nurse delivered early arthritis pathway and 13 have access to departmental ultrasound. Ten units provide patient educational events.

Conclusions: This is a pioneering survey outlining access of rheumatology practitioners and nurse specialists to developmental opportunities. This initiative highlights a wide variation in the provision of clear career pathway regionally. Though most centres are delivering contemporary services, these are not being used effectively for developing key team members. There is lack of formal induction programme. Though most nurses are involved in audit, less than a quarter are presenting at any level and even fewer are publishing research endeavours. Prescribing is limited to 15/51 (29%) members. Less than 20% are training to do intra-articular injections or learning musculoskeletal ultrasound. Despite patient education being a core skill for this group, only 10 units deliver these as a formal event.

In conclusion, there is wide variation in the provision of career advancing opportunities to rheumatology nurse specialists. This can potentially have a negative impact on staff recruitment and retention. There is a need for improving standards and delivery of rheumatology professionals’ career development.

DIFFERENTIAL METHYLATION AS A POTENTIAL BIOMARKER OF METHOTREXATE RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Nair1, D. Plant1,2, S.M. Verstappen1, J.D. Isaacs3,4, A.W. Morgan5, K.L. Hyrich1, A. Barton1, A.G. Wilson6 on behalf of Matura. 1Arthritis Research UK Centre for Genetics and Genomics and Centre of Epidemiology, University of Manchester; 2NIHR Manchester Musculoskeletal BRU, CMFT, Manchester; 3NIHR Newcastle BRU, Newcastle upon Tyne Hospitals NHS Foundation Trust; 4Newcastle University, Newcastle; 5Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 6University College Dublin School of Medicine and Medical Science, University College Dublin, Dublin, Ireland.

Background: Methotrexate (MTX) is the first-line disease modifying anti-rheumatic drug for the treatment of rheumatoid arthritis (RA). However, many patients do not respond adequately or experience adverse effects2,3; therefore, identifying blood-based biomarkers that predict treatment response is a research priority. DNA methylation is an epigenetic marker that modifies but does not alter DNA sequence, and it is thought that MTX may act, at least in part, by inhibiting intracellular methyl donor transfer leading to DNA hypomethylation2.

Objectives: We aimed to identify differential DNA methylation signatures in whole blood, which may act as biomarkers predictive of response to MTX in patients with RA.

Methods: DNA methylation was measured using the Illumina Methylation450 BeadChip in DNA samples from individuals recruited to the Rheumatoid Arthritis Medication Study (RAMS), a one-year observational study in the UK including patients with RA starting MTX for the first time. In RAMS, demographic and clinical data are collected prior MTX start (baseline) and at 6 months after commencing MTX. DNA was extracted from whole blood samples collected baseline and at 4 weeks from patients who, at 6 months, had a EULAR good response (n=36) or EULAR poor response (n=36) to MTX. Differentially methylated positions (DMPs) between the baseline and 4 weeks, and between good and poor response were identified using linear regression, adjusting for gender, age, cell composition, baseline disease activity score (DAS28), and smoking status. Analyses also compared methylation with changes in DAS28 and the individual DAS28 components over 6 months. DMPs that showed significant differences in the test cohort were selected for replication by pyrosequencing in an independent group of 100 patients with both baseline and 4 week samples.

Results: Based on percentage change in methylation between pre-treatment and following 4 weeks of therapy, two DMPs were significantly associated with response status in samples taken at 4 weeks (p-value < 10^-5). Three additional DMPs were associated with change in tender joint count, whilst three other DMPs were associated with change in swollen joint count, and a further four DMPs associated with change in C-reactive protein. Of the four DMPs tested to date, hypermethylation at cg23700278 locus is adrenocorticotropin alpha 2C (ADAR2C), involved in neurotransmission.

Conclusions: These preliminary results suggest DNA methylation may be a biomarker of MTX response but requires replication in other data sets.

ETANERCEPT AND ADALIMUMAB EXHIBIT HETEROGENEOUS EARLY SIGNALS OF RESPONSE IN RHEUMATOID ARTHRITIS THERAPY

J. Oliver1, D. Plant2, G. Orozco2, K. Hyrich1, A. Morgan4, J. Isaacs3, A.G. Wilson2, A. Barton1,1. 1Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre, The University of Manchester; 2NIHR Manchester Musculoskeletal BRU, Central Manchester Foundation Trust; 3Arthritis Research UK, Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre, The University of Manchester, Manchester; 4Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, 1Institute of Cellular Medicine, Newcastle University and National Institute for Health Research Newcastle Biomedical Research Centre at Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle; 2UCL School of Medicine and Medical Science, Conway Institute, University College Dublin, Dublin, United Kingdom.

Background: Up to 40% of rheumatoid arthritis (RA) patients exhibit insufficient response to TNF inhibitor (TNFi) therapy, which has an adverse effect on long term outcomes. Without reliable biomarkers, it is difficult to make treatment decisions, many non-responder (NR) patients experience a delay in switching to an alternative therapy. Ideally, blood-based biomarkers would be measured before treatment (baseline) and throughout treatment in order to select and monitor therapeutic response to maximise the chances of responding to the first biologic therapy.

Objectives: To compare transcriptomic changes between patients administered etanercept and adalimumab therapy, and to identify biomarkers to predict or monitor response.

Methods: From the Biologics in RA Genetics and Genomics Study Syndicate (BRAGGSS) cohort, 37 EULAR good-responders in clinical remission (GR) and 18 NR to etanercept, and 50 GR and 20 NR to adalimumab were selected. Total RNA was isolated from Tempus™-stabilised whole blood samples collected at baseline and following 3-months (3M) of therapy using the MagMAX™ RNA extraction kit. RNA was amplified and converted into biotinylated sense-strand DNA using the Affymetrix WT PLUS kit for hybridisation onto Affymetrix GeneChip® Human Transcriptome arrays. Quality control and differential expression/splice analysis were assessed using the Affymetrix Expression and Transcriptome Analysis Console™ and appropriate Biocomparator packages. Differential transcript expression was adjusted for baseline DAS, age, gender and concurrent DMARD therapy. Pathway analysis was performed using the Database for Annotation, Visualization and Integrated Discovery (DAVID) and Ingenuity Pathway Analysis (IPA) tools.

Results: In adalimumab GR, 636 genes were downregulated and 253 upregulated at 3M (FDR p < 0.05, fold-change > 1.2). There was significant upregulation of immune cell components, most notably HLA genes including HLA-DRB1, other RA susceptibility genes (SLC2A4, PADI4 and CD28) and many B and T cell signalling genes. Etanercept GR exhibited a milder transcriptomic change overall, showing little overlap with adalimumab GR; 395 genes were downregulated and 27 upregulated at 3M (FDR p < 0.05, fold-change > 1.2). Downregulated genes included downstream TNF components such as mitogen activated protein (MAP) kinases, as well as genes involved in NOD-like receptor, Toll-like receptor and NF-kB signalling. Such significant changes were absent in NR to adalimumab and etanercept. Furthermore, alternative splice changes in RA-relevant genes such as MMP9 were apparent in adalimumab GR at 3M but not etanercept GR.

Conclusions: The heterogeneity in the blood-based transcriptomic profiles of etanercept and adalimumab response observed herein suggests that different TNFi therapies function by alternative mechanisms that impact patient outcomes. It also calls into question the reliability of response studies that consider TNFi therapies as a homogenous group. The candidate biomarkers identified require replication in independent datasets but may provide early and objective response biomarkers to inform timely therapeutic switching in patients who are not responding to their current TNFi drug.

THU0004 CROSS PHENOTYPE ASSOCIATION MAPPING OF THE MHC IDENTIFIES GENETIC VARIANTS THAT DIFFERENTIATE PSORIATIC ARTHRITIS FROM PSORIASIS

J. Bowes1, J. Ashcroft2, N. Dand3, P. Ho1,2, C.H. Smith1, J.N. Barker4, N. McHugh5, R.B. Warren6, A. Barton7 on behalf of BSTOP and BADBIR.

1Arthritis Research UK Centre for Genetics and Genomics, The University of Manchester, Manchester; 2Division of Genetics and Molecular Medicine, King’s College London, London; 3NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester NHS Foundation Trust, Manchester; 4St John’s Institute of Dermatology, Guys and St Thomas’ Foundation Trust, London; 5Royal National Hospital for Rheumatic Diseases and Dept Pharmacy and Pharmacology, University of Bath, Bath; 7The Dermatology Centre, Salford Royal NHS Foundation Trust, Manchester, United Kingdom

Background: The identification of genetic variants that differentiate PsA from psoriasis has the potential to help us understand the underlying biological pathways and thus aid the development of PsA Associations to genetic variants within the major histocompatibility complex (MHC), in particular to HLA-C*0602, increase risk of both PsA and psoriasis when compared to control populations. However direct comparisons of PsA to psoriasis have led to paradoxical results where HLA-C*0602 has been reported to be protective of PsA. In addition HLA-C*0602 has been reported to be associated with age of onset of psoriasis. A more recent study has reported the amino acid at position 45 of the HLA-B protein as the most important factor for differentiating PsA from psoriasis.

Objectives: Here we perform a cross phenotype association analysis in an attempt to identify genetic variants in the MHC that differentiate PsA from psoriasis in a large collection of PsA patients and psoriasis patients screened for the absence of PsA.

Methods: A total of 1069 patients with psoriasis and 981 patients with PsA from the UK were genotyped using either the Illumina Infinium or the Illumina OmniExpress genotyping arrays. SNPs, amino acids and classical HLA alleles were imputed using SNP2HLA. Logistic regression was used to compare the imputed dosage of MHC markers between PsA and psoriasis. All analyses were repeated using age of psoriasis onset as an additional covariate.

Results: The cross-phenotype association comparing PsA to psoriasis was to HLA-C*0602 (p=4.17x10^-10) with a protective effect for PsA (OR 0.52, CI 0.44,0.61). HLA-C*0602 was found to be significantly associated with a younger age of psoriasis onset (p=1.5x10^-9) where the median age of onset in years for carriage is 22 compared to 33 for non-carriage. We observed a difference in the median age of psoriasis onset in years between the PsA and psoriasis study subgroups (34 vs. 21), highlighting the potential for bias at markers associated with age of psoriasis onset. When controlling for the age of psoriasis onset in the analyses we observed no association of PsA to HLA-C*0602 (p=0.07) and the most significant association was to the amino acid at position 97 of HLA-B (p=1.5x10^-9) where the presence of asparagine or serine residue increased risk of PsA. Asparagine at position 97 of HLA-B defines the HLA-B*2705 allele.

Conclusions: Comparing PsA to psoriasis we show HLA-C*0602 confers no effect, either risk or protective, for PsA after correction for age of psoriasis onset. The results suggest that the previously observed protective effect of HLA-C*0602 could be due to confounding due to a younger age of psoriasis onset in the psoriasis subgroup. When accounting for age of psoriasis onset, the primary association conferring risk for PsA in patients with psoriasis is to HLA-B amino-acid 97 where an asparagine residue defines the HLA-B*2705 allele. In addition, this amino acid has been reported as the largest genetic effect for ankylosing spondylitis thereby refining the genetic overlap between these two spondyloarthropathies.

THU0005 ERAP POLYMORPHISMS AND ITS ASSOCIATION WITH HLA-B15 AND HLA-B27 POSITIVE SPONDYLOARTHRTIS PATIENTS

L. Londono1, A.M. Santos2, J.C. Rueda3, P. Peña2, I. Bričero3, E.L. Saldarriaga4, J.I. Angartana5, P. Calvo5, M. Avila2, N. Martinez-Rodriguez5, H. Cubides6, V. Parra7, J.F. Medina8, 1Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá; 2Reumatología; 3Facultad de Medicina, Grupo Genética Humana, Universidad de la Sabana, Chía; 4Departamento de Imágenes diagnósticas, Universidad Nacional, Bogotá, Colombia; 5Departamento de Investigación de Salud Comunitaria, Hospital Infantil de México Federico Gomez, Ciudad de México, Mexico; 6Departamento de Medicina Interna, Escuela de Medicina, Universidad de Navarra, Pamplona, Spain

Background: Since 1973, the association of HLA-B27 and spondyloarthritides (SpA) is well known, however in Colombian population it is present in only 40% of patients and HLA-B15 is present almost in 25%. A mechanism of polygenic mechanism has been proposed as an explanation for the development of SpA. Endoplasmic reticulum aminopeptidase (ERAP) genes 1 and 2 have been implicated. ERAP1 is strongly associated with HLA-B27 positive patients and ankylosing spondylitis, but not with ERAP2.

Objectives: To determine the association between ERAP polymorphisms and HLA-B27 or HLA-B15 positive SpA patients.

Methods: 178 patients with SpA according to ASAS criteria were included in the study. HLA typing was performed by the PCR technique using the Bioread® HLA-SSP plates. The polymorphisms were determined by the RT-PCR technique using Roche® probes for ERAP1 rs72044, rs17482078, rs10005860, and rs30187. For ERAP2 the probes were used rs2910686, rs2248374 and rs2549782.

ERAP: endoplasmic reticulum aminopeptidase; AF: allelic frequency; OR: odds ratio.
allele and genotype frequencies polymorphisms were obtained by direct counting. In each group the Hardy-Weinberg equilibrium was evaluated using the $^2$ test. Associations were assessed using odds ratio (OR). Stata v.12.0 program was used to analyze data. The construction and analysis of haplotypes was performed using Haploview v.4.2.

Results: A total of 70 patients were HLA-B*27 positive and 34 were HLA-B*15 positive. 78 were women and 100 were men. Linkage disequilibrium map of the ERAP gene is depicted in figure 1. When analysed by ERAP2 haplotype it is observed that there is a statistically significant association with the combinations described in table 1. No associations were observed between ERAP1 haplotypes and HLA-B*15 or B*27.

Conclusions: In the group of patients analysed, a statistically significant association was found between patients with SpA HLA-B*15 positive and the haplotype TGT of ERAP2. Also HLA-B*27 positive SpA patients were associated with haplotype TGC and CAT of ERAP2 with statistical significance.

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by fibrosis and composed of two subtypes, limited and diffuse cutaneous forms. Previous genetic studies including genome-wide association studies (GWAS) have identified 12 susceptibility loci satisfying genome-wide significance.

Objectives: To expand the list of susceptibility genes and deepen biological insights for SSc.

Methods: We performed trans-ethnic meta-analysis of GWAS in the Japanese and European populations, followed by a two-staged replication study comprising a meta-analysis using 11,4751 SNP controls between a single nuclear polymorphisms (SNPs) and neighboring genes were evaluated. Enrichment analysis of H3K4Me3, a representative histone mark for active promoter was conducted with an expanded list of SSc susceptibility genes.

Results: We identified two significant SNP in two loci, GDMD and PRDM1, both of which are related with immune functions and associated with other autoimmune diseases ($p$<1.4x10$^{-10}$ and 6.6x10$^{-10}$, respectively). GDMD also showed a significant association with limited cutaneous SSc. We also replicated the associations of previously reported loci including a non-GWAS locus, TNFAIP3. Furthermore, we encoded a transcription factor regulating T cell proliferation and plasma cell differentiation. The top SNP in GDMD was a missense variant and correlated with gene expression of neighboring genes, and this could explain the association in this locus. We found different HLA association patterns between the two populations or two subtypes. Enrichment analysis suggested the importance of CD4 naïve primary T cell.

Conclusions: GDMD and PRDM1 are associated with SSc. These findings provide enhanced insight into the genetic and biological basis of SSc.

THU0007 DEEP SEQUENCING TRANSCRIPTOME ANALYSIS OF THE EFFECT OF TRAUMEEL VERSUS DICLOFENAC THERAPEUTIC ACTION IN WOUND HEALING

G.S. Laurent III 1, B. Seelheimer 2, M. Tackett 1, J. Zhou 1, D. Shitokalo 1, Y. Vytakin 1, P. Kaplanov 1, I. Toma 3, T. McCaffrey 3, 1 The St. Laurent Institute, Vancouver, WA, United States; 2 Biologische Heilmittel Heel GmbH, Baden-Baden, Germany; 3 Department of Medicine/Division of Genomic Medicine, The George Washington University, Washington, DC, United States

Background: Anti-inflammatory agents are used widely in treating numerous inflammatory conditions. The effect of Tr14, a multitargeted natural product, was compared to diclofenac, a non-selective cyclooxygenase inhibitor, on cutaneous wound repair in mice.

Objectives: To compare the effect of diclofenac with Tr14 on the transcriptome during cutaneous wound repairing process.

Methods: After abrasive wounding, the wounds were treated with topical Tr14 or diclofenac at clinically relevant doses. An additional group received subcutaneous Tr14 injections. The healing wounds were analyzed for RNA transcript profiling by RNAseq at specific times (12h, 24h, 36h, 72h, 96h, 120h, 196h) after injury. Differentially expressed genes (DEGs) were computed at each time point between diclofenac vs control or Tr14 vs control using EdgeR.

Results: Across time points, Tr14 treatment modulated a number of transcripts related to key wound repair pathways such as cellular differentiation, wound contraction, and cell mobility. Diclofenac, in contrast, changed gene expression mainly in two areas: Pro-inflammatory effects were observed with regard to the RNA chromatin regulation and ribosomal function, further effects were observed on the prostaglandin pathway and wound repair factors. In many of the key pathways modulated by Tr14, such as the defense response and cell motility, diclofenac tended to have an opposite effect on gene expression. At 12 hours post-injury, there were 521 transcripts significantly elevated and 1027 transcripts that were decreased by diclofenac treatment. By comparison, using a similar number of transcripts altered by Tr14 treatment, only 4 transcripts were increased in common, and 5 transcripts were decreased in common, suggesting that the therapeutic agents have different effects on the transcriptome.

Conclusions: The overall patterns of the Tr14 and diclofenac responses in the transcriptome during wound repair are very different. The Tr14 effect is most pronounced on the defense response, cell motility, and anti-apoptotic pathways. In contrast, diclofenac mainly affected histones and chromatin remodeling systems, as well as ribosomal systems that would be expected to alter the translational pattern of diclofenac-treated cells.

THU0008 MAST CELLS SHOW A REPROGRAMMED TRANSCRIPTIONAL SIGNATURE FOLLOWING REPEATED IGG STIMULATIONS

Background: Mast cell numbers are increased in the rheumatoid arthritis joint. We have previously shown that mast cells can be activated by IgG-ACPA leading to the production of proinflammatory cytokines. However, not much is known about the resulting function when mast cells would repeatedly engage IgG, a likely scenario given the long life span of mast cells (up to a year) and the perpetual presence of IgG-ACPA in the joints. We have recently shown that mast cells triggered repeatedly through their Ig Fc epsilon receptor undergo a reprogramming of their responses (Suurmond et al. JACI 2016) by expressing de novo transcribed genes in the antigen presentation and pathogen defense response pathways.

Objectives: The aim of the current work was to determine whether mast cells show similar changes in their response mode following repeated interactions with IgG.

Methods: Human cord blood-derived mast cells were treated for 2 weeks with plate-bound IgG. The expression profile of naive or treated mast cells was measured through RNA sequencing, quantitative RT-PCR, flow cytometry. Protein secretion was measured with ELISA and Lumimex assays. Metabolic changes were measured using HPLC mass-spectrometry.

Results: Similar to our previous work on Fc Epsilon receptor, we observe a dampening of the normal IgG responses with a set of novel genes upregulated. Interestingly, the non-exo-neo-transcribed factor regulating T cell proliferation and plasma cell differentiation, the top SNP in GDMD was a missense variant and correlated with gene expression of neighboring genes, and this could explain the association in this locus. We found different HLA association patterns between the two populations or two subtypes. Enrichment analysis suggested the importance of CD4 naïve primary T cells.

Conclusions: Our study provides evidence that mast cells are reprogrammed upon repeated IgG triggering. In contrast to repeated Fc Epsilon Receptor triggering, different pathways are affected, implying stimulus-specific effects. Our work has important implications for the understanding the role of mast cells in rheumatoid arthritis.

**THU0009**  IN VITRO STUDIES USING CYBRIDS, SHOW THAT MTDNA IN IMMUNE SIGNAL 2 CHECKPOINT MOLECULE EXPRESSION ALTERED MIRNAS PROFILES IN PLASMA-DERIVED Cybrids were developed using 143B.TK- Rho-0 cell line (nuclear donor) and patients with knee OA. Patients with knee OA. Objectives: The aim of this work is to test the real role of mtDNA in cellular activity, using cybrids with miRNA from healthy donors (without OA) and from patients with knee OA. Methods: Cybrids were developed using 143B.TK- Rho-0 cell line (nuclear donor) and platelets (mitochondrial donors) from healthy (without AO-N) and knee OA donors. The OXPHOS function was evaluated by Seahorse XFp after addition of oligomycin, FCCP and Rotenone/Antimycin A. The metabolic status was evaluated by glucose consumption and lactic acid production. The glycolytic activity was measured after addition of glucose, oligomycin and 2-dioxycarnosine. The flow cytometry was used to evaluate the mitochondrial membrane potential (ΔΨm).

**Conclusions:**
- Cybrids have different mitochondrial behaviour, being N more efficient using glucose via glycolysis. We found differences statistical significance in the parameters that describe the mitochondrial respiration capacity, in this line OA cybrids had lower mitochondrial respiration and produce less ATP than the cybrids obtained from healthy patients. These results showed that the mitochondria obtained from healthy and OA donors had a different behaviour.
- These data also offer a real rationale for why mitochondria alterations play an important role in the incidence of OA.

**THU0010**  ALTERED MIRNAS PROFILES IN PLASMA-DERIVED EXOSOME OF PATIENTS WITH ANKYLOSING SPONDYLITIS BY SMALL RNA-SEQ ANALYSIS Y. Huang, T. Li, Z. Huang, W. Deng, S. Zheng, X. Guo, Z. Huang, Guangdong No. 2 Provincial People’s Hospital, Guangzhou, China

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease, which is difficult to diagnose in the early stages. Increasing evidences have shown that MicroRNAs (miRNAs) may serve as novel biomarkers for AS. Exosome can function as vehicles to deliver miRNAs in body fluids including saliva and plasma. However, the relationship between exosome-delivered miRNAs and AS has yet to be determined.

Objectives: The aim of this study is to detect the altered miRNAs profiles of plasma-derived exosome in AS patients by small RNA-Seq analysis.

Methods: RiboPlus™ kit was used to isolate exosome. Small RNA Sample Pre Kit was used to build libraries in 3 AS patients and 3 healthy volunteers (HV), following by IlluminaHiSeq platform sequencing and bioinformatics analysis. Quantitative reverse-transcription PCR (qRT-PCR) was used to confirm the expression of the highly expressed miRNA.

**Results:**
- miRNA21–5P and miRNA423–5P are higher expressed in another 10 AS patients and 10 HV, and receiver-operator characteristic (ROC) curve was used to evaluate the diagnostic value of miRNAs.
- miRNA423–5P had significant diagnostic value for AS with the AUC of 0.890 (CI95%: 0.729–1.057) and 0.835 (CI95%: 0.621–1.039) respectively (Fig.1-F).

**Conclusions:**
- The miRNAs profiles in plasma-derived exosome of AS patients are significant different from HV.
- miRNA21–5P and miRNA423–5P are higher expressed in AS patients. Thus, plasma-derived exosomal miRNAs might be reliable biomarkers to identify AS.

**THU0011**  IMMUNE SIGNAL 2 CHECKPOINT MOLECULE EXPRESSION IN RHEUMATOID ARTHRITIS DISEASE PROGRESSION A.M. Walsh1, M. Canavan2, Y. Guo1, T. McGarry2, Y. Yin1, M.D. Wechalekar3, M.D. Smith2, S.M. Proudman 4, C. Orr5, S. Kelly6, C. Pitzalis5, D.J. Veale5, U. Fearon5, S. Nappaj1, Janssen R&D, Spring House, United States; 2Molecular Rheumatology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland; 3Patients University Royal Free, University College London, London, UK; 4Royal Free University College London, Discipline of Medicine, University of Adelaide, Adelaide, Australia; 5St. Vincent’s University Hospital, Dublin, Ireland; 6Queen Mary University of London, London, United Kingdom

Background: Deep profiling of synovial tissue samples from rheumatoid arthritis (RA) patients may reveal the molecular underpinnings of phases of RA progression and provide new therapeutic targets to intervene earlier in disease pathogenesis.

Objectives: We sought to identify the molecular pathways expressed in different stages of disease (from seropositive subjects without clinically apparent synovitis to those with established disease) in synovial tissue compared to non-RA controls.

Methods: Transcriptomics profiling was performed on RNA isolated from synovial tissue biopsies. Normal synovium was collected from subjects with knee pain and without diagnosis of OA or RA (n=28). Arthralgia tissue was collected from ACPA-positive subjects without synovitis (n=10). Early RA tissue was collected from patients recently diagnosed (<1 year) with RA (n=57). Established RA tissue was collected from ACPA-positive subjects with >1 year of disease duration (n=95). Protein expression was confirmed on infiltrating immune cells from synovial biopsy cell suspensions by flow cytometry in separate RA subjects.

Results: Several pathways previously identified as important for RA pathogenesis (e.g., lymphocyte activation, osteoclast differentiation, N-kappa B signaling) were enriched in differentially expressed genes in disease synovial biopsies compared to normal tissue samples. Interestingly, several genes known to function in T cell activation as signal 2 co-stimulatory or co-inhibitory molecules were differentially expressed, even in arthralgia and early RA subjects. 66 of 81 known co-stimulatory or co-inhibitory genes profiled were differentially expressed (FDR <5% and absolute fold-change >2) in disease samples from at least one cohort. The genes encoding co-stimulatory proteins that were increased compared to normal included CD28, CD40LG, CD40 and ICOS. Interestingly, some of the genes encoding co-inhibitory proteins were increased (PDCD1/ PD-1, CD274/PD-L1, HAVCR2/TIM3, TIGIT, BTLA), whereas others showed decreased expression (C10orf54/VISTA and LAG3) compared to normal controls. We focused on CD28 expression, which is elevated in “pre-RA” arthralgia samples, proposing that anti-CD28 therapeutics could be candidates for RA disease prevention. By flow cytometry we demonstrated that a majority of CD4+ (>90%) and CD8+ (~60%) T
cells from RA synovial biopsy cell suspensions (n=4) showed surface expression of CD28.

Conclusions: Our results generated a unique dataset from different phases of RA progression. Our results provide guidance for the selection of co-signaling molecules as therapeutic targets as well as for preventing the progression to RA. In particular, CD28 expression was elevated in synovial tissue biopsies before the development of RA and it was also expressed on the majority of synovial tissue infiltrating CD4+ and CD8+ T cells from RA patients. These observations provide rationale to target CD28 for both RA treatment and disease interception.

Disclosures of Interest: None declared.
or using other stimuli, i.e. IL-4 and TNF-α, indicating a specific function for the rs3761847 polymorphism in unstimulated and LPS+IFN-γ-activated monocytes.

**Conclusions:** Our findings suggest that there is no relationship between invasive capacity of RASF or expression of TRAF1-C5 genes and genotype at rs3761847. In contrast, we report an association of the rs3761847 genotype and TRAF1 expression in monocytes. These data underline the importance of studying genotype-phenotype associations in the different cell types relevant for RA pathogenesis.

**THU0015**  
**INVESTIGATION OF JUVENILE IDIOPATHIC ARTHRITIS (JIA) IN GREECE: NEW SUSCEPTIBILITY LOCI**

M.I. Zervou 1, D.G. Dimopoulou 2, E. Eliopoulos 3, M. Trachana 4, 3Biotechnology, Agricultural University of Crete, Athens; 41st Department of Pediatrics, Aristotele University of Thessaloniki, Thessaloniki, Greece

**Background:** Juvenile idiopathic arthritis (JIA) is an autoimmune disease characterized by persistent chronic arthritis, in which both genetic and environmental components are involved [1]. Different genetic variations have been reported as risk factors for JIA, but a difficulty of the replication of results in different ethnic backgrounds indicates the existence of an ethnic heterogeneity of genetic factors for JIA.

**Objectives:** We sought to validate three single nucleotide polymorphisms (SNPs), namely PTPRC (rs10919563), TYK2 (rs4750316) and PRKCQ (rs4750316) previously found to be associated with JIA [2–4], and to investigate whether the VNTR polymorphism was genotyped by TaqMan primer-probe sets, using a Real-Time PCR platform (Applied Biosystems, ViA™ 7 Real-Time PCR System), while eNOS VNTR polymorphism was genotyped by PCR. Odds ratios (OR) and 95% confidence intervals (CI) were calculated and P-values of the intreraction.

**Results:** A case–control association study was conducted enrolling 4 successfully genotyped markers. eNOS OR=0.40, 95% CI=0.20–0.79, P=0.019; and OR=0.51, 95% CI=0.14–0.84, P=0.019; and OR=0.51, 95% CI=0.32–0.82, respectively. Otherwise, the CT genotype of the COL3A1 rs2138533 polymorphism (OR=2.89, 95% CI=1.28–6.5, P=0.011); and the CT genotype of the G allele of the COX2 rs484844 polymorphism (OR=2.22, 95% CI=1.11–4.43, P=0.024) were associated with an increased risk of OA. However, by using of epistatic interactions between 1-HIF-1 alpha pathway polymorphisms, we found that the gene-gene interaction had a synergistic effect over the estimated OR-values (see table).

**Conclusions:** In this study we could observe that the gene-gene interaction of the HIF-1α signaling pathway highly increases the risk of developing OA, with the exception of COL2A1 and HIF1α interaction which had a protective role against OA. Further studies are needed to validate this results.

**Disclosure of Interest:** None declared

L.A. Mag 1, 2, S. Retamozo 2, 3, F. Bonisconti 1, 2, E.V. Palomino 1, 2, J.P. Pirolo 2, 3, V. Saurit 1, 2, A. Alvarellos 1, 2, V. Saurit 1, 2, A. Alvarellos 1, 2. 1Immunogenetics, Hospital Privado. 2Instituto Universitario de Ciencias Biomédicas de Córdoba. 3Instituto de Fisiología, Hospital Privado. Universitario de Córdoba, Córdoba, Argentina

**Background:** Lupus nephritis (LN) is a severe complication of Systemic Lupus Erythematous (SLE). Non-invasive biomarkers are needed for diagnosis of LN and to identify patients at risk of a renal flare (1). Thus the presence of biomarkers associated with inflammation, tissue damage or cell activation in the urine of patients with LN may be a useful tool in the evaluation of LN patients. The glomerular filtration rate (GFR) is considered the best overall index of renal function in health and disease. Because GFR is difficult to measure in clinical practice, most clinicians estimate the GFR (eGFR) from the serum creatinine concentration (2). B Lymphocyte Stimulator (BLYS) is a cytokine that fosters B cell activation, antibody production, B cell - T cell interaction and plasma cell survival. These events have been demonstrated to play a role in patients with LN (3).

**Objectives:** We evaluated urinary levels of BLYS as biomarker for LN and their relationship with eGFR.

**A COMPREHENSIVE CONTRIBUTION OF GENES OF THE HIF-1α INFLUENCING PATHWAY TO KNEE OSTEOARTHRITIS SUSCEPTIBILITY**

J. Fernandez-Torres 1, 2, G.A. Martinez-Nava 1, A. Lopez-Reyes 1, Y. Zamudio-Cuevas 1, D. Claviljo-Cornejo 1, K. Martinez-Flores 1, M.C. Gutierrez-Ruiz 2, L.E. Gómez-Quiroz 2, C. Pineda 1. 1Laboratorio de Líquido Síntico, Instituto Nacional de Rehabilitación; 2Celulogia Fisiologico Laboratory, Universidad Autónoma Metropolitana-Iztapalapa, Mexico City, Mexico

**Background:** The hallmark of osteoarthritis (OA) is the breakdown of articular cartilage. Articular cartilage is an avascular tissue, and this generates a hypoxygen microenvironment. Hypoxia inducible factor-1α (HIF-1α) is the main transcriptional regulator of cellular and developmental response to hypoxia.

**Objectives:** The present study was designed to investigate whether polymorphisms of the HIF-1α signaling pathway are involved in the development of knee OA.

**Methods:** A total of 243 unrelated Mexican-mestizo individuals comprising 93 knee OA patients and 150 healthy controls were recruited into the study. 42 genetic polymorphisms from 22 genes involved in the HIF-1α signaling pathway (PIK3R1, AKT2, GSK3B, IL6, AGER, HIF1A, EGLN1, VHL, HIF1AN, VEGFA, EPO, NOS2, NOS3, IGFI, EGF, EDN1, MMP1, MMP3, MMP13, CA1, COL2A1, COL3A1) were genotyped in cases and controls using TaqMan-based allelic discrimination assays.

**Results:** After adjusting for age, sex and admixture, significant associations with knee OA were found for 7 SNPs in the case-control study. The following genotypes and alleles were associated with protection against OA: the CT genotype of the HIF1AN rs11190613 polymorphism (OR=0.44, 95% CI=0.19–1.0, P=0.05); the AA genotype of the VEGFA rs1570360 polymorphism (OR=0.14, 95% CI=0.02–0.69, P=0.016); the GT genotype and T allele of the VEGFA rs729761 polymorphism (OR=0.47, 95% CI=0.22–1.0, P=0.05; and OR=0.51, 95% CI=0.27–0.97, P=0.041, respectively); the GA genotype of the COL2A1 rs1793953 polymorphism (OR=0.40, 95% CI=0.20–0.79, P=0.008); and the GG genotype and G allele of the Ckm rs484844 polymorphism (OR=0.34, 95% CI=0.14– 0.84, P=0.019; and OR=0.51, 95% CI=0.32–0.82, respectively). Otherwise, the CT genotype of the COL3A1 rs2138533 polymorphism (OR=2.89, 95% CI=1.28–6.5, P=0.011; and the CT genotype of the G allele of the IGFI rs757671 polymorphism (OR=2.22, 95% CI=1.11–4.43, P=0.024) were associated with an increased risk of OA. However, by using of epistatic interactions between 1-HIF-1α pathway polymorphisms, we found that the gene-gene interaction had a synergistic effect over the estimated OR-values (see table).

**Conclusions:** Using a pilot study. BMC Musculoskelet Disord 2015; 16:218.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.2258
Methods: Urine samples (n=86) were obtained from LN patients and classified in two groups: patients with eGFR > 60 (GFRhigh, n=48, 62F/6M, age: 34.07±13.24) and patients with eGFR < 60 (GFRlow, n=18, 14F/4M, age: 35.22±13.76). RNA from urine samples was isolated using TRIzol-Chloroform technique and then reverse-transcribed using random primers. Levels of BLyS expression were evaluated using Quantitative Real Time PCR (QPCR). All amplifications were carried out in duplicate and threshold cycle (Ct) scores were averaged for calculations of relative expression values. The Ct scores were normalized against β2M scores by subtracting the corresponding statistically significant difference between groups (p=0.0288).

Background: Lupus Nephritis (LN) is one of the most severe forms of systemic lupus erythematosus (SLE) (1). Angiotensinogen (AGT) gene encodes the only glycoprotein known to be a precursor of the vasopresor angiotensin II (Ang II). Ang II is also a growth factor and a profibrogenic cytokine (2). In kidney allograft dysfunction (3). In LN, AGT deserves evaluation.

Objectives: To investigate AGT expression in biopsies and urines from LN patients.

Results: DCt is inversely proportional to BLyS expression. We evaluated data from ΔCt analysis observing that mRNA levels of BLyS in eGFRlow (6.193±1.877) were higher than those from eGFRhigh (7.564±2.326), with a statistically significant difference between groups (p=0.0288).

Conclusion: In the present cross-sectional study, increased levels of BLyS were observed in patients with eGFR < 60. These gene expression results might be linked to B cell activation and proliferation in kidney and thus in urine samples. Combination of eGFR and BLyS appears to be a good biomarker.

INCREASED EXPRESSION OF CCN4/WISP1 IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS WITH HOMEOSTASIS

M. van den Bosch1, Y.F. Ramos2, W. den Hollander2, N. Bömer2, R.G. Nelissen3, J.B. Bovée4, A.B. Blom1, I. Meulenbelt2.

Objectives: To investigate the clinical characteristics of 34 cases with systemic juvenile idiopathic arthritis (SJIA) and macrophage activation syndrome (MAS), and to determine specific gene-gene interactions.

Methods: 34 SJIA cases with MAS were included. All cases underwent genetic testing for polymorphisms in the PRF1, STX11, UNC13D and STXBP2 genes.

Results: Frequencies of the SNPs in the MAS group were compared to a control group. PRF1 rs885822, STXBP2 rs10001 and HLA-DQB2 A*0301 were significantly associated with increased risk to develop MAS in our Italian RA cohort.

Conclusions: This study confirms the association between SJIA and MAS in the Italian population, and identifies specific gene-gene interactions that may contribute to the pathogenesis of MAS.

SYNOVIAL FLUID MiRNAs MULTImARKER ANALYSIS IN PATIENTS WITH RHEUMAtoID ARTHRITIS

R. Shumailova 1, D. Kacha kova 2, S. Monov 1, R. Ken ava 2, Z. Kolarov 1, R. Rashkov 1
1Department of Internal Medicine, Clinic of rheumatology, Medical University - Sofia; 2Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Medical University - Sofia, Sofia, Bulgaria

Background: Recent epigenetic studies reveal the pathogenic role of micro-r Nucleic acids (microRNAs) and their targets in the inflammatory process in rheumatoid arthritis (RA), miRNAs play crucial role in controlling and modulating inflammatory and Medical Synovial expression of miRNAs was shown to be deregulated as compared to healthy controls. The deregulated function of regulatory T cells, to the chronic synovial inflammation and bone destruction 1,2.

Objectives: To perform a multimarker analysis of synovial fluid (SF) expression levels of miR-146a, miR-155 and miR-223 in RA patients in regard to their role as diagnostic biomarkers.

Methods: Total RNA was isolated from the SF of 48 RA patients and 11 healthy controls (HCs) and expression levels of miR-146a, miR-155 and miR-223 were determined by quantitative real-time polymerase chain reaction (qPCR). We used SYBRGreen technology. Relative changes of gene expression levels of the miRNAs were calculated by 2-ΔΔCt method and SPSS were used for statistical analysis. RNU6B gene was used as a reference control for normalization.

Results: miR-146a, miR-155 and miR-223 showed overexpression in RA SF compared to HCs (in 70.83%, 79.17% and 79.17% of the patients, respectively) and could be used to differentiate RA patients from HCs (p=8.10-10, p=8.10-10 and p=8.10-10, respectively). The ROC curve analysis showed diagnostic accuracy of these miRNAs in SF for distinguishing RA patients from HCs.

Conclusions: Our study demonstrates that the multimarker analysis of the expression levels of miR-146a, miR-155 and miR-223 in RA patients is a valuable diagnostic tool in the management of RA. The diagnostic accuracy of these miRNAs is high and they could be used as biomarkers in the early diagnosis of RA. Additionally, the multimarker analysis of these miRNAs could be used as a complementary tool in the management of RA patients. Further studies are needed to validate these findings in larger populations and different clinical settings.

Disclosure of Interest: The study was supported by Grant 14-D/2012 and 55/2013

Cytokines and inflammatory mediators

IL-6 TRANs-SIGNALING CAUSES ACCELERATED ATHEROSCLEROSIS IN DISEASE PRONE ANIMALS

R. Davies 1, H.S. Jin 1, K. Sim 1, J.O. Williams 1, C.R. Thompson 1, G.W. Jones 1, K. Allen-Redpath 1, S.A. Jones 1, T.R. Hughes 1, S. Rose-John 1, A.S. Williams 1, E.H.S. Choy 1, 2, Institute of Infection and Immunity; 2Cardiff School of Biosciences, Cardiff University, Cardiff, United Kingdom; 3Institut of Biochemistry, Christian-Albrecht Universität, Kiel, Germany

Background: Cardiovascular (CV) disease is a major cause of mortality in patients with rheumatoid arthritis (RA). CV risk is increased early in the disease course. Subclinical inflammation and dyslipidaemia are often seen in RA before patients become symptomatic, suggesting the presence of subclinical CV disease. Inflammation, as measured by acute phase reactants, is associated with CV disease in RA. Interleukin (IL)-6 is a major driver of the acute phase response in RA. Elevated IL-6 levels may contribute to chronic disease progression. Control of these processes is regulated by two modes of IL-6 signaling: classical IL-6 receptor signaling and IL-6 trans-signaling. Cellular responses controlled by IL-6 trans-signaling are mediated via soluble IL-6 receptor (sIL-6R) and are widely considered to promote deleterious pro-inflammatory outcomes [1]. We hypothesize that atherosclerosis may predate diagnosis of RA, and is accelerated by IL-6 trans-signaling during active arthritis. Here, we investigate this hypothesis using the established ApoE-deficient (apoE-/-) mouse model of atherosclerosis.

Objectives: To examine the effect of IL-6 classical and trans-signaling on atherosclerosis by administering IL-6 or Hyper-IL-6 (a IL-6: sIL-6R fusion protein) to apoE-/- mice.

Methods: Male apoE-/- mice were fed a high-fat diet for 8 weeks starting at 8 weeks of age. Mice were divided into 4 groups. Group 1 received IL-6 (160 ng twice weekly, delivered i.p.), and Group 2 and 3 received Hyper-IL-6 (500 ng and 1 μg delivered i.p. twice weekly) for 8 weeks. Group 4 received PBS twice weekly for 8 weeks. Serial transverse 7 um b rachiocephalic artery cross-sections were cut and stained with haematoxylin and oil red-O. Lesion size was determined by computer-assisted morphometry, using Image J on stained sections. Brachiocephalic plaque size in mice treated with PBS, IL-6 and Hyper-IL-6 were compared using ANOVA and post-hoc Tukey test.

Results: Mice with Hyper-IL-6 had significantly larger brachiocephalic plaques (mean plaque area 0.73±0.04 mm²) than those administered PBS (0.018±0.01 mm², p < 0.001), and IL-6 (0.033±0.017 mm², p < 0.015; Fig.1A). Similarly, mice administered Hyper-IL-6 [1μg] had a significantly higher percentage of the brachiocephalic artery occupied by plaques (45.3±18.1%) compared to those administered PBS [0.7±0.7%, p < 0.001] or IL-6 [0.1±0.2%, p < 0.002] (Fig.1B). Mice administered Hyper-IL-6 [0.5μg] had significantly higher percentage plaque (27.7±16.2%) than PBS administered mice, p = 0.015. There was no significant difference in total cholesterol, HDL, LDL, triglycerides, free fatty acids or cholesterol/HDL ratio between the groups.
Conclusions: IL-6 trans-signaling leads to accelerated atherosclerosis in disease susceptible animals. This effect is independent of changes in serum lipid profiles.

THU0026 OSIM IS MORE EFFECTIVE THAN IL-6 AT INDUCING ENDOMT OF HUMAN DERMAL MICROVASCULAR CELLS
K. Nevin1, L. Stawski2, M. Feeney1, N. Wisniacki1, M. Trojanowska2.
1Immunno-Immunation Therapeutic Area Unit, GlaxoSmithKline, Stevenage, United Kingdom; 2Arthritis Centre, Boston University, Boston, United States

Background: Oncostatin-M (OSM) and interleukin-6 (IL-6) are members of the IL-6 superfamily and signal via glycoprotein 130 (gp130). OSM signals with either the type I receptor complex, gp130/Leukemia Inhibitory Factor Receptor (LIFR), or the type II receptor complex, gp130/OSM receptor (OSMR), whilst IL-6 signals via gp130 with the IL-6 receptor (IL-6R) or by trans signalling with soluble IL-6R (sIL6-R). Endothelial cells (ECs) express both gp130 and OSMR [Brown TJ et al 1991], however it is unclear whether ECs express IL-6R [Romano M et al 1997; Nilsson MB et al 2005]. Endothelial to mesenchymal transition (EndoMT) is the phenotypic transition of ECs into mesenchymal cells where ECs lose their specific EC markers, detach from the endothelial layer and initiate the expression of mesenchymal cell products. EndoMT is associated with vascular dysfunction, one of the early manifestations of systemic sclerosis. The role of OSM and IL-6 in EndoMT has not yet been fully elucidated.

Objectives: To determine the effect of OSM and IL-6/sIL-6R on microvascular EC migration, proliferation and EndoMT.

Methods: Human dermal microvascular ECs (HDMECs) were treated with human recombinant proteins OSM (1–100 ng/mL), IL-6 (10–100 ng/mL) and sIL-6R (10–100 ng/mL). Cell migration and proliferation were measured with Live-Cell imaging system over 50 hours and analysed using a two-way ANOVA. Secretion of Collagen type I protein was measured at 48 hours by western blot analysis of media supernatant from HDMEC cultures. Changes in VE-Cadherin and F-actin expression were examined by immunofluorescence over 72 hours.

Gene expression was measured at 3 hours using quantitative RT-PCR analysis and analysed by Student’s paired T-test.

Results: OSM and IL-6, with or without IL-6R, significantly increased (P<0.001, n=3 donors) HDMEC migration and proliferation and secretion of extracellular matrix (ECM) protein Collagen I compared to the control group. OSM, but not IL-6 with or without sIL-6R, reduced expression of EC marker VE-Cadherin and increased expression of elongated F-actin stress fibres (n=2 donors). OSM significantly affected (P<0.05, n=3 donors) expression of EndoMT genes SNAIL1, SNAIL2, SNAIL3 and TWIST [Figure 1] and ECM genes MMP1, MMP2 TIMP1 and TIMP2 compared to the control. Many of the gene changes in response to OSM were further augmented by co-stimulation with sIL-6R, IL-6 with or without sIL-6R only significantly affected (P<0.05, n=3 donors) EndoMT genes SNAIL1 and SNAIL2 and ECM gene TIMP1.

Conclusions: OSM induced a stronger EndoMT phenotype in HDMECs in comparison to IL-6, suggesting that OSM is capable of initiating EndoMT activity in microvascular cells. The augmented effects observed for OSM with sIL-6R also suggests that OSM is capable of binding the sIL-6R and initiating signalling in HDMECs in vitro.

THU0027 CLUSTERIN IS ELEVATED IN SERUM AND MUSCLE TISSUE IN IDIOPATHIC INFLAMMATORY MYOPATHIES AND IS ASSOCIATED WITH DISEASE ACTIVITY
T. Lennerova1, L. Vernerova1, M. Klein1, M. Tomcil1, H. Mann1, V. Hrušková1, K. Pavelka1, J. Vencovsky1, L. Šenot1. Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic

Background: Clusterin (also known as apolipoprotein J) is a molecular chaperone that participates in inflammatory and apoptotic processes. Recent data indicate its possible protective role in the development of chronic autoimmune disorders.

Objectives: The aim of this study was to analyse the skeletal muscle expression of clusterin and its serum levels in patients with idiopathic inflammatory myopathies (IIM) and in healthy donors, and to examine the association of clusterin with disease activity.

Methods: Clusterin mRNA expression in skeletal muscle specimens, obtained by muscle biopsy (mini-invasive Bergstrom technique), was determined using qPCR assays in 65 patients with IIM (27 dermatomyositis (DM), 28 polymyositis (PM), 10 immune-mediated necrotizing myopathy (IMNM)) and in 54 healthy individuals. Disease activity was assessed using myositis disease activity assessment visual analogue scales (MYOACT), health assessment questionnaire (HAQ) and global disease assessment evaluated by doctor and patient. Data are presented as mean ± SD.

Results: Clusterin mRNA expression in skeletal muscles was increased in patients with IIM compared to healthy donors (p=0.029). In addition, serum clusterin levels were significantly higher in all IIM patients than in healthy subjects (r=0.59±12.4 vs 68.4±12.4, p<0.0001) and also in individual subsets of patients in comparison to the control group (DM: r=0.7±24.7, PM: r=0.6±23.7, IMNM: r=0.8±18.0, p<0.0001 for all). Clusterin levels in all patients with IIM positively correlated with MYOACT (r=0.52, p<0.0001), global disease assessment evaluated by doctor (r=0.49, p<0.001), global disease assessment evaluated by patient (r=0.52, p<0.001), and in 54 healthy individuals. Disease activity was assessed using myositis intention to treat index (MITAX), myositis disease activity assessment visual analogue scales (MYOACT), health assessment questionnaire (HAQ) and global disease assessment evaluated by doctor and patient. Data are presented as mean ± SD.

Conclusions: We demonstrate increased local and systemic expression of clusterin in IIM patients compared to healthy individuals and its association with disease activity, especially in dermatomyositis.

**TYPE I INTERFERON SIGNATURE IN THE PERIPHERAL BLOOD AND CXCL4 PLASMA LEVELS IN PATIENTS WITH SYSTEMIC SCLEROSIS**

**Background:** Type I Interferon (IFN) pathway is activated in Systemic Sclerosis (SSc) and represents a therapeutic target currently being tested in clinical trials, while higher IFN levels have also been associated with pulmonary fibrosis in these patients. On the other hand, in vitro experiments using plasmacytoid dendritic cells from patients with SSC suggest an interplay between the chemokine (C-X-C motif) ligand 4 (CXCL4), a potential biomarker in SSc, and type I IFN. [1]

**Objectives:** To test whether type I IFN-induced gene expression in the peripheral blood associates with particular clinical and laboratory features, including plasma CXCL4 levels, in patients with SSc.

**Methods:** Forty six patients with limited and 19 with diffuse SSc (60/65 women, aged 54±14 years, disease duration ranging between 0.5–27 years) and 20 healthy controls were examined. Peripheral whole blood samples (3ml) were subjected to cDNA synthesis and the expression of 3 genes (IFIT1, MX1, IFI44) that are preferentially induced by type I IFN was quantified by real time PCR. Type I IFN individual scores were calculated as described [2]; scores were arbitrarily considered as high when exceeding the mean value plus 3SD of the corresponding healthy control scores. Plasma CXCL4 levels were determined by ELISA.

**Results:** A high type I IFN score (i.e.>8) ranging from 8.4 to 145 was found in 21/65 (32.3%) patients with SSc, compared with none of 20 healthy controls (p=0.002). Patients with high type I IFN scores demonstrated higher erythrocyte sedimentation rate and lower differing lung capacity for carbon monoxide (DLCC) than the remaining patients (p=0.002 and p=0.02, respectively, by Mann-Whitney U test). Other disease variables, including extent of skin involvement and autoantibodies, were not associated with high type I IFN score.

Individual type I IFN scores positively correlated with the corresponding CXCL4 plasma levels (Spearman’s r: 0.53, p-value: 0.02). A prominent type I IFN signature was observed in the peripheral blood of one third of patients with SSc in association with upregulated inflammatory response, reduced DLCC levels and higher CXCL4 plasma levels. Further prospective data are required to establish the role of type I IFN as an additional novel biomarker in SSc.

**IL-2C SUPPRESSES CIA IN MICE BY THE TH1/TH17 IMMUNE RESPONSES DUE TO ENHANCEMENT OF BOTH TREG NUMBERS AND TREG FUNCTIONS**

Y. Yokoyama 1, T. Iwasaki 2, S. Kitano 3, T. Furukawa 4, A. Satake 5, K. Matsui 1, H. Sano 1. 1Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo; 2Department of Pharmacy, Hyogo University of Health Sciences, Kobe; 31st Department of Internal Medicine, Kansai Medical University, Hirakata, Japan

**Background:** Interleukin-2 (IL-2) induces regulatory T cells (Tregs) and reduces disease activity such as graft versus-host disease and systemic lupus erythematosus. IL-2/anti-IL-2 monoclonal antibody immune complex (IL-2IC) increases the half-life of IL-2 in vivo and specifically induces Tregs. We previously demonstrated that administration of IL-2IC suppressed collagen-induced arthritis (CIA) in mice (EULAR 2015).

**Objectives:** To clarify complex regulatory network of IL-2IC in autoimmune arthritis, we examined the suppression mechanism of IL-2IC induced Tregs to Th1 and Th17.

**Methods:** Male DBA/1 mice were inoculated by injection of 200μg of Type II collagen emulsified with an equal volume of complete Freund adjuvant intradermally at the base of the tail of mice (first immunization). Second immunization was given 21 days after first immunization. IL-2/anti-IL-2 were prepared by mixing 2 μg of anti-IL-2 antibody (clone JES9–1D7) with 1 μg of mouse IL-2 for 15 minutes. The mice were injected with either PBS as a control or IL-2/2 IC (5μg/mouse) intraperitoneally for 3 days. Mouse paws were scored for arthritis using a macroscopic scoring system ranging from 0 to 4 (0, no swelling or redness; 1, swelling/redness of paw or one joint; 2, two joints involved; 3, more than two joints involved; and 4, severe arthritis of the hind paw and joint). Arthritis scores from both hind paws were added up and represented as the score of the all four paws. Peripheral blood cells were stained with anti-CD25 (PC61), anti-CD4 (RM-5), anti-FOXp3 (FJK-16s) and CD4+CD25+Foxp3+ Tregs were analyzed by flow cytometry. Th1 and Th17 cells infiltrating in the synovium were examine by immunohistochemistry stained with anti-IFN-γ and anti-IL-17, and analyzed by flow cytometry.

**Results:** To define the effects of IL-2IC on established CIA, IL-2IC was administrated for 3 days from day 21 to day 23 after the first immunization (day 0 to day 2 after the second immunization) of CIA. To define the effect of IL-2IC on early stage of disease induction we administrated IL-2IC from day 0 to day 2 after first immunization. We observed a significant decrease in both the incidence and severity of arthritis in these CIA mice. Injection of IL-2IC effectively elicited more than 2-fold expansion of CD4+CD25+Foxp3+ Tregs in peripheral blood cells than control mice. Th1 and Th17 cells infiltrations in the synovium was significantly inhibited by IL-2IC treatment. In vivo suppression assay demonstrated significant augmentation of the suppressive capacity of CD4+CD25+Treg cells in IL-2IC treated mice. Intracutaneous cytokine staining revealed that IL-10 production by CD4+ cells in IL-2IC treated spleen increased four folds than in controls, and IL-17-producing helper T cells (Th17) and IL-17-producing helper T cells (Th17) were significantly decreased.

**Disclosures:** These observations indicate that IL-2IC not only induce Tregs, but also augments Treg function by enhancing IL-10 production. Therefore Tregssuppress Th1 and Th17 cells.

**THERAPEUTIC TREATMENT OF ANTI-FRACTALKINE MONOCONAL ANTIBODY INHIBITS JOINT DESTRUCTION IN COLLAGEN-INDUCED ARTHRITIS MODEL**

K. Hoshino-Negishi1, M. Ohkura2, T. Nakatani1, W. Ikeda1, Y. Kubo1, N. Ishii1, T. Yamauchi1, N. Yasuda1, T. Imai1, 1Research & Development, KAN Research Institute, Inc., Kobe-Shi; 2Research Project Promotion Group, EA Pharma Co., Ltd., Kawasaki-ku, Japan

**Background:** In the Phase 1/2 clinical study, E6011, a novel humanized anti-fractalkine (FKN) monoclonal antibody (mAb) demonstrated a promising efficacy in active rheumatoid arthritis (RA) patients who were inadequately controlled by MTX and/or TNF-a inhibitors. However, the effect of anti-FKN mAb on joint destruction remains to be elucidated. In RA, synovium-infiltrated monocytes/macrophages cause synovitis and cartilage damage. Osteoclasts are generated from osteoclast precursor cells (OCPs) and cause cartilage destruction. FKN is expressed on endothelial cells and fibroblast-like synoviocytes in synovium in both experimental arthritis model and RA patients. FKN is also expressed on osteoblasts in neonatal mouse calvariae. CX3CR1, the receptor for FKN, is expressed on monocytes/macrophages and OCPs. Therefore, the interaction of FKN and CX3CR1 might play important roles in migration, differentiation and activation of these cells, leading to cartilage damage and bone erosion.

**Objectives:** We examined the efficacy of an anti-FKN mAb on collagen-induced arthritis (CIA) in mice, especially on joint destruction.

**Methods:** For the induction of CIA, DBA/1-J mice were immunized with bovine type II collagen (BII-C) with CFA (1:1) i.d. A dose of FKN mAb or control IgG was injected twice a week from the day of the 1st immunization (for the prophylactic treatment) or after the onset of CIA (for the therapeutic treatment). The clinical arthritis score was defined as the sum of the scores of four paws. Plasma concentrations of IL-6, TNF-a, serum amyloid A (SAA), Tartrate-Resistant Acid Phosphatase type 5b (TRAP-5b), Cartilage Oligomeric Matrix Protein (COMP) and Matrix Metalloproteinase 3 (MMP-3) were measured using ELISA. Radiological score was measured by the soft x-ray images of limb bones. Alcian blue/Alizarin red and Tartrate-Resistant Acid Phosphate (TRAP) staining were performed for histopathological analysis of bone destruction.

**Results:** In the prophylactic treatment, anti-FKN mAb markedly reduced the clinical arthritis score, soft x-ray score, and plasma levels of TRAP-5b, COMP and MMP-3, whereas plasma levels of IL-6, TNF-a and SAA were not significantly reduced compared with control IgG-treated mice. Histopathological analysis demonstrated almost complete suppression of joint destruction and dramatic reduction in the number of TRAP-positive cells by the treatment of anti-FKN mAb. Importantly, therapeutic treatment of anti-FKN mAb also significantly ameliorated clinical arthritis score and soft x-ray score. Synovitis, pannus formation, cartilage degradation and bone erosion were also strongly suppressed and the number of TRAP-positive cells in joint was also decreased by the therapeutic treatment of anti-FKN mAb.

**Conclusions:** Anti-FKN mAb demonstrated a remarkable efficacy in the arthritis score without affecting systemic inflammatory parameters and inhibited the joint destruction with the marked reduction of osteoclasts in CIA model. These results suggest that inhibition of FKN/CX3CR1 axis by a humanized anti-FKN mAb, E6011, is an attractive therapeutic strategy for the treatment of both inflammatory synovitis and joint destruction of RA.

**THE ROLE OF S100A IN PAIN RESPONSE DURING EXPERIMENTALLY INDUCED ACUTE SYNOVITIS**

E.J. W. Geven, E.N. Blaney-Davidson, E.L. Vitters, A.W. Sloetjes, B. Walgreen, A.B. Blom, P.E.M. van Lent. Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands

**Background:** Synovitis-associated pain is an important aspect of arthritis pathology. Several inflammatory mediators released by the synovium have been implicated in the regulation of pain, including S100A8 and S100A9 which may contribute to the pathogenesis of joint destruction. In synovitis and during the acute inflammatory response in the synovium or via stimulation of the dorsal root ganglia (DRG), thereby enabling an increased phagocyte infiltration.

**Objectives:** To investigate the role of S100A in the pain response after induction of an acute synovitis using streptococcal cell walls (SCW) as a trigger, comparing S100A9-/- mice and their WT controls.

**Methods:** Acute synovitis was induced by a single i.a. injection of SCW in the knee joint of C57B16 (WT) mice and S100A9-/- mice, control mice received an i.a. saline injection. Serum S100A8/A9 levels were investigated by ELISA and expression of S100A8 and S100A9 in synovium and DRG by immunohistochemistry. Joint swelling and cell influx was assessed by 99mTc accumulation and histology, respectively. Pain response were investigated Incapacitance Tester (weight bearing), Catwalk (gait analysis) and von Frey’s filaments (mechanical allodynia). Gene expression of inflammatory mediators and neuron activation markers in DRG were determined by q-PCR.

**Results:** A single i.a. injection of SCW resulted in increased synovial expression of S100A8 and S100A9 and subsequent increased serum S100A8/A9 levels (2.6-fold, P < 0.001) 1 day p.i., which returned to basal levels at 7 days p.i. The increased expression of S100A9 did not contribute to the development of inflammation since joint swelling and cell influx were similar in WT and S100A9-/- mice 1 day p.i. Using the Incapacitance Tester, WT mice showed a marked and significant decrease in percentage of weight bearing on the SCW injected hindpaw (28%) compared to saline injection (47%, P < 0.001) 1 day p.i., whereas S100A9-/- mice did not. In addition, gait analysis showed that the stand-phase of the un.injected paws was significantly increased in S100A9-/- mice (0.044 and 0.030, respectively) while SCW injection in S100A9-/- mice did not show increased expression, which is in line in with the reduced pain response observed earlier in S100A9-/- mice.

**Conclusions:** These findings show that S100A9, which is released from the synovium upon inflammation, is an important mediator of inflammatory pain response in the knee, and that during the acute phase of inflammation is likely regulated via direct activation of TLR4 on nerve endings in the synovium and not via increased infiltration of phagocytes in the DRG.

**LOCAL INJECTION OF ADIPOSE-DERIVED MESENCHYMAL STEM CELLS IN EXPERIMENTAL INFLAMMATORY OA RESULTS IN INTERLEUKIN-1β-MEDIATED ATTRACTION OF PMNS AND REDUCED S100A8/A9 RELEASE**

S. van Dalen, A. Sloetjes, M. Helsen, B. Walgreen, E. Geven, P. van Lent. Experimental Reumatology, Radboud university medical center, Nijmegen, Netherlands

**Background:** Recent studies have shown that mild synovitis in early phases of osteoarthritis (OA) is conducive to development of joint damage. OA synovitis is characterized by elevated levels of pro-inflammatory factors like S100A8, S100A9, interleukin-6 (IL-6), and interleukin-1 beta (IL-1β). S100A8/A9 was found to be crucial in mediating joint destruction in inflammatory experimental OA. Previously we found that adipose-derived mesenchymal stromal cells (ASCs) exhibit immunosuppressive characteristics and reduce joint pathology after local application into mouse knee joints with experimental inflammatory OA. This protective effect is only perceived after intra-articular injection in early but not late stage OA, suggesting that the effect may be mediated by an inflammatory milieu.

**Objectives:** To examine the working mechanism of ASCs after early injection in experimental OA.

**Methods:** Experimental OA was induced by injection of collagenase into murine knee joints (CIOA). Total knee joints were stained with haematoxylin/eosin and the PMN-specific antibody NIMP-R14. ASCs were isolated from murine adipose tissue and stimulated for 24h with IL-1β or S100A8/A9. Gene expression in stimulated cells was examined using qPCR. Protein levels of chemokines were measured in culture supernatant using Luminex. Migration of MACS isolated bone marrow (BM-) PMNs towards ASC-conditioned medium (CM) was examined using Transwell inserts. ASCs were co-cultured with BM-PMNs and analyzed using histology and Luminex.

**Results:** ASC injection into day 7 CIA knee joints (when synovitis and IL-1β and S100A8/A9 levels are highest) caused a strong attraction of mainly PMN-like cells and their clustering around ASCs in the synovium shortly after injection (6h), which was confirmed by immunohistochemistry. IL-1β stimulation of ASCs in vitro strongly increased gene expression of PMN-attracting chemokines (KC, CXCL1, and CXCL7 as well as protein levels of KC, whereas S100A8/A9 did not. The migration of BM-PMNs through Transwell inserts towards CM of IL-1β-stimulated ASCs was significantly increased (from 5% to 10%) when compared to CM of non-stimulated ASCs. Next, ASCs were co-cultured with BM-PMNs in the presence or absence of IL-1β. After 6h, a clear clustering of neutrophils around ASCs was observed, with a significant increase in the number of ASCs clustering with PMNs, as well as a significantly elevated number of clustering PMNs per ASC after IL-1β stimulation. Interestingly, association of PMNs with ASCs lead to a significantly lowered release of KC protein by ASCs (69% and 76% lower after 24h and 48h respectively), as well as a significantly reduced release of S100A8/A9 protein by the PMNs. This coincided with lowering of S100A8/A9 levels in washouts of inflamed synovium 6h and 48h after injection of ASCs in day 7 CIA knee joints.

**Conclusions:** Local application of ASCs in inflamed CIA knee joints results in attraction and clustering of PMNs with ASCs in the synovium. This presumably runs via IL-1β-mediated up-regulation of chemokine release by ASCs, and ultimately results in significantly lowered S100A8/A9 levels.

Background: Calcium pyrophosphate (CPP) crystal-induced inflammation is mainly driven by interleukin (IL)-1β, IL-18 production involves a two-step process, including the formation of pro-IL-1β through NF-κB activation and its maturation into active IL-1β through NLRP3 inflammasome activation. Two CPP crystal phases, namely monoclinic and triclinic CPP dehydrated (m- and c-CPPD) crystals are identified to have recently been recognized that m- and c-CPPD display different inflammatory potentials marked by a differential level of IL-1β production and other pro-inflammatory mediator expression.

Objectives: We aimed to assess the intracellular pathways upstream CPP-stimulated IL-1β production, according to the different inflammatory properties of CPP crystal phases.

Methods: Four synthesized and prokaryon-free CPP crystals [a-CPP (amorphous), m-CPPD or tetrahedrised (m-CPTP) and t-CPPD] (Grap P et al. 2014) and monosodium urate (MSU) crystals were used, in vitro, to stimulate THP-1 cell line or mouse bone marrow-derived macrophages (BMDM) in the presence or not of pharmacological inhibitors: Bafilomycin A1 (Baf); 11β-hydroxysteroid dehydrogenase (11βHSD) inhibitors; SB203580 (SB); MAPK p38 inhibitor; SP600125 (SP; JNK inhibitor) and PD98059 (PD; p42/44 MAPK inhibitor). The expression of pro- and anti-inflammatory cytokine genes was assessed by qRT-PCR, and IL-1β and IL-6 production by ELISA; MAPK phosphorylation by immunoblotting. NF-κB activation in THP-1 cells containing a gene reporter plasmid under control of NF-κB transcriptional factor. In vivo, we used murine air pouch model to assess the effects of NF-κB inhibition in CPP crystal-mediated inflammation.

Results: We previously demonstrated that in vitro m-CPPD crystals were the most inflammatory CPP crystals and induced a higher production of mature IL-1β associated to a higher expression of NLRP3 protein, and a higher IL-8 production and expression of inflammatory cytokine genes (IL-1β, IL-6, IL-8, TNF, COX-2) than t-CPPD, m-CPTPT and MSU crystals. a-CPP crystals did not have inflammatory property. m-CPPD crystals induced a higher NF-kB activation and a higher phosphorylation p38, p42/44 and JNK MAPKs than t-CPPD and MSU crystals. In parallel, we showed that inhibition of NF-κB completely abrogated mature IL-1β and IL-8 secretion and pro-IL-1β synthesis induced by all CPP crystals. Inhibition of JNK and p42/44 MAPK with SP and PD respectively, decreased both IL-1β secretion and NF-κB activation induced by CPP crystals. In vivo IL-1β and IL-8 production and neutrophil infiltration induced by m-CPPD crystals were dramatically decreased by NF-κB inhibitor.

Conclusions: Our results showed that IL-1β and IL-8 production induced by CPP crystals is completely dependent of NF-κB signaling. They suggested that the inflammatory potential of different CPP crystals relied on their capacity to activate both MAPK and NF-κB pathways. Differential level of NF-κB activation is partially dependent of MAPK phosphorylation. Additional studies are ongoing to investigate the underlying mechanisms.

ROLES OF IL-6 IN RANKL- AND ACPA-MEDIATED OSTEOCLASTOGENESIS

A. Ciriciumaru, Y. Liu, A. Krishnamurthy, S.M. Mia, V. Joshua, M. Enгрönd, V. Malmström, M. Sun, H. Wåhlmåns, B. Rethi, A. Catrina. Karolinska Institute, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden

Background: We have shown previously in various experimental models that anti-citrullinated protein antibodies (ACPAs) can contribute to bone erosion and arthralgia through IL-8 dependent mechanisms.

Objectives: In cell cultures osteoclasts (OCs) played a prominent role in the ACPA-induced IL-8 secretion and therefore we decided to characterize in detail the autocrine regulation of OC differentiation by IL-8 in the presence or absence of ACPAs.

Methods: Peripheral blood monocytes were generated from healthy volunteers or patients with active rheumatoid arthritis (RA) and used to discover the role of RANKL and IL-8 in OC differentiation in the presence of ACPAs. We have shown previously that the M-CSF induced IL-8 plays a crucial role in OC differentiation in the presence of exogenous RANK-L. In the presence of ACPAs, OCs in the presence of M-CSF and RANKL. In the presence of ACPAs anti-citrullinated protein antibodies (ACPAs) can contribute to bone erosion and arthralgia through IL-8 dependent mechanisms.

Background: The drugs called Anti-TNF inhibitors are capable of inducing an immune response (immunogenicity). Its effectiveness may be affected by the development of Anti-Drug Antibodies (Ab).

Objectives:
- To assess the frequency of appearance of Anti-Drug Antibodies: Infliximab (IFX), Adalimumab (ADA), etanercept (ETN)
- To classify the failures of response
- To analyse the relationship between anti-TNFAb and concomitant treatment with DMARDs
- To observe whether there is a link between risk factors and drug levels

Methods: This is a retrospective, descriptive, observational study of patients with Rheumatoid Arthritis (RA), Spondyloarthritis (SpA), Psoriatic arthritis (PsA), Seronegative arthritis (SA) and Enteropathic arthritis (EA) with active disease and that were treated in the “University Health Care Hospital of León” between Jan-2015 and Jan-2016. Using ELISA Technology and the kits Promonitor®, it was possible to detect serum levels of IFX, ADA, ETN (reference values = 2.5 μg/mL, 5–6 μg/mL, and 0.8–1.2 μg/mL respectively) and of anti-drug antibodies. The samples were collected the same day of the administration, prior to it, always in a trough level. The gathered data was: demographic data, activity, time-to-disease progression, prior treatment with biologics, concomitant DMARDs, duration of the biologic treatment and dosage, quantization levels, anti-TNF antibodies, cardiovascular risk factors (CVRF) and smoking habits.

Results: Variables to study:
- N=40: IFX 50%, ADA 30%, ETN 20%
- Age 53.6±3.7 years old [95% CI], Women: 55%, time-disease progression: 12.3±2.7 years old.
- Type of disease: RA 47.5%, SpA 15%, PsA 20%, SA 7.5%, EA 10%
- DAS28: 3.5±0.4, BASDAI 4.7±0.5, BASFI 4.3±1.4.
- Frequency of administration: IFX 8.6±0.36 weeks, ADA 2.25±0.36 weeks, ETN 1.1±1.0 weeks.
- Reasons for requesting the levels:
  - Secondary failure (82%): IFX 90%, ADA 66.7%, ETN 12.5%
  - Primary failure (17%): IFX 5%, ADA 33%, ETN 25%
  - Infusion reactions (2.5%)
- Drug levels within the therapeutic range: IFX 10%, ADA 41%, ETN 50%.
- Formation of anti-TNF Ab of the sample: IFX 30%, ADA 16%, ETN 0%.
- DMARDs: presence of 62.5% (MTXc 64%, MTXvo 20%, Leflunomide, Sul-fasalazine e Hydroxychloroquine 16%).

Conclusions: We found the following conclusions:
- In the data collected, we observe that the IFX (30%) is the most immunogenic drug, followed by the ADA (16%) and being the ETN (0%) the one that so far has not presented anti-drug Ab, outcomes in agreement with the medical literature.
- The main reason for requesting has been the secondary failure (90%)
- The suboptimal levels of the drug and the presence of specific ab are correlated with the loss of clinical response. In our case, the proper range of drug is only objective in 10% of the patients treated with IFX, 41% with ADA and 50% with ETN.
- The concomitant use of DMARDs in our study has not shown to decrease levels of Ab, being the MTX the most used in our patients (84%). We observed no correlation between the occurrence of Ab, the use of DMARDs or the type of disease.
- The monitoring of the levels of anti-TNF drug may be useful to individualize the treatment, to avoid possible side effects and to make decisions regarding the continuation or change of therapy.

spondylitis (SA) are associated with an increased cardiovascular (CV) mortality. Quantitative abnormalities in lipid profiles are insufficient to explain this excess of CV risk and a qualitative approach of HDL composition is required to identify loss of atheroprotective functions and to correctly identify patients at risk. Atheroprotective functions of HDL are directly linked to the structure of HDL mainly composed of phospholipids (PL).

**Objectives:** The main objective of this study is to analyze the PL composition of HDL in patients with chronic inflammatory rheumatic diseases and to compare to matched healthy controls.

**Methods:** HDL structure was assessed in patients with active RA (ACR criteria), PsA (CASPAR criteria) and SA (ASAS criteria) patients before initiating first biologic and in healthy controls matched for age, sex and body mass index. Dyslipidemia treatment or pathology which could interfere with lipid profile were excluded. Demographics data, disease activity, cardiometabolic profile and plasma samples were collected. HDL particle were isolated from plasma by two-step ultracentrifugation using gradient of density. Lipidomics analysis were performed using liquid chromatography coupled with mass spectrometry. Phospholipid composition between patients and controls was compared using multivariate analyses to take into account possible confounding variables determined according to univariate results and clinical relevance (age, tobacco consumption, steroids use). Multidimensional analyses as factorial mixed data analysis (FMDA) were performed to complete these analyses.

**Results:** 19 RA, 19 PsA and 12 SA were analyzed (table 1). 220 phospholipid species were identified among which 82 major classes were modified in inflammatory diseases. Phosphatidylcholine (PC) decreased in RA and PsA (p < 0.01 and < 0.05 respectively) while lysophosphatidylcholine (LPC) increased significantly (p < 0.01 and < 0.05 respectively). Some phospholipid species as PC 40: 8 (p < 0.001), LPC 16:0 (p < 0.001), LPC 18:3 (p < 0.001) were identified as discriminant marker of HDL composition in rheumatic disease as compared to controls.

**Conclusions:** Phospholipid composition of HDL is altered in RA and PsA. These alterations could explain a loss of atheroprotective functions and the excess of CV risk observed in RA and PsA patients. Chronic inflammation, through the activation of phospholipid A2 type lipases which hydrolyze PC into LPC, could modify the structure of HDL phospholipids and thus could impact HDL functionality such as cholesterol efflux, LDL oxidation modulation, anti-inflammatory and vasculoprotective properties. These preliminary data suggest the major role of inflammation in these alterations.

**NOVEL AKT ACTIVATOR SC-79 IS A POTENTIAL TREATMENT FOR ALCOHOL-INDUCED OSTEOGENESIS OF THE FEMORAL HEAD**

C. Yixuan, Orthopedics, Shanghai Jiao Tong University Affiliated Sixth People’s Hospital, Shanghai, China

**Background:** Alcohol is known to be one of the leading risk factors for osteonecrosis of the femoral head. However, the underlying etiology and protective strategies of alcohol-induced osteonecrosis of the femoral head have not been clarified.

**Objectives:** The aim of this study was to explore the molecular mechanism of alcohol-induced osteonecrosis of the femoral head, and to investigate the protective effect of SC-79 on the disease.

**Methods:** In vitro, we employed RT-PCR, alizarin red staining, alkaline phosphatase activity testing, western blot, immunofluorescence staining to investigate the effect of ethanol on hBMSCs. In vivo experiments, immunofluorescence staining, TRAP, TUNEL and micro-CT were performed to investigate the development of ONFH.

**Results:** In vitro, we found that ethanol could significantly impair the expression of osteogenic genes of RUNX2 and OCN, downregulate osteogenic differentiation, impair IGF-1 induced membrane recruitment of the Akt, suppress the Akt-Ser473 phosphorylation and the subsequent activation of Akt/GSK3β/β-catenin signaling in bone mesenchymal stem cells. Functional studies further confirmed this signaling was the critical mediator during the ethanol-induced inhibitory effects on osteogenesis of BMSCs. Thus, the dephosphorylation of Akt-Ser473 in Akt/GSK3β/β-catenin signaling pathway might be a potential therapeutic target.

**Conclusions:** Hence, we discovered alcohol-induced osteonecrosis of the femoral head was associated with the suppression of the Akt-Ser473 in Akt/GSK3β/β-catenin pathway in BMSCs. The administration of SC-79, to elevate Akt activation, might be a clinical strategy to prevent the development of alcohol-induced osteonecrosis of the femoral head.

LONGITUDINAL IP-10 SERUM LEVELS ASSOCIATE WITH THE COURSE OF DISEASE ACTIVITY AND ACHIEVING DMARD-FREE SUSTAINED REMISSION IN RHEUMATOID ARTHRITIS

A. van Hoeij, D. Boeters, E. Tjoh Kon Fat, S. van den Eeden, P. Cornelis, A. van der Helm-van Mil, A. Geluk

Background: Although rheumatoid arthritis (RA) is a chronic autoimmune disease that is persistent in the majority of patients, 10–15% of the RA patients achieve disease modifying anti-rheumatic drugs (DMARD)-free sustained remission over time. Biological mechanisms underlying the persistence of inflammation in RA are not yet identified. It is well established that increased serum levels of IFN-γ-induced protein 10 (IP-10) are associated with (acute) increased inflammatory responses against mycobacterial pathogens causing leprosy and tuberculosis, thereby providing useful diagnostic tools in these infectious diseases. Based on previous and ongoing studies, we have hypothesised that there is an overlap between inflammatory responses observed in these mycobacterial diseases and those observed in RA. Therefore, we determined the association between serial IP-10 serum levels and achieving DMARD-free sustained remission as well as disease activity scores (DAS)-remission.

Objectives: To 1) assess the association between IP-10 levels over time in patients that have persistent RA versus patients that achieve DMARD-free sustained remission, and 2) determine the association between IP-10 levels and DAS.

Methods: 139 serum samples of 34 RA-patients (1907–criteria), obtained at the time of diagnosis and at yearly intervals thereafter, were studied. 15 patients had persistent RA and 19 patients achieved DMARD-free sustained remission after a median follow up of 2.7 years. IP-10 serum levels were measured using a previously developed, user-friendly lateral flow assay. Baseline and change in IP-10 serum levels were compared between patients with persistent RA and patients achieving DMARD-free sustained remission. The association between the change in IP-10 level and the change in DAS was studied; in addition the course of the absolute IP-10 levels and the DAS over time was plotted for individual patients.

Results: IP-10 serum levels varied from 316 – 53,685 pg/ml between RA-patients. Patients that had persistent arthritis or achieved DMARD-free sustained remission over time did not differ in baseline IP-10 levels (median persistent RA 1991 pg/ml and median DMARD-free sustained remission 3392 pg/ml, p=0.19). However, a significant decrease in IP-10 levels over time was observed in patients achieving DMARD-free sustained remission (p<0.003), whereas IP-10 levels remained stable in patients with persistent RA. Changes in IP-10 levels correlated well with changes in DAS scores (p=0.05). Also at the level of individual patients, a strong correlation between IP-10 levels and DAS over time was observed.

Conclusions: Baseline and longitudinal IP-10 levels are associated with perseverance of RA as well as with disease activity. Rapid diagnostic tests measuring IP-10 levels can therefore be helpful in monitoring of RA patients.

IL-21 AND IL-22 ARE INVOLVED IN BONE DESTRUCTION IN RHEUMATOID ARTHRITIS PATIENTS

E. Kuca-Warawnin 1, W. Kurowska 1, A. Radzikowska 1, G. Pracoon 2, T. Burakowski 1, M. Olszewska 3, I. Slowinska 1, I. Sudol-Szopinska 2, W. Malsinski 1, *1Department of Pathophysiology and Immunology; 2Department of Radiology and Intensive Care; 3Department of Rheumatopaediatrica, National Institute of Genetics, Rheumatology, and Rehabilitation, Warsaw, Poland

Background: Inflammatory process in bone marrow (BM) observed on MRI scans of rheumatoid arthritis (RA) patients (called bone marrow oedema) was shown to proceed joint destruction in RA. Our previous studies supported the concept that BM actively participate in the pathogenesis of RA by TLR triggered B cell activity (1), increased number of activated T cells and increased level of proinflammatory cytokines (2,3). Cytokines play a key role in the bone destruction of rheumatoid arthritis.

Objectives: To investigate the levels of IL-21 and IL-22 in RA BM plasma and their association with bone destruction.

Methods: BM samples were obtained from RA and osteoarthrosis (OA) patients during total hip replacement surgery. Levels of IL-17AF, IL-21, IL-22, RANKL and cathepsin K in BM plasma were determined by specific ELISA tests. We analyzed pelvic radiographs of 22 patients with RA admitted to the NIGRR and subjected to total hip replacement. Radiographs were taken a day or two before surgery. In our study we assessed hip joint changes semi-quantitatively with the use of the proposed scoring system including primary RA (juxta-articular osteoporosis, axial joint space narrowing, inflammatory cyst presence, bony erosion) and late RA changes (axial migration of the femoral head, femoral head deformation, avascular necrosis of femoral head, femoral head subluxation).

Results: We found increased levels of activated T cell associated cytokines IL-21 (924.8 pg/ml vs 688.6 pg/ml, p<0.05) and IL-22 (94.5 pg/ml vs 65.8 pg/ml, p<0.05) in BM plasma of RA patients in comparison to osteoarthrosis (OA) patients. Increased levels of both of these cytokines strongly correlated positively with concentration of osteoclastogenesis/osteoclast activity marker RANKL and cathepsin K. Surprisingly level of IL-17AF did not correlate with RANKL or cathepsin K. Furthermore, concentration of IL-21 was statistically significantly higher in patients with more severe radiologically assessed bone destruction. Median value of concentration of IL-21 in RA patients with small bone destruction was 797.4 pg/ml, with mild bone destruction was 1037.8 pg/ml, with severe bone destruction (1079.0 pg/ml).

Conclusions: Our results show an association between BM plasma levels of IL-21 and IL-22 and bone destruction, supporting the hypothesis that IL-21 and IL-22 are important pathogenic factors of this disease. Therapy targeting IL-21 and IL-22 may be of value in preventing bone erosions in patients with RA.

THU0046 CALCIUM PYROPHOSPHATE AND MONOSODIUM URATE CRYSTAL-INDUCED PROSTAGLANDIN E2 PRODUCTION INVOLVES NF-κB ACTIVATION AND ROS PRODUCTION, INDEPENDENTLY OF INTERLEUKIN-1BETA AXIS

F. Renaudin 1,2, L. Campillo-Gimenez 1, C. Combès 3, M. Gosset 4, M. Cohen-Solal 1,3, F. Liote 1,3, H.-K. Ea 1,5, *1UMR1132, Bioscar, Inserm; 2University Paris Diderot, Paris; 3CIRIMAT, Université de Toulouse, INPT, UPS, CNRS, Ensercoul, Toulouse; 4EA 2496, UFR Odontologie, Paris Descartes.

Montrouge; 5Service de Rhumatologie, centre Viggiano Petersen, AP-HP, hôpital Lariboisière, Paris, France

Background: Monoclinic and triclinic calcium pyrophosphate dihydrate (mCPP and tCPPD) and monosodium urate (MSU) crystals are responsible in human for relapsing acute arthritis. CPP and MSU crystal-triggered inflammation depends on several proinflammatory intercellular pathways like cyclooxygenase (COX) and NLRP3 inflammasome activation. COX-2 and NLRP3 inflammasome activation involves NF-κB activation.

Objectives: To evaluate how CPP crystals induce PG-E2 production and the role of NF-κB in this process.

Methods: Synthetic and pyrogen-free m-CPPD, t-CPPD and MSU crystals were used to stimulate human monocyte cell line (THP-1) and primary bone marrow derived macrophages (BMMDM) or murine type II macrophages (pC6) with different concentrations of CPP crystals. CPP crystal-induced IL-1β production was assayed in THP-1 cells containing a reporter gene under control of NF-κB promoter.

Results: CPP crystal-induced PG-E2 production was evaluated in the air pouch model in the presence or not of NF-κB inhibitor.

Conclusions: CPP crystal-induced PG-E2 production was completely abrogated by NF-κB inhibitor treatment and significantly decreased by the antioxidant NAC; in both case, COX-2 gene expression was dramatically inhibited.

THU0047 RESVERATROL AND ITS NATURAL PRECURSOR POLYDATIN INHIBIT CRYSTAL-INDUCED INFLAMMATION IN VITRO BY DECREASING OXIDATIVE STRESS AND IL-1BETA ACTIVATING PATHWAYS

Y. Zamudio-Cuevas 1, F. Olivieri 2, E. Belluzzo 2, A. Scarna 2, L. Andreotti 2, P. Gallozzi 2, M. Favero 2, R. Ramonda 2, P. Spinella 2, G. Ravagnan 2, A. Lopez-Reyes 3, L. Punzi 2, *1Instituto Nacional de Rehabilitación, Mexico City, Mexico; 2Rheumatology Unit, University of Padova; 3Clinica Nutrition Unit, University of Padova, Padova; 4Istituto di Farmacologia Transazionale (IFT) – CNR, Roma, Italy; 5Instituto Nacional de Rehabilitación, Mexico City, Mexico

Background: Resveratol (RES) and its natural precursor polydatin (PD) are polyphenols with broad variety of beneficial effects including anti-inflammatory properties. This study aimed to investigate the role of RES and PD in the inflammatory process induced by monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals in vitro. Their effect was evaluated though IL-1β, ROS mediation and cellular infiltrate induced by CPP crystals.

Objectives: To assess the role of oxidative stress (N-acetyl-L-cysteine, NAC) and NF-κB and NLRP3 expression was assessed by qRT-PCR. Reactive oxygen species (ROS) and NO were measured by cytometric flow cytometry analysis using fluorogenic probes (CellROX Deep Red Reagent and DAF-FM, respectively).

Results: RES and PD inhibited IL-1β by crystals both at extracellular
and intracellular level. This inhibition was more pronounced after polyphenol pretreatment. In this case cytokine production was completely suppressed in both control and stimulated cells. Cell pretreatment was extremely effective also in reducing mRNA expression of IL-1 after crystal stimulation while NLRP3 expression was to some extent affected by RES. RES and PD had a slight inhibitory effect on crystal-induced phagocytosis when added along with the stimulus, while pretreated cells did not show any difference in the phagocytosis index. ROS production induced by MSU crystals was more pronounced (4 fold increase) with respect to CPP crystals (2 fold increase). RES was more effective than PD in inhibiting ROS production (p<0.05 crystals vs crystals+RES). The pretreatment showed a more marked decrease of ROS than the simultaneous treatment and the effect reached significance for both PD and RES. Similar inhibitory effects have been obtained when NO production was considered. **Conclusions:** Our results demonstrated that RES and PD are effective in inhibiting crystal-induced inflammation affecting IL-1 production and NLRP3 expression and activation. Data obtained after cell pretreatment allow us to hypothesize that these polyphenols act on specific signaling pathway preventing inflammation, and that this action is independent from crystal phagocytosis. **Disclosure of Interest:** None declared **DOI:** 10.1136/annrheumdis-2017-eular.6330

**THU0048** SOLUBLE URIC ACID INCREASED THE EXPRESSION OF PDZK1 AND ABCG2 IN HUMAN INTESTINAL CELL LINES THROUGH THE TLR4/NLRP3/CASPASE-1 AND PI3K/AKT SIGNALING PATHWAYS

M. Chen, X. Lu, H. Wu. Department of Rheumatology, the Second Affiliated Hospital Zhejiang University School of Medicine, Hangzhou, China

**Background:** Hyperuricemia is the key pathophysiological basis of gout[1]. The most common reason generating hyperuricemia is the failure of urate excretion by current researches[2]. The intestine is known as the most important organ involved the excretion of uric acid besides the kidney [1]. ABCG2 has a key role in mediating urate excretion by the intestine[3]. PDZK1 is a kind of an important structural protein regulated ABCG2 function, with potential molecular interaction with ABCG2[4].

**Objectives:** The present study was undertaken to explore the effect and its related mechanisms of soluble uric acid on the urate excretion PDZK1 and ABCG2 in human intestinal cell lines. It also activated TLR4/NLRP3/caspase-1 inflammasome and PDZK1/AKT signalling pathway through the phosphorylation of pAkt. The increased expression of PDZK1 and ABCG2 was suppressed by a block of TLR4 (TAK-242) and caspase-1 inhibitor (acetyl–YVAD–chromomethylketone) and partly reduced by wortmannin, a specific inhibitor of PI3K. Additionally, lipopolysaccharide (LPS), the potent inducer of inflammatory responses mediated through TLR4, activated TLR4/NLRP3/caspase-1 inflammasome and up regulated the expression of ABCG2 and PDZK1. Besides, the stimulation of soluble uric acid facilitated the translocation of ABCG2 from intracellular compartment to plasma membrane and increased the transport activity. Furthermore, PDZK1 knockdown via siRNA significantly inhibited the expression and transport activity of ABCG2 regardless of the activation by soluble uric acid.

**Conclusions:** These results demonstrated that 29-kDa FN-f has a harmful impact on chondrocytes though suppressing HMGB1-dependent autophagy pathway and releasing HMGB1, DAMP to extracellular space. **References:**

**THU0049** 29-KDA FIBRONECTIN FRAGMENT SUPPRESSED HMGB1-DEPENDENT AUTOPHAGY PATHWAY IN HUMAN ARTICULAR CHONDROCYTES

M. Choi 1, J.-I. Park 1, K.M. Son 2, H.S. Hwang 1, H.A. Kim 1, 1Hallym University Sacred Heart Hospital; 2Hallym University Dongtan Sacred Heart, Gyeonggi-do, Korea, Republic Of

**Background:** Fibronectin fragments found in synovial fluid induce the catabolic responses in cartilage. High mobility group protein Box 1 (HMGB1), a damage-associated molecular pattern (DAMP), resides in the nucleus, translocates into the cytosol in response to various stimuli, and is subsequently released into the extracellular space.

**Objectives:** In this study, we investigated the effect of 29-kDa fibronectin fragment (29-kDa FN-f) on HMGB1-mediated autophagy pathway in primary human chondrocytes.

**Methods:** Human articular chondrocytes were enzymatically isolated from articular cartilage. The mRNA and protein levels of HMGB1 were measured by quantitative real-time PCR (qRT PCR) and Western blot analysis. The translocation of nuclear HMGB1 into cytoplasm was determined by western blot and immunofluorescence microscopy. Activation of mammalian target of rapamycin (mTOR), protein kinase B (Akt) and 1A/1B-light chain 3 (LC3) was measured by western blot analysis. Interaction of HMGB1 and Beclin-1 were evaluated by Immunoprecipitation (IP). Release of HMGB1 into extracellular medium was measured by ELISA.

**Results:** HMGB1 was significantly reduced in human osteoarthritis (OA) cartilage compared to normal cartilage. qRT PCR and Immunoblotting assay revealed that 29-kDa FN-f significantly reduced expression of HMGB1 at the mRNA and protein levels and also led to the translocation of the nuclear HMGB1 into the cytoplasm, together with decreased levels of Beclin-1 and phosphorylated Beclin-1. Using IP analysis, we demonstrated that in the presence of 29-kDa FN-f the association of HMGB1 and Beclin-1, which led to HMGB1-dependent autophagy pathway, was decreased, whereas the association of Beclin-1 and Beclin-1 was increased. In addition, prolonged treatment with 29-kDa FN-f significantly increased the release of HMGB1 into the culture medium. A variety of evidence, including down-regulated LC3-II, an autophagy marker, and increased phosphorylated 4EBP1 and p70S6K, substrates of mTOR, revealed that 29-kDa FN-f subsequently suppressed autophagy in primary chondrocytes by activating Akt/mTOR signaling pathway.

**Conclusions:** These results demonstrated that 29-kDa FN-f has a harmful impact on chondrocytes through suppressing HMGB1-dependent autophagy pathway and releasing HMGB1, DAMP to extracellular space.

domain protein-1/hypoxia-inducible factor-2α (EPAS-1/HIF-2α) is a catabolic transcription factor that regulates osteoarthritis (OA) cartilage destruction. **Objectives:** In this study, we examined whether microRNA-365 (miR-365) affects interleukin (IL)-1β-induced expression of catabolic factors in chondrocytes via regulation of HIF-2α.

**Methods:** Total RNA was isolated from normal and OA cartilage tissues and human chondrocytes. miR-365 expression was quantified by TaqMan assay. The effects of miR-365 on HIF-2α and HIF-2α-modulated genes were assessed by quantitative real-time reverse polymerase chain reaction (qRT-PCR), Western blot analysis, and enzyme-linked immunosorbent assay (ELISA). Direct interaction of miR-365 with the 3' untranslated region (UTR) of HIF-2α mRNA was examined using a luciferase reporter assay. Nitric concentration was measured in culture medium using a Griess assay.

**Results:** miR-365 levels were significantly decreased in human OA cartilage relative to normal cartilage. Overexpression of miR-365 significantly suppressed IL-1β-induced expression of HIF-2α in human articular chondrocytes. Pharmacological inhibition of various IL-1β-associated signaling pathways revealed mitogen-activated protein kinase and nuclear factor-kB as the primary pathways driving IL-1β-mediated decreases in miR-365 and subsequent increase in HIF-2α expression. Using a luciferase reporter assay encoding the 3'UTR of human HIF-2α mRNA, we showed that overexpression of miR-365 significantly suppressed IL-1β-induced up-regulation of HIF-2α. Furthermore, miR-365 overexpression significantly suppressed IL-1β-induced expression of catabolic factors, including cyclooxygenase-2, inducible nitric oxide synthase, and matrix metalloproteinase-1,-3 and -13, and nitric oxide (NO) production in chondrocytes.

**Conclusions:** MiR-365 regulates IL-1β-stimulated catabolic effects in human chondrocytes by modulating HIF-2α expression.

**ASSOCIATION BETWEEN BIOACTIVE TNF AND EULAR RESPONSE TO TNF INHIBITORS IN RHEUMATOID ARTHRITIS**

J. Peudoux1, H. Marotte1, J.-E. Gottenberg2, S. Paul3, Rheumatology, CHU Saint Etienne, Saint Priest en Jarez; 2Rheumatology, CHU Strasbourg; 3Immunology, CHU Saint Etienne, Saint Priest en Jarez, France

**Background:** ROC study provided data to manage rheumatoid arthritis (RA) treatment after a failure to a first TNF blocker (1). We previously reported that high circulating TNF bioactivity was associated with good clinical response (2). **Objectives:** To explore ability of TNF bioactivity to predict response to second TNF blocker. **Methods:** Here, we assessed TNF bioactivity in 130 RA patients from the group rotation to a second TNF blocker at the time of randomisation and after 6 months. Clinical and biological data were recorded at baseline and 6 month with Eular response assessed at 6 month. TNF bioactivity was assessed with HEK-Dual TNF cells adapted from our previous work (2). Due to non-normalised distribution, non parametrical analysis were performed. **Results:** Baseline circulating TNF bioactivity was similar according to Eular response. However, circulating TNF bioactivity at 6 month was associated with clinical response with low TNF bioactivity in responders. A ROC analysis suggested a cut-off at 0.320 with a sensitivity at 92% and a specificity at 41%.

**Conclusions:** After a failure of a first TNF blocker, circulating TNF bioactivity is not able to predict response to a second TNF blocker despite a lower level in responders compared to non-responders.

**LEVELS OF INFLAMMATORY SEROLOGIC BIOMARKERS IN HLA-B27 AND HLA-B15 POSITIVE PATIENTS WITH SPONDYLOARTHRITIS**

**Background:** A main challenge in spondyloarthritis (SpA) management was the availability of reliable biomarkers related with disease activity, or predicting joint damage and the response to treatment. Although erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) are currently used as biomarkers for disease activity, they lack sensitivity, specificity and reproducibility. With the understanding of SpA pathogenesis, additional biomarkers like metalloproteinase 3 (MMP-3), interleukin (IL)-1α, IL-6, lipopolysaccharide-binding protein (LBP), tumour necrosis factor α (TNFa), macrophage colony stimulating factor (M-CSF), interferon gamma (INF-g), IL-17 and IL-23, had been proposed.

**Objectives:** We aimed to evaluate the associations of MMP-3, IL-1α, IL-6, M-CSF, LBP, IL-17 and IL-23 levels in SpA patients positive for HLA-B27 or HLA-B15. **Methods:** 176 patients (100 men and 76 women) with SpA according to ASAS criteria were included in the study. HLA typing was performed by PCR using the Biorad® HLA-SSP ABDR plates. The levels of TNFa, IL-1α, IL-6, INF-g and IL-17 were measured by a cyrometric bead-array (CBA Flex Set) using a FACS Canto II Flow Cytometer®. Enzyme-linked immunosorbent assay (ELISA) was used to determine serum levels of IL-23, M-CSF and MMP-3. CRP and LBP levels were measured by chemiluminescence. Statistical analysis was made with SPSS v19. For comparison of quantitative variables with a normal distribution we used the Student’s t-test. Categorical variables were presented in frequency charts and percentages, and the Chi-squared test and Fisher’s exact test were used when necessary, for comparing groups. Two-tailed P-value <0.05 was considered statistically significant.

**Results:** Of the 178 patients, 70 were positive for HLA-B27, 34 for HLA-B15 and 74 had other HLA-B. According to ASAS classification criteria, 152 patients had axial SpA (axSpA) manifestations, 161 had peripheral SpA (pSpA) manifestations, and 148 patients had mixed axial and peripheral manifestations. Figure 1 shows the mean levels of inflammatory serologic biomarkers in these subgroups of patients.

**Conclusions:** High levels of IL-17 and IL-23 were associated with the presence of HLA-B27, which mainly correlates with an axial presentation of the disease as
SELECTIVE ACTIVATION OF AN AMPK-CREB-NF-κB-DEPENDENT PATHWAY BY CELECOXIB INDUCES VASCULOPROTECTIVE GENES AND MITIGATES AGAINST CARDIOVASCULAR RISK

Background: Although concern remains about the athero-thrombotic risk posed by COX-2-selective inhibitors (COXIBs), the recent PRECISION trial demonstrated non-inferiority of moderate dose celecoxib when compared to naproxen and ibuprofen with respect to cardiovascular safety, with fewer actual CV events recorded for celecoxib. Moreover, celecoxib proved significantly safer than either comparator in regard to gastrointestinal events1. Given the markedly different cardiovascular risk associated with celecoxib and rofecoxib, we investigated the hypothesis that, in addition to cyclo-oxygenase inhibition, celecoxib specifically activates COX-2-independent AMPK signalling to exert protective effects in the vascular endothelium. Objectives: To investigate COX-2-independent vasculoprotective signalling pathways activated by celecoxib in human endothelium. Methods: In vitro studies of celecoxib, rofecoxib, ibuprofen and naproxen were performed on human umbilical vein and human aortic endothelial cells (HUVEC and HAEC). Inhibition of signalling pathways was achieved using siRNA. The vascular effects of celecoxib in vivo were studied in C57Bl/6 mice fed celecoxib (1000 ppm) or control chow (48 hrs). Aortic tissue was snap-frozen and sections studied by immunohistochemical techniques. Results: At therapeutically relevant concentrations celecoxib (1–10 μM) protected the vasculoprotective protein heme oxygenase-1 (HO-1) in HUVEC and HAEC (EC) (p < 0.01). In contrast, rofecoxib and the commonly used non-selective NSAIDs ibuprofen and naproxen failed to induce HO-1. Celecoxib derivative 2,5-dimethyl-celecoxib (DMC), which lacks COX-2 inhibition, also upregulated HO-1, NSD1 and SIRT1 (p < 0.05). Similarly, celecoxib prevented the IL-1-mediated silencing of HO-1 induced by IL-1α-induced NF-κB (p < 0.05). These responses were not seen with ibuprofen or naproxen, while siRNA depletion of AMPKα2 abrogated celecoxib-mediated CREB and NFκB activation (p < 0.05). Acting via the same pathway, celecoxib induced additional cytoprotective genes including H-ferritin. In vivo, celecoxib similarly increased HO-1 and H-ferritin in murine aortic endothelium when compared to control-fed mice (p < 0.05). Functionally, celecoxib treatment inhibited TNFα-induced NFκB p65/SIRT1 phosphorylation by increasing AMPK activity. This attenuated VCAM-1 upregulation via induction of HO-1, as revealed by HO-1 siRNA (p < 0.05). Similarly, celecoxib prevented the IL-1 mediated increase of IL-6 mRNA (p < 0.01). These responses were not seen with ibuprofen or naproxen. Conclusions: Celecoxib induces anti-inflammatory, anti-oxidant proteins HO-1 and H-ferritin in human vascular endothelium via a novel AMPK-CREB-NFκB-dependent pathway. This mechanism may contribute to the important and marketed cardiovascular risk reduction between celecoxib and rofecoxib. Understanding mechanisms underlying NSAID heterogeneity may ultimately lead to the development of safer anti-inflammatory drugs.

LOW MOLECULAR WEIGHT BAFF SIGNALING INHIBITORS AMELIORATE IL-6, IL-10 AND IGG PRODUCTION IN VITRO AND IN VIVO MODELS OF AUTOIMMUNE DISEASES

K. Yoshimoto 1, K. Suzuki 1, K. Sugahara 2, T. Takeuchi 1, 1Keio University School of Medicine, Tokyo; 2Mitsubishi Tanabe Pharma Corporation, Yokohama, Japan

Background: In our previous study, we reported that soluble BAFF (sBAFF) robustly enhanced IL-6 production by peripheral monocytes of patients with primary Sjögren’s syndrome (pSS) and that the expression level of a BAFF receptor (BR3) was significantly elevated in pSS monocytes. We also found that the proportion of BR3-positive monocytes to total monocytes was positively and significantly correlated with the serum IgG level of pSS patients. Investigation of the interaction of monocytes and B cells showed that IgG production by B cells was enhanced by sBAFF-stimulated monocytes. These data collectively suggest that the elevated expression of BR3 on monocytes is involved in IgG overproduction by B cells. We then often observed IgG overproduction by B cells resulting in IgG overproduction. Interestingly, serum levels of an anti-dsDNA antibody, IL-6 and IL-10 were measured in patients with primary Sjögren’s syndrome and the expression level of a BAFF receptor (BR3) was significantly elevated in pSS monocytes. We also found that the proportion of BR3-positive monocytes to total monocytes was positively and significantly correlated with the serum IgG level of pSS patients. Investigation of the interaction of monocytes and B cells showed that IgG production by B cells was enhanced by sBAFF-stimulated monocytes. These data collectively suggest that the elevated expression of BR3 on monocytes is involved in IgG overproduction by B cells. We then often observed IgG overproduction by B cells resulting in IgG overproduction.

Objectives: To elucidate the mechanism of inhibitory activities of these compounds on BAFF signaling pathways, we measured production of IL-6 as well as IL-10 by monocytes in vitro with or without peripheral B cells in the presence of BIK-12 or BIK-13. The amounts of IL-6, IL-10 and IgG were measured by ELISA. BIK-13 was administered intraperitoneally to MRL/lpr mice, an animal model of autoimmune diseases, three times a week for 6 months. Serum levels of an anti-ds DNA antibody, IL-6 and IL-10 were measured by ELISA.

Methods: The study included 98 GCA patients (67% female) with a median (IQR) age 74.1 (67.3–78.8) years and a median (IQR) symptome duration time of 30 (20–90) days. Healthy blood donors (HDs, n=52, 61.5% female, median (IQR) age of 41.95 (20.64–63.1) years) served as controls. GCA complications studied were visual disturbances (including permanent loss of vision), relapses, peripheral artery disease and claudication. Levels of 27 serum analytes were measured using Lumine xMAP Technology. Interleukin-6 (IL-6) and serum amyloid A (SAA) levels were tested using ELISA and nephelometry, respectively.

Results: The highest, significantly elevated analytes in GCA vs. HDs were SAA (85-fold > HDs mean values), IL-23 (63-fold) and IL-6 (11-fold). IL-13, a-efetoprotein and MMP-2 were significantly increased in GCA, while levels of IL-2, IL-17A and TNFα were unchanged. PCA analysis revealed a signature analyte profile positioning towards the HD cluster. SAA, CRP, haptoglobin, ESR, thrombocyte # and matrix metalloproteinase-1 (MMP-1) all negatively associated with visual disturbances, confirming visual examination data. Age showed significant association to permanent visual loss, with older patients being more affected2. SAA, CRP and ESR at presentation were found to be predictive of relapsing disease, while MMP-2 negatively associated with relapse. VCAM-1, a-efetoprotein, MARCO and IL-27 were all negatively associated with peripheral artery involvement. MMP-2 and MARCO showed positive association with claudication, while IL-18 was negatively associated.

Conclusions: In our large study of untreated GCA patients we highlight the importance of using serological acute phase parameters, MMPs and other analytes for predicting complications.

by B cells through affecting monocytes. IL-6 and/or IL-10 may mediate the effect. Our findings strongly suggest that BAFF signaling via BR3 is a possible therapeutic target for drug discovery to treat pSS or other intractable autoimmune diseases which accompany hypergamaglobulinemia. Moreover, these compounds may provide novel tools to explore the pathological mechanism of the development of these autoimmune diseases.

THU0056 | FREE FATTY ACIDS PROMOTE INFLAMMATION VIA OSTEOSTRALLS AND OSTEOCLASTS FROM PATIENTS WITH RHEUMATOID ARTHRITIS OR OSTEOARTHRITIS

K. Frommer1, A. Schäffler2, U. Lange1, S. Rehart1, J. Steinmeyer2, M. Rickert2, U. Müller-Ladner1, E. Neumann1. 1. Dept. of Internal Medicine and Rheumatology, Kerckhoff-Klinik, Justus-Liebig-University of Giessen, Bad Nauheim; 2. Dept. of Internal Medicine III, Endocrinology, Diabetes, Metabolism, Justus-Liebig-University of Giessen, Giessen; 2. Dept. of Orthopaedics and Trauma Surgery, Agapelesis Markus Hospital, Frankfurt; 3. Dept. of Orthopaedics and Paediatric Surgery, University Hospital Giessen and Marburg, Giessen, Germany

Background: Various inflammatory cardiovascular and metabolic diseases such as atherosclerosis, coronary heart diseases and type 2 diabetes are associated with chronically elevated free fatty acid (FFA) levels. With inflammation being a factor in pathological bone loss, FFA may also be contributors to bone loss in context of these autoinflammatory diseases.

Objectives: To investigate whether FFA have an influence on osteoblasts and osteoclasts from patients with RA or OA, in a way that may alter bone degradation in these diseases.

Methods: Primary osteoblasts (OB) were isolated from cancellous bone of OA and RA patients undergoing knee joint surgery. Osteoclasts (OC) were differentiated from peripheral blood mononuclear cells (PBMC). OB and OC were stimulated with the saturated FFA palmitic acid (PA) and the unsaturated FFA linoleic acid (LA) (100 μM each). Immunofluorescence was used to quantify protein secretion, mRNA expression levels were quantified by real-time PCR. Mineralization activity was quantified using Alizarin Red S staining, differentiated OC were quantified by counting TRAP-positive multinuclear cells (>2 nuclei). Toll-like receptor (TLR) 4 and TLR2 were blocked by neutralizing antibodies.

Results: When stimulated with FFA, OB from RA and OA patients secreted higher amounts of the proinflammatory cytokine IL-6 (up to 9-fold) and the chemokines IL-8 (up to 221-fold), GRO-a (from below detection level to detectable levels) and MCP-1 (up to 16-fold). Differences in the degree of response were more dependent on the patient than the disease. RANKL and OPG, OB-secreted modulators of OC differentiation, as well as OB differentiation markers (e.g. osteonectin) were not influenced by FFA on mRNA or protein level. The effect of FFA on mineralization activity of OB varied between patients, yet overall there was a significant difference between FFA-treated and untreated OB. Expression of the two Wnt signaling molecules, axin-2 and b-catenin, was not altered. RA patients showed a 2-3 fold increase in TRAP secretion by a factor of 2–3 at d14. mRNA expression of various osteoclast activity markers (CLCN7, CTSK, TCIRG) was not altered.

Conclusions: Inflammation is promoted by FFA both via OB and OC from patients with RA or OA, thus possibly indirectly contributing to bone loss while no direct effect on OB/OC activity could be observed. In OB, these effects are probably mainly mediated by TLR4, while TLR2 and Wnt pathways do not play a role.

THU0057 | LIPID PROFILING OF PLASMA IN RHEUMATOID ARTHRITIS PATIENTS BY LIQUID CHROMATOGRAPHY–TANDEM MASS SPECTROMETRY

K. Murakami1, I. Murakami1, A. Ioan-Facsinay2, M. Giera3, M. Hashimoto4, K. Ohmura1, T. Mimori1. 1. Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 2. Department of Rheumatology, Center for Proteomics and Metabolomics, Leiden University Medical Center, Leiden, Netherlands; 3. Department of the Control for Rheumatic Diseases, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Background: Previously it has been described that lipid and lipid mediators are present in synovial fluid from patients with rheumatoid arthritis (RA). It is, however, currently unknown to what extent these lipid mediators are involved in disease pathophysiology.

Objectives: The aim of this study is to clarify which lipid mediators in plasma correlate with disease activity of RA.

Methods: We obtained blood from RA patients registered in the KURAMA (Kyoto University Rheumatoid Arthritis Management Alliance) cohort. None of the patients was treated with glucocorticoids or NSAIDs, both of which could affect lipid metabolism. Targeted lipids, using a LC–MS/MS (liquid chromatography–tandem mass spectrometry) platform was used for the identification of lipids present in the patients’ plasma. SDAI (simplified disease activity index) was examined in this cohort. Lipidomics profiling and disease status were combined. Data were statistically analyzed by Spearman’s rank correlation coefficient test or multivariate regression analysis.

Results: Twenty-six RA patients were enrolled; female ratio: 84%, mean age: 63.5, disease duration: 18.7 years and mean SDAI 5.28. In this group, patients age was significantly correlated with SDAI (p value <0.005, Spearman’s rho = -0.552). By LC-MS/MS analyses, 23 lipid components were identified and quantified. Multivariate regression analysis (Standard Least Squares) revealed that 19,20-diHDPA (Dihydroxydocosapentaenoic acid) and 14,15-diHETE (Dihydroxyeicosatetraenoic acid) significantly explained SDAI score independently of sex and age.

Among the composite measure for SDAI, the best correlated component with TJC (tender joint count) was LA (Linoleic acid, p=0.002, rho = -0.611), while with patient global analogue scale was 19,20-diHDP (p=0.032, rho = -0.440), and that with CRP was DHA (Docosahexaenoic acid, p=0.021, rho = -0.452). Additionally, principal component analysis was carried out. In the first principal component (PC1), absolute eigenvector values of ADA (Adrenic acid), ALA (Alpha-linolenic acid), DHA, EPA (Docosahexaenoic acid) and LA are more than 0.25, among which they are strongly correlated with PC1 (p = 0.001, rho = -0.902). PC1 positively and significantly explained TJC count independent of sex and age.

Conclusions: Since 19, 20-diHDP (metabolized from DHA) and 14,15-diHETE (from EPA, eicosapentaenoic acid) are both generated by cytochrome P450-catalyzed epoxidation followed by conversion to the vicinal diols by epoxide hydrase, such kind of enzymes might be key molecules connecting lipid metabolism and RA. Although a replication study is inevitable, a certain kinds of lipid and lipid mediator profiles may be associated with disease activity, especially analgesic descriptors such as tender joint count.

THU0058 | S100A11 PROTEIN IS UP-REGULATED IN PATIENTS WITH IDIOPTIC INFLAMMATORY MYOPATHIES AND IS ASSOCIATED WITH DISEASE ACTIVITY

L. Andres Cerezo1, H. Hulejova1, B. Šumová1, T. Lennerova1, M. Klein1, H.F. Mann1, J. Zámečník2, K. Pavelka1, J. Vencovsky1, L. Šenolt1. 1. Department of Rheumatology, 1st Faculty of Medicine, Charles University Prague, Institute of Rheumatology; 2. Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University Prague, University Hospital Motol, Prague, Czech Republic

Background: S100A11 (calgazzin) is a member of the S100 protein family that participates in regulating number of biologic functions and is associated with oncogenesis and inflammation. Recent data suggest involvement of S100A11 in myocardial damage.

Objectives: The aim of our study was to analyze the expression of S100A11 in patients with idiopathic inflammatory myopathies (IMMs) and its potential association with disease activity parameters and IMMs-related clinical features.

Methods: Immunohistochemistry in patients with polymyositis/dermatomyositis (PM/DM, n=5/6) and control individuals with myasthenia gravis (MG, n=5). S100A11 in plasma was measured by ELISA (Biovendor) in 112 patients with IMMs (PM, n=41; DM, n=41; and cancer associated myositis (CAM), n=30) and in 42 healthy controls (HC). Patients with PM/DM fulfilled Bohan and Peter diagnostic criteria and CAM was defined as cancer occurring within 3 years of the diagnosis of myositis. Clinical disease activity was assessed by myositis disease activity (MDACT), physician and patient’s global activity using visual analogue scales (VAS), manual muscle testing (MMT) and health assessment questionnaire (HAQ); Muscle enzymes CK, LD, ALT and CRP were measured by routine laboratory techniques. Autoantibodies were detected by immunoprecipitation.
Results: S100A11 protein was up-regulated in the muscle from patients with IIMs compared to MG. In PM/DM patients, S100A11 was accumulated in the muscle of most fibers. Only some mononuclear infiltrate cells showed S100A11 positivity. In patients with MG, S100A11 was detected on the sarcolemma only. Moreover, S100A11 staining was observed on the sarcolemma of all muscle fibers in S100A11-positive patients.

Background: S100A11 has been described as a marker for skeletal muscle inflammation, regeneration, and hypertrophy. However, the role of S100A11 in IIMs is not well understood. In this study, we aimed to investigate the expression of S100A11 in various muscle diseases and its potential association with disease activity.

Methods: Muscle biopsies were obtained from patients with IIMs and healthy controls. The muscle tissue was immunostained with anti-S100A11 antibody and counterstained with hematoxylin.

Results: S100A11 was significantly increased in the muscle biopsies of patients with IIMs compared to controls. The intensity of S100A11 staining was positively correlated with muscle strength and fiber regeneration.

Conclusions: S100A11 is a useful marker for muscle inflammation in IIMs. Its expression can be used as a clinical indicator for disease activity and muscle regeneration.

Disclosure of Interest: None declared.

THU0059
ONCOSTATIN M INDUCES INFLAMMATION AND DIFFERENTIALLY REGULATES TNF-ALPHA-INDUCED PRO-INFLAMMATORY MECHANISMS AND NOTCH SIGNALLING IN THE RA JOINT

1Molecular Rheumatology, Trinity Biomedical Sciences Institute, Trinity College Dublin; 2Centre for Arthritis and Rheumatic Diseases, St Vincent's University Hospital, University College Dublin, Dublin, Ireland

Background: Oncostatin M (OSM) is a pleiotropic cytokine, highly expressed in the RA joint that displays both agonistic and antagonistic effects depending on the inflammatory microenvironment. This study examines the effect of OSM on inflammation, the Notch-1 signalling pathway which plays a critical role in vascular development and angiogenesis and finally on TNFα-induced pro-inflammatory mechanisms in Rheumatoid Arthritis.

Objectives: To examine the effect of OSM on cytokine/chemokine production, angiogenesis and the Notch-1 signalling pathway in synovial fibroblasts and endothelial cells and whether OSM potentiates the effects of TNFα-induced pro-inflammatory effects.

Methods: Primary RA synovial fibroblasts (RASF) isolated from RA synovial biopsies obtained at time of knee arthroscopy and human dermal microvascular endothelial cells (HMVEC) were grown to confluence. RASFC and HMVEC were cultured with OSM (10ng/ml) alone or in combination with increasing concentrations of TNFα (0.01–1ng/ml). IL-6, IL-8, RANTES, GROα and MCP-1 cytokines/chemokines were quantified in culture supernatants by ELISA. Notch-1, its ligands Delta-like-ligand 4 (DLL-4) and Jagged-1 (Jag-1) and downstream transcriptional repressors – Hey-1 and Hey-2 were quantified by Real-time PCR. Finally, Notch-1, its ligands Delta-like-ligand 4 (DLL-4) and Jagged-1 (Jag-1) and downstream transcriptional repressors – Hey-1 and Hey-2 were quantified by Real-time PCR.

Results: OSM alone significantly induced IL-6 and MCP-1 while inhibiting IL-8 and GROα in RASF and HMVEC culture supernatants, compared to basal control. OSM alone induced RANTES expression in HMVEC with little effect observed for RASF. OSM potentiated the effect of increasing concentrations of TNFα on IL-6 and MCP-1 secretion from RASF and HMVEC. Conversely OSM significantly inhibited TNFα-induced IL-8 and GROα secretion from both RASF and HMVEC. Interestingly, OSM significantly inhibited TNFα-induced RANTES expression in HMVEC yet conversely potentiated this effect in RASF. At a functional level, OSM alone induced RASFC invasion whereas matrigel tube formation and Transwell invasions assays respectively, and VEGF in cell lysates quantified by Real-time PCR. Finally, Notch-1, its ligands Delta-like-ligand 4 (DLL-4) and Jagged-1 (Jag-1) and downstream transcriptional repressors – Hey-1 and Hey-2 were quantified by Real-time PCR.

Discussion: Our data show that both IL-17A and IL-17F enhance in vitro osteogenic differentiation and bone formation from hPDSCs. The source of these cytokines has not been established but is likely to involve entheseal resident γδ-T cells. We propose that following their release, IL-17A and IL-17F drive pathological bone formation resulting in entheseopathies at the enthesis/periostium interface.

Conclusions: These data show that both IL-17A and IL-17F enhance in vitro osteogenic differentiation and bone formation from hPDSCs. The source of these cytokines has not been established but is likely to involve entheseal resident γδ-T cells. We propose that following their release, IL-17A and IL-17F drive pathological bone formation resulting in entheseopathies at the enthesis/periostium interface.

Second, human osteoarthritic (OA) patients who underwent total knee arthroplasty. First passage human OA OB were treated either with RvD1 (0.1 – 1 μM) alone, or with 20 nM VitD3 with or without RvD1 (0.1 - 1 μM), for 48 hours. Cell viability was evaluated with the MTS test. Alkaline phosphatase (PAP) activity and osteocalcin (OCN) release was determined by colorimetric reaction and ELISA, respectively.

**Results:** In RAW264.7 cells, our results clearly show that RvD1 strongly reduces OC recruitment and activation as indicated by the inhibition of TRAP and cathepsin K expression as well as TNF-α, IL-1β, IL-6, PGE2 and NO release, as well as the concurrent enhancement of IL-10 levels. Besides, RvD1 decreases bone resorption through the inhibition of plots formation in hydroxyapatite matrix. In human OA OB, RvD1 partially decreases VitD3-induced PAP activity, while it maintains OCN expression at control levels.

**Conclusions:** Our in vitro results clearly show that RvD1 may play an important role in the regulation of bone metabolism. Additionally to our previous data, our findings suggest that RvD1 may offer a novel and original perspective to make a real contribution to musculoskeletal and bone diseases therapy.

**NOVEL ANIMAL MODEL OF AROMATASE INHIBITOR-INDUCED ARTHRALGIA SUGGESTS AN ESTROGEN-INDEPENDENT INFLAMMATORY MECHANISM**

1Rheumatology and Immunology; 2Department of Neuroscience; 3Small Animal Imaging Core; 4Medical Oncology, The Ohio State University Wexner Medical Center, Columbus, United States

**Background:** Aromatase Inhibitors (Ais) block physiological estrogen production in peripheral tissues and significantly improve overall survival rates of post-menopausal, hormone receptor-positive breast cancer patients by reducing tumor recurrences. However, half of patients taking these drugs develop aromatase inhibitor induced arthralgia (AIA), which is characterized by severe pain and inflammation in various joints. Since AIA leads to suspension of therapy in 20% of patients, reducing incidence may provide sustained AI treatment and enhanced long-term survival.

**Objectives:** In order to establish a better understanding of the inflammatory mechanism and to create a platform that can be used to explore interventional strategies, our objective in this study was to design a novel animal model of AIA.

**Methods:** Female BALB/c-Tg (Nf-β-RE-luc)-Xen mice, which have a firefly luciferase cDNA reporter gene under the regulation of 3 β responsive binding sites, were oophorectomized and treated with AI (letrozole) by daily subcutaneous injections. Control groups included oophorectomized mice receiving vehicle control injections and non-oophorectomized mice treated with AI. Bioluminescent imaging of hind limbs was performed after 3 weeks on the in vivo imaging system (IVIS) to measure NF-κB activation. At 5 weeks, knee joints and surrounding tissue were imaged on the BioSpec 94/30 micro-MRI. Legs were collected for histopathological analysis and serum cytokine levels were measured at experimental endpoint.

**Results:** Bioluminescent imaging showed significantly enhanced NF-κB activation in the hind limbs compared to oophorectomized controls receiving vehicle treatment. Analysis of knee joints and legs by MRI imaging showed enhanced signal detection in the joint space and surrounding tissue following AI treatment. Surprisingly, enhanced MRI detection was also demonstrated in non-oophorectomized mice that were treated with AI. Histopathological analysis further demonstrated mild inflammation in the synovial tissue and joint damage in mice treated receiving AI both with and without oophorectomy. Moreover, tenosynovitis and inflammatory muscle tissue infiltrates were detected in AI-treated mice and serum cytokine levels of IL-2, IL-4, IL-6, and CXCL1 were significantly elevated.

**Conclusions:** Collectively, these data establish a novel mouse model of AIA and suggest that the pathogenesis of AI-induced inflammation is estrogen-independent. Future studies will be directed into the characterization of this inflammatory mechanism to provide insight into potential therapeutic strategies directed at mitigating this adverse inflammatory burden.

**IL-1 FAMILY CYTOKINES AND RECEPTORS IN IGG4-RELATED DISEASE**

1Clinical and Experimental Medicine, Clinical Immunology Unit, University of Pisa, pisa; 2Institute of Protein Biochemistry, National Research Council, Naples; 3Clinical and Experimental Medicine, University of Pisa, Clinical Immunology Unit, University of Pisa, pisa, Italy

**Background:** IgG4-related disease (IgG4-RD) is a fibroinflammatory condition that can affect almost any organ, characterized by lymphoplasmacytoid infiltrate, obliteratoric phlebitis and storiform fibrosis often associated with eosinophilia and increased levels of IgG4. Cytotoxic CD4 T cells producing IL-1β [D1], TGFB1 and IFN-gare detectable in peripheral blood of patients and high IL-18 expression has been found in affected organs.

**Objectives:** To evaluate the role of IL-1 family cytokines in IgG4-RD, by analyzing cytokines and receptors in sera.

**Methods:** Nine patients fulfilling the proposed criteria (Umehara, 2012) for the diagnosis of IgG4-RD were recruited. Cytokines of the IL-1 family (IL-1α, IL-1β, IL-33, IL-18), soluble receptors (sIL-1R1, sIL-1R2, sIL-1R3, sIL-1R4) and antagonists (IL-1Ra, IL-18BP) were measured in sera by multiaxial ELISA assay. Free IL-1β was calculated using the law of mass action.

**Results:** Most patients had a multiorgan disease; retroperitoneum, salivary glands, pancreas and lymph nodes were most frequently affected. IL-18 (p=0.007) and free IL-1β (p<0.0001), sIL-1R1 (p=0.0005), sIL-1R2 (p=0.0013), and sIL-1R4 (p=0.0006) were significantly increased in IgG4-RD sera compared with healthy controls.

**Conclusions:** In IgG4-RD patients, at variance with other autoimmune or autoinflammatory conditions, the increase in IL-18 levels is not counterbalanced by IL-18BP, leading to high levels of free IL-1β. The free cytokine may affect T cell subset balance and induce IFN-g production. The parallel increase of sIL-1R1 and sIL-1R2 suggests an efficient dampening of inflammatory IL-1βsignaling at the tissue level, while high levels of sIL-1R4 may be associated with vascular remodeling and fibrosis, as observed in animal models of obesity and in human cardiovascular disorders.

**ADAM-10 AS A TICLOZUMAB TREATMENT PREDICTIVE FACTOR IN RHEUMATOID ARTHRITIS**

Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan

**Background:** A disintegrin and metalloproteinases (ADAMs) are a family of transmembrane and secreted proteins. ADAM-10 has been reported to be the enzyme responsible for the release of a number of chemokines and cytokine receptors. We have shown that ADAM-10 is overexpressed on rheumatoid arthritis (RA) synovial tissue endothelial cells (ECs) and lining cells compared with osteoarthritides and normal tissues. We also demonstrated that ADAM-10 mediates EC migration and tube formation.

**Objectives:** In order to demonstrate for ADAM-10 in clinical side, we focused on ADAM-10 as predictive factor for treatment with biologics in RA.

**Methods:** The serum was collected from patients before the initial treatment with biological therapies. Fifteen patients were treated with adalimumab (ADA), and 20 patients were treated with tocilizumab (TCZ). ADAM-10 and fractalkine/OCX/CL1 were measured by enzyme-linked immunosorbent assay at 0, 12, 24 and 54 weeks. Clinical disease activity was evaluated by clinical disease activity index (CDAI). Following biological therapies, we defined biologic-responders as patients whose DAS28 scores decreased by more than 1.2 at 24 weeks. ADAM-10 baseline was also compared between responders and nonresponders at 24 weeks.

**Results:** There were no significant differences were observed in the mean age, gender ratio, dosages of prednisolone and methotrexate between ADA and TCZ groups. In ADA group, baseline DAS28 for the 15 patients was 4.8±0.3 (2.5–7.2).
On the other hands, baseline DAS28 for the 20 patients was 4.8±0.3 (2.5–6.8) in TCZ group. There were no differences between ADA and TCZ groups. RA patients with an insufficient response to ADA or TCZ showed highly significant improvement of DAS28 after 12 weeks (2.9±0.3 and 2.2±0.4, respectively), and 24 weeks (2.5±0.4 to 2.2±0.2, respectively). ADAM-10 highly correlates with cDAI, and serum ADAM-10 levels in patients with TCZ were significantly higher after treatment with ADA despite decrease of disease activity of RA. On the other hand, serum ADAM-10 levels in patients who were treated with TCZ were significantly diminished following successful treatment and clinical improvement (baseline 408±88 pg/ml and 54 weeks 138±51 pg/ml, p<0.05). Univariate logistic regression of serum activity of DAS28 (Esr) baseline of cDAI and ADAM-10 were selected as significant variables for improvement of DAS28 (Esr) at 24 weeks. Multiple regression analysis showed that ADAM-10 was only identified as an independent predictive variable for improvement of DAS28 (ESR) at 24 weeks. GMR of ADAM-10 baseline in TCZ responder was significantly higher than TCZ nonresponders at 24 weeks (620±134 pg/ml and 105±25 pg/ml, respectively, p<0.05).

Conclusions: This study indicates that ADAM-10 is correlated with RA disease activity, and is higher in TCZ responders. These results suggest that ADAM-10 may be a predictor of treatment effectiveness for RA with TCZ.

THU0065 CYTOKINES AND LIPOCALIN-2 IN PREGNANT WOMEN WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

T.T. Pedersen,1 M.H. Fenstad2, T.S. Moksnes1, M. Wallenius1, T.H. Fio2, M. Hauk3,1 Norwegian National Advisory Unit on Pregnancy and Rheumatic diseases;2 Dep. of Immunology and Transfusion Medicine, St. Olavs Hospital;3 Centre of Molecular Inflammation Research and Dep. of Cancer Research and Molecular Medicine, NTNU, Trondheim, Norway

Background: Rheumatoid arthritis (RA), and especially seronegative RA, is often ameliorated by pregnancy, while systemic lupus erythematosus (SLE) is prone to flare and associated with pregnancy complications. Cytokines and chemokines are of great importance for immune processes during pregnancy. The inflammatory marker Lipocalin-2 (LCN2) has become increasingly relevant as a potential clinical biomarker of rheumatic diseases (1). LCN2 is produced in the maternal-fetal interface during normal pregnancies and correlates with the presence and severity of pre eclampsia (2).

Objectives: To obtain a better understanding of immune regulation and the disparate immune responses in pregnant women with RA and SLE. In this study, we analyzed levels of multiple cytokines, chemokines and LCN2 in women with seropositive RA, seronegative RA, SLE and healthy controls during pregnancy and postpartum.

Methods: The Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases collect serum samples in a biobank from women with inflammatory rheumatic diseases before pregnancy, during pregnancy week 10–12, week 23–25, week 30–32 and 6 weeks, 6 months and 12 months postpartum. Control serum samples were collected from healthy pregnant women at matching time-points. We analyzed serum cytokines and chemokines levels using a complex assay. A sandwich ELISA was used to measure LCN2. In this pilot study we included pregnant women with SLE (n=4), seropositive RA (n=4), seronegative RA (n=2) and healthy pregnant controls (n=4). The total cohort consists so far of 18 pregnant women with SLE and 23 pregnant women with RA.

Results: We observed lower LCN2 levels during pregnancy in SLE patients, compared to controls and RA patients. LCN2 levels in seropositive RA patients and controls were found to be comparable during pregnancy, whereas pregnant women with seronegative RA showed higher LCN2 levels. Levels of IFNγ, IL-6 and IL-10 were higher in SLE than in RA patients during the course of pregnancy. IL-17 was slightly higher only in seropositive RA patients compared to controls. TNFα was slightly higher in both SLE and RA patients compared to controls, levels of anti-inflammatory IL-10 were very low or undetectable in all groups.

Conclusions: We found interesting differences in cytokine, chemokine and LCN2 levels during pregnancy in women with SLE, seropositive RA and seronegative RA. The results need confirmation in the total cohort and will be further explored for a better understanding of the disparate immune modulation of RA and SLE during pregnancy.

THU0066 OSTEOCLAST DifferENTIATION gENE EXPRESSION PROFILING REVEALS CCL4 MEDIATES RANKL-INDUCED OSTEOCLAST MIGRATION

W. Xuan1, X. Feng2, Y. Shi1, F. Wang3, M. Zhang3, W. Tan3,1 Rheumatology;2 Traditional Chinese Medicine;3 Department of Cardiology, The First Affiliated Hospital of Nanjing Medical University, China, nanjing, China

Background: The migration of osteoclast from circulation and bone marrow into bone surface has suggested as a novel therapeutic point for bone erosion in RA. Objectives: We explored the mechanisms involved in osteoclast migration.

Methods: Gene expression for osteoclast migration was identified by microarray analysis and validated by Real-time PCR during differentiation of bone marrow-derived macrophages (BMMs) into osteoclast (OCs). RANKL induced osteoclast precur- sor cell line RAW264.7 migration and invasion in the presence and absence of anti-CCL4 antibody was measured in vitro. Intracellular signaling pathway was as- 

essed by Western blotting. Osteoclast formation was identified by TRAP staining. Results: A panel of 11 chemokines signal was significant increase in osteoclast differentiation of BMMs by Microarray. High expression of CCL4 was validated in primary BMMs and RAW264.7 cell line during differentiated into OCs. RANKL induced osteoclast precur- sor cell line RAW264.7 migration and invasion was decreased upon addition of anti-CCL4 antibody. OCs formation and OCs related genes expression were not affected by CCL4 inhibition. Neutralization of CCL4 promoted the PI13K phosphorylation at 45 to 60min after RANKL stimulation in RAW264.7.

Conclusions: CCL4 regulates RANKL-induced OCs migration, suggesting that CCL4 inhibition could be bone protective in RA.

THU0067 NLRP3 INFLAMMASOME ACTIVITY IN MONOCYTES IS REGULATED BY 12/15-LOX-OPXENASE

Y. Kusche, K. Barczyk-Kahlert, J. Roth, Institut Der Immunologie, Münster, Germany

Background: Activation of the NLRP3 inflammasome is a major inflammatory pathway in monocytes in response to various exogenous and endogenous stimuli. However, negative regulation of inflammasome activity is not well understood. Glucocorticoids (GC) are drugs of choice for the treatment of various inflammatory diseases. Recently, we could show that treatment of monocytes with GC leads to re-programming towards a specific population involved in resolution of inflammation. Gene analysis has shown up-regulated expression of 12/15-lipoxygenase (12/15-LOX) in GC and LPS/GC-treated monocytes. 12-15-LOX reacts with polyunsaturated fatty-acids to generate anti-inflammatory lipid mediators, which contribute to resolution of inflammation.

Objectives: The aim of our study was to determine the contribution of 12/15-LOX on the inflammatory response on murine monocytes.

Methods: Bone marrow-derived monocytes were isolated from wild-type (wt) C57BL/6 and 12/15-LOX-/- mice and stimulated with GC and/or LPS as well as various inhibitors or stimulants. Gene expression was analyzed using qRT-PCR. Protein expression was examined by Western Blot. Flow-Cytometry and ELISA. Toll-like response was analyzed by co-culture of stimulated monocytes with allogenic T-cells.

Results: 12/15-LOX-/- monocytes showed slightly higher secretion of IL-1α as compared to wt cells after LPS stimulation. The differences between wt and 12/15-LOX-/- were much more pronounced when monocytes were additionally exposed to ATP. LPS treatment markedly enhanced expression of pro-IL-1β in 12/15-LOX-/- monocytes. No differences could be observed between wt and 12/15-LOX-/- monocytes in secretion of other proinflammatory mediators as well as the expression of inflammasome components. However, expression of cleaved caspase-11 was up-regulated in 12/15-LOX-/- monocytes exposed to LPS. Additionally, inhibition of caspase-1, caspase-1 and 5-LOX significantly reduced the high secretion of IL-1β in 12/15-LOX-/- monocytes. Interestingly, 12/15-LOX-/- rather than wt monocytes stimulated with LPS led to enhanced T-cell proliferation.
Conclusions: Our results demonstrate that 12/15-LOX plays a regulatory role during inflammatory immune response by counteracting the NLRP3 inflamma-
some activity through down-regulation of caspase-11 and 5-LOX activity. Thus, we identified a novel negative regulatory pathway of inflammasome activity.

Rheumatoid arthritis - prognosis, predictors and outcome

THUO0689 HOW MANY RHEUMATOID ARTHRITIS PATIENTS IN REMISSION EXPERIENCE PAIN? WHAT TYPES AND WITH WHAT FREQUENCY WERE PAINKILLERS RECEIVED? IS REACHING REMISSION A REALISTIC GOAL?

E. Torikai, M. Suzuki, Y. Matsuyama. Orthopaedic Surgery, Hamamatsu University School of Medicine, Hamamatsu, Japan

Background: The primary treatment goal in rheumatoid arthritis (RA) patients is to reach remission. Earlier diagnosis, advancements in disease-modifying antirheumatic drugs, and improved treatment strategies have enabled increasing numbers of RA patients to achieve remission. However, the definition of remission involves the fulfillment of specific criteria, which include a number of swollen and tender joints, the erythrocyte sedimentation rate (ESR), and the visual analog scale of pain (VAS pain).

Some patients with RA in remission wished to take painkillers because they experienced pain and physical limitations in their daily life or at work. Is reaching remission a realistic goal?

Objectives: To evaluate VAS pain and patient's global assessment (PGA) in those with RA in remission, and to determine the types and frequency of which painkillers were received.

Methods: In a study of 554 RA patients with a definite RA diagnosis according to 1987 ACR criteria, we enrolled 235 patients (82% females). All patients had DAS28-ESR <2.6, defined as clinical remission, and had no acute pain as a result of operation or trauma. The mean age and disease activity were 53.6 years and 2.67, respectively. Seventy-one percent of patients were treated with MTX, 30.2% with glucocorticoids, and 58.4% with a biological agent. We evaluated VAS pain and PGA and investigated why patients experienced dissatisfaction with VAS pain and PGA. Moreover, we elucidated how many patients used painkillers and what types of painkillers were used.

Results: The mean values of clinical and laboratory data were described as follows: 28 swollen joints, 0.69; 28 tender joints, 1.56; RF, 157 IU/mL; C-reactive protein, 0.14 mg/dL; ESR, 19 mm/h; and health assessment questionnaire disability index score, 0.618.

Steinblocker stages (I/II/III/IV) were (165/61/18/0), respectively and Steinblocker classes (I/II/III/IV) were (159/68/12/0), respectively. The mean VAS pain was 1.81.

Thirty-five (14.9%) of 235 patients had VAS pain >3 (Fig. 1). The mean PGA was 1.54. Seventeen patients (7.2%) reported PGA >3 (Fig. 2). Reasons for VAS pain or PGA of >3 were: musculoskeletal pain (48.6%), neuropathic pain (23.1%), psychological reasons (9.3%), and other (19%). Thirty-one patients (13.2%) were treated with painkillers such as NSAIDs (46.2%), acetaminophen (22.5%), pregabalin (16.6%), tramadol (4.1%), and other (86%).

The mean values for VAS pain and PGA were improved after using painkillers by 0.73 and 0.36, respectively. There was a significant difference in the improvement rate of VAS pain and PGA between pre-use and post-use of pain-killer (Fig. 3).

Conclusions: VAS pain and PGA are important for understanding the patients' functional disabilities and problems. We should attend to patients' demands and make an informed decision to form a realistic goal for RA treatment. Given that VAS pain and PGA were improved because of the use of painkillers in the current study, we suggest that the ability to appropriately prescribe painkillers is an important method with which to satisfy RA patients in remission.

THUO070 TREAT-TO-TARGET IN RA: WHAT LEVEL OF TREATMENT RESPONSE IS NECESSARY BY 3 MONTHS IN ORDER TO ACHIEVE THE TREATMENT TARGET BY 6 MONTHS? RESULTS FROM A REAL LIFE STUDY

1Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; 2Division of Rheumatology, Department of Internal Medicine 3, Medical University of Vienna, Vienna, Austria

Background: When initiating therapy with disease-modifying anti-rheumatic drugs...
(DMARDs) in patients with rheumatoid arthritis (RA); treatment adoptions are recommended if no improvement in disease activity is seen within 3 months, or if the treatment target has not been reached by 6 months. A pooled analyses from several pivotal RCTs showed that RA patients who did not achieve a minor treatment response by 3 months were unlikely to reach the treatment target by 6 months.1

**Objectives:** To examine what level of treatment response is needed after 3 months of therapy in order to achieve the treatment target of remission (REM) or low disease activity (LDA) by 6 months in a routine clinical setting.

**Methods:** Data were provided by NOR-DMARD, a prospective, multicentre, observational study. We selected RA-patients enrolled between December 2000 and November 2012, who were biological DMARD-naive and had moderate or high disease activity (MDA or HDA, respectively) according to the Simplified Disease Activity Index (SDAI) when initiating therapy. All analyses were performed for the total group of included patients (n=1610), as well as for the following sub-groups: disease duration over (n=895) or under (n=681) 12 months, baseline SDAI MDA (n=825) or HDA (n=785), DMARD-naive patients starting methotrexate (MTX) (n=537) and patients starting tumour necrosis factor inhibitor (TNFi) (n=248). We used a diagnostic test approach, created receiver operating characteristic curves and generated sensitivities, specificities and likelihood ratios (LRs) for all improvement cut-points (0–100%) at the 3-month visit. Furthermore, we tested the ability of established response criteria (SDAI 50/70/85/90 response) at 3 months to predict the desired target of SDAI remission or SDAI LDA at 6 months.

**Results:** At inclusion median (IQR) disease duration was 2 (0.2–8.8) years and mean (SD) SDAI was 28.3 (12.8). At 6 months 46.8% of all patients had achieved LDA and 10.8% had reached remission. Not achieving a minor treatment response (SDAI 50% response) by 3 months was associated with decreased probability of reaching remission at 6 months (LR-0.27), but gave little prognostic information regarding the probability of reaching LDA (LR-0.49). Patients with HDA at baseline who did not achieve at least 50% improvement in disease activity by 3 months had very low probability of reaching the treatment target by 6 months (LR-0.15 for remission and LR-0.30 for LDA). SDAI 85% response at 3 months was predictive of reaching the treatment target at 6 months (LR+ 6.56 for remission and LR+ of 6.45 for LDA). For the total group of patients, a reduction in SDAI of 60.2% was needed at 3 months to predict LDA at 6 months with 80% specificity, while 69.2% improvement was necessary to predict remission.

**SDAI response at 3 months and probability of achieving the treatment target by 6 months:**

**Conclusions:** These results from a routine clinical setting confirm results from RCTs demonstrating a predictive association between treatment response at 3 months and achievement of the treatment target by 6 months in RA-patients. Assessments at 3 months can inform clinicians to continue or adjust ongoing DMARD-therapy in a treat-to-target strategy aiming for remission or LDA by 6 months.

RISK OF REVISION, PROSTHETIC JOINT INFECTION AND DEATH FOLLOWING TOTAL HIP OR KNEE ARTHROPLASTY IN PATIENTS WITH RHEUMATOID ARTHRITIS – A NATIONALWIDE COHORT STUDY FROM DENMARK

L. Dreyer

Methods: An electronic search was performed by two independent reviewers.

Objectives: Identifying and targeting potential factors influencing nonadherence is therefore crucial in optimising patient management. Adherence was found to be negatively associated with socioeconomic status, health literacy, and beliefs/perceptions/knowledge of the disease and treatment.

Background: Studies have shown that rheumatoid arthritis (RA) patients are at increased risk of prosthetic joint infection (PJI) but with non-uniform results for mortality risk, following total hip and knee arthroplasty (THA and TKA, respectively). The impact of biological DMARD (bDMARD) treatment on the risk of these outcomes is unknown.

Objectives: To investigate the risk of revision, PJI and death following THA and TKA in RA compared with osteoarthritis (OA) patients and 2) RA patients treated with bDMARDs compared with those not.

Methods: Register-based cohort study linking the National Patient Register, DANBIO, Danish Hip Arthroplasty Register and Danish Knee Arthroplasty Register. Follow-up: from date of THA/TKA to date of any of the outcomes, to 10 years of follow-up or end of 2014, whichever came first.

Statistics: Fine-Gray competing risks analyses to calculate confounder adjusted sub-Hazard Ratios (aSHR) with 95% confidence intervals (95% CI) for revision and PJI; Cox proportional hazard models to calculate aHR for risk of death.

Results: We identified 3913 RA and 120 499 OA patients. In DANBIO, 360 bDMARD and 1586 not-bDMARD treated RA patients were eligible for analysis. See Table for results.

Conclusions: We report an increased risk of death and PJI but a lower risk of revision in patients with RA compared with OA following THA and TKA. In RA patients, prednisolone, but not bDMARD treatment within the year prior and/or following THA and TKA was associated with an increased risk of death.

FACTORS ASSOCIATED WITH TREATMENT ADHERENCE IN RHEUMATOID ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

E.T. Goh 1, A.J.X. Soo 1, J. Galloway 2, S. Norton 2, E. Nikgazavari 2, 1 University College London, 2King’s College London, London, United Kingdom

Background: Nonadherence to treatment in rheumatoid arthritis (RA) has been shown to negatively impact on treat to target goals and disease outcomes. Identifying and targeting potential factors influencing nonadherence is therefore crucial in optimising patient management.

Objectives: To determine factors associated with nonadherence in patients with RA.

Methods: An electronic search was performed by two independent reviewers using MEDLINE and focusing on articles published from inception to January 2017. The search strategy combined the thesaurus (MeSH) and expanded keyword searches of two concepts: RA and treatment adherence. Inclusion criteria included observational studies and clinical trials examining potential factors associated with nonadherence. Exclusion criteria included articles not in English or without online access and those with a focus on forms of therapy other than medication. Agreement between raters at the screening stage was high (97%, kappa=.87).

Results: The primary search yielded 1411 papers, from which 75 were eventually identified as suitable for full review (Figure). Of the 75 papers, 65 were based on observational studies and 10 on clinical trials. Factors associated with nonadherence were broadly categorized into patient-related factors (socio-demographic factors, patient perceptions [beliefs/knowledge/attitudes]), disease-related factors (disease duration/severity, comorbidities, functional disability) and treatment-related factors (drug type/duration/ regimen/complexity, combination therapy). The majority (70% of all included studies) of studies reported significant associations between patient-driven factors and nonadherence.

Conclusions: Patient-related factors including personal perceptions were among key contributors to nonadherence to medication in RA patients. This highlights the need for addressing patient-driven perceptions, along with disease and treatment acceptance.

BODY MASS INDEX IN EARLY RHEUMATOID ARTHRITIS IN UNDERWEIGHT PATIENTS IS ASSOCIATED WITH MORE PROGRESSION OF EROSIONS OVER 15 YEARS AND IN OBESE PATIENTS WITH LESS PROGRESSION OF JOINT SPACE NARROWING

S. Ajeganova 1, K. Forslind2, B. Svensson2, I. Hafström 1. 1Department of Medicine Huddinge, Karolinska Institutet, Stockholm; 2Department of Clinical Sciences, Lund University, Lund, Sweden

Background: Previous short-term follow-up studies and subanalyses of clinical trials in rheumatoid arthritis (RA) have suggested that low body mass index (BMI) is associated with more radiographic joint progression and high BMI with less. The effect of BMI on progression of erosion score (ES) and joint space narrowing (JSN) could be different in underweight and obese patients.

Objectives: To identify the association between BMI in early RA with radiographic damage during 15 years; to examine if known predictors of a worse radiographic outcome could explain differential radiographic outcome in low and high BMI groups.

Methods: Four hundred and seventy-three patients from the BARFOT study included from 1992 to 1999 who performed their 15-year assessment were studied. The patients were assessed at inclusion and after 1, 2, 5, 8 and 15 years. The groups were defined by BMI (kg/m²) at inclusion: BMI <20, (n=27), BMI 20–25 (n=210), BMI 25–30 (n=179), and BMI >30 (n=57). X-rays of hands and feet were taken by the Sharp-van der Heijde scoring method (SHS). Linear mixed models with SHS, ESR, CRP, SJC and TJC as outcome, and BMI at inclusion as predictor was used, adjusted for age, sex, initial treatment, ACPA and smoking.

Results: At baseline, total score of SHS, ES and JSN did not differ between BMI groups. There were more women and smokers in BMI<20 group and older patients in BMI>30 group. The baseline disease characteristics were similar in the BMI groups.

For the patients with BMI<20 at inclusion, BMI was associated with a higher predicted SHS progression during follow-up, effect size 5.11 (95% CI 1.72 to 15.15) p=0.005, while for the patients with BMI≥20 at inclusion, BMI was associated with lower SHS, effect size 0.92 (0.86 to 0.99) p=0.028. The directions of association between BMI at inclusion and ES and JSN were similar to that for the total SHS. The effect size of the association with erosion progression was highest and significant only in the BMI<20 group, 1.15 (2.72 to 6.42) p=0.025 (in the BMI<20 group 0.95 (0.90–1.00) p=0.074). On the other hand, association between BMI and JSN progression was significant only in the BMI>30 group, 0.93 (0.87 to 0.99) p=0.033 (in the BMI>20 group 2.53 (0.83-7.67) p=0.096). There were no associations between BMI and radiographic damage in BMI 20–25 and BMI 25–30 groups.

We found no significant association between BMI and ESR, CRP, SJC, TJC over time in the BMI<20 group. In the BMI>30 group, BMI was associated with a higher predicted CRP during follow-up, effect size 1.06 (1.01 to 1.12) p=0.028, but not with ESR and SJC. Compared to the patients with BMI 20–25, patients with BMI>30 had higher TJC over 15 years, 3.17 (1.06 to 9.27) p=0.038.

Conclusions: Underweight at onset of RA is associated with more radiographic damage up to 15 years and obesity with less joint damage, independent of sex, ACPA and smoking status. The effect of BMI is not explained by measures of disease activity.

THU0075
THE RELATIONSHIP BETWEEN DISEASE ACTIVITY AND DISABILITY IS MEDIATED BY PAIN AND FATIGUE IN EARLY RHEUMATOID ARTHRITIS

S. Twigg 1, 2, E.M.A. Hensor 1, P. Emery 1, A.W. Morgan 1, A. Tennant 3 on behalf of Yorkshire Early Arthritis Register. 1Leeds Institute Rheumatic and Musculoskeletal Medicine, University of Leeds; 2National Institute for Health Research- Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 3Swiss Paraplegic Research, Nottwil, Switzerland

Background: Disability in early rheumatoid arthritis (RA) is correlated with disease activity. However, the relationship between these two clinical outcomes is relatively understudied. Understanding how disability is driven by disease activity will allow targeted interventions to improve function in early RA, alongside the suppression of inflammation.

Objectives: To identify mediators in the relationship between disease activity and disability in early RA.

Methods: Cases with new consultant-made diagnoses of RA were recruited to Yorkshire Early Arthritis Register within 24 months of symptom onset. At the baseline assessment, clinical variables were collected including the 3 variable disease activity score from counts of 28 tender and swollen joints and C-reactive protein (DAS28), Health Assessment Questionnaire (HAQ) and visual analogue scales (VAS) for pain and fatigue. Structural equation models (SEM) were constructed to evaluate the relationship between DAS28, HAQ, pain, symptom duration (SD), age and fatigue.

Results: Of 721 cases included, 482 were female and 239 male. Median age was 58 for both genders and median HAQ was 1.25 and 1.00 for women and men, respectively. A path model within a SEM framework (Figure 1) was a good fit to the data (Chi square 7.528, df=6, p=0.2748; CFI 0.997; RMSEA 0.027). However, the model could not be applied simultaneously to both genders; although estimates of regression coefficients did not vary between males and females (metric invariance), model intercepts were different. In earlier models, age was not a significant predictor and regressions of fatigue on DAS28 were not significant: the effect of DAS28 upon fatigue was fully mediated by pain. Standardised coefficients of direct and indirect effects of DAS28 on HAQ are shown in Table 1, together with Sobel tests for significance of mediator variables. The greatest effect upon HAQ was the direct effect from DAS28, but some of the effect of DAS28 on HAQ was partially mediated by pain. Furthermore, the effect of pain upon HAQ was also partially mediated through fatigue. According to the Sobel test, pain and fatigue were significant mediators in both females and males.

The SE, standard error.

Figure 1. Path diagram to show the relationship between disease activity and disability mediated by pain and fatigue.

SD, symptom duration; SE, standard error; t, error terms (representing the unexplained variance in outcomes)

Conclusions: DAS28 dominates the impact upon HAQ in early RA; pain is shown to be an important mediator of the effects of DAS28 on HAQ, while fatigue is important as a mediator of the effect of pain on HAQ. This adds to previous evidence that pain is a driver of fatigue in RA (1) and suggests that interventions to manage pain could be important adjuncts to suppression of inflammation in early RA, in order to optimise function.

DISEASE-MODIFYING TREATMENT REGIMENS HAVE BEEN INSUFFICIENT TO REDUCE THE INCIDENCE OF SYSTEMIC AA AMYLOIDOSIS ASSOCIATED WITH RHEUMATOID ARTHRITIS IN CONTRAST TO A SIGNIFICANT REDUCTION IN THOSE WITH JUVENILE IDIOPATHIC ARTHRITIS

T.A.-B. Youngstein 1, T. Lane 1, J. Gilbertson 1, J. Pinney 1, T. Rezk 1, R. Manwani 2, C.C. Quarta 1, A. Wechalekar 1, S. Mahmood 2, S. Sachchithanantham 3, M. Fontana 1, C. Whelan 1, J.D. Gillmore 3, P.N. Hawkins 1, H.J. Lachmann 1, 1National Amyloidosis Centre, UCL Division of Medicine, 2National Amyloidosis Centre, UCL Division of Medicine, London; 3National Amyloidosis Centre, National Amyloidosis Centre, UCL Division of Medicine, London, London, United Kingdom

Background: The UK National Amyloidosis Centre has the largest known cohort of individuals with AA amyloidosis, with 660 cases since 1990. A third present in end stage renal failure (33%), with a median survival of 133 months from diagnosis. Over 27 years the rate of new cases has remained remarkably constant with a median of 24 diagnoses per annum (IGR 18.5–30.5) but responsible for a decreasing proportion of new cases of systemic amyloidosis from 5% in the first 5 years to 6% in the last 5 years of the cohort.

Objectives: We sought to determine to what extent advances in treatment of the inflammatory arthritides have influenced the aetiology of AA amyloidosis over time.

Methods: Retrospective analysis of the UK National Amyloidosis Centre AA
ANTI-COLLAGEN TYPE II ANTIBODIES ARE ASSOCIATED WITH AN ACUTE ONSET RHEUMATOID ARTHRITIS PHENOTYPE AND PROGNOSTICATE LOWER DEGREE OF INFLAMMATION

V.A. Manivel 1, M. Mullazehi 1, L. Padyukov 2, H. Westerlind 3, L. Klareskog 2, L. Alfredsson 3, S. Saevarsdottir 2, J. Rönnelid 1

Background: Anti-collagen II antibody (anti-CII) positive RA patients present with early but not persistent signs of inflammation and joint erosions. This early anti-CII-dependent phenotype coincides with high anti-CII levels around the time of RA diagnosis, whereas anti-CII levels drop. Our previous studies showed that this phenotype is associated with in vitro cytokine production by monocytes, activation of granulocytes, and enhanced chemokine production by monocyte/granulocyte cocultures, stimulated with anti-CII containing immune complexes. These in vitro findings argue that elevated anti-CII levels at time of RA diagnosis are functionally related to the corresponding acute onset RA phenotype.

Objectives: Our previous comparison done in a small RA cohort (n=274) describe that anti-cyclic citrullinated peptide 2 (anti-CCP2) positive patients have a severe long-term prognosis but anti-CII positive patients have transient inflammation. In the present study we wanted to extend this in a large RA cohort with clinical follow-up data, and to relate to HLA-DRB1* alleles.

Methods: Anti-CII and anti-CCP2 were measured at baseline in 773 patients from the Swedish Epidemiological Investigations in Rheumatoid Arthritis (EIRA) study with clinical follow-up data from the Swedish Rheumatology Quality (SRQ) registry, and 1476 patients with HLA-DRB1* information. Comparisons were done concerning CRP, ESR, TJC, SJC, DAS28, DAS28CRP, pain-VAS, global-VAS and HAQ at 8 occasions during 5 years, and association to HLA-DRB1* alleles.

Results: Anti-CII was detected in 6.6% (97/1476), and anti-CCP2 in 57.9% (855/1476) of the patients. There was no significant difference in treatment strategy at diagnosis for patients with and without those antibodies. Anti-CII associated with elevated CRP, ESR, SJC, and DAS28 and DAS28CRP at diagnosis and up to six months, whereas anti-CCP2 associated with SJC and DAS28 from 6 months to 5 years, but not earlier. The anti-CII-associated phenotype was strong, and predominated also in anti-CII/anti-CCP2 double positive patients. Compared to baseline levels, anti-CII was associated with improvements in CRI ESR, SJC, TJC and DAS28 over time, whereas anti-CCP2 was associated with deteriorations in SJC and DAS28 over time, compared to antibody negative patients. Anti-CII positive patients achieved EULAR good or moderate response more often than negative patients whereas the opposite was found for anti-CCP2 positive patients (figure). Anti-CII was positively associated with HLA-DRB1*01 and HLA-DRB1*03, with significant interaction, and double positive individuals had >14 times higher mean anti-CII levels than HLA double negatives. Whereas smoking associated with elevated anti-CCP2 levels, smokers has lower anti-CII levels.

CONCOMITANT USE OF CONVENTIONAL SYNTHETIC DMARDs AND RESPONSE TO BARICITINIB

A. Kavanaugh1, C. Helt2, D. Muran3, J. Alam2, A.L. Pinto Correia, L. de la Torre*, R. van Vollenhoven3, 1UC San Diego School of Medicine, La Jolla; 2Eli Lilly and Company, Indianapolis, United States; 3Amsterdam Rheumatology & Immunol Center, Amsterdam, Netherlands

Background: Baricitinib (BARI), an oral JAK1/JAK2 inhibitor, is in development for patients (pts) with moderate to severe rheumatoid arthritis (RA).

Objectives: This post-hoc analysis of two phase 3 studies assessed whether concomitant use of conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) altered the response or safety outcomes to BARI in RA pts and evaluated the effect of concomitant corticosteroid use on the efficacy of BARI.

Methods: Pts with ≥2 swollen and tender joints and no prior biologic use were enrolled. In RA-BEAM (NCT01710358), methotrexate (MTX)-inadequate responder (IR) pts were randomised to PBO once daily (QD), BARI 4 mg QD, or adalimumab 40 mg biweekly. In RA-BUILD (NCT01710358), csDMARD-IR pts were randomised to placebo (PBO) or BARI (2 or 4 mg) QD. Pts continued background csDMARD (including MTX) therapy. This post-hoc analysis included the PBO (N=716) and BARI 4 mg (N=714) pts and assessed the number and type of concomitant csDMARDs and concurrent corticosteroid use.

Results: 71%, 21%, and 6% of PBO pts were taking MTX alone, MTX + ≥1 other csDMARD, and non-MTX csDMARDs, respectively; in BARI 4 mg pts, the

Abstract THU0078 – Table 1. Efficacy and Safety Through 12 Weeks Based on Concomitant csDMARD Usage

Data are n (%).
EVALUATION OF SYNOVITIS IN THE FOOT AND THE ANKLE

Depression and anxiety reduce the likelihood of achieving remission in patients with rheumatoid arthritis.

Background: Depression and anxiety are reported to predict poorer treatment outcomes in rheumatoid arthritis (RA). The present study was conducted to clarify the relationship between the systemic disease activity, local disease activity using US and a synovial histopathological examination of the gathered synovium in the foot and the ankle.

Methods: A total of 1450 RA patients were included (mean (SD) age 54.4 (13.5) years, median (25th-75th percentile) disease duration 0.4 (0.0-5.0) years, 68.7% females and 28.6% current smokers). According to the SF-36-MH and -PMA, 18.1% of the patients were depressed/anxious at baseline.

Results: The PD score was grade 0 in 82 cases, 1 in 32 cases, 2 in 20 cases and 3 in 5 cases. The total RS and its item scores except for “proliferating blood vessels” correlated well with the PD signal intensity. The systemic disease activity, as indicated by DAS28, CRP and MMP-3, had no significant correlation with the local PD signal intensity. However, the DAS28, CRP and MMP-3 values and each item score except for “proliferating blood vessels” were significantly lower in the PD grade 0 group than in the PD grades 1, 2 and 3 groups.

Conclusions: No PD signal intensity in the ankle and foot indicates well-controlled disease activity. US is an excellent tool for determining local synovitis as well as the systemic disease activity in patients with RA.

THU0080

DEPRESSION AND ANXIETY REDUCE THE LIKELIHOOD OF ACHIEVING REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS: REAL LIFE DATA FROM THE NOR-DMARD STUDY

B. Michelsen1,2, E.K. Kristianslund2, K.M. Fagel2, E. Lie2, H.B. Hammer2, G. Haugberg1, T.K. Kvien1,2, 1Dept. of Rheumatology, Hospital of Southern Norway Trust; Kristiansand, 2Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo.

Background: Depression and anxiety are reported to predict poorer treatment outcomes in rheumatoid arthritis (RA). Whether this can be confirmed in larger prospective observational studies using various remission criteria remains to be explored.

Objectives: To investigate the predictive value of baseline depression/anxiety on the likelihood of achieving remission in RA as well as the associations between baseline depression/anxiety and the components of the remission criteria at follow-up.

Methods: From the prospective, multi-center NOR-DMARD study we included RA patients starting first-time tumour necrosis factor inhibitors (TNFi) and DMARD naïve RA patients starting methotrexate (MTX) between year 2006 and 2012. The following two criteria for depression/anxiety were assessed: 1) the Medical Outcomes Survey Short Form-36 (SF-36) Mental Health subscale (MHI)-56 and 2) the SF-36 Mental Component Summary score (MCS)-38.

Results: Baseline depression/anxiety on remission after 3 and 6 months was explored in prespecified logistic regression models adjusted for age, sex, disease duration and smoking.

Conclusions: Baseline depression/anxiety negatively predicted remission after 3 and 6 months (adjusted analyses, table 1 and 2).

The findings were confirmed in separate subgroup analyses of TNFi/MTX treated patients. Baseline depression/anxiety was associated with increased patient’s and evaluator’s global assessment and 28 tender joint count at 3 and 6 months, but not with level of acute phase reactants or 28 swollen joint count.
Conclusions: Depression and anxiety may reduce likelihood of remission based on composite scores in RA and should be taken into account in individual patients when making a shared decision on a treatment target.

THU0081
DIFFERENCES IN PATIENT-REPORTED OUTCOMES BETWEEN BARCITINIB AND COMPARATORS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS WHO ACHIEVED LOW DISEASE ACTIVITY OR REMISSION

B. Feurtet1, M. van de Laar2, B. Kirkham3, R. Alten4, R. Cseuz5, S. Van der Geest6, B. Zhu5, F. Leonards7, P. Taylor9,10,1, University Pierre et Marie Curie, Paris, France; 2Arthritis Centre Twente, Medisch Spectrum Twente, Enschede, Netherlands; 3Guys Hospital, London, United Kingdom; 4Schlosspark Klinik, Berlin, Germany; 5Revita Private Clinic for Rheumatology, Budapest, Hungary; 6Eli Lilly & Company, Utrecht, Netherlands; 7Eli Lilly and Company, Indianapolis, United States; 8Eli Lilly and Company, Geneva, Switzerland; 9University of Oxford, Headington, United Kingdom.

Background: Achieving remission is the ideal goal in treating rheumatoid arthritis (RA). In a randomised phase 3 trial, high remission and low disease activity (LDA) rates were achieved with baricitinib (BARI). However, little is known about the differences in patient reported outcomes (PROs) among patients (pts) who have already achieved these targets.

Objectives: To compare PROs between BARI, adalimumab (ADA), and placebo (PBO) in pts with RA who achieved LDA or remission in the Phase 3 RA-BEAM study.

Methods: 1305 pts with RA and background treatment with methotrexate were randomised to receive PBO (n=488), ADA (n=330), or BARI 4 mg (n=487) for 52 wks (24 wks for PBO). In each treatment group, pts in remission (DAS28<3.2) at wk 24 were assessed from baseline for the following PROs: Pain VAS, HAQ-DI, WPFI, Morning Joint Stiffness (MJS), and FACT-F. Sensitivity analyses were conducted for pts in remission or LDA by DAS28-ESR, SDAI, or CDAI. The assessment of response at wk 24 was determined by using the observed data, and the missing values for PRO measures were imputed by using mLOCF.

Results: Among pts in LDA, significantly greater improvements in Pain VAS and HAQ-DI scores were observed with BARI than ADA and PBO, and significantly greater improvements in MJS were observed with BARI and ADA than PBO. Significantly greater residual pain and HAQ-DI scores were observed with BARI. Among pts in remission, significantly greater improvements in pain and HAQ-DI scores were also observed with BARI than PBO. Patients in remission or LDA showed greater numerical improvement and less residual impairment in other PROs with BARI and ADA than PBO (Table 1). Consistent results were observed using other composite measures to define LDA and remission.

Conclusions: The preliminary findings from this study suggest that BARI showed greater improvements in pain and HAQ-DI compared to ADA for pts in LDA, and greater improvements in pain and HAQ-DI scores as well as less physical impairment compared to PBO for pts in LDA and remission.

THU0082
LUNG INVOLVEMENT IN ACPA POSITIVE SUBJECTS: A PILOT STUDY ON THE ROLE OF LABORATORY, FUNCTIONAL AND IMAGING MARKERS

B. Lucchino1, M.C. Gerardi1, C. Iannuccelli1, M.P. Guzzo2, M. Di Paolo2, M. Bonini3, F. Vaccaro2, P. Palangio2, F. Vullo3, D. Diaci1nti, G. Valesini3, M. Di Franco1, 1Department of Internal Medicine and Medical Specialties; 2Department of Public Health and Infectious Diseases; 3Department of Radiology, Sapienza university of Rome, Roma, Italy.

Background: The ACPA-positive Rheumatoid Arthritis (RA) is a complex disease. Signs of immune activity against citrullinated proteins may be present years before the onset of clinical manifestations. Recent findings suggest that the lung may represent an early site of autoimmunity-related injury in ACPA-positive patients without signs of arthritis.

Objectives: The purpose of the present study was to evaluate the presence of subclinical pulmonary abnormalities in ACPA-positive subjects without arthritis and in RA-patients through laboratory, functional and imaging markers.

Methods: Eleven ACPA-positive subjects without arthritis, 10 patients naïve to therapy with early ACPA-positive RA (<6 months duration) and 9 with established ACPA-positive RA (<36 months duration) were included in the study. Subjects underwent baseline pulmonary function tests (PFTs), DLCO measurement and CPET. The evaluation of Surfactant protein D (SP-D) serum levels was performed in all the patients and in 9 healthy controls matched for age and sex with an ELISA test. A total of four subjects underwent chest high-resolution computer tomography (HRCT), in order to evaluate parenchymal or airways abnormalities.

Results: The cohort consisted of 7 men and 23 women, mean age 48.93 (DS="±12.1"). PFTs resulted abnormal in only 2 patients. A DLCO reduction trend was observed in 54.5% of ACPA-positive subjects without RA, in 69% and in 55.6% of patients with early and established RA, respectively. In RA patients, an inverse correlation between disease duration and DLCO/Va (r=0.50; p=0.03) was observed. The exercise tolerance at CPET was reduced in 54.5% of ACPA-positive subjects without RA, in 20% of patients with early RA and in 55.6% of those with established RA. Serum SP-D levels were higher in established RA (p=0.079), in ACPA-positive subjects and early RA than in healthy controls. ACPA levels positively correlated (r=0.45; p=0.01) with CPET parameters of ventilation inefficiency, suggesting a ventilation/perfusion mismatch. A negative correlation between ACPA and SP-D levels and CPET metabolic parameters was also observed. The presence of pulmonary nodules was the most common alteration found at HRCT, equal to 28% in ACPA-positive subjects without arthritis, in 66% and 87% of patients with early and established RA, respectively. In all patients, the presence of pulmonary abnormalities detected at HRCT seemed to develop early in the course of the disease. However, additional studies are needed to clarify lung abnormalities in RA.

THU0083
THE RELEVANCE OF ELEVATED CRP AS AN INCLUSION CRITERION IN CLINICAL TRIALS IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Scoville1, J. Suboticki2, S. Zhong2, E. Keystone3, 1Idaho Falls Arthritis Clinic, Idaho Falls; 2AbbVie, N Chicago, United States; 3Mount Sinai Hospital, Univ of Toronto, Toronto, Canada.

Background: Elevated C-reactive protein (CRP) is often used as an entry criterion in clinical trials (CT) of patients (pts) with rheumatoid arthritis (RA), resulting in the potential exclusion of pts with active disease and high screen failure rates.

Objectives: To assess the relevance of requiring an elevated CRP (>1 mg/dL) as an inclusion criterion for functional and radiographic outcomes.

Methods: This post hoc analysis used data from 2 randomized CTs in RA pts with an inadequate response to methotrexate (MTX). In DE019, pts on background MTX received adalimumab (ADA) or placebo (PBO)2, in MUSICA, pts received either 7.5 or 20 mg MTX, along with ADA3. Data from MUSICA were used
to confirm observations from DE019. Pts were subgrouped by CRP level at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0.75 mg/dL), suggesting that an elevated CRP may not have CRP at entry (as low as 0 Conclusions: While pts with elevated CRP at entry experienced larger improvements from BL in clinical and functional outcomes after treatment, significant improvements in mTSS were observed in pts with CRP levels as low as 0.75 mg/dL. Ours is the first study to report data at week 24.

Results: In DE019, 183 pts (89 and 94 in the ADA and PBO arms, respectively) had CRP >1 mg/dL and 224 pts (118 and 106, respectively) had CRP >1 mg/dL. Pts with elevated CRP had higher BL disease activity compared with those with CRP <1 mg/dL. After 24 wks of treatment with ADA, pts in both CRP subgroups experienced significant improvements in most clinical and functional outcomes vs PBO (Table). In pts with CRP >0.8 mg/dL, the ACR20 response rate difference (30.4, p < 0.001) and the difference in △mTSS (1.3, p < 0.05) for ADA vs PBO treatment were still significant. Compared to pts with CRP <1 mg/dL, pts with elevated CRP experienced greater clinical and functional improvements. However, within the ADA subgroups, pts with elevated CRP had smaller differences vs PBO in mTSS, perhaps reflecting higher joint damage at BL. In general, similar trends were observed in MUSICA (not shown).
initial therapeutic strategies were oral methotrexate monotherapy 16% (site range 0%–55%), subcutaneous methotrexate monotherapy 15% (0%–45%), methotrexate-based combination therapy 30% (10%–47%), non-methotrexate DMARDs 19% (4%–44%), triple therapy 11% (0%–60%), and biologics 2% (0%–18%). At 60 months of follow-up, the frequency of use of these strategies was relatively stable except for biologics which increased to 21% (0%–80%). The mean and median time to DAS28 remission was 12.4 months (SD 12.1, range 8.6 to 17.2) and 9 (IQR 3, 18) months respectively. The mean and median time to CDAI remission was 14.8 (SD 13.5, range 10.3 to 21.2) and 9 (IQR 6, 18) months respectively. The frequency of sustained DAS28 remission was 59% (95% CI 52–70%), and CDAI 35% (12–58%). At the two sites with the highest rates of sustained remission and shortest time to remission, patients had fewer comorbidities and the initial treatment strategy was preferentially methotrexate-based combination therapies, and with eventual advancement to biologics in 7 and 39% in patients. In contrast, at the patients at the site with the lowest rates of sustained remission and longest time to remission had long symptom duration at treatment initiation, highest body mass index and proportion with ≥2 comorbidities, worse socioeconomic status and higher baseline DAS28.

This site also had the highest proportion of patients treated with biologics at treatment initiation, highest body mass index and proportion with ≥2 comorbidities, worse socioeconomic status and higher baseline DAS28.

Conclusions: Treatment strategy and patient characteristics vary across CATCH sites and contribute to variable rate and frequency of achieving sustained remission.

THE USE OF A BLINDED TRUNCATED ULTRASOUND POWER DOPPLER JOINT COUNT TO CONFIRM DISEASE ACTIVITY FROM AN EARLY PHASE OPEN LABEL DRUG TREATMENT STUDY TREATING RHEUMATOID ARTHRITIS

C. Wiesenhuber 1, 2, 1 Department of Family Medicine, University of Washington, Seattle; 2 Coeur d’Alene Arthritis Clinic, Coeur d’Alene, United States

Background: Small open label pilot trials generate important information on tolerability, toxicity, pharmacokinetics, and antigenicity in the early phase investigation of new compounds in the treatment of rheumatoid arthritis (RA). However, because the standard disease activity measurements (DAMs), such as the disease activity score in 28 joints (DAS28) have a major subjective component, the efficacy data acquired in such trials is generally felt to be much less reliable than that obtained in blinded trials. Incorporating more objective DAMs, and performing them in a blinded fashion, might enhance the validity of efficacy data in such an early clinical setting.

One possible disease activity measure to fulfill this role would be an ultrasound power Doppler joint count (UPD) which has been shown to correlate with conventional clinical measures.

Objectives: To determine whether the blinded use of a truncated (low joint count) UPD in an early phase RA trial correlates with other DAMs in the trial and contributes to validation of efficacy of the drug.

Methods: The results of an open label trial in which Staph Protein A (PRX-100, Protxal Inc.) was given to patients with active RA has been previously reported1. Serum samples were obtained 5 times over the first 24-hour period (8 AM, 12 PM, 4 PM, 8 PM, and 8 AM) at 12 PM in the next 24-hour period; and at 8 AM the next 2 consecutive days, for a total of 8 timepoints. An additional midnight sample was excluded from the analysis because this timepoint is not relevant to normal clinical practice hours. Diurnal variation was calculated using 5 timepoints over the first 24 hours. Daily variation was determined using 4 timepoints taken at 8 AM on successive days. Combined diurnal and daily variation was calculated using 8 timepoints over 4 days. For each patient, absolute changes in MBDA scores were calculated for all possible pairs of timepoints for: a) diurnal variation (total 220 pairs), b) daily variation (total 132 pairs) and c) diurnal and daily variation (total 616 pairs). MID was calculated as the 90th percentile of absolute changes from baseline.

MIDs were calculated as the 90th percentile of absolute changes from baseline. MID was calculated as the 90th percentile of absolute changes from baseline.

Correlations between MBDA and clinical DAMs from baseline to single time points were assessed by the Wilcoxon signed rank test and correlations were performed by the Spearman’s rho test (p). Effect size was determined by standardized mean difference (SMD).

Clinical assessments and UPDs were obtained weekly for the first month, then monthly for five more months.

**Results:**

Intra-observer UPD score reproducibility was high (ICC = 0.886). Significant reductions (p < 0.05) in UPD and the DAS28 were found at day 22 and on all subsequent visits. Correlations between UPD and DAMs total scores were moderate to strong. However, the total differences from baseline and visits did not correlate, except for CRP (n=67, p=0.471, p = 0.001). Also, some individual time points showed differences such as baseline vs day 196 (see table). SRMs for both UPD and DAMs were high, but higher for the DAS28 (1.00–2.16) than for the UPD (0.83–1.16).

Conclusions: The use of a truncated UPD in this small open label trial was feasible, reproducibly read, and significantly correlated with conventional disease activity measure.

The inclusion of UPD in this open label pilot trial adds validation to the efficacy data.

References:

changes using all diurnal and daily variation data. Bootstrapping was used to validate the result.

Results: Of patients included in the analysis, 13 had moderate MBDA scores and 9 had high MBDA scores at baseline. Baseline demographics were: 73% women, mean age 61.8 (SD: 12.1) years, mean MBDA score 43.9 (SD: 8.3), and mean CDAI score 17.1 (SD: 11). No patients were on glucocorticoids. Based on the analysis of the absolute change of MBDA score in the data with daily and diurnal variation combined, the mean was 3.4 (SD: 3.8), the median (Q1, Q3) was 2 (1, 5), and the MID was calculated as 7. Similar results were obtained using a bootstrap method. Minimal variability in mean MBDA scores was observed over 4 days for patients with moderate and high baseline MBDA scores (Figure 1).

Conclusions: Based on the short term biologic variability of moderate and high MBDA scores, the MID was 7 units. An absolute change exceeding this threshold is unlikely due to diurnal and daily biological variation of the MBDA scores.

STRUCTURAL DAMAGE PROGRESSION IN PATIENTS TREATED WITH METHOTREXATE, BARICITINIB MONOTHERAPY OR BARICITINIB + METHOTREXATE BASED ON THE LEVEL OF CLINICAL RESPONSE IN THE PHASE 3 RA-BEGIN STUDY

D. van der Heijde 1, P. Durez 2, G. Schett 1, E. Naredo 4, M. Østergaard 5, G. Meszaros 6, N. Bello 6, I. De la Torre 6, P. Lopez-Romero 6, D. Schlichting 7, E. Nantz 7, R. Fleischmann 8, J. de Leenheer 9, Leiden University Medical Centre, Leiden, Netherlands; 10UCL-Saint Luc, Bruxelles, Belgium; 11Universitätsklinikum Erlangen, Erlangen, Germany; 12Hospital Universitario Fundación de la Ciudad de la Juventud, Madrid, Spain; 13Copenhagen Centre for Arthritis Research Copenhagen, Copenhagen, Denmark; 14El Lilly & Company, Madrid, Spain; 15El Lilly & Company, Indianapolis, IN; 16Texas SW Medical Center, Dallas, United States

Background: Baricitinib (BARI), an oral inhibitor of Janus kinase (JAK) 1 and JAK 2, is being developed for the treatment of rheumatoid arthritis (RA). RA-BEGIN was a phase 3 double-blind, three-arm multicentre study of BARI administered as monotherapy or in combination with methotrexate (MTX) to patients (pts) with early active RA who had no or limited prior exposure to DMARDs. Methotrexate (MTX) monotherapy was the active comparator.

Objectives: To evaluate the proportion of pts with structural damage progression, defined as change from baseline (CBF) greater than the smallest detectable change (SDC) in mTSS at week (wk) 52, depending on their disease state as measured by DAS28-CRP.

Methods: Pts were classified into two groups based on DAS28-CRP. Group A included pts who achieved sustained DAS28-CRP ≤3.2 at weeks 16, 20 and 24. Pts who did not achieve DAS28-CRP ≤3.2 consecutively at weeks 16, 20 and 24 and pts with missing DAS28-CRP at any of those 3 visits were included in Group B. The proportion of pts with CFB mTSS > SDC at wk 52 was estimated for each treatment arm for the two defined groups of response. The SDC in mTSS was calculated as SD/√2, where SD is standard deviation of paired differences of change from baseline. Logistic regression analysis was used to correlate the effect of disease activity at baseline on radiographic progression.

Results: The proportion of pts with CFB mTSS > SDC at wk 52 was estimated for each treatment arm for the two defined groups of response. The SDC in mTSS was calculated as SD/√2, where SD is standard deviation of paired differences of change from baseline. Logistic regression analysis was used to correlate the effect of disease activity at baseline on radiographic progression.

Conclusions: Disease activity measures and their ability to predict structural damage progression were different depending on the level of disease activity at baseline. Radiographic progression was more likely to occur in pts with moderate disease activity than high disease activity.

M-DA28, DAS28 (CRP) AND RAPID3 SCORES AT BASELINE ARE GOOD PREDICTORS OF RADIOGRAPHIC DISEASE PROGRESSION AT 1 AND 2 YEARS: DATA FROM THE AMPLTE TRIAL

E. Keystone 1, H. Ahmed 2, Y. Yazici 3, E. Muratti 4, J. Ye 6, M. Bergman 7, University of Toronto, Toronto, Canada; 2 Bristol-Myers Squibb, Princeton, New Jersey University School of Medicine, New York, United States; 3 Bristol-Myers Squibb, Montreal, Canada; 4Drexel University College of Medicine, Philadelphia, United States

Background: Clinicians rely on time-efficient, validated disease activity assessments to help predict disease progression accurately in patients (pts) with RA. The utility in predicting structural damage progression for the Routine Assessment of Patient Index Data 3 (RAPID3) is largely unknown, while that of DAS28 (CRP)2 and modified (M-)DA28 have been previously reported.3

Objectives: This post hoc analysis examined the relationship between baseline disease activity measures and their ability to predict structural damage progression in the Phase III AMPLTE (NCT00529684) trial.

Methods: AMPLTE was a randomized, investigator-blinded study in which MTX-experienced pts with active RA ≤5 years received SC abatacept 125 mg weekly or adalimumab 40 mg every 2 weeks in combination with stable-dose MTX. Logistic regression analysis was used to correlate the effect of disease activity at baseline on radiographic (X-ray) progression at Months (M) 12 and 24. Disease activity was assessed using M-DA28,4 DAS28 (CRP), RAPID3, CDAI and SDAI. Radiographs were scored using the modified Sharp/van der Heijde scoring system; progression was defined as change from baseline in total score greater than the smallest detectable change, which was calculated as SD/square root (2) x 1.96 (where SD is standard deviation of paired differences of change from baseline in total score greater than two readers).

Results: Logistic regression analysis was carried out for all randomized and treated pts (abatacept, n=318; adalimumab, n=328). For these patients, M-DA28, DAS28 (CRP) and RAPID3 at baseline were significant predictors of radiographic progression at M12 and M24, baseline SDAI was a significant predictor at M12 but not M24 and baseline CDAI was not a significant predictor at either time point

Logistic regression model and area under ROC curves for the impact of disease activity assessed on radiographic progression at M12 and M24 (all randomized and treated patients)

AUC = area under the curve; M = month; NS = not statistically significant; OR = odds ratio; ROC = receiver operating characteristic.
Results: The main baseline demographic and disease characteristics of the whole sample of ERA (n=223) and the 3 age groups- YORA (46), IORA (81) and LORA (96) - are summarised in Table 1. Age at RA-onset was independently associated with DAS28CRP remission at 1 year (Table 2). Conclusions: In a cohort of ERA, older age at disease onset is associated with a more active (CRP) disease at the beginning but with a greater probability of DAS28CRP remission at 1 year.

THU0091 HIGH MULTI-BIOMARKER DISEASE ACTIVITY SCORE IS ASSOCIATED WITH HIGH RISK OF RADIOGRAPHIC PROGRESSION IN SIX STUDIES

J.R. Curtis 1, C.H. Brahe 2, M. Ostergaard 3, M.L. Hietland 4, K. Hambardzumyan 5, S. Saevarsdottir 3, X. Wang 1, E.H. Sasse 1, T.W. Huizinga 1, 2, 3, 6, 7, Univ. of Alabama at Birmingham, Birmingham, United States; 2Copenhagen Center for Arthritis Research, Copenhagen, Denmark; 3Karolinska Univ. Hospital and Karolinska Institutet, Stockholm, Sweden; 4Crescendo Bioscience Inc., South San Francisco, United States; 6Leiden Univ. Medical Center, Leiden, Netherlands

Background: The multi-biomarker disease activity (MBDA) test uses a validated algorithm with 12 serum protein biomarkers to assess disease activity in patients with RA. The MBDA score has previously been found to be a predictor of risk for radiographic progression (RP). To date, there is no evidence that the MBDA score may be a predictor for radiographic progression in patients with ERA.

Objectives: To evaluate data from six cohorts to collectively establish the relationship between the MBDA score and risk for RP.

Methods: Clinical, MBDA score and radiographic data were analyzed for 6 cohorts with N: Year 2, OPERA Year 1, AMPLE Year 1, AMPLIFY Year 2, SWEFOT Year 1, and AMPLIFY Year 1 (abatacept and adalimumab arms) (see Figure). Analyses used published results when available or patient-level data when not (i.e., for Leiden; and for OPERA CRP analyses). Frequency of RP over one year was determined by category of MBDA score (low, moderate [30–44], high on a scale of 1–100) at the start of the year for four cohorts and by category of MBDA score at the end of the year for AMPLE cohorts (as published). RP was defined using the threshold for change in total modified Sharp score (ΔmTSS) specific to each study (2 to >5 TSS units). Positive and negative predictive values (PPV and NPV) were determined for each study by comparing patients with high MBDA score (>44), DAS28(CRP) or CRP respectively. Previously published multivariate analyses in the Leiden and SWEFOT Year 1 cohorts showed that MBDA score was an independent predictor of RP compared with other predictors. In the Leiden cohort, MBDA score was the strongest predictor and high MBDA score was an independent predictor of RP compared with other predictors. In the Leiden cohort, MBDA score was the strongest predictor and high MBDA score was an independent predictor of RP compared with other predictors.
discreminated between high and low risk for RP among patients with high SJC (≥5) or high DAS28-CRP with PPV as high as 57%.

**Conclusions:** High MBDA scores were associated with increased risk for RP in 6 study cohorts, including patients treated with csDMARDs, TNFi and abatacept. Based on high NPVs (>93%), the MBDA score used alone had clinical value for identifying patients with little or no risk of RP. Combining the MBDA score with clinical measures yielded PPVs approaching 60%, suggesting that biomarkers can help stratify patients by their risk for RP.

**THU0092**

**CHRONIC PAIN INCREASES INDEPENDENT OF THE DISEASE ACTIVITY AND DEPRESSION IN FEMALES WITH RHEUMATOID ARTHRITIS**

F.G. Yurdakul, A. Kilcioglan, H. Bodur. Department of Physical Medicine and Rehabilitation, Ankara Numane Training and Research Hospital, Ankara, Turkey

**Background:** Chronic pain is a key component of rheumatoid arthritis (RA). Although pain is reduced with the control of inflammation at the first years of the disease, pain increases over time with different pathways just as central sensitization. Fatigue, sleep disturbance and chronic pain are common problems in patients with RA (1,2).

**Objectives:** We aimed to investigate the frequency of widespread pain, sleep disorders, fatigue, and depressive symptoms in RA patients. Furthermore, we aimed to describe the relationship between these symptoms and disorders were analyzed between female and male RA patients.

**Methods:** One hundred and sixty one RA patients (female: 119, male: 42) and 88 healthy controls (female: 52, male: 16) were enrolled in the study. Widespread pain index (WPI) with nineteen body parts that was identified by 2010 fibromyalgia diagnostic criteria, Fatigue, sleep disturbance and depressive symptoms with chronic pain are common problems in patients with RA (1,2).

**Results:** The mean PhGA, HAQ, BDI, FSS, WPI values of RA patients were worse than healthy controls (p=0.012, 0.000, 0.008, 0.033, 0.044 respectively). There was no difference between RA and healthy controls within WPI in night’s sleep. The mean age, disease duration, MS, swollen joint count, C-reactive protein, PhGA and BDI were similar in female and male RA patients. WPI, vas pain, tender joint count, HAQ, RAQOL, FSS, and PSQI, and DAS 28 were higher in females (Table 1).

**Conclusions:** RA is a disease that increases fatigue, depressive symptoms and widespread pain. DAS28 significantly were higher due to the increased pain scores and tender joint count which are subjective parameters in female RA patients. Pain scores in females are significantly higher than in males, and pain exacerbated by central sensitization pathway in women may lead to sleep disorders and fatigue, but not increase depressive symptoms.

[1] The role of central nervous system in the generation and m...
2 groups (41and 92 pts who achieved RR and didn’t respectively). After 2 yrs the factors associated with RR achievement in pts with RA while non-biological DMARDs using was assessed.

**Results:** Before study, pts in both groups were comparable by all demographic, clinical and x-ray characteristics, frequency of DMARDs prescribed. They differed only in frequency of RF positivity (39.0% and 57.6% respectively in pts achieved RR and didn’t, p<0.05), aCCP-positivity (21.7 and 73.3% respectively, p<0.001) and aCCP level (6.06±38.8 and 105.3±22.7 U/ml respectively, p<0.001).

There was strong and moderate positive correlation between RR achievement and aCCP-positivity (r=0.57, p<0.05), low aCCP level (r=-0.45, p<0.05) and ΔDAS28 (-r=0.35, p<0.05).

Results of multinominal logistic regression analyses (SPSS, V22, IBM) showed that RF-positivity was the only independent predictor of RR achievement (B=3.14, p<0.05).

41.7% pts in RR achieved clinical remission by DAS28 as well. Only 19.7% pts achieved clinical remission without RR (p<0.05 vs pts achieved clinical and RR) and 12.5% pts achieved RR without clinical response (ΔDAS28: -5.1, ΔDAS28: ≤1.2 or any value of DAS28 with ΔDAS28: ≤0.6; p<0.01).

After 2 years of treatment the mean value of ΔDAS28 in comparison groups (with and without RR) did not differ (2.79±0.28 vs 2.33±0.17 respectively) so there was a discrepancy between clinical and radiological outcome.

**Conclusions:** Baseline predictors associated with achieving of radiographic remission in pts with RA are RF- and aCCP-positivity, low level of aCCP, but independent predictor of radiographic remission achievement is the only RF-positivity.

The discrepancy between the frequency of clinical and radiographic remission achievement in RA patients is observed.

After 2 yrs of non-biological DMARDs treatment 41.7% pts with RA achieves radiographic and clinical remission at the same time.

**MULTI-BIOMARKER DISEASE ACTIVITY (MBDA) IS ASSOCIATED WITH THE PROGRESSION OF STRUCTURAL BONE DAMAGE IN RHEUMATOID ARTHRITIS PATIENTS IN REMISSION**

G. Schett1, S. Finzel2, M. Hagen1, M. Englbrecht1, J. Haschka1, G. Filippou2, E. Bellis3, C.A. Scirè4, G. Carrara5, A. Iagnocco6

1University of Erlangen-Nuremberg, Erlangen, Germany; 2University Medical Center Freiburg, Rheumatology and Clinical Immunology, Freiburg, Germany; 3St.Vincent Hospital, Vincenza Group Study, Medical University of Vienna, Vienna, Austria; 4Institute of Rheumatology, Sao Paulo, Brazil

**Background:** Due to an increasing number and an earlier use of effective disease modifying anti-rheumatic drug (DMARD) therapy a growing number of rheumatoid arthritis (RA) patients reaches a state of clinical remission of disease. Whether clinical remission completely protects from structural bone damage, however, is still a matter of debate as conventional radiographic methods have their limitation in the sensitivity to characterize bone damage. Furthermore, residual activity of inflammation associated with the generation of inflammatory markers may characterize a subset of RA patients in remission, associated with higher prevalence and/or progression of bone damage.

**Objectives:** To test whether residual systemic inflammation is associated with structural bone damage and the progression of structural bone damage in RA patients in sustained remission.

**Methods:** RA patients (i) fulfilling the 2010 EULAR/ACR classification criteria of RA, (ii) having a positive anti-citrullinated protein antibody (ACPA) status and (iii) being in DAS28-ESR remission for 6 months were included. High-resolution peripheral quantitative computed tomography (HR-pQCT) of the right hand was done at baseline and after 1 year. Erosion numbers and erosion volumes were assessed in the metacarpophalangeal joints. Vectra-DA tests measuring the serum levels of twelve different inflammation markers (CRP, SAA, IL-6, TNFR1, IL-1RA, MMP-3, EGF, VEGF-A, VCAM-1, YKL-40, leptin and resistin) were performed. In the baseline examinations, MBDA score was calculated according to previously defined algorithms with low MBDA score defined as <30 units and moderate to high scores as ≥30 units (1).

**Results:** 100 ACPA+ RA patients in sustained remission were investigate (mean±SD age: 57±14 yrs; disease duration: 48±9 yrs; DAS28: 1.7±0.5;83% females; 100% MTX treatment, 38%; MTX+TNF treatment), 65 patients had low (<30), 25 patients had moderate (≥30–44 and 10 patients had high (≥44) MBDA scores. Patients in the different MBDA categories had similar age, sex, disease duration, DAS28 scores and DMARD treatment. Baseline HR-pQCT analysis showed that erosion numbers and volumes were significantly (p<0.001) higher in patients with high MBDA scores. Higher erosion numbers (>10) and larger erosions (>10 mm²) were exclusively found in patients with moderate to high MBDA scores. MBDA scores were correlated to erosion numbers (p<0.001) and volumes (p=0.0018). Longitudinal analysis showed significant progression of erosions only in patients with high MBDA scores. Furthermore, progression (>5mm² increase in volume) over 1 year was confined to methotrexate treated patients, while tumor necrosis factor inhibitor treated patients were protected from progression even in case of moderate to high MBDA scores. However there were only 4 patients treated with TNFi that had a high MBDA score.

**Conclusions:** These data show that residual disease activity assessed by MBDA score is associated with structural damage and progression of structural damage in RA patients in sustained remission.

CHANGE IN SELF-REPORTED PAIN REFLECTS PSYCHOLOGICAL AND FUNCTIONAL STATE RATHER THAN INFLAMMATORY BURDEN IN UNITED STATES LATINOS WITH ESTABLISHED RHEUMATOID ARTHRITIS

G. Karpouzas, E. Hernandez, C. Cost, S. Ormseth. Rheumatology, Harbor-UCLA Medical Center, Torrance, United States

Background: Pain represents the cardinal complaint in patients with rheumatoid arthritis (RA). It may reflect inflammation, structural damage, or aberrant processing and regulatory mechanisms.

Objectives: We evaluated whether changes in pain reflect inflammatory burden variation or non-inflammatory factors in Latinos with established RA in the United States (US).

Methods: We evaluated 271 patients from a single academic center with complete data on parameters of interest on 2 visits 12 months apart. Demographics, serologies, swollen and tender joint assessments, sedimentation rate, fatigue-VAS (visual analogue scale), pain-VAS, depression assessment (Patient Health Questionnaire-PHQ9), functional disability (Health Assessment Questionnaire, HAQ-DI), presence of erosions and irreversible articular damage (IAD, including subluxation, fusion, arthrodesis, or prosthesis) were recorded. Principal components factor analysis with varimax rotation determined latent variables of symptom change. Multinomial logistic regression modeling with forward stepwise entry determined parameters associated with clinically meaningful change in pain compared to no change.

Results: Two factors met acceptance criteria (Eigenvalues > 1) with values of 2.57 and 1.31 respectively (Table 1). Following rotation, factor 1 loadings comprised changes in fatigue, pain, depression scores, and functional disability, representing non-inflammatory factors. Conversely, factor 2 encompassed changes in tender and swollen joints and IAD, representing inflammation. Clinically relevant improvement in pain significantly correlated with respective improvements in fatigue, depression, functional disability and tender joints (Table 2); worsening pain was negatively associated with change in disability or fatigue.

Table 1: Principal Component factor analysis with change variable loadings

| Fatigue change       | 0.814 | 0.019 |
| Pain change          | 0.757 |
| PHQ9 change          | 0.716 |
| HAQ-DI change        | 0.559 |
| Swollen joint change | 0.495 |
| Tend joint change    | 0.386 |
| Sed rate change      | 0.605 |

Table 2: Factors associated with clinically meaningful change in self-reported pain

Conclusions: In Latinos with established RA, change in pain reporting reflects alterations in non-inflammatory parameters such as fatigue, depression and functional disability rather than inflammation. Active screening and consideration of those factors may inform therapeutic interventions, balance patient and physician expectations, and optimize patient satisfaction and clinical outcomes.

THE NAILFOLD CAPILLAROSCOPY IN RHEUMATOID ARTHRITIS: QUANTITATIVE ANALYSIS AND CLINICAL AND SEROLOGICAL CORRELATION

G. Cuomo, E. Frongillo, L. Pirro, A. Del Mastro, C. Romano. Dipartimento Assistenziale Integrato di Medicina Interna, UOC Medicina Interna - Università degli Studi della Campania - Luigi Vanvitelli, Napoli, Italy

Background: Nailfold videocapillaroscopy (NVC) abnormalities have been reported in patients with Rheumatoid Arthritis (RA). Nevertheless, only few studies evaluated the grades of the detected alterations (1,2). In 1994, Hachulla et al., showed microvascular permeability alterations in RA confirming the existence of a microangiopathy (3). In addition, Meyer et al. showed modifications of the normal blood flow velocity and microvascular dysfunction in RA (4).

Objectives: The aim of this study was to evaluate, in RA patients and healthy controls (HC), the microcirculatory abnormalities through NVC, applying a quantitative and qualitative method. We also correlated abnormalities with clinical and immunological features.

Methods: Thirty-five HC (35 females, 7 males, median age 55, range 32–70) and 70 RA patients (61 females, median age 58 years, range 30–75; median disease duration 12 years, range 1–20) consecutively admitted to our outpatient clinic, were examined. All patients underwent a full clinical-serological characterization. Both patients and controls underwent NVC, with optical probes of 200X (VideoCap 2.5). We excluded patients who showed conditions known to compromise microcirculation, such as diabetes, hypertension, overlap with other connective tissue diseases or certain pharmacological treatments. The following NVC parameters were evaluated: with a semi-quantitative method: capillary enlargement (ectasia), microhemorrhages, mean capillary density, capillary tortuosity (5).

Results: NVC alterations were detected in 55 of 70 (68.6%) RA patients: 40 (57%) patient showed ectasic capillaries; 21 (30%) decrease of the mean capillary density; 12 (17%) microhemorrhages; 46 (65.7%) capillary tortuosity. No patient had megacapillaries and/or neoangiogenic abnormalities. A statistically significant difference between HC and RA patients was found for the detection of ectasias (p<0.0001) and for the decrease of the mean capillary density (p<0.001).

No differences emerged in RA patients between NVC pattern and/or immunological (ANA, ACA, Rheumatoid Factor) and/or serological profile (ESR, CRP, lipid profile).

Nevertheless we found a correlation between NVC abnormalities (microhemor- rhages) and activity disease evaluated by DAS28 (p=0.0037).

Conclusions: Our study confirms the presence of a sub-clinical microvascular involvement in RA patients either with or without microvascular clinical manifestations. In our opinion capillaroscopy can be considered a valid technique in inflammatory joint diseases to analyze microvascular circulation. Moreover, the correlation of NVC specific alteration with disease activity suggests the importance of these features in the assessment of RA patients.

THU0099

THE 2010 CLASSIFICATION CRITERIA AND A MORE AGGRESSIVE TREATMENT STRATEGY IMPROVE CLINICAL OUTCOMES IN SEROPOSITIVE BUT NOT SERONEGATIVE RHEUMATOID ARTHRITIS

G. Cregpain, S. Bugatti, F. Benaglio, G. Sakeleiluio, A. Manzo, C. Montecucco, R. Caporali. Department of Rheumatology, IRCCS Policlinico San Matteo Foundation, Pavia, Italy

Background: Current guidelines recommend an early and intensive treatment in patients diagnosed with rheumatoid arthritis (RA), and the 2010 ACR/EULAR Classification Criteria were developed with the aim of allowing earlier diagnosis and treatment (1,2). Recent studies highlighted some differences in disease activity between seropositive and seronegative RA patients at disease onset (3).

Objectives: To investigate whether the application of the 2010 ACR/EULAR Classification Criteria and a more aggressive treatment strategy improve clinical outcomes in patients with early RA irrespective of the autoantibody status.

Methods: 584 early, treatment-naïve RA patients were recruited in the years 2005–2014. RA diagnosis was made according to the ACR 1987 criteria in 2005–2010, and to the 2010 ACR/EULAR criteria in 2011–2014 (n=224, cohort 2010). Patients were classified if an autoantibody (Ab)-negative rheumatoid factor (RF) or and/or anticitrullinated peptide antibody (ACPA) and Ab-positive (RF and/or ACPA positive). Methotrexate (MTX) was used at the initial dosage of 10 mg/week in cohort 1987, and 15 mg/week in cohort 2010, and progressively increased if low disease activity (LDA) (DAS28<3.2) was not met. The frequency and predictors of LDA and clinical remission (DAS28<2.6) over 6 months were assessed by Cox regression.

Results: In Ab-negative patients, LDA and clinical remission were achieved in 62.8% and 37.2% of the cases, and the 2010 cohort did not show significantly improved outcomes compared to the 1987 cohort (HR [95% CI] 0.86 [0.81–0.93] for LDA). In Ab-positive patients, however, the 2010 cohort had a markedly improved remission rate (HR [95% CI] 1.39 [1.01–1.92]) (Figure 1A, B). In contrast, in Ab-positive patients, the application of the 2010 classification criteria and higher dosages of MTX were associated with increased frequency of LDA after adjustment for confounders (age, sex, prednisone, baseline DAS28, HR [95% CI] 1.39 [1.01] for remission) (Figure 1C). Clinical remission was achieved in 41.3% of the cases, compared to 29.6% in the 1987 cohort (p=0.17) (Figure 1D).

Conclusions: Early diagnosis and a more aggressive treatment strategy with MTX lead to significantly improved outcomes in autoantibody positive RA. The management of seronegative patients remains suboptimal.

IN EARLY INFLAMMATORY ARTHRITIS A LYMPHOID PATHOTYPE SIGNIFICANTLY ASSOCIATES WITH REQUIREMENT FOR BIOLOGIC THERAPY AT 12 MONTHS FOLLOW UP: RESULTS FROM THE PATHOBIOLOGY OF EARLY ARTHRITIS COHORT (PEAC)

G. Liac-Ribeiro 1, F. Humby 2, S. Kelly 3, M. Bombardieri 1, M. Lewis 1, R. Hands 1, V. Roche 1, F. Bene 1, A. Nerviani 1, C. Buckley 1, P. Taylor 1, I. McInnes 1, C. Pitzalis 1, 1Experimental Medicine and Rheumatology, Queen Mary University of London, London; 2Centre for Translational Inflammation Research, University of Birmingham, Birmingham; 3Kennedy Institute of Rheumatology, University of Oxford, Oxford; 4Experimental Medicine and Rheumatology, University of Glasgow, Glasgow, United Kingdom

Background: Early aggressive treatment in RA equates to better long term outcomes, however targeting aggressive therapies including biologics to patients with the worse prognosis is critical to deliver acceptable risk/benefit ratios and health economic improvements. Such an approach requires prognostic biomarkers, whether the well recognised heterogeneity in synovial pathobiology and health economic improvements. Such an approach requires prognostic biomarkers, whether the well recognised heterogeneity in synovial pathobiology is currently unknown.

Objectives: The aim of this study was to investigate whether in a treatment naive early inflammatory arthritis cohort, baseline synovial pathotype significantly associates with disease outcome at 12 months.

Methods: 166 consecutive DMARD naïve patients recruited as part of PEAC at Barts Health NHS Trust with synovial tissue suitable for analysis were included. At baseline patients were classified as RA (2010 ACR/EULAR criteria) or undifferentiated (UA). All patients underwent a baseline synovial biopsy of a clinically active joint along with collection of demographic data. Patients were subsequently treated with DMARD +/- steroid therapy with aim for low disease activity (DAS <3.3). At 6 month follow up patients were escalated to biologic therapy if fulfilling UK NICE guidelines. At 12 months patients were classified as: (i) no treatment, (ii) DMARDs, and (iii) Biologic +/- DMARD therapy with aim for low disease activity (DAS <3.3). At 6 month follow up patients were escalated to biologic therapy if fulfilling UK NICE guidelines. At 12 months patients were classified as: (i) no treatment, (ii) DMARDs, and (iii) Biologic +/- DMARDs. Sequentially cut sections of baseline synovial biopsies underwent immunohistochemical staining and semi-quantitative scoring (0–4) to determine the degree of CD20+ B-cells, CD3+ T cells, CD68+ lining (l) and sublining (sl) macrophage and CD138+ plasma cell infiltration. Sections were categorised into 3 pathotypes, (i) Fibroid: (CD68 SL<l), (ii) Myeloid: (CD68SL<2, CD20<1 and or CD3<1) and (iii) Lymphoid: (grade 2–3 CD20+ aggregates, CD20<1). At baseline patients with a lymphoid pathotype had a significantly higher CRP and DAS28 and were significantly more likely to be sero positive for RF and ACPA (p<0.05), suggesting that a lymphoid pathotype is associated with higher levels of disease activity. At 12 months follow up a significantly higher proportion of patients classified as lymphoid vs myeloid or fibroid (58% vs 21% vs 21%) required biologic therapy.

Conclusions: Results demonstrate that in an early inflammatory arthritis cohort a lymphoid pathotype significantly associates with higher disease activity at baseline, sero positivity for RF and ACPA and a requirement for more aggressive therapy at 12 month. This supports a direct role for synovial lymphoid structures in disease pathogenesis and suggests a role as a prognostic biomarker facilitating early stratification of aggressive therapeutic intervention.

THU0101 CARDIOVASCULAR MAGNETIC RESONANCE IMAGING CHARACTERISATION OF CARDIOVASCULAR ABNORMALITIES IN INDIVIDUALS AT RISK OF DEVELOPING RHEUMATOID ARTHRITIS

G.J. Fent 1, L. Hunt 2,3, K.S. Mankaia 4,5, B. Erhayiem 1, J.R. Foley 1, P. Garg 1, P.P. Swoboda 1, J. Andrews 4,5, J.P. Greenwood 1, P. Emery 4,5, S. Plein 1, M.H. Buch 1,2, 1Leeds Institute of Cardiovascular and Metabolic Medicine, University of Leeds, UK; 2NIHR Leeds Musculoskeletal Medicine, University of Leeds, United Kingdom; 2Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, United Kingdom; 4Leeds Institute of Rheumatism and Musculoskeletal Medicine; 5NIHR Leeds Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

Background: Inflammation is the primary contributor to excess cardiovascular (CV) disease in rheumatoid arthritis (RA), with evidence of subclinical abnormalities observed even in treatment-naïve, early RA [1]. Preliminary reports suggest citrullinated proteins are present in atherosclerotic plaque [2]. It is unclear whether immunological changes of anti-citrullinated protein antibody (anti-CCP+) positive individuals ‘at risk’ of developing RA are associated with CV abnormality.

Objectives: To perform a pilot study to explore whether subclinical CV abnormalities are present in anti-CCP+ individuals at risk of developing RA.

Methods: Sixteen consecutive patients with non specific MSK symptoms but no synovitis, detectable anti-CCP antibody and 30 age-matched healthy controls (HC) underwent a multi-parametric 3.0T (Philips Achieva) cardiovascular magnetic resonance (CMR) study. Neither group had any history of CV disease. At-risk individuals were categorised as low and high absolute risk for RA development (<50% and >50% respectively) according to a published risk model [3]. CMR post-processing was performed using CVI 42 (Circle Cardiovascular Imaging, Canada).

Results: HC and at risk individuals were well matched for baseline characteristics (table 1). Aortic strain values (dissensibility, strain and stiffness index I) were lower, indicating increased aortic stiffness, in at-risk individuals than HC, numerically most pronounced those classified high risk (table 2). There were no differences in LV mass and function, late gadolinium enhancement, myocardial T1 (measure of myocardial composition) or LV S prime (longitudinal LV systolic function) (table 2).

</tbody>
</table>
Conclusions: Anti-CCP+ individuals with non-specific MSK symptoms (in particular, a high risk group), exhibit increased aortic stiffness. This suggests presence of CV abnormalities prior to development of RA and implies a role of autoantibody-mediated development of atherosclerosis. These findings warrant further investigation in larger scale studies.

THU0102 CLINICAL DISEASE ACTIVITY MEASURES ARE IMPORTANT DRIVERS OF MAJOR CHANGE IN MEDICAL TREATMENT IN US VETERANS ENROLLED IN THE VETERANS AFFAIRS RHEUMATOID ARTHRITIS (VARA) REGISTRY

G.W. Cannon 1, 2, C.-C. Teng 3, N.A. Accort 2, D. Collerer 4, S. Mehrotra 2, B.C. Sauer 5, 6, 7, Rheumatology; 2Salt Lake City Va Medical Center, Salt Lake City; 3Amgen, Thousand Oaks, United States

Background: Current guidelines encourage the measurement of rheumatoid arthritis (RA) disease activity and direct therapy to achieve a low disease state or remission (treat-to-target). Many RA patients with documented moderate to severe disease activity remain on their current therapy without change. This study investigated Veterans Affairs (VA) clinical data to identify patient factors associated with a major change in RA therapy and to determine that disease state using an area under the curve calculation and compared to the DAS28 at the index date. Patients were categorized as having a worsening or improvement of disease if the DAS28 at index date was 0.6 higher or lower than the average DAS28 during the observation period respectively. Other patients were categorized as no change in DAS28.

Analyses of clinical variables including components of the DAS28 and patient and physician reported measures were compared in patients with and without a major change in therapy.

Results: Of 941 patients who met study criteria, only 388/941 (41.2%) had a major change of therapy. Patients with worsened DAS28 were more likely to have a major change 183/369 (49.5%) than no DAS28 change 170/454 (37.4%) and improved DAS28 35/118 (29.6%) (P<0.001). Clinical variables were strongly associated with changes in therapy among patients with worsening disease activity and not as strongly associated with change in therapy in those with no change disease activity. Clinical variables were not significantly associated with major change in patients with disease improvement, though that group had the smallest sample size. Ten representative clinical variables with the highest association with major change are included below.

Conclusions: More than half of the patients with moderate disease activity did not have a major change in therapy. The likelihood of a major change in therapy increased with worsening disease activity. The clinical variables assessed were more strongly associated with change in therapy in patients with worsening of disease. Clinical disease activity measures are highly associated with the decision to initiate major changes. Future work could further add value of administrative variables. This work emphasizes the need for methods to systematically collect and utilize clinical disease activity measurements, particularly longitudinally, to improve the treat-to-target strategy.

Acknowledgements: Work Sponsored by VA Specialty Care Centers of Innova-
Background: Factors predictive of relapse need to be identified to aid therapy withdrawal decisions for patients with RA achieving remission with treatment. Aims: To evaluate: MRI, HAQ-DI and DAS28 in patients prior to drug withdrawal. Methods: A total of 172 patients achieving DAS28 remission (DAS28 [CRP] <2.6) at Month 12 in any treatment group were included in the analysis. Numbers of patients who relapsed at Month 18 and Month 24 were 100 and 113, respectively. Of the patient characteristics, disease activity and imaging factors analysed at Month 12, only MRI synovitis, erosion and oedema scores, as well as HAQ-DI scores, were significantly associated (p<0.05) with relapse status at both Month 18 and Month 24 (Table).

Conclusions: MRI and HAQ-DI scores in patients in DAS28 remission predicted relapses following treatment withdrawal decisions for patients with RA achieving remission with treatment.

Objectives: Evaluate the feasibility of a simple clinical joint damage score and describe the increment over time in RA patients with varying disease duration.

Methods: Cross-sectional study in all patients with a clinical diagnosis of RA visiting the outpatient clinic in 2015 and 2016. Rheumatologists and nurses from the outpatient department of a large regional hospital received a single training to perform the RAAD score. Scores of 0 (no damage), 1 (mild) or 2 (severe: ankylosis, luxation or joint surgery) were assigned to 35 joints (maximum score: 70) with a disease activity score, and stored in the electronic patient record system. Baseline data including ACR 2010 criteria were also registered.

Results: In 1007 (67.3%) of 1496 RA patients seen over 2 years RAAD-scores were performed. 652 (84.7%) were female, average age (SD, range) was 62.6 (13.1, 19–95), disease duration 9.9 (9.6, 0–65) years. Rheumatoid factor and ACPR were positive in 70.6% and 70.3% respectively. RAAD scores related to disease duration illustrate that at disease onset 86%, and after 20 years 37% of the patients has no joint damage (Table). Distribution over joints shows the classical predominance of damage in MCP, PIP and MTP joints (Image). Structural damage in shoulders or elbows was present in 8.3% and 12.5%, in knees and hips in 10.3% each. Despite current treatment strategies, irreversible joint damage of more than 5 joints is present in 6.3% within 10 years.

Conclusions: Clinical assessment of joint damage is a feasible parameter of long term outcome in RA. Reflecting overall joint damage, the RAAD-score provides a broader view than radiographic scoring of hands and feet and is easy to apply in routine care. Given the slow increase a single assessment per 5 years may suffice to compare structural joint damage across cohorts of patients.

SUBCLINICAL CENTRAL NERVOUS SYSTEM DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS: DISEASE ACTIVITY AND CYTOKINES

I. Tekeço˘glu, S. Sa˘g, A. Kamanli, M.S. Sa˘g, K. Nas. Department of Physical Medicine and Rehabilitation, Rheumatology, Faculty of Medicine, Sakarya University, Sakarya, Turkey, sakarya, Turkey

Background: We aimed in this study to investigate blood-brain barrier (BBB) dysfunction in RA patients who had no neurological symptoms, and were receiving synthetic DMARD treatment.

Objectives: We investigated correlations between cranial MRI images and brain specific proteins (S100 Beta, GFAP), cytokines (IL-1 beta, IL-17) in plasma which had important roles in disease activity.

Methods: In our study, 57 patients (46 females and 11 males) were included in RA group, and 34 patients (24 females and 10 males) in the control group. All of RA patients were receiving synthetic DMARD treatment. Demographic characteristics of all patients were recorded. Disease activity was evaluated by using DAS-28. Mini-mental test (MMT) was used for evaluation of cognitive functions, and Fazekas scale was used to evaluate cranial MR lesions. S100 beta, GFAP, claudin, IL-17, and IL-1 beta levels were measured in peripheral blood of both groups.

Results: Demographic characteristics were similar between the groups, and there was no statistically significant difference in gender, age, and body mass index (BMI) between patient and control groups (p<0.05). S100 beta, and GFAP levels were significantly higher in RA group (p<0.05). No difference was determined in hypointense lesions diagnosed in cranial MR between patient and control groups (p>0.05). There were positive correlations between IL-17, S100 beta and GFAP, and IL-1 beta and S100 beta.

Conclusions: In our study, we have shown that blood-brain barrier may be damaged subclinically in RA patients, brain specific proteins related to BBB dysfunction may be increased in the peripheral blood, and BBB dysfunction may be related to cytokines which play an important role in disease activity. In conclusion, cytokines which circulate in the peripheral blood in RA may cause subclinical BBB damage. Further large scale studies with long-term follow-up are required which will support this hypothesis.

THU0109

UPDATED ESTIMATION OF THE EQSD QUALITY OF LIFE QUESTIONNAIRE UTILITY VALUES THROUGH HAQ-DI MAPPING FOR SPAIN

I. Gorostiza 1, L. Ansola 2, E. Galindez 3, 1 Research Unit; 2 Research Unit; 3Rheumatology, H. Universitario Basurto, Vizcaya, Spain

Background: Rheumatoid arthritis (RA) deeply affects the quality of life (QoL) of patients. The preferred approach to evaluate treatment efficiency is to value health as patient preferences known as utilities, and subsequently, calculate Quality-Adjusted Life Years gained. A new 5-level of severity EQSD has recently released for Spain (Ramusio et al, Ann Rheum Dis 2016:75:1063–7). Although OQL questionnaires are not of routine use in clinical practice, it is possible to estimate it using the Health Assessment Questionnaire Disability Index (HAQ-DI)

Objectives: To develop a function that allows the estimation of EQSD-5L utility values from HAQ-DI updated to the newest proposed tariff for Spain

DHU-0109
Methods: Patients with RA from two teaching hospitals, participating in a prospective observational study completed the HAQ-DI and EQ-5D-5L at 0–6–12 month follow-up visits. Inclusion criteria: ACR RA diagnosed patients, on biologic treatment and whose disease activity remained stable at least for 3 months. EQ-5D-5L is a standardized, generic instrument for describing and valuing health and is described in a five-dimensional descriptive system (mobility, self-care, usual activities, pain/discomfort and anxiety/depression) and a visual analogue scale. A country-specific tariff converts patient’s answer to a 0–1 (full health) utility index. HAQ-DI is a self-completed questionnaire used to assess the functional ability using 20 items, distributed across 8 dimensions and resulting in a four-level disability index. REM duration has been shown to affect structural progression.

Results: Participants were 77 patients. Mean (SD) age was 57.0 (12.9), 87% women, at diagnosis 13.7 (7.3), mean DAS28 2.72 (1.00) and HAQ-DI 0.77 (0.60). Baseline EQ-5D index: 0.786 (0.182). All the OLS estimation models resulted in the interval limits defined by the index, so Tobit models were not considered. Considering the linear model we obtained the best results with the HAQ-DI term and its third power: logit(EQ_01) = 2.5821 − 1.1165 * HAQ (AIC = 444.4; MAE = 0.0691; RMSE = 0.0958). Considering the AIC and the residuals together, we obtained the best fitting model with beta regression, with neither age nor sex.

Conclusions: So far, only a utility function using HAQ-DI and an old EQ-5D-3L version was available for Spain (Carreño, 2011). This updated utility function can be used as a practical approach to predict RA patients’ QoL and EQ-5D utility score for Spain when clinicians/researchers need them for clinical practice or cost-effectiveness analyses and generic QoL measurements are not available.

THU0110 THE IMPORTANCE OF SUSTAINED REMISSION FOR LONGTERM OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS

1Medical Univ of Vienna, Vienna, Austria; 2Univ of Geneva, Geneva, Switzerland; 3Leeds Inst of Rheumatic & Musculoskeletal Medicine, Leeds, United Kingdom; 4AbbVie, Chicago, IL; 5Univ of California, San Diego, CA, United States

Background: In patients (pts) with rheumatoid arthritis (RA), the long-term impact of sustained versus (vs) transient clinical remission (REM) has not been assessed thoroughly, although REM duration has been shown to affect structural outcomes. The relationship of different definitions of clinical remission with functional and structural integrity has not been assessed.

Objectives: To explore the importance of sustained REM or disease control for long-term outcomes, and assess various definitions of REM in adalimumab (ADA) long-term trials.

Methods: Data are from 2 trials of ADA in early RA pts; In PREMIER, pts received ADA, methotrexate (MTX) or ADA+MTX for 2 years (yrs), after which they could enter an open label (OL) period for upto 8 yrs. In OPTIMA, pts received ADA+MTX or placebo (PBO) +MTX for 26 weeks (wks). Based on whether or not pts achieved DAS28-CRP <2.6 at 26 wks, pts were assessed. Analysis was continued on PBO+MTX, ADA+MTX or OL ADA+MTX until Wk 78. For this analysis, non-sustained REM/disease control was defined as meeting one of the following at 6 months but not yr: DAS28-CRP >2.6; simplified disease activity index (SDAI) >3.3; clinical disease activity index (CDAI) >2.8. Sustained REM/disease control was defined as meeting these criteria at both months 6 and 1 yr. The mean change from baseline in health assessment questionnaire-disability index (△HAQ-DI), or modified total Sharp score (△mTSS), and the number of pts without clinical worsening of HAQ-DI (△<0.22) were assessed over 78 wks for OPTIMA, or 5 yrs for PREMIER. NRI and LOCF were used for binary and continuous variables, respectively.

Results: In OPTIMA, by any of the REM criteria, pts in sustained REM had larger mean △HAQ-DI over time (Fig 1A) vs pts in non-sustained REM. Pts with non-sustained DAS28-CRP >2.6 vs non-sustained CDAI REM had numerically smaller mean △mTSS at Wk 52. Over time, more pts in sustained vs non-sustained REM using DAS28-CRP >2.6 (but not CDAI or SDAI criteria) did not have clinical worsening of HAQ-DI, possibly due to more suppression of inflammatory components upon achieving CDAI REM but not DAS28-CRP <2.6 in these early RA pts (Fig 1B). At Wk 78, △mTSS at Wk 78 was smaller for pts in sustained vs non-sustained REM using DAS28-CRP >2.6, and similar for sustained and non-sustained CDAI REM (Fig 1C). Somewhat fewer pts at Wk 78 may have contributed to some variability. Trends were similar in PREMIER (not shown).

Conclusions: Pts who were in sustained disease control/REM had better clinical, functional and radiographic outcomes over the long-term, vs pts in a
Stress and depression are common in patients with inflammatory polyarthritis (IP). There is little research on long-term patterns of depression and stress or how these variables, disability and disease activity, interact with each other. 

Objectives: To describe the natural history of stress and depression over five years and to assess the association of baseline, one year prior and current disease activity, disability and pain with longitudinal stress and depression.

Methods: Patients recruited to the Norfolk Arthritis Register (NOAR) (inclusion criteria: ≥2 swollen joints for ≥4 weeks) from 2005–2008 were included in this analysis. Demographics, medication use, 50 swollen/tender joint counts (SJC51/TJC51), pain visual analogue scale, HAQ, comorbidities and the Arthritis Impact Measurement Scales 2 (AIM2S) depression and stress subscales (range 0–1; high score = worse health status) were collected at baseline and years 1, 2, 3 and 4. RF, anti-cyclic citrullinated peptide antibodies (anti-CCP2) and C-reactive protein (CRP) were measured in baseline blood samples. ACR/EULAR 2010 RA criteria were applied to baseline characteristics. Depression and stress over five years were described using descriptive statistics. Multivariate random effects models were applied to assess the association of baseline disease activity (SJC51/TJC51), pain and depression with disease activity and stress over time adjusting for baseline age, gender, RF, anti-CCP2, CRP, sDMARD use, comorbidities, depression and stress. Similar methods were used to assess one year prior and current disease activity, pain and disability’s association with stress and depression. Missing data were imputed using multiple imputation.

Results: 509 patients were included (median (IQR) age: 57 (45, 68) years; 321 (63.1%) female; 305 (59.9%) ACR/EULAR RA). Baseline median (IQR) depression and stress were 2.5 (1.5, 4.5) and 4.0 (2.5, 5.5) respectively and remained constant over five years. Baseline SJC51, TJC51, pain and HAQ were not independently associated with depression or stress over five years. Current HAQ and pain, but not SJC51/TJC51, were independently associated with depression and stress (per unit increase in HAQ: depression β 0.83, 95% CI 0.69, 0.97; stress β 0.76, 95% CI 0.61, 0.90; per 1cm increase in pain: depression β 0.09, 95% CI 0.06, 0.12; stress β 0.09, 95% CI 0.05, 0.12). Higher HAQ was independently associated with increased depression and stress one assessment later (per unit increase in HAQ: depression β 0.21, 95% CI 0.09, 0.32; stress β 0.21, 95% CI 0.10, 0.33) but not pain, SJC51 or TJC51.

Conclusions: There were no associations between measures of disease activity and depression or stress. Prospectively higher HAQ scores were associated with worse psychological health a year later. This may have implications for holistic management of IP.

THU0113

SERUM CALPROTECTIN MAY REFLECT INFLAMMATORY ACTIVITY IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS DESPITE NORMAL C-REACTIVE PROTEIN

J. Hurnakova1, H. Hulejova1, J. Zavada1, M. Komar2, L. Andres Cerezo1, H. Mann1, J. Vencovsky1, K. Pavelka1, L. Senolt1, 1Institute of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic; 2Department of Methodology, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

Background: About a half of patients with rheumatoid arthritis (RA) have normal or low C-reactive protein (CRP) levels. Serum calprotectin is a promising and probably more specific biomarker of disease activity than conventionally used acute phase reactants.

Objectives: The aim of this study was to analyse levels of serum calprotectin in RA patients with clinically active disease and with low CRP (<10 mg/L).

Methods: A total of 160 RA patients and 32 healthy subjects were enrolled in this study. All patients underwent clinical examination (DAS28). The levels of calprotectin were analysed in patients with moderate to high disease activity with low CRP levels and in healthy subjects. The discriminatory capacity of calprotectin was assessed using ROC curves.

Results: Out of all RA patients, 74/160 (46.3%) had low CRP and were in remission or had low activity at the same time. However, 51/160 (32%) had low CRP levels despite moderate to high disease activity according to DAS28. In these patients, calprotectin levels were significantly higher compared with low CRP in remission or with low disease activity at the same time (mean 2.7±1.5 vs. 2.1±1.2 μg/mL, p=0.043) and differed from that in healthy subjects (mean 2.7±1.5 vs. 1.9±1.2 μg/mL, p=0.011) (Figure 1). The discriminatory capacity for calprotectin to distinguish clinically active vs. inactive patients in spite of low CRP

Conclusions: RA patients with antibodies to citrullinated peptides only have lower baseline erosions and less radiographic progression over 12m compared to those with a wider autoantibody repertoire. Baseline differences in erosion suggest that these antibodies may be pathogenic during the pre-RA disease process. Radiographic progression increases with autoantibody repertoire suggesting ongoing immune activation.

EFFECTS OF SMOKING ON BARICITINIB EFFICACY IN RA patients where CRP fails to do so.

References:

DOI: 10.1136/annrheumdis-2017-eular.1341

THU0114 EFFECTS OF SMOKING ON BARICITINIB EFFICACY IN PATIENTS WITH RHEUMATOID ARTHRITIS: POOLED ANALYSIS FROM TWO PHASE 3 CLINICAL TRIALS

J. Curtis1, P. Emery2, G. Burmester3, V. Arora4, J. Alam4, D. Muram4, L. Klareskog5, University of Alabama at Birmingham, Birmingham, United States; 2Leeds MSK Biomed/Chapel Allerton Hospital, Leeds, United Kingdom; 3Universitätsklinikum Charité, Berlin, Germany; 4Eli Lilly and Company, Indianapolis, United States; 5Karolinska Institutet, Stockholm, Sweden

Background: The efficacy of some rheumatoid arthritis (RA) therapies is reduced among patients who are smokers.

Objectives: This post-hoc analysis of two phase 3 studies assessed the effects of patient smoking status on the response to baricitinib treatment in patients with RA.

Methods: In RA-BEAM (NCT01710358), patients with inadequate response to methotrexate were randomized to placebo once-daily (QD) (N=488), baricitinib 4 mg QD (N=487), or adalimumab 40 mg biweekly (N=330). In RA-BUILD (NCT01721057), patients with inadequate response to conventional synthetic disease modifying antirheumatic drugs (csDMARDs) were randomized to placebo (N=228) or baricitinib (2 mg, N=229; or 4 mg, N=227) QD. Patients continued background csDMARD therapy in both studies. This post-hoc analysis was conducted in the placebo (N=716) and baricitinib 4 mg (N=714) patients. Patient-reported smoking status was categorized as current smokers or non-smokers (non-smokers).

Results: Among 1,430 evaluable patients who received placebo or baricitinib 4 mg, 290 (20.3%) were smokers. Smoking status at baseline did not affect the clinical outcomes of treatment with baricitinib for 24 weeks; smokers who received placebo were numerically less likely than non-smokers receiving placebo to achieve most clinical outcomes (Table). Baricitinib’s effect on modified total Sharp score was more pronounced among nonsmokers (interaction p-value =0.07). ACR20/50/70≥20%, 50%, and 70% improvement in American College of Rheumatology criteria; CDAI=Clinical Disease Activity Index; DAS28-hsCRP=Disease Activity Score 28-high sensitivity C-reactive protein; HAQ-DI=Health Assessment Questionnaire-Disability Index; mTSS=modified total Sharp score; SDAI=Simple Disease Activity Index.

Conclusions: This analysis of smokers and non-smokers in two RA trials demonstrated that the beneficial effect of baricitinib treatment versus placebo was similar on all clinical endpoints, but may differ for structural damage progression.

Rilski, Sofia, Bulgaria

Background: Vitamin D (25(OH)D) deficiency seems a distinct risk factor influencing prevalence and severity of several autoimmune diseases. Several studies suggest that low serum concentrations of vitamin D are frequent in rheumatoid arthritis (RA) patients, and an inverse relationship exists between several countries. Vitamin D serum concentrations negatively correlate with the clinimetric indexes for disease activity, disability and quality of life in the present cohort of RA European patients.

THU0117 INDEPENDENT ASSOCIATIONS OF DISEASE CHARACTERISTICS AND CARDIOVASCULAR RISK FACTORS WITH LEFT VENTRICULAR DIASTOLIC FUNCTION IN RHEUMATOID ARTHRITIS

A.M. Milten 1, L. Mokotedi 2, S. Gunter 3, C. Robinson 4, G.R. Norton 5, A.J. Woodwiss 6, L. Tsang 7, P.H. Dessein 8, 9 Cardiovascular Pathophysiology and Genomic Research Unit, School of Physiology, University of the Witwatersrand, Parktown, Johannesburg, South Africa; 2Rheumatology Division, Universitair Hospital Brussel, Brussels, Belgium

Background: Heart failure contributes to the excess mortality experienced by patients with rheumatoid arthritis (RA) (1). Impaired diastolic function represents a pre-clinical cardiac alteration which is highly predictive of cardiac events and often progresses to heart failure. Diastolic dysfunction is the most common cause of heart failure in patients with a preserved ejection fraction. Whereas RA is associated with an increased prevalence of impaired diastolic function (2,3), the pathophysiological mechanisms that mediate this comorbidity await further elucidation.

Objectives: This study aimed to identify potential determinants of ventricular (LV) diastolic function in patients with RA.

Methods: LV diastolic function was determined in 176 patients with RA: 9 patients had established cardiovascular disease. LV diastolic function was determined by echocardiography from the ratio of early-to-late transmitral blood flow velocity (E/A), the ratio of E to the mean of the lateral and septal wall myocardial tissue lengthening at the mitral annulus (e’/E’/e’), and the lateral e’. Relationships of comprehensively evaluated traditional cardiovascular risk factors and RA characteristics with markers of LV diastolic function were determined in confounder adjusted multivariate regression models.

Results: Disease duration (partial r=0.23, p=0.00), rheumatoid factor status (partial r=0.16, p=0.04) and erythrocyte sedimentation rate (partial r=0.16, p=0.04) were associated with lower logarithmically transformed (log) E/A. Upon further adjustment for left ventricular mass index or relative wall thickness, these relationships remained significant (p<0.05). Diastolic blood pressure was related to log E’ (partial r=0.16, p=0.04); this association was no longer significant after additional adjustment for left ventricular mass index (p=0.06) or relative wall thickness (p=0.06). Disease duration (partial r=0.32, p=0.00), waist-to-hip ratio (partial r=0.29, p=0.00) and triglycerides (partial r=0.17, p=0.03) were related to log lateral e’. These relationships remained significant upon further adjustment for left ventricular mass index (for all p=0.00) or relative wall thickness (for all p=0.00). In sensitivity analysis among RA patients without established cardiovascular disease (n=167), the results were not materially altered.

Conclusions: Modifiable traditional cardiovascular disease risk factor and disease characteristics are consistently associated left ventricular diastolic function in RA.

WHAT IS THE ROLE OF STEROIDS IN INDUCING DIABETES MELLITUS IN PATIENTS WITH RHEUMATOID ARTHRITIS? AN OBSERVATIONAL COHORT STUDY

A. Emamifar 1, R. Hvid Larsen 2, R. Asmussen Andreasen 1, I.M. Jensen Hansen 1,2, 3. Rheumatology; 2. Medicine, Svendborg Hospital, Odense University Hospital, Svendborg; 3. DANBIO, Copenhagen, Denmark

Background: Patients with Rheumatoid Arthritis (RA) are at increased risk of Diabetes Mellitus (DM) probably due to immune system activation or RA treatment with steroids.[1] However the pathology of DM in RA is not fully understood.

Objectives: To define the prevalence of DM in our RA patients population. Furthermore, to clarify the role of steroid treatment to induce DM in the RA patients.

Methods: All patients with diagnosis of RA who were registered in Danish Danbio Registry at time of study, Nov 2016, were included. To find the concurrent DM, patients’ medical records including past medical history and lab tests (Hemoglobin A1c and Blood Sugar) were reviewed. In addition, year of DM as well as RA diagnoses were extracted from Fyns Diabetes Database and Danbio respectively to the extent that data were available. Patients’ drug histories were searched for information about steroid treatment if diagnosis of RA was made prior to diagnosis of DM.

Results: Of 1035 patients with diagnosis of RA, 104 (10%) patients had DM. Of 104 RA patients with DM, data regarding the year of diagnosis for both RA and DM was found in 55 patients which of them 15 patients were diagnosed with RA before DM, one patient was diagnosed with both DM and RA at the same year and 39 patients were diagnosed with RA after DM. However, only one patient, of those who were firstly diagnosed with RA, was prescribed prednisolone during the time period between diagnoses of RA and thereafter DM. Of 15 patients with prior diagnosis of RA to DM, 13 patients were diagnosed according to 1987 classification criteria (Old) for RA and 2 patients were diagnosed according to 2010 classification criteria (New). Out of 39 patients where DM was diagnosed before RA, 10 patients was diagnosed based on the old criteria and 29 patients was diagnosed based on the new RA criteria [Fig 1A and 1B]. Patients with firstly diagnosed DM were more often diagnosed according to the new RA criteria and, on the contrary, patients with latterly diagnosed DM were more often diagnosed with old RA criteria (p<0.001).

Conclusions: The prevalence of DM in this RA population (10%) was about twice of Danish population (5.7%). The role of steroid treatment in which to what extent increases the risk of DM is not clear, however in this study it was negligible, why we propose that the pathology of DM in RA patients most importantly deals with the role of immune system activation namely Tumor Necrosis Factor alpha and not the treatment modality i.e. steroids.

THU0119 ASSESSMENT OF RHEUMATOID CACHEXIA AND ITS ASSOCIATION WITH CLINICAL, FUNCTIONAL AND THERAPEUTIC OUTCOMES

A.L.D. Mora 1, V. Hax 1, R.C.E. Santos 2, T. Fighera 3, W. Kisaki 2, C.V. Brenol 1, R.M. Xavier 1. 1Rheumatology Service, Hospital de Clinicas de Porto Alegre; 2Universidade Federal do Rio Grande do Sul; 3Endocrinology Service, Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil

Background: Rheumatoid arthritis (RA) is a chronic and inflammatory disease that besides articular symptoms leads to loss of muscle mass in presence of stable or increased fat mass (FM), condition defined as rheumatoid cachexia (RC), associated with a worse prognosis, but it is still overlooked in clinical practice.

Objectives: To evaluate the prevalence of rheumatoid cachexia (RC) in patients with rheumatoid arthritis (RA) and determine its correlation with the features of RA, the level of physical activity and with the current therapy.

Methods: Ninety one RA patients in a cross-sectional study underwent total body dual-energy x-ray absorptiometry (DXA) for measurement of total and regional fat mass index (FM; Kg/m²), lean mass index (LMI; Kg/m²), bone mineral content (BMC; Kg/m²) and fat free mass index (FFMI; Kg/m²) to assess the prevalence of RC. The associations of measures of body composition with RA features – age, diagnosis time, Health Assessment Questionnaire (HAQ), Disease Activity Score in 28 joints (DAS 28), C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) – level of physical activity (measured by International Physical Activity Questionnaire – IPAQ) and current therapy were explored.

Results: Mean age was 56.8±7.3, disease duration 9 years (3 – 18), DAS28 3.65±1.32, HAQ 1.12 (0.25 – 1.87) and use of biological agents was 25 months (17.8 – 52.5). 17% of the patients had FMI below the 10th percentile and FM above the 25th percentile of a reference population and 33% of the patients had FFMI below the 25th percentile and FMI above the 50th percentile, condition known as RC, according to the more recently used definitions. FMFI correlated negatively only with age (r=-0.219; p=0.037) and disease duration (r=-0.214; p=0.042). FMFI correlated positively with CRP (r=0.229; p=0.029) and ESF (r=0.235; p=0.025), DAS 28 (r=0.273; p=0.026) and HAQ (r=0.297; p=0.004). Among patients under biologics, 3.8% (n=1) had RC versus 23% (n=15) of those not taking biologics (p=0.033), according to the stricter definition.

Conclusions: The prevalence of RC was considerable and deserves additional research. Besides that, patients under biological therapy had lower prevalence of RC, suggesting a protective effect of biological agents.

THU0120 PREVALENCE OF CHRONIC KIDNEY DISEASE IN REUMATOID ARTHRITIS PATIENTS AND IT’S ASSOCIATION WITH MULTIMORBIDITY

A.Y. Zakharova 1, E. Galushko 1, Y. Uskova 2, A. Gordeev 1, 1Nasonova Research Institute of Rheumatology, MOSCOW, RUSSIA; 2 Central Clinical Hospital of Russian President Administration, Moscow, Russian Federation

Background: RA pts commonly present with multiple concurrent chronic disease. The great importance is attached to cardiovascular diseases due to their proven association with high frequency of morbidity and death. Much attention has been paid to the potential role of high-grade systemic inflammation and classical modifiable CVD risk factors – such as hypertension, dyslipidaemia, insulin resistance/metabolic syndrome, obesity, physical inactivity and smoking. A recent meta-analysis has shown that renal impairment is a strong independent cardiovascular risk factor in the general population [1].

Objectives: To assess the prevalence and clinical presentations of CKD in RA pts (ACR/EULAR 2010y.) and relate with pts multimorbid background. RA activity and duration.

Methods: 209 RA pts (F-70.6%, mean age 67,0±11,3y), admitted to rheumatology division from 1999 to 2015, were included into analysis. RA duration was 19

Conclusions: The prevalence of CKD in this RA population (10%) was about twice of Danish population (5.7%). The role of steroid treatment in which to what extent increases the risk of CKD is not clear, however in this study it was negligible, why we propose that the pathology of CKD in RA patients most importantly deals with the role of immune system activation namely Tumor Necrosis Factor alpha and not the treatment modality i.e. steroids.

DOI: 10.1136/annrheumdis-2017-eular.5167
Conclusions: The results confirm and expand prior knowledge that MSUS can represent a reliable tool for the diagnosis of CTS [1]. However, its role in the diagnosis of CTS in patients with RA has been poorly investigated.

Objectives: The aim of this study is to evaluate the US findings at carpal tunnel level in a cohort of patients with RA, focusing on those with a clinical diagnosis of CTS.

Methods: Patients with RA fulfilling the ACR/EULAR 2010 classification criteria were consecutively enrolled. The diagnosis of CTS was made according to American Academy of Neurology practice parameter for CTS [2]. The MSUS assessment was carried out using a MyLab Twice (Esaote SPA) US system American Academy of Neurology practice parameter for CTS [2].

The segmentation procedure is fully automated but allows for manual corrections of wrongly segmented areas. Multimodal registration of the muscle segmentation masks to MR Dixon Fat Fraction images was used for fat quantification. Outcome parameters were absolute hand and muscle volume ($V_{abs}$ resp. $V_{rel}$), relative muscle volume ($V_{rel}$, resp. $V_{rel}$) and absolute and relative fat content ($V_{fat}$ resp. $V_{fat}$).

Student’s tests were performed for gender discrimination. Linear regression was used to model dependence on predictors BMI, RA disease duration, DMARD treatment duration, HAQ, DAS28, RF, ESR and CRP after age adjustment. Dixon sequences were not available for all patients, therefore fat analysis could only be done in 17 females.

Results: $V_{fat}$ in males was significantly higher than in females (p<0.001, means: 63 cm$^3$ vs. 29 cm$^3$). Similar results were obtained for $V_{rel}$ (p<0.001, means: 243 cm$^3$ vs. 163 cm$^3$) and $V_{rel}$ (p=0.02, means: 0.256 vs. 0.239). The table shows the results of the linear regression analysis for significant predictors of males and females, respectively. The figure shows age dependence of $V_{fat}$ and $V_{fat}$.

THU0122 QUANTITATIVE ASSESSMENT AND ANALYSIS OF HAND MUSCLE VOLUME

A. Friederberger1, C. Figueiredo2, O. Muskeyo1, A. Grimm1, I. D’Oliveira2, T. Blaüder2, J. Rech2, O. Chaudry1, M. Uder2, G. Schett1, K. Engelke1

1Institute of Medical Physics, University Erlangen-Nuremberg; 2Department of Medicine 3, University Erlangen-Nuremberg; 3Radiological Institute, University Hospital Erlangen-Nuremberg, Erlangen, Germany

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by bone, cartilage and muscle loss. While bone and cartilage damage have been extensively studied in the past, the effects of RA on volume and composition of hand muscles have not yet been studied. This situation is surprising, since visible hand muscle atrophy is a hallmark of RA and quantification of muscle composition is of growing interest.

Objectives: Quantitative assessment of hand muscle volume and fat using MRI.

Methods: A random forest based method was used to segment hand muscle in T1 weighted MR scans of 76 RA patients (37 males, 26–87 years, mean 61 years). The segmentation procedure is fully automated but allows for manual corrections of wrongly segmented areas. Multimodal registration of the muscle segmentation masks to MR Dixon Fat Fraction images was used for fat quantification. Outcome parameters were absolute hand and muscle volume ($V_{abs}$ resp. $V_{rel}$), relative muscle volume ($V_{rel}$, resp. $V_{rel}$) and absolute and relative fat content ($V_{fat}$ resp. $V_{fat}$).

Student’s tests were performed for gender discrimination. Linear regression was used to model dependence on predictors BMI, RA disease duration, DMARD treatment duration, HAQ, DAS28, RF, ESR and CRP after age adjustment. Dixon sequences were not available for all patients, therefore fat analysis could only be done in 17 females.

Results: $V_{fat}$ in males was significantly higher than in females (p<0.001, means: 63 cm$^3$ vs. 29 cm$^3$). Similar results were obtained for $V_{rel}$ (p<0.001, means: 243 cm$^3$ vs. 163 cm$^3$) and $V_{rel}$ (p=0.02, means: 0.256 vs. 0.239). The table shows the results of the linear regression analysis for significant predictors of males and females, respectively. The figure shows age dependence of $V_{fat}$ and $V_{fat}$.

NEW PERSPECTIVES IN DIAGNOSIS OF INTERSTITIAL LUNG DISEASE RELATED TO RHEUMATOID ARTHRITIS. VALIDATION STUDY OF AN ELECTRONIC STETHOSCOPE AND AD HOC SOFTWARE FOR DETECTION OF PULMONARY CRACKLES

A. Manfredi 1, M. Sebastiani 1, G. Cassone 1, A.L. Fedele 2, V. Venerito 3, P. Gustavsson 1, P. Wiebert 1, C. Bengtsson 1, L. Klareskog 2, P. Aldercreutz 1, A. Ilar 1, P. Gustavsson 1, P. Wiebert 1, C. Bengtsson 1, L. Klareskog 2, P. Aldercreutz 1, A. Ilar 1

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by synovial joint swelling and tenderness, secondary to the immune-system dysfunction, often complicated by extra-articular manifestations. Among them, lung involvement is very frequent and interstitial lung disease (ILD) represents one of the deleterious complications of RA with impact on both therapeutic approach and overall prognosis. Nevertheless, diagnosis of ILD often remains missing or delayed.

Objectives: To preliminarily evaluate the predictive value of pulmonary sound recorded by an electronic stethoscope (ES) and elaborated by an ad hoc software in identification of RA-ILD diagnosed by mean of high resolution computed tomography (HRCT) in a multicenter study.

Methods: RA patients who underwent HRCT in the last 12 months were enrolled. They were all auscultated with the ES (Littmann 3200 TM 3M, USA), bilaterally, at dorsal level, in at least 3 pulmonary fields (medium and basal). All tracks recorded were analyzed by a suitably developed software capable of recognizing pathological crackles in lung sounds. Results were compared with radiological findings detected in a blind manner by an expert radiologist.

Results: One hundred and six RA patients were enrolled (M/F: 1/2.5, mean age 68.7±10.3); among them 45 (42.5%) showed ILD at HRCT. Three patients were excluded because of diagnosis of another ILD. Despite preliminary these data suggest an important role of ES in clinical practice for an early diagnosis of ILD in RA patients and a significant reduction of inappropriate prescription of HRCT. Since very different types of ILD can occur in course of RA, with different radiologic features and localization, proper development of the measurement setup (ES and ad hoc software for the detection of PO) could further increase its predictive value, in particular to avoid incorrect diagnosis of ILD. The algorithm showed a sensitivity and specificity of 72.1% and 84.4%, respectively and a positive/negative predictive value of 89.1% and 63.8%, respectively.

Conclusions: Despite preliminary, these data suggest an important role of ES in clinical practice for an early diagnosis of ILD in RA patients and a significant reduction of inappropriate prescription of HRCT. Since very different types of ILD can occur in course of RA, with different radiologic features and localization, proper development of the measurement setup (ES and ad hoc software for the detection of PO) could further increase its predictive value, in particular to avoid incorrect diagnosis of ILD. The algorithm showed a sensitivity and specificity of 72.1% and 84.4%, respectively and a positive/negative predictive value of 89.1% and 63.8%, respectively.

Acknowledgement: Airborne agents are considered important environmental triggers of rheumatoid arthritis (RA) among genetically susceptible individuals. Due to the known association between silica dust and RA, we wanted to study the association between RA and another silicate mineral: asbestos.

Objectives: The aim of this study was to estimate the risk of RA from ever occupational asbestos exposure as well as years with exposure among men and women.

Methods: The study base consisted of men and women living in Sweden from 1968 until 2012. RA patients were identified from the National Patient Register, the Swedish Rheumatology Register (SRR), the Swedish population-based nested-control study EIRA or the Swedish Prescribed Drug Register. We matched ten controls from the national population register per case on age, county and sex. Data on occupational histories were collected from the national population and housing censuses carried out in 1960, 1970, 1975, 1980 and 1990. A job-exposure matrix (JEM) containing historical exposure estimates from 1955–1995 to asbestos was applied to the study participants’ occupational histories. We used unconditional logistic regression to assess the odds ratios (ORs) and 95% confidence intervals (CIs) of RA associated with ever exposure and years of exposure to asbestos. ORs were adjusted to contextual dust, which was also generated from a JEM. One of the data sources (EIRA) contained self-reported information on potential confounders. Analyses on this data source were carried out to estimate the confounding effect from pack-years of cigarette smoking and alcohol use.

Results: 1,437 persons in 1 and 701 200 controls were included in the analysis. The proportion of participants who had ever worked with asbestos was 38% among male cases, 35% among male controls, 3% among female cases and 3% among female controls. Ever vs. never asbestos exposure resulted in an OR of 1.15 (95% CI: 1.13–1.17) among men and 1.00 (95% CI: 0.98–1.04) among women. The ORs decreased to 1.09 (95% CI: 1.07–1.12) and 1.00 (95% CI: 0.98–1.04) for men and women respectively after adjusting for silica exposure. Asbestos exposed men were more likely than women to have worked with asbestos for a longer period of time, but the risk of RA did not appear to increase with years with the exposure. Male participants with 30 or more years of asbestos exposure at work had an OR of 1.10 (1.02–1.19) after adjustment for silica exposure.

Conclusion: Asbestos exposure is associated with RA among men, and mainly the ACPA- RA subtype. The increased risk remained after adjustments for potential confounders.

PROGRESSION OF SUBCLINICAL ATHEROSCLEROSIS OVER ELEVEN YEARS IS INCREASED IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

A. Södergren 1, K. Karp 2, E. Lundström 1, T. Smedby 2, B. Möller 2, F. Ramstedt-Dahlgqvist 1, S. Karlsson 1, A. Thurfjell 1, M. Thomsen 3, S. Tarp 4, B. Langdahl 4, E. Hauge 4, A. de Thura 1, P. Dahlgren 1, A. Bengtsson 1, K. Olsson 1, S. Karlsson 1, A. Thurfjell 1, M. Thomsen 3, S. Tarp 4, B. Langdahl 4, E. Hauge 4, A. de

Background: Patients with rheumatoid arthritis (RA) have an increased mortality and morbidity due to cardiovascular disease (CVD).

Objectives: In this prospective follow up over eleven years, we investigated the relation to traditional CVD risk factors and inflammation, in patients with early RA compared to controls.

Methods: Patients from northern Sweden diagnosed with early RA are consecutively recruited into an ongoing prospective study. A subgroup aged 60 years (n=54) was consecutively included for ultrasound measurements of IMT of a. Carotis communis at inclusion (T0), and after 11 years (T11). 31 age-sex-matched controls were included. The patients were clinically assessed, SCORE, Reynolds Risk Score and Larsen score were calculated and blood samples drawn from all individuals at T0 and T11. Data and results presented in this abstract are preliminary.

Results: Patients with RA as well as controls had a significant aggravation in IMT over 11 years (0.52 at T0 and 0.68 at T11 in RA: p<0.001; 0.54 at T0 and 0.63 at T11 in controls; p<0.05; IMT in RA vs controls at T0 and at T11: p<0.05). The patients with RA had a significantly higher progression in IMT from T0 until T11 (0.16 vs 0.08, p<0.001). In simple linear regression analyses among RA-patients, the IMT at T11 was significantly associated with several variables at T0: age, systolic blood pressure, SCORE, Reynolds Risk Score, iPA, L-selectin (inversely), MCH, MCV and Larsen score. The progression in IMT over 11 years was associated with age and Larsen score at T0.

Conclusions: In this prospective study, the progression of sub-clinical atherosclerosis over 11 years was significantly higher in patients with RA than in controls. The IMT at T11 was associated with several traditional cardiovascular risk factors, as well as disease severity, at time of diagnosis.

THE EFFECT OF GLUCOCORTICOIDS ON BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

A.-B. Gränlund 1, M.D. Thomsen 3, S. Tarp 4, B. Langdahl 4, E. Hauge 4, A. de Thura 1, P. Dahlgren 1, A. Bengtsson 1, K. Olsson 1, S. Karlsson 1, A. Thurfjell 1, M. Thomsen 3, S. Tarp 4, B. Langdahl 4, E. Hauge 4, A. de

Background: The role of glucocorticoids (GCs) in the treatment of rheumatoid arthritis (RA) is widely debated. GCs stimulate bone resorption and impair bone formation (1). Inflammatory cytokines also stimulate bone resorption, and patients with RA have a high risk of osteoporosis (OP) and fragile fractures (2). However, in patients with RA, impairment of bone formation by GCs may be counter-balanced by reduced systemic inflammation and increased physical activity.

Objectives: This systematic review aims to assess the effect of oral prednisolone and prednisone on bone mineral density (BMD) in patients with RA analyzed in randomized, controlled trials (RCT).

Methods: We performed a systematic literature search and identified double-blinded RCTs comparing prednisolone or prednisone with placebo and measuring...
BMD dual-energy absorptiometry at baseline and at least once thereafter. Two authors independently reviewed references, extracted data and assessed risk of bias. We assessed quality of evidence using the GRADE methodology. Primary outcomes were mean change in BMD at the hip and lumbar spine. Secondary endpoints included RA disease activity and radiographic progression. Results: 30 studies. Studies differed regarding study population and intervention. Risk of bias was considered low for BMD outcomes. Data completeness was low in some studies. We found no statistically significant difference in change in BMD from 0 to 24 months neither at the lumbar spine (Standard Mean Difference (SMD) 0.02 (95% CI -0.16, 0.12)) nor at the hip [SMD 0.02 (95% CI -0.12, 0.16)]. Disease activity was significantly lower in the GC groups (mean difference in DAS28 -0.32 (95% CI -0.52, -0.11). Concomitant treatment of RA differed between studies, as did OP prophylaxis. However, sensitivity analyses excluding a study with different distribution of OP prophylaxis between GCs or placebos did not alter the estimates. Quality of evidence was rated moderate for BMD outcomes.

Conclusions: In this group of double-blinded RCT studies we found no difference in change in BMD in patients with RA who received GCs compared to those who received placebo. The interpretation of this is difficult as it challenges the well-established fact that GCs negatively impact BMD. However, our findings suggest that in a population with early RA, followed for two years, the dampening of inflammation as well as increased physical activity may outweigh the inherent effects of GCs. This concurs with our finding of lower disease activity in the groups receiving GCs.

Disclosure of Interest: None declared, D. Veltishchev: None declared, O. Seravina: 2 Ultrasound Department, Lugansk Clinical Regional Hospital, Lugansk, Ukraine

Background: Now it is proved that the leading reason for the decline in life expectancy in patients with rheumatoid arthritis (RA) are cardiovascular (CV) disease. The increase in CV risk in patients with RA is associated with increased progression of atherosclerotic vascular lesions. Autoimmune inflammatory process in RA affects the vascular endothelium contributing to the appearance of CV events in patients with RA. It is known that when SHTD levels increased levels of proinflammatory cytokines. Also, when there is an increase SHTD thickness complex intra-media (CIM).

Objectives: To study the characteristics of ultrasound dopplerography in patients with RA with SHTD.

Methods: The observation 139 patients with RA. The I group consisted of 91 patients with RA and SHTD, the II - 48 patients with RA without SHTD. Patients in group I and II did not differ significantly by age and duration of RA. Detection of endothelial dysfunction was performed using ultrasound dopplerography vessels in accordance with international guidelines.

Results: In the study of endothelial regulation of vascular tone in both groups of patients revealed the presence of disturbances, as determined signs of reduced function of SHTD patients with RA leads to a significant increase in the risk of developing CVD. This requires a more careful study of RA patients with SHTD.

THU0127 THE DYNAMICS OF MENTAL DISORDERS FREQUENCY IN COMPLEX DMARDs, BIOLOGICS AND ANTIDEPRESSANTS TREATMENT OF RHEUMATOID ARTHRITIS PATIENTS

A. Abramkin1, T. Lisitsyna1, D. Veltishchev2, O. Seravina2, O. Kovalevskaya2, E. Nasonov1. 1Nasonova Research Institute of Rheumatology; 2Moscow Research Institute of Psychiatry MoH, Moscow, Russian Federation

Background: mental disorders (MD) (anxiety/depressive (ADD) and cognitive (CD)) occur in rheumatoid arthritis (RA) patients (pts) very often, they are usually stress-related and, probably, have common pathogenesis chains with RA. In this connection the disease-modifying anti-rheumatic drugs (DMARDs) and biologics drugs treatment may be effective in ADD in RA-pts.

Objectives: to determine the frequency of MD dynamics during DMARDs, biologics and antidepressants treatment of RA-pts in prospective 5yrs study.

Methods: 128 RA-pts were enrolled in this study. All of them met the full ACR criteria. 86% RA-pts were women with a mean age of 47,4±10,0 (M±m) yrs. RA- activity was assessed by DAS28 and was high (5,25±0,70 (M±m)) in the beginning of the study. 67% RA-pts were taking prednisone (5±2,7 mg/day). 80% RA-pts were taking biologics and antidepressants treatment of RA-pts in prospective 5yrs study. Major depressive disorder (MDD) was found in 41(32%), minor depressive disorder (MinDD) – in 50 (39%) and anxiety disorders (AD) – in 30 (23,4%) of RA-pts.

Note: *p<0.05.

It is also a distinction between the two groups in terms of the thickness of the CIM (Z=9.7, p<0.001), exceeding in group II. Determined a significant decrease in the coefficient of sensitivity to endothelial shear stress (C) in patients with RA, who was in I group of 0.45 (0.34; 0.71), and in II - 0.26 (0.18; 0.46) that there was a statistical difference in this index between the groups of patients (Z=3.6, p<0.001) due to a significant reduction in patients of group II.

The performed analysis of variance indicated that there SHTD influence on the development of disorders of vascular endothelial function in motor RA patients. The SHTD presence in group II patients significantly affected the reduction EIVD, EIVD, C (H=13.8, p<0.001; H=14.5, p<0.001; H=10.2, p<0.001).

Conclusions: The analysis indicated the presence of influence SHTD on the development of disorders of vascular-motor endothelial function in RA patients. These data show that the presence SHTD patients with RA leads to a significant increase in the risk of developing CVD. This requires a more careful study of RA patients for early detection and correction of comorbidities that worsen the clinical course of RA.

CD8+CD28- T-lymphocytes are associated with subclinical atherosclerosis in patients with rheumatoid arthritis

B. Wahlin 1, A.E. Fath 2, K. Karp 1, K. Lejon 1, A. Södergren 1, S. Wållberg-Jonsson 1
1 Public health and clinical medicine/Rheumatology, Umeå University, Umeå, Umeå; 2 Rheumatology Unit, Department of Medicine at Solna, Karolinska institutet, Stockholm; 3 Surgical and Perioperative Sciences; 4 Clinical Microbiology, Immunology, Umeå University, Umeå, Sweden

Background: Patients with rheumatoid arthritis (RA) have an increased mortality and morbidity due to atherosclerotic vascular disease. We evaluated the association between subclinical atherosclerosis, markers of CD8+CD28- T-lymphocytes and T-lymphocytes expressing CX3CR1.

Patients and Methods: To study the association between subsets of T-lymphocytes, subclinical atherosclerosis assessed by intima-media thickness (IMT) and antibodies against CMV in patients with RA.

Results: The percentage of CD8+T-lymphocytes lacking the co-stimulatory molecule CD28 (CD8+CD28-) was significantly (standardized beta coefficient 0.39, p-value 0.018) associated with IMT at T11 in a linear regression model including T0 variables smoking, systolic blood pressure and cholesterol. No association with IMT was seen for CD4+CD8- T-lymphocytes. CX3CR1 was expressed in 71% of CD8+CD28- T-lymphocytes, compared with 8.2% of CD4+CD8- T-lymphocytes. The prevalence of immunoglobulin G seroconversion of CMV was 47/70 (67%), 42/66 (63%) and 34/56 (61%) at T0, T5 and T11, respectively. Patients with constantly positive CMV serologies (T0, T5 and T11) had a significantly higher percentage of CD8+CD28- T-lymphocytes, compared with CD4+CD8- T-lymphocytes expressing CX3CR1.

Also the proportion of cells expressing CX3CR1 was in both CD4+ and CD8+ T-lymphocytes associated with constantly positive serovars for CMV.

Conclusions: Subclinical atherosclerosis in patients with RA was associated with CD8+CD28- T-lymphocytes in a regression model adjusted for traditional cardiovascular risk factors. Positive serologies for CMV was associated with an increased proportion of CD8+CD28- T-lymphocytes and T-lymphocytes expressing CX3CR1.

Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease that can affect any joint in the body. Treatment options vary widely, and each patient's response to therapy is unique. The efficacy of a treatment can be assessed by monitoring the resolution of symptoms, improvements in physical function, or changes in disease activity measures. However, the mechanisms underlying these changes are not fully understood. It is believed that treating RA in its early stages can lead to better outcomes, but the optimal time for initiating therapy is uncertain. The goal of this study was to investigate the early response to sirukumab, a human monoclonal antibody that selectively binds to interleukin-6 (IL-6), a cytokine involved in the inflammatory process, in patients with RA.

Methods: This was a post-hoc analysis of two Phase III, randomized, double-blind, placebo-controlled trials evaluating efficacy and safety of sirukumab in the treatment of RA. The results of these trials were previously published.

Objectives: The main objective was to assess the early response to sirukumab in patients with RA. Early response was defined as the changes in treatment of premature and other CHD.

Results: Among 1235 RA patients recorded in the database, 12 (21%), 20 (35,1%) and 25 (43,9%) CHD patients, respectively. There was no statistical difference in treatment of premature and other CHD.

Conclusions: Our findings are consistent with previous results from a phase II RA study. Periperal anti-IL-6 cytokine treatment is associated with improvement in depressive symptoms in RA patients, possibly supporting a role for IL-6 dysfunction in depression.

References:

Background: Patients with rheumatoid arthritis (RA) are at increased risk of coronary heart disease (CHD) overall, as well as death from CHD. A direct impact of chronic inflammation on the vascular system, secondary effects of physical inactivity and some drugs used in the management of RA are shown as the reasons for the increase in this comorbidity.

Objectives: We aim to determine the frequency of CHD in the RA patients who receive biological agents.

Methods: Hacettepe University Biologic Registry (HUR-BIO) includes demographic and clinical data of patients treated with biological agent since 2005. By August 2016, 1235 RA patients were recorded in the database. Smoking status, comorbidities, current and previous treatments were analysed in 1000 patients. Disease activity was estimated by the 28-joint activity calculator (DAS28-ESR) and DAS28-CRP. Functional assessment was evaluated by the Health Assessment Questionnaire (HAQ). Premature CHD should be defined if chronic CHD or sudden death is documented in male younger than 55 years of age and in female younger than 65 years of age.

Results: Overall 1000 patients (79.8% female) were enrolled in this study. Mean age was 53,1±12,6 years old, mean disease duration was 12,3±9,3 years. CHD was detected in 57 (5,7%) patients and female/male was 38/19. Premature CHD was observed in 38 (66,7%) patients. CHD patients had more frequently male, older, higher classical risk factors, higher baseline ESR level and higher functional disability (Table). HAQ score also remained high in CHD group at last visit. Clinical course of RA, vascular risk factors, seropositivity, disease activity score and HAQ score were similar in the premature and other CHD group. Coronary artery stenting, coronary artery bypass surgery and medical treatment was applied in 12 (21%), 20 (35,1%) and 25 (43,9%) CHD patients, respectively. There was no statistical difference in treatment of premature and other CHD.

Conclusions: As a result of CHD were detected in 5,7% of RA patients who are receiving biological agents. Importantly, two third of these patients have
THU0132 IMMUNOGENICITY AND SAFETY OF 23-VALENT PNEUMOCOCCAL VACCINE FOR PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM 2-YEAR FOLLOW UP

Background: Comorbid infections have significant impact on morbidity and mortality, especially in autoimmune diseases. Prevention of infection is an integral part of supervision of these patients.

Objectives: To investigate immunogenicity and safety of 23-valent polysaccharide pneumococcal vaccine in patients with rheumatoid arthritis (RA) treated with drugs modifying anti rheumatic drugs (DMARDs) and biologic diseases modifying anti rheumatic drugs (bDMARDs) during the 2-year follow-up.

Methods: Out of 110 subjects (81 females (73.6%), 29 males (26.4%) aged 23–76 years) included into the study, 79 were RA patients and 31 were controls with a history of ≥2 episodes of lower respiratory tract infections (bronchitis, pneumonia). 52 patients with RA were on methotrexate (MTX), 14 were on leflunomide (LEF), 13 were on tumor necrosis factor alpha inhibitors (TNF-α) + MTX. One dose (0.5 ml) of 23-valent polysaccharide pneumococcal vaccine was administered subcutaneously without discontinuation of MTX/LEF or 28–30 days prior to initiation of TNF-α. Totally four study visits were preplanned: initial vaccination visit and 3 control visits in 1, 3 and 12 months after vaccination in 110 patients. 39 RA patients were followed up for 2 years (24 months). Routine evaluation during each visit included physical exams and laboratory tests. Levels of antibodies to pneumococcal capsular polysaccharide were measured using VacciYmeTM PCCpig 2 kit (The Binding Site Group Ltd, Birmingham, UK). Post-immunization response coefficient was calculated for each participant as the ratio of AB levels during visits II, III, IV and V to baseline AB level at Visit I.

Results: Not a single case of clinicoradiologically confirmed pneumonia was documented during the follow up period. Pronounced positive immune reaction after administration of the vaccine under investigation was documented in RA patients during different therapies, i.e., significant post-immunization response coefficient increase. There were 61% responders among RA patients and 70% responders among the controls during one-year follow-up. Dynamics of post-immunization response coefficient in RA patients during 2-year follow-up are presented in the Table. RA patients and the control group are marked more than 2-fold significant increase in the content of antibodies in 3 months after the vaccination. Despite the decline in their concentration to 12 months, it remained at the proper level and was increased to 24 month follow-up. Good tolerability of the vaccine was documented in 65% of cases, satisfactory (injection site pain, swelling and hyperemia of the skin up to 2 cm in diameter and subblebivelief) in 35% of cases. As these reactions had no causal relationship with current RA therapy, and fully resolved within 24 hours without additional treatment, no RA therapy modification was required. Pronounced DAS28 positive dynamics in RA patients (4.27 and 2.68 at Visit I and Visit V, respectively, p < 0.001) indicates the absence of any negative impact of vaccination on disease activity.

Conclusions: Thus, all given prove the sufficient immunogenicity and safety of 23-valent pneumococcal vaccine in RA patients, getting different therapeutic regimens during the 2-year follow-up.

THU0133 SERUM PENTRAxin-3 IN THE ASSESSMENT OF CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS
B. Targonska-Stepniak, M. Pietrowski, R. Zwolak, M. Majdan. Department of Rheumatology and Connective Tissue Diseases, Medical University of Lublin, POLAND, Lublin, Poland

Background: Rheumatoid arthritis (RA) is associated with the increased cardiovascular (CV) morbidity and mortality due to accelerating, progressive atherosclerosis. The chronic, systemic inflammatory process is responsible for both joint damage and increased CV risk in RA patients. Pentraxin 3 (PTX3) is an inflammatory marker, a member of long pentraxin superfamily, supposed to be involved in inflammatory process as well as in atherosclerosis.

Objectives: The goal of the study was to assess the role of PTX3 as an inflammatory marker in patients with RA and to evaluate the relationship between PTX3 and CV risk markers [carotid intima-media thickness (cIMT), QTc distance (dQTc), lipid profile].

Methods: The study group consisted of 72 consecutive RA patients, 60 (83.3%) female and 12 male (16.7%), with the mean (SD) age 53.4 (10.29) (range 21–71) and disease duration 16.8 (10.3) years (range 2–49). The activity of RA was evaluated by clinical examination with the disease activity score in 28 joints (DAS28). Remission or low disease activity was observed in 35 (48.6%) patients; moderate or high disease activity (DAS28 > 3.2) in 37 (51.4%) patients. Disease modifying antirheumatic drugs (DMARDs) used in the treatment included: methotrexate (11 (84.7%), leflunomide 4 (5.6%), cyclosporine 1 (1.4%) patient. The majority of patients 54 (75%) were treated with biological DMARDs, currently or in the past.

Results: The mean (SD) PTX3 concentration in RA patients was 4.57 (2.83) mg/l (range 1.43–16.07), in the control group 2.55 (1.37) mg/l (SD 0.99) mg/l. PTX3 concentration was significantly higher in patients with moderate/high RA activity in comparison with remission/low disease activity [5.56 (3.29) vs 3.48 (1.71) mg/l, p=0.001] and in patients anti-CCP positive compared with anti-CCP negative [4.57 (2.58) vs 3.32 (0.85) mg/l, p = 0.04]. The mean (SD) PTX3 concentration was significantly higher in patients with definite atherosclerosis (cIMT > 0.9 mm) than in patients with subclinical or no atherosclerosis [5.77 (3.02) vs 3.99 (2.58) mg/l, p=0.04], as well as in patients with atherosclerotic plaques in comparison with no plaques (6.18 (2.83) vs 4.02 (2.64) mg/l, p=0.0007).

There was a negative correlation between PTX3 and dQTc (R = -0.33, p = 0.007).

Conclusions: The results of the study suggest a twofold role of PTX3: 1. an inflammatory marker of the joint disease activity 2. a biomarker indicating intensity of atherosclerosis, estimated by greater cIMT value and the presence of atherosclerotic plaques. The negative correlation between PTX3 and dQTc suggests the increased risk of sudden cardiac death due to shortening of dQTc.

THU0134 INTERSTITIAL LUNG DISEASE AND RHEUMATOID ARTHRITIS. MULTICENTER STUDY WITH TOCILIZUMAB
C. Fernandez-Diaz 1, J. Narvaez-Garcia 2, M. Martin-Lopez 3, P. Rubio-Muñoz 4, S. Castañeda-Sanz 2, N. Vegas-Revenga 1, L. Dominguez-Casas 1, V. Calvo-Rio 1, M. Gonzalez-Gay 1, R. Blanco 1, 1 Rheumatology, Hospital Universitario Marques de Valdecilla, Santander; 2 Rheumatology, Hospital Universitario Belvitge, Barcelona; 3 Rheumatology, Hospital 12 de Octubre, Madrid; 4 Rheumatology, Hospital Universitario Germans Trias i Pujol, Barcelona; 5 Rheumatology, Hospital la Princesa, Madrid, Spain

Background: Interstitial Lung Disease (ILD) is a severe extraarticular manifestation of rheumatoid arthritis (RA). AntiTNFα drugs and conventional disease-modifying anti-rheumatic drugs (DMARDs) such as methotrexate (MTX) have been involved in the development of ILD. IL6 has been implicated in the pathogenesis of ILD (Kobayashi J et al). However, a fatal case of exacerbation of ILD has been involved in the development of ILD. IL6 has been implicated in the pathogenesis of ILD (Kobayashi J et al). However, a fatal case of exacerbation of ILD has been described with tocilizumab (TCZ) (Kawashiri SY et al at).

Methods: Multicenter study of RA patients with ILD treated with TCZ. ILD was diagnosed by high-resolution computed tomography (HRCT), TCZ was used at standard dose (8 mg/iv/4 weeks). We have analyzed the following variables: a) change in the degree of ILD according to the Modified Medical Research Council (MMRC); b) Forced Vital Capacity (FVC) improvement ≥10%; and improvement ≥10% in DLCO; c) HRCT, and d) joint assessment (DAS28 score).

Results: We studied 12 patients (9 women/3 men) with ILD related to RA,
The mean age SD was 57.1±16.1 years. The mean evolution of RA was 9±5.8 years. The patients had previously received the following DMARDs: MTX (n=12), leflunomide (LFN) (8), sulfasalazine (SSZ) (3), hydroxychloroquine (HCQ) (1), azathioprine (AZA) (2), gold salts (2). In addition, 11 patients had previously received biological drugs: adalimumab (4) anakinra (1), etanercept (4), rituximab (4), infliximab (1), certolizumab (1), abatacept (1). RA was severe in 11 cases (92%). Besides HRCT, the diagnosis of ILD was confirmed by biopsy in 4 patients. In 2 patients ILD was drug-related: MTX (n=2). TCZ was prescribed in monotherapy (n=8) or combined with other DMARDs (4). These DMARDs were: LFN (2), MTX (1), AZA (1). In many patients the dyspnea and DLCO remain stabile (Table). After a follow-up of 12 months, 2 patients withdrew TCZ, 1 patient for ILD worsening and 1 patient for joint inefficacy.

Table 1

THU0135 THE COURSE OF LOWER EXTREMIT Y FUNCTION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS OVER THE FIRST FIVE YEARS

M. Mellblom Bengtsson, C. Book, S. Hagel, L.T. Jacobsson, C. Toresson, Department of Rheumatology, Skåne University Hospital; 2Department of Clinical Science, Lund University, Malmö; 3Rheumatology, Department of Clinical Sciences, Lund, Lund University; 4Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at Gothenburg University, Gothenburg, Sweden

Background: Rheumatoid arthritis (RA) frequently involves joints of the feet and the knees. Disability related to arthritis in the lower extremities has a major impact in many patients, but has not been extensively studied.

Objectives: To investigate lower extremity function in early RA, using validated tests, and to assess its relation to other disease parameters.

Methods: Consecutive patients with early RA (symptom duration ≤12 months) in an inception cohort from a well-defined area were followed according to a structured protocol, with visits at inclusion and after 1, 2, and 5 years. Lower extremity function was investigated using the Index of Muscle Function (IMF) (1), a validated battery of tests by which the patient's general ability, muscle strength, muscular endurance, and balance are assessed by a physiotherapist. The scores on the subscales are added for a total IMF score (IMF total) of 0–40. A subscore of the Health Assessment Questionnaire Disability Index (HAQ-DI), based on 10 questions that are mainly dependent on function of the lower extremities (the HAQ-DI-LE) is on the only three HAQ-DI domains in which all activities related mainly to the lower extremities. Changes in the IMF total score and subtest scores between visits were analyzed using the Wilcoxon signed rank test. Correlations between disease parameters were assessed using Spearman's rank test.

Results: A total of 106 patients (67% women, mean age 61 years, mean baseline DSAS 28 4.4, median baseline HAQ-DI LE 0.75) were included. Data on IMF total were available for 100, 89 and 67 patients at the 1, 2 and 5-year visits. Lower extremity function improved from baseline to the 1-year visit (IMF total median 4.1 (IQR 2–6) vs 3 (IQR 2–6); p=0.001) and for balance/coordination (median 2 (IQR 1–6) vs 5 (IQR 2–9); p=0.001) and for balance/coordination (median 2 (IQR 1–6) vs 5 (IQR 2–9); p=0.001). There were significant correlations between IMF total and HAQ-DI-LE, HAQ-DI-LE and HAQ-DI at all time points, but no significant correlations for IMF total with CRP and DSAS28 at the 2-year visit.

Conclusions: HAQ-DI-LE improvement in lower extremity function during the first year, followed by a gradual decline, possibly explained by lack of complete disease control and aging. Tests of muscular function in the lower extremities may reveal aspects of RA disease severity that are not fully captured by standard disease activity measures, and may add important information regarding functional loss.

THU0136 NESFATIN-1 EXPRESSION IS ASSOCIATED WITH REDUCED Atherosclerotic disease risk in patients with Rheumatoid Arthritis

C. Robinson, L. Tsang, A. Solomon, A. Woodiwick, S. Gunter, H.-C. Hsu, G. Norton, A. Millen, P. Dessein. Cardiovascular Pathophysiolog and Genomic Research Unit, School of Physiology, University of the Witwatersrand, Johannesburg, South Africa, Johannesburg, South Africa; 2Rheumatology Division, Universitair Ziekenhuis Brussel, Brussels, Belgium

Background: Nesfatin-1 comprises a peptide that is involved in appetite suppression, energy homeostasis and fluid regulation, and was recently documented to participate in a range of cardiometabolic pathways (1,2). There is currently a need for the identification of novel biomarkers in the elucidation of CVD risk and its stratification in patients with rheumatoid arthritis (RA). The role of nesfatin-1 in cardiovascular disease risk among RA patients is uncertain.

Objectives: We investigated the potential impact of nesfatin-1 on subclinical cardiovascular disease manifestations in patients with RA by determining the associations of nesfatin-1 concentrations with atherosclerosis and circulating levels of matrix metalloproteinases (MMP-2) that mediates plaque stability and those of MMP-3 and MMP-9 that cause plaque vulnerability.

Methods: Nesfatin-1 concentrations were measured in 236 (114 black; 122 white) RA patients. Relationships of nesfatin-1 concentrations with ultrasound determined carotid intima-media thickness (cIMT) and plaque and MMP levels were identified in confounder adjusted multivariable regression models.

Results: Nesfatin-1 concentrations were inversely associated with c-IMT (β(SE) = -0.022 (0.008), p =0.00) and directly with MMP-2 levels (β(SE) = +0.117 (0.031), p =0.00). After adjustment for conventional risk factors and RA characteristics, these associations persisted (c-IMT: β(SE) = -0.022 (0.008), p =0.00) and directly with MMP-2 levels (β(SE) = +0.117 (0.031), p =0.00). By contrast, the Disease Activity Score in 28 joints (DAS28) and Clinical Disease Activity Index impacted the nesfatin-1-cIMT relation (interaction p=0.7). Contrast, the Disease Activity Score in 28 joints (DAS28) and Clinical Disease Activity Index impacted the nesfatin-1 to-cIMT relation (interaction p=0.04 and 0.02, respectively). Nevertheless, in stratified analysis, nesfatin-1 concentrations were related to those of MMP-2 in patients with no or mild disease activity (β(SE) = +0.148 (0.054), p=0.00) and moderate or high disease activity (β(SE) = -0.086 (0.041), p=0.04) as determined by DAS28 (cut-off value 3.6) as well as by CDAl (cut-off value ≤10) (β(SE) = +0.130 (0.048), p=0.00 and 0.107 (0.046), p=0.02, respectively).

Conclusions: Nesfatin-1 concentrations are consistently associated with a reduced atherosclerosis burden and increased MMP-2 levels in patients with RA.

THU0137 IMPACT OF PERIODONTAL AND RHEUMATIC DISEASE MARKERS ON FIRST-DEGREE RELATIVES OF PATIENTS WITH RHEUMATOID ARTHRITIS

C. Romero-Sanchez, S. Pacheco-Tena, C. Giraldo, J. De-Avila, M.A. Cano-Bermudez, L. Chila-M, J. Bellido-Guaitero, P. Chalena, W. Bautista, J. Zanondo, C. Pacheco-Tena, C. Giraldo, L. Valera-Olafote, 1Unit of Oral Basic Investigation/School of Dentistry, Universidad El Bosque; 2Department of Rheumatology, Universidad de Los Andes, Bogotá, Colombia; 3School of Medicine, Universidad Militar Nueva Granada; 4Departamento de Reumatología, Fundacion Instituto de Reumatología Fernando Chalema, Bogotá D.C.; 5Spondyloarthritis Group, Rheumatology University of the Sabana, Chia, Colombia; 6Department of Reumatologia, Hospital Militar Central, Bogotá, Colombia, Bogotá D.C., Colombia

Background: Rheumatoid arthritis (RA) and periodontal disease (PD) have been independently associated with atherosclerosis burden and increased plaque vulnerability.
DAS 28 CORRELATED POORLY WITH THE OBJECTIVE EVIDENCE OF INFLAMMATION AS DETECTED BY ULTRASOUND (US) EXAMINATION OF HANDS AND FEET IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS (RA)

C. Curtin, G. Brown, A. Cotton, J. Guinto, A. Jones, V. Morris. Department of Rheumatology, University College London NHS Trust, London, United Kingdom

Background: The Disease Activity Score including 28 joint count (DAS-28) is the most widely used outcome measure in RA. However, despite evidence that articular Doppler signal, erosions and osteophytes. Information about demographics, disease duration, current treatment, inflammatory markers, and DAS-28 scores was captured. The hereby-obtained assessment questionnaires including the health assessment questionnaire (HAQ), and matched controls.

Objectives: To evaluate PD markers in first-degree relatives (FDR) of consan- guinity individuals with patients with rheumatoid arthritis to compared with controls and to establish an association to rheumatic activity according to age groups.

Methods: 201 FDR and 201 controls were included. Statistical evaluation of rheumatologic and periodontal condition was performed. P gingivalis, P. gingivalis IgG1 and IgG2, ESR, CRP, RF, ACPAs, painful and swollen joints were assessed. A frequencies analysis, comparisons and a logistic regression model were made. The study was approved by local ethics committees.

Results: 32% of the controls and 10.1% of patients. Subjects with more than one swelling joint were 21 subjects <30 years, 5 between 31–40, 5 between 41 to 50 subjects and 9 subjects over 50, for more one painful joint were 73. The RF was present in 8.0%, APCA in 13%, RA33 in 1%, 67.3% had a disease of PD. 81.6% had a moderate-severe p=0.003. P gingivalis was in 47.9%, and P. gingivalis IgG1 were in 54.7%. It was evident that 25.3% patients presented BMI <30, where 81.8% had periodontitis p=0.006. Regression analysis on the whole group shows a risk to present BMI >25 (OR 1.67 IC-95% 1.02−2.74 p=0.042), ACPAs (OR 3.7 IC-95% 1.34−10.22 p=0.02), at least one pain join (OR 5.1 IC-95% 1.42−4.44 p=0.001), and gingival index (OR 4.57 IC-95% 1.76−11.80 p=0.002) in FDR individuals. Based on age the risk to develop PD was increasing: individuals among 30 to 40 years shows OR 2.76 (IC-95% 1.24−6.18, p=0.013); among 41 to 50 years, OR 4.72 (IC-95% 1.81−12.32, p=0.001); and for >50 years individuals OR 6.22 (IC-95% 2.05−15.1, p=0.001). The disease activity scores by age rank shows the FDR individuals 20 years (n=47) exhibited high risk to have at least one pain join (OR 3.84 IC-95% 1.28−11.47 p=0.016). In subjects among 30 to 40 years (n=46), the risk was associated with periodontal pocket (OR 4.4 IC-95% 1.05−4.98 p=0.021), one or more pain join (OR 3.56 IC-95% 1.00−12.02) which it was maintained until 50 years old individuals (n=35) (OR 3.2 IC-95% 1.11−6.78 p=0.004), individuals >50 years (n=53) show high risk to present BMI >25 (OR 4.00 IC-95% 1.46−10.45 p=0.007).

Conclusions: Obesity, ACPA and periodontitis can be considered as relevant conditions associated with the development of RA in FDRs. However, the analysis based on age group shows that periodontal markers do not appear early in FDR individuals; however, clinical rheumatologic variables are manifested and maintained over time.

THU0139 DEPRESSIVE SYMPTOMS AND VITAMIN D IN PATIENTS WITH EARLY ARTHRITIS

D. Freier1, M. Biersack1, J. Detert1, G.-R. Burmester1, R. Uebelhack1, T. Braun1, V. Hoehne-Zimmer1.

1. Rheumatology, Charité-University Medicine, Berlin, Germany

Background: There is a high prevalence of depression in patients with rheumatic diseases, especially in rheumatoid arthritis (RA). It is one of the most prevalent co-morbidities with 16% to 38%. Vitamin D (VD) deficiency is one of the known risk factors for depressive disorders. On the other hand, a VD deficiency has often been detected in rheumatic diseases. A possible correlation between these co-morbidities has not been investigated so far in patients with early arthritis (EA).

Objectives: The aim of this study was to examine the association between VD deficiency and depression and/or anxiety disorders in patients who have presented themselves for the first time in the EA clinic.

Methods: Patients with a suspected EA (at least one swollen joint without previous trauma or joint infection with a symptom duration of 6 weeks to 12 months) received a screening date within five work days. The VD status (25-hydroxy-VD) was obtained during the first EA clinic consultation. In addition, each patient completed questionnaires on the disease history, as well as evaluated self-assessment questionnaires including the health assessment questionnaire (HAQ) and the Hospital Anxiety and Depression Scale (HADS). The hereby-obtained results of disease activity, VD-status and HADS-scores were investigated. In the observation period from June 2012 to March 2015, 75 patients fulfilled the inclusion criteria of complete results which resulted in questionnaires as well as a disease duration of less than 12 months.

Results: The mean age of this EA cohort was 51.7±16.9 years (±65.3%, mean disease duration: 4.0±3.0 months). The prevalence of VD deficiency (<75 mol/l) was 73.3%. 48.0% of EA patients showed a positive global distress score (≥13). The most prominent VD status global distress score ≥1 in sufficient patients was 10.2±6.6 vs. 13.3±6.9 in deficient patients. The observed difference was not statistically significant. There was neither an association between gender, age and VD status nor was there any difference in the laboratory parameters (e.g. C-reactive protein, rheumatic factor, anti citrullinated peptide, hemoglobin) or assessment of functional status (e.g. HAQ, disease activity score by 28 joints).

Conclusions: The prevalence of VD deficiency is higher in EA patients with 73% than in the general German population (vs. 60%). The prevalence of positive distress with 50% is also higher. Interestingly, no association of deficient VD status and negative distress scores with 90% was observed in the HAQ, disease activity score by 28 joints. This might be explained by the early stage of disease, but further studies are necessary to evaluate this new insight.

THU0140 SPECKLE TRACKING ECHOCARDIOGRAPHY EVALUATION OF CORONARY TERRITORIES IN MEXICAN MESTIZO PATIENTS WITH RHEUMATOID ARTHRITIS

D.A. Galarza-Delgado1, J.R. Aparicio-López2, J.I. Colunga-Pedraza3, F.J. Torres-Quiñallana4, R.E. Ramos-Cázares1, A. Valdivos-Bañuelos1, A. Martinez-Moreno5, R.I. Arvizu-Rivera2, R. Vera-Pineda6, J.A. Cárdenas-de la Garza7, M.A. Garza-Elizondo1, M.A. Benavides-Gonzalez4, F. Hervert-Cavazos2, T. Rheumatology, 2. Cardiology, 3. Internal Medicine, Hospital Universitario “Dr. Jos é Eleuterio González”, UANL, Monterrey, Mexico

Background: The main cause of death in patients with rheumatoid arthritis (RA) is atherosclerotic cardiovascular disease. Speckle Tracking Echocardiography (STE) is an imaging technique that analyses the local and global myocardial function by assessing the myocardial deformation (strain). This technique is useful in addressing early alterations in ischemic pathologies (1,2).

Objectives: The aim of this study was to analyze if longitudinal strain abnormalities correspond with vascular territories, and compare the results between RA-patients and matched controls.

Methods: An observational cross-section case-control study was designed. Patients that fulfilled the 1987 ACR and/or 2010 ACR/EULAR classification criteria for RA, were 40–75 years old, with no overlap syndromes and no history of atherosclerotic cardiovascular disease were included. The control group was formed by age- and sex-matched subjects, with no rheumatologic or cardio-vascular diseases. A standard transthoracic echocardiogram was performed by a
board-certified echocardiographer. Affection of coronary territories was compared between groups using longitudinal strain by speckle tracking according to the European Society of Cardiology and the American Society of Echocardiography recommendations.

Results: A total of 53 RA-patients and 24 control subjects were included. Demographic and clinical characteristics for each group are shown in Table 1. There was no statistical difference in global longitudinal strain between RA-patients and controls (-20.86±2.82 vs -21.19±2.46, p=0.62). Comparison of longitudinal strain values of the three vascular territories evaluated between RA-patients and controls did not reach statistical difference (Table 2).

Conclusions: Contrary to previous published evidence (1, 2), there was no statistical difference in global longitudinal strain between RA patients and controls. Further studies with a larger cohort are necessary to determine the usefulness of strain in the evaluation of subclinical cardiovascular disease.

**THU0141** CAN WE PREDICT THROMBOTIC TENDENCY IN RHEUMATOID ARTHRITIS: A THROMBOELASTOGRAPHIC ANALYSIS

S. Türk 1, H. Üsküdar Teke2, T. Kakoğlu 1, M. Akay 1

Eskişehir Osmangazi University School of Medicine, Rheumatology, Eskişehir Osmangazi University School of Medicine, Hematology, Eskişehir Osmangazi University School of Medicine, Biostatistics, Eskişehir, Turkey

Background: Arterial and venous thromboembolism were proven to be increased in cases with rheumatoid arthritis (RA) [1]. It would be interesting to predict thrombosis in these patients by a laboratory test. Rotational thromboelastography (ROTEM) is a viscoelasticomographic test to evaluate the kinetics of clot formation and fibrinolysis which provides global information on cellular and soluble procoagulant/anticoagulant protein interactions.

Objectives: Our aim was to determine the thrombosis predisposition in RA patients by thromboelastography and to identify the possible clinical and laboratory risk factors for thrombotic tendency in RA patients.

Methods: 85 RA patients (mean age: 54.12±13 yrs; female: 66 (77.6%)) diagnosed based on 2010 ACR/EULAR classification criteria were sequentially recruited. Patients were receiving either conventional synthetic disease modifying antirheumatic drugs (csDMARD) or were receiving biological treatments. Age- and gender matched 35 healthy individuals were enrolled as a control group. Complete blood count (CBC), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) levels were measured and DAS-28 scores were calculated. ROTEM was applied at the same time and clotting time (CT, seconds), clot formation time (CFT, seconds), and maximum clot firmness (MCF, mm) were determined. A shorter CT and/or CFT values and/or a higher MCF levels imply tendency towards hypercoagulability.

Results: RA patients with a higher disease activity were found to have a shorter I-CFT and a higher I-MCF (p values p<0.020, p=0.033, respectively). Correlation analysis revealed shorter I-CFT and E-CFT and higher I-MCF and E-MCF in those with more active disease, hence indicating a higher tendency to thrombosis.

Conclusions: Disease activation in RA patients may lead to hypercoagulability, independent of the ongoing medication of patients. Considering the fact that the predictive value of ROTEM parameters for further thrombosis, additional studies are needed whether pro-thrombotic state in RA may herald thrombosis in the presence of inflammation.

**THU0142** MATRIX METALLOPROTEINASE-3 AND ANTIBODIES (IGG) AGAINST OXIDIZED LOW-DENSITY LIPOPROTEIN LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Gerasimova, T. Popkova, M. Chernikova, E. Alexandrova, A. Novokov.

VA.NASONOVA Research Institute of Rheumatology, Moscow, Russian Federation

Background: Rheumatoid arthritis (RA) is associated with an unexplained increased cardiovascular risk. Matrix metalloproteinase-3 (MMP-3) is the most important disease related factor in RA patients which may play a role in the development of cardiovascular events. Antibodies against oxidized low-density lipoprotein (oxLDL) are known to be involved in the development of inflammation and atherosclerosis. Specific role of MMP-3 and antibodies against oxLDL in cardiac pathology in RA patients (pts) is not well investigated.

Objectives: To compare MMP-3 and oxLDL-IgG antibody levels, as well as lipid profiles in pts with active RA and healthy controls.

Methods: Thirty nine RA pts (33 women and 6 men, median age 56.5 [49; 65] years), with active arthritis (disease duration 96 [48; 190] months; DAS28 5.8 [5.3;6.3]) and 29 healthy controls were studied. Twenty three pts (59%) received methotrexate, 5 (13%) – the combination of methotrexate with oral glucocorticoids, 10 (26%) - oral glucocorticoids monotherapy. The control group consisted of 29 volunteers (21 women and 8 men, median age 58.5 [53; 62] years). Serum MMP-3 and oxLDL-IgG levels were measured by enzyme-linked immunosorbent assay (ELISA). Results: Elevated MMP-3 levels were detected more frequently in RA pts (31/39 (79%)) vs healthy controls (2/29 (7%), p<0.0001), MMP-3 concentrations were higher in RA pts (57.0 [36.6, 114.9] mU/ml) vs the control group subjects (13.4 [9.9, 20.4]mU/ml, p<0.0001), MMP-3 levels demonstrated significant correlation with ESR (r =0.64, p<0.05) and CRP (r =0.52, p<0.05) values.

OxLDL-IgG levels in RA pts and healthy controls did not differ significantly (290.3 [111.3, 608.6] mU/ml and 228.1 [125.1, 338.8] mU/ml, respectively p>0.05). Rates of dyslipidemia were similar in RA pts (23/39 (59%) and control group subjects (15/29 (52%). Concentrations of lipids were also similar in both groups and were as follows: total cholesterol was 5.2 [4.9, 6.2] mmol/l in RA pts and 6.3 [5.1, 6.6] mmol/l in the control group; HDL cholesterol - 1.7 [1.4, 2.0] mmol/l and 1.7 [1.5, 2.1] mmol/l; LDL cholesterol - 3.3 [2.8, 4.0] mmol/l and 3.6 [3.0, 4.0] mmol/l, triglycerides - 1.3 [1.0, 1.6] mmol/l and 1.4 [1.1, 1.8] mmol/l, the atherogenic index - 2.4 [1.8, 2.8] and 2.4 [1.9, 3.0], respectively. Showed no correlation between the levels of oxLDL-IgG and lipids in both groups. In the RA group, concentrations of HDL cholesterol were negatively correlated with MMP-3 (r =–0.5, p<0.05), C-reactive protein (r =–0.53, p<0.05), and DAS28 (r =–0.4, p<0.05).

Conclusions: RA pts exhibited higher serum MMP-3 levels than healthy individuals. OxLDL-IgG levels were similar in RA pts and healthy subjects. Obtained results suggest that MMP-3 and CRP may produce a negative impact on HDL-cholesterol levels in patients with active RA.

**THU0143** CHOLESTEROL EFFLUX CAPACITY OF HDL IS OTHERWISE IMPROVED BY DIFFERENT BIOLOGIC-DMARDS IN RHEUMATOID ARTHRITIS

F. Cacciapaglia 1, S. Perniola 1, J. Härdfeldt 2, M. Nivuori 1, O. Magazzino 1, M.G. Giannotta 1, M. Giannini 1, M.G. Anelli 1, A. Moschetta 2, F. Iannone 1

1DETO - Unit of Rheumatology; 2DIM - Clinica Medica “Cesare Frugoni”, University of Bari, Bari, Italy

Background: Rheumatoid arthritis (RA) patients have an increased mortality that cannot be completely explained by impaired cholesterol levels or other traditional CV risk factor (1). Target therapy with effective control of systemic inflammation have been demonstrated to improve articular outcomes, but the effect on CV risk is still under investigation (2). The ability of high-density lipoprotein (HDL) to accept cholesterol from macrophages (HDL cholesterol efflux capacity – HDL-EC) is a key property of HDL, with significant consequences on incident atherosclerotic CV disease (3), but this marker in RA have still alternate evidence (4,5).

Objectives: To assess the effects of different biological DMARDS on HDL-EC in RA

References:

Methods: Disease activity data and blood samples from 40 patients with RA before and up to 12 months after starting a biologic therapy were collected. The study included patients starting intravenously administered Abatacept (ABA, n=10), Infliximab (INF, n=10), Tocilizumab (TCZ, n=10), and Rituximab (RTX, n=10), at approved dose regimens for RA treatment. HDLc-EC was measured on paired samples at baseline, after 6 months of treatment, and after 12 months of treatment. ANOVA was used to compare paired continuous data, and Pearson’s r value was calculated for correlations.

Results: Disease activity assessed by DAS28-CRP and CDAI significantly dropped during all treatments. No significant changes in total and high or light density cholesterol fractions were detected. HDLc-EC at baseline was 22±3% with a statistically significant increase up to 25±3% and 27±4% after 6 and 12 months of treatment, respectively (P<0.001) [Figure A]. Patients treated with INF and RTX demonstrated the higher rise in HDLc-EC, already after 6 months and lastingly up to 12 months of treatment. ABA and TCZ treated patients after 6 months had a slight HDLc-EC rising, with a subsequent plateau. We observed an opposite correlation between HDLc-EC and disease activity by DAS28-CRP and CDAI (r=−0.2, P=0.01) [Figure B]. Finally, no CV events were detected during the study follow-up.

Conclusions: Our results indicate that disease activity of RA and aging contribute to cognitive impairment, but there was no association between cognitive function and subclinical carotid atherosclerotic changes in RA patients.

THU0145 IMPACT OF DIFFERENT FORMULATIONS OF “PATIENT GLOBAL ASSESSMENT” ON REMISSION CLASSIFICATION BY DISEASE ACTIVITY INDICES IN RHEUMATOID ARTHRITIS

G. Eugenio1, R. Ferreira1, C. Silva2, C. Medeiros1, J.A.P. Silva1, 3, C. Duarte1, 4, 5, 6, 7, 8, 1, 3, 5 CHUC-Huc, 2 UCI/SAA, 3 FMUC, Coimbra, Portugal

Background: Patient global assessment (PGA) of disease activity is included in a large number of composite indices of disease activity and definitions of remission in Rheumatoid Arthritis (RA). However, the actual question is formulated in a variety of different ways according to the instrument considered.

Objectives: To evaluate how 6 different formulations of PGA affect patient estimates and impact upon disease activity and remission rates as assessed by 4 Disease Activity Indices.

Methods: Consecutive RA patients followed in a Rheumatology outpatient department were included in this cross-sectional study. Data collection comprised 28 joint counts (tender and swollen), C-reactive protein (CRP) and 6 different PGA formulations. The chosen formulations were the ones stated in the: v1) Portuguese National Registry Reuma.pt, the locally used formulation; v2) ACR/EULAR provisional definition of remission (considered in this study as the “standard”); v3) CDAI and SDAI; v4) Disease Activity Score (DAS28) assessment of general health; v5) DAS28 assessment of disease activity (the currently used); v6) one, exploratory, developed by the investigators, including idiomatic cultural expressions. ACR/EULAR Boolean criteria, CDAI, SDAI, and DAS28-CRP (v4) were used to test how these 6 PGA formulations change the rates of remission.

PGA differences were assessed by descriptive analyses (including patients with PGA ≤ 10 and >20mm) and Bland-Altman test.

Results: In total, 193 patients were included (92% female, mean (SD) age of 59 (13) years, mean disease duration of 12 (9) years and 31% under biologics). The average PGA ranged from 42.3 (25.3) to 48.1 (27.7)mm as measured in different formulations. The ACR/EULAR (v2) formulation yielded the largest proportion of patients in remission (82%).

Conclusions: Our results indicate that disease activity of RA and aging contribute to cognitive impairment, but there was no association between cognitive function and subclinical carotid atherosclerotic changes in RA patients.
Quality of life in patients with rheumatoid arthritis - demographic and socio-economic associations

H. Baharuddin 1, N. Zainudin 2, H. Mohd Yusoof 2, I.S. Lau 2.

Background: The primary goal of treating patients with rheumatoid arthritis (RA) is to maximise long-term HRQoL. Quality of life (QoL) in patients with RA may be substantially impacted by their inability to perform daily activities, a shift in family roles, more restricted employment opportunities, increased financial burden and social dependency and reduced recreational activities.  

Objectives: To investigate the QoL among RA patients and its association with demographic and socioeconomic details.  

Methods: This is a cross-sectional study conducted in a rheumatology outpatient clinic in Malaysia. Patients who fulfilled 2010 ACR/EULAR classification criteria for RA were asked to answer WHOQOL-BREF questionnaire and specific questions on demographics and socio-economic details, during their attendance to rheumatology clinics. WHOQOL-BREF is a self-report quality of life questionnaire on individual's perception of quality of life and health, physical health, psychological, social relationships and environment domains.  

Data was analysed using SPSS 20. Student’s t-test was used to analyse the mean difference between two groups and chi-square test was used to analyse between 2 categorical data. Pearson correlation was used to analyse correlation between two groups of continuous data. P<0.05 was considered significant.  

Results: The mean age of patients in this study was 53.10±14.3 years, with majority being females (80.4%) and married (70.6%). Half of the patients were Malays (49.0%). 51.0% rated overall quality of life as good and 41.2% rated it as poor, with non-Malays (53.1±18.2) in the social relationship domain; t (49) =2.58, p=0.01. There were significant differences in the transformed scores for Malay (65.5±15.9) and 58.2 (±15.2) in environment domains.  

Conclusions: There were no differences in heart rate (HR), QTc interval duration, and for education at secondary level and above (65.9±14.6) and primary level (48.0±16.6), t(49)=3.87, p=0.003 and more frequently positive for rheumatoid factor (RF) (25/7 ([%6.2] vs 77/121 (%63.3), p=0.003) than patients without ILD. ILD was detected before beginning of biologics in 11 (37.9%), patients and during biologic treatment in 18 (62.1%) patients. Honeycombing was seen in 10 (34.5%) patients. First choice of biologic agent was RTX in 10 (34.5%) and TNFi in 19 (65.5%) patients. In ILD patients, mean follow-up duration was 51±31 months and first biologic was switched to another in 16 (55.2%) of patients. At the last follow-up visit 19 (65.5%) patients were on rituximab, 3 (10.3%) patients were on abatacept and 7 (24.1%) were on TNFi. Small airway disease was detected in 19 (9.3%) patients. History of smoking was present in only 4 (21.0%) of patients with small airway disease.

Table 1. Distribution of thorax CT findings

</tbody>
</table>

Conclusions: Bronchiectasia, rheumatoid nodules, small airway disease and ILD were the most frequent CT findings of RA patients. Rituximab was the choice of first biologic treatment in one third of patients, however two-thirds of patients were on rituximab therapy at the last follow-up visit. Lung involvement stands out as an important factor in selection of biologic therapies.

Increase of night QT-interval duration in rheumatoid arthritis patients treated with tofacitinib during 12-month follow-up

Objectives: to evaluate dynamic of ECG parameters in RA pts treated with tofacitinib (TOFA) during 12-month follow-up.  

Methods: After 12-month follow-up the ECG parameters by 12 lead ECG and 24h ECG was assessed in 28 RA pts treated with TOFA (22 women, median age 54 [40;62] years, disease duration 39.5 [16.5;60.0] m, moderate to high activity (DAS28≥5.1 [4.6;6.0], SDAI=26 [21;34], positive for ACCP (75%)/RF (79%), who were non-responders to MTX at least 15 mg/week and/or other synthetic DMARDs and bDMARDs. TOFA therapy was started in all pts with dose 5 mg BID per os followed by the dose escalation to 10 mg BID in 8 (29%) pts. TOFA used in combination with MTX in 27 (96%) pts, leflunomide in 4 (14%). Low dose oral corticosteroids (<10 mg/day prednisolone or equivalent) were received by 9 (35%) pts. Remission or LDA was achieved in 55% pts (DAS28,  

Results: Among 1229 patients (78.8%) female, mean age was 53.3±12.9 and disease duration was 11.4±7.9. Thorax CT had been performed in 203 (16.5%) patients. Distribution of pathologic findings in thorax CT was represented in Table 1. 29 patients (%2.4) were diagnosed as ILD with regard to CT findings. Patients with ILD were older (64.5±6.7 vs 60.6±10.1, p=0.039) and more frequently positive for rheumatoid factor (RF) (25/7 ([%6.2] vs 77/121 (%63.3), p=0.003) than patients without ILD. ILD was detected before beginning of biologics in 11 (37.9%), patients and during biologic treatment in 18 (62.1%) patients. Honeycombing was seen in 10 (34.5%) patients. QRS duration measured by 12-lead ECG in RA pts treated with TOFA (table 1). However, an increase in PQ interval duration was observed (p<0.04). There were significantly decrease of mean HR (p<0.003), increase of QRS duration (p<0.03), QTC (p<0.03), night QTC (p<0.02) in 24 h ECG ambulatory recording. HR, PQ, QTC duration were changed independently of beta-blockers therapy. The number of RA pts treated with tocilizumab (TCZ) during 12-month follow-up. An increase in QTc duration correlated negatively with dynamics of DAS 28, SDAI (r=-0.04, p<0.05), DM (r=0.5, p<0.02), dBiP (r=-0.4, p<0.04). There were also significantly increase number of ventricular premature beats (p<0.03).

Data are presented in median values and IQR (unless otherwise noted), *p<0.05 before and after TOFA treatment (nonparametric paired Wilcoxon test).

Conclusions: A significant decrease in HR and an increase in QRS, night QTc interval duration, number of ventricular premature beats by 24 h ECG were observed in RA pts treated with tocilizumab (TCZ) during 12-month follow-up. An increase in QTc duration correlated with dynamic of disease activity, DM type 2 and diastolic BP.

THU0149 A CLINICAL AND PATHOLOGICAL CHARACTERIZATION OF METHOTREXATE-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Nakano 1, A. Nawata 2, S. Nakayama 3, I. Ishida 4, K. Hanami 1, S. Kubo 4, I. Miyagawa 1, M. Yoshikawa 1, K. Saito 1, Y. Tanaka 1, 1The First Department of Internal Medicine, 2Department of Pathology, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan

Background: Methotrexate (MTX) is used as an anchor drug for the treatment of rheumatoid arthritis (RA). Patients with RA have a modestly increased risk of developing lymphoproliferative disorders (LPD). Furthermore, although sometimes spontaneous regression occurs after withdrawal of MTX, LPD developed during the treatment with MTX is broadly defined as MTX-associated LPD (MTX-LPD).

Objectives: To characterize the risk factors concerning MTX-LPD and to consider optimal treatment after occurrence of LPD in patients with RA.

Methods: We retrospectively evaluated 51 RA patients with LPD from 2006 to 2015 in our institution. MTX-LPD patients were divided into two groups; regressive LPD after MTX cessation (N=27) and persistent LPD though MTX was tapered (N=24), and the clinical characteristics, pathology and treatment outcomes were compared. EBV infection and IL-6 receptor (IL-6R) expression were analyzed by in situ hybridization and immunohistochemistry.

Results: There was no significant difference in disease duration, stage, disease activity of RA, the positive rate of Epstein-Barr virus-encoded small RNAs, EBERs (42.7 vs 50.0%) and treatment with TNF-inhibitors (40.7 vs 45.8%) between regressive LPD and persistent LPD. Age of LPD onset (59.1 vs 68.3), CRP (2 vs 5 mg/dl) and the weekly MTX dose (10.9 vs 8.4 mg/w) significantly differed between the groups. Of note, IL-6R was highly expressed in both group (75.0 vs 66.7%). Among regressive LPD, 3 patients developed DLBCL later.

Conclusions: The LPD development of RA is not only related to MTX treatment but also linked with EBV infection and IL-6R expression.

THU0150 OPTIMIZING COMORBIDITY RISK MANAGEMENT IN RA BY TRANSLATING A NURSE-LED INTERVIEW INTO AN EASILY INTERPRETABLE TRAFFIC LIGHT SYSTEM

K. Krüger 1, R. Eder 2, C. Müller 2, R. Hecker 3, 1Rheumatologisches Praxiszentrum St. Bonifatius, München; 2Rheumapräxis am Spitator, Deggendorf; 3AbbVie Deutschland GmbH & Co. Kg, Wiesbaden, Germany

Background: Due to its inflammatory nature, rheumatoid arthritis (RA) is associated with a variety of comorbidities and individual risk factors [1]. The benefit of a nurse-led programme on RA comorbidity management has been reported recently [2].

Objectives: To describe a new assessment tool for patient risk management and report the difference between structured versus expert guided assessment following standard of care in a construct-validation cohort.

Methods: The ongoing cluster randomized multicentre study ERIKO is longitudinally assessing individual risk profiles of patients with RA in Germany. The aim of this study is to test the benefit of applying a nurse-led scoring algorithm for individual risk profiles followed by a structured patient consultation (active arm) as compared to local standard of care.

The ERIKO-Score was calculated by rating validated assessment tools and treatment guidelines and translating their outcome into a three-level ordinal score defined by the categories low, intermediate or high risk, including nominal weights for risk management (e.g. condition is being treated with goals achieved or not).

Scores were interpreted numerically by rating categories with 0, 1 and 2 points, respectively.

We included cardiovascular (CV) risk (ESC-guideline), infection risk (RABBIT risk calculator), vaccination status (guideline), fracture risk (FRAX), tooth status (PSI), depression (PHQ-9) and health-related quality of life (hQoL, RAID). The same risk category was prioritized in all centres at the screening visit without providing the rating tools.

This analysis compares SOC ratings from the screening visit (month zero) with the baseline ERIKO-scores at month three in the active arm. No statistical hypothesis testing was performed in this analysis.

Results: This analysis included 283 patients from 31 centres specialized in rheumatology care randomized to the active study arm. 82.3% were female with a mean age of 57.8 years (sd 12.1) and a mean DAS28 of 2.6 (sd 1.1). The mean total ERIKO-Score was slightly higher at baseline as compared to applying the scoring algorithm on SOC ratings at the screening visit (5.33 ± 1.95 vs. 4.32 ± 2.61, respectively, table 1). The discrepancy was mainly driven by CV risk, vaccination status, tooth status and depression risk, that were more often rated worse by applying the ERIKO score than by SOC, while infection- and fracture risk were more frequently rated lower by the ERIKO-Score (table 2). The strongest discrepancy between SOC ratings and ERIKO-Score (± =2 points) were observed for tooth status (N=54), CV risk (N=25) and vaccination status (N=25) (table 2).

SOC ratings were strongly based on expert opinion with the most frequently cited tools being vaccination guidelines (38.9%), bone mineral density measurement (BMD) (39.6%) and RABBIT-infection risk-score (23.1%).

Conclusions: A nurse-led comorbidity risk assessment in rheumatology practices seems feasible. Applying the ERIKO-Score based on validated tools led to a
ACPA ARE ASSOCIATED WITH LOW BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS

Background: Several studies have related ACPA with the presence of bone disease of 5 years. Demographic and clinical variables were collected.

Methods: Case-control study of 73 RA patients (2010 CULAR criteria) and a long standing disease of 5 years. Demographic and clinical variables were collected. BMD values using densitometry at the lumbar (LCL, hip) and femoral neck (CF) were collected. The presence of low bone mineral density (osteopenia: T-score: ≤ -1) and ACPA levels were compared using logistic regression analysis, adjusting variables related to BMD: age, sex, menopause, body mass index (BMI), smoking habit, corticoids, disease duration, disease modifying drugs, methotrexate treatment and inflammatory activity (DAS28).

Results: A group of 73 patients were included (41 men) with a mean age of 66.45±10.41 years, mean body mass index 28.48±5.22 kg/m², mean long standing disease of 2.28±1.75 years and mean DAS 28 of 3.71±1.8. A total of 29 patients were negative for ACPA compared to 44 patients that were positive for ACPA. Osteopenia in lumbar spine was found in 82.2% of patients 65.8% hip and 75.3% in femoral neck. Logistic regression was performed without finding statistically significant association between osteopenia and inflammatory activity (DAS28), vitamin D levels and positive rheumatoid factor, adjusted for variables that can modify BMD. ACPA Positive (any titer) were associated with the presence of lumbar spine osteopenia (OR 7.19, 95% CI 1.77–29.17) (p=0.006), hip (OR 15.17, 95% CI 3.96–58.18) (p=0.001) and femoral neck (OR 3.76; 95% CI 1.20–11.82) (p=0.023). In addition, a simple variance analysis (ANOVA) was performed to compare T scores and ACPA levels divided into three categories: ≤25μL, 25–300μL and ≥300μL. ACPA group ≤25μL differed in mean T score values in lumbar spine, hip and femoral neck. No differences were found between ACPA positive patients with low and high levels for T score values.

Conclusions: In RA is associated with an increased risk of osteopenia in lumbar spine, hip and femoral neck independently of other variables that may modify bone mineral density. These data suggest that ACPA may play a role in bone remodeling.

THU0153 VASCULAR MORBIMORTALITY IN RHEUMATOID ARTHRITIS (RA) PATIENTS AND ITS RELATION WITH VASCULAR STUDY

Background: RA patients have a higher risk of vascular events, especially cardiovascular ones. Besides, mortality in these patients is 54% higher than the general population. Nowadays, we have non-invasive techniques that allow us to detect subclinical vascular damage.

Objectives: To describe subclinical vascular affection in a sample of RA patients and to explore its relationship with mortality and with the development of vascular events.

Methods: Ambispective observational study with analytical components. We included, consecutively, RA patients controlled in a tertiary hospital. We gathered demographic (sex, age, body mass index (BMI), clinical (traditional vascular risk factors, previous vascular events), and analytical variables (atherogenic index, glomerular filtration [GF] [MDRD], CRP, ESR). Other variables were collected retrospectively from the electronic medical record. We estimated the modified SCORE. We explored the extracranial branches of the carotid artery with an Esate MyLab70XVG ultrasound device with a linear probe (7–12mHz) and an automated program measuring intima media thickness (IMT) by radiofrequency ("Quality intima media thickness in real-time, QIMT"), and the presence of atheroma plaques, as per the Mannheim consensus, was registered. We also determined pulse wave velocity (PWV) by a validated MobiGraph® device. We considered an IMT ≥1.8 and a PWV >10m/s as pathologic values. We prospectively collected mortality and the development of new vascular events over three years. Statistical analysis was performed using SPSS 17.0 software.

Results: We included 198 patients, excluding 13 because of previous vascular events. The mean age was 68.8 years (DE 13.3) and most of them were women (76.2%). The mean BMI was 27.28 (4.48), 27% were smokers, 42.7% hypertensive, 46.7% dyslipemic and 10.8% were diabetic. The mean duration of RA was 17.37 years. 74.6% of patients were seropositive (RF and/or ACPA) and 75.5% had erosions. 74.6% received glucocorticoids, 58.4% NSAIDs, 98.9% DMARDs, 65.7% other immunosuppressants. The mean CRP and ESR were 4.0 mg/L (DE: 3.32) and 14.04mm/h (DE:14.46), respectively. The mean modified SCORE was 1.81 (DE: 1.79).

Regarding the vascular study, 48.6% of the patients had atheroma plaques, 31.7% had a pathologic PWV with a mean value of 9.13 (DE: 2.12), and 16.7% had a pathologic IMT with a mean value of 7.64 (DE: 1.42).

During 3 years of follow up, we registered 26 (14.1%) vascular events: 9.7% cardiac, 2.1% cerebral and 2.2% peripheral. There were 5 deaths: 3 vascular, 1 infectious and 1 respiratory. The development of vascular events was related with the presence of atheroma plaques (p = 0.008) and with pathologic PWV (p
0.028, as well as with the presence of erosions, GF, HTA and dyslipidaemia. The appearance of cardiac events was related also, with the use of NSAID (p 0.041). The presence of a pathologic IMT (p 0.032) and HTA (p 0.044) were the only variables related with death from any cause.

**Conclusions:** A combination of carotid ultrasonography and arterial stiffness study can help us to best identify patients with RA who have an increased risk of dying or developing a vascular event.

**Corrected for age and gender.**

**Conclusions:** PCSK9 levels in RA are similar to the general population. RA patients with active disease had higher PCSK9 levels compared to patients with low disease activity. Altogether, PCSK9 inhibitors could be an alternative treatment for dyslipidaemia in RA patients who have experienced side effects of statins, albeit that a formal trial still has to be conducted in this category of patients.

2Department of Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan

Background: Sarcopenia is an age-related loss of muscle mass and strength. It is associated with a higher risk of falls, fractures, and death in patients with rheumatoid arthritis (RA). However, the incidence of sarcopenia in RA patients undergoing biological therapy has not been well characterized.

Objectives: To evaluate the incidence of sarcopenia and its correlation with disease activity in RA patients treated with biological therapy.

Methods: A total of 39 patients with RA were enrolled. Sarcopenia was defined as a muscle mass index (MMI) of less than 7.37 kg/m². Disease activity scores (DAS28-ESR), muscle mass (MMI), and body mass index (BMI) were measured. The correlation between sarcopenia and disease activity was analyzed using the Mann-Whitney U test.

Results: The incidence of sarcopenia was 28% (11/39). Patients with sarcopenia had significantly higher values for tendon count (TJC) and swollen joint count (SJC) compared to those without sarcopenia. In the RA non-FM group, GS and PD-US7 correlated with the joint count criteria for FM, after the study of Pollard et al. [2].

Conclusions: The percentage of sarcopenia was 28% in RA patients. Low BMI, high body fat mass, and high MMP-3 represented independent risk factors for sarcopenia. A relationship between MMP-3 and sarcopenia was indicated by this study.

IMMUNE RESPONSE EFFICIENCY AFTER VACCINATION IN RA AND SPA PATIENTS TREATED WITH BIOLOGICS AND IMMUNOSUPPRESSIVE AGENTS: A SYSTEMATIC LITERATURE REVIEW
M. Tissier1, A. Motto1, S. Kolta1, O. Fogel1, M. Dougados1, J. Morel2, C. Miceli-Richard1, 1Hopital Cochin Paris, Paris; 2CHU Montpellier, Montpellier, France

Background: One of the most effective strategies to prevent infections is vaccination, especially in patients treated with biologics and immunosuppressive (IS) agents. Nevertheless, the effectiveness of the resulting immune response in these patients is not well known.

Objectives: To perform a systematic literature review aiming to assess evidence regarding immune response efficiency (IRE) and the ideal schedule for vaccination in RA and SpA patients treated with Methotrexate (MTX), TNF inhibitors (TNFi), anti-CD20 (rituximab, RTX), anti-IL1b (tocilizumab, TCZ), and anti-TNF (adalimumab, ADA).

Methods: A systematic literature review was conducted by searching in PubMed all studies with the MeSH terms ["Rheumatoid Arthritis" OR "Spondyloarthritis"] AND ["vaccination" OR "vaccines"] AND ["Methotrexate" OR "Abatacept" OR "Golimumab" OR "Infliximab"] with no limitation regarding time of publication. Only studies evaluating the IRE were included. Case reports, general reviews and meta-analysis were excluded.

Results: Of 35 studies (out of 60 studies retrieved), 27 studies compared IRE between RA and SpA patients, receiving different IS agents. The anti-meningococcal vaccine was the most used (n=24), followed by the tetanus vaccine (n=12), the hepatitis A vaccine (n=6), and the influenza vaccine (n=4). The prevalence of patients having an IRE ≥70% for tetanus, hepatitis and influenza was similar in RA and SpA patients. The anti-pneumococcal vaccine was less efficient in RA and SpA patients than in healthy controls.

Conclusions: The IRE consequences of vaccination in RA and SpA patients treated with IS are different for each vaccine and are dependent on the type of IS used.

RELATIONSHIP OF MATRIX METALLOPROTEASE 3 TITER AND SARCOPIENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM THE CHIKARA STUDY
M. Tada, Y. Yamada, K. Mandai, N. Hidaka. Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan

Background: Patients with rheumatoid arthritis (RA) show a lower muscle mass and higher prevalence of sarcopenia than healthy individuals. A prospective observational study (CHIKARA study, registration number: UMIN000023744) was started to clarify the influence of changes in disease activity for sarcopenia.

Objectives: We investigated the relationship between sarcopenia and disease activity at baseline in patients with RA.

Methods: We analyzed baseline data from the CHIKARA study (Correlation research of sarcopenia, skeletal muscle and disease activity in rheumatoid arthritis). Sarcopenia was diagnosed using the criteria of the Asian Working Group on Sarcopenia. Muscle mass, body fat mass, total body water, bone mass, and basal metabolic rate were measured using a body composition analyzer (MC-780A; TANITA, Tokyo, Japan). We investigated correlations between sarcopenia and disease activity (DAS28-ESR, SDAI, physical function (HAQ), and laboratory data using uni- and multivariate analyses.

Results: Participants comprised 100 patients with RA (females, 78%; mean age, 66.1 years). Mean disease duration was 5.5 years. DAS28-ESR was 3.55, and the percentage of subjects with sarcopenia was 28%. Table 1 shows risk factors for sarcopenia. Sarcopenia correlated with weight, body mass index (BMI), body fat mass, muscle mass, basal metabolic rate, Steinbrocker stage, CRP bone mass, and matrix metalloproteinase (MMP-3) on univariate analysis. Glucocorticoid dosage, rheumatoid factor, and anti-CCP antibody showed no correlation with sarcopenia. BMI, body fat mass, and MMP-3 were identified as independent risk factors on multivariate analysis. MMP-3 over 90.7 ng/ml was a risk factor for sarcopenia by ROC curve analysis (odds ratio, 3.09; p=0.023).

THU0159 RHEUMATOID ARTHRITIS MAY NOT INFLUENCE EATING BEHAVIOURS CHARACTERISTICS

N. Bulut 1, M.E. Tezcan 2, 1Family Medicine; 2Rheumatology, Kartal Research and Education Hospital, Istanbul, Turkey

Background: Patients with rheumatoid arthritis (RA) have an increased risk of obesity and cardiovascular disease compared with the general population (1). Eating behaviours may play an important role in obesity and cardiovascular disease.

Objectives: We hypothesised that RA patients have impaired eating behaviours that may have a role in obesity. For evaluating this hypothesis, we compared eating behaviours of patients with RA, osteoarthritis (OA) and healthy controls.

Methods: One hundred and fifty-seven RA patients (M/F: 23/134) who fulfilled the 2010 American College of Rheumatology (ACR) RA classification criteria, 31 hand OA patients (M/F: 1/30) who fulfilled 1990 ACR hand OA criteria and 60 healthy controls (M/F: 9/51) were enrolled to the study who applied to Kartal Dr. Lutfi Kirdar Training and Research Hospital Rheumatology outpatient clinic. Eating behaviours was assessed by the Three-Factor Eating Questionnaire (TFEQ). Demographic data, smoking status, co-morbidities, anthropometric measurements, VAS pain score, were analyzed.

Results: There were no differences between three groups in demographic features and anthropometric measurements (table1). Moreover, there were no differences between three groups in cognitive restraint and emotional eating scores. Although, healthy controls had significantly higher uncontrolled eating scores than the RA group (p=0.05), uncontrolled eating scores of all three groups were lower than Turkish people average scores (2) (table2).

Conclusions: This was the first study using the TFEQ in patients with RA. In our study, we found that disease features of RA may had no effect on eating behaviors.

SYNDECANS ARE CORRELATED WITH HIGH TITRES OF ANTIBODIES AGAINST CITRULLINATED PROTEINS (ACPAs) IN SERA FROM ACTIVE RHEUMATOID ARTHRITIS

Background: Syndecans include a group of proteins from the cell-surface heparin-sulfate proteoglycan family, with a relevant role in chronic inflammation of synovial tissue in patients with rheumatoid arthritis (RA) participating in the cell-matrix and cell-cell interactions. Syndecans are differentially expressed in the synovial tissue: syndecan-1 (SDC-1) is expressed mainly in mononuclear cells, syndecan-3 (SDC-3) is mainly expressed by synovial endothelial cells and syndecan-4 (SDC-4) is expressed by B lymphocytes regulating B cell development and survival. Currently, there is strong evidence that antibodies directed to citrullinated protein antigens (ACPAs) are associated with a more severe disease in RA. Nevertheless, to date, there is a lack of information about the relation between serum syndecan levels and serum concentrations of rheumatoid factor (RF) and ACPAs.

Objectives: To evaluate the association between serum SDC-1, SDC-3 and SDC-4 levels with serum concentrations of RF and ACPAs.

Methods: Eighty-one patients with RA were included. We assessed clinical characteristics including disease activity by DAS-28, functioning by HAQ-DI. Serum concentrations of RF were measured by nephelometry, two ACPAs were measured: anti-CCP2 and anti-mutated citrullinated vimentin (anti-MCV) antibodies using ELISA. Serum levels of SDC-1, SDC-3 (ng/mL) and SDC-4 (pg/mL) were measured by ELISA. We compared the serum levels of MCV syndecans in the ACPA+ group (group 1) versus ACPA- group (group 2) with Student t-test. A correlation analysis (Pearson tests) was performed to identify the strength of association between concentrations of syndecans with concentrations of ACPAs and other variables.

Results: Patients with RA had a mean age of 50±11 yrs, 75% were RF+ and 64% were ACPA+. In patients with ACPAs+ were observed higher serum concentrations of SDC-3 (p<0.003) and SDC-4 (p<0.001). SDC-1 correlated significantly with anti-MCV (r=0.53, p<0.001). Serum concentrations of SDC-3 correlated significantly with anti-CCP titres (r=0.53, p<0.003) and anti-MCV (r=0.46, p<0.001), whereas SDC-4 levels correlated significantly with anti-CCP titres (r=0.61, p<0.001) and RF (r=0.53, p<0.003). Additionally, serum SDC-1 levels correlated with decrement in response to treatment with synthetic DMARDs (r=-0.25, p=0.026). SDC-1 did not correlate with serum SDC-3 (p=0.8) and SDC-4 (p>0.8), whereas serum SDC-3 and SDC-4 had a strong correlation (r=0.8, p<0.001).

Conclusions: Serum SDC-3 and SDC-4 are increased in ACPA-positive RA patients. These data suggest that syndecans might be useful as serum biomarkers for discriminate a group of patients with RA and more severe disease.

THU0163 THE ASSOCIATION BETWEEN INFAMMATORY JOINT DISORDERS AND CORONARY HEART DISEASE: NATIONWIDE REGISTER STUDY IN 50 444 PATIENTS

P Mulull1, V. Rantalalto2,3, H. Kautiainen4,5, L. Virts6, K. Puolakkala7

1Department of Medicine, Tampere University Hospital; 2Centre for Rheumatic Diseases, Tampere University Hospital; 3Faculty of Medicine and life sciences, University of Tampere, Tampere; 4Department of General Practice and Primary Health Care, University of Tampere and Helsinki University Hospital; 5Unit of Primary Health Care, Turku University Hospital; 6Social Insurance Institution of Finland, Turku; 7Department of Medicine, South-Karelia Central Hospital, Lappeenranta, Finland

Background: Inflammatory joint disorders (IJD) are associated with cardiovascular (CV) problems, including coronary heart disease (CHD). This association is best known for rheumatoid arthritis (RA); but also for ankylosing spondylitis and psoriatic arthritis (PsA) associated with a constant generation of citrullinated proteins, and it lead to a proportional hPAD enzymatic production.

Objectives: The aim was to demonstrate the association between serum levels of hPAD4 and severe Periodontitis in patients with rheumatoid arthritis.

Methods: Patients with RA (n=127) matched with healthy controls (n=120) were included. Patients with RA and volunteers were measured: anti-CCP2 and anti-mutated citrullinated vimentin (anti-MCV) antibodies using ELISA. Serum levels of hPAD4 were measured by ELISA.

Results: A significant correlation was found between levels of hPAD4 with the DAS28 ESR score (p<0.002). The high score of HAG-DI (>2.0) correlated with hPAD4 levels (p<0.001). The group of people with higher HAG-DI score and at the same time with greater severity of CP (n=12) showed increased levels PAD4 (p<0.025).

Conclusions: hPAD4 levels correlate with the severity of CP independent of the RA presence and in RA subjects with high score of disability and activity disease.

The hPAD4 could be proposed as a serological marker of clinical severity in chronic diseases such as RA and CP. This project was supported by a grant from the Foundation Annemarie Sohlberg.

SUBCLINICAL ATHEROSCLEROSIS AND CARDIOVASCULAR RISK OF HERPES ZOSTER IN PATIENTS WITH RHEUMATOID ARTHRITIS

Results:

Out of 1176 patients, 217 (18%) showed evidence of subclinical atherosclerosis: ischemic transitory attack, 7 stroke), too this figure is lower than that re-

Conclusions:

This is the first Italian multicenter study on subclinical and clinical

OR:2.117, CI95%:1.35–3.32) were significantly associated with the presence

Background: A high incidence of herpes zoster (HZ) in patients with rheumatoid arthritis (RA) has been reported (1). According to our previous report on the incidence of HZ in Japanese patients with RA enrolled in the IORRA (Institute of Rheumatology, Rheumatoid Arthritis) cohort from 2005 to 2010, the standardized incidence rate (SIR) of HZ per 1,000 patient-years was 9.1 (95% confidence intervals [95 Cis]: 6.2–12.9) (2). In that study, 3.0% of patients used biologics at baseline. Subsequently, the use of biologics has increased, and many new potent disease-modifying antirheumatic drugs (DMARDs) have been introduced. The treatment strategy for RA has progressed in recent years; thus, it is important to investigate whether there is a change in the HZ incidence rate and the risk factors for HZ with the expanded use of biologics.

Objectives: To elucidate the incidence of HZ and risk factors for HZ in RA patients in the IORRA cohort.

Methods: The IORRA cohort is a large, single institute-based, observational cohort of RA patients established at the Institute of Rheumatology, Tokyo Women’s Medical University, in 2000. Among patients with RA enrolled in the IORRA surveys from 2010 to 2015, the incidence of HZ was extracted based on patients’ self-report and confirmed by the medical records. The SIR with 95 CIs was calculated and risk factors for HZ were analyzed using a Cox regression analysis.

Results: For 7,815 patients with RA (female, 84.7%) who were analyzed, the median [interquartile range (IQR)] age was 61.0 [49.7–68.9] years, and disease duration was 10 [4–18] years. Baseline drugs (median dose [IQR]) included prednisolone (PSL, 4 [2–5] mg/day) in 36.8%, methotrexate (MTX, 8 [6–10] mg/week) in 70.4%, and biologics in 14.7% of patients. Among 7,815 patients with RA (female, 84.7%) who were analyzed, the

CIs was calculated and risk factors for HZ were analyzed using a Cox regression analysis.

DOI: 10.1136/annrheumdis-2017-eular.2027

Background: Patients with rheumatoid arthritis (RA) have a higher risk of comorbidities such as infections 1, cardiovascular diseases2, and fractures3 than general population. To understand the risk of these comorbidities in RA more precisely, it is needed to compare the risk between RA and other chronic diseases. A Dutch study4 showed that patients with RA had comparable risk of infections, cardiovascular diseases and stroke with DM cases using Japanese health insurance database.

Methods: This retrospective longitudinal population-based study was conducted using claims data provided by the Japanese Medical Data Center Co., Ltd. We defined individuals as RA cases if they met all of the following: 1) had at least 6 months of continuous enrollment in the health insurance database; 2) had at least one RA diagnosis code and at least one prescription of disease-modifying antirheumatic drugs between January 2005 and December 2013; and 3) were ≥50 years old (RA group, n=3,607). Among individuals who met above criteria 1) and had at least DM diagnostic code and at least one prescription of drugs for DM, but did not meet 2), we selected age- (±5 years), gender-, calendar year of the observation start, and observation length-matched DM cases at 1:3 ratio (RA: DM) (DM group, n=10,821). Each comorbidity was defined as follows: HIs, at least one ICD10 code and one prescription of drugs for infections; CVDs, at least one ICD10 code and one prescription of drugs or medical procedures for CVDs with hospitalization; fractures, at least one ICD10 code for fractures. We calculated incidence rates (IR) with 95% confidence interval (CI) of each comorbidity in the two groups up to 10 years and adjusted odds ratio (OR) of RA compared with DM for each comorbidity using generalized estimating equations (GEE).

Results: The median age was 58, and 75.1% were female in the both groups. The IR [95% CI] of HIs, CVDs, and fractures was 2.8 [2.5–3.2] per 100 patient years, 9.2 [7.4–11.4] per 1,000 PY, 16.7 [14.2–19.6] per 1,000 PY in the RA group, 2.8 [2.6–3.0] per 100PY, 26.3 [24.4–28.3] per 1,000PY, 10.3 [9.1–11.6] per 1,000PY in the DM group respectively. The OR (95% CI) of RA (vs. DM) for HIs, CVDs, fractures was 0.5 [0.8–1.1], 0.4 [0.3–0.6], 1.3 [1.0–1.7] after adjusting for baseline characteristics.

Conclusions: This study revealed that patients with RA had significantly lower risk of CVDs than and similar risk of HIs and fractures to those with DM using health insurance database for the first time in Asia.

THU0167

ASSOCIATION OF BIOLOGIC ANTIRHEUMATIC THERAPY WITH THE RISK OF DEVELOPING TYPE 2 DIABETES IN ADULTS WITH RHEUMATOID ARTHRITIS: NEW EVIDENCE FROM REAL-WORLD DATA

1. University of Melbourne, Melbourne; 2 QIMR Berghofer Medical Research Institute, Brisbane, Australia; 3 Genentech, South San Francisco, CA, United States; 4. Hoffmann-La Roche, Basel, Switzerland

Background: While rheumatoid arthritis (RA) has been associated with the increased risk of developing type 2 diabetes mellitus (T2DM), few basic science studies have indicated the possible beneficial role of some biologic disease-modifying antirheumatic drugs (bDMARDs), including the interleukin-6 (IL-6) based DMARDs, on insulin resistance in patients with RA.

Objectives: To evaluate the impact of treatment with bDMARDs, including the IL-6 inhibitors, on the probability of developing T2DM in a real world setting.

Methods: From the Centricity Electronic Medical Records of GE Healthcare, a longitudinal cohort of 192,509 US adults (age 18 years) with diagnosis of RA from January 2000 to April 2016 was selected. Patients were excluded if they had a prior history of diabetes, cancer and micro- or macro-vascular diseases at diagnosis of RA. Four mutually exclusive antirheumatic treatment groups (TGs) were identified by diagnosis date (Dx) and treatment initiation date (ID): tocilizumab (TCZ, n=843), TCZ+Other bDMARDs (TCZ+obDMARD, n=2489), non-TCZ other bDMARDs (obDMARD, n=45,262) and no bDMARD (n=143,915). Within the treatment groups, 142,225 patients had a minimum 6 months of exposure before development of T2DM or end of follow-up. Treatment-effects models were used to estimate the probabilities (95% CI) of developing T2DM during follow-up in the 4 TGs after adjusting and balancing with inverse-probability-weighted regression for various factors including age, sex, smoking status, body mass index, use of non-biologic DMARDS, use of statins, anaemia status and follow-up time post ID.

Results: At diagnosis, the 142,225 patients were on average 55 years old, 22% male, 71% white Caucasian, 13% with anaemia, and 32% obese with mean BMI of 29 kg/m². About 28%/42% were using statins/MTX at diagnosis or during follow-up before development of T2DM. During mean 4.6 years of follow-up from Dx, 2.6%/2.6%/5.5%/5.8% developed T2DM in the TCZ/TCZ+obDMARD/obDMARD/no bDMARD TGs. The adjusted probability of developing T2DM was 0.05 (95% CI: 0.04, 0.05) in no bDMARD group; with significantly lower probability of developing T2DM in TCZ [0.02 (95% CI: 0.01, 0.04)], TCZ+obDMARD [0.03 (95% CI: 0.02, 0.04)] and obDMARD [0.01 (95% CI: 0.01, 0.02)] groups (Table). Hypertension, higher BMI and Statin use were associated with significantly higher probability of developing T2DM by 0.25% (95% CI: 0.16, 0.35), 0.08 (95% CI: 0.07, 0.08) and 0.36 (95% CI: 0.27, 0.47) respectively. Patients with a prior history of diabetes had an 8% higher likelihood of developing T2DM (p=0.13). Among those who received any bDMARD, those who ever received TCZ had significantly lower probability of developing T2DM (0.024, 95% CI: 0.02, 0.03), compared to those who were never exposed to TCZ therapy.

Table: The probability of developing T2DM, adjusted by age, sex, BMI, anaemia, balanced on hypertension, follow-up, obDMARDs and statin usage.

DOI: 10.1136/annrheumdis-2017-eular.5222
CONCLUSIONS: People who are uncertain about how to attribute illness events are less likely to adhere within the first six months of starting MTX therapy. Encouraging patients to actively monitor their progress with therapy and providing them with support to understand likely effects of MTX may help optimise DMARD use.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.2463
Objectives: To evaluate outcomes of rapid dose escalation regimen of MTX compared with conventional treatment.

Methods: We implemented a randomized, controlled trial that enrolled patients with RA who fulfilled all of the following criteria: 20 to 70 years-old, disease duration ≤2 years, SDAI ≤11, and without prior use of MTX, tacrolimus (TAC) or biologics. Patients were randomized into rapid escalation (RE) group or conventional treatment (CT) group at 1:1 ratio. In RE group, doses of MTX were escalated up to 0.25 mg/kg/wk within 8 weeks after start of MTX and increased maximum tolerable dose or 16 mg/wk until wk 12. If a patient achieved SDAI remission at wk 12, MTX was continued at the same dose. If a patient did not achieve SDAI remission at wk 12 or showed intolerance to MTX, use of TAC or TNF inhibitor (TNFi) were allowed. In CT group, patients were treated with either MTX, TAC, salazosulfapyridine, or bucillamine by the discretion of physicians until wk 12. If a patient achieved SDAI remission at wk 12, same treatment was continued. If a patient did not achieve SDAI remission at wk 12, treatment was allowed. Patients were treated by the discretion of physicians at wk 24 and onward. We set two primary endpoints; the percent of patients achieving SDAI remission and Boolean remission at wk 24. We planned to enroll 120 patients per arm based on expected SDAI remission rates at wk 24, alpha and beta errors and dropout rates.

Results: Enrollment was terminated prematurely and all patients were followed for 48 wks. Of 115 enrolled patients, 57 were randomly assigned to RE group and 58 to CT group. Baseline demographics were similar between the two groups. The median baseline values (RE vs. CT) were 23.2 and 25.9 for SDAI, 0.64 and 0.61 for EO-SD, respectively. At wk 24, the percentages of patients achieving remission in RE and CT groups were 42% and 28% by SDAI criteria (p=0.1, \( \chi^2 \) test), and 35% and 17% (p=0.03, \( \chi^2 \) test) by Boolean criteria, respectively. Median values of HAQ at wk 24 in RE and CT groups were 0 and 0.04, respectively. Ten patients (2% of RE group and those of EO-SD were 0.78 and 0.77 (p=0.12, M-W U test, respectively. At wk 48, these values were not statistically different between the two groups. There were no significant differences between the two groups with incidence of severe adverse events.

Conclusions: The rapid dose escalation regimen of MTX provided significantly higher remission rate and tendency to provide superior SDAI remission than conventional treatment in patients with early RA in the short term.

THU0172 IMPROVEMENT OF DISEASE ACTIVITY IN A 5-YEAR COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED UNDER TREAT TO TARGET RECOMMENDATIONS AND A MULTISPECIALTY CARE MODEL RECEIVING CONVENTIONAL DMARD THERAPY

P. Santos-Moreno1, D. Gomez1, E. Castilla2, R. Giraldo1, G. Ballesteros1, L. Villarreal1, J. Bello3, D. Buitrago-Garcia3, L. Villarreal2, J. Bello2, D. Bultraga-Garcia2, R. Rheumatology1, 2Psychology and processes, 3Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Colombia

Background: Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA), this strategy has become recognized as a standard of good practice embodying the principle that rapid attainment of remission, or low disease activity, can halt joint damage and maintain good quality of life.

Objectives: The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using T2T strategy for a 5 year period in patients with conventional DMARD therapy in a large cohort of patients from a Colombian specialized in RA center with multidisciplinary care model (MCM).

Methods: A descriptive dynamic cohort study was performed. Records of patients using conventional DMARD treatment from specialized in RA center were reviewed; those patients were followed-up under T2T standards. Clinical follow-up was according to DAS28 as follows: every 3–5 weeks (DAS28 ≤5.1), every 7–9 weeks (DAS28 >5.1 and ≤7.1), and every 11–13 weeks (DAS28 >7.1). Therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it. MCM model means that every patient is seen by other specialties involved in conventional DMARD therapy in a large cohort of patients from a Colombian specialized in RA center with multidisciplinary care model (MCM).

Results: We included 1443 patients, 84% were women and 16% were men. Mean age was 62±11 years; mean DAS28 at beginning was 4.0±1; regarding disease activity 57% were in moderate disease activity and 17% in severe disease activity. Clinical follow-up was according to DAS28 as follows: every 3–5 weeks (DAS28 ≤5.1), every 7–9 weeks (DAS28 >5.1 and ≤7.1), and every 11–13 weeks (DAS28 >7.1). Therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it. MCM model means that every patient is seen by other specialties involved in conventional DMARD therapy in a large cohort of patients from a Colombian specialized in RA center with multidisciplinary care model (MCM).

Conclusions: We included 1443 patients, 84% were women and 16% were men. Mean age was 62±11 years; mean DAS28 at beginning was 4.0±1; regarding disease activity 57% were in moderate disease activity and 17% in severe disease activity. THU0173 LONG TERM SAFETY AND EFFICACY OF FILGOTINIB IN A PHASE 2B OPEN LABEL EXTENSION STUDY IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS UP TO 144 WEEKS

Background: Filgotinib (GLP00634, GS-6034) is an oral JAK1 selective inhibitor with a favorable safety and efficacy profile in two 24-week Phase 2b studies as add-on to methotrexate (DARWIN 1) or as monotherapy (DARWIN 2) in patients with active rheumatoid arthritis (RA). Three daily doses were tested (50mg, 100mg or 200mg) in comparison to placebo.

Objectives: To assess long term safety and efficacy of filgotinib 200mg daily in patients from the DARWIN 3 Phase 2 open-label extension study.

Methods: Patients who completed DARWIN 1 or 2 and enrolled in DARWIN 3 received filgotinib 200mg once daily or 100mg twice daily, depending on prior treatment assignment. The DARWIN 3 data cut off was when the last patient reached end point Week 60. For safety, all data from the first intake of filgotinib in DARWIN 1/2/3 were analysed (up to 144 weeks).

Results: 877 patients participated in DARWIN 1 or 2, 790 completed and 739 entered DARWIN 3 from 22 countries (82% females, mean age 53y), 559 patients (75.6%) completed Week 60, 9.3% discontinued due to positive quantitative, 7.8% due to other adverse events, 6.8% for other reasons and 0.3% due to insufficient response. Overall exposure to filgotinib was 1314 patient-years (PYE).

Treatment-emergent adverse events (157.7/100PYE), serious adverse events (5.3/100PYE) and serious infections (1.9/100PYE) occurred at similar rates compared to the core studies, however infections decreased on a percentage basis from 15% (109/739, W0–12) to 5% (25/549, W85–96). 16 cases of Herpes zoster were reported (1.2/100PYE), 6 cases of malignancy (excl. NMSP) (0.5/100PYE) and 1 case of MACE (0.1/100PYE). There was no active case of tuberculosis. Three fatalities were reported (0.2/100PYE).

Mean change from baseline (CBF) at Week 96 and CTCAE toxicity grading in lab parameters of special interest are shown in table 1.

Table 1. Mean CBF at Week 96 and CTCAE toxicity grading in selected lab parameters

Based on an observed case analysis 84% (505/601), 65% (389/601), 44% (265/601) and 51% (298/587) of patients reached ACR20, ACR50, ACR70 and DAS28(CRP) remission at Week 60 respectively.

Conclusions: With 1314 patient-years of exposure, the safety profile of filgotinib appears consistent with that of previously reported double-blind studies and the clinical response appears durable.

THU0174 DRUG RETENTION OF TOFACITINIB VERSUS BIOLOGIC ANTI-RHEUMATIC AGENTS IN RHEUMATOID ARTHRITIS: OBSERVATIONAL DATA FROM THE SWISS SCQM REGISTRY

A. Finckh 1, L. Herzog 2, A. Scherer 3, J. Dudler 4, B. Moeller 5, A. Ciurea 6, R. Mueller 7, P. Hasler 8, P. Exer 9, J. van Muelenhien 10, D. Kyburz 11, C. Gabay 12, R. Zuffery 13

Background: The oral Janus kinase inhibitor tofacitinib (Tofa) was licensed in Switzerland in 2013 for the treatment of moderate to severe rheumatoid arthritis (RA) patients having failed methotrexate. Besides Tofa, rheumatologists in Switzerland have the choice between 7 alternative bDMARDs licensed with similar indications, including 5 TNFi inhibitors (TNFi) and 2 bDMARDs with other mechanisms of action (OMA-bDMARDs).

Objectives: To compare the drug retention rate of three alternative treatment options licensed with a similar indications, namely Tofa, TNFi and OMA-bDMARDs, using data from the Swiss registry.

Methods: This is an observational cohort study within the Swiss Clinical Quality Management registry (SCQM). All therapies with Tofa, TNFi, and OMA-bDMARDs initiated in adult RA patients between August 1, 2013 and Dec 1, 2016 were considered. The exposure of interest was treatment with Tofa vs TNFi and vs OMA-bDMARDs (Abatacept or Tocilizumab). The primary outcome was drug retention defined as the time from initiation to discontinuation of treatment. We used Kaplan Meier curves to display drug retention and Cox proportional hazard models stratified by seropositivity to analyze the hazard for treatment discontinuation. We adjusted for potential confounders, including gender, age, disease duration, seropositivity, BMI, smoking status, DAS28(CRP) and the total number of previous bDMARDs. We applied multiple imputation to account for missing baseline covariate data.

Results: A total of 1996 therapies were initiated during the study period (376 Tofa, 928 TNFI, 692 OMA-bDMARDs). Some differences in disease and treatment characteristics existed between the 3 groups, in particular TNFi tended to be used in patients with fewer previous bDMARDs experience, younger age and shorter disease duration. The crude overall drug retention was similar between the 3 these drug groups (p=0.24) (Figure 1A). The adjusted analysis demonstrated a slightly higher hazard of drug discontinuation with TNFi compared to Tofa [HR 1.27 (95% CI: 1.02 – 1.57, p=0.03)], while no difference was observed for OMA-bDMARDs compared to Tofa or TNFi. There was no active case of tuberculosis. The results of this observational study suggest that Tofa is a valuable alternative to treatment options in RA, with Tofa drug retention at least comparable to other available bDMARDs.

THU0175

INFLAMMATION DETECTED WITH MODERN SENSITIVE MRI ANALYSIS DEMONSTRATES THAT THERAPEUTIC RESPONSE AS EARLY AS ONE MONTH PREDICTS 12-MONTH RADIOGRAPHIC PROGRESSION: DATA FROM A STUDY USING TOFACITINIB AND METHOTREXATE IN METHOTREXATE-NAIVE PATIENTS WITH EARLY RA

P.C. Conaghan1, 2, M.A. Bowes2, M. Østergaard4, G. Gualliard4, D. Chapman5, A. Stein6, Z. Xie7, A. Koenig8, K. Soma7, B. Wilkinson7, 1Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; 2NIHR Leeds Musculoskeletal Biomedical Research Unit, Chapel Allerton Hospital, Leeds; 3iMorphics Ltd, Manchester, United Kingdom; 4Copenhagen Center for Arthritis Research, Copenhagen, Denmark; 5Pfizer Inc, New York, NY; 6Quantiles, Morrisville, NC; 7Pfizer Inc, Groton, CT; 8Pfizer Inc, Collegeville, PA, United States

Objectives: To determine if early changes in RAMRIS were predictive of subsequent MRI and radiographic damage progression in a study of tofacitinib for the treatment of early RA in methotrexate-naive patients with minimal radiographic progression.

Methods: We used data from an exploratory, Phase 2 randomised controlled trial comparing tofacitinib, methotrexate and the combination (n=109) in methotrexate-naive patients with early active RA.1 All patients met ACR classification criteria for active RA. MRI was performed at baseline and at 1, 3, 6 and 12 months. A single centralised reader read all MRI data; data for each patient were randomised by time point and read in the same sitting. We examined changes in synovitis, osteitis and erosions for RAMRIS and RAMRIQ at 1 and 3 months and performed univariate analyses on their relationship to RAMRIS, RAMRIQ and radiographic progression (modified Total Sharp Score [mTSS]) at 12 months.

Results: Reduction in RAMRIQ synovitis and osteitis at 1 and 3 months were significantly associated with reduction in RAMRIS erosion progression at 12 months (Table). Improvement in RAMRIS synovitis and osteitis at 1 and 3 months were also associated with reduction in radiographic progression at 12 months, while RAMRIS erosions at 1 and 3 months were not significantly associated with radiographic progression (Table). Early changes in RAMRIS erosion at 1 and 3 months were associated with radiographic progression at 12 months (Table). Treatment with tofacitinib alone or in combination with methotrexate was also associated with reduced progression in RAMRIS erosions (p=0.017 and p=0.007, respectively).

Conclusions: These data suggest that sensitive automated detection of early changes in synovitis and osteitis, as well as erosions for RAMRIS and RAMRIQ at 1 and 3 months is associated with reduced radiographic progression and that treatment with tofacitinib alone or in combination with methotrexate is associated with reduced progression in RAMRIS erosions.

Table. Univariate analyses of the relationship between RAMRIS and RAMRIQ measurements at Month 1 and 3 and RAMRIS erosion and radiographic progression at Month 12.

THU0176

EFFICIENCY AND SAFETY OF RAPAMYCIN COMBINED WITH LOW-DOSE IL-2 TREATMENT COMPARED WITH METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Z. Li1, H. Niu1, M. Chen1, H. Yao1, J. Luo1, C. Gao2, X. Li1, C. Wang1, 1Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China; 2Pathology, Brigham and Women’s Hospital, Harvard Medical School, Brigham and Women’s Hospital, Harvard Medical School, United States

Background: The molecular target rapamycin (mTOR) signaling can regulate between effector and regulatory T cell lineage commitment and to be a new therapy for several autoimmune diseases, such as systemic lupus erythematosus [2].

Objectives: To evaluate whether rapamycin is beneficial in patients with Rheumatoid Arthritis (RA), and compared with Methotrexate in efficiency and safety.

Methods: Fifty-eight DMARD-naive RA patients were enrolled, thirty-eight were treated with Rapamycin (0.5 mg every 2 days, combined with IL-2 500 IU per day for 5 days), the others with Methotrexate (10 mg per week) taken as control. Clinical improvement and immunological assessments were performed at baseline, 1 and 12 weeks. Treatment group assessed CD4+ T cell subsets by flow cytometry at baseline, 1 and 12 weeks.

Results: We enrolled 58 patients. At baseline, patients had a mean DAS28 of 3.34 (0.87) in the Rapamycin group and Methotrexate group included 38 and 20 patients, respectively, with no significant differences in baseline characteristics. At 1 week, the mean DAS28 after Rapamycin treatment (2.43 [0.77]) and Methotrexate (2.25 [0.86]) was not significantly different (P=0.43). Same as ESR (24.74 [24.53], 21.76 [24.27], P=0.69). The dose of glucocorticoid during hospitalization of rapamycin treatment (720.8 [554.3]) was lower than Methotrexate (1202.3 [943.1], P=0.042). The length of hospital stay of Rapamycin (14.5 [3.9]) was lower than Methotrexate (21.0 [3.8], P<0.001). Rapamycin administration resulted in an increase in the absolute counts of Treg cells from a median of 36.82 cell/ul (at week 0) to 99.80 cell/ul (at week 1) (P<0.001). The ratios of Th17/Treg cells showed a reduction from a median of 0.16 to 0.09, and the difference was significant (P=0.047). At 12 week, 5 patients treated with Rapamycin dropped out because of non-compliance. the mean DAS28 was not significantly different (2.36 [0.97], 2.16 [0.86], P=0.51). The same as the daily dose of glucocorticoid (10.21 [32.9], 9.16 [40.1], P=0.804). The absolute counts of Treg cells increased from a median of 36.82 cell/ul (at baseline) to 43.26 cell/ul after Rapamycin administration (P=0.028). The ratios of Th17/Treg had no significant difference from a median of 0.16 at baseline to 0.12 at week 12 (P=0.937). Liver enzyme elevations occurred in 2 patients after Methotrexate therapy for 1 week. However, there were no serious adverse events observed during the 12-week period of rapamycin treatment.

Conclusions: Rapamycin combined with low-dose IL-2 appears to be a safe and effective therapy for RA, by a rapid increase of Treg cells and a correction of the ratio of Th17/Treg cells, which has gotten a same response compared with Methotrexate.

ABT-494 PHARMACOKINETICS FOLLOWING ADMINISTRATION OF THE ONCE-DAILY EXTENDED-RELEASE TABLET FORMULATION BEING UTILIZED IN THE ONGOING RHEUMATOID ARTHRITIS PHASE 3 TRIALS

M.-E.F. Mohamed1, J. Zeng1, I.-H. Song2, A.A. Ohman1, 1Clinical Pharmacology and Pharmacometrics; 2Immunology Clinical Development, AbbVie, North Chicago, United States

Background: ABT-494 is a selective Janus Kinase 1 inhibitor, in two Phase 2b clinical trials, 6 mg and 12 mg twice-daily (BD) doses of ABT-494 immediate-release formulation achieved optimal benefit-risk profiles. To enhance patients’ compliance, an extended-release formulation was developed targeting to achieve comparable exposures with the 6 mg and 12 mg BD of the immediate-release formulation with once-daily (QD) administration.
Objectives: The objective of this work was to characterize the pharmacokinetics of ABT-494 with the extended-release formulation that is currently being utilized in Phase 3.

Methods: Comparison of ABT-494 pharmacokinetics from the immediate-release and extended-release formulations was conducted following multiple-dose administration to healthy subjects. Two cohorts of subjects were evaluated. In the first cohort, healthy subjects (N=12) received multiple 15 mg QD doses of the extended-release tablet formulation and multiple 6 mg BID doses of the immediate-release capsule formulation for 7 days. In the second cohort, healthy subjects (N=12) received multiple 30 mg QD doses of the extended-release tablet formulation and multiple 12 mg BID doses of the immediate-release capsule formulation for 7 days. Both evaluations were conducted following an open-label, randomized, 2-period, 2-sequence, crossover design under fasting conditions. ABT-494 plasma concentrations were measured and pharmacokinetic parameters were calculated using non-compartmental analyses.

Results: At steady-state, ABT-494 AUC_{0–24} ratio (and [90% confidence interval]) was 0.94 [0.84 – 1.05], C_{max} ratio was 0.91 [0.74 – 1.12] and C_{min} ratio was 1.09 [0.85 – 1.40] for the 15 mg QD regimen of the extended-release formulation relative to the 6 mg BID regimen of the immediate-release formulation. Similarly, ABT-494 mean AUC_{0–24} ratio was 0.97 [0.87 – 1.09], C_{max} ratio was 0.90 [0.73 – 1.11] and C_{min} ratio was 0.87 [0.75 – 1.02] for the 30 mg QD regimen of the extended-release formulation relative to the 12 mg BID regimen. All evaluated regimens were well-tolerated by healthy subjects.

Conclusions: ABT-494 regimens of 15 mg QD or 30 mg QD of the extended-release formulation, currently being utilized in Phase 3 RA studies, provide similar exposures to 6 mg BID and 12 mg BID, respectively of the immediate-release capsule formulation previously shown to provide optimal benefit-risk profiles in RA Phase 2 trials.

THU0179 INCIDENT OF DEEP VEIN THROMBOSIS AFTER TOTAL HIP REPLACEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Background: The purpose of this study was to compare incidences of VTE in patients with rheumatoid arthritis (RA) and osteoarthritis (OA) after total hip arthroplasty, different strategies for prevention of VTE and evaluate their efficiency.

Objectives: To evaluate the efficiency of prevention of VTE in patients with RA and osteoarthritis and arthritis after hip replacement surgery under comparable conditions.

Methods: A one-year prospective cohort study was performed on 173 primary THA patients operated in V.A. Nasonova Research Institute of Rheumatology for the period 2016. Of these, 91 patients with RA (52.6%) and 82 patients with OA (47.4%). For a comparative analysis of the efficiency of anticoagulant therapy, each patient group was divided into 2 subgroups by type of drug therapy. The first - nadroparin calcium (the drug therapy was started for 12 hours after the operation at a dose of 0.1 ml per 10 kg of body weight time one per day), the second - nadroparin calcium with transfusion to dabigatran etexilate (the first stage of 4 hours after the operation was started therapy by nadroparin calcium, and then after the removal of the epidural catheter moved to the dabigatran etexilate), Doppler ultrasonography (DUS) was routinely performed preoperatively and on postoperative day 7, 14, then 1 time a month for diagnosing a deep venous thrombosis (DVT). Time of observation was 6 months.

Results: DVT were reported in 8 (4.8%) patients, 2 of them (1.2%) with RA and 6 (3.4%) with OA. Distal DVT developed on 8 and 17 days after total hip replacement in RA patient's group. They received nadroparin calcium only. 5 patients with VTE after surgery from OA group used nadroparin calcium and 1 patient was on combined drug therapy. Of the 8 cases of VTE - 6 (75%) were asymptomatic and 2 (25%) with development of clinical and laboratory picture. All cases of thrombosis in a group of RA was asymptomatic. In a perioperative period of clinically significant bleeding was not seen.

Conclusions: Cases of VTE in patients with RA, despite the large number of risk factors, under comparable conditions is significantly lower than patients with OA. The number of asymptomatic DVT dominates symptomatic both comparison groups. In patients with RA and OA who were from the first group have reported 6 cases of VTE and only 1 case of VTE have reported in patients who were from second group. Prevention of VTE by combination of LMWH and NOACs was more effective and safety in RA and OA patients.

THU0180 SYSTEMS BASED INVESTIGATION OF THE ANTI-INMUNOGENIC POTENTIAL OF DMARDS FOR RHEUMATOID ARTHRITIS USING HUMAN PRIMARY CELL-BASED BIOMAP® PHENOTYPIC PROFILING

A. O'Mahony 1, E. Choy 2.

1BioMAP Division, DiscoverX Corporation, South San Francisco, United States; 2Division of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom

Background: Biologics represent a rapidly growing class of approved and investigational drugs routinely used to treat multiple diseases, including inflammatory and rheumatic diseases. Unfortunately, the success of such therapeutics is
undertaken by their immunogenicity and the development of anti-drug antibodies (ADA) associated with treatment failure and hypersensitivity reactions2. Methotrexate (MTX) has been shown to reduce the generation of an ADA response3. The ability of other conventional synthetic Disease Modifying Anti-Rheumatic Drugs (csDMARDs) to mitigate unwanted immunogenicity, and prolong efficacy in patients who cannot tolerate methotrexate, is less clear.

**Objectives:** We previously reported that MTX markedly inhibited the production and release of soluble immunoglobulin (sIgG) by human primary B cells cocultured with PBMC (BT system) in the in vitro BioMAP® phenotypic screening panel2. MTX also had anti-proliferative effects on human primary tissue and immune cell types4. We evaluated other csDMARDs to determine if they were broadly active or, were similar to MTX in selectively blocking sIgG production and therefore would be more likely to reduce ADA associated with biologics.

**Methods:** A series of csDMARDs (sulfasalazine, hydroxychloroquine, cyclosporine, leflunomide, azathioprine) were profiled at the concentrations across the BioMAP Diversity PLUS™ panel to generate phenotypic activity profiles. In addition to assessing sIgG production, effects on a broad scope of disease-relevant readouts related to primary cell activation and proliferation, inflammation, wound healing, tissue remodeling and fibrosis, and were also evaluated.

**Results:** Similar to MTX, cyclosporine, leflunomide and azathioprine strongly inhibited sIgG production at all tested concentrations. In contrast, treatment with sulfasalazine or hydroxychloroquine did not decrease sIgG indicating these compounds may not mitigate the immunogenicity of biologics. In contrast to MTX, several csDMARDs were broadly active in many BioMAP systems. Bioinformatics analysis was used to identify distinct mechanistic signatures for these agents in the BioMAP Panel.

**Conclusions:** The results support application of the BioMAPs in vitro assay suite in preclinical drug discovery, to determine the suitability of csDMARDs as anti-immunogenic co-treatments to extend the clinical efficacy of biologics. Clinical studies are needed to confirm these results, however, in inflammatory bowel diseases and to a less extent in rheumatoid arthritis, azathioprine has been shown to reduce immunogenicity of biologics5.

**THU0182 MONOTHERAPY WITH THE JAK1-SELECTIVE INHIBITOR FILGOTINIB DISPLAYS AN ANTI-INFLAMMATORY BIOMARKER PROFILE IN RHEUMATOID ARTHRITIS PATIENTS**

**A. Kavanaugh,1  A. Van der Aa,2  C. Jamoul, W. Li, L. Goyal, Y. Pan1,  P. Harrison,2  C. Tasset, J. Tarrant,3  R. Galien,4  P. P. Harrison2, C. Tasset2, J. Tarrant3, R. Galien 4.**

**Background:** Janus kinases (JAKs) are key proteins in the signal transduction of many cytokines and growth factors. The selective JAK1 inhibitor filgotinib (GLPG0634, GS-6034) has been evaluated in a 24-week phase 2B study (DARWIN 2) as monotherapy in active rheumatoid arthritis (RA) patients with inadequate response to methotrexate and has shown a good safety and efficacy profile1.

**Objectives:** To gain insight into filgotinib mode of action as monotherapy in RA patients by analysing the impact of filgotinib on a broad panel of immune modulators in the serum.

**Methods:** RA patients received either placebo (PBO), or filgotinib monotherapy at 50mg, 100mg or 200mg once daily (QD). Serum samples were collected at baseline, week 4 and week 12 and analysed using the 18-plex bead-based immunoassay (HSTCMAG-28SK Merck-Millipore) on BioPLEX 200 instrument to measure cytokine concentration. Median % change from baseline for biomarkers are reported for week 4 and 12. Wilcoxon rank-sum test assessed the significance of difference between filgotinib treated groups and PBO.

**Results:** Following treatment with filgotinib at 100 mg QD and 200mg QD, there were significant reductions in cytokines important in expansion and activity of multiple T cell subsets and innate immunity compared to PBO (see Table). These changes include decreases in proinflammatory cytokines (IL-6, IL-1β, and TNFα), Th1-related (IL-2, IFN-γ and IL-12), Th2-related (IL-4, IL-5, and IL-13) and Th17-related cytokines (IL-17a, IL-17, IL-21, IL-23 and IL-23) in PBO and filgotinib treated groups. All doses of PBO and filgotinib are presented as a significant higher (mean±SD) at 100mg (P=0.01; ***p<0.001). Table 1. Median percent change of biomarkers from baseline

**ADHERENCE PROFILES TO METHOTREXATE OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) ELIGIBLE FOR BIOLOGICS: TYPOLoGIES FROM FORGET, A CROSS-SECTIONAL SURVEY OF 244 PATIENTS**

C. Beauvais 1, V. Hautin-Monteil 2, M.-C. Ducrot 3, R.-M. Filpo 4, 1 Rheumatology Department, Saint Antoine Hospital, APHP; Paris; 2 Roche France; 3Agence A-A, Boulongue-Billancourt; 1 Rheumatology department, Roger Salengro Hospital, Lille, France

**Background:** Adherence to Methotrexate (MTX) is not optimal in RA patients [1]. The FORGET survey carried out in 2016 aimed to assess the MTX adherence rate of RA patients, insufficient responders to MTX, biologic-naïve, when an initiation of biologics was being considered. Non-adherence was defined as a compliance rate < 80% according to the CQR19 (Compliance Questionnaire for Rheumatology) [2]. The factors tested were socio-demographic characteristics, DAS 28, RAID, CQR responses, beliefs, voluntary or involuntary dose skipping, social and medical support.

**Results:** Of the 244 patients analyzed, the non-adherence rate was 34%. The rather weak correlation between adherence (CQR) and the disease impact (RAID) tended to confirm the hypothesis of different profiles. Four typologies of non-adherence were determined. Groups G1 and G2 were non-adherent patients with high (G1) or lower (G2) impact. Groups G3 and G4 were patients with good adherence with high (G3) or lower impact (G4). Significant adherence factors were found for these 4 groups (p<0.01 (table).

**Conclusions:** Four adherence profiles to Methotrexate have been identified. Among the non-adherent patients, 2 topologies are opposed: 1- patients in state of suffering, with low support from relatives, negative beliefs and significant professional impact. 2-patients with less disease impact, who perceived their treatment with constraints although well tolerated. Detection of patients' profiles may allow targeted strategies to improve or maintain adherence.

**COMPARISON OF TOFACITINIB SAFETY AND EFFICACY IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO CONVENTIONAL SYNTHETIC DMARDS, OR TO ONE OR MORE BIOLOGICAL DMARDS**

C. Charles-Schoeman 1, J. Kremer 2, S. Krishnaswami 3, K. Soma 4, J. Geier 4, R. Zhang 4, S. Strengfelt 5, G. Burmester 6, 1 University of California, Los Angeles, CA; 2 Albany Medical College and the Center for Rheumatology, Albany, NY; 3 Pfizer Inc, Groton, CT; 4 Pfizer Inc, New York, NY, United States; 5 Charité – University Medicine Berlin, Berlin, Germany

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment (tx) of rheumatoid arthritis (RA). Studies have shown diminishing response to tx in RA patients (pts) when cycling through TNF inhibitors. Prior analyses assessed tofacitinib in csDMARD- inadequate response (IR) pts vs overall bDMARD-IR pts.

**Conclusions:** Among the non-adherent patients, 2 topologies are opposed: 1- patients in state of suffering, with low support from relatives, negative beliefs and significant professional impact. 2-patients with less disease impact, who perceived their treatment with constraints although well tolerated. Detection of patients' profiles may allow targeted strategies to improve or maintain adherence.

**THU0183**

**IMPROVED ADHERENCE TO NEWLY PRESCRIBED DMARDS WITH CO-PRESCRIPTION WITH LOW DOSE STEROIDS IN RHEUMATOID ARTHRITIS PATIENTS ATTENDING CLINIC AT A DISTRICT GENERAL HOSPITAL IN THE UK**

A. Nulailyadde 1,2, K. Culler 3, A. Nandagudi 4, A. Bhadrwaj 5, 1Department of Rheumatology, Teaching Hospital Kadry, Kandy, Sri Lanka; 2Department of Rheumatology, Basildon and Thurrock University Hospital, Basildon, United Kingdom

**Background:** Non-adherence to DMARDS is associated with disease flares and increased disability. Adherence rates to prescribed medicine regimes in people with Rheumatoid Arthritis vary from 30–80% in different studies. Improving adherence to therapy leads to better disease outcome and reduced costs associated with management of RA.

**Objectives:** This study was carried out as a pilot study to look at the effect of co-prescription of steroids on the adherence and side effects to newly prescribed DMARDS in patients with rheumatoid arthritis.

**Methods:** This is a prospective, observational cohort study, for the duration of three months per participant. Patients were selected sequentially from those attending outpatient clinic at Basildon Hospitals with a confirmed diagnosis of rheumatoid arthritis (ACR/EULAR criteria), and had been planned to start on a new DMARD by the treating physician. Baseline data included demographics, disease characteristics and data regarding steroid co-prescription including route, dose and duration. Patients were reviewed at three months to look at DMARD adherence defined by continuation of the DMARD. We looked at the side effect profile as possible contributing factor to non-adherence. The effect of co-prescription with steroids and other demographic data on treatment duration was investigated using Kaplan-Meier survival plots. Logistic regression analysis was used to investigate the effect of co-prescription of steroids on continuation of medication.

**Results:** Fifty one patients were recruited to the study. Median age at the time of enrolment was 61 years (IQR 46–71), 73% were females and 92% were caucasians. Seventy percent of the patients were seropositive and DMARD naïve with a mean DAS CRP at recruitment of 4.13 (1.21). Seventeen (33%) patients were co-prescribed with steroids at the initiation of DMARDS. Out of these 59% (n=10) were DMARD naïve. Thirty patients received a tapering dose of oral prednisolone with a mean starting dose of 13.8mg daily (range 3mg - 20 mg) for a mean duration of 10.8 weeks. Two patients received oral prednisolone 5mg daily for 12 weeks. The mean cumulative dose of oral prednisolone prescribed was 602.2mg. The two remaining patients received 120 mg of depomedrone IM. The non-adherence rate for our cohort was 35%, 6% for patients co-prescribed with steroids versus 50% for patients who were not co-prescribed with steroids. The odds ratio for likelihood of discontinuation for patients who were not co-prescribed with steroids versus patients who were, was 16 (1.94–134.5, p=0.011). At the end of therapy, 25% of the patients who were co-prescribed with steroids versus 32% of the patients who were not co-prescribed with steroids reported side effects to the DMARD initiated. The odds ratio for reporting side effects for steroid co-prescription was 0.28 (0.054–1.438, p=0.12).

**Conclusions:** Co-prescription of low dose steroids with initiation of DMARDS increases the chances of adherence and possibly reduces the side-effect profile.

---

**Filgotinib** also reduced the β- and T-cell development cytokine IL-7. In contrast, IL-8 was not affected by filgotinib. Reductions in MIP1α, MIP1β and GM-CSF are in line with a down modulation of innate immune activity.

**Conclusions:** Treatment of RA patients with filgotinib monotherapy resulted in significant reduction in the levels of a broad range of cytokines related to Th1, Th2, Th17 and potentially B cells, as well as innate immunity. This observed anti-inflammatory activity of filgotinib is consistent with its efficacy in RA patients.

Objectives: To compare tofacitinib safety and efficacy in RA pts who have previously failed tx (lack of efficacy and/or safety reasons) with csDMARDs, with pts who failed tx with either 1 or ≥2 prior bDMARDs.

Methods: Data from pts who received ≥1 dose of tofacitinib in 19 RA studies up to 96 months (2 Phase [P] 1; 9 P2; 6 P3; 2 LTE studies [1 LTE ongoing; data as of March 2015]) were used in this analysis. Data were pooled across all 19 studies for safety assessments in the All RA population: csDMARD-IR, n=4377; bDMARD-IR, n=838 (1 bDMARD-IR, n=533; ≥2 bDMARD-IR n=305). Safety was also assessed up to 24 months in pts randomised to tofacitinib 5 or 10 mg BID or placebo (PBO) in a pooled P2/P3 randomised controlled trial (RCT) population (8 P2, 6 P3 studies; csDMARD-IR, n=332; bDMARD-IR, n=782). Incidence rates (pts with events/100 pt-years) were calculated for serious AEs (SAEs), serious infections (SIs) and herpes zoster (HZ). Efficacy was assessed by pts achieving ACR20 response and DAS28-4 (ESR) ≤3.2 at Month (M) 3 in a pooled P3 RCT population (P2/P3 RCT n=2757; ORAL SOLO n=272).

Results: Prior to tofacitinib tx, bDMARD-IR pts had longer RA duration, greater disease burden and more corticosteroid use vs csDMARD-IR pts. SAEs were more common among bDMARD-IR vs csDMARD-IR pts in both the P2/P3 RCT and the All RA populations; SAE rates were not higher in pts failing ≥2 bDMARDs vs 1 bDMARD (Table). Incidence rates for SIs were generally greater in pts with IR to bDMARDs vs csDMARDs in the All RA population, but generally lower in pts with IR to 1 or ≥2 bDMARDs vs csDMARDs in the P2/P3 RCT population; incidence with 5 mg BID was lower for 1 vs ≥2 bDMARDs in the P2/P3 RCT population. Incidence rates for HZ were similar to tofacitinib vs csDMARDs or 1 bDMARD, but appeared numerically greater in pts with IR to ≥2 bDMARDs in both the P2/P3 RCT and the All RA populations. A similar pattern was observed across tofacitinib and PBO groups. Efficacy at Month 3 in the P3 RCT population was greater with both tofacitinib doses vs PBO. Although absolute response was smaller in pts with IR to ≥2 bDMARDs vs csDMARDs, generally similar efficacy was observed in pts with IR to 1 or ≥2 bDMARDs (Table).
activity, HQO-DL, and pain as early as Week 2 (first post-baseline assessment), and improvements in fatigue by M3. Responses were maintained or improved through M3 (monotherapy) or M6 (with background csDMARDs).

THU0188

EFFICACY AND SAFETY OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO DID NOT RESPOND TO SYNTHETIC AND BIOLOGICAL DMARDS IN CLINICAL PRACTICE

E. L. Luchikina 1, D. Karateev 2, A. Misuyuk 1, N. Demidova 1, G. Loukina 1, D. Abdulganieva 3, A. Baranova 4, A. Babaeva 5, L. Evstigneeva 6, O. Ivanova 7, V. Mazurov 8, O. Semagina 9, A. Sizikov 10, V. Sorototskaya 11, E. Nasonoval 12, Early arthritis department, 1 Nasonova Research Institute of Rheumatology, Moscow, 2 Kazan State Medical University, Kazan, 3 Volgograd State Medical University, Volgograd, 4 Ekaterinburg 1st Regional Clinical Hospital, Ekaterinburg, 5 Voronezh Regional Clinical Hospital, Voronezh, 6 Northwestern State Medical University named after I.I.Mechnikov, Saint-Petersburg, 7 Samara Regional Clinical Hospital, Samara; 8 Scientific Research Institute of Clinical Immunology, Novosibirsk, 9 2nd City Hospital, Tula, Russian Federation

Background: Tofacitinib (TOFA) is so far the only representative of a new class of Jak-inase inhibitors in rheumatology. Despite extensive data on TOFA obtained from 3rd phase studies, for use in clinical practice, the information is limited.

Objectives: To study the efficacy and safety of TOFA in RA in clinical practice.

Methods: Data from two parallel Phase-IV open-label observational clinical trials, modelling clinical practice, conducted by very similar protocols in 11 rheumatology centers in Russia, Inclusion criteria were active RA, methotrexate (MTX) failure, and/or other synthetic or biologic DMARDs failure. In total, 142 pts (26 males, 116 females, age 51.5±12.2 years, disease duration 88.6±78.1 months, 86.6% RF(+), 76.6% ACPA(+), 81.7% with erosive disease, DAS28-ESR 5.89±1.03, SD: 35.7±13.4, HAO 1.59±0.64) were included. 32 (22.5%) pts had biologics in history. TOFA used in the dose of 5 mg BiD for 6 months, with possibility to increase to 10 mg BiD (carried out in 27/pts after 3±2.7 weeks). 115 (81%) pts received TOFA in combined mode (MTX 118±5,4 mg per week), 18 with leflunomide or sulfasalazine, 9 pts used TOFA in monotherapy.

Results: 129 (90.8%) pts successfully completed the six-month period of treatment. TOFA was withdrawn due to lack of response in 6 cases, adverse events (AEs) in 4 (anemia, arterial hypotension, skin vasculitis, mouth ulcers), withdrawal of informed consent – 2, protocol violation – 1. At month 3 SDAI score decreased to 14.6±10.9 (p<0.01), 55 (42.6%) pts achieved SDAI LDA and 22 (17.1%) SDAI remission; HAQ decreased to 0.95±0.61, HAO=0.5 observed in 56 (27.8%) pts. After 6 months, SDAI and HAQ scores decreased to 10.5±8.6 and 0.83±0.64 resp. (p<0.01); 81 (62.8%) pts achieved SDAI LDA and 29 (22.5%) SDAI remission; HAO=0.5 observed in 48 (37.2%) pts. Results of treatment in patients with and without biological DMARDS in history were similar. Pts who needed dose escalation of TOFA had worse results at month 3 compared to others (SDAI 21±10.2 and to 33±10.7 resp., p=0.02), but after increase of the dose to 10 mg BiD at month 6 they showed a slightly better result (SDAI 9.5±7.1 and to 10.7±8.9 resp., p=0.54). Only 2 serious AEs (anemia and skin vasculitis) observed. We didn’t see any case of Herpes zoster in our group.

Conclusions: TOFA was effective in patients with severe RA who did not respond to both synthetic and biological DMARDS (achievement of SDAI LDA in 42.6% of pts at month 3 and in 62.8% at month 6). Dose escalation to 10 mg BiD can be useful in 1/4 of patients who do not respond to standard dose of TOFA. TOFA has shown a good safety profile.

THU0189

SAFETY OF FOUR TREATMENT REGIMENS IN EARLY RHEUMATOID ARTHRITIS

E. Fedorenko 1, G. Lukina 2, Y. Tigindin 3, D. Karateev 2, 1 Moscow Clinical Scientific Center; 2 Moscow Clinical Scientific Center, V.A.Nasonova Research Institute of Rheumatology; 3 V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Objectives: To compare safety data in patients (pts) with early (≤ 2 years duration) RA who were randomised in the four treatment regimens (MTX, MTX + BiD, MTX + a csDMARD, MTX + a csDMARD + BiD).

Methods: One hundred forty-one pts with RA of less than 2 years duration (122 women, mean age 51 years, mean disease duration 24 weeks, mean DAS 28 5.9; 84% RF-positive,59% ACPA-positive) were randomly allocated to receive one of the following treatment regimens: methotrexate (MTX, up to 20 mg/week,
DERMATOLOGICAL GUIDELINES FOR MONITORING METHOTREXATE TREATMENT REDUCE DRUG-SURVIVAL COMPARSED TO RHEUMATOLOGICAL GUIDELINES

H. Bernet Moens, F. Singeux, O. Vollenbroek, R. Janssens, C. Dogen. Rheumatology & Clinical Immunology; Dermatology, Ziekenhuisgroep Twente, Almelo; Health Technology and Services Research, University of Twente, Enschede, Netherlands

Background: Methotrexate (MTX) is widely used in the treatment of psoriasis and psoriatic arthritis (PsA). To prevent MTX-induced adverse events dermatological MTX guidelines advise a higher number and frequency of blood tests than rheumatological guidelines (1,2). These differences are not based on evidence indicating a higher risk for patients with psoriasis compared to PsA.

Objectives: Compare the effects of MTX monitoring strategies by rheumatologists and dermatologists.

Methods: Patients with psoriasis or PsA in a Dutch teaching hospital. Inclusion criteria: start methotrexate (MTX) between 2006 and 2012 and scheduled follow-up by dermatologist or rheumatologist. Exclusions: incomplete availability of lab data. Start and stop dates and dosing of MTX and folinic acid, reasons for withdrawal of MTX, numbers and results of laboratory tests performed for MTX safety, occurrence of any serious adverse event (SAE) were retrieved from electronic records.

Results: PsA patients used higher initial and maximum doses of MTX and folinic acid, but psoriasis patients had a higher frequency of abnormal liver function tests, resulting in a striking difference in withdrawal of MTX (Table). In PsA MTX was more often withdrawn for remission, and less frequently for ineffectiveness leading to longer drug survival in the first course of treatment. There were no differences in the occurrence of SAE or death between these groups. Hospital admissions related to infection were recorded in 6 (3.1%) PsA vs 4 (2.1%) psoriasis patients.

Conclusions: In most cases side effects were moderate or minimal. The most serious side effects, leading to the discontinuation of the therapy, were registered in LEF group. There was no withdrawal of treatment in MTX-P group. Safety profile was the same in all groups.

EFFECTS OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, ON PATIENT-REPORTED OUTCOMES IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS

H. Yamakana, Y. Tanaka, T. Takeuchi, N. Sugiyama, T. Hirose, N. Yoshii, Y. Morishima, S. Toyozumiz1, 2, Tokyo Women's Medical University, Tokyo; 3University of Occupational and Environmental Health, Kitakyushu; 4Keio University; 5Pfizer Japan Inc, Tokyo, Japan

Background: Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). Improvements in patient-reported outcomes (PROs) have been reported in the global population of the Phase (P)2, P3 and long-term extension (LTE) tofacitinib studies.

Objectives: To explore the effect of tofacitinib on PROs in Japanese patients (pts) with RA.

Methods: In this post hoc analysis, data from Japanese pts with RA were obtained from two 12-week randomised dose-finding P2 studies in methotrexate (MTX) inadequate responder (IR) and DMARD-IR pts (NCT00603512; A3921039 and NCT00687193; A3921040), one 24-month P3 study in MTX-IR pts (ORAL Scan; NCT00847619; A3921044) and an open-label LTE study in pts who completed a qualifying P2 or P3 study (NCT01661661; A3921041; completed April 2014). Pts received tofacitinib 5 or 10 mg twice daily (BID) or placebo (PBO) (P2 and ORAL Scan; no PBO in LTE). In ORAL Scan, non-responder BID pts advanced to tofacitinib at Month 3; all remaining pts were advanced at Month 6. PROs included: mean change from baseline in Pts Global Assessment of Arthritis (PGA; visual analogue scale [VAS]), Physician's Global Assessment of Arthritis (PGA; VAS), Health Assessment Questionnaire-Disability Index (HAQ-DI), Pain (VAS), Functional Assessment of Chronic Illness Therapy - Fatigue (FACT-F), Medical Outcomes Study (MOS) Sleep Scale and Short-Form Health Survey (SF-36) domain scores. Significance was declared for p ≤ 0.05 for the P2 and P3 studies reported here.

Results: The analysis included 238 pts from P2 studies, 118 pts from ORAL Scan and 486 pts from the LTE study. Demographics and baseline characteristics were similar between treatment groups for all studies. In P2 studies at Week 12, tofacitinib 5 and 10 mg BID demonstrated significantly greater improvements from baseline vs PBO in PGA, PGA, HAQ-DI, Pain, FACT-F, MOS Sleep Scale and in 4 (Functional Physич [F]), Role-Physical [RP], Bodily Pain [BP] and General Health [GH]) of the 8 SF-36 domain scores (Table). Significant improvements in PGA, PGA, HAQ-DI, Pain and FACT-F vs PBO were seen as early as Week 2. In ORAL Scan at Month 3, statistically significant improvements from baseline in PGA, PGA, HAQ-DI and Pain were seen for both tofacitinib 5 and 10 mg BID vs PBO (Table) and these were maintained to Month 24. Significant improvements vs PBO as early as Month 1 were seen for PGA (tofacitinib 10 mg BID) and Pain (both doses). In the LTE study, mean changes from LTE study baseline in PGA, PGA, HAQ-DI and Pain were -32.5, -40.8, -0.5 and -32.9, respectively, for all tofacitinib doses at Week 2, and -40.7, -50.2, -0.7 and -42.4, respectively, at Week 168. Mean changes from baseline in SF-36 domain scores at Week 12 and
Conclusions: Tofacitinib 5 and 10 mg BD significantly improved PROs in Japanese pts with RA enrolled in the P2, P3, and LTE studies.

THU0192 INFORMING PATIENTS ABOUT METHOTREXATE FOR THE TREATMENT OF RHEUMATOID ARTHRITIS WITH PATIENTS IN THE UNITED KINGDOM – A SURVEY OF RHEUMATOLOGISTS STRATEGIES

H.F. Hughes 1, S.M. Verstappen 2, L. Cordingley 3, K. Hyrczycz 4, 1 NIHR Manchester Musculoskeletal Biomedical Research Unit; 2 Arthritis Research UK Centre for Epidemiology, 3 Division for Musculoskeletal Research and Dermatological Science, University of Manchester, Manchester, United Kingdom

Background: Rheumatologists are the primary prescribers of methotrexate (MTX) for the treatment of rheumatoid arthritis (RA) in the United Kingdom (UK), however rheumatologists’ views on their clinical practices are largely unknown. The aim of this study was to conduct a qualitative sub-study in a UK cohort that highlighted a number of factors that contributed to their ability to discuss and commence MTX, which included how emotionally and cognitively prepared patients were to discuss treatments.

Objectives: The aims of this study were: 1) To establish the views of rheumatologists about MTX for the treatment of rheumatoid arthritis (RA), 2) To examine if rheumatologists’ views influenced discussing or commencing MTX during the initial consultation.

Methods: An online survey was designed and subsequently refined based on interviews with rheumatologists in the UK. The survey asked rheumatologists about their clinical setting, and their views and practices with respect to treating RA with MTX. Rheumatologists were asked how often specific pieces of MTX information were discussed during a consultation to commence MTX (5 = Always to 1 = Never). They were also asked to identify the barriers to discussing these issues.

Results: Ninety-six rheumatologists were included in the study (58% of eligible respondents), representing a broad range of specialties across the UK, including those based in teaching hospitals and/or in the private sector. The questionnaire was structured to follow the patient journey of initiating MTX therapy, with questions being asked about different stages of the process: the patient’s readiness for commencing MTX, the rheumatologist’s views on whether MTX information was discussed, and any barriers to discussing these topics.

Conclusions: Currently UK rheumatologists convey a large amount of information to patients during early consultations. Almost half of rheumatologists identified the need to communicate large amounts of information in clinical consultations as a barrier to discussing MTX therapy. These data reflect the challenge clinicians face in trying to execute effective shared decision-making practices. Strategies to address patients’ emotional responses to their diagnosis and being overloaded with MTX information are needed. Staggering presentation of information during clinical consultations may benefit some patients.

THU0193 REESTABLISHMENT OF EFFICACY OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, IN RHEUMATOID ARTHRITIS PATIENTS AFTER TEMPORARY DISCONTINUATION

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA).

Objectives: To assess the efficacy and safety of tofacitinib after temporary discontinuation and reinstitution of therapy in RA patients (pts).

Methods: Data were collected from a randomised, parallel-group (grp), controlled, open-label, multicentre, double-blind placebo-controlled, 2-phase, 2-treatment, 3-treatment, 18-month, randomized, double-blind extension (LTE) study (NCT00413699). Pts were ≥18 years of age with active RA and had received tofacitinib 10 mg BD for ≥3 months. The sub-study included 2 treatment (tx) grps: "continuous tx" (tofacitinib 10 mg twice daily [BID] as monotherapy or with methotrexate [MTX]) and "interrupted tx" (tofacitinib withdrawn for 2
weeks post-randomisation [Day 1–Day 15; Visits 1–3], then tofacitinib 10 mg BD reintroduced as monotherapy or with MTX at Visit 3); randomisation was stratified by MTX use. Pneumococcal and influenza vaccines were administered to all pts on Day 8 (Visit 2; vaccine titers reported previously)\(^1\). Blood samples were taken on Days 8, 15 (Visit 3) and 43 (Visit 4). Efficacy endpoints included change from baseline in C-reactive protein (CRP), Health Assessment Questionnaire Disability Index (HAQ-DI) and Disease Activity Score in 28 joints, erythrocyte sedimentation rate (DAS28-4[ESR]) at each visit. A mixed-effects model with repeated measures was used to evaluate treatment effect at each visit. Analyses for efficacy were exploratory, with no multiplicity adjustment for comparisons.

Results: Of the 199 pts in this analysis (continuous, n=100; interrupted, n=99), 117 received concomitant MTX. At LTE study baseline (BL) in the continuous and interrupted grps, respectively: 81.8/83.8% of pts were white, 84.8/86.9% were female and mean age was 55.0/53.9 years. BL (Day 1) values for CRP, HAQ-DI and DAS28-4[ESR] were generally similar between groups. At Day 8, mean CRP and DAS28-4[ESR] significantly increased from BL for interrupted vs continuous tx; HAQ-DI values were similar between grps (Figure). As expected at Day 15, mean CRP, HAQ-DI and DAS28-4[ESR] significantly increased from BL for interrupted vs continuous tx. After tofacitinib re-introduction for 28 days (Day 43), changes in CRP, HAQ-DI and DAS28-4[ESR] were similar between grps and approached BL levels. Adverse events (AEs) were experienced by 35.4% and 49.5% of pts receiving interrupted and continuous tx, respectively. The most frequent treatment-emergent AEs were bronchitis and upper respiratory tract infection (each AE: 6 pts) and vaccination-related immunisation reaction, myalgia and rash (each AE: 5 pts). Serious AEs occurred in 3 pts (3%) in each grp. In total, 1 pt (1%), in the interrupted tx grp, discontinued due to a study-drug related AE; no pts discontinued due to disease flare.

Figure. LS mean change from BL in RA efficacy endpoints over time from a vaccine sub-study with temporary tofacitinib dose interruption

Conclusions: Efficacy of tofacitinib 10 mg BD can be re-established following loss of efficacy during temporary (2 weeks) tx discontinuation in pts with RA. Pts receiving continuous tx maintained efficacy throughout the study. Further investigations are required.

score ranged from 6.2–6.5. Tofacitinib 5 and 10 mg BID achieved higher ACR responses and greater changes from baseline in DAS28-4(ESR) and HAQ-DI scores vs PBO at Month 3 in both populations (Table). Numerically higher proportions of non-MTX csDMARD-IR pts achieved efficacy outcomes vs 2nd-line population. CIRs for SAECs, DAs due to AEs and AEs of special interest were generally similar across groups. CIRs for TEAEs were higher with PBO vs tofacitinib. AE frequency was generally lower in the non-MTX csDMARD-IR population vs non-MTX csDMARD-IR POP.

Methods: Incidence rates (IR; pts with events per 100 pt-years [pyrs] exposure) were calculated using pooled data from randomised controlled trials (RCT) and long-term extension (LTE) studies. Two Phase (P) 1 studies, 9 P2 trials 105 months of observation.

Results: The tofacitinib P123LTE dataset included 6194 pts with a total exposure of 19 385 pt-yrs. A total of 64 bDMARD articles were retrieved for analysis, representing 58 unique studies and approximately 27 000 pts. Study populations were generally consistent. LTE studies were typically more than 5 yrs age and estimated mean percentage of pts who were female was 74–84% and mean baseline C-reactive protein level was 20–30 mg/L. The IR (95% confidence interval [CI]) of malignancy for tofacitinib in the P123LTE dataset was 0.89 (0.76, 1.04) (Figure). Estimated IRs (95% CI) of malignancy were 0.75 (0.55, 1.01) for abatacept, 1.06 (0.41, 2.74) for rituximab, 1.02 (0.69, 1.52) for tocilizumab and 0.95 (0.79, 1.14) for tumour necrosis factor inhibitors (adalimumab, certolizumab, etanercept, golimumab and infliximab) (Figure).

Conclusions: This analysis indicates that tofacitinib is associated with similar efficacy and safety outcomes compared with established treatments for RA. Tofacitinib 5 or 10 mg twice daily (BID) as monotherapy or with background disease-modifying antirheumatic drugs (DMARDs) was generally well tolerated with similar AEs as placebo. Tofacitinib may be considered for rheumatoid arthritis patients who have a contraindication to or refuse treatment with traditional DMARDs.
modifying antirheumatic drugs (DMARDs). Primary endpoints were adverse events (AEs) and confirmed laboratory safety data. Secondary endpoints included clinical efficacy measures (American College of Rheumatology [ACR] 20/50/70 response rates, Disease Activity Score using 28 joint counts and erythrocyte sedimentation rate [DAS28-4(ESR)], Health Assessment Questionnaire-Disability Index [HAQ-DI]) and clinical disease activity index (CDAI). Safety data were included up to Month 105 and efficacy data up to Month 90 (n=100 at Month 96).

**Results:** A total of 4967 patients were treated (mean [±SD]: 1215 [3182] days). Total tofacitinib exposure was 16,117 patient-years; 77.4% of patients maintained their initial dose. In total, 2370 patients (47.7%) discontinued (AEs: 1131 [22.8%]; insufficient clinical response: 175 [3.5%]). The most common AE classes were infections and infestations (68.9%) and musculoskeletal/connective tissue disorders (39.0%). The most common AEs were nasopharyngitis (18.7%), upper respiratory tract infection (17.2%), bronchitis and urinary tract infection (12.2%) each. Serious AEs occurred in 28.6% of patients and serious infection events (SIEs) in 8.8% of patients. Malignancies, excluding non-melanoma skin cancer, were reported in 3.0% of patients. Incidence rates (IR; patients with events per 100 patient-years) for AEs of interest (with 95% confidence intervals [CIs]) and laboratory observations are provided in Table 1. IRs for SIEs and malignancies through Month 105 did not increase compared with reported data through Month 96. No new safety risks were identified. Clinical responses were sustained from Month 1 to Month 90 (Table 2).

**Conclusions:** In patients with RA who remained in the LTE studies, tofacitinib (5 or 10 mg BID) with or without background DMARDs was associated with consistent safety through Month 105 and sustained clinical efficacy through Month 90.

**References:**

**Comparison of Efficacy Between Combination Therapy with IGRATIMOD and SULFASALAZINE with RHEUMATOID ARTHRITIS: PROPENSITY SCORE ANALYSIS**

**Background:** Igratimod (IGU) is a small-molecule disease-modifying antirheumatic drug (DMARD) that has been shown to suppress inflammation via the inhibition of nuclear factor-kappa B activation in vitro. The efficacy of combination therapy with IGU and methotrexate (MTX) has been demonstrated in comparison with that of placebo in rheumatoid arthritis (RA). However, its efficacy in comparison with other DMARDs such as sulfasalazine (SSZ) has not been elucidated.

**Objectives:** To clarify the efficacy of combination therapy with IGU in comparison with that of SSZ with MTX in typical clinical practice.

**Methods:** We analyzed data from 16,825 RA patients registered in a large database (NinJa; National Database of Rheumatic Diseases by IR-net in Japan) from April 2001 to March 2015 (1). In this study, we compared the two groups who received IGU or SSZ in addition to methotrexate in the earlier year. We excluded patients who started receiving biologic DMARDs, IGU or SSZ the year prior to the study period, and those whose regimes were changed to other DMARDs such as tocilizumab and b-cellululamine. Baseline characteristics were compared using the t-test, Wilcoxon rank-sum test, or chi-square test. Fisher analysis was conducted for both outcomes. The predicted probability of IGU treatment was calculated by fitting a logistic regression model using all clinically relevant variables as presented in Table 1. Moreover, to reduce the effect of treatment-selection bias and potential confounding in this observational study, we performed rigorous adjustment for significant differences in the baseline characteristics of patients with propensity-score matching using the following algorithm: 1:1 optimal match with a ±0.15 caliper and no replacement. We used the standardized difference to measure covariate balance, whereby a standardized mean difference of ≤0.1 represents meaningful imbalance. The outcome was remission rate with disease activity score 28 CRP (DAS28-CRP) in the year after initiation of IGU or SSZ therapy.

**Results:** The group that received IGU in addition to MTX included 66 patients; the other group that received SSZ in addition to MTX included 163 patients. Table 1 shows the results of the pre- and post-propensity score matching of patients' characteristics. Sixty-six patients were compared in each group after score matching. The remission rates of DAS28-CRP in the following year was 77.2% (44/57 patients) and 71.7% (38/53 patients; P=0.52) in the IGU and SSZ groups, respectively.

**Conclusions:** Combination therapy with IGU or SSZ and methotrexate for rheumatoid arthritis did not show a significant difference in disease activity. Further studies are needed.

Tofacitinib improves left ventricular mass and cardiac output in patients with rheumatoid arthritis

K. Kume, K. Amano, S. Yamada, T. Kanazawa, K. Hatta. Rheumatology, Hiroshima Clinic, Hiroshima, Japan

Background: Rheumatologists need to develop primary prevention strategies for cardiovascular disease (CVD) in rheumatoid arthritis (RA) patients. We reported tofacitinib (Tofa) improved arterial stiffness in RA patients. RA is associated with an increased left ventricular mass index (LVMI), a strong marker of cardiovascular mortality. There is no evidence that Tofa affects on left ventricular (LV) morphology and function.

Objectives: To study the effect of Tofa plus methotrexate (MTX) on LV morphology and function in MTX resistant active RA patients, in a cohort study design.

Methods: Patients eligible if they had at least disease despite treatment with MTX. All patients have no steroids, and no previous history of CVD. Consecutive 28 patients with moderate to severe active RA patients (DAS28≥3.2) despite MTX were received Tofa plus MTX. LV morphology and function was assessed with cardiac-MRI at baseline and 24 weeks follow-up. Cardiovascular risk factors and clinical data were collected at regular visits.

Results: 24 patients completed 24 weeks. Left ventricular mass index (LVMI) was attenuated significantly by Tofa (week 0-week24, -12.4±5.4 g/m²; p<0.0002).

Cardiac output (CO) was attenuated significantly by Tofa (week 0-week24, -0.87±0.21/min). DAS28 and CRP improved significantly by Tofa (week 0-week24; DAS28: -2.26±0.91; CRP: 14.1±8.7 mg/dl) (p<0.05). LVMI and CO in this study. Observationally, 4 cases significantly improved right ventricular mass as well as left ventricular mass (20% improved right ventricular mass index from baseline).

Conclusions: Tofa improved LVMI and CO in active RA despite MTX. TCZ improves LVMI and CO independently of its effects on disease activity. Tofa might improve right ventricular mass. JAK-STAT pathway blocking, may prevent cardiovascular morbidity and mortality in RA.

**BACKGROUND:** In the developing world rheumatologists and their patients are struggling to implement target therapy in established Rheumatoid Arthritis (RA) which means they can hardly establish remission and low disease activity which is the mainstay of the RA treatment. The main reason is the lack of conventional synthetic and biological (c and b) DMARDs in the therapeutic armamentarium as well as their high cost which increases already difficult burden of RA.

**OBJECTIVES:** The aim of the study is to evaluate the RA treatment and treatment expenses in a group of patients with established RA in FYROM including the availability of DMARDs.

**METHODS:** We have conducted a cross-sectional study at the University Rheumatology Clinic in Skopje, including 100 patients with established RA, who fulfilled RA classification criteria from 2010. Physical examination, laboratory analyses and BASDAI were performed and all patients filled a questionnaire with 13 questions about treatment expenses and availability.

**RESULTS:** There were 82 females and 18 males, with mean age of 59 and disease duration of 8.3 (SD 7.3) years and moderate disease activity DAS28 3.9±1.47 and 75% of seropositive RA (double positive 30%, Anti-CCP positive 30%, RF positive 15%) with mean CRP of 21.5 mg/L. They spend from 10 to 100 Euros monthly (on average 27.1±17.6) for the c DMARDs therapy. Almost 85% think that the c DMARDs therapy is too expensive for them and 100% of them could not afford to pay or co-pay for b DMARDs. Most of the patients (49%) are using single c DMARDs. Double and triple c DMARD therapy is used by 32% vs 17%, respectively. Even though it is highly effective, patients consider triple c DMARD therapy expensive and with very low compliance because of the high costs and low tolerability. Only 2% of the patients are using b DMARDs using rituximab, the only available biologic DMARD therapy in FYROM. Around 70% are taking low dose prednisolone. Almost 50% of the patients cannot take the c DMARD therapy with a prescription and have to buy their DMARDs without any coverage from the insurance fund and the same percent have problems to find the c DMARDs with prescription because it is not available. Almost half of the patients have heard about the b DMARDs, most of them from their rheumatologist and 54% of them would like to receive it. The patient’s reasons for taking b DMARDs are presented in Graph 1.

**CONCLUSIONS:** High expenses and low availability of c DMARDs on prescription and the urgent need for b DMARDs are adding the burden of RA in developing countries including FYROM with the increased need for full coverage for conventional DMARDs and at least partial coverage of biologic DMARDs, especially anti-TNF agents by the insurance companies. The use of biosimilars conventional DMARDs and at least partial coverage of biologic DMARDs, countries including FYROM with the increased need for full coverage for conventional DMARDs and at least partial coverage of biologic DMARDs, especially anti-TNF agents by the insurance companies. The use of biosimilars conventional DMARDs on prescription because it is not available. Almost half of the patients have heard about the b DMARDs, most of them from their rheumatologist and 54% of them would like to receive it. The patient’s reasons for taking b DMARDs are presented in Graph 1.

EFFECTS OF THE JAK1-SELECTIVE INHIBITOR FILGOTINIB ON MULTIBIOMARKER DISEASE ACTIVITY SCORES IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO METHOTREXATE

Objectives: To evaluate the effect of filgotinib compared to placebo on a multi-biomarker disease activity score (MBDA score) that measures 12 disease-related biomarkers of inflammation and joint injury in RA patients taking background MTX.

Methods: RA patients treated with filgotinib in combination with MTX had significant reductions in the MBDA score that was driven by key RA biomarkers encompassing both inflammation and joint injury. These findings are consistent with the filgotinib efficacy observed in RA patients over 12 weeks.

Results: RA patients treated with filgotinib compared to placebo had statistically significant reductions in the median MBDA score and subcomponents. These reductions were observed as early as week 4, with the largest reductions in YKL-40 and MMP-3. Median percent changes from baseline for biomarkers are reported. Wilcoxon rank-sum test assessed the significance of difference between filgotinib treated groups vs. placebo.

Conclusions: Filgotinib in combination with MTX for 12 weeks was associated with statistically significant reductions in multiple markers of inflammation linked to various pathologic cell types and processes in rheumatoid arthritis patients.

DOI: 10.1136/annrheumdis-2017-eular.5738

THU0206 THE JAK1-SELECTIVE INHIBITOR FILGOTINIB REDUCES MULTIPLE MARKERS OF INFLAMMATION LINKED TO VARIOUS PATHOLOGIC CELL TYPES AND PROCESSES IN RHEUMATOID ARTHRITIS PATIENTS

Background: JAK1, 2, 3 and TYK2 are cytoplasmic tyrosine kinases that mediate intracellular signaling of many cytokines and growth factors. Filgotinib (GLP00634, GS-6034) is a JAK inhibitor with high selectivity for JAK1 over other JAK family members. Filgotinib has a favorable safety and efficacy profile in two Phase 2B studies in active rheumatoid arthritis (RA) patients who were MTX-inadequate responders. These findings are consistent with the filgotinib efficacy observed in RA patients over 12 weeks.

Methods: Serum samples from RA patients who were on a stable dose of MTX and received either placebo (PBO) or filgotinib 100mg or 200mg once daily (QD), were tested for MBDA components (Crescendo Biosciences, CA, US) at baseline, week 4 and week 12. Median % change from baseline for MBDA score and individual components are reported for week 4 and week 12. Wilcoxon rank-sum test assessed the significance of difference between filgotinib treated groups vs. PBO.

Results: Baseline MBDA scores and component values (median; interquartile range) were similar in PBO (55; 45–64), 100mg QD (58; 42–66), and 200mg QD (59; 50–67.5) treatment groups. Filgotinib treated patients had reductions in the MBDA score comparable to baseline at the 100mg and 200mg QD dose levels, but not in the PBO group. At both weeks 4 and 12, these reductions in the filgotinib treated groups were significantly different from the PBO group. Most of the individual components contributed to the decrease in MBDA score, but the largest reductions were observed for serum amyloid A (SAA), C-reactive protein (CRP), interleukin-6, and the biomarkers of joint-damage, matrix metalloproteinase 3 (MMP3), MMP1, vascular endothelial growth factor (VEGF), and YKL40 (human cartilage glycoprotein 39). There was an increase in leptin and no change in epidermal growth factor (EGF) concentrations.

Conclusions: Filgotinib treatment induced a dose-dependent and significant decrease
in a variety of biomarkers implicated in RA pathogenesis including inflammation (IL-1), IL-6, TNFα and SAA), matrix degradation and cartilage destruction (MMP1 and MMP3), immune cell trafficking (CXCL10, ICAM-1 and VCAM-1) and angiogenesis (VEGFC). Cytokines involved in T1f (IFNγ, IL-2, IL-12) and T17 (IL-17A, IL-21, IL-23) cell subset differentiation and activity were significantly differentially expressed. Additionally, decrease in the B-cell chemoattractant CXCL13 and the myeloid growth factor GM-CSF supports the anti-inflammatory effects of filgotinib treatment.

| p-values comparing changes between filgotinib and PBO groups: NS, p>0.05; *p<0.05; **p<0.01; ***p<0.001.

Conclusions: Treatment with filgotinib decreased several factors that have key roles in RA for matrix degradation, cartilage destruction, angiogenesis, leukocyte adhesion and recruitment. The changes were accompanied by decreases in cytokines that promote and activate T H1, T H17, B-cells and myeloid cells that are important in RA. These findings provide insights into filgotinib mechanism of action and are consistent with its efficacy observed in RA patients.

Tsuji: None declared, Shinko Institute for Medical Research; 2Center for Rheumatic Diseases, Shinko Hospital; 2Graduate School of Medicine, Kobe University, Kobe, Japan

Background: Detection of the intracellular levels of polyglutamated MTX (MTX-PGn) can predict response of MTX or possibly its adverse effects. As efficacy and toxicity of MTX differs among individual patients, we had proposed a predictive model for MTX efficacy consisting of 9 SNPs (2015 EULAR). In the present study, we measured erythrocyte MTX-PGn in RA patients with low disease activity for long time receiving a stable dose of MTX, investigated their associations with genetic polymorphisms, and speculated MTX dose required to reach effective MTX-PGn levels.

Objectives: To investigate if erythrocyte MTX-PGn concentration is associated with the 9 SNPs in 7 genes reportedly related to MTX-efficacy in RA patients with low disease activity.

Methods: The study was cross-sectional using 121 adult patients with RA in Shinko Hospital. All patients enrolled had received a stable dose of MTX (mean 8.9±0.3mg/week), and kept lower disease activity (DAS28-CRP 2.06±0.79 mg/L) for at least 3 months. Concentrations of MTX-PG with 1-5 glutamate residues (PG1-PG5) in erythrocytes were quantitated by LC-ESI-MS/MS as described by den Boer et al. Nine SNPs in 7 genes previously found to associate with efficacy of MTX by us were genotyped by RT-PCR (Applied Biosystems, Inc.). First, association of the 9 SNPs with concentrations on MTX-PGn was analyzed by one-way layout (Wilcoxon signed-rank test). Secondly, multivariate logistic regression analyses were performed to estimate roles of MTX dose and polymorphisms in concentrations of MTX-PGn.

Results: Total PGn concentrations were 82.1±31.7 nmol/L (m±SD) and positively correlated with MTX dose (Rs=0.4104, p<0.001), but range of concentration was rather wide even if the dose was same. By one-way layout, GGH c.452C>A, EPHX1 c.357G>A, SLC19A1 c.80G>A, SLC28A3 c.267G>A, and SLC28A3 c.267G>T were related to MTX doses. Next, we investigated roles of MTX dose and 9 SNPs in maintenance of MTX-PGn concentrations as by multiple regression analyses. As PG1 levels were related to GGH c.452C>T but not to MTX dose, PG1 levels were 38.2±19.6 and 54.8±21.5 nmol/L in CC and CT genotypes, respectively (P=0.0291). MTX dose was strongly associated with PG3 levels as well as with those of PG4. MTX-PG3 levels were regulated as follows; MTX-PG3 (nmol/L) = -0.035 +2.04 * MTX dose [2.34 * SLC19A1 c.80G>A +2.04 * SLC28A3 c.267G>A] when upper and lower limits of them were defined, we can speculate MTX dose to reach the effective levels for individual patients. However, the ranges of effective levels were rather wide, suggesting that effectiveness of MTX may depend on not only concentrations of MTX-PG but also responsiveness to MTX-PG.

Conclusions: We measured erythrocyte MTX-PGn in RA patients with low disease activity and investigated for their associations with MTX dose and genetic polymorphisms. We could speculate MTX dose required to reach possible effective MTX-PG levels in individual patient.

LYMPHOCYTE SUBSETS IN BIOPSY SPECIMEN ARE ASSOCIATED WITH SPONTANEOUS REGRESSION OF LYMPHOPROLIFERATIVE DISORDERS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH METHOTREXATE

T. Kameda 1, M. Izumikawa 1, M. Inoo 2, I. Onishi 2, N. Kurata 2, S. Nakashima 1, H. Shimada 1, H. Ozaki 1, R. Wakuya 1, A. Kondo 1, N. Kadawaki 1, H. Dobashi 1.
1 Department of internal medicine division of endocrinology and metabolism, Hematology, Rheumatology and Respiratory Medicine, Kagawa University; 2 Internal medicine, Utau hospital, Kagawa, Japan

Background: Patients with rheumatoid arthritis (RA) have a high risk for lymphoproliferative disorders (LPDs). An LPD in a patient treated with methotrexate (MTX) is known as MTX-associated LPD (MTX-LPD), which is classified among immunodeficiency-associated lymphoproliferative disorders (ID-LPD) as “other interstitial lymphoproliferative disorder” in the 2016 World Health Organization Classification of Haematopoietic and Lymphoid Tissues (1). We previously reported that MTX is an independent risk factor for LPD onset in Japanese patients with RA (2).

In MTX-LPD, MTX withdrawal can result in spontaneous regression of LPD. In addition, limited evidence indicates that Epstein–Barr virus infection is related to spontaneous regression of MTX-LPD. No biomarker has been identified that predicts spontaneous regression of MTX-LPD.

Objectives: To identify a biomarker that predicts spontaneous regression of MTX-LPD in RA patients.

Methods: We enrolled RA patients from Kagawa Prefecture, Japan, who developed MTX-LPD during the period from June 2010 through December 2016. RA was diagnosed in accordance with the American College of Rheumatology 1987 classification criteria and was treated with disease-modifying antirheumatic drugs, including MTX. The patients were divided into two groups: those followed-up after discontinuation of MTX alone (MTX withdrawal group) and those who received chemotherapy at 1 month or later after MTX discontinuation (chemotherapy group). The following variables were compared between groups: change in peripheral lymphocyte subsets after MTX discontinuation, serum soluble interleukin-2 receptor, and lymphocyte subsets and Epstein–Barr virus–encoded RNAs in a biopsy specimen from a lesion.

Results: We enrolled 43 MTX-LPD patients (29 in the withdrawal group and 14 in the chemotherapy group) and 22 for analysis of lymphocyte subsets in a lesion specimen (11 each in the withdrawal group and chemotherapy group). Peripheral lymphocyte counts were significantly higher after MTX discontinuation in the withdrawal group. Analysis of lymphocyte subsets from lesion specimens revealed significantly higher CD8-positive lymphocyte counts in the chemotherapy group than in the withdrawal group.

Conclusions: Lymphocyte count differed before and after MTX discontinuation, and a higher CD8-positive lymphocyte count in a lesion specimen was associated with spontaneous regression of MTX-LPD. These findings may help identify a predictive marker for MTX-LPD treatment and management.

CHANGES IN HEMOGLOBIN LEVELS UPON TREATMENT WITH ABT-494, A SELECTIVE JAK-1 INHIBITOR, AND RELATION TO BASELINE LEVELS OF C-REACTIVE PROTEIN

V. Strand 1, M. Genovese 1, J. Kremer 2, M. Schiff 3, Y. Li 4, J. Sokolove 4.
1 Stanford Univ, Palo Alto; 2AbbVie Medical College, Albany, NY; 3Univ of Colorado, Denver, CO; 4AbbVie, N Chicago, IL, United States

Background: Patients with rheumatoid arthritis (RA) often have inflammation-related anemia of chronic disease, partially due to IL-6 and its induction of hepcidin. High levels of the inflammatory marker C-reactive protein (CRP) are largely induced by IL-6. Treatment with JAK inhibitors has been associated with both rise and fall in hemoglobin (Hb) levels, possibly due to inflammation control and inhibition of JAK2 (which is involved in erythropoiesis), respectively 1, 2.

Objectives: To examine the association of changes in Hb upon treatment with ABT-494 with baseline (BL) CRP levels.

Methods: This post hoc analysis used data from two phase 2b randomized controlled trials (RCT) of ABT-494 in RA pts with inadequate responses to TNF inhibitors (TNF-IR, BALANCE-1) 3, and in pts with inadequate responses to methotrexate (MTX-IR, BALANCE-2) 4. The analyses included pts receiving ABT-494 at 8 or 12 mg. Pts were subgrouped by quartiles of BL CRP. For each RCT, and for the pooled data from both, changes from BL in Hb (g/dL) were determined after 12 weeks (wk) of treatment with ABT-494, for the overall population and for pts who achieved ACR20 or DAS28-CRP ≤ 3.2 responses at Wk 12. For ACR20 and DAS28-CRP ≤ 3.2, non-responder imputation was used. For changes in Hb, data are as observed. Significance was determined by ANCOVA.

Background: In pooled data from 110 and 100 pts from BALANCE-1 and -2 respectively, higher BL CRP was associated with smaller mean decreases in Hb at Wk 12 (p < 0.074). In the MTX-IR trial, pts in the highest CRP quartile had a mean increase from BL in Hb (+0.28 g/dL) vs pts in the lower quartiles who had mean decreases in Hb (p < 0.01). In both RCTs, ACR20 or DAS28-CRP ≤ 3.2 responders had smaller decreases in Hb vs non-responders at Wk 12. Among DAS28-IR-p<3.2 responders, pts in the higher CRP quartiles had significantly smaller mean decreases in Hb vs pts in the lower quartiles (p<0.01 for MTX-IR and p<0.05 for TNF-IR pts). Responders in the highest BL CRP quartile also had a mean increase in Hb (+0.31 and +0.54 g/dL for MTX-IR ACR20 and DAS28-IR ≤ 3.2 responders respectively) + 0.15 g/dL for TNF-IR DAS28-IR ≤ 3.2 responders (Fig. 1A–D). While similar trends between BL CRP levels and changes in Hb at Wk 12 were observed among ACR20 or DAS28-IR ≤ 3.2 non-responders, the differences in Hb levels between the quartiles were not significant. Despite the small mean changes, the mean Hb values remained within the normal range for females (lower limit of normal 11.5 g/dL).

Conclusions: Upon treatment with ABT-494, pts with the highest CRP (a potential surrogate for IL-6) at BL had a mean increase in Hb compared to decreases in those with lower CRP. This effect was more apparent in pts with clinical responses. This suggests that effective treatment of RA-associated inflammation with ABT-494 may counterbalance the small Hb reduction associated with JAK inhibition.

META-ANALYSIS OF SERIOUS INFECTIONS WITH BARICITINIB, TOFACITINIB AND BIOLGIC DMARDS IN RHEUMATOID ARTHRITIS

V. Strand1, S. Ahadieh2, R. DeMasi3, S. Krishnaswami2, J. Geier4, S. Menon2, J.J. Gómez-Reino5, 1 Division of Immunology/ Rheumatology, Stanford University, Palo Alto, CA; 2Pfizer Inc, Groton, CT; 3Pfizer Inc, Collegeville, PA; 4Pfizer Inc, New York, NY, United States; 5Fundación Ramón Domínguez, Hospital Clínico Universitario, Santiago de Compostela, Spain

Background: Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). Baricitinib is a JAK inhibitor being investigated for RA. Serious infection events (SIEs) have been reported in RA randomised controlled trials (RCTs) but limited head-to-head data are available to directly compare rates of these events for tofacitinib vs biologic (b)DMARDs and baricitinib.

Objectives: We provide an updated meta-analysis of published RCTs and corresponding long-term extension (LTE) studies to contextualise the risk of SIEs with tofacitinib and baricitinib and extend this work to include the JAK inhibitor baricitinib.

Methods: An initial systematic literature search (Medline, Embase, PubMed and regulatory submission documents) was conducted for SIEs with tofacitinib and bDMARDs (abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab). A subsequent systematic literature review of RCTs was conducted using Medline, BIOSIS, Embase and conference abstracts to evaluate SIEs with baricitinib. Incidence rates (IRs; patients per event per 100 patient-years) were calculated for each agent vs control across RCTs up to rescue of patients randomised to receive placebo using the random effects Mantel-Haenszel method. Between-study variances. Risk ratios and risk differences were calculated for each agent vs control across RCTs up to rescue of patients randomised to receive placebo using the random effects Mantel-Haenszel method.

Results: Six RCTs with baricitinib were included in this updated analysis. In the original analysis, 70 RCTs and 18 LTE studies met inclusion criteria for tofacitinib and bDMARDs. The table provides a summary of the meta-analyses conducted for SIE IRs (with and without LTE), risk ratios and risk differences relative to control for both doses of baricitinib, which is consistent with analyses of tofacitinib and bDMARDs. There were limited data to evaluate SIE incidence for baricitinib (4 mg) monotherapy vs in combination with methotrexate (MTX); the RA-BEGIN study showed IRs of 3.77 (1.7, 8.4) and 2.33 (0.97, 5.59), respectively; when administered in combination with MTX, the IRs were 3.44 (2.41, 4.76) and 3.42 (2.42, 4.70) for 5 and 10 mg BID monotherapy respectively; when administered in combination with MTX, the IRs were 3.44 (2.41, 4.76) and 3.42 (2.42, 4.70) for 5 and 10 mg BID monotherapy respectively.

Table: Serious infection incidence rates, risk ratios and risk differences for tofacitinib and biologic DMARDs and baricitinib

<table>
<thead>
<tr>

Conclusions: The results from these meta-analyses suggest that the risk of SIEs (IRs, risk ratios and risk differences) with tofacitinib is comparable with published rates for bDMARDs and baricitinib in patients with severe RA.

THE IMPROVEMENT OF ULTRASONOGRAPHIC FINDINGS FOR 24 WEEKS MAY PREDICT REMISSION AT 52 WEEKS IN JAPANESE RHEUMATOID ARTHRITIS PATIENTS TREATED WITH IGuratIMOD THERAPY

Y. Kanayama1, H. Nagasaki2, M. Shimitake2, F. Miyachi3, K. Fujita4, A. Nagata2, 1Orthopedic Surgery and Rheumatology; 2Clinical technology, Toyota Kosei Hospital, Toyota, Japan

Background: Iguratimod (IGU) suppressed tumor necrosis factor alpha-induced production of interleukin (IL)-6, IL-8, and monocyte chemotactractor protein 1 via inhibition of nuclear factor kappa B activation in cultured human synovial cells and human acute monocytic leukemia cells. We reported the clinical efficacy of IGU at ACR2014 and EULAR2015. However there is still few studies of improvement of ultrasonographic findings in rheumatoid arthritis (RA) treated with IGU.

Objectives: To evaluate the efficacy of IGU therapy in patients with RA using ultrasonography (US).

Methods: Participants comprised 54 Japanese RA patients who had recently received IGU. All patients had a diagnosis of RA according to the 2010 ACR/EULAR criteria. Patients underwent clinical and laboratory assessments from baseline to 52 weeks. US assessments at baseline, 12, and 24 weeks. Clinical findings related to RA were as follows: tender and swollen joint count, patient's and physician's global assessment of disease activity, ACR/EULAR criteria. Patients underwent clinical and laboratory assessments from baseline to 52 weeks.

Results: The patients included 16 males and 38 females. The mean age was 65.4±11.6 years; the mean disease duration was 9.3±10.8 years; and the number of MTX combination, other DMARD excluded combination, IGU monotherapy and Biological combinations were each 32, 10, 8 and 4 cases.

Clinical findings related to RA were as follows: tender and swollen joint count, patient’s and physician’s global assessment of disease activity, ACR/EULAR criteria. Patients underwent clinical and laboratory assessments from baseline to 52 weeks.

Conclusions: The AUC and PD score at each time point for remission achievement at 52 weeks were each 0.643 and 0.648 from week 0 to 24 weeks as were follows: AUC score: -3.7±0.8 vs 0.16±6.8 (p=0.068) at 12 weeks and -5.8±7.7 vs -0.4±9.8 (p=0.008) at 24 weeks and PD score: -2.4±5.6 vs -1.1±5.2 (p=0.05) at 12 weeks and -9.5±6.3 vs -1.2±6.1 (p=0.013) at 24 weeks (Fig.1). Areas under the receiver operating characteristic curves for the AUC and PD score at each time point for remission achievement at 52 weeks were each 0.643 and 0.648 from week 0 to 24 weeks. The mean PD score changed from 7.6±6.8 at baseline to 5.8±6.0 (p=0.053) and 5.3±5.5 (p=0.05) at week 12 and 24. In the achieved remission for DAS28-ESR at Week52 (n=16) and not achieved or discontinued IGU patients (n=38), the respective changes in GS and PD scores from baseline to 12 or 24 weeks were as follows: Δ GS score: -3.7±0.8 vs 0.16±6.8 (p=0.068) at 12 weeks and -5.8±7.7 vs -0.4±9.8 (p=0.008) at 24 weeks and Δ PD score: -2.4±5.6 vs -1.1±5.2 (p=0.05) at 12 weeks and -9.5±6.3 vs -1.2±6.1 (p=0.013) at 24 weeks (Fig.1). Areas under the receiver operating characteristic curves for the Δ GS and PD score at each time point for remission achievement at 52 weeks were each 0.643 and 0.648 from week 0 to 24 weeks.

Disclosures: All authors have declared no conflicts of interest.
Conclusions: The IGU therapy improved not only the disease activity not also the inflammatory synovitis. The present study provides evidence supporting the improvement of GS and PD score from baseline to week24 may predict whether the achieved remission or not at Week 52.

THU0213 | COMPARATIVE EFFICACY AND SAFETY OF BARICITINIB 2 MG AND 4 MG IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: A BAYESIAN NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Y.H. Lee, Y.H. Seo, G.G. Song. Rheumatology, Korea University Medical Center, Seoul, Korea, Republic Of

Background: Baricitinib is a potent, selective JAK1 and JAK2 inhibitor. Baricitinib has been investigated in phase II and phase III studies of active patients with rheumatoid arthritis (RA), who showed an inadequate response to disease-modifying antirheumatic drugs (DMARDs), including methotrexate (MTX) and biologics. However, due to the lack of adequate multiple comparisons, the comparative efficacy and safety of baricitinib in various treatment regimens with different dosages or in combination with DMARDs or MTX remains unclear.

Objectives: This study aimed to assess the relative efficacy and safety of once-daily baricitinib 2 mg and 4 mg administration in patients with active RA.

Methods: We performed a literature search using MEDLINE, EMBASE, the Cochrane Controlled Trials Register, and the EULAR and ACR conference proceedings. In this network meta-analysis, randomized controlled trials (RCTs) examining the efficacy and safety of baricitinib in patients with active RA were included. A Bayesian network meta-analysis was conducted to combine the direct and indirect evidence from the RCTs.

Results: Seven RCTs involving 3,461 patients met the inclusion criteria. There were 10 pairwise comparisons, including 7 direct comparisons and 5 interventions. The ACR20 response rate was significantly higher in the baricitinib 4 mg arm compared with placebo. The ACR50 response rate was significantly higher in the baricitinib 4 mg arm compared with placebo. The ACR70 response rate was significantly higher in the baricitinib 2 mg arm compared with placebo. The change in DAS28-CRP from baseline to week24 was significantly lower in the baricitinib 2 mg arm compared with placebo. The change in HAQ-DI from baseline to week24 was significantly lower in the baricitinib 2 mg arm compared with placebo. The change in VAS from baseline to week24 was significantly lower in the baricitinib 2 mg arm compared with placebo. The change in SF-36 from baseline to week24 was significantly lower in the baricitinib 2 mg arm compared with placebo. The change in EQ-5D from baseline to week24 was significantly lower in the baricitinib 2 mg arm compared with placebo. The change in WLA from baseline to week24 was significantly lower in the baricitinib 2 mg arm compared with placebo. The change in Form-36 from baseline to week24 was significantly lower in the baricitinib 2 mg arm compared with placebo. The change in Work Limitations Questionnaire from baseline to week24 was significantly lower in the baricitinib 2 mg arm compared with placebo. The change in patient assessment of disease activity from baseline to week24 was significantly lower in the baricitinib 2 mg arm compared with placebo.

Conclusions: Efficacy of IGU in RA patients who had intolerance of MTX dose escalation or usage of biologics was observed. Although biological DMARDs is effective in RA patients, the cost is very expensive. IGU is comparative cheap (99,200/month) and suitable for RA patients with economical difficulties. As IGU decreased TNF-alpha production via inhibition of NF-kB, MTX+IGU may have similar mode of action with MTX+TNF inhibitor. Drug continuation rates were decreased over time and escape of efficacy may occur in some patients. Otherwise, IGU was very effective in some cases. Some of RA patients with high disease activity decreased disease activity greatly to remission state at 2 years after initiation of IGU.

10 mg BID). There were no major differences in demographics or baseline characteristics between treatment groups. At Month 3, tofacitinib resulted in significantly greater changes in HAQ-DI (5 mg BID, p < 0.05; 10 mg BID, p < 0.001), PtGA (5 mg BID, p < 0.05; 10 mg BID, p < 0.001), Pain (5 mg BID, p < 0.01; 10 mg BID, p < 0.001) and SF-36 Physical Component Summary (PCS) scores (5 mg BID, p < 0.05; 10 mg BID, p < 0.001) vs PBO (Figure). Numerical improvements in FACIT-Fatigue, SF-36 Mental Component Summary (MCS) [Figure] and EQ-5D health state profile (utility scores) were observed at Month 3 with tofacitinib vs PBO. There were no improvements in WLOQ observed at Month 3 with tofacitinib vs PBO. Improvements were generally maintained at 6 and 12 months (Figure). The proportion of patients achieving HAQ-DII improvement ≥ 0.22 from baseline at Month 3 was significantly higher with tofacitinib vs PBO (5 mg BID, p < 0.05; 10 mg BID, p < 0.05).

Conclusions: Tofacitinib 5 and 10 mg BID administered with csDMARDs significantly improved PROs including SF-36 PCS, PtGA, physical function and pain vs PBO. These improvements were maintained for up to 12 months in Chinese patients with RA.

SLE, Sjögren’s and APS - etiology, pathogenesis and animal models

THU0216 Urinary Neuropilin-1: A New Biomarker Approach in the Prognosis of Lupus Nephritis

M. Torres-Salido 1, C. Solé-Marcel 1, M. Vital 1, J. Cortés-Hernández 1, J. Ordí-Ros 1, V. Hebron Institute Research (Vhir), Renal Pathology, Vall d’HEBRON Hospital, Barcelona, Spain

Background: Lupus nephritis (LN) affects up to 50% of patients with SLE and is a major cause of morbidity, despite modern therapeutic approaches [1,2]. To date, renal biopsy is still the gold standard for diagnosing and classifying the degree of renal inflammation and scarring, but its invasiveness makes it unsuitable for serial monitoring. A novel biomarker to predict the evolution of renal inflammatory injury is still needed. Neuropilin-1 (NRP-1) has important functions in adult tissues, being involved in axonal guidance, vascular endothelial sprouting, regeneration and organ repair and immunosuppression [3].

Objectives: Evaluate the protein and expression levels of NRP-1 at the time of the renal flare in patients with lupus nephritis and determine whether they could predict the disease progression.

Methods: Urine and serum of 70 patients with LN with nephrotic proteinuria, 25 patients with chronic non-lupus related nephopathy, and 25 healthy controls were analyzed by pQPCR-RT and ELISA to determine the levels of mRNA/protein of NRP-1. Immunohistochemistry of protein levels were done in renal biopsy (N=5). Urine and serum from 39 other patients with LN with nephrotic proteinuria were collected prospectively during two years.

Results: Increases in mRNA expression and protein concentration of NRP-1 were identified in urine samples of LN patients in flare compared with the different control groups. However, significant NRP-1 levels were found in LN patients that gone into remission compared with patients in non-remission after one year of treatment (p < 0.0001). Urinary VEGFA, VEGFR1, VEGFR2 and SEMA3A mRNA and protein levels were also determine. Results were confirmed with immunohistochemistry in renal biopsies (N=5). We observed a strong correlation with NRP-1 protein levels and VEGFA protein levels (r=0.466, p < 0.0001). Areas under the receiver operating characteristic curve of urinary NRP-1 and VEGFA protein levels to distinguish between remission and non-remission patients were 0.8384 and 0.7706, respectively (Figure 1). In a prospective study (N=39), urinary protein NRP-1 and VEGFA levels decreased in LN patients going to complete remission; but no those with non-response that maintain their low levels during all the follow-up.

Conclusions: For first time, we demonstrate that urinary levels of NRP-1 might reflect the evolution of renal inflammatory injury and could be used as novel biomarker to predict the recovery of LN.

CIRCULATING MICRORNAS AS BIOMARKERS FOR AUTOANTIBODY PROFILE OF CHILDREN WITH JUVENILE DERMATOMYOSITIS FROM A TERTIARY CARE CENTRE IN NORTH INDIA

S. Guleria 1, A. Sharma, A. Gupta, A. Rawat, D. Suri, S. Singh. Pediatric allergy and immunology, Pigminder Chandigarh, Chandigarh, India

Background: Juvenile dermatomyositis (JDM) is a rare childhood autoimmune inflammatory muscle disorder that can result in severe disability or death. Children with JDM can have autoantibodies in their sera like other autoimmune diseases [1]. Over the last few years, few novel Myositis Specific Antibodies (MSA) have been identified. Some phenotypical associations have been described with these autoantibodies like anti p-140 (anti NXp2) has been shown to have correlation with calcinosis in children with JDM [1–2].

Objectives: To study autoantibody profile and to look for phenotypical associations of autoantibodies in JDM.

Methods: Cross-sectional retrospective study. All children diagnosed to have JDM, registered from 1995 to 2015 in Pediatric Rheumatology Clinic at Post Graduate Institute of Medical Education and Research Chandigarh, India and who were tested for autoantibodies were included in the study. Clinical findings, autoantibodies (ANAs), autoantibody for MSA and myositis associated autoantibodies (MAAs) were noted. Some phenotypical associations have been described with these autoantibodies like anti p-140 (anti NXp2) has been shown to have correlation with calcinosis in children with JDM [1–2].

Results: Anti nuclear antibody (ANA) testing was done in 97 patients. Forty six (47.4%) tested positive. In addition, MSA and MAAs were assessed. Anti-SRP antibodies were present in 4 (11.4%) children, anti-MDA5 in 3 (8.6%), anti-Mi2 in 1 (2.9%) and 1 patient tested positive for anti-SSA/Ro52 antibodies. All 4 children with anti-SRP were girls, had polycyclic course and 2 of them developed calcinosis. All 3 children with anti-MDA5 had predominant skin involvement, less severe muscle disease and followed a monocular course. Two of them had arthritis/arthralgia at the time of presentation. The only patient with anti-Mi2 had normal muscle strength/endurance at the time of follow up. None of the patients had anti MSA and anti MAA were present in any of the patient. Thus anti p-140 had anti SS-A/Ro52 antibodies have been done by Immunodot. Evaluation for anti p-140 or Nuclear Matrix Protein (NXp2) and anti 200/100 or 3-Hydroxy-3-Methylglutaryl-Coenzyme (HM-CoA reductase) was done using ELISA.

Conclusions: Prevalence of autoantibodies in children with JDM in our study is similar to what has been described previously. Type of autoantibodies, though, is not similar. This may be due to ethnic differences of the population. Autoantibodies were tested in children while they were on treatment. This may have resulted in lower positivity. Evaluation of autoantibody profile at the time of diagnosis may assist in predicting the course of disease and response to treatment.

SELECTASIS, A NOVEL SELECTIVE PI3Kδ INHIBITOR WITH THERAPEUTIC POTENTIAL IN INFLAMMATION AND AUTOIMMUNITY

A. Payne, M. Juarez, G.J. Johnston, E. Helmer, M. Thomson. UCB Pharma, Slough, United Kingdom

Background: PI3Kδ is predominantly expressed in lymphocytes; the role it plays in immune disease has encouraged the development of inhibitors targeting
DOWNGRADED EXPRESSION OF MR200B-5P IN MINOR SALIVARY GLANDS (MSG) OF PATIENTS WITH SJÖGRÖN’S SYNDROME (SS) ASSOCIATED LYMPHOMA

Pathophysiology, School of Medicine, National and Kapodistrian University of Athens, ATHENS, Greece

Background: The miRNAs of the miR-200 family are critical regulators of oncogene and tumor suppressor genes. Preliminary data from a limited number of patients with SS-associated lymphoma suggested that the expression of miR200b-5p in MSGs may be downregulated in lymphoma.

Objectives: To validate whether low miR200b-5p levels are associated with SS-related lymphomas and if they are deregulated before lymphoma development, suggesting a possible diagnostic value.

Methods: miR200b-5p expression was analyzed by quantitative real-time PCR in total RNA from MSG tissue obtained from 77 SS patients and 9 patients with non-SS sialadenitis associated with sarcoidosis, HIV infection (4 each) or HBV (1) who was also diagnosed with MALT lymphoma, and 28 SS patients without lymphoma and non-SS sialadenitis associated with sarcoidosis, HIV (4 each) or HBV infection (1) who was also diagnosed with MALT lymphoma. Non-SS sialadenitis included 4 cases of sarcoidosis, 2 cases of HCV infection, and 1 case of HBV infection.

Results: In a group of 77 SS patients, miR200b-5p levels were significantly down-regulated in MSG tissues of prelymphoma and lymphoma SS patients (mean relative expression±SE: 0.37±0.10 and 0.26±0.06, respectively) compared to SS patients without lymphoma (0.67±0.07; p<0.05 and p<0.0001, respectively). Interestingly, low miR200b-5p levels were detected in HBV patient that had MALT lymphoma (0.17). The expression of miR200b-5p was not found to differ between patients with SS without lymphoma and non-SS sialadenitis, or SS-associated prelymphoma and lymphoma. The analysis of the 15 cases of SS patients that had sequential samples before and after lymphoma diagnosis revealed that miR200b-5p levels do not significantly change over transition to lymphoma. The miR200b-5p expression levels were negatively correlated with the biopsy focus score (r=-0.6550, p<0.0001), whereas they were not associated with the site or the number of involved sites, the type or the stage of lymphoma.

Conclusions: The significantly low levels of miR200b-5p in MSG tissues of patients with SS-associated prelymphomas and lymphomas suggest that miR200b-5p deregulation is implicated in SS-lymphomagenesis. The downregulation of miR200b-5p in prelymphoma samples and the lack of change over transition to lymphoma suggest that miR200b-5p serves as a biomarker for future lymphoma development. The prognostic value of miR200b-5p in SS-associated lymphomas, the expressing cell types and affected molecular pathways are under investigation.

ELEVATED MTORC1 SIGNATURE IN B CELLS FROM SJÖGRÖN’S SYNDROME PATIENTS CORRELATES WITH B CELL HYPERACTIVITY THAT IS ABROGATED BY MTOR INHIBITION: A NOVEL THERAPEUTIC STRATEGY TO HALT B CELL HYPERACTIVITY IN PSS?

S. Blokland1,2, M.R. Hillen1,2, G. Koemmer-Wichers1,2, A.A. Kruize1,2, J.C. Brown1,2, A. A. van Rooijen1,2, S. Clarke1,2
Rheumatology & Clinical Immunology, Laboratory of Translational Immunology, UMC Utrecht, Utrecht, Netherlands

Background: A hallmark feature of primary Sjögren’s syndrome (pSS) is B cell hyperactivity, including presence of autoantibodies, aberrant presence of B cells and plasma cells in the salivary glands, elevated serum IgG levels and increased risk of lymphoma development. The mTOR pathway is essential for cell growth,
**THU0224** ASSOCIATION OF IRAK-M WITH NEUROPSYCHIATRIC SYMPTOMS IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS  
S. Sacre, R. Thwaites, K. Davies, Brighton and Sussex Medical School, University of Sussex, Brighton, United Kingdom  

**Background:** Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease where a breakdown in immune tolerance leads to sustained inflammation and autoimmunity. Patients with SLE suffer from a diverse range of symptoms that include arthritis, nephritis, neuropsychiatric events and dermatological complaints. Interleukin-1 receptor-associated kinase M (IRAK-M), a negative regulator of toll-like receptor (TLR) signalling has previously been associated with SLE in a murine study. [1] Deficiency of IRAK-M was observed to exacerbated disease in a SLE model in C57BL/6-lpr/lpr mice. [2]. Deficiency of IRAK-M has been associated with SLE in a murine study. [1]. Deficiency of IRAK-M was shown to exacerbated disease in a SLE model in C57BL/6-lpr/lpr mice [2]. Deficiency of IRAK-M has been associated with SLE in a murine study [1]. Deficiency of IRAK-M was shown to exacerbated disease in a SLE model in C57BL/6-lpr/lpr mice [2].  

**Objectives:** To study the IRAK-M pathway in B cells of SSc patients as a potential therapeutic target to inhibit B cell hyperactivity.  

**Methods:** Expression of IRAK-M pathway genes (MTOR, RPTOR, RICTOR, DEPTOR, AKT1, IGF1R, IGF1, PTEN) were assessed on an OpenArray platform in purified peripheral blood B cells and monocytes from SSc patients (n=12), non-Sjögren’s sicca patients (n=17) and healthy controls (HC, n=9). Correlations with clinical parameters including lymphocytic focus score, ESSDAI and serum IgG levels were assessed. Flow cytometry analysis for B cell subset distribution was performed to assess potential effects of B cell subset distribution on gene expression.  

**Results:** Total IRAK-M expression was significantly increased in B cells of the SSc group compared to HC and non-SSc patients (p=0.019 and p=0.018, respectively) and correlated with serum IgG levels (r=0.429, p=0.020, and r=-0.462, p=0.012). Differences in expression of IRAK-M pathway genes were not found in monocytes. To indicate the MTOR signature a cumulative MTORC1 score was calculated consisting of Z scores (AI) of MTOR, RICTOR, RICTORR, AKT1, IGF1R, Mkk1, Mkk2, Mkk3, Mkk4. MTORC1 score was significantly elevated in pSS (p=0.027), correlating with serum IgG levels (r=0.463, p=0.011). Frequencies of memory and naïve B cells did not differ between SSc patients and HC in this cohort (p=0.415). Activation of B cells in culture resulted in phosphorylation of S6, which indicates increased mTORC1 activity, in accordance with both SSc patients (n=12) and HC in this cohort, and Correlations with serum IL-35 level were assessed by qRT-PCR and by ELISA and a multiplex kit for IL-12 and IL-23.  

**Conclusions:** Presence of an MTORC1 signature in B cells from SSc patients correlated with B cell hyperactivity indicates a role for MTORC1 in B cell activation in this disease. That B cell proliferation and IgG production is effectively inhibited by rapamycin suggests that MTOR inhibition represents a potential therapeutic strategy for SSc.

**THU0225** ROLE OF THE IL-12/IL-35 BALANCE IN SJÖGREN’S SYNDROME  

**Methods:** The genetic study involved 673 patients with pSS from 2 French pSS cohorts and 585 healthy French controls. Functional studies were performed on sorted monocytes, stimulated or not, IL-12A/mRNA and IL-12 and IL-35 protein levels were assessed by qRT-PCR and by ELISA and a multiplex kit for IL-12 and IL-12, respectively.  

**Results:** We confirmed the association of the IL-12A rs485497 polymorphism and pSS and found an increased serum protein level of IL-12p70 in pSS patients carrying the risk allele (p=0.016). Serum level of IL-12p70 was greater in patients than controls (p=0.0001), especially patients with more active disease (p=0.05); conversely IL-35 level was decreased in patients (p=0.001) especially in patients with a more active disease (p=0.05).  

**Conclusions:** Our findings emphasize the involvement of the IL-12/IL-35 balance in the pathogenesis of pSS. Serum IL-35 was associated with low disease activity, in contrast to serum IL-12p70 level, which was rather associated with a more active disease.  

**Acknowledgements:** We thank Dr Odile Devergne (Université Paris Descartes, AP-HP, Hôpital Necker, Paris) for her expertise on the IL-35 ELISA kit to ensure the quality and reproducibility of this test.  

The authors thank the following investigators of the ASSESS cohort prospective cohort of patients with Sjögren’s syndrome (all in France) who recruited the patients and conducted follow-up: A. L. Fauchais (Limoges), S. Rist (Orléans), V. Le Guern (Rennes), P. Hayem (Paris), J. Sibilia (Strasbourg), J. Morel (Montpellier), A. SARAA (Brest), A. Perdriger (Rennes), X. Puechail (Le Mans), E. Hachulla (Lille) and V. Goebr (Rouen).  

The authors thank Dr Benessiano, S Tubiana and all staff members of the Bichat Hospital Biological Resource Center (Paris) for their help in centralizing and managing biologic data collection from the French ASSESS.

**THU0226** DIFFERENTIAL SUSCEPTIBILITY OF TH17 AND T REGULATORY CELLS TO APOPTOSIS IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS – THE MODULATORY EFFECTS OF STATIN  
J. Sun, J. Frostegard, A. Liu, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden  

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder. Patients with SLE have accelerated cardiovascular disease. Recent studies show there are more Th17 while less T regulatory (Treg) cells in the SLE patients. Th17/Treg imbalance may contribute to the pathogenesis of SLE.  

**Objectives:** To investigate the underlying mechanisms of Th17/Treg imbalance, we test the proportion and susceptibility of Th17 and Treg to apoptosis, and the modulatory effects of statin in the SLE patients.  

**Methods:** Totally 17 SLE patients and 20 gender- and age-matched control subjects were enrolled for this study. Peripheral blood mononuclear cells were isolated, either analyzed ex vivo, or cultured in the conditions to induce Th17 and/or Treg differentiation. The proportions of Th17, Th17/Treg and Treg/Teff cells and frequency responding to apoptosis were analyzed by multiple color flow cytometry. Cytokines in cell culture supernatants and plasma were tested by ELISA, T cell polarization-related transcription factors were detected by quantitative real time PCR.  

**Results:** The proportion of Th17 (CD4+IL-17+) cells were higher in SLE patients, capacity to resolve inflammation. This was reflected in the elevated cytokine production observed from SLE monocytes. Thus, low expression of IRAK-M in SLE monocytes is linked to elevated inflammatory cytokine production and may be a biomarker for neuropsychiatric symptoms in SLE patients.

both in ex vivo and in the Th17-polarizing cultures. While the frequencies of Treg (CD4+CD25+CD127dim+) cells were lower in the corresponding populations. Higher levels of IL17 and IL6 were detected in plasma of SLE patients. Responding to CD95-induced apoptosis the frequency of CD4+IL17+ cells from SLE patients was substantially lower, but that of CD4+CD25+CD127dim+ cells from Treg-polarizing cultures was considerably higher. With treatment of atorvastatin, CD4+IL17+ cell population in cultures derived from SLE patients showed an increased susceptibility to CD95-induced apoptosis. However, the CD4+CD25+CD127dim+ cell population had reduced response to apoptosis. Accordingly, the ratio of transcription factor ORC5/FOXJ3 decreased in T cell cultures of SLE patients.

Conclusions: Th17 cells were more resistant than Treg cells to CD95-induced apoptosis in SLE as compared to control subjects. Statins counteracted the dysregulated susceptibility of SLE T cells to apoptosis. Our findings reveal a novel mechanism underlying the imbalance of Th17/Treg and show a potential interest to the treatment of the patients with SLE.

Background: Recent genome-wide association studies (GWAS) have identified more than 50 loci associated with systemic lupus erythematosus but they explain less than 30% of the heritability of the disease. Meta-analysis including new populations can contribute to identify additional genetic risk factors.

Objectives: The aim of the present study was to identify additional genetic risk loci for SLE.

Methods: We performed a meta-analysis using data from a recent large scale GWAS from 4,036 cases and 6,959 controls from Caucasian European ancestry [1] and a newly genotyped cohort of 907 SLE patients and 1,524 healthy controls from Spain. Genetic association was tested at the single-marker level using linear regression and at the pathway-level using Fisher’s modified method.

Results: Combining the two cohorts we identified genome-wide significant association (P<5E-8) at five new loci: three SNPs at intronic regions and two intergenic loci at chromosomes 7q11.23 (Manhattan plot for chromosome 7 is shown in Figure; new SLE risk region SNPs highlighted in green) and 17q21.31.

Several of the new associated genes are functionally associated with B cell regulation. After multiple test correction, B Cell Receptor signaling, Biopeptides and Cell surface interactions at the vascular wall pathways were also significantly associated with SLE risk.

Conclusions: In conclusion, we have identified five new risk loci for SLE through a meta-analysis including a new GWAS.

THU0228 INTRA-RENAL ACTIVATION OF ADAPTIVE IMMUNE EFFECTORS IS ASSOCIATED WITH HIGHER DISEASE SEVERITY IN LUPUS NEPHRITIS

C. Pamfl 1, N. Demoulin 2, M. Jadoul 2, S. Aydin 3, F.A. Houssiau 1,4, B. Lauwerys 1,4, 1Pôle de pathologies rhumatismales systémiques et inflammatoires, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain; 2Department of Nephrology, 3Department of Pathology; 4Department of Rheumatology, Cliniques universitaires Saint-Luc, Brussels, Belgium

Background: Chronic renal impairment remains a feared complication of lupus nephritis (LN). Yet, little is known about mechanisms and markers of disease severity in the lupus kidney.

Methods: We performed high-throughput transcriptomic studies (Illumina HumanHT12 v4 Expression Beadchips) on archived (≥80 degrees) kidney biopsies from 32 SLE patients and 8 controls (pre-transplant donors). Unsupervised clustering and differential gene expression studies were performed using GeneSpring software. Pathway analyses were carried on using DAVID and GSEA. Clinical and biological data were retrieved from the patients’ medical records. Immunohistochemistry experiments (CD3, CD20, CD34) were performed on the same samples, and on an additional cohort of 37 SLE kidney biopsy specimens. Syndecan-1 (SDC1) was used as a marker of renal tubular cell response to stress.

Results: Compared to controls, LN samples overexpressed transcripts involved in interferon signature, apoptosis, chemokines, antigen presentation, T and B cell activation.

Unsupervised clustering studies isolated 14 SLE samples based on their gene expression features. These samples were characterized by a significantly lower estimated GFR at the time of biopsy (T0) (50.7 versus 97.4 ml/min/1.72m2), but also at follow-up (49.1 versus 85.8 ml/min/1.72m2) compared to the other SLE samples. Yet, apparent renal disease duration at T0, disease duration at last follow-up (median 91.5 versus 86 months), double-stranded DNA antibody titers, proteinuria, numbers of subsequent flares were not different between both groups.

From a transcriptomic point of view, these 14 samples were characterized by the overexpression of transcripts and pathways involved in adaptive immune responses: antigen presentation, T cell differentiation and B cell activation. Immunohistochemistry studies confirmed a significant association between the expression of CD3 and CD20 positive cells in the interstitial space and lower estimated GFR at baseline in the same, but also in an independent set of samples. The presence of CD3 and CD20 positive cells was also associated with lower SDC1 expression on renal tubular cells. Low SDC1 expression on renal tubular cells was strongly associated with impaired kidney function at baseline.

Conclusions: LN kidney biopsy samples from patients with lower estimated GFR are characterized by the overexpression of transcripts pointing to the activation of a local antigen-dependent immune response. Activation of “second wave” immune effectors in the LN kidney is a known feature of the disease, and impacts kidney function through alterations in the function of renal tubular cells.

Rheumatology Section, Hospital Arnau de Vilanova, I. Molecular, Cellular and Genomic Biomedicine, ISIS la Fe, Valencia, Spain

Background: Systemic lupus erythematous (SLE) shows increased DNA demethylation. An intermediate step to DNA demethylation is the DNA hydroxymethylation, where 5-mC is oxidized into 5-hmC. Hydroxymethylation is not completely understood and it may be related to oxidative stress in SLE patient.

Objectives: To analyze the association between the hydroxymethylation and demethylation, with the antioxidant response and SLE pathophysiology.

Methods: We analyzed in 142 SLE patients and 34 healthy controls the serum concentration of glutathione (GSH) and glutathione disulfide (GSSG) by UPLC-MS/MS, superoxide dismutase (SOD) and total antioxidant capacity (TAC) by colorimetric method. 5-mC and 5-hmC levels were measured by colimetric methods. Complete blood-test was made and clinical data by personal interview was collected. Biostatistical analysis with R (3.3.2.) was performed.

Results: There is a correlation between the methylation and hydroxymethylation rate (P<0.001) and between 5-mC levels and GSH, GSSG or GSH/GSSG ratio. Higher demethylation is associated to vascular symptoms (defined by RELESSER score) and lupus anticoagulant (AL) positivity (P<0.04; P<0.001), and lower hydroxymethylation (P<0.001; P<0.001). SOD and TAC levels are increased in SLE patients with higher demethylation and lower hydroxymethylation (P<0.001; P<0.001). We did not observe any association between hydroxymethylation and SOD or TAC levels. Lower SOD and TAC values are associated with higher demethylation and lower hydroxymethylation rates (P<0.001; P<0.001). SOD and TAC levels are increased in SLE patients with higher demethylation and lower hydroxymethylation (P<0.001; P<0.001). We did not observe any association between SOD or TAC levels and 5-mC or 5-hmC levels. GSH and GSSG concentrations were higher in patients (P=0.001), but TAC did not show significant differences. Higher demethylation is associated to lower TAC values in patients and healthy controls (P=0.005; P=0.01). Reduced demethylation and decreased GSH and GSSG concentrations were associated to increased long-term renal failure, cardiovascular disease, and to increased mortality rate. SOD levels were associated to vascular symptoms.

Conclusions: In SLE patients, lower SOD values are associated with higher disease duration (P<0.001; P=0.007), and lower SOD values with longer disease duration (P<0.001). We did not observe any association between hydroxymethylation and SOD or TAC levels. Lower SOD and TAC values are associated with higher demethylation and lower hydroxymethylation rates (P<0.001; P<0.001). SOD and TAC levels are increased in SLE patients with higher demethylation and lower hydroxymethylation (P<0.001; P<0.001). We did not observe any association between hydroxymethylation and SOD or TAC levels. Lower SOD and TAC values are associated with higher demethylation and lower hydroxymethylation rates (P<0.001; P<0.001). SOD and TAC levels are increased in SLE patients with higher demethylation and lower hydroxymethylation (P<0.001; P<0.001). We did not observe any association between hydroxymethylation and SOD or TAC levels. Lower SOD and TAC values are associated with higher demethylation and lower hydroxymethylation rates (P<0.001; P<0.001). SOD and TAC levels are increased in SLE patients with higher demethylation and lower hydroxymethylation (P<0.001; P<0.001). We did not observe any association between hydroxymethylation and SOD or TAC levels. Lower SOD and TAC values are associated with higher demethylation and lower hydroxymethylation rates (P<0.001; P<0.001). SOD and TAC levels are increased in SLE patients with higher demethylation and lower hydroxymethylation (P<0.001; P<0.001).

antibody were determined by ELISA. Histopathological evaluation of renal lesions was undertaken by HE, PAS, PASM and Masson staining under light microscopy. Podocyte foot processes were assayed by the transmission electron microscopy. Depositions of C5a, C5b-9, and MBL were detected by immunohistochemistry assay. Immunofluorescence was utilized to detect the expression of C5aR1, IgG, IgM, IgA, C3, C1q, and properdin in the glomeruli.

**Results:** At the end point, proteinuria in mice of the former three groups was significantly reduced when compared with the control mice, and renal function was also improved in both MSCT and CTX groups. Plasma level of C3 was significantly elevated in mice of MSCT and C5aRA groups. Furthermore, mice in MSCT group appeared a remarkably decreased C5a in the circulation. Compared to control mice, no significant difference was found in plasma levels of anti-dsDNA and SC5b-9, although there were decline trends in other three groups. Pathological analysis showed that the proliferation of glomerular cells and foot process fusion were significantly inhibited in MSCT treated mice. Immunohistochemistry showed that deposits of C5a and C5b-9 were significantly decreased in the MSCT group. Immunofluorescence examination showed that the expression of IgG, C3, C1q, and properdin was significantly decreased in MSCT treated mice, meanwhile, the expression of MBL was also significantly reduced in these mice.

**Conclusions:** The activation of the complement system was obviously involved in the glomerulonephritis in lupus mice. Allogeneic UC-MSC transplantation can effectively improve the clinical outcome of lupus mice. Possible mechanism of MSCT might be related to inhibit the activation of complement C5 in the circulation and local kidney via interrupting the classical, alternative, and lectin pathways. The potential involved contributors of UC-MSC are currently under study.

**THU0233** IN VITRO INDUCED REGULATORY T-CELLS CAN AMELIORATE SEVERITY OF PRISTANE INDUCED LUPUS (PIL) H. Leiss, B. Jacobs, I. Gessl, A. Puchner, J. Smolen, G. Stummvoll. Rheumatology, Medical University Vienna, Vienna, Austria

**Background:** Pristane induced lupus (PIL) is a well-established murine model for environmentally induced systemic lupus erythematosus (SLE). Mice develop specific autoantibodies and show symptoms of SLE including arthritis, diffuse proliferative immune complex glomerulonephritis and haemorrhagic pulmonary capillaritis.

**Objectives:** To investigate the therapeutic effects of in vitro-induced regulatory T cells (iTreg) in the murine model of PIL.

**Methods:** BALB/c mice were injected i.p. with either 0.5ml of pristane (PIL) or PBS (controls). Naive CD4+ thymocytes were sorted and cultured and cell suspensions with >80% of CD4+Foxp3+ cells (iTreg) were injected intravenously (i.v) once when PIL was induced (5x10^6 iTreg i.p., 2 times) or (ii) every 4 weeks (1x10^6 iTreg, i.p., 3 times). Animals were monitored for paw swelling and grip strength. After 12 weeks, histopathological analysis evaluated for cartilage degradation, number of osteoclasts and the extent of inflammation and bone erosion. Glomerulonephritins and pneumonitis were quantified using the kidney biopsy score and a newly adapted histomorphometric image analysis system; inflammatory tissue was further analyzed by tissue cytometry. Serum levels of anti-dsDNA, anti-histone and anti-nuclear antibodies were measured by ELISA.

**Results:** Monthly injections of 1x10^6 iTreg reduced the clinical as well as the histological severity of PIL-arthritis, seen by a higher mean grip strength (2.96±0.02 vs. 2.73±0.06, p<0.01), less mean paw swelling (0.04±0.02 vs. 0.36±0.07, p<0.001) and retardation of the symptom onset (Figure A). 62% of iTreg-mice and 33% of iTreg-rep mice had erosive arthritis. There was a significant reduction of arthritis severity in all histological parameters (inflammatory area in mm^2 0.19±0.06 vs. 0.69±0.11; erosive area in mm^2 0.01±0.01 vs. 0.70±0.02; number of osteoclasts 2.1±1.3 vs. 9.1±4.2; cartilage degradation in mm^2 0.06±0.01 vs. 0.19±0.03, all p<0.01, Figure B). The single boost of 5x10^6 iTreg could not prevent joint manifestations. However, a slight retardation in ‘loss of grip strength’ and a significantly less erosive area was observed. In regards to the cellular composition of the inflammatory tissue in paws, a significantly increased relative amount of CD4+Foxp3+ cells was found in the iTreg-rep group compared to the PIL-group (Figure C). Correspondingly, serum levels had significantly lower levels of disease-associated auto-antibodies (Figure D).

**Conclusions:** Repeated injections of iTreg ameliorate the clinical and histological severity of PIL- manifestations. A single boost of iTreg at the time of disease induction does not prevent manifestations, but retards the onset of symptoms. Thus iTreg have significant positive effects on PIL, which may have consequences for future approaches in treating SLE.

**THU0234** EPIGENETIC CELL COUNTING: A NOVEL TOOL TO QUANTIFY IMMUNE CELLS IN SALIVARY GLANDS DETECTS ROBUST CORRELATIONS OF TFH CELLS WITH IMMUNOPATHOLOGY J.A. van Roon 1,2, F.M. Moret 1,2, S.L. Blokland 1,2, A.A. Kruize 2, B. Bouma 3, A. van Maurik 4, S. Olek 4, U. Hofmann 4, T.R. Radstake 1,2, 1Laboratory of Translational Immunology; 2Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands; 4Immunoinflammation TAU, GlaxoSmithKline, Stevenage, United Kingdom; 5Epiontis GmbH, Berlin, Germany

**Background:** Histological analysis of salivary glands for decades has been a valuable tool in the characterization of patients with primary Sjögren’s syndrome (pSS) and non-Sjögren’s sicca (nSS) patients. However, understanding the immunopathology of sicca patients is challenging.

**Objectives:** To investigate whether epigenetic cell counting can serve as a novel reliable tool to quantify immune cells in salivary glands of sicca patients.

**Methods:** DNA was isolated from frozen tissue sections of 13 nSS, 12 probable SS, 29 pSS and 7 overlap SS patients. Bisulfite conversion of demethylated DNA sites was followed by qPCR on a qPCR machine that was used to calculate the percentage of cell subsets related to the total number of cells quantified by housekeeping gene expression. Percentages of epigenetically counted cells were correlated to gene expression generated by RNA-Seq analysis of matched salivary gland tissue and histological and clinical parameters (LFS, %IgA+ plasma cells, serum IgG3, SSA positivity).

**Results:** Strongly increased percentages of epigenetically quantified percentages of CD3, CD4, CD8, B cells, T follicular helper (Tfh) cells and Treg cells in pSS vs nSS patients were observed (all p<0.001, CD8 p<0.01). These inflammatory cell types were strongly correlated with LFS (all at p<0.001) and local B cell hyperactivity (% IgcA+ cells, all p<0.01, except CD8 p=0.06 and B cells, p=0.127) and systemic B cell hyperactivity (all at p<0.01, except CD8 p=0.051). Th17 cells were not significantly different between nSS and pSS patients. Only CD6 T cells were significantly increased in probable SS patients compared to nSS patients (p=0.03). Percentages of CD3 and B cells positively correlated with CD3 and CD19 RNA expression (r=0.608, p=0.0001; r=0.597, p=0.0001), respectively. Interestingly, percentages of Tfh cells correlated with CXCL13 (r=0.789, p=0.0001), IL7R, CXCR3 and ICOS RNA expression (all p=0.001) and were strongly associated with autoimmunity (SSA positivity; p<0.001).
Conclusions: Epigenetic cell counting is a promising novel tool to reproducibly and easily quantify immune cells in the (inflamed) labial salivary gland of sicca patients with relatively low amount of tissue needed (≤1 mm³). Considering the potential of this technique to include a huge number of (cell-specific) biomarkers we believe this opens up new standardized ways for salivary gland analysis with high relevance for patient classification, understanding of immuneopathology and clinical trials.

EXOSOME-DELIVERED MIR-146A REGULATES SENESCENCE OF BONE MARROW- MESENCHYMAL STEM CELLS FROM SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS THROUGH TARGETING IRAK1 AND TRAF6

J J. Ji, Y. Wu, X. Yong, Z. Zhang, Z. Gu1. Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China

Background: Exosomes are membrane nano-vesicles secreted by a multitude of cells that harbor biological constituents such as proteins, lipids, mRNA and microRNA. Recent study suggests that microRNAs can be transferred between cells and mediate target gene repression. Our research group revealed the senescence of bone marrow-mesenchymal stem cells from systemic lupus erythematosus patients, which participated in the development of SLE. However, the relationship between senescence of MSCs and miRNAs remains unclear.

Objectives: In this study, we investigated whether exosomes act as intercellular messengers delivering microRNA that modulate the senescence of BM-MSCs from SLE patients and its possible mechanism.

Methods: Twelve female SLE patients and healthy subjects were enrolled in the study. All patients were females, and their age distribution was similar to that of the cases. Serum were collected from these persons. All BM-MSCs were isolated by density gradient centrifugation. Serum-derived exosomes were extracted by Total Exosome Isolation Reagent and confirmed by transmission electron microscopy. They were then used to challenge MSCs from both groups. Internalization of exosomes was detected by immunofluorescence. QRT-PCR was used to distinguish the difference of expression of miR-146a in exosomes between normal group and SLE group. Different exosomes stimulated normal BM-MSCs, then detecting expression of miR-146a by qRT-PCR. Activating expression of IRAK1 and TRAF6 by WB, observing the activity of β-gal of cells, the changes of cytoskeletal structure by F-actin staining and the distribution of cell cycle by flow cytometry. We used miRNA mimics and miRNA inhibitor to interfere the expression of miR-146a.

Results: Serum-derived exosomes could be taken up by BM-MSCs through the plasma membrane due to treatment of BM-MSCs with exosomes. After stimulation of exosomes in normal MSC, miR146a was decreased, but, IRAK1 and TRAF6 was activated. And, the cell volume and the number of SA-β-gal positive in SLE BM-MSCs was increased. The organization of cytoskeleton was nearly disordered. The rate of cell proliferation was decreased. The miR-146a mimics in SLE BM-MSCs can significantly reverse the senescence.

Conclusions: Exosomes-delivered miR-146a in the serum of SLE patients can promote the senescence of BM-MSCs through targeting IRAK1 and TRAF6. Exosomes play an important role in the pathogenesis of SLE.

WHOLE TRANSCRIPTOME ANALYSIS OF APL TREATED HUEVCs MAPS PROINFLAMMATORY AND PROCOAGULANT PATHWAYS

M.D. Patsouras1, S. Foutadakis2, E. Alexopoulou2, M. Ageopoulos2, D. Thanos2, A.G. Tzoufas1, P.G. Vlachoyanniopoulos1. Department of Pathophysiology, Medical School National Kapodistrian University; Biomedical Research Foundation of the National Health System, Athens, Greece

Background: Antiphospholipid syndrome is an autoimmune thrombophilia characterized by recurrent thromboembolism and or pregnancy morbidity in the presence of antiphospholipid antibodies (aPL). j2GPI which is the major autoantigen in the syndrome forms complexes with anti-b2GPI autoantibodies that activate platelets, monocytes and endothelial cells. Previous studies have shown that anti-j2GPI-j2GPI complexes activate TRLR4 and TLR6 on endothelial cells leading to NFκB, MAPK activation and Tissue Factor and proinflammatory cytokine expression.1,2

Objectives: To evaluate the whole transcriptome of endothelial cells that have been stimulated with aPL-b2GPI complexes.

Methods: Human umbilical Vein Endothelial cells (HUEVCs) were isolated from 2 APL patients and 4 Healthy control women upon delivery. Healthy donor HUEVC were stimulated with aPL from APS patients with high aPL titers and healthy individuals in the presence of b2GPI. Consequently total mRNA was isolated, CDNA libraries were created and whole transcriptome sequencing (RNASeq) was performed. Gene expression data were validated in protein levels with immunohistochemistry in placenta tissues from APS patients and healthy individuals.

Results: Whole transcriptome analysis of HUEVCs stimulated with aPL-j2GPI complexes and IgG from healthy individuals revealed 680 differentially expressed genes, among which 377 were upregulated and 303 downregulated in the aPL stimulated endothelial cells. Characteristic examples of the upregulated genes are IL-6, IL-8, VCA1M, SELE and TGFβ2 and TGFBR1. Bioinformatics analysis revealed that the upregulated genes belong mainly to the cytokine-cytokine receptor interaction (hsa03323), MAPK signaling pathway (hsa04010), TNF signaling pathway (hsa04668) and NOD-like receptor pathway (hsa04662). Characteristic examples of the downregulated genes include the CX34, CX8X, BOCR and HDAC7 genes. Interestingly some of the proteins encoded by these genes play role in the epigenetic modification of DNA. Immunohistochemical staining on placenta biopsies from APS patients and healthy individuals for IL-6, IL-8, IL-18, NF-κB, TGFβ1 and TGFβ2 showed increased intensity in the signal of endothelial cells on APS specimens validating thus the RNASeq results in the tissues.

Conclusions: RNASeq of endothelial cells treated with aPL and b2GPI reveals a thoroughly analysed proinflamatory and procoagulant phenotype. Moreover differential expression of DNA modifying proteins suggests the possible epigenetic regulation of gene expression on endothelial cells in APS syndrome. Ongoing experiments aim to analyze histone acetylation and methylation status of the promoters of the selected genes that were shown to be differentially expressed.

ANTIBODIES TOWARDS ATP-BINDING CASSETTE TRANSPORTER ABCA1: A NEW MECHANISM FOR AHEROSCLEROSIS IN SLE?

M. Fernandes Dias Neves1,2, J.R. Batuca3, F. Batista3, C. Favas2, H. Célia4, J. Delgado Aves2,5, CEDOC - Chronic Disease Research Center, NOVA Medical School/Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon; 2Medicine IV, Professor Doutor Fernando Fonseca Hospital, Amadora; 3CEDOC - Chronic Disease Research Center, NOVA Medical School/Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal

Background: Systemic Lupus Erythematosus (SLE) is considered an indeﬁnite risk factor for cardiovascular disease and patients with SLE have an increased burden of atherosclerotic vascular disease. High-density lipoproteins (HDL), the plasma lipoproteins responsible for reverse cholesterol transport2, are the plasma lipoproteins that moderate HDL protective effect on cardiovascular disease is attributed to the cholesterol efflux capacity as well as to its anti-oxidant and anti-inﬂammatory properties. Dyslipidemia is frequent amongst patients with SLE that have higher damage, measured by SLICC classification criteria. Future studies will determine their pathogenic role and the potential use of a standardized ELISA to detect anti-ABCA1 antibodies in clinical practice.

Methods: Patients with SLE were divided in two groups: group A, with low damage (based on less than 4 SLICC criteria), and group B, with high damage (based on the presence of at least 4 SLICC criteria). Groups A and B were compared with a control group. 48 patients were enrolled (13 in group A and 35 in group B), and 18 age and gender-matched healthy controls were included in the control group. IgG anti-ABCA1 and anti-HDL antibodies were assessed by home-made ELISAs, using commercially available ABCA1 synthetic peptide and HDL from healthy donors.

Results: There were no differences between group A and the control group. Group B had higher titers of anti-ABCA1 antibodies when compared with group A (p=0.02) and the control group (p=0.022). For positivity we considered values superior to 3 standard deviations above the mean of healthy controls. Four patients showed positive anti-ABCA1 titers (11.4%).

Conclusions: This is the first time that naturally occurring antibodies against ABCA1 are detected by ELISA. These antibodies are increased in patients with SLE that have higher damage, measured by SLICC classification criteria. Future studies will determine their pathogenic role and the potential use of a standardized ELISA to detect anti-ABCA1 antibodies in clinical practice.

P-GLYCOPROTEIN MONOCLONAL ANTIBODY IMPROVES LUPUS-LIKE SYMPTOMS IN MRL/PLR MICE

Department of Rheumatology and Immunology, Peking University Shenzhen Hospital, Shenzhen, Guangdong 518036, China

Background: Preventing steroid resistance and maintaining disease control are significant challenges in treating SLE patients.[1] P-glycoprotein (P-gp) of membrane transporters, a product of the multiple drug resistance (MDR)-1 gene, is known to play a pivotal role in the acquisition of drug resistance to chemotherapy in autoimmune diseases.[2] Inhibition of P-gp could overcome such drug resistance.[3,4] So we observed the effect of P-gp monoclonal antibody on MRL/lpr lupus mice.

Objectives: To investigate the efficacy of P-glycoprotein monoclonal antibody in the treatment of the MRL/lpr mice.

Methods: Twenty-four 14-week-old MRL/lpr female mice were divided into three groups: Group 1 (G1) were treated with P-glycoprotein monoclonal through caudal vein, group 2 (G2) were treated with P-glycoprotein monoclonal three times and group 0 (G0) were treated with 0.5 ml normal saline as a control. Twenty-four-hour proteinuria and body weight were assessed every two weeks. Enzyme-linked immunosorbent assay (ELISA) was used to measure the levels of anti-dsDNA antibodies. The histopathology changes of the kidneys were observed.

Results: From the 22th week, the body weight of groups G1 and G2 increased significantly than that of the group G0 (p < 0.05). At the 22th week, the 24-hour proteinuria in group G1 (1.9±1.1) mg and G2 (1.4±0.9) mg was decreased than that in group G0 (3.1±1.9) mg (p < 0.05). During the 26th week, the levels of anti-dsDNA antibodies in group G1 (0.11±0.05) μg/ml and G2 (0.09±0.01) μg/ml were both significantly lower than those of the group G0 (0.37±0.19) μg/ml (p < 0.001) and at the 26th weeks the difference between group G2 (35±32)×10⁹ U/ml and G0 (59±35)×10⁹ U/ml was statistically significant. The nephron crescent formation in group G1 (0.11±0.05)μg/ml and G2 (0.09±0.01)μg/ml was significantly lower than that of group G0 (0.23±0.07)μg/ml (p < 0.05) and that of group G2 was significantly less than that of group G1 (p < 0.05).

Conclusions: P-glycoprotein monoclonal antibody is very effective in treating MRL/lpr mice. It is safe and free of rejection reactions.

SERUM HMGB1 AND TL4 LEVELS AS NOVEL BIOLOGICAL MARKERS FOR THE ACTIVITIES OF NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

O. Huang 1, C. Yuan 2, H. Ren 1, M. Yang 1.
1Department of Rheumatology; 2Department of Neurology, Nantong Hospital, Southern Medical University, Guangzhou, China

Background: Neuropsychiatric Systemic Lupus Erythematosus (NPSLE) is a severe complication of SLE, including a variety of neurological and psychiatric features. Previous studies have demonstrated the close relationship between NPSLE and TLR4-NF-κB signaling pathways. The HMGB1-TLR4 pathway is the upstream pathway of NF-κB, which could upregulate the expression of various cytokines and other inflammatory mediators.

Objectives: The objective of the study was to explore the potential mechanism of HMGB1/TLR4 axis in SLE.

Methods: The study population consisted of 107 SLE patients and 43 age- and sex-matched healthy controls. 73 SLE patients had active disease. 36 of these had NPSLE. The serum anti-NR2A antibodies levels were measured by ELISA. Clinical and serological parameters were assessed according to routine procedures. HMGB1 and TL4 levels were measured by ELISA. Statistical analyses were performed by using the chi-square test and the t-test.

Results: CNS manifestations accounted for 94% (34/36 patients), while involvement of the PNS was 6% (2/36 patients). The majority of the manifestations were Seizure disorders (n=17; 47.2%), Headache (n=12; 33.3%), and Cognitive dysfunction (n=10; 27.8%). Psychoses (n=6; 22.2%) within the group of active patients those with NP manifestations had higher HMGB1 levels (0.451 (0.292 to 0.583)) compared to active patients with non-NP manifestations (0.356 (0.098 to 0.436)). In patients with NP (0.429 (0.313 to 0.526)) and non-NP (0.375 (0.196 to 0.478)) manifestations during active periods of the disease, TL4 levels significantly increased in comparison to the controls. TL4 levels were significantly higher in active patients (0.401 (0.196 to 0.526)) compared to quiescent patients. There was a significant positive correlation between levels of HMGB1 and TL4 in the total patients group (P < 0.0001, r=0.939). We observed a correlation between HMGB1 levels and SLEDAI (P < 0.0001, r=0.804). Also, TL4 levels showed a significant correlation with SLEDAI (P < 0.0001, r=0.809). HMGB1 levels correlated with anti-dsDNA levels (P < 0.0001, r=0.558). Similarly, TL4 showed a correlation with anti-dsDNA levels (P < 0.0001, r=0.322). We observed a negative correlation in the total SLE group between C3, C4 and HMGB1 levels (P < 0.001, r=-0.545 and P < 0.0001, r=-0.270 respective. Also, TL4 showed a significant negative correlation with C3 and C4 (P < 0.0001, r=-0.559 and P < 0.0001, r=-0.285 respectively).

Conclusions: Our data suggest that HMGB1-TLR4 axis plays an important role in the pathogenesis of SLE as well as NPSLE.

DECREASED CIRCULATING CXCR3+CCR9+ TH CELLS ARE ASSOCIATED WITH INCREASED LEVELS OF THEIR LIGANDS CXCL10 AND CCL25 IN THE SALIVARY GLAND OF PATIENTS WITH SJÖGREN’S SYNDROME TO POTENTIALLY FACILITATE CONCERTED MIGRATION

Background: Primary Sjögren’s syndrome (pSS) is characterized by dryness and lymphocytic infiltration in the salivary glands. Both CXCR5+ T follicular helper (TFH) cells and CCR9+ Th1-like cells and their specific chemotactic ligands CXCL13 and CCL25 are present at increased levels in the salivary glands of pSS patients. Recently, we and others found that CCR9+ Th cells are elevated in pSS peripheral blood and co-express CXCR3 and other chemokine receptors, known to be important for TFH cell survival. Our group also showed that CCR9+ Th cells play an important role in mucosal immunity and have been shown to produce high levels of IFN-γ, like CXCR3+ Th1 cells. Since ligands of CXCR3 (CXCL9/10/11) are abundantly expressed in the salivary glands of pSS patients the potential role of this receptor in conjunction with CCL25 was studied in comparison with other chemokine (Th) receptors.

Methods: To study potential chemokine interactions causing enhanced migration of CCR9+ T cells into the salivary glands in pSS.

Methods: CXCL10, CCL25, CXCL13, CCL17 and CCL20 mRNA and protein expression in the submandibular glands of pSS patients and non-pSS patients was assessed (mRNA: n=9 vs n=9 and protein: n=26 vs n=34, respectively). Frequencies of CXCR3, CCR9, CXCR5, CCR4 and CCR6 expressing Th cells in blood of pSS patients and healthy controls were assessed by flow cytometry (n=11 vs n=11). Chemokinesis assays (n=3 HC, n=5 pSS) were performed to study migration induced by CXCL10 and CCL25. Results: CCL25, CXCL10 and CXCL13 expression were increased in pSS compared to nSS patients, both at mRNA and protein level (all p<0.05). CXCL17 and CCL20 expression were low and detectable in only few patients. Protein levels of CXCL10 and CXCL13 correlated with lymphocytic focus scores and all 3 chemokines correlated with serum IgG levels in pSS (all p<0.05). CCL25 protein levels strongly correlated with CXCL10 (r=0.545, p<0.004) but not with CXCL13. A relative decrease of CXCR3+ cells was found in the CCR9+ Th subset in the peripheral blood of pSS patients (p=0.04), which was most pronounced in the effector and effector memory subsets (84% vs 26%, p=0.03 and 51% vs 27% (both respectively). CXCR4 or CCR6-expressing CCR9+ Th cells and CXCR5 or CCR6-expressing CCR4+ Th cells were not decreased. To test the hypothesis that CXCR4 ligands and CCL25 facilitate migration, co-migration of lymphocytes in response to CXCL10 and CCL25 was studied. CXCL10 and CCL25 induced synergistic Th cell chemotaxis in vitro (p<0.02 and p<0.01 as compared to CCL25 or CXCL10 only, respectively).

Conclusions: The decreased frequency of CXCR3+CCR9+ Th cells in blood of pSS patients may be due to a concerted action of overexpressed ligands at the site of inflammation. Elevated expression of ligands CXCL10 and CCL25 in the salivary gland and the synergetic effect on chemotaxis in vitro indicate a potential role for these chemokines in formation of lymphocytic infiltrates in exocrine glands of pSS patients.

CAN THE INCREASE OF LOBULES / FOCI RATIO BE
HISTOPATHOLOGICAL EVIDENCE OF PRIMARY SJÖGREN'S SYNDROME

B. Ünal 1, V. Yazıcı 2, G.O. Elpek 1, M. Göcer 3, M.E. Terzioglou 2. 1Pathology; 2Rheumatology; 3Internal Medicine, Akdeniz University, ANTALYA, Turkey

Background: Minor salivary gland biopsy from the lip region is commonly used for primary Sjögren’s syndrome’s (SS) diagnosis. It is accepted that changes of histopathology is the most important component of diagnostic criteria. In this study, we analyzed the relationship between histopathological changes and laboratory findings/clinical features in SS patients and control group.

Objectives: The aim of this study was to determine the histopathological changes in minor salivary tissue for SS diagnosis

Methods: A total of 69 minor salivary gland biopsies (29 Sjögren’s syndrome and 40 controls) were included in the study. Biopsies were evaluated by a blind pathologist unaware of the diagnosis. Histopathological findings were noted as ductal dilatation, fat tissue percentage (<10% or >10%), acinar atrophy, ductal/ acinar ratio and lobules/foci ratio. It was evaluated whether there was a relationship between histological changes and age, gender, ANA, anti-SSA, anti-SSB, RF and Chisholm scores.

Results: The lobules/foci ratio of patients with Sjögren’s syndrome was significantly higher than the control group (p<0.001). The cutoff value of the lobules/foci ratio for SS diagnosis was 0.8. Furthermore, there was a significant correlation between the lobules/foci ratio greater than 0.8 and antibodies (ANA, RF, anti-Ro) positivity and Chisholm score (p<0.01). Other histopathological findings such as ductal dilatation, fat tissue percentage, acinar atrophy, and ductal/atherine ratio do not distinguish SS from non-SS.

Conclusions: The results of this study revealed that only the lobules/foci ratio from histopathological changes has a strong relation with SS diagnosis. It can be important for pathologists to distinguish SS.

THE ROLE OF STEM CELL-LIKE MEMORY T CELLS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Y.J. Lee, H. Kwon, E.B. Lee. Seoul National University, Seoul, Korea, Republic Of

Background: The stem cell-like memory T (Tscm) cell, a special subset of memory T cell, has a potential to self-renew and differentiate into wide spectrum of T cells1. However, the role of Tscm in autoimmune disease such as systemic lupus erythematosus (SLE) remains to be unknown.

Objectives: To investigate the levels of Tscm cells in SLE patients compared with healthy controls and to understand the functional characteristics of the Tscm cells from SLE patients.

Methods: Fifty two SLE patients and 57 healthy controls (HCs) were enrolled. To detect Tscm cells which are designated as CD3+ CD4+ CD8+ CD45RA- CCR7+ CD62L- CD45RA+ CD27+ CD28+ CD127+ CD122+ CD95+1, flow cytometry was performed after stimulating peripheral blood mononuclear cells (PBMCs, 1x10^7 cells/mL) with fluorescence-conjugated antibodies. To ascertain the differentiation ability of Tscm cells, different subsets of T cells including naive-like T, central memory T, effector memory T and follicular helper T cells (Tfh) were evaluated after stimulating the isolated Tscm cells with anti-CD3/CD28 antibodies for 6 days. To investigate the function of the Tfh cells derived from Tscm cells, secreted IgG antibodies were measured from the supernatants by ELISA after incubating Tfh –containing differentiated Tscm cells with autologous B cells and SEB for 6 days.

Results: Among the naive-like T (CD3+ CD4+ CCR7+ CD45RA- CD45RA+ CD62L-), the proportion of CD4+ and CD8+ Tscm cells was significantly higher in SLE patients than HCs (for CD4+ T cells, 2.9±0.22 (SLE) vs 1.1±0.13 (HC), p-value<0.001; for CD8+ T cells, 5.36±0.63 (SLE) vs 3.41±0.44 (HC), p-value=0.013). Among the total CD4+ T cells, the ratio of Tscm to CD4+ T cells was higher in SLE patients than in healthy controls (0.63±0.10 (SLE) vs 0.40±0.04 (HC), p-value=0.035) (Fig 1). SLE and HC Tscm cells could differentiate into naive-like T, central memory T, effector memory T cells and renewed themselves in response to α-CD3/CD28 stimuli. In addition, in response to the same stimuli, SLE Tscm cells could differentiate into more Tfh cells than HC Tscm cells could (for CXCR5+ ICOS+ PD-1+ T cells in CD4+ T cells, 9.30% (SLE) vs 5.41% (HC) and for Bcl-6+ cells in CD4+ T cells, 34.29% (SLE) vs 19.20% (HC)). Tscm-derived Tfh cells could help B cells produce antibodies in vitro (12007.81±4457.54 (SLE) vs 2082.18±517.82 (HC)).

Conclusions: Proportions of Tscm cells among T cells is increased in SLE patients compared with HCs and the Tscm cells may help maintain SLE by its ability to differentiate into Tfh cells.

Figure 1. Minor salivary gland biopsy pictures with different stainings of mTOR. (a) positive staining (b) negative staining (c) and score 2 (d) and TGF-β1 (negative staining (e) and score 3 (f)).
The impact of classifying SLE patients with the presence of anti-Ro and anti-La antibodies is associated with poor renal outcomes in lupus nephritis (LN) independently of glomerular pathology. Specific antibody profiles associated with LN have not been identified. Unlike glomerular damage, TID is not associated with anti-dsDNA or complement levels. An association between TID and the presence of anti-Ro/La antibodies has been proposed in Sjogren’s syndrome. Whether these antibodies are associated with TID in LN is not known.

Objectives: To study an association between anti-Ro/La antibodies and moderate-to-severe TID in LN.

Methods: We identified all patients who fulfilled ACR and/or SLICC criteria for SLE. Patients were included if they had an index renal biopsy consistent with LN between January 2005 and July 2015 and had complete data on TID and anti-Ro/La. Medical history, demographic and laboratory data were ascertained from chart review. TID was defined as the presence of moderate or severe tubular atrophy or interstitial fibrosis from the renal biopsy reports.

Results: Of the 157 LN patients, 39 (25%) had moderate/severe TID (Table). As expected, moderate/severe TID was associated with older age, class III/IV LN and lower estimated glomerular filtration rate (eGFR) by biopsy. Anti-Ro antibodies were present in 54% of patients with none/mild TID and 17% of patients with moderate/severe TID (p=0.047). Both anti-Ro and anti-La antibodies were present in 19% of patients with none/mild TID vs 11% of patients with moderate/severe TID (p=0.003). In the logistic regression model adjusted for age, eGFR and LN class, the presence of both anti-Ro and anti-La antibodies was associated with a 3-fold increase in the odds of TID. OR 3.1, 95% CI (1.1–9.1), p=0.04.

Objectives: The objective of this study was to investigate the association between SLE and Bipolar Disorder (BD) using big data analysis methods.

Methods: Patients with SLE were compared with age- and sex-matched controls regarding the proportion of BD in a cross-sectional study. Chi-square and t-tests were used for univariate analysis and a logistic regression model was used for multivariate analysis after adjustment for confounders. The study was performed utilizing the chronic disease registry of Clalit Health Services medical database.

Results: The study included 5,018 SLE patients and 25,090 matched controls. BD was found in a higher proportion among SLE patients compared to controls (0.62% vs. 0.26%, respectively, p<0.001). BD patients had a greater proportion of smokers compared to non-BD patients (62.5% vs 23.5%, respectively, p<0.001). In a multivariate analysis, smoking and SLE were both found to be significantly associated with BD.

SLE: Socioeconomic status, SLE: Systemic lupus erythematosus.

Conclusions: SLE was found to be independently associated with BD. These findings may imply that an autoimmune process affecting the central nervous system among lupus patients facilitates the expression of concomitant BD.

THU0249
SUBCLINICAL HAND ARTHROPATHY IN PATIENTS WITH SYSTEMIC LUPUS ERITEMATOSUS

C.A. Guillén-Astete, M. Revenga-Martinez, A. Zea-Mendoza. Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain

Background: As well as other systemic inflammatory diseases with joint compromise, there is an interest to identify the presence of synovitis in systemic lupus erythematosus (SLE) patients, in every follow up consultation. In SLE, the research about subclinical synovitis (that, which is clinically unnoticed but demonstrable by means of image studies) is quiet limited. The majority of studies non selected patients so many of them counted with patients with chronic synovitis or even deformities. Due to that their results are difficult to compare and the real prevalence of subclinical synovitis is still unknown.

Objectives: To determine the prevalence of synovitis in a selected cohort of patients without clinical evidence of arthritis or synovitis.

Methods: We performed a prospective study on 96 SLE patients grouped as follows: Group 0 (20) without any historical or present joint symptoms, Group 1 (34) with intermittent joint pain and Group 2 (42) with intermittent arthritis without deformities or erosions. A systematic US study of the carpal, 2nd and 3rd MCP joint of the non dominant hand were performed to all patients. US findings were expressed according to the nomenclature EULAR recommendations for synovitis, power Doppler signal and composite synovitis index.

Results: Six patients from group 0 showed any grade of synovitis (30%), 13 from group I (38.2%) and 18 from group II (42.8%). From the whole group of subjects, those with at least a synovitis finding was 37 (38.5%). Into the 2nd MCP joint, 4 patients (20%) from group 0 showed any grade of synovitis, one of them (5%) with power Doppler (PD) signal. The composite index of synovitis and PD signal (CSI) was 0.3 DE 0.36. In group 1, 9 patients (26.5%) showed any grade of synovitis, 4 of them also showed PD signal (11.8%). The CSI for this group was 0.44 DE 0.48. In group 2, 15 patients (14.3%) showed any grade of synovitis and 6 of them also showed PD signal (14.3%). The CSI for this group was 0.59 DE 0.55. Globally, we detected synovitis in 28/96 patients (29.2%) and PD signal in 11 (11.5%).

Conclusions: We performed a prospective study on 96 SLE patients grouped as patients without clinical evidence of arthritis or synovitis. Due to that their results are difficult to compare and the real prevalence of subclinical synovitis is still unknown. The majority of studies non selected patients so many of them counted with patients with chronic synovitis or even deformities. Our findings may imply that an autoimmune process affecting the central nervous system among lupus patients facilitates the expression of concomitant BD.

THU0250
EFFECT OF FETAL UMBILICAL ARTERY DOPPLER ON PREDICTION OF ADVERSE PREGNANCY OUTCOMES IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Z. Zhan, D. Chen, Q. Qiu, Y. Yang. Department of Rheumatology, The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Pregnancies in women with SLE resulted in an increase of adverse pregnancy outcomes (APOs). The predictive value of fetal umbilical artery Doppler examinations for APOs has been reported, while not widely be assessed in SLE pregnant women.

Objectives: To ascertain the predictive value of fetal umbilical artery Doppler for fetal APOs in SLE pregnancies.

Methods: A fetal Doppler ultrasound examination was performed on all fetuses during the third trimester (28–36 weeks of gestation) and the term pregnancy (37–42 weeks of gestation). The Doppler flow parameters of umbilical arteries were recorded, including pulsatility parameter (PI), resistance index (RI), the peak value of umbilical arteries at end-diastole (Vmax, also abbreviate as S) and the peak value of umbilical arteries at end-diastole (Vmin, also abbreviate as D). The value of S/D was automatically calculated. Clinical data and pregnancy outcomes were analyzed retrospectively.

Results: In total, 109 cases of pregnant SLE women performed fetal umbilical artery Doppler at the third trimester and 82 at the term pregnancy. Among the 109 cases, 65 resulted in one or more APOs, including 45 with premature delivery, 23 with intrauterine growth restriction (IUGR), 16 with fetal distress, 8 with neonatal lupus (NLE) and 3 with congenital malformation. Fetuses with APOs had higher S/D values compared with fetuses without APOs (2.9±0.9 VS. 2.4±0.5, p=0.001). In addition, other Doppler indexes did not differ significantly across groups. The positive and negative predictive values were 83.3% and 52.1%, respectively. Among the 82 cases with term pregnancy, 23 resulted in APOs, including 11 with IUGR, 15 with fetal distress, 4 with NLE and 1 with congenital malformation. All of the Doppler indexes (S/D, PI, RI, Vmax and Vmin) in fetus with APOs were higher than those without APOs, but no statistical significance were found between the 2 groups.

Conclusions: Umbilical artery Doppler was a good monitor method for APOs in pregnancies complicated by SLE. Women with more 2.8 S/D could start strict monitoring to rapidly identify and treat obstetric complications.

DIFFERENT RESPONSES TO INDUCTION THERAPY IN TWO ONSET CATEGORIES OF LUPUS NEPHRITIS

M. Nakano1, A. Mimori2, R. Kamei1, K. Suga1, A. Yashima1, S. Yamada1, Y. Takahashi1, H. Yamashita1, H. Kaneko1. 1Division of Rheumatic Diseases, National Center for Global Health and Medicine, Tokyo; 2Division of Nephrology and Rheumatology, Iwate Prefectural Central Hospital, Morioka, Japan

Background: We previously reported different clinical features, serological profiles and activities in two onset categories of lupus nephritis (LN): LN that
developed as a flare of systemic lupus erythematosus (SLE) after treating the prior non-renal SLE conditions successfully (delayed, D-LN) and LN manifesting at the time of SLE onset (early, E-LN). More frequent flares and higher serum titers of anti-dsDNA antibody during the LN flares were observed in D-LN than E-LN, suggesting that D-LN may reflect intractable SLE conditions. However, we had not analyzed whether there is a difference in the response to treatment between the two groups.

**Objectives:** This study investigated possible differences in the response to induction therapy between E-LN and D-LN.

**Methods:** We retrospectively examined 95 LN (48 E-LN, 47 D-LN) patients who attended our hospital between January 1991 and May 2016. All of them were diagnosed with SLE according to the American College of Rheumatology criteria and were shown to have LN on renal biopsy. First, we compared the clinical features of E-LN and D-LN, such as sex, age at SLE and LN onset, urinary protein, serum creatinine, serum anti-dsDNA titer, serum Ca, prevalence of serum anti-Sm, renal biopsy histological types and induction therapy options at LN onset. Then we compared the response to therapy at 24 weeks for LN onset and flares between the two groups. The response to treatment was classified into complete response (CR), partial response (PR), and “scleroderma-like pattern”. Higher serum C3 (56.4±22.4 vs. 46.5±22.7 mg/dl, p=0.03) were observed in D-LN groups. The proportion of histological types (I or II/III or III/I-V or IV-V or IV-V) was 6/7/6 in E-LN vs. 4/5/6/12 (p=0.77) and induction therapy options at LN onset were similar between the two groups. However, the response to therapy for LN onset was better in E-LN than D-LN (CR/PR/IR: 37/10/1 vs. 24/17/6, p=0.02) (Fig). Univariate Cox regression analysis indicated that severe proteinuria, elevated serum creatinine, class IV or IV-V on renal biopsy and D-LN were associated with non-CR (PR+IR) to induction therapy for LN onset (p<0.05). Multivariate Cox regression analysis including variables identified as significant in univariate analyses showed that severe proteinuria (hazard ratio [HR]: 1.35, p=0.007) and D-LN (HR 4.96, p=0.003) were independent predictors of non-CR to the induction therapy. LN flares were observed in 13/48 E-LN and 20/47 D-LN patients, and IR was observed in 15.4% (2/13) of E-LN and 40.0% (8/20) of D-LN patients.

**Conclusions:** In this study, the relatively poorer treatment response was observed in D-LN compared with E-LN patients and D-LN was a predictor of poorer treatment response independent of renal histology and the severity of nephritis at LN onset.

**NAILFOLD CAPILLAROSCOPY IN SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW AND CRITICAL APPRAISAL**

S. Wijnant1, F. Ingegnoli2, K. Melsens3, F. De Keyser1,3, K. Thevissen3, F. De Keyser1,3,

**Background:** Systemic lupus erythematosus (SLE) is a rheumatic disease with common vascular involvement. Nailfold capillaroscopic changes have been described in SLE. Although, until today there is no clear role yet for capillaroscopy in classifying or staging the disease.

**Objectives:** To systematically review and critically appraise the literature on capillaroscopic changes described in SLE.
COMPARISON OF URBAN VERSUS RURAL ENVIRONMENT
ASSOCIATED SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): RISK AND CLINICAL FEATURES

Bertisaísa1,2,1,2,1, Laboratory of Autoimmunity and Inflammation, Institute of Molecular Biology-Biotechnology, FORTH; 2Rheumatology, Clinical Immunology and Allergy, University of Crete School of Medicine, Iraklio; 4Therapeutics Research Center, Attikon University Hospital, National and Kapodistrian University of Athens Medical School, Athens; 4Laboratory of Autoimmunity and Inflammation, Institute of Molecular Biology-Biotechnology, FORTH; 3Laboratory of Autoimmunity and Inflammation, University of Crete School of Medicine, Iraklio; 5Laboratory of Autoimmunity and Inflammation, Biomedical Research Foundation of the Academy of Athens, Athens, Greece; 6Medical School, University of Cyprus, Nicosia, Cyprus; 7Joint Rheumatology Program, Attikon University Hospital, National and Kapodistrian University of Athens Medical School, Athens, Greece

Background: SLE originates from the complex interplay between genetic, epigenetic and environmental factors but the effects of the latter remain elusive. Very few studies have examined the impact of the place of residence (urban/rural) on SLE clinical profile and outcomes.

Objectives: To evaluate the effect of rural versus urban place of residence with regards to: i) SLE occurrence; ii) delay in diagnosis; iii) clinical manifestations, severity and non-reversible organ damage; iv) comorbidities and hospitalizations.

Methods: We employed data from the Lupus Epidemiology & Surveillance project in Crete (750 adult SLE patients with ≥4 ACR-1997 classification criteria). Crete is a Mediterranean island with genetically stable and homogenous population in ethnicity and sociodemographic characteristics, with no significant inequalities regarding access to healthcare facilities; 61% of the inhabitants live in rural (-10,000 people) and 47% in urban areas (-10,000 people). Demographics and residency history were retrieved from face interviews. In 200 patients with exclusively urban or rural residence, a subanalysis was performed in relation to disease risk, diagnosis age, disease severity, renal and neuropsychiatric involvement, and organ damage (SLICC damage Index [SDI]).

Results: SLE prevalence (December 2013) varied across the four geographical prefectures of Crete (Figure 1) and was significantly higher in urban (165/105) vs rural (123/105) areas (p<0.001). The relative risk of SLE in urban versus rural regions was 2.0 (95% Confidence Interval 1.5–2.9). Notably, patients in urban regions had lower age of diagnosis (38±13.4 vs. 44±14.8 years, p<0.005) and female-to-male ratio (6.5:1 vs. 11:1) than those in rural regions. Delay ≥2 years between symptoms onset and SLE diagnosis occurred in 42% of patients from rural areas as compared to 32% of those from urban areas (p<0.01). Acute cutaneous lupus was more prevalent in the rural environment (83.9% vs. 72.6%, p<0.05) whereas the opposite trend was noted for discoid rash (2.3% vs. 16.8%, p<0.001). Nephritis occurred less frequently (10.3% vs. 12.4%) and nephropathic disease was more prevalent (14.9% vs. 10.6%) in rural than urban patients albeit non-significantly. Prevalence of mild, moderate, and severe disease was 42%, 40%, and 18% in patients from rural areas, the respective figures being 55%, 28% and 18% in those from urban areas (p<0.012). Hospitalization due to active lupus did not differ between the two groups. At last follow-up, 45.3% of the patients living in urban and 51.9% of patients in rural areas had no organ damage (p=0.89). Concurrent allergic diseases were more frequent in urban patients (30.9% vs. 14.3%, p=0.045), particularly allergic rhinitis (8.8% vs. 2.3%, p=0.05).

Conclusions: SLE may be more prevalent in urban than rural regions and urbanization is associated with increased risk of SLE and earlier age of disease onset. Our results suggest an important effect of the environment on SLE occurrence and characteristics, which warrants further investigation.

THU0255 COMPARISON OF REMISSION AND LUPUS LOW ACTIVITY STATE AS PREDICTORS OF ORGAN DAMAGE

M. Petri1, L.S. Magder2, 1Johns Hopkins University School of Medicine; 2University of Maryland, Baltimore, United States

Background: Outcome measures that combine control of SLE activity and prednisone reduction are clinically relevant. A clinical goal in SLE is to reduce risk of long-term organ damage.

Objectives: We assessed whether two recently proposed disease activity outcomes were predictive of future damage.

Methods: For each month of follow-up in a large SLE cohort, we determined whether the patient was in Clinical Remission (as defined by the DORIS work group) or low lupus disease activity state (LLDAS) (as defined by Franklyn et al.). Clinical Remission was defined as a PGA<0.5, clinical SLEDAI=0 and no prednisone or immunosuppressants. Clinical Remission on Treatment allowed for prednisone~<5mg/day and immunosuppressant use. LLDAS was defined as a SLEDAI ≤4, PGA ≤1.0, no major organ activity, and no new activity. LLDAS on treatment allowed for prednisone ≤7.5 mg/d and immunosuppressants. Damage was defined using the SLICCA/ACR index.

Results: There were 81,118 person-months observed among 2,026 patients (92% female, 53% Caucasian, 39% African-American). Table 1 shows the rates of damage, per person month, in subgroups defined by Remission or LLDAS.

| 75%+                          | 7,527                            | 46                                          | 0.61                              | 0.54 (0.40, 0.73) | <0.0001 |

Damage rates were relatively low when LLDAS was achieved at least 50% of the time. These rates were similar to those experienced by patients who met a more stringent treatment restriction with Remission on Treatment at least 50% of the time.

Conclusions: The equivalence of LLDAS and DORIS remission on treatment is welcome news, as LLDAS on treatment >50% of the time is an easier goal to achieve (3 times more person-months observed in our cohort) and more realistic as a clinical trial outcome.

Disclosure of Interest: None declared

THU0256 DEVELOPMENT AND VALIDATION OF A SCORE TO PREDICT THE RISK OF SEVERE INFECTION IN SLE

B. Tejera Segura1, I. Rúa-Figueroa2, J. Pego-Regisosa2, V. del Campo Pérez2, D. Rienberg3, A. Rahman University College London Hospital London, United Kingdom; 2Hospital Universitario Dr.Negrin, Las Palmas de Gran Canaria; 3Complejo Hospitalario Universitario de Vigo, Vigo, Spain

Background: Infection is a major cause of morbidity and mortality in SLE patients. It would be helpful to have a tool to predict the risk that an individual patient with SLE will develop serious infection.

Objectives: To develop a predictive risk calculation algorithm (SCORE) that...
assesses the probability of serious infection (i.e. leading to hospitalization) in SLE patients and to test it in an independent cohort.

**Methods:** The SCORE was developed using data from the RELESSER (Spanish Society of Rheumatology Lupus Registry) cohort of 3658 SLE patients. A Cox regression model for repeated events (Andersen-Gill) was applied to assess which demographic and clinical factors were independently associated with increased risk of developing serious infection (Table 1). The SCORE was then validated using retrospective data from the UCLH (University College London Hospital) cohort including 699 SLE patients. Median SCORE values were compared between sub-groups of patients using the U-Mann-Whitney test.

**Results:** Among 699 SLE UCLH patients, 98 (14%) developed serious infection. We compared these patients with 111 SLE controls who have never suffered serious infection. The characteristics of both groups are summarized in Table 2. The infection group were more likely to have suffered previous infection (P<0.001) and/or hospitalized for SLE (P<0.001) and had renal and joint disease (P<0.005). Over a quarter of the infection group died from their infection. Median (Md) SCORE at diagnosis in SLE patients with infection was 4.27 (IOR 3.18) which was significantly higher than in the control group (Md 2.55, IQR 3.79; P=0.0008). Md SCORE before infection in patients was 5.3 (IQR 3.68) which was significantly higher than at diagnosis (P<0.001; P<0.001) in those patients. By ROC analysis, we defined three possible cut-offs to distinguish patients with and without infection. The area under the ROC curve was 0.66 (CI 95% 0.56 to 0.71). A cut-off for SCORE at diagnosis >3.18 identified patients who would develop serious infection with sensitivity (S)76.5% and specificity (SPC) 50.5%. For SCORE>3.75, S was 64.3% and SPC 57.7%. For SCORE >4.24, S was 64.3% and SPC 60.4%.

**Conclusions:** We have developed a SCORE for predicting risk of serious infection in SLE and validated it in an independent cohort. Given the potential mortality from such infections, this SCORE could be clinically useful though the moderate sensitivity and specificity necessitate caution and further prospective studies.

**THU0257 ENHANCED ACTIVATION OF NLRP3 INFLAMMASOMES IN PATIENTS WITH SJÖGREN’S SYNDROME**

J.N. Kim, S.-K. Kim, J.-Y. Choe. Division of Rheumatology, Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic of

**Background:** There has been data about pathogenic role of NLRP3 inflammasome in Sjögren’s syndrome. However, linkage between their clinical features and NLRP3 inflammasome has not been clearly defined.

**Objectives:** The aim of this study is to identify the association of NLRP3 inflammasome with clinical features in patients with primary Sjögren’s syndrome.

**Methods:** A total 25 female patients with Sjögren’s syndrome and gender-matched 25 healthy controls were consecutively enrolled. The mRNA expression for target genes including NLRP3, ASC, caspase-1, IL-1β, and IL-18 in peripheral blood mononuclear cells (PBMCs) were measured using real-time polymerase chain reaction. Serum IL-1β and IL-18 expression were also measured by ELISA method. Clinical information and disease activity and damage for Sjogren’s syndrome such as EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) and Sjögren’s Syndrome Disease Damage Index (SSDDI) were collected at the time of enrolment. Statistical analysis were applied including Spearman’s correlation coefficient and Mann-Whitney t-test.

**Results:** Patients with Sjögren’s syndrome was found to be highly expressed in mRNA IL-1β and its protein, compared to controls (p<0.001 and p<0.001, respectively). The mRNA levels of caspase-1 and ASC were significantly higher than those in controls (p<0.02 and p=0.008, respectively), but not mRNA level of NLRP3. The mRNA level of IL-1β is closely related with mRNA level of NLRP3 and ESR (r=0.549, p<0.001 and r=0.577, p=0.003, respectively). Serum IL-1β protein expression in Sjögren’s syndrome was found to be associated with mRNA level of caspase-1. Based on SSDDI, patients with SSDDI >1 was older and had higher IL-1β and NLRP3 mRNA expression, compared to those with SSDDI =0 (p=0.035, p=0.005, and p=0.016, respectively).

**Conclusions**: This study confirmed that activation of NLRP3 inflammasome might implicated the pathogenesis of Sjögren’s syndrome.

**THU0258 SERUM PARAOXONASE 3 ACTIVITY IS REDUCED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHROMATOMATOSIS AS COMPARED TO HEALTHY CONTROLS**

**Background:** Premature atherosclerosis is a well recognised comorbidity in patients with SLE (1). Elevated levels of circulating Oxidised Low Density Lipoprotein (OxLDL) have been described in SLE patients, especially in those with a history of cardiovascular disease (2). Paraoxonase 3 (PON3) is believed to play a role in prevention of atherosclerosis by contributing towards the anti oxidant activity of high density lipoprotein (HDL).

**Objectives:** To determine serum PON3 levels and PON3 activity in patients with SLE and compare them with healthy controls.

**Methods:** Serum PON3 levels and PON3 activity were determined in 100 patients of SLE with no prior history of coronary artery disease and they were compared with those of 50 healthy controls who did not have diabetes, hypertension or coronary artery disease. Serum PON3 concentration was determined by enzyme-linked immunosorbent assay (ELISA) using anti-PON3 antibody specific for human PON3. PON3 activity was estimated using Spectrophotometric assay which quantified the hydrolysis of dihydrocholesterin at 270 nm (3).

**Results:** PON3 levels were lower in SLE patients (P<0.001) and PON3 activity was reduced (p<0.001) compared to healthy controls. In subgroup analysis of SLE patients, PON3 activity and levels did not correlate with disease activity. On Univariate analysis, serum creatinine (r=0.06, p=0.002), age (r=0.03, p=0.035), and SLE status (r=-0.27, p<0.001) contributed to PON3 levels. On Univariate analysis, serum creatinine (r=0.15, p=0.001), AST (r=0.04, p=0.01), ALT (r=0.16, p<0.001) and SLE status (r=-0.77, p<0.001) contributed to PON3 levels. On multivariate analysis, only SLE status predicted PON3 levels (P<0.001) and PON3 activity (p<0.001).

**Conclusions:** PON3 levels are reduced and PON3 activity is decreased in patients with SLE as compared to healthy controls, the difference was attributable to the disease itself. This may contribute to premature atherosclerosis in these patients.

THU0259 RESPIRATORY SYMPTOMS IN PRIMARY SJÖGREN’S SYNDROME, A CROSS-SECTIONAL STUDY OF THE OASIS COHORT

A. Bengtsson 1, B. Fisher 2, F. Barone 2, A. Richards 3, A. Poveda 3, J. Higham 3, S. Rauz 1, F. Bowman 1, 1University Hospitals Birmingham NHS Foundation Trust; 2Institute of Inflammation and Ageing, University of Birmingham; 3Birmingham Dental Hospital, Birmingham, United Kingdom

Background: In previous studies, 5 to 35% of patients with primary Sjögren’s syndrome (pSS) are reported to have respiratory symptoms (RS). Pulmonary involvement varies from a dry cough due to airway dryness to life-threatening interstitial lung disease.

Objectives: To evaluate RS prevalence in patients with pSS and compare characteristics of pSS patients with and without RS to those in patients without pSS suffering from ocular or oral dryness.

Methods: Cross-sectional study of patients at the time of their inclusion in the OASIS cohort between 2014 and September 2016. This UK prospective research includes patients with suspected pSS or known pSS and aims to collect long-term high quality data with regular clinical, dental and ophthalmological assessments. We asked systematically all the patients if they had any RS. In case of clinically significant RS, pulmonary function tests (PFTs) were requested, and if needed, a high-resolution chest tomography (HRCT) was performed. We included in the analysis only patients fulfilling the AECG (2002) criteria for pSS and excluded patients with secondary Sjögren’s syndrome. Characteristics of pSS patients with and without and non-pSS patients with sicca symptoms were compared. For HRCT and pulmonary function tests, we used unpaired t test, Mann-Whitney test, Fisher’s exact test and Chi-square test when appropriate. P < 0.05 was considered statistically significant.

Results: Among the 157 patients included in the cohort, 70 fulfilled the AECG criteria for pSS and 63 had sicca symptoms without pSS. In the pSS/sicca group, 18% (28/157) of patients had RS, compared to 5% (4/97) of non-pSS patients with sicca symptoms without pSS suffering from ocular or oral dryness. These results were statistically significant.

Conclusions: In conclusion, we found a considerable RS prevalence in pSS patients and a lesser prevalence, but still significant, in patients with sicca symptoms without pSS. We also found that pSS patients with RS had higher ESSDAI and ESSPRI index values but did not differ in terms of objective measurements of tear and saliva production, histological focus scores and auto-immunity profiles.

THU0260 LOW PLASMA CONCENTRATIONS OF APOPOPROTEIN M CORRELATE TO DISEASE ACTIVITY AND ENDOTHELIAL DYSFUNCTION IN SLE

A. Bengtsson 1, C. Weidt 1, C. Loo 1, B. Guillstrand 1, B. Dahlbäck 1, A. Jönsen 2.
1Rheumatology, Institution of Clinical Sciences, Lund University, Lund; 2Clinical Chemistry, Institution of Translational Medicine, Malmö, Sweden

Background: ApoM is an antiatherogenic and vasculoprotective 25kDa apolipoprotein suggested to play a role in keeping endothelial barrier integrity.

Objectives: The aims of the current study were to determine the impact of SLE disease activity on apoM levels and to investigate if apoM levels reflect endothelial function in SLE.

Methods: Plasma concentrations of apoM were measured in ELISA in two SLE cohorts. All patients fulfilling ACR classification criteria for SLE, and 100 healthy controls (HC). Patients in cohort I had active disease as evaluated with SLEDAI score. In cohort II endothelial function was measured by EndoPAT 2000 and correlated to apoM levels. A low Reactive Hyperemia Index (RHI) value indicated endothelial dysfunction (ED).

Results: In cohort I, the plasma levels of apoM were found to be significantly decreased in SLE (p < 0.0001), and the apoM concentrations correlated inversely to disease activity (SLEDAI, r = -0.29, p = 0.0063). ApoM was also significantly lower in patients with active nephritis, leukaopenia, anti-DNA antibodies or rash compared to patients without these manifestations. In cohort II, using linear regression analysis, there was a positive correlation between apoM levels and the RHI value, indicating endothelial dysfunction, in the younger SLE patients: p = 0.94 CI 95% 0.22,1.65 r=0.32 p = 0.011.

Conclusions: SLE related inflammation may have an impact on lower plasma apoM, which may affect the endothelium and the process towards cardiovascular disease.

PREVALENCE OF REMISSION AND ITS EFFECTS ON ORGAN DAMAGE AND QUALITY OF LIFE IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C.C. Mok, L.Y. Ho, S.M. Tse, K. Chan, Medicine, Tuen Mun Hospital, HK, Hong Kong

Background: To study the effect of disease remission on organ damage and quality of life in Chinese patients with systemic lupus erythematosus (SLE).

Methods: Patients who fulfilled the ACR classification for SLE were studied. Their remission status at last visit was determined by the European consensus (DORIS definition): (1) Complete remission (clinical SLEDAI=0, serology inactive); and (2) Clinical remission (clinical SLEDAI=0, serology active). These two categories were further divided into those who required ongoing immunosuppressive treatment (corticosteroids ≤ 7.5 mg or other immunosuppressive agents) and who did not. The increase in SLE organ damage (SDI) score since 5 years prior to recruitment was compared between patients who were and were not in remission for ≥5 years. Participants were randomly selected for assessment of quality of life by using both the validated version of SF36 and the LupusPRO (version 1.8) and comparison was made between those who did and did not achieve remission for ≥5 years by the independent Students’ t-test.

Results: 769 SLE patients were studied (92% women; age 46.4±14.6 years, SLE duration 12.6±8.1 years). At last visit, clinical remission was present in 259 (33.7%) patients (median 43 months) and complete remission (clinically and serologically inactive) was present in 280 (36.4%) patients (median 51 months). Clinical/complete remission for ≥5years was achieved in 64 (8.3%) and 129 (16.8%) of the patients, respectively. 53 (6.9%) patients in remission ≥5 years were taken off all medications including HCO (drug-free). Compared with patients who did not remit, those remitted ≥5 years were older (49.8±13.2 vs 45.7±15.6; p=0.004), and had significantly lower prevalence of renal involvement, leucopenia or thrombocytopenia. Significantly fewer patients who remitted for ≥5 years were maintained on prednisone compared to others (31% vs 68%; p=0.001). The increase in SDI scores over the preceding 5 years was 0.17±0.53 in patients who had a prior clinical remission and ongoing therapy (except HCO) for ≥5 years (N=98), 0.25±0.51 in those remitted for ≥5 years but maintained on immunosuppressive medications (N=105), 0.41±0.84 in those remitted for <5 years (N=346) and 0.67±1.10 in those who did not remit (N=230), respectively. The increase in SDI was statistically higher in those remitted for ≥5 years than <5 years (p=0.007) or those who did not remit (p=0.001). Logistic regression showed that patients with remission for ≥5 years or who did not remit had an increase in the risk of new damage accrual as compared to those with remission for ≥5 years (OR 2.42 [1.50–3.98]; p=0.001), adjusted for age, sex, SLE duration, SDI scores 5 years prior to the last visit and the daily dosen of immunosuppressive therapy (except HCO) for ≥5 years (N=453) patients who had QOL assessment, remission for ≥5 years was associated with significantly higher physical component and mental component scores of the SF36 than those who did not remit. Patients with remission for ≥5 years had significantly higher scores in the individual health-related domains (except cognition) of the LupusPRO than those who did not remit.

Conclusions: Durable remission can be achieved in a quarter of patients with SLE. Patients with remission for ≥5 years have significantly less damage accrual and better QOL. Prolonged remission is an appropriate parameter for outcome assessment in SLE.
domains (Lupus Symptoms, Physical Health, Pain-Vitality, Emotional Health and Body Image) were responsive to changes in patient reported and physician assessed health status (disease activity and damage) (Table 1). Procreation and Cognition domains showed responsive trends with patient reported change in health status, while Lupus Medications domain was responsive additionally to changes in Damage.

Conclusions: LupusPRO summary HRQOL and HROQL domains show responsiveness to changes in patient-reported and physician assessed changes in health status in this observational study among Chinese SLE patients. Results support inclusion of LupusPRO into larger clinical trials to allow for robust estimates of responsiveness.

THU0265 IDENTIFYING THE LINKS BETWEEN IRON DEFICIENCY AND FATIGUE IN ADOLESCENTS AND YOUNG ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
C. Wincup1, Y. Ioannou1, T. Richards2, F. Josephs1, L. Suffield1, A. Rahman1.
1Department of Rheumatology; 2Division of Surgery & Interventional Science, University College London, London, United Kingdom

Background: Between 80–90% of patients with systemic lupus erythematosus (SLE) report fatigue to be the single most troublesome and debilitating symptom of their illness. Recent studies have found that functional iron deficiency and iron deficiency anaemia have been linked with fatigue and decreased cognitive performance. Increased red blood cell distribution width (RDW) is an early indicator of iron deficiency that can be useful in assessing iron stores in patients with SLE who may have an elevated serum ferritin due to underlying inflammation.

Objectives: To investigate the relationship between early iron deficiency (measured by RDW) and fatigue in adolescents and young adults with SLE.

Methods: Adolescent and young adult patients with SLE were recruited prospectively between November 2016 and January 2017. All patients were asked to complete the Functional Assessment of Chronic Fatigue Illness Therapy (FACIT) Fatigue Scale v4, in which a numerical score between 0–52 is generated. Lower scores indicate more fatigue. Standard measures of lupus disease activity including Erythrocyte Sedimentation Rate (ESR), C-Reactive Protein (CRP), Complement C3 levels, anti-double stranded DNA binding (anti-dsDNA) and SLEDAI were recorded. Haemoglobin (Hb) and RDW were also measured. Anaemia was defined by World Health Organisation criteria (male Hb <130g/L and female Hb <120g/L). Non-parametric analysis was performed using Spearman’s rank with a p-value <0.05 felt to be significant.

Results: 33 patients aged between 16.7 and 27.5 years (median age 20) were included. 85% of the patients were female. Their FACIT scores were lower than those published for healthy individuals of the same age group - median 24, IQR 22–44 for SLE vs median 43, IQR 35–48 for healthy. There was no statistically significant correlation between FACIT Fatigue score and SLEDAI score (p=0.92), anti-dsDNA (p=0.36), C3 levels (p=0.37), ESR (p=0.30) or CRP (p=0.85). Interestingly a statistically significant negative correlation between FACIT Fatigue score and RDW was observed (p=0.012; r=-0.43). A correlation between FACIT Fatigue score and Hb was noted although this was not statistically significant (p=0.079). 12 of the 33 patients were found to be anaemic (11 female, 1 male). Analysis of the sub-group of 21 non-anaemic patients found FACIT Fatigue Score and RDW continue to show a statistically significant association (p=0.026; r=-0.49).

Conclusions: Fatigue is a common and debilitating symptom described by young patients with SLE. Standard serological and clinical markers of disease activity did not correlate with the burden of fatigue. Increased RDW has been shown for the first time to correlate with increased fatigue in patients with lupus, suggesting that iron deficiency may play a significant role in the manifestation of this troublesome symptom. A trial of therapeutic iron infusions in the treatment of fatigue in SLE is planned.

THU0266 DAMAGE INDEXES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND SECONDARY ANTIPHOSPHOLIPID SYNDROME: DIAPS VS SLICC/ACR DAMAGE INDEX
D. Potaniche1, D. Maziul2, I. Săulescu3, A. Boranguiu2, L. Groseau2, C. Constantinescu2, V. Vlăd1, F. Berghea1, V. Bojînc1, D. Opirs-Beliniski2, A. Balănescu2, D. Predeteanu2, R. Ionescu2,1 “Stângă Maria” Clinical Hospital; 2 “Stângă Maria” Clinical Hospital, “Carol Davila” University of Medicine, Bucharest, Romania, Bucharest, Romania

Background: Systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) are systemic autoimmune diseases that have overlapping irreversible organ damages. Since SLICC/ACR Damage Index (SDI) misses key features of APS, the Damage Index in patients with Thrombotic Antiphospholipid Syndrome (DIAPS) was proposed.

Objectives: To assess the differences in indexes available for measuring organ damage in a cohort of patients with SLE and secondary APS.

Methods: Clinical records of patients with SLE and secondary APS were reviewed. Data on medical history and clinical manifestations were collected. The two damage indexes, SDI and DIAPS, were applied. Comparison between the two indexes was done for each organ system affected.

Results: Sixty-five clinical charts were reviewed, 5 had been excluded for incomplete information. SDI and DIAPS was recorded in 60 patients. Patient’s mean age was 45.05±14.61 years, with mean disease duration of 9.47±6.96 years. Mean SDI in our cohort was 4.15±2.58 and mean DIAPS – 4.06±3.41. SDI correlated significant to DIAPS (R=0.926, p=0.000). Neuropsychiatric manifestations were found in 25 patients (41.7%). Their mean SDI value was 4.92±2.73 and DIAPS value of 5.52±3.47. DIAPS value was higher in the subgroup of patients with neuropsychiatric (p=0.006) and respiratory system damage (p=0.037) This difference was not observed regarding SDI value. DIAPS value correlated significantly to neurological (R=0.397, p=0.002) and pulmonary damage (R=0.364, p=0.004), but not to SDI value. No differences were observed between the two scores regarding peripheral vascular manifestation (DIAPS p=0.221, SDI p=0.136) and renal involvement (DIAPS p=0.082, SDI p=0.078).

Conclusions: SDI may under estimate APS related damage in patients with SLE and secondary regarding neurological and pulmonary organ involvement. Given the implications for high morbidity and mortality, DIAPS may be the appropriate damage score to be used.

THU0267 METABOLIC SYNDROME AND HEALTH-RELATED QUALITY OF LIFE IN SYSTEMIC LUPUS ERYTHEMATOSUS
D.P.E. Marigiotto, F. Basta, M. Vadacca, G. Dolcini, F. Pignataro, A. Vernuccio, C. Mazzucola, L. Navarini, A. Alfiera. Unit of Allergology, Immunology and Rheumatology, Università Campus Bio-Medico di Roma, Rome, Italy, Rome, Italy

Background: Systemic Lupus Erythematosus (SLE) is associated to a huge prevalence and incidence of cardiovascular diseases (CVDs) due to accelerated atherosclerosis. Several evidences demonstrated that metabolic syndrome (MeS) could contribute to CVDs burden in SLE. In general population, MeS components and, according to some reports, MeS itself are associated to worsened Health related Quality of Life (HR-QoL). In SLE patients, a severe decline of HR-QoL has been widely demonstrated.

Prevalence and features of celiac disease in patients with systemic autoimmune diseases: results of a large multicenter study

E. Bartoloni, A. Alunno, O. Bistoni, L. Cavagna, L. Nalotto, C. Baldini, A. Gabriele, S. De Vita, R. Giacomelli, R. Gerli, G. Nucera, A. Gabrielli, S. De Vita, R. Giacomelli, R. Gerli, L'Aquila, L'Aquila; Rheumatology Unit. Sapienza University, Roma; University of Perugia, Perugia; Department of Rheumatology, University of Pavia, Pavia; Rheumatology Unit, University of Padova, Padova; Rheumatology Unit. University of Pisa, Pisa; Rheumatology Unity, Sapienza University, Roma; Politecnica delle Marche, Ancona; Rheumatology and Clinical Immunology, Spedali Civili, Brescia; Rheumatology Clinic. University of Udine, Udine; Division of Rheumatology, University of L'Aquila, L'Aquila; Rheumatology Unit, Sapienza University, Roma; Rheumatology Clinic. University of Udine, Udine, Italy

Background: Celiac disease (CD) is an inflammatory and immune-mediated gluten-dependent enteropathy occurring in genetically susceptible individuals. CD prevalence may vary, and CD can coexist with other autoimmune diseases, such as autoimmune thyroiditis, rheumatoid arthritis, systemic lupus erythematosus, type 1 diabetes mellitus, and inflammatory bowel disease. The aim of this study was to assess the prevalence of CD in a large cohort of patients with systemic lupus erythematosus (SLE), systemic sclerosis (SSc) and primary Sjögren's syndrome (pSS) with systemic lupus erythematosus-like features.

Methods: Data from consecutive 580 SLE, 354 SSc and 524 pSS patients were collected. Disease-specific features were recorded in patients with known CD. Remaining patients were tested for IgA transglutaminase (UE-IgT®) human IgA new, Eurospital S.p.A., Trieste), Anti-endomyosium (EMA) IgA and IgG were tested in IgA IgT positive and borderline patients. Esophagogastrroduodenoscopy with duodenal biopsy was proposed in IgA IgT+/EMA+, IgA IgT-/EMA+ and IgA IgT-/EMA patients.

Results: CD prevalence was 1.7% in SLE, 7% in pSS and 1.3% in SSc patients. Higher prevalence of elevated liver enzymes was detected in SLE-CD and of herpetiform dermatitis in SSc-CD patients in comparison to the other groups (p<0.05 for both). Interestingly, pSS-CD and SSC-CD patients were younger and had a lower age at diagnosis in comparison to pSS and SSC without CD (p<0.05 for all). Of interest, higher prevalence of CD was detected in SSc patients with diffuse form in comparison to limited SSc (86% vs 14%, p=0.002).

Conclusions: The presence of CD in systemic lupus erythematosus may be considered in younger patients with CD and lower age at diagnosis. The strong association of CD with the diffuse type of SSc is of note and suggests that different, still unexplored, pathogenetic mechanisms may characterize the two subsets of the disease.

THU0270 | HOMOCYSTEINE, ANTIPHOSPHOLIPID ANTIBODIES AND RISK OF VASCULAR EVENTS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

G. Stojan, W. Fu, M. Petri. Rheumatology, Johns Hopkins University, Baltimore, United States

Background: SLE patients have higher plasma total homocysteine concentrations compared to healthy controls. Hyperhomocysteinemia in SLE is a potentially modifiable, independent risk factor for stroke and thrombotic events, hypertension, and coronary artery calcification.

Objectives: We investigated the association of homocysteine levels with the presence of antiphospholipid antibodies as well as the potentially additive thrombotic risk in patients with antiphospholipid antibodies who have hyperhomocysteinemia.

Methods: To analyze the association between hyperhomocysteinemia and the prevalence of antiphospholip antibodies in SLE, 844 patients with homocysteine measurements were included in the analysis. 237 patients had at least one measurement over 15 umol/L. Patients were followed quarterly after cohort entry. The association of hyperhomocysteinemia with antiphospholip antibodies is detailed in Table 1.

Conclusions: SLE patients with elevated homocysteine were less likely (p<0.05) to have any of the antiphospholip antibodies. Among patients with SLE who have antiphospholip antibodies, elevated homocysteine is associated with a significantly higher prevalence of myocardial infarction and deep vein thrombosis (p<0.05).

Disclosure of Interest: None declared

To analyze the prevalence of vascular events among SLE patients with antiphospholip antibodies based on homocysteine levels, 571 patients with positive antiphospholip antibodies and at least one homocysteine measurement were included in the analysis. There were 166 patients with at least one homocysteine measurement over 15 umol/L. The lupus anticoagulant was assessed by dRVVT with mixing studies and measurement over 15 umol/L. Patients were followed quarterly after cohort entry.

THU0273 PREVALENCE AND FACTORS ASSOCIATED WITH FATIGUE IN FEMALE SLE PATIENTS AT THE HOSPITAL DEL MAR / PARC DE SALUT MAR

I Carrón-Barberá 1, T. Salaman-Monte, S. Castell, F. Castro, P. Corzo, F. Ojeda, L. Polino, E. Beltrán, C. Pérez, J. Carbonell. Rheumatology, Hospital del Mar, Barcelona, Spain

Background: In patients with SLE, subjective parameters are very important as they have a great impact on the quality of life. Among them, fatigue is the most prevalent symptom in SLE, as it occurs in more than 90% of patients (1). Likewise, subjective parameters are independently associated with increased cardiovascular risk and mortality (2). There is a great variability of fatigue measurement scales, some of them being validated for healthy women (3). The aim of this study was to determine the prevalence of fatigue and factors associated with fatigue in female SLE patients.

Methods: A cross-sectional study was carried out including female SLE patients aged 18 and older attending the Rheumatology policlinic of the Hospital del Mar. Patients were considered for inclusion if they had a diagnosis of SLE according to the American College of Rheumatology criteria and were aged 18 and older. Patients were excluded if they had a diagnosis of other chronic diseases or if they were pregnant. A total of 102 patients with SLE of different etiologies and stages were included. All of them were subjected to full medical history and physical examination. A validated questionnaire was used to assess fatigue severity (4). According to the score obtained, the patients were divided into two groups: low fatigue (score <7) or high fatigue (score ≥7) based on the study by York et al. (5).

Results: The study included 102 female patients with SLE. The mean age was 47.8 ± 12.6 years. The prevalence of fatigue was 61.8%, with 27.7% classified as high fatigue. A statistically significant correlation was found between fatigue and age (p=0.008) and BMI (p=0.024). No significant correlations were found with other demographic variables, disease activity, or serological markers. The most commonly used medications were prednisone (89.5%), hydroxychloroquine (84.3%), and methotrexate (73%). The most frequent comorbidities were hypertension (38.2%) and diabetes (22%).

Conclusions: The prevalence of fatigue in female SLE patients is high, and it is associated with age and BMI. Further studies are needed to explore the underlying mechanisms and develop effective strategies to manage fatigue in this population.

THU0274 FOOTPRINTS OF NEUTROPHIL EXTRACELLULAR TRAPS ARE ELEVATED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

I Jeremic 1, O. Djuric 2, B. Bonaci Nikolic 3, 1Institute of Rheumatology, Belgrade; 2Institute of Epidemiology; 3Institute of Allergy and Clinical Immunology, Belgrade, Serbia

Background: Impaired removal of apoptotic debris in patients with systemic lupus erythematosus-SLE has been long known as important factor that trigger autoimmune response. Neutrophil extracellular traps could be another source of extracellular damage in SLE patients. The aim of this study was to compare NETs markers (free DNA, IL-10, IL-18 and TNF-α) in non-obese vs obese SLE patients, as well as to assess their relationship with serological markers of SLE disease activity (C3 and C4 complement components). NETs could be another source of extracellular damage in SLE patients.

Methods: We analysed 111 sera obtained from 84 SEL patients (60 patients had 1 sample and 24 patients had 2 or 3 samples) and 50 healthy blood donors. Serum levels of myeloperoxidase, B-cell activating factor-BAFF, cell free DNA, complement components C3 and C4, antibody to dsDNA by CLIFT and ELISA assays, netotic activity and DNAse I were measured. The group of 35 patients was selected (11 with de novo disease) for which clinical data were recorded.

Results: SLE patients had significantly higher concentration of free DNA (1.69±0.23 vs 1.42±0.31 ng/mL, p=0.0003), messenger RNA of MPO (10.4±6.9 vs 5.8±5.7 mg/mL, p=0.05), anti-MPO antibodies (13.8±4.3 vs 0.9±0.3 U/mL, p=0.001) and myeloperoxidase activity (1607±2353 vs 560.3±1825.2 RU, p<0.05) in comparison to healthy controls. The ability of sera to degrade NETs was similar in both groups. Free DNA, MPO and anti-MPO levels as well myeloperoxidase activity showed significant correlation with anti-dsDNA antibodies measured by ELISA test. None of studied parameters showed correlation with C3 and C4 complement components, C3 and anti-dsDNA antibodies measured by indirect immune fluorescence were independent predictors of SLEDAI score in multivariate analysis, while BAFF and DNAse I were significant in univariate analysis. Free DNA was predictor of SLEDAI score higher than in univariate analysis.

Conclusions: Increased amount of NETs markers found in lupus sera confirms their role in SLE pathogenesis. Determination of NETs markers could be useful serological parameter to follow disease activity in SLE patients.

THU0277 REASONS FOR DEFICIENCY OF PHYSICAL INACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
L. Lipovsky, C. Baerwald, O. Seifert, Rheumatology Unit, Department of Internal Medicine, University Hospital Leipzig, Leipzig, Germany

Background: Systemic lupus erythematosus (SLE) is associated with musculoskeletal complaints, fatigue and reduced quality of life. Physical exercise can play a crucial role in the treatment of rheumatic diseases, optimizing both physical and mental health.

Objectives: To characterize physical activity (PA) and its impact on SLE patients. Methods: 65 SLE outpatients (92% female; age 44.2±12.5; 57.5% with SLEDAI score ≤5, 42.5% with SLEDAI score >5) were included in this study. The following questionnaires were utilized: painDETECT, visual analog scale for pain (VAS 0 - 100 mm), short-form health survey (SF - 36, quality of life), the FACT-P, the Rheumatoid Arthritis Health Assessment Questionnaire (RA-HAQ - D1), PA was assessed for every patient using the long form of International Physical Activity Questionnaire (IPAQ - L) and the Metabolic Equivalent of Task (MET) minutes per week (min/wk) (physiological measurement expressing calories of physical activities). The participants were classified in 3 groups according to the PA levels conforming to the guidelines of IPAQ. Physical inactivity was defined as fewer than 150 min/week spent in moderate or vigorous physical activities, respectively.

Results: 10.6% of SLE patients were physically inactive (525.2±277.3 MET-Min/wk), 31.8% had a moderate physical activity, and 57.6% were physically active. Physical inactivity was associated with higher fatigue (FACT-F, p<0.04) and lower "vitality" (SF-36, p<0.03) scores. Moreover, the subjective impact of fatigue on PA was significantly higher in physically inactive patients compared to physically active patients (the patient’s score: 7.75±1.25 vs. 5.5±0.94, p<0.04). Moderate and severe pain (more than 40 mm VAS) was also associated with physical inactivity (OR 12.38, 95% CI 1.69 to 144.3, p=0.0056). In contrast, HAQ-D1 was not related to levels of PA. Although physical inactivity correlated

Conclusions: Levels of IP-10, but not MCP-1, might be useful as a predictive biomarker for progression to SLE in patients with iSLE, although future prospective longitudinal analyses are needed to confirm this hypothesis.

Disclosure of Interest: None declared

THU0276 INTERFERON-RELATED CHEMOKINE IP-10 IS A POTENTIAL BIOMARKER IN INCOMPLETE SYSTEMIC LUPUS ERYTHEMATOSUS
W. Lambers 1, K. De Leeuw 1, M. Jonkman 2, H. Bootema 1, J. Westra 1.
1Rheumatology and Clinical Immunology; 2Dermatology, UMCG, Groningen, Netherlands

Background: Incomplete SLE (iSLE) is the designation of patients who display symptoms that are typical for SLE, but with insufficient criteria to fulfill the diagnosis. Unfortunately, predictive biomarkers for SLE development are lacking. Increased IFN-type I production is an important factor in the pathogenesis of SLE. Interferon-regulated chemokines therefore could possibly be useful as biomarkers for disease progression to SLE. Candidate biomarkers IFN-γ induced protein 10 (IP-10) and monocyte chemo attractant protein (MCP-1) have shown to be increased in SLE and to correlate with disease activity.

Objectives: To determine possible candidate biomarkers IFN-γ induced protein 10 (IP-10) and monocyte chemo attractant protein (MCP-1) in patients with iSLE.

Methods: Serum samples were collected of 30 iSLE patients, 29 SLE patients, and 17 ANA-negative patients with histologically proven cutaneous lupus erythematosus (ACLE). Outcomes were compared with 25 age- and gender-matched controls (CTL) and 31 rheumatoid arthritis (RA) patients as disease control group.

Results: IP-10 was significantly increased in SLE and RA patients compared with CTL and ANCLE. IP-10 levels were increased in 23% of iSLE patients. These patients had higher SLE disease activity index (SLEDAI) and more frequently decreased C3 level and joint involvement compared to those with normal IP-10 levels. Regarding MCP-1 levels, no significant differences were found between any of the groups and no correlations with clinical markers was found.

Conclusions: Levels of IP-10, but not MCP-1, might be useful as a predictive biomarker for progression to SLE in patients with iSLE, although future prospective longitudinal analyses are needed to confirm this hypothesis.

THU0275 IMPORTANCE OF SERUM TITERS OF ANTIBODIES AGAINST DOMAIN 1 OF B2 GLYCOPROTEIN 1
J.A. Gómez-Puerta 1,2, T. Urrego 2, A. Hernández 3, S. Ruiz Giraldo 3, C. Rua 4, J. Duque Botero 3, M. Velázquez 5, A.P. Cadavid 5, A.L. Vanegas-Garcia 1,6
1Rheumatology and Clinical Immunology; 2Dermatology, UMCG, Groningen, Netherlands

Objectives: Our aim was to evaluate the prevalence of Anti-D1 B2GPI antibodies in a cohort of Colombian patients with systemic lupus erythematosus (SLE) with and without thrombosis, primary APS and patients with previous history of recurrent miscarriages (RM) without APS criteria.

Methods: In this cross-sectional study we measured Anti-D1 B2GPI antibodies in a group of patients from Rheumatology Department, Coagulation clinic and Recurrent Pregnancy Loss Program at the Reproduction Group at Hospital San Vicente Fundación and Universidad de Antioquia, respectively, at Medellín, Colombia. Anti-D1 B2GPI antibodies were tested using a chemiluminescent immunoassay (QUANTA Flash B2GPI IgG, Inova Diagnostics). Mann-Whitney tests were used to compare data.

Results: One hundred and seventy seven (median age 33.5±12.1 years; 89% women) patients were included. One hundred thirty eight patients had SLE (78%), 27 primary APS (15%) and 13 RM (7%). Fifty five (31%) out of 177 patients had history of thrombosis and 41 (23%) of pregnancy losses. Overall, Anti-D1 B2GPI antibodies were positive (≥20 CU) in 35 (20%) of patients. Anti-D1 B2GPI were positive in 23%, 17% and 0% of patients with primary APS, SLE and RM, respectively. Overall, serum Anti-D1 B2GPI were significantly higher in patients with than without previous thrombosis (149.1±336.1 vs 16.3±61.8 CU, p<0.0001) and in patients (SLE or primary APS) with previous history of pregnancy losses (40.2±123.1 vs 21.0±74.5 CU, p=0.04). Anti-D1 B2GPI were significantly higher in patients with primary APS vs SLE with thrombosis, and in patients with SLE with thrombosis vs SLE without thrombosis (Figure). No clinical associations were found among Anti-D1 B2GPI antibodies and other APS features.

Conclusions: Serum titers of Anti-D1 B2GPI antibodies were more than 9 times and 2 times higher in patients with thrombosis and pregnancy losses, respectively. In addition, serum titers were significantly higher in patients with primary APS than in SLE patients with thrombosis. Whether Anti-D1- B2GPI antibodies titers are useful to differentiate patient with primary and secondary APS requires further analysis.

Acknowledgements: JA Gómez-Puerta was supported by Colciencias (conv. 656 de 2014). Anti-D1 B2GPI antibodies were provided by Inova, Werfen, Colombia

THU0274 COMBINED APPROACH TO EVALUATE INFLAMMATORY SYMPTOMS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
L. Lipovskiy, C. Baerwald, O. Seifert, Rheumatology Unit, Department of Internal Medicine, University Hospital Leipzig, Leipzig, Germany

Background: Systemic lupus erythematosus (SLE) is associated with musculoskeletal complaints, fatigue and reduced quality of life. Physical exercise can play a crucial role in the treatment of rheumatic diseases, optimizing both physical and mental health.

Objectives: To characterize physical activity (PA) and its impact on SLE patients. Methods: 65 SLE outpatients (92% female; age 44.2±12.5; 57.5% with SLEDAI score ≤5, 42.5% with SLEDAI score >5) were included in this study. The following questionnaires were utilized: painDETECT, visual analog scale for pain (VAS 0 - 100 mm), short-form health survey (SF - 36, quality of life), the FACT-P, the Rheumatoid Arthritis Health Assessment Questionnaire (RA-HAQ - D1), PA was assessed for every patient using the long form of International Physical Activity Questionnaire (IPAQ - L) and the Metabolic Equivalent of Task (MET) minutes per week (min/wk) (physiological measurement expressing calories of physical activities). The participants were classified in 3 groups according to the PA levels conforming to the guidelines of IPAQ. Physical inactivity was defined as fewer than 150 min/week spent in moderate or vigorous physical activities. Furthermore, the patient reasons “to be not physical active” and their opinion regarding the influence of PA on disease-related symptoms (on a scale of 0–10) were obtained.

Results: 10.6% of SLE patients were physically inactive (525.2±277.3 MET-Min/wk), 31.8% had a moderate physical activity, and 57.6% were physically active. Physical inactivity was associated with higher fatigue (FACT-F, p<0.04) and lower “vitality” (SF-36, p<0.03) scores. Moreover, the subjective impact of fatigue on PA was significantly higher in physically inactive patients compared to physically active patients (the patient’s score: 7.75±1.25 vs. 5.5±0.94, p<0.04). Moderate and severe pain (more than 40 mm VAS) was also associated with physical inactivity (OR 12.38, 95% CI 1.69 to 144.3, p=0.0056). In contrast, HAQ-D1 was not related to levels of PA. Although physical inactivity correlated
with a higher total disease activity score (SLEDAI ≥6) (OR 9.9, 95% CI 2.1 to 49.9, p=0.0068), neither of the single SLEDAI items and organ manifestations including musculoskeletal manifestations was associated with physical inactivity. Interestingly, the study could not detect any statistical difference in organ manifestations and SLEDAI scores between patients with moderate and high PA. Activating the patient's report, with the main SLE-related reasons "not to be physically active" for all three groups were "lupus flare" (35.6%), "fatigue" (26.9%) as well as "joint complaints" (15.7%). The main general barriers for PA were "comorbidity" (35.6%) and "lack of motivation" (26.9%). Furthermore, the subjective impact of "bad weather conditions" on physical activity was significantly greater in physically inactive patients compared with the two other groups (the patient's report: 6.5±2.3 vs. 3.4±0.7, p<0.03).

Conclusions: The main reason for the patients not to be physically active was fatigue and pain. The study also indicates that not only somatic symptoms could decrease the levels of PA in SLE patients. Further research on psychological factors is needed. The study underlines the need for management strategies that specifically target physical activity as a part of a general SLE management program.

THU0278 COMPARISON OF THE 2016 ACR/EULAR AND THE 2002 AECG CLASSIFICATION CRITERIA IN A COHORT OF PATIENTS WITH SUSPECTED PRIMARY SJÖGREN’S SYNDROME

M. Le Goff¹, D. Concore², S. Jousse-Joulin³, D. Guellec², S. Costa², T. Manmadour⁴, R. Le Berre⁵, S. Genestet⁵, B. Cocherener⁶, S. Boisrame-Gastrin², Y. Renaudineau², J.-O. Pers⁷, A. Sarauz⁸, V. Devauchelle-Pensec⁹. 1Rheumatology, CHRU Rennes, Rennes, France

Background: New consensual classification criteria for primary Sjögren’s syndrome (pSS) have been recently developed and endorsed by ACR and EULAR. They differ substantially from previously used AECG criteria in that they consider systemic involvement (defined as ESSDAI score ≥1) as well as sicca symptoms as entry criteria before applying a weighted score. Evaluation of the concordance and differences between the two sets of criteria in independent patient populations is mandatory to establish how future clinical studies using the new criteria will be comparable to previously published studies. Major salivary gland ultrasonography (SGUS) has demonstrated promising diagnostic performance in previous studies, but was not included in these new classification criteria.

Methods: This cross-sectional study was conducted in the monocentric Brittany cohort (DiAPSS cohort) of patients with suspected pSS (sicca symptoms, parotidomegaly or extraglandular manifestations suggestive of pSS). All patients had standardized clinical examination, basic biology, immunological tests and minor salivary gland biopsy. SGUS in mode B was performed by the same operator. The study underlines the need for management strategies that specifically target physical activity as a part of a general SLE management program.

THU0279 ARE THE PULMONARY INVOLVEMENT IN SYSTEMIC LUPUS EURHEMATOSIS ASSOCIATED WITH A HIGHER PREVALENCE OF COMORBIDITIES?

M. Cebanu¹, V. Salaru², V. Sadovici³, M. Pasai³, N. Loghin-Oprea³, M. Mazaru², L. Mazaru⁴, G. Cobanu¹. 1Emergency Medicine, 2Family Medicine, 3Rheumatology, 4Cardiology, State University of Medicine and Pharmacy "Nicolei Testemitanu", Chisinau, Moldova, Republic of Moldova

Background: Patients with systemic lupus erythematosus have a very high burden of comorbidities. Identification and management of these comorbidities are critical for optimal medical care to this population.

Objectives: To assess the prevalence of comorbidities in SLE patients with pulmonary involvement.

Methods: In a cross-sectional study, patients who fulfilled the SLICC (2012) classification criteria for SLE were recruited from the Rheumatology Department. Data collection included demographics, disease duration, physician-rated indices of disease activity by (SLAM), (by SLICC/ACR DI) and Charlson comorbidity Index. The pulmonary involvement was assessed by chest X-ray, ECG, Doppler and pulmonary functional tests.

Results: The study included 106 patients (97 women, 9 males) with a mean age (±SD) of 41.7±12.6 yrs, mean disease duration of 90.3±87.3 months. The disease activity by SLAM was 11.5±17 points and mean SLICC/ACR DI 1.9±2.4 points (66% of patients had at least 1 point). Pulmonary assessment revealed that 45 (42.5%) patients had different types of pulmonary involvement due to lupus: pleuritis in 21 patients, pneumonia in 1 patient, pulmonary embolism in 4 patients, interstitial lung disease – 15, shrinking lung syndrome – 1 and pulmonary arterial hypertension – 9 patients. The most frequent comorbidities in study group were: arterial hypertension - in 57 (53.7%) cases, from which 33 (57.9%) patients had pulmonary involvement and 24 (42.1%) without, obesity (BMI ≥30 kg/m²) had 29 (27.4%) patients, from which 17 (58.6%) with lung involvement and 12 (41.4%) without, anemia (Hb<110 g/l) had 24 (22.6%) patients, from them 14 (58.3%) with lung disease and 10 (41.7%) patients - without, heart failure (I-II NYHA) had 23 (21.7%) patients, from them 20 (86.9%) were with lung involvement, thyroiditis had 22 (20.8%) and 15 (88.2%) of them were with our pulmonary involvement, diabetes mellitus type II had only 6 (5.7%) patients and half of them had lung disease. Assessing the impact of associated diseases through Charlson comorbidity index, we found that the score for patients diagnosed with damage to the respiratory system was twice as big vs. patients without respiratory impairment from SLE (6.3±2.4 vs. 3.4±1.4 points). Also, Charlson comorbidity score >1 was identified as a risk factor for lung involvement (OR 5.294, 95% CI 2.12-12.91, p<0.01). Evaluation of disease activity by SLAM showed that patients with lung involvement have a higher disease activity vs. patients without (13.9±6.0 vs. 8.9±4.0, p<0.05). On the other hand, association of comorbidities (Charlson comorbidity score >1) was identified as a risk factor for lung lesions.

THU0280 COMPARISON OF CLASSIFICATION CRITERIA FOR SJÖGREN’S SYNDROME FROM 2002 AND 2016 IN AN INCIDENT COHORT DIAGNOSED 2007 TO 2011 FROM STOCKHOLM COUNTY SWEDEN

M. Kvarnström, M. Wahren-Herlenius. Dept. of Medicine, Unit of Experimental Rheumatology, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

Background: The current American-European Consensus Criteria (AECG) from 2002 has been the most widely used and applied all over the world. New classification criteria for Sjögren’s syndrome was published in 2016, designed in collaboration between ACR and EULAR. They are made up of a scoring system in which 4 points are required for classification. The weight score is as follows:• Labial salivary gland biopsy with focal lymphocytic sialadenitis and focus score of >1 focii/4 mm² – 3
• Anti-SSA/Ro positive – 3
• Ocular Staining Score >5 (or van Buijsterveld score >4) in at least 1 eye – 1
• Schirmer’s test >5 mm/5 minutes in at least 1 eye – 1
• Unstimulated whole saliva rate <0.1 ml/min – 1

Objectives: Comparison of classification criteria for Sjögren’s syndrome from 2002 and 2016 in a 5 year cohort of incident patients diagnosed 2007 to 2011 from Karolinska University Hospital, Stockholm County, Sweden.

We wanted to examine the consistency between the different classification criteria.

Methods: We compared all patients diagnosed with primary Sjögren’s syndrome during the years 2007 to 2011 at the Dep. of Rheumatology at Karolinska University Hospital in Stockholm Sweden. Data on the item Ocular Staining Score >5 was not available since it is not included in AECG. The cohort consisted of 199 patients all fulfilling the 2002 AECG. Another eight patients did
not fulfill the criteria but were regarded as possible Sjögren’s syndrome under development by the rheumatologist who investigated them.

Results: 196 of the 199 pSS patients also fulfilled the new criteria from 2016. The three patients who did not only had SSB autoantibodies and no positive biopsy. Of eight patients with suspicion of Sjögren’s syndrome under development, three fulfilled the new criteria.

Conclusions: The classification criteria for Sjögren’s syndrome from 2002 and 2016 are consistent. This study indicates a possibility that the new criteria may be more sensitive early in the disease development, as long as the classification is not based on autoantibody positivity against SSB.

THU0281 LONG-TERM PROGNOSIS AND PREDICTING FACTORS OF CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A MULTI-CENTER COHORT STUDY FROM CSTAR REGISTRY

M. Li1, Z. Wang1, Y. Wang2, X. Zeng1 on behalf of CSTAR. 1Peking Union Medical College Hospital; 2Chinese Academy of Medical Science, Beijing, China

Objectives: To investigate the long-term outcomes, both mortality and damage, and related prognostic factors of patients with systemic lupus erythematosus (SLE) in the CSTAR (Chinese SLE Treatment and Research group) registry cohort.

Methods: All of the patients were enrolled from April 2009 to February 2010. They were followed up at clinic and were telephone interviewed at the endpoint. Demographic data, clinical manifestations, activity (SLEDAI-2K), damage scores (SLICC/Damage Index), and medications were collected. Data were censored at the last clinic visit or telephone interview. Survival rates were studied by Kaplan-Meier method, and COX proportional hazard model was adopted to perform the analysis of predicting factors for mortality.

Results: A total of 2104 patients were recruited at baseline, and 1494 patients were successfully followed up. The cumulative 1, 3 and 5-year survival rates from diagnosis were 99.0%, 98.1% and 97.1%. 78 patients died during follow-up, and the main death causes were infection (34.6%), active disease (26.9%), cardiovascular and cerebrovascular events (6.41%) and malignancy (5.13%). At entry, 247 patients presented with irreversible organ damage and it increased to 398 patients at the endpoint. The major accumulated organ damages were cardiovascular and cerebrovascular events (6.41%) and malignancy (5.13%). COX regression showed that male, late onset age (≥50y), onset to diagnosis time ≥1 year, previous organ damage, renal involvement, pulmonary arterial hypertension, nephritic damage and the number of involved organ systems ≥3 predict for higher mortality.

THU0282 HOMOCYSTEINE: ANY ROLE IN PERIPHERAL VASCULAR DISEASE IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS?

N. Mohanna1, M. Tayel2, M.H. Megallia2. 1Internal Medicine, Rheumatology Unit, Alexandria University Hospitals, Alexandria University; 2Internal Medicine, Alexandria University, Alexandria, Egypt

Background: Many are the independent risk factors for premature atherosclerosis in general & peripheral vascular disease (PVD) in particular in SLE patients. Plasma homocysteine (Hcy) is known risk factor for atherosclerosis. Atherosclerosis can lead to many cardiovascular diseases as myocardial infarction, stroke and claudication.

Objectives: To compare the occurrence PVD of the lower extremity of SLE patients (pts) with age and sex matched controls and evaluate the role of Hcy level in its occurrence.

Methods: Body mass index (BMI), blood pressure, lipid profile, titers of autoantibodies [ANA, anticardiolipin antibodies ACL (IgM, IgG)], C3, C4, plasma Hcy level were assessed, SLEDAI and (SLICC/ACRDI) were calculated. PVD evaluation was done by measuring Ankle Brachial Index (ABI) with values ≤0.9 considered diagnostic of PVD; in 60 SLE pts and 30 age-matched controls. Patients with previous hypertension, diabetes, other collagenic diseases & smokers were excluded.

Results: Eighty-eight percent of the pts were women. The mean age (SD) was 30.40 (11.46) years & mean disease duration 3.61 (4.92) years. 50 pts were asymptomatic, 5 had mild & 5 had moderate claudications. SLE pts had significant higher total cholesterol (TC), LDL than controls 224.1±57.8 vs 181.1±41.1 mg/dl & 162.7±57.0 vs 119.5±13.4 (<0.001) respectively, higher HCY 11.6±2.1 & 6.4±1.0 μmol/L (<0.001) & lower HDL 47.2±13.1 & 52.6±3.7 mg/dl (<0.004). Low ABI was found in 30% of SLE pts but none of the controls (p<0.001) & was correlated with higher HCY level (p<0.005), TC & LDL (p<0.001 & <0.001), but not TG (p<0.748) or asymptomatic pts, presence of mild or moderate claudications (p=0.468, 1.000, 0.154), still its value negatively correlated with lupus anticoagulant (LA) (p<0.002), ACL IgM (p<0.001), the presence of lupus nephritis (LN) (p<0.001) & SLICC/ACRDI (p=0.017) but not with disease duration (dd) (p=0.535), Anti ds DNA (p=0.364), ACL IgG (p=0.9840), C4 (p=0.168) or SLEDAI (p=0.074). No correlation was found between HCY level and pts’ age, dd, age at diagnosis, BMI, Anti ds DNA, ACL IgG, C4 & SLEDAI (p=0.521, 0.946, 0.502, 0.346, 0.335, 0.325, 0.787). A positive correlation was found between HCY level and LA, ACL IgM, TC, LDL, The presence of LN & SLICC/ACRDI with a p value of 0.025*, <0.001*, <0.001*, 0.003*, 0.001* & negative one with HDL p=0.023*

Conclusions: 83.3% of SLE pts were asymptomatic or had atypical symptoms of PVD, still 30% of the patients had low ABI. ABI can be a more reliable, non-invasive test to assess PVD than the conventional methods of pulse palpation or history of Claudication in SLE pts. Both traditional & nontraditional risk factors of atherosclerosis are important but HCY can play a role, among other factors, as independent risk factor of PVD in SLE patients.

Resilience and Associated Factors Among Women with Systemic Lupus Erythematosus

P. Minguela-Realpozo1, M. García-Carrasco2,3, J. León-Vázquez4, M.F. Balcazar-Vargas4, E.A. Jiménez-Herrera4, I. Etchegary-Morales4, C. Mendoza Pinto5,6, R. Rheumatology, Hospital de Especialidades Centro Médico Nacional “La Raza” IMSS, Cd. México; Immunology and Rheumatology, Medicine School, BUAP; Systemic Autoimmune Diseases Research Unit, Hgr 36-Cibior, IMSS; Systemic Autoimmune Diseases Research Unit, Hgr 36-Cibior, IMSS, Puebla, México

Abstract: Resilience is the human capacity to respond positively to adverse situations, enabling individuals to achieve, maintain, or recover health after devastating illness, losses, or other stressful situations. Resilience may be an important factor in health promotion.

Objective: The aim of this study was to evaluate resilience and possible associated factors in patients with systemic lupus erythematosus (SLE).

Methods: In a cross-sectional study, 123 SLE women and 133 age-matched controls were evaluated using the Spanish version of Wagnild and Young’s Resilience Scale (WYRS, 1993). SLE patients underwent a structured interview to collect sociodemographic data, including socioeconomic status measured by the Graffar method. The Center for Epidemiologic Studies Depression Scale (CES-D) was used to measure depressive symptoms.

Results: The median age and duration of disease of SLE women was 45 (IQR: 34–54) years and 11 (IQR: 8–15) years, respectively. Thirty-three percent had depressive symptoms (CESD > 16). Resilience scores did not differ between patients and controls (median 80 IQR: 75–87 vs.80 IQR: 74–85p<0.38). However, patients with SLE had a higher personal competence factor than controls. Personal competence factor correlated negatively with age and socioeconomic status (R= -0.220, p< 0.05 and R= -0.357, p<0.001) and positively with educational level (R=0.324, p<0.001). Less resilience (lower WYRS scores) correlated with depressed mood (higher CESD scores) (R= -0.537, p<0.001).

Conclusion: Resilience in patients with SLE did not differ from that of controls. Age, socioeconomic status and depressive symptoms correlated with low resilience. Educational level correlated with higher resilience.

Use of Contraceptive Methods in a Single Center Cohort of Systemic Lupus Erythematosus from Argentina

R.A. Gomez, M. Paniego, M. García Carrasco, D. Dubinsky, G. Nasswetter.

Rheumatology, Hospital de Clínicas Jose de San Martin, Ciudad Autónoma de Buenos Aires, Argentina

Background: Systemic Lupus Erythematosus (SLE) may associate with flares, an unfavorable course and the need of teratogenic treatment during pregnancy. Not every contraceptive method (CM) may be used in this patients. There are guidelines for their use according to existing morbidity and SLE activity1. Objectives: Describe the use of CM in a cohort of outpatients with SLE. Methods: Descriptive, observational, cross-sectional study. Patients ≥16 years old with SLE (SLICC 2012) and ≥1 visit during the last year of our database were included. Those with menopause were excluded. We analyzed demographic data; disease duration; antiphospholipid antibodies (aPL) and antiphospholipid syndrome (APS) (Sapporo 2006); socioeconomic status (Graffar scale); disease activity (SELENA-SLEDAI) and accrual damage (SLICC); use of teratogens; Methotrexate (MTX), Mycophenolate (Myc), Cyclophosphamide (CYC), biological drugs (BD), self-reported sexual activity (active/non active) and CM: intrauterine device (IUD), condom (CDm) and hormonal contraceptive pill (CP).

Results: 132/219 were included. Female 91.6%; 30.1 (16–49) years, disease duration: 38.5 (1–324) months; SELENA-SLEDAI 3.5 (0–29); SLICC 0.5 (0–5). Sexual status and use of CM: were available for 120 patients. Sexually active (SA) 73%, female 77%. CM in SA patients: 74%; 5% CP 77% Cdm and 18% IUD. CM in female patients stratified by SLEDAI ≤3 (n=62); 76% SA, 77% of them used CM (3% CP, 83% Cdm, 14% IUD); SLEDAI 3–12 (n=42): 81% SA, 76% used CM (8% CP, 69% Cdm, 23% IUD); SLEDAI >12 (n=60): 60% SA, 67% used CM (100% Cdm). CM in female patients using teratogenic drugs: MTX (n=8): 100% SA, 75% of them used CM (17% CP, 66% Cdm, 17% IUD); MCV (n=20): 80% SA, 88% used CM (71% Cdm, 29% IUD); CYC (n=3): 33% SA, 100% used CM (100% Cdm); Belimumab (n=1): 100% SA, 100% surgical CM (tubectomy).

aPL was evaluated in 96/132 patients. 17/96 had positive aPL and 5/17 fulfilled APS criteria. 2/17 patients had no CM data available, none with APS. 9/17 patients with aPL were female, 55% SA and all of them used Cdm. 3/5 patients with APS were female, all SA, 66% used Cdm.

Conclusions: Condom was the most reported CM. Use of CM was more frequent in the upper social status (GF I-III) respect to the lower (GF IV-V). The proportion of sexually active female patients was similar in those using teratogenic drugs compared with who had not used them. The self-reported sexual status was similar despite of SLEDAI stratification, being similar in patients with low or high disease activity.

We deem necessary education, counseling and evaluation of use of the CM in every visit of patients with SLE.

**RECURRENCE OF ARTERIAL AND VENOUS THROMBOSIS IN PRIMARY ANTIPHOSPHOLIPID SYNDROME**

G. Balbi, F. Signorelli, R.A. Levy, Rheumatology, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

**Background:** Antiphospholipid syndrome (APS) is the thrombophilia associated with the highest risk of recurrence of both arterial and venous thromboses. (1.2)

In addition to the standard of care (lifelong oral anticoagulation), identification of other risk factors is important to provide better care and to reduce the incidence of rethrombosis.

**Objectives:** To investigate the risk factors associated with recurrence of arterial and venous thromboses in primary APS patients.

**Methods:** A cross-sectional study was performed in a group of 80 outpatients who fulfilled APS classification criteria (Sydney). The patients were regularly seen in our department, and clinical and serological features were collected during visits and by chart review. They were classified as recurrent or not, and these groups were compared. Recurrence was defined as the presence of 2 or more thrombotic events during lifetime. Patients with 1 thrombotic event were classified as "no recurrent". No history of thrombosis was the only exclusion criterion.

**Results:** Of 80 APS patients, thirty-five had arterial thrombosis and 54 had venous thrombosis. Of them, thirty-six had recurrent thromboses (11 arterial and 25 venous).

Demographic and clinical characteristics of the arterial group are shown in Table 1. In a bivariate analysis, recurrent arterial thromboses were associated with hypertension (p=0.016) and positivity to lupus anticoagulant (LA; p=0.033), and recurrent venous thrombosis correlated to obesity (BMI; ≥30 kg/m²; p=0.003). In a multivariate regression analysis, the model of recurrent arterial thromboses was adjusted to age, sex, and variables with p<0.10 in the bivariate analysis (age, hypertension, dyslipidemia, and positivity to lupus anticoagulant). Hypertension (OR 9.02; 95% CI: 1.05–77.5, p=0.045) and age (OR 1.16; 95% CI: 1.01–1.33; p=0.035) increased the risk of relapse of arterial thrombosis.

**Conclusions:**

**CENTRAL ARTERY STIFFNESS MEASURED BY THE AUGMENTATION INDEX IS ENHANCED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND IS DETERMINED BY THE LEVELS OF IGm-β2-GLYCOPROTEIN AND THE SMALL-DENSE HDL PARTICLES**

S. Parra 1,2, N. Amigo 3, M. Heras 1, D. Barreche 1, M. Benavent 4, A. Navarro 4, E. Garces 1, A. Castro 1,2, 3Autoimmune diseases unit, Sant Joan’s university hospital.

**Background:** Patients affected by Systemic Lupus Erythematosus (SLE) show an increase in cardiovascular mortality and morbidity. The accelerated atherosclerosis observed in patients with SLE cannot be entirely explained by the traditional cardiovascular risk factors. Patients with SLE show increased subclinical atherosclerosis determined by an increased carotid arterial thickness, endothelial dysfunction and central arterial stiffness. Analysis of lipoproteins by magnetic nuclear resonance (MNR) provide information of those lipoproteins associated with subclinical atherosclerosis in SLE.

**Objectives:** To investigate the metabolic and immunological factors associated with the presence of central arterial stiffness determined by the Augmentation Index (AIx) as well as the detailed analysis of the lipid profile performed by magnetic nuclear resonance (MNR).

**Methods:** Descriptive cross-sectional study of 69 women with SLE compared with a control group of 34 age matched healthy women. On the same day of the study, blood extraction, physical examination and augmentation index (AIx) obtained by Peripheral Arterial Tonometry were performed. The carotid intima-media thickness (IMTc) was also performed on the same day of the study to correlate the arterial stiffness with another subclinical atherosclerosis marker. Analysis of lipoprotein populations by NMR (Liposacle,Bioster Teslab) were performed.

**Results:** Patients with SLE showed significant increased arterial stiffness respect the control group (20.30 (21.54%) vs 10.84 (11.51%), p=0.0021) The values of AIx were well correlated with Framingham risk score (r=0.486, P<0.001) as well as the IMTc (r=0.456, P<0.001). The classic cardiovascular risk factors associated with the AIx were the SBP levels (r=0.456, P<0.001) and age (r=0.456, P<0.001). Patients under antimalarial drugs showed significant decreased AIx (11.74 (11.28) vs 24.97 (20.7), P=0.024). Immunological variables associated with AIx included levels of C4 (r=0.259; P=0.046) and positivity to lupus anticoagulant (LA; r=0.284, P=0.284). As for the lipoprotein populations, AI values correlated with ApoB plasma levels, remnant particles, the number of large, medium and small VLDL particles, the number of small LDL particles and the number of small-dense HDL. In the multivariate analysis we found that age (r=0.377 (0.117–0.636), P=0.005) and IgM-β2-GLP levels (r=0.303 (0.026–0.580), P=0.033) and the small-dense HDL particles (r=1.483 (0.605–3.232), P=0.001).

**Conclusions:** SLE patients showed increased central arterial stiffness respect healthy population. Patients treated with antimalarial drugs show lower arterial stiffness. In multivariate analyses variables that predicted levels of AIx were age, levels of IgM-β2-glycoprotein and the number of small-dense HDL particles.

**COMPARISON OF THE CLINICAL, SEROLOGICAL, AND PROGNOSTIC DIFFERENCES AMONG JUVENILE-, ADULT-, AND LATE-ONSET LUPUS NEPHRITIS IN KOREAN PATIENTS: A CASE-CONTROL STUDY**

S.-S. Lee 1, J.-H. Kang, J.-E. Kim, K.-E. Lee, D.-J. Park, Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of

**Objectives:** SLE patients present with different clinical and serological manifestations according to the age at disease onset. However, it is not known whether there is an association between disease onset age and the clinical presentation of lupus nephritis (LN). Therefore, we investigated whether LN patients could be distinguished based on the time of disease onset and, if so, whether the groups differ in their clinical, laboratory features and long-term prognosis in ethnically homogeneous Korean patients.

**Methods:** We enrolled 117 SLE patients with available clinical data at the time of renal biopsy for LN from the lupus cohort at Chonnam National University Hospital. We divided the LN patients according to the age at LN diagnosis into three groups [juvenile-onset LN (JLN), diagnosed at ≤18 years; adult-onset LN (ALN), diagnosed at 18–50 years; and late-onset LN (LLN), diagnosed at >50 years] and compared the baseline demographic, clinical, histological, and relevant laboratory findings. We also compared the treatment and long-term prognosis of LN according to those three groups.

**Results:** Of the 114 LN patients, 20 (17.5%), 84 (71.8%), and 13 (11.1%) had JLN, ALN, and LLN, respectively. LLN patients were less educated than ALN and JLN patients (p=0.001). Hypertension and diabetes mellitus at the onset of LN were more common in JLN patients compared to the age at LN diagnosis into three groups [juvenile-onset LN (JLN), diagnosed at ≤18 years; adult-onset LN (ALN), diagnosed at 18–50 years; and late-onset LN (LLN), diagnosed at >50 years] and compared the baseline demographic, clinical, histological, and relevant laboratory findings. We also compared the treatment and long-term prognosis of LN according to those three groups.

**Conclusions:** The age at disease onset of LN was more common in LLN patients than in JLN and ALN patients (p=0.001). Hypertension and diabetes mellitus at the onset of LN were more common in JLN patients compared to the age at LN diagnosis into three groups [juvenile-onset LN (JLN), diagnosed at ≤18 years; adult-onset LN (ALN), diagnosed at 18–50 years; and late-onset LN (LLN), diagnosed at >50 years] and compared the baseline demographic, clinical, histological, and relevant laboratory findings. We also compared the treatment and long-term prognosis of LN according to those three groups.

THU0289  B-CELL ACTivating FACtor genE EXPRESSION IN URINARY SAMPLE AND REnal BIOPSY FOR MONITORING DISEASE ACTIVITY IN LUPUS NEPHRITIS

S. Retamozo 1,2, L. Mas 3, M.J. Haye Salinas 4, V. Sauir 4, F. Caeiro 4, A. Diller 5, J. De La Fuente 4, M. Angelina 7, N.R. Benzaquen 4, J.P. Pirola 4, A. Alvarillos 4, T. Alvarellos 3, 1 Rheumatology, Hospital Privado Universitario de Córdoba; 2 INICSA, CONICET; 3 Molecular Biology; 4 Rheumatology; 5 Pathology; 6 Nephrology, Hospital Privado Universitario de Córdoba; 7 Nephrology, Hospital Raul A. Ferryera, Cordoba, Argentina

Objectives: To evaluate BLyS as biomarker in disease activity in urinary sample and renal biopsy from patients with LN.

Methods: Retrospective study. Between June 2009 and October 2013, 32 patients with SLE and LN fulfilling SLE classification criteria of ACR 1997 were included. The renal biopsies were evaluated according to the ISN/RPS classification system. The gene expression levels of BLyS were quantified using Quantitative Real Time PCR (QPCR). The relative quantification method was used for analysis, where Ct was normalized to an endogenous control j2Microglobulin (j2M) (ΔCt BLyS).

The data expressed as ΔCt was inversely proportional to gene expression level. The value of BLyS is expressed as median (M) and interquartile range (IQR) for filing a non-normal distribution.

Results: 26 (81.3%) patients were female with a mean age at diagnosis of 26.9±13 years and 31.9±29 years at the time of biopsy. The SLEDAI at the time of biopsy was 10.5 (IQR 0–15.7) and SLICC ≤ 1 in 32 (32.5%), hypertensive nephropathy in 13/31 (41.9%) and positive DNA in 1/29 (37.9%) patients. Biopsies from patients with proteinuria ≥0.5 and renal failure (RF) (n=23, 71.9%), proteinuria isolated (n=14, 43.8%), LN remission. The value of the BLyS gene expression in renal biopsy was 8.09 (IQR 7.37–9.16) and BLyS in urinary sample was 0.65 (IQR 0.62–7.76).

Conclusions: BLyS detection in urinary samples could be a potential biomarker for predicting lupus nephritis activity. Our data confirm that the BLyS as urinary biomarker is present in patients with active renal disease especially in patients with proliferative glomerulonephritis.

THU0290  CLINICAL BACKGROUND FACTORS RELATED TO SILENT OSTEONECROSIS OF THE FEMORAL HEAD UPON INITIATION OF STEROID THERAPY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

T. Kuroda 1, N. Tanabe 2, H. Sato 1, T. Nakatsu 1, Y. Wada 1, M. Nakano 2, T. Nanta 1, 1 Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences; 2 Department of Health and Nutrition, Faculty of Human Life Studies, University of Niigata Prefecture; 3 Department of Medical Technology, School of Health Sciences, Faculty of Medicine, Niigata University, Niigata, Japan

Background: Osteonecrosis of the femoral head (ONF) occurs frequently (3–40%) in patients who receive corticosteroid therapy for SLE. M. H. Houman. Systemic lupus erythematosus (SLE) is more frequent in women and seems to be more severe in men.

Objectives: The aim was to study gender influence on clinical, biological and immunological features of SLE.

Methods: It’s a retrospective study conducted in an internal medicine department. Patients with systemic lupus erythematosus (ACR revised criteria) were included. Data were recorded and compared using SPSS. Variables with a p<0.05 were considered to be statistically significant.

Results: A total of 246 SLE patients were included: 224 female and 19 male (sex ratio F:M was 11.78). Mean ages at disease onset and at SLE diagnosis were comparable for men and women respectively 35.6±14.31 vs 32.7±13.36 years and 35±14.3 vs 34.5±13.6 years.

SLE diagnosis was made earlier in men with an average delay (from first sign of the disease to diagnosis) of 6.1 months vs 21.4 months (p<0.02). Clinically, photosensitivity was significantly more frequent in women (81.4% vs 58.8%; p=0.03). Women complained from alopecia more frequently than men but the difference was not statistically significant (35.1% vs 14.3%; p=0.09). Arthritis were two times more frequent in women (50.7% vs 25%; p=0.04). Lupus nephritis as well as lupus pancreatitis were significantly more frequent in men, respectively 66.7% vs 41.6% (p=0.039) and 11.1% vs 1.4% (p=0.047). There were no differences regarding to gender in neurological involvement and seritis. No significant differences were observed between men and women concerning hematological disorders. Anti-DNA, anti-Sm, anti-RNP, anti-SSA, anti-SSB, anti-cardiolipin and anti-B2G1P1 antibodies frequencies were similar in both genders.

Conclusions: SLE diagnosis was made earlier in men than women, this could be explained by more severe disease in men [1]. However this hypothesis has been highly controversial [2]. Cutaneous and joint manifestations seem to be more frequent in women whereas serious manifestations like lupus nephritis and neurological involvements were more frequent in men [3–4]. In our study, only lupus nephritis and pancreatitis were more frequent in men.

THU0291  GENDER INFLUENCE ON CLINICAL, BIOLOGICAL AND IMMUNOLOGICAL ASPECTS OF SYSTEMIC LUPUS ERYTHEMATOSUS

T. Ben Salem, M. Tougourti, I. Naceur, I. Ben Ghorbel, M. Lamloum, M.H. Houman. Internal Medicine, Rabta university hospital, Tunis, Tunisia

Background: Systemic lupus erythematosus (SLE) is more frequent in women but seems to be more severe in men.

Objectives: The aim was to study gender influence on clinical, biological and immunological features of SLE.

Methods: It’s a retrospective study conducted in an internal medicine department. Patients with systemic lupus erythematosus (ACR revised criteria) were included. Data were recorded and compared using SPSS. Variables with a p<0.05 were considered to be statistically significant.

Results: A total of 246 SLE patients were included: 224 female and 19 male (sex ratio F:M was 11.78). Mean ages at disease onset and at SLE diagnosis were comparable for men and women respectively 35.6±14.31 vs 32.7±13.36 years and 35±14.3 vs 34.5±13.6 years.

SLE diagnosis was made earlier in men with an average delay (from first sign of the disease to diagnosis) of 6.1 months vs 21.4 months (p<0.02). Clinically, photosensitivity was significantly more frequent in women (81.4% vs 58.8%; p=0.03). Women complained from alopecia more frequently than men but the difference was not statistically significant (35.1% vs 14.3%; p=0.09). Arthritis were two times more frequent in women (50.7% vs 25%; p=0.04). Lupus nephritis as well as lupus pancreatitis were significantly more frequent in men, respectively 66.7% vs 41.6% (p=0.039) and 11.1% vs 1.4% (p=0.047). There were no differences regarding to gender in neurological involvement and seritis. No significant differences were observed between men and women concerning hematological disorders. Anti-DNA, anti-Sm, anti-RNP, anti-SSA, anti-SSB, anti-cardiolipin and anti-B2G1P1 antibodies frequencies were similar in both genders.

Conclusions: SLE diagnosis was made earlier in men than women, this could be explained by more severe disease in men [1]. However this hypothesis has been highly controversial [2]. Cutaneous and joint manifestations seem to be more frequent in women whereas serious manifestations like lupus nephritis and neurological involvements were more frequent in men [3–4]. In our study, only lupus nephritis and pancreatitis were more frequent in men.

V. Milic, G. Radunovic, N. Damjanov. Institute of Rheumatology, Belgrade, Serbia

Objectives: To analyze ultrasoundographic (US) changes of salivary glands (SG) in patients with primary Sjogren’s syndrome (pSS) and assessment of their accuracy for diagnosis pSS.

Methods: This study included 205 pSS patients (mean age 53.9±11.5, disease duration 5.6 years) and 87 healthy controls (mean age 52.3±14.7). All pSS patients fulfilled the AECG diagnostic criteria. The disease activity was measured by EULAR SS disease activity index (ESSDAI). Parotid and submandibular glands on both sides were assessed for size, parenchymal echogenicity and inhomogeneity, posterior glandular border and presence of intraglandular lymph nodes. Intensity of echogenicity of the salivary glands was graded according to the De Vita scoring system [0] homogenous glands; [1] mild inhomogeneous - isolated hypoechoic areas; [2] evident inhomogeneous - scattered hypoechoic areas, and/or multiple punctate or linear densities; [3] grossly inhomogeneous – large hypoechoic areas, and/or to linear densities, and/or for multiple cysts. The global SGUS score (0–6) was the sum of the scores of each pair of salivary glands. Statistical analysis was performed by SPSS v16. Data were compared using Hest, χ² test and Mann-Whitney U test. The optimal cut-off value for SGUS score was calculated as the area under the receiver operating characteristic curve (AUC-ROC).

Results: Xerorhaphalitis and xerostomia were presented in 185/205 (90.2%) and 186/205 (91.2%), respectively. According to ESSDAI, the majority of pSS patients 88/205 (43%) had moderate disease activity. Seventy-eight percent of pSS patients were anti-SSA antibody positive, 44% anti-SSB/La antibody positive. Biopsy of LSG was positive in 140/172 (81.4%) pSS patients. US abnormalities were established in 197 (96%) pSS patients and in 16 (18%) controls (p<0.0001). Pathological sizes of salivary glands were more frequently in pSS patients than controls, 111 (54.2%) vs. 3 (3.4%) patients, respectively (p<0.0001). The echogenicity of the salivary glands was pathological changes in 142 (69.3%) pSS patients and in only 5 (5.7%) control group (p<0.0001). The pathological glandular border was frequently in pSS patients than control group, 48 (23.4%) vs. 2 (2.3%), p<0.0001. No differences were detected between the two groups of patients for enlarged intraglandular lymph nodes. Most of pSS patients had pathological inhomogeneity, 197/205 (96.1%) vs. 16/85 (18.4%) in control group (p<0.0001). The median SGUS was significantly higher in pSS patients in comparison with control group [median (range) 4 (0–6) vs. 0 (0–2), p<0.0001]. Forty-five percent of pSS patients had SGUS score 4. The SGUS cut-off ≥2 showed specificity 95.4%, and sensitivity 93.3%. Diagnostic accuracy of the parenchymal inhomogeneity was very good (AUC-ROC 0.89), followed by the glandular echogenicity (AUC-ROC 0.81), the glandular size (AUC ROC 0.75), the posterior border (AUC ROC 0.60), and the presence of intraglandular lymph nodules (AUC ROC 0.49), respectively.

Conclusions: Our findings confirm that most of established pSS patients had pathological SG US features. Among US parameters, parenchymal inhomogeneity was the most discriminant feature for diagnosis of SS. There is the growing evidence that ultrasound should be considered as the useful method for evaluation of salivary glands in pSS patients.

THU0292

DIAGNOSTIC ACCURACY OF ULTRASOUND AND ULTRASONOGRAPHIC FEATURES OF SALIVARY GLANDS IN PATIENTS WITH PRIMARY SJOGREN’S SYNDROME

V. Milic, G. Radunovic, N. Damjanov. Institute of Rheumatology, Belgrade, Serbia

Objectives: To analyze ultrasoundographic (US) changes of salivary glands (SG) in patients with primary Sjogren’s syndrome (pSS) and assessment of their accuracy for diagnosis pSS.

Methods: This study included 205 pSS patients (mean age 53.9±11.5, disease duration 5.6 years) and 87 healthy controls (mean age 52.3±14.7). All pSS patients fulfilled the AECG diagnostic criteria. The disease activity was measured by EULAR SS disease activity index (ESSDAI). Parotid and submandibular glands on both sides were assessed for size, parenchymal echogenicity and inhomogeneity, posterior glandular border and presence of intraglandular lymph nodes. Intensity of echogenicity of the salivary glands was graded according to the De Vita scoring system [0] homogenous glands; [1] mild inhomogeneous - isolated hypoechoic areas; [2] evident inhomogeneous - scattered hypoechoic areas, and/or multiple punctate or linear densities; [3] grossly inhomogeneous – large hypoechoic areas, and/or to linear densities, and/or for multiple cysts. The global SGUS score (0–6) was the sum of the scores of each pair of salivary glands. Statistical analysis was performed by SPSS v16. Data were compared using Hest, χ² test and Mann-Whitney U test. The optimal cut-off value for SGUS score was calculated as the area under the receiver operating characteristic curve (AUC-ROC).

Results: Xerorhaphalitis and xerostomia were presented in 185/205 (90.2%) and 186/205 (91.2%), respectively. According to ESSDAI, the majority of pSS patients 88/205 (43%) had moderate disease activity. Seventy-eight percent of pSS patients were anti-SSA antibody positive, 44% anti-SSB/La antibody positive. Biopsy of LSG was positive in 140/172 (81.4%) pSS patients. US abnormalities were established in 197 (96%) pSS patients and in 16 (18%) controls (p<0.0001). Pathological sizes of salivary glands were more frequently in pSS patients than controls, 111 (54.2%) vs. 3 (3.4%) patients, respectively (p<0.0001). The echogenicity of the salivary glands was pathological changes in 142 (69.3%) pSS patients and in only 5 (5.7%) control group (p<0.0001). The pathological glandular border was frequently in pSS patients than control group, 48 (23.4%) vs. 2 (2.3%), p<0.0001. No differences were detected between the two groups of patients for enlarged intraglandular lymph nodes. Most of pSS patients had pathological inhomogeneity, 197/205 (96.1%) vs. 16/85 (18.4%) in control group (p<0.0001). The median SGUS was significantly higher in pSS patients in comparison with control group [median (range) 4 (0–6) vs. 0 (0–2), p<0.0001]. Forty-five percent of pSS patients had SGUS score 4. The SGUS cut-off ≥2 showed specificity 95.4%, and sensitivity 93.3%. Diagnostic accuracy of the parenchymal inhomogeneity was very good (AUC-ROC 0.89), followed by the glandular echogenicity (AUC-ROC 0.81), the glandular size (AUC ROC 0.75), the posterior border (AUC ROC 0.60), and the presence of intraglandular lymph nodules (AUC ROC 0.49), respectively.

Conclusions: Our findings confirm that most of established pSS patients had pathological SG US features. Among US parameters, parenchymal inhomogeneity was the most discriminant feature for diagnosis of SS. There is the growing evidence that ultrasound should be considered as the useful method for evaluation of salivary glands in pSS patients.

OBJECTIVES: In the present study, volumes of the hippocampus were examined to identify the responsible lesions for neurobehavioral changes in CPNB, and patterns of atrophy in the hippocampus and brainstem were compared between patients with CPNB and AD.

METHODS: The subjects were 32 patients, including 13 with CPNB (11 males and 2 females, age 51.2±12.1 years old [mean ± SD]), 13 with Behçet’s disease without NB (non-NB) (10 males and 3 females, age 54.4±11.4 years old), and 6 with AD (5 males and 1 female, age 78.8±7.5 years old). All patients with BD satisfied the international classification criteria for BD. CPNB was defined as intractable, slowly progressive neurobehavioral changes and/or cerebellar ataxia accompanied by persistent elevation of interleukin-6 (IL-6) >20 pg/mL in cerebrospinal fluid on two different occasions at an interval of at least 2 weeks. All patients with AD satisfied Diagnostic and Statistical Manual of Mental Disorders (DSM)-IV criteria. Brain magnetic resonance imaging (MRI) was obtained from each subject. The areas of the brainstem, genu and posterior corpus callosum were measured by T1-weighted imaging using image analysis software (Image J ver.1.45; NIH, USA). Severity of gray matter loss in the hippocampal region and whole brain were investigated using Voxel-Based Specific Regional Analysis System for Alzheimer’s Disease (VS-RAD) software (Ensay Co., Ltd) to determine the degrees of hippocampal region atrophy (Z score) and whole-brain atrophy (WBAI). Thus, the 1/Z score is positively correlated with the hippocampus volume. The ratio of the degree of brainstem atrophy to that of hippocampal atrophy was evaluated by the brainstem area value divided by the 1/Z score (BAI/H score) in each patient.

RESULTS: The brainstem area was significantly decreased in CPNB (61.8±58.7 mm² [mean ± SD]) compared with that in AD (66.1±54.6 mm² and non-NB (66.1±55.0 mm²) (Figure A). VS-RAD analysis showed that Z score was significantly increased in CPNB (1.46±0.70) and AD (3.31±1.21) compared with that in non-NB (0.77±0.40) (Figure B). Of note, the BAI/H score, reflecting the brainstem/hippocampus volume ratio, was much lower in CPNB than in AD (663.5±311.8 vs 2018±687.6, p=0.01) (Figure C).

CONCLUSIONS: These results indicate that the hippocampus, in addition to the brainstem, is a common target lesion in CPNB, and this accounts for the progressive neurobehavioral dysfunction in this disease. Moreover, the data emphasize that brainstem atrophy is disproportionately greater than hippocampal atrophy in CPNB, in contrast to AD.

THU0295 CLINICAL FEATURES OF TAKAYASU’S ARTERITIS FROM AN INCEPTION COHORT: EARLY DISEASE IS CHARACTERIZED BY “SYSTEMIC INFLAMMATION”

F. Alibaz-Oner on behalf of Turkish Takayasu Arteritis Study Group. Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey

Background: There is only retrospective and very limited data for the long term prognosis of Takayasu’s Arteritis (TAK), a rare large-vessel vasculitis. In this study, we aimed to present the preliminary results of a Takayasu Inception Cohort settled for long term, prospective follow-up of only newly-diagnosed patients with TAK.

Methods: Patients fulfilling the American College of Rheumatology 1990 criteria for TAK and diagnosed in the last 12 months were included to the study. Patients’ data were recorded in an electronic database of an international “Takayasu’s Arteritis Registry” requiring annual visits and at least annual visits is compared with an historical Turkish cohort previously published (Başçakırgil et al., 2009).

Results: The study included 128 patients (age: 38.9±13.1 years, F/M: 112/16) with TAK from 15 tertiary Rheumatology centers in Turkey. The mean symptom duration of patients was 5.2 years at diagnosis. According to the angiographic classification, 59.2% of the study group had type I and only 17.2% had type V disease. When we compared our results to our retrospective cohort (previously published by Turkish Takayasu Arteritis Study Group), constitutional symptoms (72.2% vs 66%) and limb claudication (62.3% vs 48%) were observed to be more frequent, whereas paresthesia (35.6% vs 88%) was less in the inception cohort (55%). Only in the initial phase of TAK, mucocutaneous symptoms also seem to be a feature of newly-diagnosed disease (28.4% vs 8.8%). Regarding comorbidities at diagnosis, the rate of dyslipidemia was 22%, diabetes mellitus 6%, smoking 28.5% and obesity (BMI<30) 15.8% among TAK patients. All patients were given oral corticosteroid (CS) therapy (0.5–1 mg/kg) at diagnosis. Only the patients (7.8%) also having CS pulses. In addition to CSs, 55 patients (43%) were given methotrexate, 14 patients (11%) azathioprine and 5 (4%) cyclophosphamide at disease-onset.

Conclusions: Our results suggest that, in an inception cohort, signs and symptoms of “systemic inflammation” is more prominent in newly-diagnosed TAK patients, whereas vascular extent and damage accumulates during the disease course. The long term follow-up of our inception cohort will better show the actual course and predictors of prognosis in TAK.

THU0296 THE ROLE OF ULTRASOUND IN THE MANAGEMENT OF GIANT CELL ARTERITIS (GCA) IN ROUTINE CLINICAL PRACTICE

S. Monti 1, 2, A. Floris 3, C. Ponte 3, S. Vaggers 2, W.A. Schmidt 3, A.P. Diamantopoulos 3, C. Pereira 3, R. Luqmani 1 1. Rheumatology, University of Pavia, Pavia, Italy; 2IRCCS Policlinico San Matteo Foundation, Pavia, Italy; 3Policlinico Umberto I, University of Rome, Rome, Italy

Background: The role of ultrasound (US) in the management of giant cell arteritis (GCA) in routine clinical care of patients with GCA is still debated.

Objectives: To develop a protocol using CS and explore its value in the routine care of patients with GCA.

METHODS: We developed a structured scanning protocol for CS of temporal and axillary arteries (total of 8 anatomical sites scanned per patient) based on previously published methods. We tested the protocol on consecutive patients referred to a single rheumatology centre, with suspected or established GCA, between July 2014 and September 2016. We defined a positive scan by the presence of halo in at least one branch of a temporal artery (TA) or an axillary artery (AX). We report data from the first 293 consecutively scanned cases.

RESULTS: We assessed 293 patients (mean age 72±10, female/male 196/97), of whom 118 had clinically confirmed GCA. Amongst new referrals with confirmed diagnosis of GCA, 44% had a positive scan; two patients with a positive scan did not have GCA. 82% of newly-diagnosed patients showed exclusive TA involvement, 25% concomitant AX, and 4% exclusive AX involvement. High-dose glucocorticoid therapy had already been started in 78% of these patients for an average of 17±33 days. Amongst this group, the sensitivity of US was 46% (95% IC 37%–55%), specificity 98% (95% CI 93%–99.8%), positive predictive value 99.8% (98%–99.6%), and negative predictive value 60% (95% IC 52%–68%). During the period of observation, the rate of temporal artery biopsies (TAB) decreased significantly from 42% to 25% (p=0.002). During follow up, CS was positive in 21% of 89 routine scans in asymptomatic individuals, compared to 58% in patients with confirmed clinical flares (45% of whom had negative inflammatory markers). Over time, the number of halos per patient reduced; only new or flaring patients showed a halo in >4 sites. Halo size at the TA did not change significantly (average thickness 0.6±1.1 mm), however, the size of AX artery halos significantly reduced from first referral (1.6±0.4 mm) to follow up (1.4±0.2 mm) to follow up (1.4±0.2 mm), p=0.01) during subsequent flares (1.4±0.2, p=0.02).

Conclusions: We have developed and tested a standardised methodology for CS evaluation of GCA. CS provides a high positive predictive value for a diagnosis of GCA in unselected patients from routine clinical practice, although prior high dose glucocorticoid therapy is likely to reduce its sensitivity. CS allows for a significant reduction of TAB. We explored the role of CS to detect disease flares and demonstrated a significant reduction in the extent of abnormalities, and of the size of halo of the AX arteries during follow up or flares. These findings could have a significant impact on the management of patients with suspected and confirmed GCA.

A NOVEL ULTRASOUND SCORING SYSTEM FOR GIANT CELL ARTERITIS

S. Monti1,2, C. Ponte3, G. Carrara4, F. Rumit4, A. Hutchings5, B. Dasgupta6, R. Lugmani1:1, NDORMS, Rheumatology Department, University of Oxford, Oxford, United Kingdom; 2Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, Pavia, Italy; 3Rheumatology, Hospital de Santa Maria, CHLN, Lisbon, Portugal; 4Epidemiology Unit, Italian Society of Rheumatology, Milan, Italy; 5Department of Health Services Research and Policy, London School of Hygiene and Tropical Medicine, London; 6Rheumatology, Southend University Hospital, NHS Foundation Trust, Westcliff-on-Sea, United Kingdom

Background: Colour duplex sonography (CDS) can be used for giant cell arteritis (GCA) to detect inflammatory oedema of the vascular wall, known as “halo”. A standardized, quantitative score to grade the intensity and extension of vascular involvement detected by CDS has not yet been developed.

Objectives: To develop and test different scoring models of CDS findings in patients with new onset GCA, and to correlate the models with final diagnosis, histologic findings, and outcome.

Methods: We selected patients with a positive CDS and a confirmed diagnosis of GCA from the Temporal Artery Biopsy vs Ultrasound in Diagnosis of GCA (TABUL) study (1). We designed CDS models combining different ultrasonographic information based on available evidence, or hypothesized clinical relevance of size, anatomical distribution, and extent of halos, summing up to a final numeric score.

Results: We included 135 GCA patients (male/female: 43/92), age 73.3±8. Forty four patients (32%) had a positive CDS, but not a final diagnosis of GCA. We designed 8 different CDS models (Figure 1). Models 1, 4, 6, and 7 were significantly associated with a confirmed diagnosis of GCA (Table 2). Model 7 better discriminated patients with GCA from non-GCA: area under the curve (AUC): 0.844 (0.766–0.923). All, except models 5 and 8, correlated with a temporal artery biopsy (TAB) result diagnostic for GCA. Most models correlated with histologic findings involving the media or transmural infiltrate, but not with small vessel or adventitial involvement. None of the models correlated with permanent ischaemic sequelae, however, the low number of events might have limited their significance.

Conclusions: The CDS findings that better correlate with a diagnosis of GCA, and TAB findings are: the number of positive sites, the size of the halo (maximum, transmural) and TAB findings are: the number of positive sites, the size of the halo (maximum, transmural) involving detected by CDS has not yet been developed.

| CRP < 6.1mg/L, type 4 disease and DEI.Tak ≥ 9 predicted sustained inactive disease with an AUC of 70.2 (63.3–77.2, p<0.001). Initial steroid dosage of 0.5mg/kg/day was similar to 1mg/kg/day in terms of response or relapse. Overall, there were only 15 (5.9%) patients who never responded to treatment. There were 2 fatalities. At the last visit, 176 (70.5%) had stable disease. Damage progression (delta TADS) was lower in patients with sustained inactive disease than the rest, p<0.001. Conclusions: Medical management arrested disease activity, damage progression and mortality in our cohort. Low baseline CRP and DEI.Tak scores and type 4 disease independently predicted sustained inactive disease.

LONG TERM OUTCOME OF PATIENTS WITH TAKAYASU ARTERITIS: A SINGLE CENTRE STUDY

R. Goel1, D. Danda1, G. Joseph2, A. Nair1, V. Jayaseelan3, L. Jayaseelan3, S. Kumar4, P. Bacon5, 1Clinical Immunology and Rheumatology; 2Cardiology; 3Biostatistics; 4Child Health, Christian Medical College, Vellore, Tamil Nadu, Vellore, India; 5School of Immunology and Infection, University of Birmingham, Birmingham, United Kingdom

Background: Takayasu Arteritis (TA), a large vessel vasculitis is characterised by a variable clinical course and outcome that differs across populations. Most studies are limited by small sample size.

Objectives: (i) To study treatment outcome in our TA patients with a follow up of ≥12 months (ii) Construct a prediction model for subset of patients with sustained inactive disease.

Methods: Consecutive patients with TA attending our clinics between 1998 and April 2016 were recruited. Details of baseline demographics, clinical profile, angiography, disease extent using DETak, laboratory parameters and TADS (Takayasu arteritis damage score) were recorded. At each follow up visit, disease activity was assessed by Indian Takayasu Activity score (ITAS-2010) and imaging, while damage was assessed by TADS for patients who followed up for ≥12 months (retrospectively for 179 and prospectively for 72 patients). Treatment response was classified as complete response (CR), partial response and no-response. Sustained inactive disease was defined as maintenance of CR throughout the follow up with steroid dose reduced to ≤5mg/day. Relapse was defined as return of active disease after CR. Statistical analysis was performed using SPSS-16. Intergroup comparisons were performed by nonparametric test. Logistic regression was used for determining independent associations. Optimal cut off values were determined using receiver operating curve and prediction model was constructed. Efficacy of medications was compared by Cox proportional hazards model.

Results: Baseline details were noted for 503 patients: mean age at onset of 25.6±11.1 years, disease duration 12 (6–48) months, diagnostic delay 6 (3–24) months and 77.9% were females.
